At the designed storm of 30.4 mm (control volume capture ratio of 80%), the LID facilities can significantly control the total runoff and peak value. However, in case of 24h 2-year and 30-year recurrence period rainfall, only adopting LID facilities does not exert significant effects on controlling the total runoff and the peak value. After adopting regional sponge city facility, the total runoff and its peak value are significantly reduced at the 24-h rainfall of 2-year and 30-year rainfall. Thus, the LID facilities is proposed as the main method for controlling the non-point source pollution in the Eco-city, and regional facilities is proposed in combination with the LID facility to control urban waterlogging.

LID facility should be chosen based on the situation of the project area. Attentions should be paid on following aspects during design and construction of LID facility for Tianjin Eco-city:

- Use soil with high permeability to increase water retaining capacity;
- Avoid secondary pollution during design and construction stage for LID facility, especially focus on the possible pollution brought by biological retention facility.
- Good regular maintenance is essential for ensuring the effect of LID facility.

The study results demonstrated that “sponge city” is a mental experiment with scientific solution for implement “sustainable neighbourhood”.

ABSTRACT

Life Cycle Assessment (LCA) is increasingly gaining importance in regards to building sustainability evaluation. Life Cycle Performance (LCP) describes the sum of all expenses for the production, operation and deconstruction in relation to the use and lifespan of a building. Considering LCP at the very early stages of the design process can have a significant impact on the overall LCP of the building. Thereby a multi-stage decision-making (MD) process allows the generation of a wide range of designs without eliminating the variants which seem to have comparatively low LCP in the beginning. Within this process all design variants are being developed until the final LCP calculation. By means of the MD tree, the planner can easily compare the different designs. This paper is questioning the order of the design stages used in the MD process for optimizing the LCP: Starting with the building volume and finishing with the construction type can be regarded as a typical sequence for arriving at a solution. But what consequences would a change of this order have? In practice planners can mix up the design order intuitively e.g. by having an idea for a specific construction type and start to develop the building volume based on that. In the following paper this process of switching the sequence of design stages is mimicked by a computational parametric tool. The aim is to investigate the impact of the stage order on the LCP and the geometry of building variants. Findings from the case study can be utilized in practice for the creation of generative tools based on MD processes.

Keywords: multi-stage decision-making process, Life Cycle Performance, design process, design automation

1. INTRODUCTION

Life Cycle Assessment (LCA) is increasingly gaining importance in regards to building sustainability evaluation, mostly in the form of building certification labels utilized in architectural practice. The application of LCA at a late stage of the design process to evaluate the environmental impact is not sufficient on its own if the results are not used to improve the design (Wittstock et al., 2009). The highest optimization potential lies within the early design stages where the decisions made have the biggest influence on energy demand (Hegger et al., 2007) and environmental impact (Schneider, 2011) while featuring the smallest costs for changes to the design (Paulson, 1976). However, in practice most fundamental decisions concerning the building geometry are made with little or no involvement of simulation software (Picco, 2014). Regarding the design process as a search process, where variants are generated, evaluated, selected and improved in an iterative manner (Newell & Simon, 1972) suggests the aid of computational tools to minimize the time for arriving at a solution. Referring to Rittel (1992), there are several methods to search for solutions: these range from a linear approach, where one single solution is produced in each design stage and no alternatives are created (Figure 1a); to a simplified multi-stage decision making approach, where for each stage of a design multiple variants are created, and the best one is developed further in the subsequent stages (Figure 1b); to a multi-stage decision-making (MD) process, where in each stage all design variants are considered (Figure 1c). The latter strategy generates a much higher number of designs than the other two methods what reduces the risk of missing out good solutions. Additionally, it holds the potential of discovering design variants which have comparatively worse performance in the early stages, although in combination with

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

aspects from the following stages, their performance can improve significantly. By means of the MD tree (Figure 1c), the planner can easily compare the different designs and decide which geometry to choose.

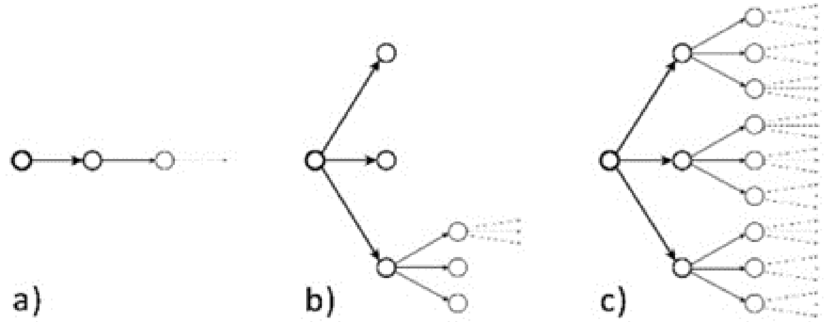

Figure 1: (a) Linear process (b) Simplified multi-stage decision-making process (c) Multi-stage decision-making (MD) process (Rittel, 1970)

The following paper is questioning the order of the design stages used in an MD process for finding optimized design variants according to the desired Life Cycle Performance (LCP). The LCP is a measure for the environmental performance of a building during the whole life cycle and in this context, it is used as an assessment value for the different designs. For arriving at a design solution it may seem logical to proceed from the general to the detail (Lawson, 2005), however, does that strategy lead to best solutions or is changing the sequence an option for achieving even better results?

2. METHODOLOGY

Is a computational tool which operates based on the MD process to be developed for the implementation in architectural practice, fundamental as well as detailed theoretical knowledge of this design process becomes necessary. In architectural theory, the topic of sequence, also referred to as stage order, in the MD process is widely unexplored. The following paper addresses this issue by means of a case study. For that matter, a parametric computational tool which is able to generate, analyze, optimize and visualize design variants in an MD tree has been programmed using the software Grasshopper3D (Rutten, 2015) for Rhinoceros3D.

Starting with the building volume plus the circulation core and concluding with the construction type can be regarded as a typical sequence for arriving at a solution. That stage order is the basis for the first MD process of the case study. Although, in practice planners can mix up the design order e.g. by having an idea concerning the construction type and develop the building volume from there. This sequence is the theory behind the second MD process explored in the case study. Both sequences are compared by regarding the design variants of the two resulting MD trees. That method should provide knowledge on the influence of stage order on the design outcomes in MD processes. Implementing those findings in future MD processes can lead to better designs with higher LCP values. The setup of the case study is explained in the following.

2.1 Parametric model generation

Generating numerous design variants in a short amount of time requires parametrically defined models which can easily be altered by changing the parameter values. In the following case study, two to four residential buildings are located on a rectangular site which is shaded at three sides. For study purposes the floor area ratio (FAR) is kept very low at 0.6, ensuring a high solution space (high FAR leads to geometrically fairly similar solutions). Each design variant has a total floor area of 2500m^2 which is divided into subareas for the individual buildings on the site. Minimum and maximum dimensions are set to ensure reasonable sizing of the building volumes. The buildings can have two to four floors and the glazing area is constantly 30% of the exterior wall area. Due to the parametric positioning of the buildings on the site it is likely that these initially intersect. Therefore, an algorithm, which resolves the intersections plus maintains a pre-set minimum distance between the buildings, has been developed. Additionally, building cores which include the main circulation spaces within the buildings are inserted. In order to enable natural lighting and ventilation, they solely can be positioned at exterior walls, preferably in shaded areas to keep the solar gains to the usable floor spaces. If a building exceeds a defined building size, further circulation cores are added. All of those model features are parametrically controlled and each combination of the parameter values generates different design variants. The analysis starts automatically after the creation of every single design variant.

2.2 Building model analysis

2.2.1 Solar analysis

Solar radiation analysis is a fast way of evaluating the solar radiation on the building exterior considering shading from surrounding buildings for the time frame of one year. Visualized on the building façade, the results display to which extend the building is exposed to sunlight and indicate the potential amount of daylight in the interior.

2.2.2 Energy analysis

In order to quickly calculate the operational energy demand, we implemented a quasi-steady state method with monthly energy balances within Grasshopper. The implemented algorithms are based on DIN V 18599-2:2011 (DIN, 2011) and have been verified in Lichtenheld et al. (2015). The developed parametric energy calculation tool is able to provide results in real time (< 0.1s).

2.2.3 LCP analysis

In this paper, a previously developed parametric Life Cycle Assessment method (PLCA) is used (Hollberg & Ruth, 2016). Based on the 3D model generated in Grasshopper, the surface areas are extracted to automatically establish a bill of quantities needed for the calculation of embodied energy and environmental impacts (life cycle modules A1-A3, C and D). The environmental indicators for the individual materials are taken from ökobau.dat (BBSR, 2011) which complies with EN 15804 (CEN/TC 350, 2012). For the calculation of the LCP, we used the weighting process included in the DGNB certification. The procedure is explained in Hollberg et al. (2016).

2.3 Optimization process

Optimization serves the finding of design variants according to a design goal, which in this case study is the maximal LCP. These optimization processes operate based on evolutionary Algorithms (Rechenberg, 1994) conducted by Galapagos (Rutten, 2011) which is an inbuilt component in Grasshopper.

For starting an optimization, a parametric model, an assessment formula called the fitness and a fitness goal are required. The optimization of the first stage in the first MD process aims to find the best sizing of the building volumes, their location on the site plus the position of the cores at the exterior walls of the buildings. Here the fitness takes into account multiple performance criteria such as the average building surface area to volume ratio (S/V), the average solar radiation of the façade and the average shading value of the cores. The latter describes the difference of the solar radiation actually reaching the cores to the desired shaded condition and is purely based on an assumption of the authors. According to this assumption, the LCP might increase by arranging the buildings in a shorter distance to each other to create small but highly shaded areas on the façades. In those areas the circulation cores should be placed. Since the areas of the exterior walls where the cores are attached are excluded from the average solar radiation value of the façades, this value might increase what leads to a higher LCP. This assumption represents ideas that planners may have for improving the design. After all performance criteria are defined, their values are remapped to a domain which goes from 0 to 1 to ensure that all values stay in the same number range for them to have approximately equal impact on the fitness. In the following mathematical equation those performance criteria are combined:

Fitness = average S/V – average solar radiation + average shading factor.

The goal of this fitness is minimization and it expresses, that the average S/V as well as the average shading factor aim for minimization, whereas the average solar radiation should be increased. In the second stage of the first sequence, the resulting optimized design variant is combined with six different construction types and accordingly six LCP values are calculated.

In contrast, for the optimization in the second MD process where the construction types are defined in the first stage and the volumes plus cores in the following, the fitness is the LCP itself which should be maximized.

3. RESULTS

As the first MD tree displays, for each configuration of two, three and four buildings, three variants for building volumes plus cores are generated by means of optimization (Figure 2, left). The fitness used for the optimizations in the first stage of sequence 1 considers the average S/V of the building, the average solar radiation on the façade and the average shading value of the cores. It is not possible to take the LCP as the fitness at that point because one more stage is following which holds multiple aspects, in this case the six pre-selected construction types. Determining the construction type is essential for the LCP calculation. Since the construction types are only included in the second stage of this sequence, defining a custom fitness equation for the optimization in the first stage becomes inevitably.

Regarding the LCP values for the different construction types, a repeating pattern becomes apparent. For every design variant the order of the LCP from best to worst is the same, which indicates, that every single construction type has a specific influence on the LCP. For example, the worst LCP comes with the concrete construction and the best with the wood construction type. For enabling a better comparison between the different design variants, distances from each building to the closest building nearby are calculated. The average distance for every individual design variant is assigned. The overall average distance of all designs in the first MD tree is 4.52m, which means that most of the buildings are positioned relatively close to each other.

In the second MD tree the order of generating the volumes plus cores and applying the construction types is switched around. Hence, the first stage in that MD tree includes the six construction types (Figure 2, right). From there in stage two, for each construction type three design variants are generated with two, three and four buildings. Since no more stages with multiple aspects are following, the fitness for the optimization of the volumes plus cores in the second stage is the LCP, which needs to be maximized. The LCP values of the second MD tree show the same pattern as described for the first MD tree. Comparing the two MD trees reveals that the LCP values are quite similar with a slight deviation from 0.7% to a maximum of 6.2%. In 83% of the calculations the second MD tree delivered the best LCP. The average distance of all design variants is roughly doubled with 10.27m.

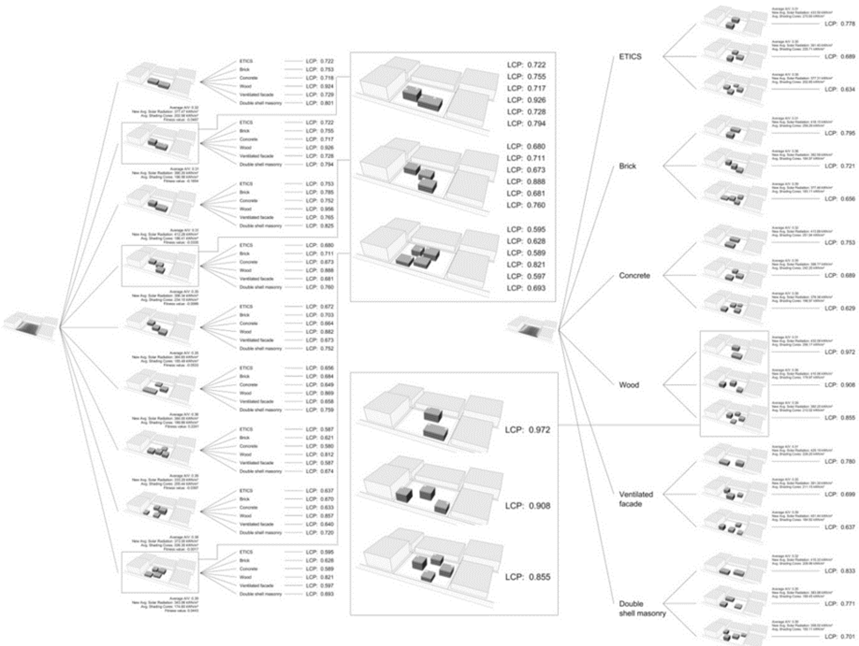

Figure 2: First MD tree (left), second MD tree (right), for each tree three variants are enlarged for readability.

4. DISCUSSION

From the results of the case study it can be concluded, that sequence has an influence on the resulting LCP and on the geometries of the design variants. However, the pattern amongst the LCP values reasoning in the influence of the different properties of each individual construction type is constantly the same for both MD trees. That shows, that the pattern-like behaviour of the LCP is not connected to the stage order. Although both, the first and the second MD tree deliver similar LCP results, there is a deviation of a maximum of 6.2% in the LCP values. In 83% of the cases, the best LCP results come from sequence 2, where first the construction type is determined and from there the volumes plus cores are developed. The reason for that, are the different fitness equations used for optimization in the two sequences (due to the missing construction types in the first stage of sequence 1). The fitness of the first stage in sequence 1 combines the three seemingly main performance criteria which influence the LCP. Those are the average S/V, the average solar radiation on the façade and the average shading value of the cores. Maintaining the number ranges of all performance criteria without scaling them to the range of 0 to 1 could result in an overly dominant influence of the criterion with the highest number range. In contrast, the one with the smallest number range would have relatively low impact. Therefore, all three performance criteria got assigned an equal influence on the fitness based on the planner's own judgement. Assigning appropriate weighting to each performance criterion is a difficult task. The weighting is indicating to which extent the LCP is influenced by the different performance criteria, but this information is mostly unavailable. Therefore, the planner has to not only decide which performance criteria to include in the fitness equation but also which weighting to apply.

In contrast, the weighting in the second fitness which is the LCP itself, is different. That influence is reflected by the average building distance of both sequences. In sequence 1, the buildings have an average distance of 4.52 m, which means they are located relatively close to each other. This is the consequence of the high influence of the average shading value of the cores on the fitness equation. For achieving a certain amount of shading for the cores at some parts of the building façades, the optimization algorithm creates shaded areas by arranging the buildings close to each other. That however, results in a lower average solar radiation on the building façades which leads to worse LCP values in comparison to sequence 2. It can be concluded, that the custom fitness equation was not completely appropriate in regards to the final goal of achieving maximal LCP. The author's assumption of improving the design outcomes by including an average shading value of the cores in the fitness equation was proven wrong and should be excluded from the fitness.

In contrast to sequence 1, the average building distance of 10.27 m of sequence 2 is resulting from the LCP as the fitness. For maximizing the LCP, the optimization algorithm is aiming for the maximum solar radiation on the building facades. This leads to the minimization of shading by arranging the buildings relatively far apart. The LCP values of sequence 2 were higher than of sequence 1 because the most efficient way of establishing a fitness equation is to take directly the final assessment method as the fitness which was the LCP in this case study.

The case study proofs that it is of importance to pay special attention to the fitness equation and to the weighting used for optimization. It can be concluded, that the optimization delivers best results when the fitness is oriented towards the final assessment method as much as possible. That means, the performance criteria included in the fitness equation plus their weighting should have a similar influence on the final result (LCP) as on the fitness. An even better option is to take the final result as the fitness, which was the case in the second sequence. For that reason, the order of the second MD process was more effective in finding optimized design variants in regards to the LCP.

5. CONCLUSION

As the case study shows, the sequence matters when it comes to MD processes. Highly dependent on the stage order, the fitness for optimizations has a major influence on the resulting design variants as well as on the final assessment value. Best optimization results can be achieved by applying the least possible amount of different fitness equations in one sequence and by using the design goal as the fitness. Findings from the case study can be regarded as theoretical background for the creation of generative tools based on MD processes. By means of MD trees planners can get a better understanding of how different construction types influence the LCP as well as the geometry of the design variants. MD trees can help designers to explore a wide range of designs according to the desired performance and choose one for further development. The processes can be programmed to function

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

highly automated, what minimizes the calculation time and makes it more likely to be applied in architectural practice.

Rethinking Architectural Passive Cooling Strategies in New Zealand's Non-residential Building Stock

Lesley METIBOGUN[a], George BAIRD[b]

[a] *School of Architecture, Victoria University of Wellington, New Zealand, lesley.metibogun@vuw.ac.nz*
[b] *School of Architecture, Victoria University of Wellington, New Zealand, george.baird@vuw.ac.nz*

ABSTRACT

Whereas traditional building designs successfully integrated passive cooling strategies, current non-residential buildings have become dependent on mechanical cooling to achieve thermal comfort. The aim of this study is to demonstrate that with appropriate design input passive methods of cooling can be successfully incorporated into non-residential buildings. Following a brief outline of how our dependence on mechanical cooling has spread over the full range of building types and climatic zones, the focus of this paper is on non-residential buildings in temperate climates where passive cooling should be feasible in principle. It was found that current design policies, regulations and guidelines and current building design practices militate against their use. Perceived association with prestige, inflexibility of design processes, rigid planning regulations and sustainability rating systems were identified as key factors forcing the need for mechanical cooling. Recommendations are made on how to further encourage development in this direction from the perspective of architectural design.

Keywords: climatic responsive architecture, passive cooling, non-residential buildings

1. INTRODUCTION

New Zealand's non-residential building stock was estimated at 41,154 with a total floor area of 39.9 million m^2 (Cory, 2016).The non-residential building stock is divided into five size ranges, namely; size S1, S2, S3, S4, and S5 with a minimum floor area of 5 m^2, 650 m^2, 1500 m^2, 3500 m^2, and 9000 m^2 respectively. It is interesting to note that the building size S4 and S5 are large and they are mostly multi-storey buildings with percentage of buildings at 4% and 1% respectively. Small buildings, S1, S2, and S3 amount to 80% of the stock. The non-residential building stock is classified into three building use types namely; commercial office, retail, and others. Cory (2016) found that air conditioning was present in large commercial buildings (mainly office buildings). Despite the development of sustainable building design strategies with the potential to avoid overheating risk, the unnecessary use of air conditioning is escalating in non-residential building stock. The use of air conditioning in the non-residential buildings has become a norm in New Zealand (NZ) due to poor architectural design (Budin & Leardini, 2015). It is also evident that some of the current design practices and guidelines militate against the implementation of architectural passive cooling strategies which could alleviate the potential for overheating (Byrd, 2012).

Lenoir et al. (2012, pp157) stressed that "thermal comfort can be achieved in public buildings without air conditioning". How has the human race survived for millions of years without air conditioning, but suddenly cannot live without it? Is it so difficult to design without air conditioning? The following paper includes a brief description of the trend towards dependence on mechanical cooling; the impact of the energy crises; the changing climate and sustainable building strategies; the relationship between current practices and the institutional drivers and the use of air conditioning; and studies on retrofitting non-residential building for passive cooling. This study aims to understand the trend towards the dependence on mechanical cooling and current design practices and regulations that have encouraged the spread of air conditioning specifically for temperate climates within the practical context of NZ non-residential building stock.

2. THE TREND TOWARDS DEPENDENCE ON MECHANICAL COOLING

Prior to the 1900s, non-residential buildings utilised passive design strategies, enabling solar penetration into the building in winter and shading to prevent it during the summertime (Arnold, 1999). Generally speaking, buildings were designed to adapt to the climate with minimal impact on the environment (Donn & Cresswell-Wells, 2014). Passive design strategies require little increase in building cost without any additional running cost. However, while passive design strategies have both economic and environmental benefits, they have perceived limitations. Between 1900 and 1920, there was a gap in research into passive design strategies (Gokarakonda & Kumar, 2016)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

leading to their gradual neglect with the result that overheating became more common in buildings. This led to a worldwide growth of alternative means to solve overheating problems in non-residential buildings. The conventional solution to overheating was the installation of air conditioning (Yu et al., 2009) and this resulted in a high market drive for air conditioners (Balaras et al., 2007).

The modern air conditioning was invented by Carrier in 1920. It was primarily aimed at controlling internal temperature (Arnold, 1999). It was first applied to Abraham and Straus city departmental store in Brooklyn, New York, USA. However, the first entirely air conditioned building was the Millam High-rise Building in 1928. It was also installed for the senate and house chamber of the US Capitol, Washington, DC, in 1928 which eventually became the largest cooling system serving offices with a capacity totaling, 4800tr (16800KW). Air conditioning was installed in the UK in 1928 in Lloyd's Bank. As of 1961, only five buildings were installed with air conditioning in London; but by the 1990s, about 80% of newly constructed office buildings were air conditioned. Currently, virtually all new office buildings have air conditioning installed (Roaf, 2015).

The use of air conditioning altered architecture and paved way for buildings to be designed without consideration for the natural environment. It displaced the need for natural ventilation and permitted building designers to ignore solar protection in hot weather (Givoni, 1998a). Despite increased use of air conditioning in the building industry, there was no significant issue with energy cost as electricity was cheap. A consequence of this is buildings became dependent on an uninterrupted supply of electricity since, without air-conditioning, they cannot operate (Byrd & Leardini, 2011).

3. ENERGY CRISES, CHANGING CLIMATE, AND SUSTAINABLE BUILDING STRATEGIES

Following the energy crises of the 1970s, governments crafted legislation that would decrease their reliance on diminishing energy sources (International Energy Agency (IEA) 2007). In addition, the spread of air conditioning has led to power cuts (Herring & Roy 2007) and increased electricity prices (Balaras et al., 2007). For example, in Australia in 2011, for every $1500 spent on air-conditioning, $7000 had to be spent on improving the electrical infrastructure (Fanning, 2012). Almost 20% of electricity consumption in U.S. homes goes to air conditioning, as much as the entire continent of Africa uses for all purposes (Cox, 2012). Electricity generated from fossil energies such as coal, oil, and gas, or from uranium, will inevitably decline in time. But before the disappearance of these resources, galloping inflation, due mainly to the scarcity of these fuels, will make their purchase at reasonable prices impossible and results in air conditioning systems becoming too expensive to operate.

The Intergovernmental Panel on Climate Change (IPCC) projected that by 2100, there would be an increase in the average earth surface temperature of between 1.4 and 5.8°C (Hallegatte, 2009). Furthermore, the reality of climate change and its associated negative impact on the built environment (Guan, 2009) has made the need for adaptive measures obvious. Climate change is expected to further exacerbate the risk of overheating in buildings (Crawley, 2008). As a response, sustainable building initiatives were developed to enhance the environmental quality of buildings by reducing their negative impacts on the natural environment (Buckman et al., 2014). The first building suitability rating tool, the Building Research Establishment Environmental Assessment Method BREEAM was developed in the United Kingdom in 1990 and the New Zealand's version, Green Star was launched in 2007 (Prins, 2015). Budin & Leardini (2015) in a study of the performance of Green Star rated office buildings in New Zealand, reported that naturally ventilated buildings in New Zealand overheat while over 90% of Green Star certified buildings in the Auckland region are air conditioned. This seems completely contradictory to the concept of sustainable building. A sustainable building should be "self- sufficient" and must aim at optimising the use of natural ventilation, wind and daylight and avoiding too much summer heat penetration into the building, to save energy consumption and enhance occupants' comfort (Givoni, 1998b).

4. RELATIONSHIP BETWEEN CURRENT PRACTICES, INSTITUTIONAL DRIVERS AND THE USE OF AIR CONDITIONING

Most of the award winning NZ non-residential buildings, even certified Green Star buildings, are fully glazed (Byrd, 2012). A typical example is the School of Business at the University of Auckland. The building is fully glazed without any means of natural ventilation. Although it is aesthetically pleasing, these kinds of buildings easily get overheated during the summer time (Byrd, 2010). It can be argued that prestige-architecture drives overheating in NZ. Modern architecture should be innovative in a way to mitigate the growing climate change challenge and not compound it.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The Green Star NZ (2016) recommends a 2.5 % daylight factor as the minimum daylight for an office building. It also specifies that 400 lux of light is adequate for visual work. This may have influenced over glazing of office buildings in NZ. Byrd & Hildon (1979) estimated that to achieve a 2.5 % daylight factor in a room of 7 metres in depth; it would require the window aperture to be 80% of the wall area. Considering glazing bars, sills and building structure, this would effectively require the entire external wall to be glazed. Also, the temperature range given by Green Star NZ for an air conditioned building is narrow while that of a naturally ventilated building is wide. Architects find it convenient to design with air conditioning to achieve this. No wonder air conditioning has become the choice of all architects designing green buildings in NZ (Budin & Leardini, 2015).

The NZ Property Council encourages air conditioning by awarding quality grading 'A', 'B', and 'C' to non-residential building based on the amount of air conditioning installed. The more air conditioning, the higher the grading with resulting higher rental value. This is consistent with Smith's (1999) claim that air conditioned office buildings are regarded as being of a high quality and attract a price premium. Why should architects bother designing for natural ventilation when the building will have a low rental value? "The New Zealand Institute of architects (NZIA) is also known to give awards, which should be based on performance, to buildings that self-evidently do not perform". They gave a 'sustainability' award in 2010 to a fully glazed office building without solar protection on the notion that the "significant environmental feature concerning its energy performance was that the building had been double-glazed; a mandatory requirement for a building that is fully glazed" (Byrd, 2016). If a building can be air conditioned, why bother with solar shading or good orientation? Is that a good thing for sustainable architecture?

Non-residential buildings have developed in many unsustainable directions over the years (Roaf et al., 2009) and while proffering expedient solutions, the unnecessary use of air conditioning has been a major contributor (Walker et al., 2014). While it is apparent that air conditioning offers a solution to overheating by controlling internal temperature, the resulting health, environmental and economic challenges caused by this technology are worth rethinking. A working architectural cooling strategy to reduce the use of air conditioning in temperate climates where passive cooling should be feasible for long periods of mild outside temperature is needed. The next section reviews strategies that could achieve this aim.

5. RETROFITTING NON-RESIDENTIAL BUILDINGS FOR PASSIVE COOLING

75% of the floor area of the existing stock will soon require retrofit upgrading (Cory 2016). Since 2011, there are several on-going seismic retrofits of the non-residential building in NZ due to recent earthquake. Thompson (2015) suggests improving natural ventilation in buildings while seismic retrofit is on-going. Apart from energy saving potential, Camilleri et al. (2001) stated that there is an opportunity for reduction in greenhouse gas (GGH) emission.

The ways in which buildings are designed, constructed, upgraded, and occupied require a real change and these are known as 'adaptation strategies' (Barbhuiya et al., 2013). There are many ways by which the construction industry and researchers can make buildings more energy efficient and reduce their green-house gas emissions in relation to climate change. These are referred to as "mitigation strategies" (Camilleri et al., 2001). Adaptation and mitigation strategies are complementary measures that can assist to effectively reduce overheating. Barbhuiya et al., (2013) propose a passive design approach aiming at minimising carbon emissions and improving occupants' comfort. They suggested reducing internal heat gain, improving window performance, proper building orientation, and wall insulation.

In a NZ study, Camilleri et al., 2001 suggested adaptation and mitigation strategies but expressed the view that "placing restrictions on window areas or prescribing shading or window treatment, might well be rejected by the design and construction sectors as being too restrictive and prescriptive, as they currently enjoy an almost unlimited reign in the form and aesthetics of their buildings. At the extremes, anything from a windowless box, to a building with roof and walls made entirely of glass can (with sufficient care) be made to comply with the NZ Building Code" (Camilleri et al., 2001 pp 448). Similarly, a recent study conducted by Cory (2016) on the possibility of retrofitting the entire New Zealand non-residential building stock to be Net Zero Energy, recommended passive strategies, energy efficient and renewable strategies. His study demonstrates these retrofit solutions would be effective in reducing energy consumption and buildings would hardly require air conditioning under current climate conditions. The next section highlights the methodology employed in a recent case study.

6. RETROFITING A PREVIOUSLY AIR CONDITIONED BUILDING FOR PASSIVE COOLLING – A RECENT CASE STUDY

The main methods for this case study were on-site physical observation and interviews with occupants. The aim was to investigate the design process employed and also to verify how the building actually performs in practice through occupants' experience. Photography was used as a means for data collection (Groat & Wang, 2002). The data from the occupants' experience were then analysed using discourse analysis. Discourse analysis is the study of social life, understood through analysis of

language in its widest sense (including face-to-face talk, non-verbal interaction, images, symbols, and documents (Potter & Wetherell, 1987).

6.1 Building description

The 12-storey Aorangi House on 85 Molesworth Street, Wellington central business district was built in 1970 with a net lettable area of about 5,000 m2. The building gradually became largely unoccupied due to ventilation, cooling, and heating problems. In terms of aesthetic, the building was no longer appealing, the environmental control systems was substandard as per performance. Structurally, it was unsafe for business activities as it was a risk to life and required a total refurbishment.

6.2 Integrated design approach

A team of architects and engineers was engaged by the building owner to work in collaboration in an integrated design process with the goal of developing a seismic upgrade of the existing building structure; critically tackle the problem of thermal discomfort by developing an improved thermal control strategy; explore the possibility of retrofitting the entire building to be naturally ventilated. After a series of coordination meetings between the design team members and the building owner, a passive design and seismic design upgrade, and other active technologies were developed. The following section describes how the passive design features were integrated into the existing building.

Figure 1: The East view showing the openable windows and overhangs used as solar shading

6.3 Passive design features

To allow for improved thermal modulation, the ceiling was left open but painted and about 40% acoustic panels laid on it. The aim was to better admit daylight into the building. The core areas were the only place covered with a suspended acoustic

ceiling. The building is largely naturally ventilated and cooled. This is made possible by utilizing both low and high-level window openings. These provide proper ventilation during winter. There is also night ventilation which assists in cooling the building during summer. Air conditioning was installed to assist in cooling should the internal temperature exceed 25°C especially during the summertime, but is rarely used. Glazing covers 33% of the total building wall area. External shading louvers were designed specifically for the north, east and west facades (see Figure 1). The concrete structure provides thermal mass which compliments passive heating and mitigates overheating in summer. An external insulation (German-engineered sto-system) was applied to the external façade and covered with a 3-coat plaster.

6.4 Feedback from occupants

It was found that the building internal temperatures have been comfortable. On those few occasions when it exceeded 25°C during the 2015/ 2016 summer the air conditioning switched on automatically (Baird et al., 2011).

7. CONCLUSION AND RECOMMENDATION

Reducing the non-essential use of air conditioning by developing a passive cooling technology means non-residential buildings will become more energy efficient. This implies a significantly reduced demand for national electricity. This will also complement government's target to make the nation carbon neutral and meet the international target of a 20% carbon reduction by 2020. It is apparent that the NZ non-residential building stock is now at the risk of overheating. Further study that seeks to understand the current overheating risk and cooling requirement in a wide range of non-residential buildings in NZ's climatic condition and offer an effective solution to inform design decisions is essential. How these decisions should be implemented in government initiated policies and regulations to develop a more sustainable non-residential building stock and reduce the use of air conditioning in it, is highly recommended. As the challenges are not just peculiar to NZ, the potential application of the developed solutions should be investigated and evaluated for other temperate climates.

Building in Existing Contexts – Densification

Paul FLOERKE[a]

[a] Department of Architectural Science, Ryerson University, Canada, paul.floerke@ryerson.ca

ABSTRACT

An important theme of applied research is the realization of climate adapted, energy efficient, and soundly constructed environments unfolding to an innovative architectural concept.

Existing buildings, especially certain building typologies are increasingly emphasized as themes. Quality criteria of buildings are much more difficult to capture and must be descriptive. Deciding on these will become a future challenge.

Research clearly shows, that dealing with buildings in existing contexts is considered a main focus. The densification of cities is an ongoing topic, which can be achieved without dissolving the embodied energy, which exists through the built environment. This is one major aspect. Another aspect at the same time being respected when activating existing structures is the reduction of necessary new energy – site management, used resources/ materials, actual construction etc.- for new buildings in identical locations, which often do not achieve higher quality architecture or comparably extended life cycles. Beyond this, the social culture value of existing structures has not been fully assessed. This is an underlying momentum for reconsidering architecture of the sixties and seventies. Roof-top extensions to existing structures is one way of adding to the densification using the potentials of the buildings while simultaneously refurbishing the envelope and considering reuse, recycling.

The approach is to work on areas that have been highly neglected. Architects often prefer to focus on the „new building object“ and less on existing structures, especially those of eras, which are deemed unattractive but will be of high importance to the future architectural profession.

Keywords: densification, building typologies, potentials of existing buildings, modernity

1. INTRODUCTION

The Catalogue of Typologies – Rooftop Extensions has been developed in the context of the research project „P845 Building in existing structures – potentials of lightweight steel constructions“.

A total number of 108 out of 154 worldwide selected projects are presented in this catalogue, focusing on existing buildings in urban situations considering densification through extensions and additions.

Similarities between the 154 projects have been analyzed by implementing an abstract graphical method.

The further uniqueness of this publication is the interdisciplinary combination of architectural and engineering documents for precedents studies.

The comparison of schematic sketches led to 6 typologies to which all projects can be related:

- A Roof
- B Cube
- C Inserted
- D Free Form
- E Add On
- F Gap

Within the typology-categories A to F, the Catalogue of Typologies – Rooftop Extensions is structured as follows:

- Chapter 4 Introduction of project related Typologies
- Chapter 5 Project-related overview

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Chapter 6 Detailed presentation of selected projects

The objective of this catalogue is to identify general conditions according to the given information of every typology. This catalogue is to be understood as a manual for clients, planners and the building industry. The presented solutions can be transferred into different contexts and provide assistance to the decision-making process. The variety of solutions, specifically considering the urban context, show how existing potentials can be used for roof-top extensions, which contribute to the densification of cities.

2. CASE STUDIES

2.1 Former IBM Building, hanover, lower saxony, Germany

Figure 1: Model photography, IBM-Building Hannover, 2012. Detlef Podehl, Fotografenmeister, Technische Universität Dortmund.

Building in existing contexts has long been one of the most important architectural challenges in Germany. The building inventory is in a phase of over saturation in Germany.

We can only operate to preserve resources if we learn to appropriately and sensibly deal with the existing ones. In this context, post-war modernism raises one of the most increasingly important challenges - buildings constructed in the 1960's and '70's.

Whereas buildings completed in the 1950's are generally well accepted, an aversion exists towards modernist buildings. It appears that the contemporary generation of protagonists of architecture in Germany, whose fathers were the planners and builders of this period, are the opponents of the typical post war architectural canon.

These buildings are demolished without investigating their potential for utilization in planning and economics; if they are demolished, both the embodied gray energy and energy for demolition as well as the historical social-cultural value are all lost. Certainly, not all buildings of this period are significant, but many are. Structures that appear, on first glance, to be almost unsolvable offer, on second glance, the potential for new solutions, especially in the context of the densification of urban areas. In this context, avoiding construction and demolition waste is a priority. Only after considering this should waste management or possible rebuilding on the same site follow.

When a site is rebuilt, there is no guarantee of equal or higher architectural quality especially considering the calculation that an amortisation based on thirty years is necessary to maximize the investment return.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The less an existing building has to be modified, the less the energy that has to be implemented and the more the social and cultural value is raised.

The degree of intervention, specifically the degree of modification, constitutes the critical factor concerning the utilization of the existing building and the method of identifying and using the building's full existing capacity.

Embedded in this method lies a process of selection, which can be either a controlled or uncontrolled sequence of events. In addition to this, it is often vague as to who decides which value is to be sustained, which criteria are to be followed, and which particular criteria are to be emphasized. This is a complex process that eventually constitutes a decision over the existing building.

The above-mentioned context raises aspects for an approach towards a "theory of disappearance", which involves processes which make it impossible to reconstruct, and in which artefacts of historical movements disappear forever, especially when they are not leading the list of architectural favourites.

Figure 2: IBM-Building, Hannover, 2011. Detlef Podehl, Fotografenmeister, Technische Universität Dortmund.

Prof. Dieter Oesterlen's IBM-building in Hannover, Germany, built in the late 1960's, is representative of the 'Braunschweiger Schule' (Braunschweiger School of Architecture). Oesterlen, a renowned post-war architect, sensitively intervened in existing buildings and contexts of what had heavily destroyed Germany, and, specifically, what Hannover was confronted with.

It could be said that in the process of disappearance, there is an underlying form of catharsis in the destruction of things we prefer to forget. Often, reconstruction or preservation of buildings is done with the intention of remembering and reminiscing. Oesterlen's approach, as illustrated by the historical site development in Hannover, shows a not very well-recognized strategy of reconstructing the urban context of a pre-war situation. A school built in 1890 in the same location was so substantially damaged that had to be demolished even after several attempts to provisionally repair it. The school was located in the urban context among several multi-storey apartment buildings and could be read as an explicit differently designed volume. Oesterlen has a similar interpretation of the situation, while following a modernistic architectural expression (see historic maps below).

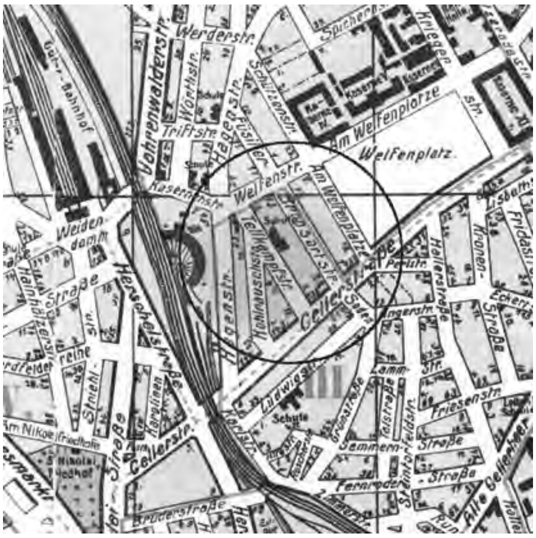

Figure 3: Historic maps, IBM-Building site, Hannover, 1914. Stadtarchiv Hannover, kpr Nr. 0966 Stadtplan Hannover, 1914 Mitte 00001.

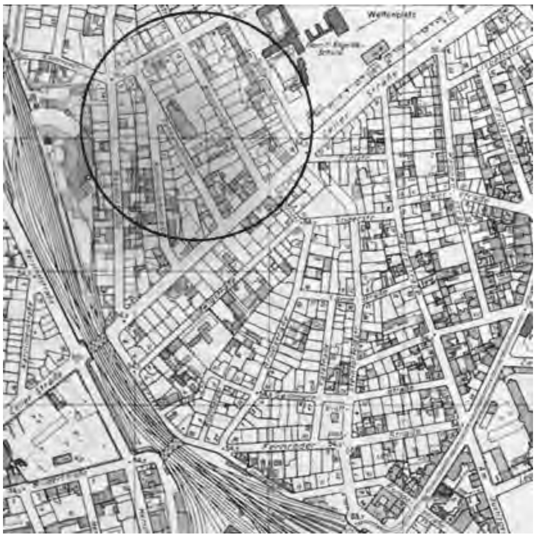

Figure 4: Historic maps, IBM-Building site, Hannover, 1954. Stadtarchiv Hannover, Dt. Grundkarte 1:5000 Blatt, Hannover 1954.

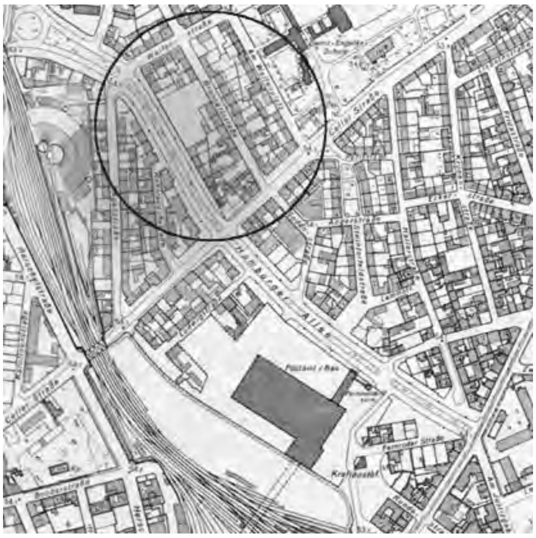

Figure 5: Historic maps, IBM-Building site, Hannover, 1961. Stadtarchiv Hannover, Dt. Grundkarte 1:5000 Blatt, Hannover 1961.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

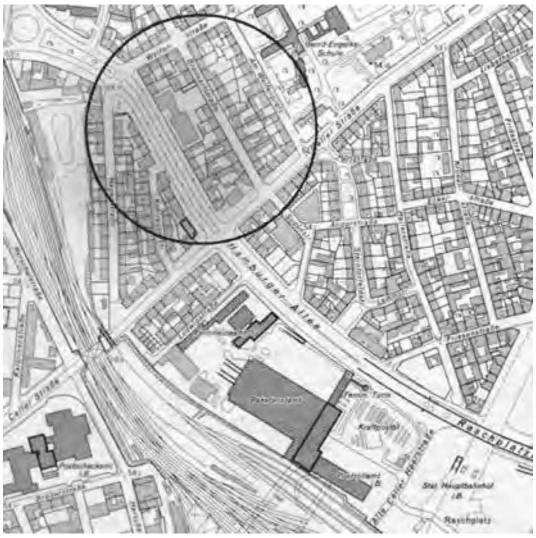

Figure 6: Historic maps, IBM-Building site, Hannover, 1971. Stadtarchiv Hannover, Dt. Grundkarte 1:5000 Blatt, Hannover 1971.

The IBM building cannot be seen as a disruptive building in an ensemble of residential buildings. As a modern office building of its time, it offers deep floor plans with multilayered grid structures, which coincided with the spatial program.

Even by today's standards, daylight simulations for the building clearly show a functional structure. The fixed sun louvers, after investigations of sunlight positioning, prove to be a sophisticated sun-screening device and cannot merely be regarded as a design-oriented application. This fixed sun-screening device is functional while simultaneously reflecting the building's expression.

Analysis of the floor plan types has shown the utilizable grids for different office typologies. Grid drawings and utilization are in accordance with the German government's criteria of building in existing contexts.

The actual measured existing potential of the primary steel reinforced concrete structure of the building would allow a 1 to 2-storey addition, provided it is executed in a light weight steel structure. However, the envelope design is not consistent with contemporary or future standards and would have to be in steel in order to maintain the narrow window framing profiles.

This building is a reflection of the context of the preservation of social and cultural values. The approach or process suggests a strategy for examining buildings of a similar type.

General assumptions and speculations concerning these building types, their architectural quality, their utilization possibilities, and feasibility studies alone do not go far enough. Only the explicit illumination of historical references, the inherent processes, and what can be evaluated as existing cultural inventory, as well as the explicit investigation of anticipated future uses can provide support in making decisions concerning conservation, modernization, or possible extensions to existing buildings. A modification is at its best when existing buildings in all of their facets and resources have been completely captured and understood.

2.2 University of Hamburg - Campus Von-Melle-Park (VMP), Hamburg (Germany)

The development of university campuses in Germany found its climax in the sixties and seventies. The architecture conceived during this period left its imprint as the architecture of the booming years of economy. This period often created university satellite campuses on the fringe of the cities.

Universities located in the down town core could only be implemented, if post-war vacated lots were made available.

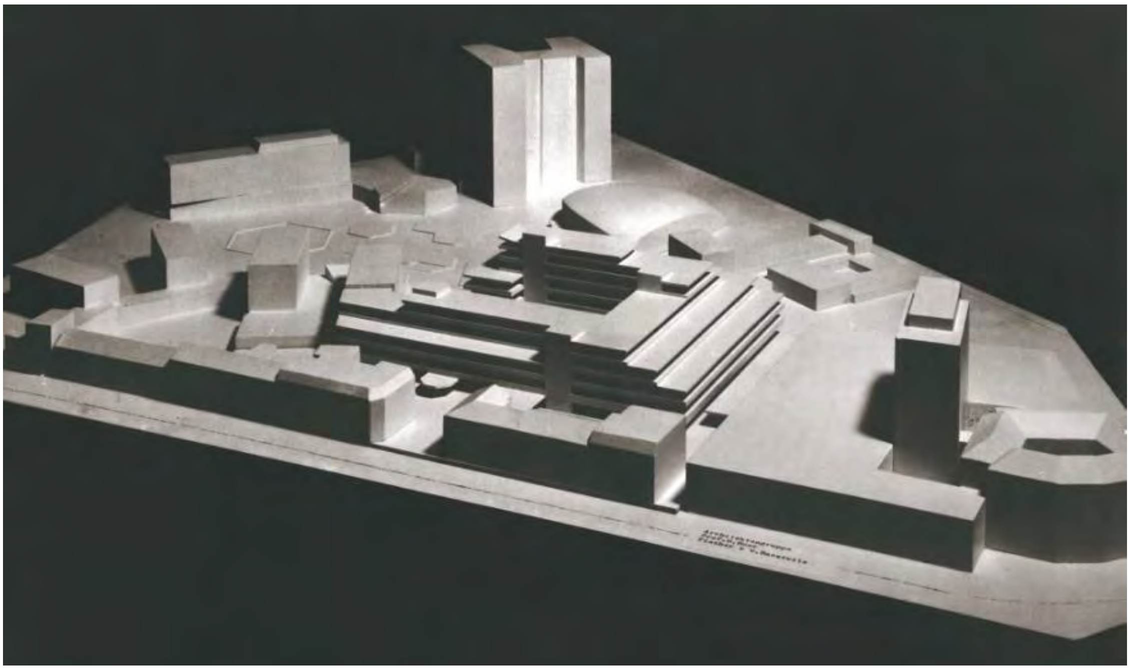

Figure 7: Model, Campus Von-Melle-Park, University of Hamburg, 1971. from: Architektengemeinschaft WIWI II. Hoor, Prof. D., Geelhaar, K., Fischer, C.F., v. Bassew, H. (1971): Erweiterungsgebäude des Fachbereichs Wirtschaftswissenschaften der Universität Hamburg. Planunterlagen als Anlage zur Leistungsbeschreibung, cover.

The development oft the main campus for the University of Hamburg began in the late 1950's according to the plans of the architect and urban planner Paul Seitz, who was the first director of the city planning division for the City of Hamburg from 1953-1963. Paul Seitz planned two of the existing buildings:

The Philosophy tower (Philosophenturm/ VMP6 (1959-91)) and the Paedagogy Institute (Pädagogisches Institut/VMP8 (1957-60)).

The university campus is characterized by a loose accumulation of individually designed buildings for separate institutes. The concept of the campus was to be comparable to the values of a democratic and pluralistic educational system.

Figure 8: Maps of existing situation and new building of VMP5, 1971. from: Architektengemeinschaft WIWI II. Hoor, Prof. D., Geelhaar, K., Fischer, C.F., v. Bassew, H. (1971): Erweiterungsgebäude des Fachbereichs Wirtschaftswissenschaften der Universität Hamburg. Planunterlagen als Anlage zur Leistungsbeschreibung, page 3.

The building ensemble of the university campus was extended in the early seventies. Von-Melle-Park 5 was planned as an extension to the Faculty of Economics and executed ready for occupancy by an architects association for the University of Hamburg.

SIEMENS using prefabricated concrete components completed the building in 1975.

Figure 9: Mapping of listed university buildings, Hamburg, 2016. www.geoportal-hamburg.de/Geoportal/geo-online/index.html (Stand 19.03.2016).

The entire university campus is under ensemble protection (see light-red coloured areas in Figure 3).All buildings are protected historic heritage (see dark-red coloured buildings). Exceptions to this are only the building VMP5 as well as the areas of the university library.

The Hamburg Ministry of Culture Office for the Protection of Historic Buildings will soon be establishing guidelines for the refurbishment process of the existing buildings.

In preliminary discussion with the Culture Office main objectives for the future refurbishment plans were determined. Maintaining materials, building volumes and nuances of colouring are of paramount concern. All interventions or modernizations should respect the principle of identifying the year the building was built this way referencing its cultural context. At the same time the buildings must adhere to the current requirements of energy efficiency.

For every required construction project in the existing context, the decision between conservation of the ensemble and the improvement of the building performance becomes a balancing act.

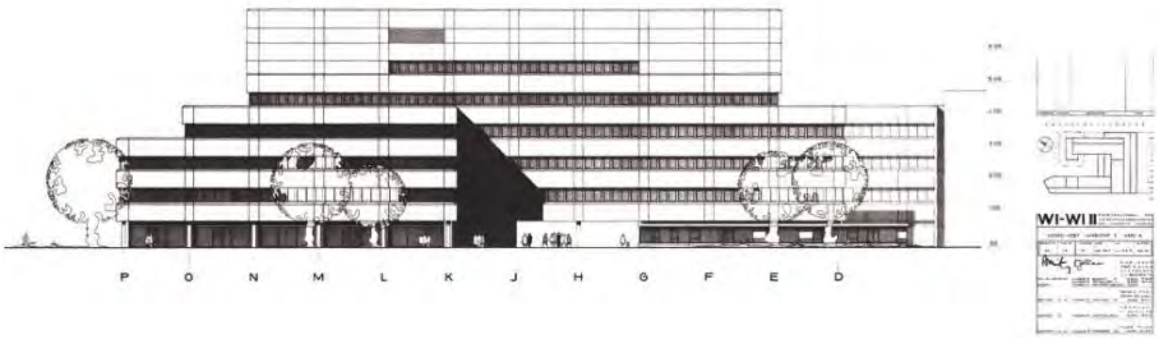

Figure 10: Northeast elevation, Von-Melle-Park 5, 1971. from: Architektengemeinschaft WIWI II. Hoor, Prof. D., Geelhaar, K., Fischer, C.F., v. Bassew, H. (1971): Erweiterungsgebäude des Fachbereichs Wirtschaftswissenschaften der Universität Hamburg. Planunterlagen als Anlage zur Leistungsbeschreibung, page 15.

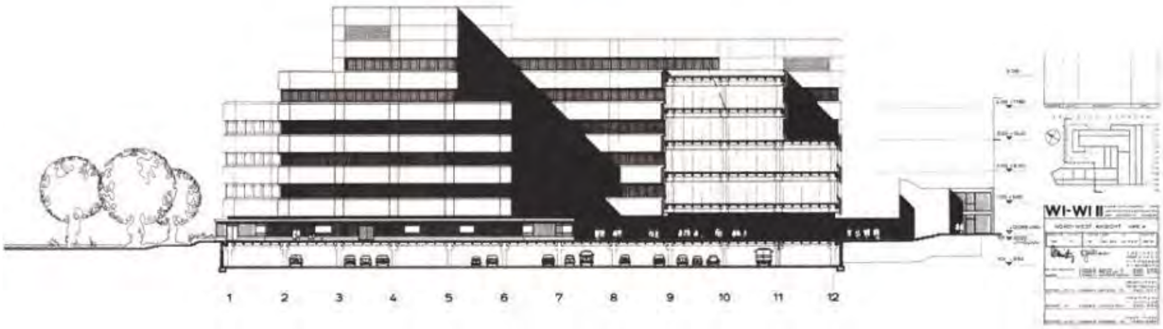

Figure 11: Northwest elevation, Von-Melle-Park 5, 1971. from: Architektengemeinschaft WIWI II. Hoor, Prof. D., Geelhaar, K., Fischer, C.F., v. Bassew, H. (1971): Erweiterungsgebäude des Fachbereichs Wirtschaftswissenschaften der Universität Hamburg. Planunterlagen als Anlage zur Leistungsbeschreibung, page 14.

Refurbishing buildings of the seventies demands, besides renewing the mechanical systems also updating to the existing fire codes, removing contaminated materials as well as improving the building envelope. After 40 years the existing envelope is in need of an upgrade. The facade consists of concrete sandwich panels and framed sliding windows with aluminum profiles. The concrete, or the exterior was exposed to harsh weather conditions and has been subject to heavy corrosion. All windows are leaky and are difficult to operate including the sun shading devices.

A refurbishment concept was developed by the architects PASD-Feldmeier Wrede (Germany), in respect to the architecture of the building as a protected ensemble.

Figure 12: Photography of north façade corner, Von-Melle-Park 5, 2016. PASD Architekten. Feldmeier Wrede. Photography taken by Mariia Tumanovska, 02/2016.

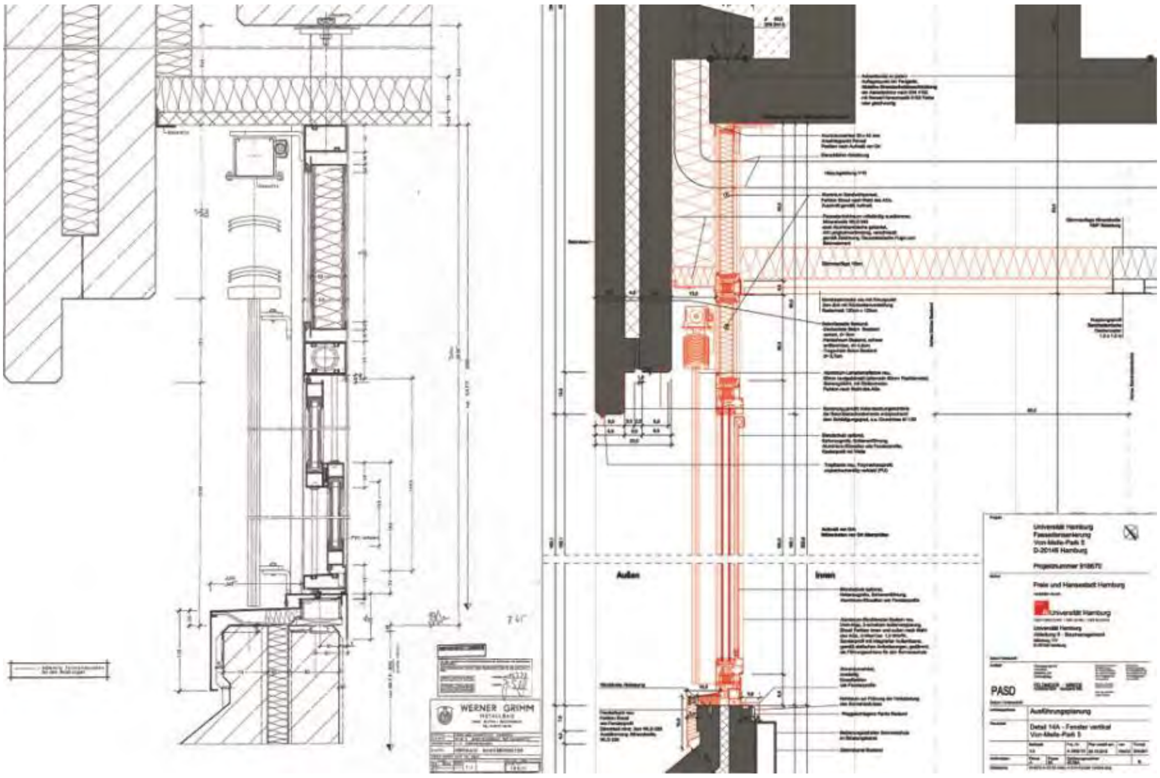

Figure 13: Vertical window section, built situation and refurbishment. Werkplanung 1971: Werner Grimm Metallbau Eutin. Ausschnitt Werkplanung 2016: PASD Architekten. Feldmeier – Wrede

The sliding aluminum windows were installed in the early seventies. These windows provide no thermal separation but were assembled with insulated double-glazing.

To bridge the structural height of 2.60 m, hollow section columns were mounted according to the secondary grid of 1.20 m. The hollow columns are used to attach the window elements vertically. All window constructions end at 2.60 m, aligned with the edge of the dropped ceiling, which runs further above the framed windows into the exterior of the facade. This void is also used to accommodate pipes for the heating system, which lead behind the prefabricated panels to the floors above.

Remaining inoperable for years are the sun-shading devices, which was to be centrally monitored and controlled by the South facing elevation.

In the frame of the obligatory analysis of the existing building, the commissioned replacement of the windows evolved into an extensive issue. The refurbishment plans include a vapour tight window construction aligned with the insulation of the exterior wall element. To compensate for the dewpoint at the bottom of the window, the windows will be insulated.

Integrating a structural pilaster strip will strengthen the window frames. These pilasters can also be utilized for the subsequent assembly of the sun-shading device. Window elements will be realized with aluminum framing in an anodised coloured tone modelled after the existing facade.

The dropped ceiling will be reduced according to the depth of the room, replacing the insulation material. Penetrating heating pipes through the sandwich panels will be sealed and taped airtight. To prevent condensation, the voids in the facade will be filled with additional insulation. The envelope facing south will be installed with a sun-shading device, which can be individually controlled by the users.

A dismantling of contaminated building materials will be undertaken during the course of the refurbishment of the windows. Applied asbestos plates as well as batten insulation will be removed. Asbestos cords, which were inserted to the points of support, will be coated with a bonding paint.

To maintain the appearance of the facade, the concrete panels will be cleansed and damaged spots repaired. The drainage line on the panels will be re-profiled. The concrete panels will be coated with a water repellent in the final process. All seals will be substituted with current compression tape along the joints and seams.

Figure 14: Visualisation of north façade corner, Von-Melle-Park 5, 2016. PASD Architekten. Feldmeier • Wrede. Visualisation made by Mariia Tumanovsk

3. CONCLUSION

The three chapters of this paper give a coherent detailed view on the discourse around buildings in existing contexts. Not only giving a view on the hidden potentials in the built environment for densification through extensions, primarily to the roof-top, but also a view on individual buildings. As case studies they deliver important strategies of approaching this area of concern towards renewable existing urban environments, which may be transferred to similar contexts.

Only through initial analysis, which delivers a deep understanding of the building in its object character and assessment of its social cultural and economic value, can appropriate decisions be made.

A detailed focus on the building components is inevitable, if refurbishment aiming at improvement of utilization and performance are to be brought in accordance with the quality of appearance. Comprehensively respecting these aspects signifies adding to the quality of the urban fabric.

ABSTRACT

The compact city is an integrated form of city with high density, mixed uses and intensification of land uses with centralised activities and higher densities. It requires provision of facilities within a walkable distance and an efficient public transport system to reduce the energy consumption and the pollution so created. The compact city is a form of sustainable urban form as it becomes a solution to the present problem of urban sprawl and rapid development of cities towards the outskirts. Indian cities are expanding in size with their urban boundaries extending outwards. There is a lot of pressure on urban land which due to haphazard development is getting wasted. The compact city is a way to reduce the pressure on land by utilising it to the maximum with higher economic productivity and better environmental quality. The following paper discusses the various parameters which are used to measure compactness of a city and using them the urban compact form of Jaipur city has been analysed.

1. INTRODUCTION

The term compact city was coined for the first time by George Dantzig & Thomas L. Saaty in 1973. The compact form has been studied in the planning literature mostly during the last twenty years to implement the sustainability within the urban environment. Sustainable urban development lays emphasis on having high residential density with mixed land uses, provision of infrastructure facilities within walkable distance, efficient public transport system, low energy consumption, reduced pollution and better social interaction.

According to various authors compact city can be defined as an intensified use of space in the city with higher residential densities and centralisation, more intensified land use and where the growth is encouraged within the boundaries of existing urban areas, but with no development beyond its periphery. It is one of the solution to the problem of the rapid development of the decentralisation outwards of the cities. The compact city includes wiser use of land as land uses are more intensified, thereby avoiding wastage of land. As the nature of the city is more compact, it reduces travel distances from office to home which saves user's travelling time. The sub-urban agricultural land can be preserved as it requires lesser land to be converted to urban area, thereby saving agricultural land. The per capita infrastructure spending also reduces as the provision of infrastructure in a compact city is made for higher serving population within smaller area. This saves spending on infrastructure to reach out to farther distances as in case of sprawl. It creates a healthy urban environment as there is lesser dependence on vehicles.

1.1 Urbanisation and compact city

At present, 50% of world population is residing in urban area which is assumed to rise to 70% by 2050. There has been a decrease in densities of cities of both developed and developing countries from 1990 to 2000. The reason for this being the space is not utilised entirely and sprawl. Large metro cities have more space as hinterland and which is underutilised. The cost of housing in suburbs is less but the hinterlands depend majorly on fuel and transport. A balance between density and sprawl, transportation, energy and resources is the need of the hour. There is a constant push for cities which can cater to higher densities.

2. EMERGENCE OF COMPACT CITY

The UNCED Agenda 21 proposals had embodied resource conservation and waste minimization in the late eighties and early nineties to achieve a sustainable urban environment. The countries around the world have started making policies to make their cities compact. A compact urban form in built up areas facilitates local energy generation technologies and at urban fringes it conserves land resources for agriculture, recreation and water and energy provision.

2.1 Measuring the urban form

Urban built form is the physical manifestation of various activity systems in a city, and is a reflection of preferences, perceptions and aspirations of the people. The activity systems are translated into various land uses on the ground. Different land uses generate different built forms. The spatial organization of the city allows planners to formulate policies for future development by incorporating the existing character of the city. The urban form of a city is suggestive of the degree of compactness that can be achieved and that exists in the city. It becomes important to know the level of compactness that exists in the built form if we plan to make it compact for future, given that compact city is accepted as the sustainable urban form.

2.2 Indicators of compact city

Since compact city is the upcoming sustainable form of urban growth it becomes essential to know the parameters that define the compact city. Various researchers have worked upon computing the indicators that can be used to depict the compact city characteristics. The indicators are directly generated from the concept of compact city which are density, land use distribution, density dispersion, transportation, accessibility and shape of the city.

3. STUDY AREA

The study area selected is Jaipur city. Jaipur is the capital city of Rajasthan and the 10th most populous city in India. The study includes measurement of various indicators of compact city for Jaipur to view its potential for future growth. Jaipur is witnessing a rapid growth in its trade and manufacturing industries. It is attracting investment opportunities from all over India. Big international companies and manufacturing industries are eyeing Jaipur as another hub for their growth in India. All these factors contribute towards a large influx of population that is moving to the city. As a result of this population growth the city boundaries have been expanding and the city is facing urban sprawl. The population has become twice from 1991 to 2011 and at the same time the area has become three times from 1991 to 2011. It suggests there has been wasteful use of land. There is a need to plan for higher density compact development which can accommodate this population growth within lesser area.

4. ANALYSIS OF THE STUDY AREA

4.1 Density

High density city is the most important indicator of a compact city. Urban sprawl is an outcome with low-density suburban residential. To preserve the precious sub urban land the compact city form should be incorporated in our cities. Density determines in large part the cost in money, energy, and resources to build and maintain public infrastructure. In addition to infrastructure, density also influences the amount of fuel needed for automobile travel. The greater the density in an urban area, the more its sewers and roads can be made compact.

The population of Jaipur is 3046163 as of Census 2011. The municipal area of Jaipur covers an area of 326 sq. km in 2011. The Jaipur Municipal Corporation (JMC) Area is further divided into the walled city and the rest of JMC area. The average developed density of Jaipur has changed from 152 pph in 1971 to 148 pph in 1991 and 123 pph in 2011. Thus there has been a continuous decline in the density of the city which shows there is a need to control the urban area per person which is increasing. There are 77 wards in the city as of 2011. Figure 1 shows the variation of the gross density in the various wards of the city. The highest gross density is found in the core area or the walled city area as high as 998 pph in ward 53. The density decreases as we go away from walled city. (Source: Census of India & Jaipur Master Development Plan)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

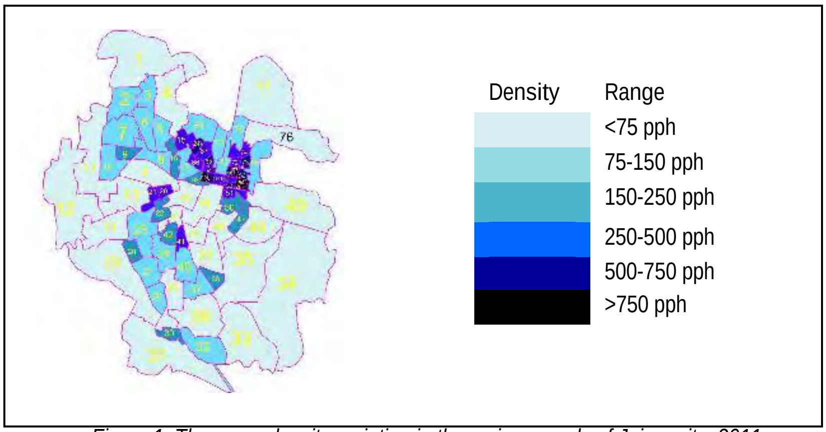

Figure 1: The gross density variation in the various wards of Jaipur city, 2011

4.2 Land use distribution

The land use distribution can be studied to understand the intensity of land use. For a compact city, high density mixed land use is preferable with ample open spaces.

Sr. No.	Major Landuse Purpose	Area (ha)	% to Total Area	% to Developed Land	
				Actual existing in city (%)	UDPFI recommendations (%)
1	Residential	14000	42.87	66.22	35–40
2	Commercial	730	2.24	3.45	4-5
3	Industrial	1600	4.90	7.57	12-14
4	Public and Semi Public	1200	3.67	5.68	14-16
5	Government	340	1.04	1.61	
6	Circulation	2203	6.75	10.42	15-18
7	Recreation	448	1.37	2.12	20-25
8	Mixed land use	620	1.90	2.93	-
	Total Developed Area	21141	64.73	-	
9	Agriculture	6900	21.13	-	-
10	Government reserved	701	2.15	-	-
11	Water bodies	520	1.59	-	-
12	Vacant & undeveloped	3396	10.40	-	-
	Total Area under Municipal Corporation	32658	100	-	-

Source: Jaipur Master Development Plan, 2025

Table 1: Existing land use distribution in Jaipur 2011

Residential land use far exceeds the norms where as all other land uses are far below the prescribed norms. Such a trend indicates wasteful use of land, inadequate infrastructure, and lack of employment opportunities in the study area. The fast growth of the built up area as compared to other land uses has adversely affected the availability of infrastructure in the system. The land use under recreation and circulation is much lower than recommended. Jaipur city is therefore, facing problems pertaining to road network, water supply, sewerage, drainage, traffic and transportation, etc.

4.3 Density dispersion

Density is an important indicator of a compact city so is the type of density distribution that exists in the city. To understand the pattern of density in the Jaipur city we have studied the density profile, the distribution of density and cumulative population as the distance from the Central Business District (CBD) increases. The approach taken

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

to study the variation is by taking the centroid of each of the ward in the city and measuring its distance from the central point of the CBD and variation in density with this distance.

A negatively sloped exponential curve is formed if the densities are high at the center of city and decrease away towards periphery. The density gradient determines the travel distances in the city and the consumption of land across the city. The density gradient map of the city of Jaipur is negatively sloped curve majorly but there are a few junctions where the graph shows peaks of high density due to presence of certain important centres such as high density town Sanganer is located here. Due to presence of natural barrier on the north east side of the city which is surrounded by hills on the major eastern and north eastern side leads to growth in the west, north and south western areas.

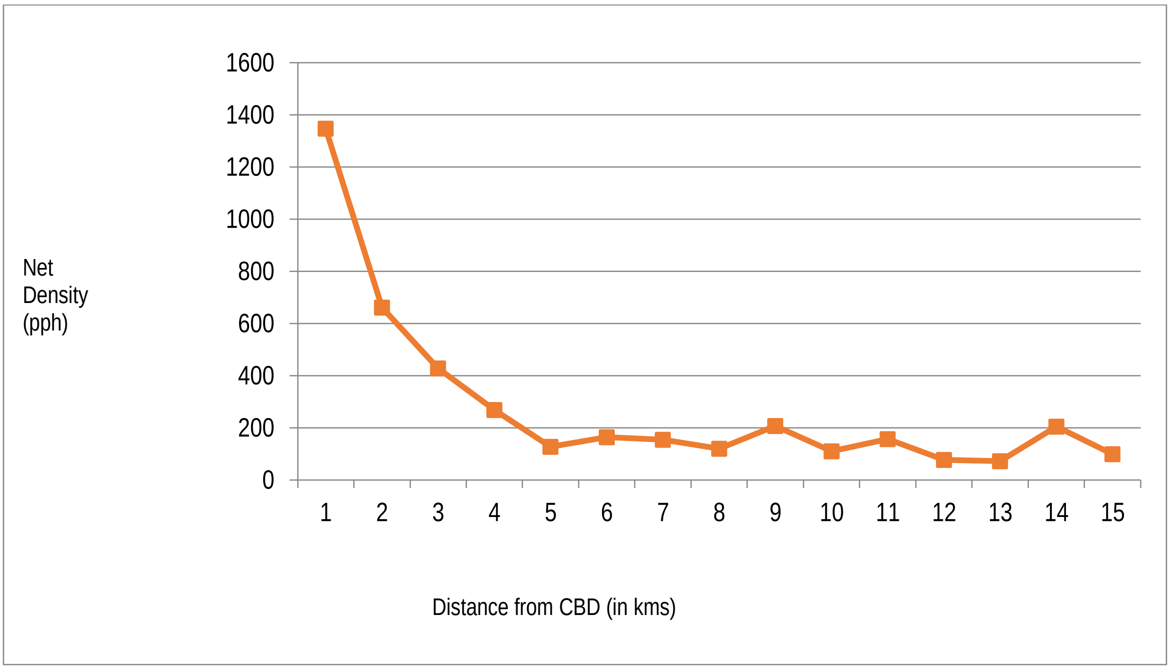

Figure 2: Density distribution pattern as the distance from the CBD increases, 2011

For the Jaipur city, as of 2011, 80% of the population resides within 9-10 kms from the CBD. The closeness to the CBD helps in determining the travel distances of the people. People within 5 km radius are considered close enough to the CBD and it is assumed the distance shall be covered within 15-20 mins by a bicycle. However, the travel distances in the city of Jaipur are to the order of 9-10 kms. For this we need a strong public transportation system to cater to the people in order to keep the city compact and reduce dependency on cars.

4.4 Transportation network

A compact city to be functional needs good connectivity and efficient movement of both goods and passengers. Therefore, public transport has a very important role to boost up activities and promote development in desired corridors. A city can be efficiently compact only when its public transport has the ability to cater to the population being served to reduce dependency on private vehicular use. Wilber Smith and Associates study shows the percentage mode share of trips that are made using each type of transit mode in Jaipur city. The non-motorized transit (NMT) is 32% which is considerably good; the share of private vehicles (35%) is more than twice the ideal values (10-15%) for a city with 2-4 million population. Jaipur city shows a very less share of transit or public transport modes (33%), which shows the lack of investment in public transport infrastructure even though we have seen that the travel distances are of the order 9-10 kms in the city which needs a strong public transport system.

For Jaipur, the evaluated value of congestion index is 0.30 which is slightly higher than the average congestion index (CI=0.26) in Indian cities reflecting an average road network system with certain congested corridors at peak hours. Chandigarh has the lowest congestion index (CI=0) which is very good quality road network.

The average walkability index in Indian cities is found to be 0.52. Jaipur has WI as 0.64 which is close to the average index which suggests that the city has an overall average pedestrianisation. The large cities have better

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

pedestrian facilities than small or medium towns. If we see developed countries, London has an index of 1.5-1.7 which is extremely good.

4.5 Accessibility index

Accessibility or proximity of a service, place, or intended activity may be described as how efficiently with less time and travel distance a person can reach there. Two types of Accessibility indices are (i) Public Transport Accessibility Index and (ii) Service Accessibility Index.

Public Transport Accessibility Index is formulated as the inverse of the average distance (in km) required to be travelled to reach the nearest bus-stop/ railway station (suburban/ metro) by residents. Higher the index means better public transport accessibility. The Average Public Transport Accessibility index over the cities is found to be 1.05. For Jaipur, the Public Transport Accessibility index is 1.38 which is slightly higher than the average.

Service Accessibility index is based on the percentage of work trips completed within 15 min time. Higher index indicates better service accessibility. In Jaipur, 51% of total work trips are made within 15 min. The accessibility index value for Jaipur is 0.7. The average service accessibility index comes to 0.68 for Indian cities. However, it is close to the average value in Indian cities.

4.6 Shape of the city

The shape of the city may affect the compactness of the city. Linear cities have longer travel distances while circularly growing cities have smaller radial travel distances. The travel distances for work, shopping and recreation vary as the shape of the city varies. The shape of the city is much affected by the locale factors which may include physical barriers, heritage sites, natural reserves, etc. The dispersion index is defined as follows:

$$p = (\Sigma\ diwi)/[2/3(A/\pi)1/2] \text{ or } p = (\Sigma\ diwi)/(2/3)r$$

Where, di is the distance of the centroid of the ith tract (or ward or zone) from the CBD or CG, weighted by the tract’s share of population wi; A is the built-up area of the city; r is the radius of a circle with area A.

The value of dispersion index as 1.0 is considered as the threshold between compactness and dispersion. Larger the index, less compact the city is. There are 77 wards in Jaipur and the distance of each ward’s centroid from the CBD has been calculated and the weighted population is multiplied to find the value of dispersion index for the city of Jaipur. It has been calculated as 1.166. It is evident that Jaipur is a lot of scope to become compact as it lags behind.

5. CONCLUSION

Jaipur city has seen a sudden urbanization which has led to a growth of city which wasn’t planned for. The core was set up in the 18th century. The city has experienced a southward and westward growth majorly due to the presence of Aravalli range on the east and north. The growth boundaries are expanding with an alarming rate and there is a need to contain the urban form. The study shows that Jaipur has all the components that are required for a compact city. The city at present is heading towards dispersion and there is an urgent requirement to contain its compactness. The dispersion index which was 1.166 suggests that there is a lot of scope for Jaipur to improve its compact character. The wards having densities lower than 150 pph can be redensified. These wards cover more than 40% of the city area. The density distribution shows a tendency of population moving from the center to the peripheral areas. The public mode of transportation’s share is poor and should be enhanced.

The compact urban form has a close relationship to the sustainability of the urban environment. The policy makers need to promote the public transportation and formulate policies to reduce car dependency/ ownership. The accessibility to the public transport and service places also helps in containing the compact character of the city. The proximity to work places and commercial areas increases the compactness of the urban form. The efficient supply of social infrastructure and public services within the neighborhood should be promoted. The compact city policies should be incorporated in the development strategies to control urban expansion caused by rapid population growth.

Where Planning Regulations and Development Practice Collide: The Multi-Storey Apartment Building in Subtropical Brisbane Australia

Rosemary Jean KENNEDY[a]

[a] *Queensland University of Technology, Australia, r.kennedy@qut.edu.au*

ABSTRACT

Brisbane Australia has been undergoing a growth cycle since 2011, with many new apartment buildings on the skyline. Brisbane City Council's e-Plan Multiple Dwelling Code unequivocally links the city's character and identity, and residents' way of life, to the local subtropical climate and landscape. Performance outcomes for code assessable apartment developments promote cross-ventilation and well-designed private outdoor spaces (for example, balconies) to be achieved by correctly designed fundamental structural controls - orientation, spatial configuration, and shading.

A sample of recently-approved 5 – 30 storeys apartment buildings in Brisbane's inner urban renewal areas was studied for performance under the Code. Spatial-structural architectural data were collected from documents submitted for development approval to Council's online system. A 65-year-old apartment building recognised as an Australian significant building of the 20th Century was also analysed.

The research identified performance gaps between planning policy and actual design. The older building out-performed the new under all criteria. Little diversity in building configurations, spatial characteristics and basic floor layouts was observed. Overall, the approach utilised by developers is producing formulaic apartments that cannot be effectively cross-ventilated and that have extremely limited or no private open space.

Developers' primary interests are to maximise yield and 'the view'. This paper provides evidence that the planning code is having little effect on key items driven by these aims. These are: compact form (large building volume enclosed by a small façade area) that reduces the extent of external walls available for effective openings; and extensively glazed, unshaded external walls that are compensated for with air-conditioning technology. The quest for views is also compromising the utility of balconies with glazed balustrades diminishing usable, comfortable, private outdoor area. These products are unlikely to meet future market preferences for more authentic innovative place-based buildings and make long-term liveability and sustainability aims difficult to achieve.

Keywords: policy and regulation, subtropical, apartments

1. INTRODUCTION

Brisbane Australia has been undergoing a growth cycle since 2011, with many new apartment buildings appearing on the skyline. Performance outcomes for code assessable apartment developments under Brisbane City Council's *e-Plan Multiple Dwelling Code* (2014) promote cross-ventilation and well-designed private outdoor spaces (for example, balconies) to be achieved by correctly designed fundamental structural controls - orientation, spatial configuration, and shading. The structural (architectural) approach to thermal comfort design aligns most closely with Brisbane residents' preferences for occupant control over indoor environments, and occasional energy use (Kennedy, Buys, & Miller, 2015).

Developers' primary interests are to maximise yield and 'the view'. Generic design strategies that are applied to achieve these aims have an effect on the factors that residents consider important for liveability in the subtropics such as availability of natural ventilation to control thermal comfort, access to private outdoor space for everyday home-based activities (Kennedy et al., 2015). Developers favour compact form, where large building volume is enclosed by a small façade area (Barton & Watts, 2013) and extensive external glazing for views. The former reduces the extent of external walls available for effective openings, while the heat gain associated with the latter is compensated for by mechanical controls (air-conditioning technology) often without shading to mitigate glare, and reflectance problems.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The purpose of this paper is to present data and discussion on how recently-approved buildings measure up to the objectives of the Multiple Dwelling Code (MDC) unequivocally links the city's character and identity, and residents' way of life, to the local subtropical climate and landscape.

2. CLIMATIC DESIGN APPROACHES AND BUILDING CONFIGURATION

Brisbane is located in Queensland Australia at 27.5°S and 153°E. The natural conditions of the mild subtropical climate fall within the "comfort zone" (Ballinger, Prasad, & Rudder, 1992) 80% of the year, and continuous air-conditioning as a function of dwellings is rarely desired by residents. Nevertheless, cooler temperate or hot humid tropical climatic conditions are experienced annually, each requiring specific design responses. It is important to admit the sun's energy and store using thermal mass when it is required during winter (Givoni, 1998); and exclude direct sun by orientation and shading strategies and remove heat by in summer (Hollo, 1995). Ventilation to provide air movement reduces the effects of humidity (Emmanuel, 2005).

The relationship between external wall area and enclosed floor area (WTF) is critical in the success of these strategies. Using the structural approach, increasing the extent of external walls is beneficial in terms of opportunities for openings for cross-ventilation, and daylight availability (Ratti, Baker, & Steemers, 2005). The natural ventilation strategy (integrating structural form, and sizes and locations of openings) can have more of an impact on comfort than thermal mass, both in summer and winter. On the other hand, if the mechanical approach is adopted, reducing the extent of external walls in apartment buildings is beneficial for restricting heat gain or loss through the façade.

Expressing this relationship as Surface Area to Volume (SAm^2/Vol m^3) ratio provides an indicator of whether the overall building form is fundamentally appropriate to the local climate conditions. The higher the ratio, the greater extent of external wall area indicated. The lower the ratio, the more 'compact' the structural form is, with greater volume being enclosed by least surface area. Thus, reducing the extent of external walls is essentially a strategy for heating conservation (Oldfield, Trabucco, & Wood, 2009) and is not suitable for tropical and subtropical conditions.

The relationship between external wall area and enclosed floor area (WTF) is also a critical measure of cost effectiveness in the value profile of a multi-storey building (Barton & Watts, 2013). From a construction cost perspective, the lower the cost of enclosing a unit of floor area with external walls, the better. The greater the number of dwellings on an individual floor plate of an apartment building means that the developer can increase profit by recouping the cost of constructing the external wall from a greater number of purchasers.

The metric is also an indicator of the spatial properties of dwellings: a high WTF ratio implies that dwellings have a greater extent of façade available to the interior spaces, while a low WTF ratio tends to indicate a "deeper" plan shape with less external façade available. In multi-storey buildings with several dwellings on each level, the lower the WTF ratio, the more the building form precludes passive forms of control over moderating the internal dwelling environment, and the more air-conditioning is needed.

The MDC Performance Outcomes (POs) and associated Acceptable Outcomes (AOs) exemplify the passive climatic structural approach to design rather than the technological approach (see Table 1 for a sample).

PERFORMANCE OUTCOME	ACCEPTABLE OUTCOME METRICS
PO 20 Development includes buildings that exhibit subtropical design character and subtropical living	• 1 of: Dual aspect / greater than 2.4m ceilings / Habitable rooms with 2 windows or openings; • Weather and sun protected external doors and windows to habitable rooms; • Sun-shading or deep recesses on North; • Sun-protection on West.
PO 28 Development must provide attractive and functional private open space for residents	• 12m^2 minimum balcony area • 3.0m minimum dimension

PO 29 Development provides a resident with functional outdoor living space that receives natural light but is shaded to protect the resident from direct sunlight	• Solar access (form, materials, orientation) • 75% of a dwelling's outdoor living area N or NE (taking into account desired street interface and privacy outcomes)

Table 1: The MDC's Performance Outcomes and Acceptable Outcomes for Assessable Development

3. METHODOLOGY

This research focuses on a sample of recently-approved multi-storey residential buildings (MSRBs) from five to 30 storeys tall in Brisbane's medium and high-density zones in inner urban renewal areas. Projects with Development Approval (DA) post-2011 were identified by searching Council's online planning application system. A sample of 15 projects was purposively selected to take into account a range of scales of development and spatial configurations. Building usage was primarily Class 2 (Apartments) as defined by National Construction Code (Building Code of Australia) Volume 1(2013) but could also be mixed-use with multiple classifications, for example Hotel (Class 3), Commercial or Professional offices (Class 5), Retail (Class 6). Relevant DA documents were accessed from the online system, and a content analysis of architectural drawings (plans, sections and elevations) was conducted.

In addition, the Torbreck Apartment building completed in 1960, situated at 182 Dornoch Terrace, Highgate Hill was selected as a benchmark case. This building is an Australian Institute of Architects 'Significant Building of the 20th Century' (2010). The researchers accessed documents from a case study (Centre for Subtropical Design, 2006).

The research was conducted as a desk-top study during the period December 2015 to February 2016. Field observations to assess any differences between approved designs and built outcomes, or to identify resident modifications were not undertaken because not all of the building construction was complete at the time.

The following spatial-structural metrics were used to gain an understanding of the extent of opportunities for cross-ventilation and daylight availability: Building form and spatial configuration - (for example: tower, podium, core location and single or double loaded corridor, and number of storeys); typical private dwelling unit size, calculated as fully enclosed covered area (FECA) measured to line of 'weather-tightness'; external wall-to-internal floor area (WTF) ratio of typical dwellings; Surface Area to Volume (SA m^2/Vol m^3) ratio of overall building.

The Floor Area Ratio (FAR) of typical apartment building floor plates were calculated to determine potential for developer's yield. The metrics for FAR included net saleable area (all dwellings areas exclusively allocated to private dwelling units including balconies or similar) and common areas (shared by the residents of each floor including lifts, corridors and lobbies, stairs, ducts, plant rooms, electrical rooms, indoor garbage storage, lift motor rooms, administration areas and any gymnasiums, indoor swimming pools, common laundries, common bathrooms, common changing facilities, business centres, community/lounge/activity rooms and so on).

Utility of private outdoor space was measured according to the metrics for minimum dimensions and screening in the MDC.

4. RESULTS AND DISCUSSION

The research identified performance gaps between planning policy and actual design. Table 2 (see over) summarises the results. Overall, the approach utilised by developers is producing formulaic apartments that cannot be effectively cross-ventilated and that have extremely limited or no private open space. Little diversity in building configurations, spatial characteristics and basic floor layouts was observed.

The older building (Case 16) out-performed the new under all criteria. The benchmark Case 16 SA/Vol metric reflects the slender forms of its two towers, and associated cooling natural ventilation strategy. Half of the buildings represented by the sample have similar or higher SA/Vol ratios, and half have lower. All three towers in Case 15, a multi-tower project, have very low SA/Vol ratios, indicating a 'compact' building form unsuited to the structural approach desired in the subtropics. Another multi-tower project (Case 14) demonstrates both the highest and one of the lowest ratios. Surprisingly one low-rise building (Case 5) also exhibits the compact characteristic that is more suitable to heating conservation, rather than cooling by cross-ventilation.

Table 3 below summarises the findings of wall-to-floor ratio investigations for typical dwellings within the buildings, showing the benchmark Case 16, and the maximum and minimum cases. Case 16 has larger more spacious apartments and high WTF ratio indicating high potential for a successful ventilation strategy. The area of glazing compared to the overall external wall area indicates that walls are solid mass material compared to Case 15 where the external wall area is fully glazed. It is also worth mentioning that the primary functional requirements of windows under the BCA are admission of daylight and ventilation. View out of the window is a secondary function that has been given primacy by developers' imperatives.

The greater external façade area of the older building provides both thermal mass and opportunities for strategic openings, balancing daylighting and cross-ventilation appropriate for warm climates in accordance with recommended climate-responsive design strategies (Ratti et al., 2005). Glazed walls in MSRBs may be desirable for views and daylight (J. Lee, Je, & Byun, 2011), but unless a holistic architectural logic that serves the occupants' needs is employed, they can become the greatest source of glare and heat transfer and thermal discomfort in both temperate (Hofer, 2008) and tropical (Lam, 2000) climates.

Table 3: External Wall-to Floor Ratio for typical dwelling units

Untreated glazing can be the main avenue for unwanted heat gain throughout the year in the subtropics (ABCB, 2010). The desk-top study could not determine whether low emissivity and spectral selective glazing technology which is of benefit to reduce heat gain (D. H. Lee, 2000) was intended. It is important to note that low-E glazing does not automatically translate into a high performance façade, and it is associated with unshaded buildings. In the subtropics, the structural approach to window design is associated with controlling thermal comfort in summer through shading to control overheating and with generating air movement to counter humidity (Szokolay, 2008). Shading devices also reduce glare and the intensity of daylight entering habitable areas (Edmonds & Greenup, 2002).

Private outdoor living spaces varied quite widely in terms of space and form. Very few dwellings in the sample had primary outdoor living spaces that exceeded 12m^2 despite outdoor living being one of the hallmarks of Brisbane's subtropical lifestyle. While the width of balconies varied across the cases, depths varied widely and many were extremely shallow (460mm, Case 15) or non-existent (Case 8). Most cases incorporated glass balustrades to balconies which offered no sun protection and inhibited air flow. Only 25% of cases had well-resolved designs that complied with the MDC.

The sample analysis demonstrates the tensions between developer's quest for yield and the planning policy's desire to promote climate-responsive building form for MSRBs to play a valuable part of the sustainable subtropical city of the 21st Century. BCC has established that 'structural' design approaches are suitable for multi-residential development Brisbane. But evidently, the current 'passing standard' is too low to achieve acceptable sustainable design. Code Assessable pathways to Development Approval are preferred by developers in order to accelerate the process and thus save money. Ironically, generic solutions are not necessarily the most cost efficient outcomes.

5. CONCLUSIONS

Successful design of private apartment dwellings depends on the overall building form and configurations that require less energy. A major challenge for planning codes is to reconcile the environmental drivers of building form (light and ventilation to dwellings) versus economic drivers (wall-to-floor area) and net-to-gross saleable floor area. This paper has revealed the tensions between the MDC and generic MSRB solutions. It provides evidence that key items driven by developers' aims to maximise yield and privilege 'views' above other important design

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

considerations make it difficult for apartment dwellers to fully embrace climate-responsive high density subtropical living.

Next steps in this research is to investigate the root problems in the current system that results in generic design in order to propose what can be done to enhance the lived experience for Brisbane residents and neighbours (including surrounding community) using effective planning to achieve design approaches suitable for the local subtropical humid climate.

ABSTRACT

There is a great potential in renovating our existing building stock, in terms of improving environmental, economic and social qualities. Meeting the increasing performance requirements for sustainable construction entails an increasing level of complexity in the design process of both new buildings and renovation projects. Decision support tools are one solution that can help the building owner manage this complexity. This study investigates the current decision-making processes among Danish professional building owners, in order to propose a conceptual framework for future decision support tools for sustainable renovation. Design Science Research Methodology has been used as the main methodological framework. Current practices for setting goals for sustainability, determining the current state of the buildings and prioritizing which buildings to renovate within a building portfolio, have been explored through semi-structured interviews with five professional building owners. The study showed that there is a need for tools to support the professional building owner in setting goals for sustainability at an early stage. Tools to support the registration of existing buildings and prioritization among buildings to renovate were not seen as a direct need among this specific user group. This work proposes a conceptual framework for future decision support tools based on the findings, focusing on setting goals for sustainability within renovation projects, either within a sustainability assessment scheme (e.g. DGNB-DK), or project specific sustainability criteria. The results presented in this paper are a part of an ongoing research project focusing on developing a new decision support tool for sustainable renovation.

Keywords: decision support, DGNB, deep building renovation

1. INTRODUCTION

Buildings are responsible for more than 40% of energy use worldwide, and one third of global greenhouse gas emissions, causing increasing attention on sustainable development within the construction industry. Along with tightening the regulations for energy efficiency in new buildings, the Danish government sees great potential in improving the energy efficiency in the existing building stock (Danish Ministry of Energy Utilities and Climate 2014). Broadening the perspective from the narrow focus on energy efficiency to a more holistic approach to sustainability, the Danish building industry has chosen DGNB-DK as a common ground for assessing sustainability in buildings, encompassing social, economic, environmental, technical, process and site quality. The increasing demand for sustainable solutions entails an increasing level of complexity in renovation projects. Multiple decisions have to be made throughout the design process; sustainability criteria are numerous and often conflicting, and on top of that, sustainability goals are not always clarified at an early stage, which makes it even harder for the professional building owner to operate and manage decisions in a systematic and efficient way. Decision support tools are one solution that can help the building owner manage this complexity.

Prior to this study, a literature review has been undertaken (Nielsen et al. 2016). In the review, 43 existing decision support tools for building renovation were analysed and categorised in relation to where in the renovation process they can support the decision maker, along with a proposed road map for designing future decision support tools for renovation projects. This study builds on the findings from the literature review by investigating the needs in practice for Danish professional building owners, within the specific areas of setting goals for sustainability, registration of existing buildings and prioritization among buildings to renovate.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

In addition to the tools included in the literature review, which were all documented in international scientific journals or conference proceedings, several tools have emerged within the Danish construction industry. The BDB-method (BDB-metoden Aps 2016) is a method designed for the building owner to manage the strategic vision from idea to construction and operation, with a flexible approach to sustainability. The BDB-method is intended to be used for both new buildings and in renovation projects. Another new tool is the BSV decision tool (Teknologisk Institut 2016), which goal is to provide a comprehensive and clear foundation for making decisions regarding energy renovation of buildings. The tool is aimed towards the professional building owner, municipalities, board of directors, advisors and contractors. A digital dialogue and prioritization tool for project managers in housing associations is currently under development; the tool is based on DGNB-DK and seeks to enhance dialogue on sustainability among the project managers, occupants and operation personnel, both in renovation projects and in new building projects (Den almene forsøgspulje 2016). The emergent development of new tools reflects the growing need for tools to support dialogue, communication and decision-making in the early stages of renovation projects among the different actors and stakeholders. The existing tools differ slightly in their aim and objectives, though revolving around the same main goal of improving the renovation process within the Danish building industry. In our opinion, developing new tools, and advancing existing tools, will only strengthen the common goal of improving the decision-making process in renovation projects.

This study contains interviews with five professional building owners so as to investigate how they currently set goals for sustainability in renovation projects, how they register the actual condition of the existing buildings and how they prioritize which buildings to renovate within a building portfolio. The study reported in this article is a part of an ongoing research process focusing on the development of a new decision support tool for sustainable building renovation aimed towards professional building owners. Involving potential users at this stage has been an important step to understanding the problem context. The main contribution of this article is a conceptual framework, which can serve as a foundation for future design and development of decision support tools for sustainable building renovation. Furthermore, the article provides useful insights into the decision-making process of professional building owners in Denmark.

2. METHODOLOGY

The methodological framework used in this research project is Design Science Research Methodology (DSRM). DSRM incorporates principles, practices and procedures of designing successful artefacts and has been widely applied in information system research. Peffers et al. (2007) have described the overall steps within DSRM as problem identification, defining objectives for a solution to the problem, design and development of the artifact, demonstration of the artifact, followed by evaluation and communication of the results. The steps are iterative, but the design and development take their point of departure in the problem definition. The results presented in this paper relate to the step of defining objectives for a solution, hereunder investigating a specific business context and developing requirements for a new artefact. Furthermore, this study follows the guidelines suggested by Hevner et al. (2004) for understanding, executing and evaluating research within Design Science Research. The method for data collection has been qualitative, semi-structured interviews with building professionals from three Danish municipalities and two housing associations. The municipalities and housing organisations chosen for the interviews are all professional building owners managing large building portfolios, with the vast majority of their construction projects being deep renovation projects. The themes of the interviews were based on findings from the preceding literature review, which suggests a roadmap for future development of decision support tools for renovation projects. In order to analyse the data, the interviews were subsequently transcribed, condensed and coded into relevant themes and sub-themes.

3. RESULTS

3.1 Decision contexts

The Danish municipalities are characterized by being political organizations, with internal departments responsible for building projects and building owner consultancy within each municipality. Technically, the building owners are other administration departments within the municipality, constituted by politicians in different fields, with none or limited professional knowledge within building design. The housing associations interviewed for this study also serve as building owner consultants, with local occupant administrations from the housing departments functioning as the "building owners" or decision makers. In both cases, the consultants are a part of the organizations, providing a foundation for politicians or occupant representatives for making qualified decisions regarding potential construction projects, both new buildings and renovation projects.

3.2 Sustainability goals in renovation projects

The interviewed professionals from the municipalities and housing associations were asked how they currently set goals for sustainability in renovation projects in their organisation. It was concluded that both the municipalities and housing associations often do not have a formal procedure for setting goals for sustainability. Often, the goals are implicit and based on “what we are used to doing”. However, one of the interviewed municipalities has recently developed a sustainability manual for both maintenance, renovation, rebuilding and new building projects, based on the DGNB-DK certification system, but slightly simplified and adapted to the different project types. They use the sustainability manual as a guide intended to be included in the building brief of their projects to ensure a focused and consistent approach to sustainability.

For the housing associations, the residents are involved in the decision of whether or not to renovate, and therefore their process includes a high level of occupants involvement. Their biggest challenge is to convince the occupant representatives to make sustainable choices, to “sell the idea” of sustainability, as they cannot always see the direct value they get in return for the increased rents following a renovation. For one of the housing associations, the goals are set from project to project; they have no standardised procedure for goal setting due to the high level of user involvement. For the other housing association, they have a goal to certify all major projects using the DGNB-DK assessment scheme. However, the initial choice to renovate one or more buildings stems from the administrative boards of the occupants. The housing association is currently in the process of certifying their first building, their own administrative office building, in order to gain experience and to evaluate the value of a DGNB-DK certified building. The housing association serves as building owner consultant, and because they are not the actual building owner, they can only inspire and “sell” the idea to the occupant representatives. Therein lies a challenge in implementing sustainability goals for their construction activities; they find it hard to convince the occupants to choose sustainable solutions. Also, they miss a common understanding of “sustainability” and feeling of ownership across the different departments in their organisation. Currently, only the construction department is concerned with the sustainability goals, but they wish to include the maintenance department and the rental department as well to ensure a common ground for their activities and goals. The importance of dialogue, both internally in the organisation and externally with included stakeholders, was addressed as an important issue, and one of the biggest challenges, for achieving sustainability goals, as well as prioritization and assessment of available options. Another organizational challenge faced by the housing associations is that they rely on funding from a public fund, and therefore they need to comply with the criteria valued by the fund to get their projects financed.

Interviewees from the municipalities addressed the issue of integrating political goals in the renovation projects as well as the issue of the politicians not being explicit in their goals regarding renovation. Not knowing what is prioritized on the political level makes it hard to implement specific goals in the renovation process. A strategic tool for enhancing dialogue among politicians and the building professionals was requested in order to strengthen the goal setting process and to make goals explicit. Furthermore, all municipalities address the organisational boundaries of their budgets being divided between a construction budget and operation budget as a major challenge in setting efficient goals for sustainability, because they are not entirely able to include a life cycle perspective in their decision-making and sustainability goals. It was specifically addressed by the municipalities that there is a need for a strategic tool that can support them in setting goals for sustainability.

All the interviewees address the importance of making explicit goals, e.g. the level of ambition regarding DGNB-DK certification, in the cases in which certification is a goal. The interviewees all agree that sustainability is important to discuss in the early stages. Also, a majority of the interviewed persons call for a common ground for the understanding and definition of “sustainability” among the included actors, not only at the early stages of the building process but also later, e.g. in the construction phase. None of the interviewees use specific tools for setting sustainability goals. However, they see their facility management system and other building administration systems as a helpful foundation for making informed decisions.

3.3 Registration of the current state of existing buildings

Another question for the interviewees was how they currently register the actual state of their buildings. All interviewees explain that they have a good idea of the current state of their buildings, and when they need deep renovation, due to on-site technical personnel. The interviewed municipalities recently started to collect and enter existing building data into new facility management systems. Before this activity, the information was stored in different places, such as physical and digital folders and Excel sheets. Up to this point, they had to rely on the specific knowledge of individual employees about the different buildings. Relying on knowledge from individual employees made it hard to transfer the knowledge because the process was not automated. Collecting and entering data has been, and still is, a comprehensive and time-consuming process. However, they expect that having their building data in one place will make the processes easier in the future.

One of the housing associations explains that they make an examination of the building before they start a renovation project and that the users take part in the building examination. The housing association mentions that e.g. creating BIM models of their existing buildings would be unnecessary and too time-consuming as they know their buildings very well and have employees on site who can easily find information on the physical building if needed.

As there are already well-used procedures and tools for registration of existing buildings among the interviewed user group, it is not considered necessary that a new decision support tool includes this specific aspect, but instead, extracts the required data from the facility management systems if needed.

3.4 Prioritization among buildings to renovate

The municipalities and housing associations were asked how they currently prioritize which buildings to renovate. After the need for renovation has been identified, the prioritization process is approached differently in the housing associations and municipalities. The housing associations have a democratic process in which the occupants have to vote whether or not to renovate as this will also entail an increased rent. For the municipalities, the prioritization lies on the political level where the politicians need to decide what to prioritize. Common is that all the interviewees act as advisors and have to communicate their professional recommendations, hereunder the aspects of sustainability, to decision makers that do not have professional knowledge in the field of building renovation, either politicians or occupants or other departments within their organisations. This makes their challenges comparable, however not similar, as the interests and background of the politicians and occupants might differ. To sum up, the prioritization aspect was not a big issue for the interviewees, simply because they are not the actual decision-makers themselves, but consultants who are providing or facilitating the decision process and priorities.

4. A CONCEPTUAL FRAMEWORK FOR FUTURE DECISION SUPPORT TOOLS FOR BUILDING RENOVATION

The need for communication and dialogue was highly emphasized among the interviewees, but the situations and needs are different for municipalities and housing associations. Therefore, it is recommended by the authors that one tool does not try to encompass all user contexts, but focus specifically on one user group, e.g. municipalities in Denmark, with the prospect of adapting the tool to different user groups and contexts. Based on the findings, the main functionality for future tools should be to help the user set goals for sustainability in renovation projects (Figure 1). If certification of the building(s) is a goal, future tools should provide a framework for setting goals for each criterion within the certification scheme. The certification schemes have predefined weights for each criterion so the user can estimate which criteria to prioritize and how many points they seek to achieve. If certification is not a goal, it is suggested that a weighting module is included in future tools, with the function of assigning weights to the chosen criteria, to reflect the values of the decision-makers. Based on the preceding literature review, the authors suggest encompassing the weighting method Analytic Hierarchy Process.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

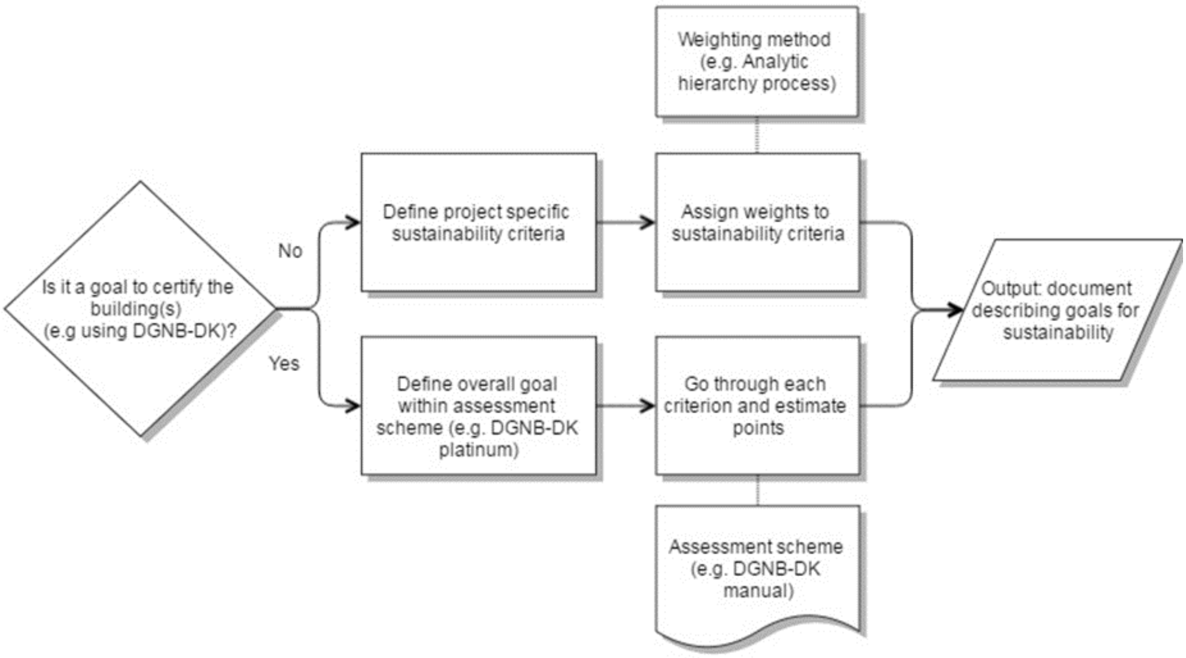

Figure 1: A conceptual framework for setting sustainability goals within renovation projects.

Providing a framework for setting goals for sustainability can enhance the dialogue between the advisor and the building owner and help ensure that goals are made explicit at an early stage. Furthermore, documenting sustainability goals early on can provide useful guidelines throughout the process, even though the goals might change later on. In that case, the tool could be useful at different stages of the design process if the goals need to be modified due to unforeseen factors. Also, the tool could be used in the design process to assess different design alternatives or to assess the final building if certification is not a goal. If the building is certified using DGNB-DK, points can be obtained by documenting sustainability goals in the early project phase. The tool could help provide this documentation.

5. CONCLUSION

The aim of this study was to investigate current practices among building professionals in Danish municipalities and housing associations in order to suggest a conceptual framework for future decision support tools for sustainable building renovation. The study has provided useful insights into how Danish municipalities and housing associations currently set goals for sustainability within renovation projects, how they register existing building data and how they prioritize which buildings to renovate. It was found that there is a need for a decision support tool that can support the professional building owner in setting goals for sustainability within renovation projects. A majority of the interviewees explained that they are already in the process of building a database of their existing building portfolio, for which reason it is not seen as a need to provide a new tool to support the registration process. Furthermore, it was found that prioritization among the buildings to renovate is not a task that lies directly within the departments of the interviewed building professionals and is, therefore, not suggested as a primary focus point in the context of this study. This does not mean that registration and prioritization are not relevant aspects to consider for future decision support tools, but it is not a need within this specific user group.

The results in this article reflect the insights gained from five interviews in a Danish context. It is suggested to focus on one specific user group in the design and development of future decision support tools in order to understand the users in-depth and, thereby, potentially increase the usefulness of new tools. Future research within this research project will focus on the design and development, demonstration and evaluation of a new decision support tool for setting sustainability goals within renovation projects in a Danish context. The focus of this article is on the decision-making process related to building renovation, but the suggested concept could be just as useful in setting goals for new buildings.

A Holistic Thriving Design Approach

Dennis LEE[a]

[a] *Architecture:Innovativ Limited, Hong Kong SAR, dennislee@arch-innovativ.com*

ABSTRACT

According to the Brundtland Report in 1987, Sustainability is to "meet the needs of the present without compromising the ability of future generation to meet their own needs." This definition suggests maintaining the status quo, limiting damage, and protecting existing resources without addressing any leap, growth, or innovation. Unfortunately, the most popular word associated with social, corporate, and individual responsibility nowadays is about not ruining it for our children, as if less bad would be good enough.

By contrast, according to strategist Ralph Thurm, "ThriveAbility" is the sum of Sustainability and Innovation. "ThriveAbility" goes beyond collecting points for sustainability evaluation program certifications, beyond specifying recycled or renewable materials, and definitely beyond mere guilt management. We shall aspire to thrive with the transcendental knowledge passed onto us, with research and development, with creativity and imagination, and rethink the way we create products and our living environments. "Thriving Design" starts from the very beginning – when we first conceive a product or a building or a neighborhood, we shall consider beyond how it is designed, constructed, used, and paid for, also how it is maintained, repaired, retired, and recycled. This is a true holistic design approach to the life-cycle of the hardware and living environments to optimize materials and energy consumption, to produce no waste, and to create lasting values.

For Thriving Design to become a reality, we also need supportive governance, rules and regulations, distribution channels, and affordable pricing structures for the mass market. Thriving Design intricately intertwines with the financial aspects of the ecosystem. One has to be both an idealist and a realist. If we could demonstrate long term benefits and quantifiable savings, the market would tip favourably towards the holistic approach. Guilt management would not be needed, as following the trend would simply be the smartest decision.

Keywords: design process, green ethics, green economics

1. INTRODUCTION

According to the Brundtland Report to the General Assembly of the United Nations in 1987, "sustainability" is to "meet the needs of the present without compromising the ability of future generation to meet their own needs." (Brundtland, 1987). This definition suggests maintaining the status quo, limiting damage, and protecting existing resources without addressing any leap, growth, or innovation. Unfortunately, the most popular word associated with social, corporate, and individual responsibility nowadays is about not ruining it for our children, as if less bad would be good enough. William McDonough and Michael Braungart, co-authors of Cradle to Cradle, ridiculed the use of vocabulary such as reduce, avoid, minimize, sustain, limit, whereas none of these "actions" halt resources depletion and destruction, only slowing them down, allowing them to take place in smaller increments over a longer period of time (McDonough et al., 2002).

By contrast, according to environmental strategist Ralph Thurm, "ThriveAbility" is the sum of sustainability and innovation. "ThriveAbility" goes beyond collecting points for sustainability evaluation program certifications, beyond specifying recycled or renewable materials, and definitely beyond mere guilt management. We shall aspire to thrive with the transcendental knowledge passed onto us, with research and development, with creativity and imagination, and rethink the way we create products and living environments. Thriving Design starts from the very beginning – when we first conceive a product or a building or a neighborhood, we shall consider beyond how it is designed, constructed, used, and paid for, also how it is maintained, repaired, retired, recycled, and re-used. This is a true holistic design approach to the life-cycle of the hardware and living environments to optimize materials and energy consumption, to produce no waste, to re-use resources, and to create lasting values. The idea echoes the concept of "Cradle to Cradle": to consider waste as food, nutrients, and raw materials for new products (McDonough et al., 2002).

2. THE CONVENTIONAL PRACTICE

Out of all hardware produced in the world, one can hardly disagree that the most expensive commodity we make are buildings and infrastructure. Electricity consumption in buildings tops the greenhouse gas emission chart in the U.S., roughly 40 percent of the total national emission, making the Architects and Engineers the de facto professionals most responsible for energy consumption and pollution (Friedman, 2008). The calculation estimated emission during the operation of buildings and have not taken into account the resources consumed in the construction of new buildings, often in large material quantity with significant wastage; and the demolition of old buildings, often resulted in substantial construction wastes that end up in incinerators and landfills.

At present, majority of buildings are still designed and constructed in conventional "Cradle-to-Grave" means where "resources are extracted, shaped into products, sold, and eventually disposed of in a 'grave' of some kind." (McDonough et al., 2002). We still specify conventional building systems and construction methods because they have been proven to work. However, one cannot blame all problems of pollution, waste production, and wasted energy on Architects and Engineers alone. How often have Architects come up with green ideas or Engineers propose renewable energy systems and got humbled by project managers in budget meetings? The fancy term "value engineering", by eliminating green design and systems, meant that owners do not see the value of such green design and systems outweighing their initial capital costs. Ultimately, Architects and Engineers' services are commission-based to design, coordinate with the project team, work with main contractors, and bring the owners' visions to reality, but they do not have the final say in decision-making. There is a financial component in any design and construction projects often more significant than any other project criteria and goals because material and labour costs are very high, lands are expensive, and owners' ultimate intention is to increase the value of their property and maximize returns on investments. Our challenge is to prove, using empirical evidence, that a holistic Thriving Design approach is more profitable in a long run. If we could demonstrate long term benefits and quantifiable savings to owners, the market would tip favourably without our need to advocate.

3. THE PROBLEM WITH THE STATUS QUO

Let us examine the common design and construction practice. For projects large or small, project phases more or less follow a linear timeline from conception to completion. Figure 1 illustrates a Typical Design and Construction Phase Flowchart. Consultants are usually engaged from Pre-Design when all parties discussed project goals, contractual terms and conditions, design fees, etc., to Final Completion when defects were rectified and the project is completed such that owners can occupy the building for the intended purpose. The duration of work phases are often clearly defined so owners would relieve consultants' liability when defects are rectified and warranty expires, and would not need to continuously engage the consultants for additional fees beyond contractual terms.

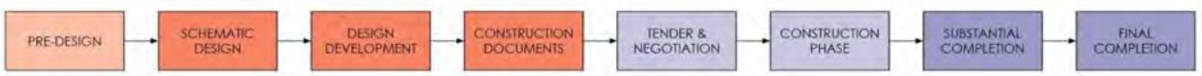

Figure 1: Typical design and construction phase flowchart

There are only so many pre-destined fates aging buildings would face. For the ones with some cultural or architectural significance, they might be rated historical monuments and would be preserved. Majority of buildings share the same fate in demolition when they aged and deteriorated to the point they no longer serve a functional purpose or generate justifiable revenue. While it takes years to design and construct buildings, demolitions are often optimized to squeeze out the last dollar of rental income, or exploded to rubbles within seconds in true Las Vegas style. The implosion of building produce plumes of smokes and tons of construction waste, sometimes enjoyed by the shouting and cheering crowds as another entertaining spectacle. The original consultants are long gone and long forgotten as their services are not needed in destruction, which is the antonym of what the team does.

Locally in Hong Kong, although less dramatic and more time-consuming, buildings are demolished for the same purpose of making ways to more valuable and profitable future. Daily construction waste generated in Hong Kong tops 4,000 tons per day and which would be moved to public filling reception facilities, sorting facilities, or landfill sites in Tseung Kwan O, Tuen Mun, and Sheung Shui. To emulate common practice in other first-world economies, Hong Kong government developed a "Polluter Pays Principle" years ago such that waste producers would be

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

charged for their disposal. Certainly, the charging scheme brought in extra revenue for the government but the problem of waste management remained. Nothing has changed except “waste disposal” became an extra line item on the budget sheet. There is zero innovation in the policy and it did not reduce waste significantly.

Other than promotion with nice slogans and taglines, there had been limited public or private revolutionary recycling program that make substantial impacts in waste management. Besides, “recycling” is probably the most abused and misused word nowadays as most of the claimed recycled products are in fact downcycled, meaning the process of converting the materials actually reduces the quality of such materials over time (McDonough et al., 2002). Downcycled materials contain less quality, less nutrients, and less properties of their previous lives while more energy or chemicals were added to make the materials useful again. We often forget to ask: how clean is the energy that was injected to making of the claimed recycled products?

4. THE WAY FORWARD: FIVE KEY CRITERIA

A holistic Thriving Design approach for the design and construction industry calls for a complete new paradigm in reconsidering the fundamental concept of building, recycle materials, use and comfort, and waste. The revolutionary design approach shall include but not limited to the following five key criteria.

4.1 Think of building as a system, not a structure

Paulo Coelho wrote in his critically acclaimed novel Brida that in life a person can choose to build or to plant. He stated, “The builders might take years over their tasks, but one day, they finish what they’re doing… Life loses its meaning when the building stops.” On the other hand, for those who plants, “they endure storms and all the many vicissitudes of the seasons, and they rarely rest. But unlike a building, a garden never stops growing. And while it requires the gardener’s constant attention, it also allows life for the gardener to be a great adventure.” (Coelho, 1990). Thomas Friedman expanded the same idea in Hot, Flat, and Crowded, “when you start to think of building as a system, not a block of bricks, all kinds of things become possible. And just imagine all these highly efficient smart buildings being integrated into an intelligent Energy Internet, where each building’s flexibility is used to serve the needs of other buildings, not just its own.” (Friedman, 2008).

As a system, buildings can take in solar, thermal, gravitational, and kinetic energy and produce more than they consume, or through on-site filtration plant to purify and produce effluents that are potable water. Buildings can have their own micro-systems to serve users and macro-system networked to share resources, to compensate one another due to differences in scale, use, foot traffic, siting, solar orientation, etc. In fact groundbreaking technologies are already out there but not commercialized for the market. We need an overhaul “creative destruction” with the “scrapping of old technologies and old ways of doing things for the new… to increase productivity and therefore is the only way to raise average living standards on a sustained basis.” (Greenspan, 2007) Similar to how light bulbs replaced candles, water heaters replaced boiling pots, fan coil units replaced fireplaces, new technologies are usually unpopular with a high premium when first introduced, but prove to be convenient, efficient, and cost-savings when the market matures. Construction industry must keep pushing cutting-edge technology to consider “building as a system for energy production” such that the "zero carbon building" is an obsolete concept, but "energy productive buildings" define the new norm.

4.2 Design beyond form and function

In a holistic Thriving Design approach, consultants cannot merely make design decisions based on form and function, also taking into account building maintenance and its afterlife. Thus, Architects and Engineers need to design not only the hardware, also the constructive process on how buildings are assembled as well as the reversal process on how they are dissembled when retired. The concept of “demolition” would be replaced by a new phase of “dissembling” to truly re-use and recycle the materials. Too often we have seen demolition in action and there are perfectly undamaged materials, products, furniture, sanitary-ware, ironmongery being dumped into the same pile. To tackle the problem of construction waste, charging disposal fees only license the guilt-free mentality and eliminating the source is the only effective way. Figure 2 illustrates a Thriving Design and Construction Phase Flowchart putting equal emphasis on the afterlife of the building and re-use what conventionally considered waste as raw materials for new buildings.

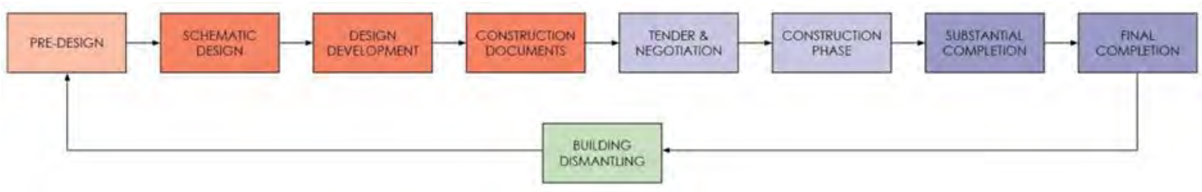

Figure 2: Thriving design and construction phase flowchart

Building Information Model, a.k.a. BIM, had been around for more than a decade and still being selectively considered by owners due to additional consultancy fees or misconception that their projects were too small in scale to justify the use. The strength of BIM is not in the "M" but in the "I", therefore scale shall not serve as a factor to consider its benefits. While 3D model is for visualization of the built environment, it is the embedded parametric information and attributes that address construction means and methods. In a Thriving Design approach, the use of BIM is mandatory because everything could be constructed and simulated in 3D space, meaning we can foresee and eliminate problems during design and construction given a capable and prudent builder, streamline replacement materials and parts during operation, and anticipate the reversal process during dissembling.

4.3 Redefine our needs and manage our consumption

The shift from consumption to experience based lifestyle is not just fashionable, but a world phenomenon as consumers nowadays increasingly demand experiential or back-to-basics values across all commerce. We are now much more acutely aware of the importance of fundamental qualities of life and authentic lifestyles, including but not limited to genuine connection with friends and family, optimal consumption, organic and non-processed food, health and exercises, etc. As much as technology leap in recent decades, also the trend to appreciate simplicity and un-engineered lifestyles. The same shall apply to buildings and energy consumption.

According to Friedman, "energy efficiency was always the quickest, cheapest, most effective way to create clean power, because the best form of power is the power that doesn't have to be generated at all because you eliminated demand for it." (Friedman, 2008). Owners and project team shall take a step back and ask fundamental questions concerning use and comfort, spatial efficiency, optimal energy use, etc. Such deliberation may lead one to consider natural ventilation instead of overloaded air conditioning system, natural lighting instead of artificial, natural landscape instead of hardscape, etc. None of these passive design techniques are new or innovative, what needs to innovate is our mind in re-defining our needs and our sense of comfort. Currently most of the utility providers in the world calculate the required loading based on peak demand networking with redundancy system to minimize service disruption. Controlling our consumption not only alleviate the high demand, also the redundancy that often went to waste.

We also need to reconsider what constitutes "green building". The true measure of a building's impact to the health of the users and the environment stretches from its initial conception to design, construction, completion, and throughout operations. Unfortunately, most popular sustainability design evaluation programs nowadays including LEED and BEAM Plus certify buildings as "sustainable" purely based on decisions and actions made during design and construction process with no means to follow up with their operational performance for years to come. While a building might take several years to design and construct depending on its scale, average building life span nowadays is over 50 years with better materials, technology and techniques. The current practice is no different than stating a woman is healthy purely based on her conditions during inception and at birth, instead of a continuous evaluation or body checks throughout her lifetime. Earning a green certificate therefore paves only halfway of the road to true responsible design if not less. An unbiased and independent performance evaluation platform shall be in place to assess any new or existing buildings during their operations and such evaluation must base on actual energy consumption data collected from utility bills, metering, and users' feedback. Management begins with measurement. With good policies and data transparency, owners and design professionals can work with utility providers who must measure consumption for billing purposes to evaluate the true energy performance of buildings.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4.4 Dream big and believe we are part of the solution

Environmentalist Paul Gilding once said, "How we respond now will decide the future of human civilization. We are the people we've been waiting for. There is no one else. There is no other time. It's us and it is now." (Friedman, 2008). Often times we got dejected by reality, by the budget-conscious owners, by the expensive green system prices that can hardly justify their life cycle costs. We shall remember, when the energy efficient and on-site renewable energy options provide clear financial benefits and rewards to owners who have long-term visions, the commercial market will tip and funding of further research and development would explode. In any revolution somebody has to play the role of a pioneer, to push, to advocate. We are the people responsible, right now. There is no one else, there is no other time.

To challenge ourselves in the spirit of thriving, we shall also consider how buildings, as systems, can upcycle their materials and components such that their intrinsic value worth more than their predecessors. Building owners and design professionals often see nature as the enemy, as it deteriorates and cracks the new look, the fresh coat of paint, the perfect alignments. In fact, nature is only doing what nature does without bias. Similar to how cedar wood ages and self-protects against insects, rotting, and temperature stress; or copper cladding and corten steel rust to become stronger and more aesthetically pleasing, Thriving Designers needs to explore, experiment, research, and develop new materials and methods that work with nature instead of against it, to consider nature and weathering as providers of fresh inputs and resources in the upcycling process.

4.5 Build rapport with the guardian and the commerce

Famed urbanist Jane Jacobs once described the two fundamental syndromes of human civilizations are the guardian and the commerce. The guardian is the government, whose primary purpose is to preserve and protect the public. The commerce is the everyday exchange of values between individuals, companies, and organizations in form of currency. While we shouldn't see nature as an enemy, individuals in the commerce also shouldn't see the guardian as one. It is the government's or the building department's job to be skeptical of new ideas and new standards, thus requesting substantial evidence or proofs or tests or internationally-recognized certification to validate the new as their core concern is public safety and common good. Once owners and design professionals recognized such parameters and rules of the game, we understand the challenge in executing Thriving Design and getting statutory approval hinge on our ability to demonstrate the add-values while maintaining public safety and common good as high priorities.

Most governments champion innovation with substantial public funding in technology and energy research, therefore we shall all be on the same boat. The challenge is that a government is not a single entity, but many subsidiary departments and they do not necessary work in synch. Consider it check-and-balances or otherwise, departments must protect their turfs and guard their interests in fear of making disastrous or careless decisions that jeopardize public safety. On the other hand, departments are often operating under pressure to innovate themselves. The process to build rapport with each and all of the subsidiary departments, along with industry leaders, manufacturers, users, and stakeholders to reach common consensus would be long and enduring, but worthy and necessary.

5. CONCLUSION

The dream of Thriving Design requires a complete change in our work habits and thinking such that we do not automatically assume the same design and construction practices repeatedly. Experience tells us certain materials and methods work, unfortunately experience is also one of the biggest obstacles in true innovation which often defies what had been done before. Charles Duhigg states in The Power of Habit, "A movement starts because of the social habits of a community, and the weak ties that hold neighborhoods and clans together. And it endures because of a movement's leaders give participants new habits that create a fresh sense of identity and a feeling of ownership. Usually, only when all three parts of this process are fulfilled can a movement become self-propelling and reach a critical mass." (Duhigg, 2012). Thriving Design approach is a movement in defying old habits of design and construction means and methods, it requires collaboration of professionals in their respective expertise as well as users and the public at large to share that common belief in thriving to bring this vision to reality.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Economist Jeffrey Sachs summed it up perfectly why innovation is the only way moving forward: “countries have a big market, further raises productivity and expands the size of the market, and creates new incentives for innovation. This momentum creates, in fact, a chain reaction, which economists call endogenous growth.” (Sachs, 2005). We need continuous growth for any economies and continuous innovation is about the only means to increase market size, creating what W. Chan Kim and Renee Mauborgne called the uncontested market places or “blue oceans” (Kim et al., 2005), raising the currency to enhance a larger market, which drives further innovation. Therefore, innovation and economic growth must be interdependent of one another, walking hand-in-hand, with a clear destiny for a better world. A holistic Thriving Design approach must be the path moving forward to build true thriving communities and living environments that protects the health and wellbeing of people while respecting the land and our finite resources.

Fostering Sustainable Buildings in Indonesia by Foreign Developer for Resilience

Dennis MUI Heung-fu[a]

[a] *Pacific Century Premium Developments Ltd, Hong Kong SAR, dhfmui@netvigator.com*

ABSTRACT

The built environment has been confronted by the global climate change and human created threats especially terrorism in today's world. The society has a strong desire in advancing the sustainable design to resilient building to cope with these vulnerabilities reactively and proactively. Resilience is the capability to adapt to changing conditions and to maintain or regain functionality and vitality in the face of stress or disturbance. In the context of built environment, it is to incorporate into the design of a building, aspects and features that allow the building to carry out its intended functions, now and in the foreseeable future. Fostering resilient building is a challenge especially for a foreign developer in the Indonesian environment, where the stakeholders have inevitably different culture, technology savvy, body of project management knowledge, mindset and approach.

The paper aims at sharing with the sustainable community from a foreign developer's perspective the experience of developing a Grade A+ office development in Jakarta to put such ideas into action, the project management strategy adopted during the project life cycle, difficulties encountered, how they have been overcome from the project outset since its inception in 2012 and the sustainable technologies employed for resilience. The development acquired the LEED Pre-certification Platinum grade in 2014, the first of its kind in Indonesia, and the Greenship Design Recognition Platinum grade certification. Besides, the project was one of the finalists under the New Building Category (Building Projects under Design) of the HKBGC 2014 Green Building Award and was conferred the Winner of the Best Green Development and a highly commended Best Office Development in the 2015 Indonesia Property Awards. The project was also the highly commended Best Green Development in the 2015 South East Asia Property Awards. To recognize the contribution in promoting sustainability to local industry, the developer was also awarded the Winner of the Special Recognition in Sustainable Development in the 2016 Indonesian Property Awards. It is due to complete in 2nd quarter of 2017.

Keywords: design process, sustainable building, resilience

1. INTRODUCTION

Since the publication of the "Our Common Future" by the United Nations World Commissions on Environment and Development in 1987, the society has been pursuing sustainability for nearly three decades. There is increasing awareness and demand of community at large for a better place to live and work. Most of the corporations have incorporated in their Corporate Social Responsibility (CSR) policy sustainable development in which environmental responsibilities is an important part of the CSR. Sustainable buildings has proliferated in the property development sector partly due to the developer's own CSR and to a larger extent, the demand of the market especially those multi-national corporations which are looking for office premises that are greener for meeting the demand of the company's CSR and aspiration of their staff. To attract prestigious tenants who are willing to pay reasonable rent, the office building has to be of high quality and sustainable.

There was forecast in 2012 estimating that around 3.2 million m2 of extra office space would appear in the central business district of Jakarta over the next six years (RICS, 2012). The estimation had indicated the expected severe competition for reputable quality tenants in the office market. With such competitive market and against the backdrop of the economic uncertainty in Southeast Asia, developers have inevitably to transcend the norm in order to compete with others for filling up the space within a reasonable timeframe. Thus, the main driver for a better world is the community at large which controls the market force while the government, professionals or technology are catalysts of the process. The property developers have to follow suit to maintain a lucrative business.

For the abovementioned reasons, it was already decided at the inception stage that the office development be targeted to transcend Grade A+ quality.

2. FROM SUSTAINABILITY TO RESILENCE

2.1 Sustainability

The establishment of the World Green Building Council in 2001 has provided an international property focus for the global sustainability agenda, with significant representation of membership across Asia (APREA, 2012). A range of green building rating schemes have developed since then in different countries to rate the design of buildings in resources conservation and efficacy, biodiversity, enhancing the indoor environmental quality for the safety and health of occupants as well as overall community connectivity.

The United States Green Building Council LEED rating system, initially developed in 2000, is the most widely used green building rating system globally. It has been used as a building standard by multi-national tenants with a deep commitment to sustainability and has established the basic framework for many green building rating systems around the world including in Asia Pacific (APREA, 2012). While utilizing the basic framework of LEED, countries have developed the detailed requirements to accommodate their local differences and put different emphasis on the elements. For example, Green Mark (Singapore) has higher weighting on energy while that of water is higher in Greenship (Indonesia).

2.2 Resilience

The built environment has been confronted by the global climate change and human created threats especially terrorism in today's world. Sustainability is all about protecting nature and the environment from human endeavours. However, there is need to protect humans from both the Mother Nature and human threats. As a result, resilience is the next evolution of sustainability (Peng et al., 2012). Hence, the society has a strong desire in advancing the sustainable design to resilient building to cope with these vulnerabilities reactively and proactively.

Resilience was defined by the United Nations Development Programme as the tendency to maintain integrity when subject to disturbance (Levina & Tirpak, 2006). RDI (n.d.a) described resilience is the capacity to adapt to changing conditions and to maintain or regain functionality and vitality in the face of stress or disturbance. It is the capacity to bounce back after a disturbance or interruption. Through resilience livable conditions in the event of natural disasters, loss of power, or other interruptions in normally available services can be maintained. In the context of built environment, resilience means incorporating into the design of a building, aspects and features that allow the building to carry out its intended functions, now and in the foreseeable future (Alfraidi & Boussabaine, 2015).

Resilient design is the intentional design of buildings, landscapes, communities, and regions in response to vulnerabilities caused by climate change and power outages. RDI, n.d.a). Resilient Design Institute (n.d.b) listed out the design principles in a more macro scale. ResilientCity (n.d.) proposed building design principles for designing and constructing buildings in a post-carbon climate responsive building environment. Alfraidi and Boussabaine (2015) more specifically addressed building resilience design in the face of climate change under the categories of site, layout, structure, envelope, system and operation. Champagne and Aktas (2016) surveyed different literatures the principles for resilience to withstand external stressors that may arise over the buildings' lifetime for it to be truly sustainable. Based on the above sources, the principles of resilient building design are listed below:

- Meeting basic human needs including potable water, sanitation, energy, livable conditions, lighting, safe air and occupant health;
- Anticipation of interruptions and a dynamic future – adaptation to changing climate such as higher temperatures, flooding, earthquakes, solar flares and anthropogenic actions like terrorism and cyberterrorism;
- Diverse and redundant systems;
- Use low carbon-input materials systems;
- Maximising the use of day-lighting;
- Design for future flexibility of use e.g. modularity and standardization;
- Durability and robustness including strong building envelope;
- Systems that can be serviced/maintained with local material/parts and labours;
- Low energy inputs for constructability and ongoing building operations;

- Renewable energy for less reliability on grid power; and
- Water capture and storage, and usage reduction.

2.3 Assessment of resilience

The existing sustainability or green rating tools, such as LEED, BREEAM, Green Star and CASBEE can be used to assess whether new developments address both the adaptation and mitigation demands of climate change (Stubbs & Beckmann, 2013). Champagne and Aktas (2016) analysed the overlaps between resilient design principles and the LEED certification system and concluded that some of the principles identified have already been incorporated by the existing LEED rating system. To address the gaps, it was recommended to use future climate projections instead of historical data for Site Assessment and Rainwater Management credits, and to revise the Regional Priority credits with regard to flood, drought, water, pest, fire, storm and air to achieve regional resilience based on regional climate projections.

Therefore, it is necessary to integrate resilience into the sustainable building certification system and consider the gaps in light of the local environment to incorporate the necessary resilient features in the development project cycle.

3. LOCAL CONTEXT

A developer constructing building in a foreign country will inevitably encounter issues such as differences in culture, technology savvy, body of project management knowledge, mindset and approach. Strenuous effort is required to foster sustainable building in environment like Indonesia. It will be even more challenging if the target is to transcend sustainability to resilience. In Jakarta, public and sustainable transportation is almost non-existence making the selection of suitable site not been easy.

According to the local professions, Greenship was first launched in June 2010. There was lack of local experience in sustainable design and knowledge on resilience at the time of the project inception in 2012. There were only few developments that had been built with sustainable features and rated by LEED or even Greenship. It was not easy to find professional consultants and contractors who are environmentally responsible and knowledgeable on the requirements of sustainable building technology and the rating tools. For examples, knowledge of recycled contents in materials, concept of using regionally manufactured materials and construction environmental management plan and waste recycling appeared to be new to the contractors and material suppliers. Chillers optimisation control for energy consumption reduction and integrated building management system are not common in Jakarta. Materials that are environmentally friendly may need to be imported and can be costly because of taxation issue besides the transportation cost.

Knowledge on local authority approval process, technological practice on design, quality control and construction methodology as well as language barrier are also challenges which foreign developers have to face.

4. APPROACH TO SUSTAINABILTY AND RESILENCE

The ten Knowledge Areas of PMBOK® (PMI, 2013) were applied to manage the project and in particular to formulate the strategies as described in the ensuing paragraphs to overcome the hurdles. Figure 1 depicts the approach.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

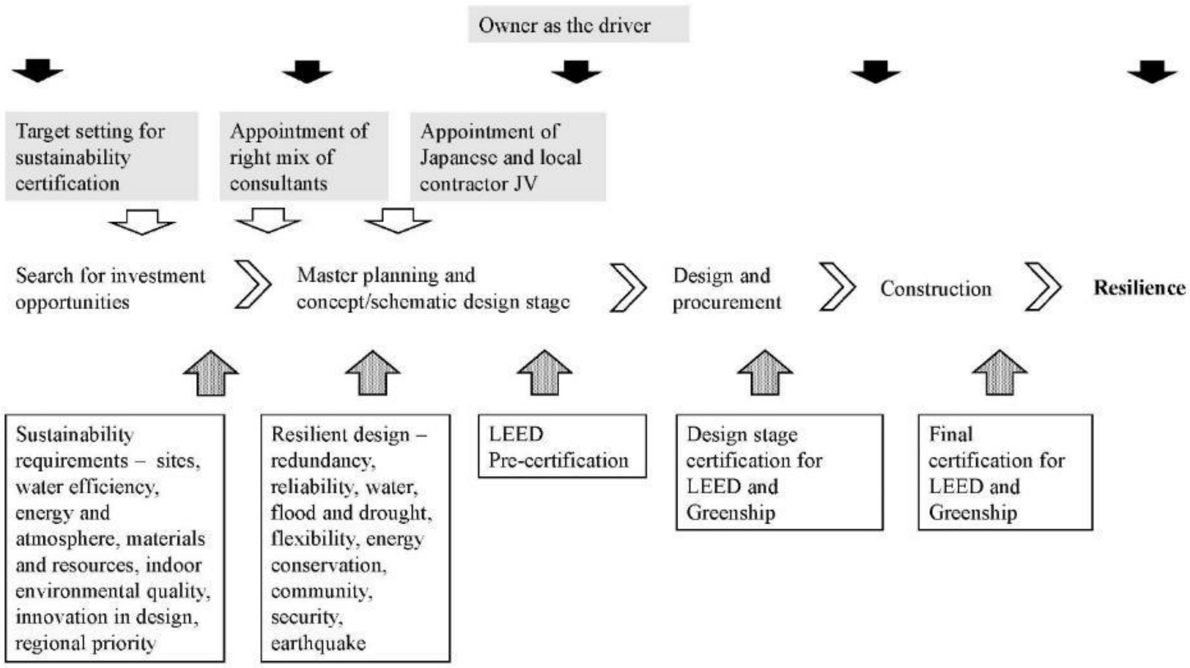

Figure 1: Approach to sustainability and resilience

Appointment of professional consultants with the appropriate mix of specialty – To complement the knowledge base of the local team on both local practice and authority approval process, and to top up the deficiency in knowledge base of sustainability in Jakarta, besides employing experienced local professionals, specialists were drawn from different regions for example, architect from Japan, sustainability consultant and independent commissioning authority from Singapore, wind tunnel laboratory from the State, façade consultant from Hong Kong and security experts from Dubai/London for design beyond the local standards.

Early appointment of the key professional team members – During the searching for investment opportunities, the local architect who is also the founder of the Green Building Council in Indonesia was appointed to assess the viability of each targeted piece of land and selection of suitable sustainable site which was located nearby the future mass transit station. The consultants were appointed at the very early stage and some even before the formalisation of the land deal. They included those for architectural (both local and overseas), quantity surveying, sustainability, mechanical/electrical, structural/civil, façade and property management. This has ensured the early incorporation of the design elements and the integration of the design for sustainability and resilience.

Ride on Japanese culture in construction – Japanese contractors are often giving the industry the impression of attentive to construction details, quality control and timely delivery. A joint operation between a Japanese contractor and the largest local contractor was appointed to construct the building to complement each other in delivering the project to meet the developer's expectation on time, cost and quality.

Early involvement of the main contractor – The main contractor was involved in the project as early as at the time of land plot searching to give advice on buildability, cost and time factors with due consideration to the locally available skill, materials and methodology and to familiar with the resilience building requirements.

Project management team of the developer as the driver of the process - The usual problem with professionals is that each member will only focus on their own specialty. This problem will be exacerbated for a multi-cultural team with different mother languages. However, sustainability and resilience need integration. The approach to circumvent is to have the project management team of the developer to reinforce the advice from the sustainability consultant and coordinate with team to ensure design integration in particular with the local context and the compatibility with local construction practice and methodology.

Setting target at project outset – The target of highest grade for LEED and Greenship rating was set at the outset of the project to ensure that the appointed team members were working towards the same common goals starting from day one.

Step by step approach for certification process – Since the local team has not much experience in the green rating tools, a step by step approach was adopted i.e. undergoing pre-certification, design stage certification and construction stage certification. This was purposely done for the team to get familiar with the process and the requirements as well as to ensure that the sustainability initiatives were incorporated in the various stages of the project development – design, tendering, construction, sales and operation.

5. HIGHTLIGHTS OF FEATURES

The development was pre-certified with platinum grade by LEED in 2014, the first of its kind in Indonesia and has undergone the design stage certification. It also acquired the Greenship Design Recognition Platinum grade certification. Besides, it was one of the finalists under the New Building Category (Building Under Design) of the HKGBC 2014 Green Building Award and was conferred the Winner of the Best Green Development and a highly commended Best Office Development in the 2015 Indonesia Property Award and the highly commended Best Green Development in 2015 South East Asia Property Awards. To recognize the contribution in promoting sustainability to local industry, the developer was also awarded the Winner of the Special Recognition in Sustainable Development in the 2016 Indonesian Property Awards. These certifications and awards have illustrated that applicable features of sustainability and resilience such as site connectivity, heat island mitigation, landscaping and biodiversity, recycled materials, regionally manufactured materials, daylighting application, energy conservation, low emitting materials, heat recovery, increased ventilation etc. were incorporated. So, instead of going through the features in details, the more salient ones with consideration are summarised in Table 1 below.

Resilience principle	Features
Redundancy and reliability	100% backup power by diesel generator; Dual electrical risers; Dual telecommunication lead in and risers; Spare chiller cooling capacity for future increase in cooling load; 100% WiFi coverage in common area for connectivity; 100% mobile network coverage for connectivity;
Water	Reduction in water use by using efficient water devices and sanitary fitments; Deep wells as backup water supply;
Flood and drought	Zero run-off design; Ground floor level at 1 m above the flood plain; Installation water gates to prevent backflow; Critical equipment on Level 6; Long soak pond to control the site run-off; Greywater and black water recycling; Rainwater harvesting; Reducing landscape water use using drip irrigation system and indigenous plants;
Flexibility	Modular and standardized design; Raised flooring; High floor to floor (4.5m) and high false ceiling (3.05m from the raised flooring); Variable air volume air-conditioning system integrated with lighting system; Coordinated ceiling and flooring grids, column spacing and façade modular size; Spare electricity and chilled water supply in each tenancy floor for future expansion;
Energy conservation	Waste heat recovery from the toilet exhaust; Chillers optimization control; LED lighting with daylight sensors in perimeter zone and motion sensors in staircase and toilets;

	VVVF lift system with destination control and regenerative braking; 25%, 30% and 33% saving as compared to baselines of LEED, Green Mark and Greenship respectively;
Community	Clear goals for sustainability parameters in tenancy lease, tenancy fit out guidelines and tenancy manual; Post occupancy evaluation; Measurement and verification plan to mitigate deviation of building performance;

Table 1: Summary of resilience features

Besides, earthquake and security are important issues for designing resilience in Jakarta. In 2012, Indonesia government introduced the new Indonesian Earthquake Regulation (SNI 1726:2012) which requires high-rise building to sustain standard seismic load to 'Life Safety' performance for withstanding earthquake occurrence equals to 8.5 Richter Scale. The building was designed to have the 'immediate occupancy' performance during Maximum Considered Earthquake (once in approximately 2475 years return period i.e. 2% probability of being exceeded in 50 years) with the Importance Factor of 1.25 which means that the building has been designed to withstand 25% more seismic forces compared to other buildings designed in accordance with the regulation. Instead of using seismic isolation or passive damping such as diagonal viscous damper or friction pad which are less appropriate for high rise buildings and reinforced concrete cast-in-place, composite structure with concrete-filled steel tube column and shear wall system was used.

A security risk assessment in accordance with ISO 31000 Standard for Risk Management and the associated Security Management Handbook and blast assessment were conducted to identify security hazards, threats and vulnerabilities facing the project in Indonesia. Protection objectives were determined against the identified medium and higher risk scenarios following the strategy of detecting threats before they can affect an asset, delaying the threats from accessing an asset, and allow enough time for a coordinated response to be deployed. Measures were incorporated to ensure critical assets have defences that will limit potential for prolonged outage of operations. It is not intended to reveal the details of measures in this paper because of sensitivity. Generally, the measures include physical protection, automatic access control, CCTV, automotive number plate recognition, intrusion detection, vehicle and personnel screening systems to mitigate high risk scenarios caused by bomb blast, petty/opportunistic theft, office theft, trespass, sabotage.

6. ONCLUSION

With the application of the PMBOK© Knowledge Areas on crafting the project management strategies by appointing the right mix of professionals and Japanese/local joint reputable partnership builder, setting the target at the outset of the project, developer' s project management team as the process driver and adopting the step by step approach for certification process, a foreign developer to develop sustainable building for resilience in environment like Indonesia could be made possible to meet the demand of the customer and market, expectation of the developer and aspiration of the sustainable community. The building was at the final stage of construction at the time of writing this paper. The challenge yet to face was to ensure that the contractor(s) would follow diligently the sustainability and resilience design intents for achieving the targets.

ABSTRACT

Malaysia have witnessed massive housing development for the last three decades. Many high-rise residential projects have mushroomed across the urban landscape in Malaysia. There is, however, a limitation of architectural design theory for high-rise buildings, especially the passive design principles. This paper aims to address this issue by proposing a flexible housing design system for the high-rise affordable housing in tropical country. The proposed alternative is a combined design and construction system that makes use of the open plan design concept and the Industrialized Building System (IBS) construction method, to produce a variety of housing design options that meet possible user requirements not yet identified at the design stage, while retaining principal uniformity to facilitate the execution of simple but accurate construction with a minimal initial cost. Such system is able to provide the physical spatial arrangements that are conductive for the socio-cultural wellbeing of a community along while complementing the environment. Besides, the system combines both machine production and mass customization, offering more than 10,000 possible designs including prefabricated structures, factory-made structures, dwelling plan and flexible design, to provide an affordable and sustainable housing for all. On a much larger scale, it can facilitate the shift towards higher quality housing in the country, and eventually provide a new dimension in the design of comfortable and sustainable housing for the tropical country.

Keywords: passive design, affordable housing, high performance building

1. INTRODUCTION

Housing emerges as a vital issue to the wellbeing of the community in many modern cities. This is especially true in countries like Japan, Singapore, and Hong Kong, where the lack of developable land in urban areas has made high-rise housing the mode of living for the vast majority of the people. High-rise housing has technical and economic advantages that enable it to form a distinctive feature of housing accommodation in virtually all densely populated urban areas around the world. Such housing type has the potential to decongest the urban sprawl on the ground level, as well as increase the urban density, and housing higher number of families in lesser space. In contrast to the low-rise and single-family houses, high-rise housing is capable of accommodating more inhabitants per unit of area of land and decrease the cost of municipal infrastructure.

As in many other Asian countries, the urban growth in Malaysia has been rapid in the past decades. According to the report titled East Asia's Changing Urban Landscape: Measuring a Decade of Spatial Growth, Malaysia is one of the most urbanized countries of East Asia, with its urban land grew with an average annual growth rate of 1.5%, from about 3,900 km^2 to 4,600 between 2000 and 2010. In terms of urban population, the rate is on the rise from 26.6% in 1960 to 74.7% in 2015, and is expected to surpass 80% by 2020. Due to the country's rapid urbanization process, the construction of high rise development is obvious, especially for the limited prime land in states such as Kuala Lumpur, Selangor, and Penang. This can be seen from the increasing number of vertical residential developments being planned and built in most major cities of these states.

While apartment living seems to be the housing solution for densely populated areas, its environmental impacts are still a matter of concern. According to the report titled Residential Apartments Sustainability Plan: A plan to achieve environmental performance in new and existing apartment buildings, the utility consumption per person at a building level is greater in high-rise apartments than landed dwellings. This is particularly high in buildings with centralized plant and equipment and underground car parks, in which up to 60% of an apartment building's total energy is used in these common areas. The report also found that residents in apartment recycle half the amount that residents in single houses do, in addition to the extremely high water consumption in apartment living as compared to the landed counterpart. In such a living environment where high density is inevitable, there are strong

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

opinions that high rise development contributes to an urban pathology and social decay in residential areas, which could undermine the character, livability, social fabric and even the public health of a city (Wan Abd Aziz et al., 2014; Cappon, 1971).

Furthermore, changes in the demographic make-up due to the diversity of family typologies and household arrangements have generated a need for housing that can adapt to different privacy, space, use requirements, and life styles. The present apartment housing, however, have rigid structure, interlocking plan, and predetermined function, in which very few of them can really satisfy the highly variable spatial needs of the various users. According to Karim (2012) and Isnin et al. (2012), users, especially in mass housing, are not satisfied with their housing conditions. Criticisms have been made upon the architectural design of this mass housing include the lack of storage area, small size and deep location of the kitchen, minimum external wall area, complicated partitions, less cross ventilation etc. (Sahabuddin and Gonzalez-Longo, 2015). Given the need for sustainability and the generally important consideration of environmental and social values in the longer term, proposing freedom to choose among options that fit individual needs and aspirations is indeed essential at the housing design stage. In this sense, flexible housing design can be a suitable solution that capable to fulfil the ever changing dweller's spatial requirements.

However, the major objection to flexible designs is that flexibility entails complex construction and hence higher costs – the economy of scale through repetition is the main reason inadequate standardized designs are being used in the first place (Wong, 2010). Besides, the theory of flexibility is still largely unconsidered in the realm of residential design, even though it has already been applied in office and commercial building developments (Habraken, 2008). Furthermore, Alegre and Heitor (2004) revealed that the capacity of the reinforced concrete building to allow for changes through the conversion of the spatial layout is limited by the construction system. It is under these circumstances that the present study is conducted, with the aim of proposing a housing design system that integrating housing design with industrial construction system. By adopting flexibility as the inherent architectural design strategy, the proposed system is able to provide the physical spatial arrangements that are conductive for the socio-cultural wellbeing of a community along while complementing the environment. Besides, the system combines both machine production and mass customization, offering more than 10,000 possible designs including prefabricated structures, factory-made structures, dwelling plan and flexible design, to provide an affordable and sustainable housing for all. It makes possible the creation of dwellings which may grow old yet without becoming obsolete; incorporating the latest design ideas and technologies, yet have a sense of history on the Malaysian housing design (the rumah kampung design); allowing the communities to live for generations, yet incorporating the potential of adaptation.

2. DIVERGENT DWELLING DESIGN (D3) SYSTEM

The Divergent Dwelling Design, or D3 in short, is a combined design and construction system directly responses to the fundamental demographic and economic pressure that heightened the need for an appropriate solution for the urban mass housing. It makes use of the open plan design concept and the Industrialized Building System (IBS) construction method, to produce a variety of housing design options that meet possible user requirements not yet identified at the design stage, while retaining principal uniformity to facilitate the execution of simple but accurate construction with a minimal initial cost.

The proposed D3 basic architectural plan is a square shaped plot (Figure 1), having a plurality of "dynamic" space lots (where the bathroom, kitchen, and other dwelling services located) arranged peripheral of the plot so as to be in contact with the outdoor environment; and a plurality of structures such as the dining room, bedroom, or any other spaces located in the "core" space lot which is capable of being arranged, modified, and customized in plurality of designs according to the user's needs. While the plot is standardized to allow for efficient manufacturing, it can take any desired shape including square, rectangle, as well as other polygonal shapes (Figure 2). With the built-in architectural flexibility, D3 basic dwelling unit can be divided into more than one plan, in which the occupant can choose the floor plan they want to live before moving in, thereby achieving harmony between the basic structure and the various sizes of dwellings in the long term. This is similar to the automotive industry, where each individual functional unit is freely bonded with the core structure to serve different occupants' requirement.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

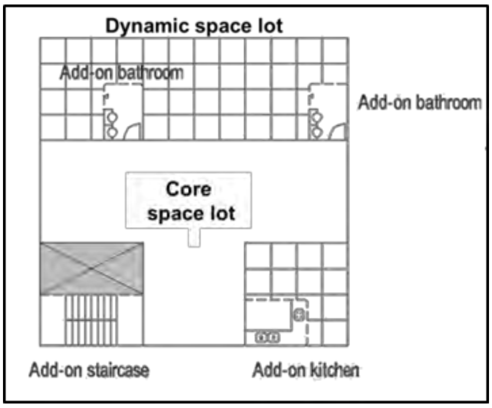

Figure 1: D3 basic architectural plan

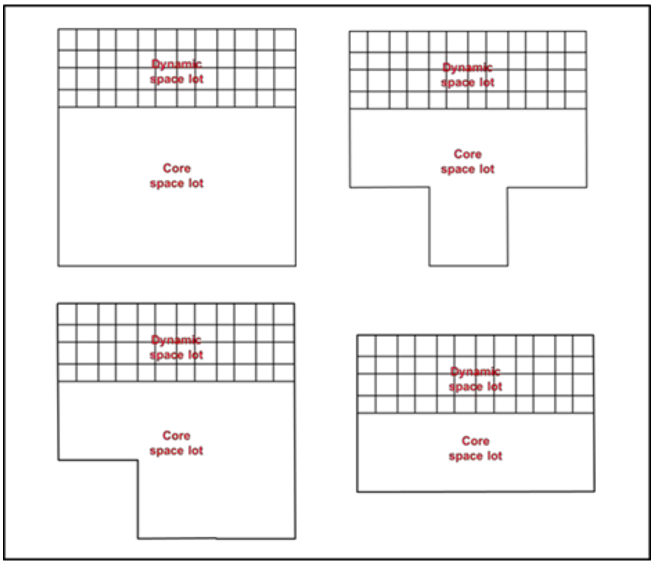

Figure 2: Various shapes of D3 basic dwelling unit

Every D3 building is designed and built in such a way that both the structure and infill of the building are treated as separate entities in order to optimize the efficiency of building assembly and modification. As depicted in Figure 3, the basic layout can be configured into various plans, simply by partitioning the core space lot or rearranging the location of bathroom and kitchen within the dynamic space lot. In other words, there is no one fixed plan in D3 design system but a flexible plan that houses endless of possibilities. Owning to the use of a number of interchangeable component sub-assemblies, D3 makes possible the transfer of construction process from building to manufacturing, with component manufacturers and end-users playing a much larger role in the design process. For example, the bathroom, kitchen, partition, façade etc. are mass produced which then divergently attached to the building structure (Figure 4). The occupant has wide spectrum of choice with regards to products in the market. Since each system is independently manufactured in a controlled environment, the development entails the use of technology and innovation, without the involvement of excessive site labour, time, and cost. In this sense, D3 comprehends the advances of science and technology over time, leading to a faster production at economical rate.

Once the design system is in tandem with serial production and standardization, there will be no bounds for the development of a sustainable community that can accommodate a wide diversity of users and household types. Prospective occupants can choose from a catalogue of available components which are tailored to individual lifestyles and budgets. This enables the occupants to consume only the type and quantity of features they currently require or can afford. For example, a variety of kitchen options that suit a wide range of household lifestyles can be offered by the manufacturers without significant increase of their administrative and operational costs due to the prefabricated nature of kitchen cabinetry. Besides, the variety of configurations available caters to desires for increased work surfaces, space economy, and the inclusion of washer, dryer and recycling facilities within the

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

kitchen. Similarly, the bathroom requirements also vary according to the occupants and their individual scenarios. Normally, two bathrooms will be provided for every affordable house in Malaysia. However, the number of bathroom is not restricted in D3 housing; if the number of occupants and their schedules justify for another bathroom, D3 open plan concept would satisfy this requirement by balancing the size and location of this additional bathroom with the remaining spaces in the dwelling unit. Consequently, the bathroom options offered by D3 housing can range in size from powder rooms to complete bathrooms with shower, bath, toilet, and sink. Since every individual dwelling unit is flexible enough to adapt to the changing needs of both existing families and future users, the combination of these units will enable a variety of sustainable habitual spaces to be processed, which then can constantly renew themselves without becoming obsolete.

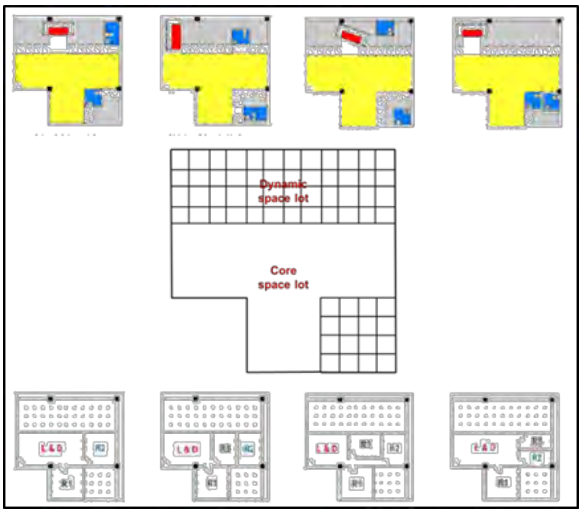

Figure 3: Different variations in the arrangement and partitioning of D3 basic dwelling unit

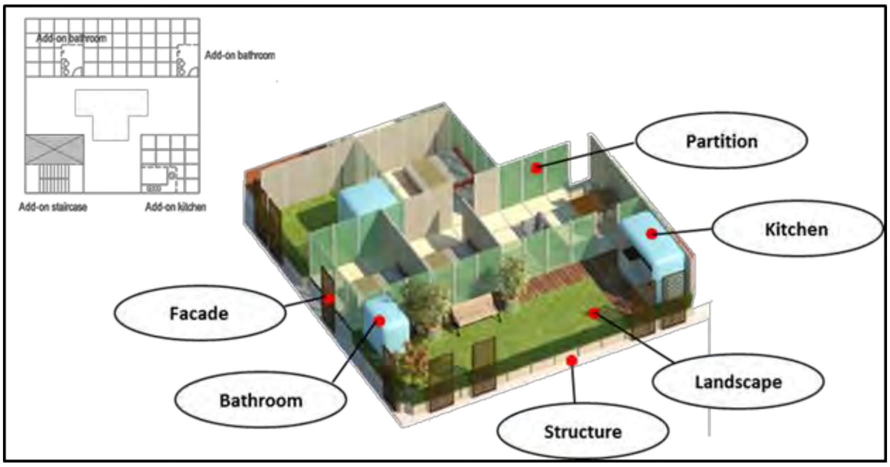

Figure 4: D3 independent building systems

The principles underlying the design of facades are analogous to those governing the structure and plan: flexibility and individual identity. By positioning the dynamic space lot in the peripheral of the plot, a setback of walls is created where no external walls to be in contact with the outdoor environment. Such setting can be well-adopted in the apartment development, imparting a sense of individual identity and differentiating vertical occupancies or uses, yet avoiding the extremes of monotony and theme park atmospheric elements (Figure 5). One of the most common drawbacks of prefabricated housing is the homogenous and repetitive nature of the development, which is a by-product of the economies of scale. The value of providing a diversity of appearances is that it satisfies the individual user's personal requirement for identity and self-expression, counteracting any potential feeling of anonymity resulting from increased density, and it incorporates – or rather predicts and pre-structures – the inevitable variety caused by change overtime.

Figure 5: Examples of flexible façade combination

3. D3 SUSTAINABLE STRATEGY

Malaysia is situated in a maritime equatorial area, where the climate is generally the same throughout the year, with uniform temperatures, high humidity, light winds, and heavy rainfall (Hyde, 2008). The very nature of the Malaysian climate necessitates mechanically ventilated or air-conditional interiors, especially in urban areas. However, poor design and indiscriminate use of air conditioning have resulted in huge increases in energy use. Passive and low energy design strategies are too often excluded from the affordable housing projects because they are deemed to add cost to the construction, though they are the solutions for a sustainable future. D3 directly responds to the fundamental demographic and economic pressure that has heightened the need for a new housing alternative which appropriately integrates affordability and sustainability. To ensure mass housing populations could enjoy eco-housing with affordable price, affordability is designed in at the beginning by adopting a simple design layout, which is flexible enough for adaptation and yet suits to the tropical climatic condition.

In the case of D3 design system, cross ventilation is optimized by having an elongated dwelling shape together with minimal partitions or interior walls. This is not only allowing for easy passage of air and cross-ventilation, but also encouraging a good lighting of the interiors, as well as the flexible use of space. Besides, the parallel arrangement of windows and the placement of high louvers on the internal walls of each bedroom also ensure adequate wind from outside flows through the house. By setting back the exterior walls 2.1m from the peripheral of the dwelling, no walls are exposed directly to the outdoor environment. Solar radiation is, thus, effectively controlled with the large thatched upper floor ceiling that acts as the overhang. Together with the installation of adjustable louvres or grilles as building façade, a barrier is created which not only provides good shading and protection against driving rain, but also to some extent maintain the quality of openness for ventilation and outdoor views. The setback also creates an open porch that makes possible the occupants to enjoy the open-air landscape. With careful planting or selection of vertical green, the open porch can function as a buffer corridor that aids in air circulation. The presence of air movement will then enhance the evaporative and convective cooling from the skin and can further increase the occupants' comfort. Glare, which is a major source of stress in the tropical climate, is effectively controlled by using louvres or grilles which break up large bright areas into tiny ones and yet allow the interiors to be lighted up; or by planting less reflective vegetation. Figure 6 illustrates the interior views of the D3 housing.

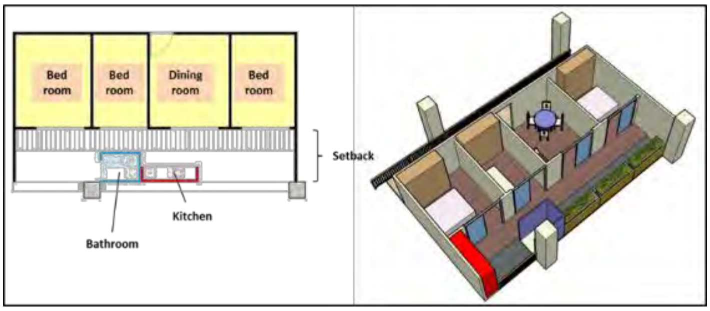

Figure 6: Typical D3 apartment layout

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The use of reinforced concrete skeleton structure ensures a lot of the qualities that aid flexibility in housing design, which then contribute to the housing affordability and sustainability. First, prefabrication construction allows for the design of flexible internal space layout are variable to accommodate different family structures. The constant improvement in prefabrication technology that supported by the incorporation of lightweight, durable, smooth edged, space efficient, and universally adopted specifications will ensure that mass housings remain affordable and sustainable for the long term. Second, the use of concrete as the main structural material contributes to a wide range of inherent benefits at no extra cost, such as its proven integral fire resistance, high levels of sound insulation, and robust finishes. Through its very nature, concrete provides robust surfaces for walls, partitions, columns, soffits and cladding that are easily sealed and free of ledges or joint details. All these may finally lead to the lower maintenance costs of the building while set in motion an efficient, cost effective and practical method for solving housing needs and overcrowding concerns in urban areas. However, realizing that the concrete industry is responsible for 10% of worldwide CO_2 emissions, the limited use of concrete is also to be considered in D3 design system. For example, complicated wall arrangements are avoided in D3 housing, so that less concrete wall panels are used as internal partition. Within a typical D3 dwelling unit, walls that facing the outdoor environment is eliminated with the installation of aluminium sliding doors. Since the infills of D3 housing are prefabricated materials that are subject to change, lightweight materials that have a low heat storage capacity such as gypsum board and plasterboard with insulation can always be used in replacement of the existing one. In short, flexibility in terms of architectural and construction process is the key strategy of sustainability in D3 housing.

4. CONCLUSION

With increasingly rapid transformation of the life-style of residents, user preferences out-grow the capacity of buildings faster than ever before. Residential housing, especially mass housing that is not designed to satisfy immediate needs only will eventually become obsolete when they can no longer serve the users' changing needs. D3 design system introduced here can generate a better and cheaper habitat option through the application of existing science, technology and machine production capability. This concept is able to provide a new dimension in the design of comfortable and sustainable housing for the tropical country. The importance of this housing solution is reflected in its ability to solve the housing problems of especially the poor in a manner that is most appropriate to their socio-economic and cultural needs, by using environmental friendly method, contribute to the sustainable development of the construction industry, offers what people demand from a house and that they can live how they want to within it, by taking into account (i) The spatial and functional arrangement, (ii) The potential to expand spaces for increased occupant's usage, (iii) Maximizing natural lighting and ventilation, (iv) The continuity of the traditional housing concepts into a modern contemporary residential development. On a much larger scale, D3 can facilitate the shift towards a higher quality housing in the country, and eventually create sustainable dwellings for everyone in anywhere in the country.

ABSTRACT

Smart and sustainable cities require a higher population density, and thus taller buildings. The general idea is that we can "invest" more into buildings, since we can "save" on transportation. But is there an optimal building height in cities? In this paper we explore the "premium" of building tall, with respect to the embodied energy of construction materials and technical systems. This paper is a first step towards understanding cities total energy consumption.

In this context a CO2 premium means: increased greenhouse gas emissions per square meter area with increasing building height. The analysis is carried out through a Life Cycle Assessment, using Simapro. The scope of the study is limited to cradle-to-gate.

The results show that there is a small premium of building tall on a per square meter basis. But there are large variations between the embodied energy of buildings, built with different construction materials. It is therefore of crucial importance to select the right construction materials in future projects, in order to move towards smart and sustainable cities.

Keywords: life cycle assessment, building tall, embodied energy

1. INTRODUCTION

Smart and sustainable cities require a higher population density, and thus taller buildings. The general idea is that we can "invest" more into buildings, since we can "save" on transportation. But is there an optimal building height in cities? In this paper, we explore the "premium" of building tall, with respect to the embodied energy of construction materials and technical systems. This paper is a first step towards understanding cities total energy consumption.

In this paper, a "CO_2 premium" means increased greenhouse gas (GHG) emissions per square meter area with increasing building height. Thus, this paper is investigating the following research questions:

- Is there a "CO_2 premium" of building tall?
- Is there an optimal building height?
- Is there a preferable construction material for the structural components?

1.1 Goal and scope of the study

The goal of this study is to understand how embodied and in-use GHG emissions varies with building height, and thus seek to determine an optimal building height with respect to optimise GHG emission per m^2 floor area of the buildings. A better understanding of these relationships are necessary to understand the dynamics of smart and sustainable neighbourhoods and cities for the future.

This study focusses on GHG emissions from buildings and building components. As such, it constitutes a first step towards a holistic understanding of integrated city environments, exploring the relationships between buildings components and infrastructure systems (transport, water, sewage, waste and telecom). Equally, it is a first step toward creating design criteria for the sustainable cities of the future.

Since the purpose of this study is to assess the impact of buildings on climate change, we have limited the study to investigating the relationship between embodied and in-use carbon emissions versus building height. In order

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

to making comparison between the results possible, we present the finding on a per m^2 basis, and thus the functional unit chosen is kg CO_{2eq}/m^2 UFA. The system borders are set to cradle-to-gate.

In addition, since the focus of the study is to investigate the relationship between environmental impact and building height, all factors that are believed to be independent of building height, such as lighting systems, materials for internal surfaces and furniture are excluded from the analysis.

1.2 The building

As a basis for this study is two real buildings that are scaled up or down, and where the material need for alternative construction materials is calculated (Ytrehus, 2015; Kaspersen, 2016 and Skullerud, 2016), Table 1.

	3	7	12	21
Location	USA	USA	USA	Norway
Design wind speed	67 m/s	67 m/s	67 m/s	26 m/s
Live load	2.4 kN/m^2	2.4 kN/m^2	2.4 kN/m^2	2-3 kN/m^2
Storey height	3.66 m	3.66 m	3.66 m	3.4 m
Building height	12 m	26.5 m	44.8 m	76 m
Gross floor area	2613 m^2	6097 m^2	10542 m^2	11823 m^2

Table 1: Building specifications

An early study (Ytrehus, 2015) showed that in-situ-cast concrete was more favourable than other construction techniques with concrete. The up and downscaling off the buildings, as well as the calculation of the timber structures were done in-house, with assistance and quality check provided by a major Norwegian engineering consultancy company. The materials needed for the structural parts of the buildings are given in Table 2.

Material	RC structures				Steel structures				Timber structures			
Stories	*3*	*7*	*12*	*21*	*3*	*7*	*12*	*21*	*3*	*7*	*12*	*21*
Concrete C25/30 (m^3)	925	2031	3436	0	23	174	261	0	23	174	261	3
Concrete C35/45 (m^3)	0	0	0	7186	0	0	0	718	0	0	0	718
Rebar steel (t)	51	105	186	955	2	24	36	93	2	24	36	93
Construction steel (t)	0	0	0	0	197	397	684	1995	0	0	0	0
Glulam (m^3)	0	0	0	0	0	0	0	0	78	125	206	234
CLT (m^3)	0	0	0	0	0	0	0	0	513	1410	2792	4639

Table 2: Material quantity data

Kaspersen et al. (2016) investigated the CO_2 premium of the technical system (Plumbing and HVAC installations, Electrical power and elevators) for the same case buildings. Their findings showed a weak decrease of embodied emissions per m^2 with building height, up until 12 stories. At heights from 12 stories and upwards, an increase (premium) in embodied emissions from the technical systems was identified. An overview of what is included is provided in Table 3;

Technical installation	Underlying system	Production phase	Use phase
Plumbing and HVAC installation	Plumbing	+	+
	Heating	+	+
	Ventilation	+	+
	Comfort cooling	+	+
Electrical power	Low currents	÷	+
	Lighting	÷	+
Other installations	Elevator	+	+

Table 3: Overview of the technical installations included in the study

In this study, we are using the findings of Kaspersen et al. on the embodied energy in the analysis. With respect to embodied energy from façade system, there are numerous different choices. In a case study on CO_2 emissions from buildings Leung and Yip (2008) found that curtain wall façade systems ranged from approximately 8 to 250 kg CO_{2eq}/m^2 of facades installed. In this study, we have varied the embodied emissions from facade systems between 15 and 150 kg CO_{2eq}/m^2 over a 60-year lifetime of the building, and thereby including different design choices and maintenance calculation.

Since we are interested both future and existing buildings, we have modelled the in-use GHG emissions based on a very low energy demand of 50 kwh/m^2 (with some synergies based on size). And, although this is a low number by today's standards, it is higher proposed regulations for the future (EU, 2010). The reason we also include in-use emissions in this study, is to understand importance of in-use emissions versus embodied emission over a

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

lifetime of 60 years for the building. Including in this is equally the pumping of water to height, which is found to be of a neglectable nature, less than 0,1% of total energy consumption (Aronsen et. al.,2015).

1.3 Sensitivity, best case versus worst case

The sensitivity analyses are based on 1) The best case and worst case for the production of varying construction materials, such as concrete, steel, facade and timber products, 2) The carbon intensity of the in-use energy mix, Table 4.

Material	Concrete C 25/30	Concrete C 40/45	Rebar Steel	Steel	Glulam	CLT	Technical installations	Façade systems	Electricity
Unit	kg CO_2/m^3	kg CO_2/m^3	kg CO_2/t	kg CO_2/t	kg CO_2/m^3	kg CO_2/m^3	kg CO_2/m^2	kg CO_2/m^2	kg CO_2/kwh
Worst case	349	404	2120	2400	159*	173*	45	300	350
Best Case	207	265	480	1600	91*	104*	32	30	132

* We are not applying consequential LCA, and thus a net carbon storage of approximately 600 kg per m3 timber products are not accounted for.

Table 4: Input data for best case and worst case sensitivity analysis

2. RESULTS AND DISCUSSION

The result below is shown as a shaded area between the best case and worst case (sensitivity analysis) for the various building parts; foundation, structural components, technical systems, façade systems and also for the in-use energy consumption. The functional unit for all the analysis is kg CO_{2eq}/m^2 floor area.

2.1 Embodied energy

Figure 1 shows embodied energy from the foundation work versus building height. As expected there is a premium for building tall, as taller buildings require a stronger fundament. In this analysis, we have used the same fundament across different structural materials. That this might be an overkill for timber buildings is here not taken into consideration. Given the goal and scope of the analysis, this is of minor concern.

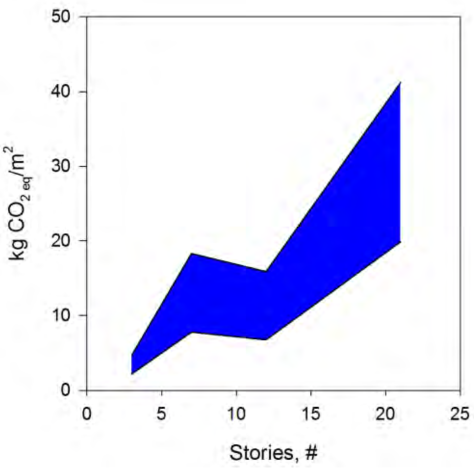

Figure 1: Embodied emissions from the foundation versus building height

The contribution of the structural components is shown in Figure 2. There is a weak negative trend in emissions up until 12 stories tall for buildings made from reinforced concrete or steel. These are cases where steel-based constructions have higher emissions than buildings of concrete. Buildings made of timber has significantly lower emissions than building made of concrete and steel. An interesting point is that the environmental impact from the timber construction is much lower than for concrete and steel buildings, although we have excluded carbon storage from this study. If carbon storage had been uncounted for, we would have negative emissions from the timber buildings of approximately 600 kg CO_2/m^2 (Skullestad, 2015).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

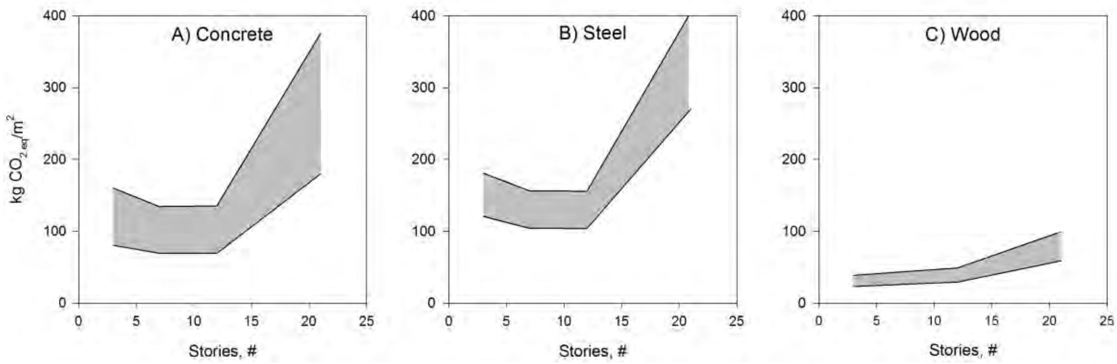

Figure 2: Embodied emissions from the structural components versus building height. A) Reinforced concrete, B) Steel and C) Timber buildings

The embodied emissions from the technical installations shows a week decrease in embodied emissions up until 12 stories, Figure 3. From 12 stories and up, there is a small increase in emissions ("premium") with building height. We believe that this "premium" will increase further with even taller buildings.

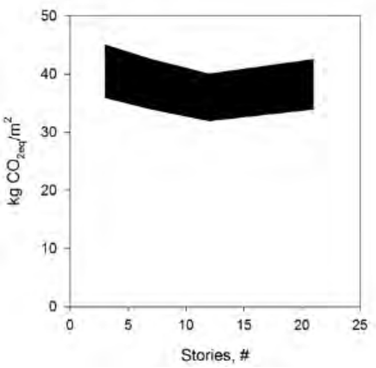

Figure 3: Embodied emissions from the technical installations versus building height

Figure 4 shows the embodied emissions from façade systems. These results are interesting for several reasons. Firstly, this reflects the great difference in embodied emissions from different façade systems per m² façade (including various maintenance interval schemes). There is a factor of 10 difference between the best and the worst case, Table 1.

Secondly, the U-shape of the curve suggests a decrease in emission with height up until 12 stories. After 12 stories, there is increase in emissions ("premium") with building height. We found that this behaviour can be explained by the surface (wall) to volume ratio of the building, and as such a more a design issue. This relationship will, however, always be there, and thus suggesting that there could be optimal building height with respect to embodied emissions.

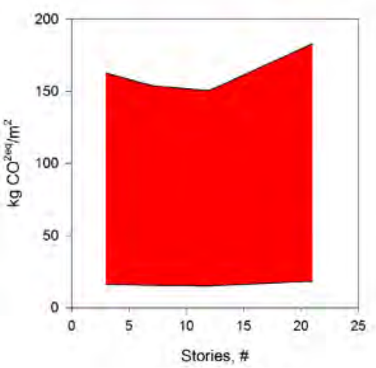

Figure 4: Embodied emissions from the facade systems versus building height

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.2 In-use-energy demand

In addition to embodied emissions from construction materials, we investigated the impact of in-use energy consumption on total emissions from the buildings over a 60-year period, Figure 5. The results clearly show that energy consumption – and the corresponding emissions – decrease with increasing building height. This change corresponds with changes in surface area to volume changes in the buildings.

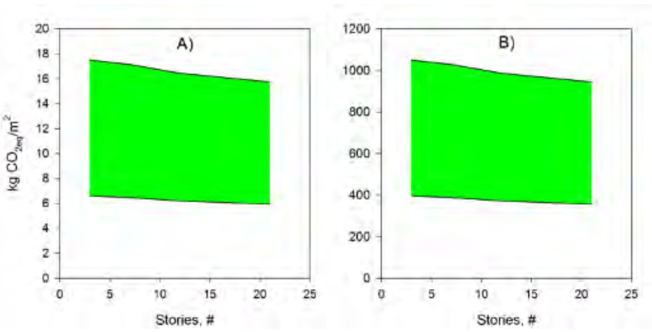

Figure 5: Emissions from the in-use energy consumption versus building height. A) Annual emissions, and B) Aggregated emissions over 60 years

The difference between the worst case and best case clearly reflects the different carbon intensities of the power grid, and are therefore outside the control of the users of the buildings. The best case reflects the expected future carbon intensity of the European grid in 2050 of 132 g CO_{2eq}/kwh, while the worst case shows todays average of 350g CO_{2eq}/kwh (Graabak and Feilberg, 2011).

2.3 Embodied and in-use GHG emissions over a 60-year service period

The total GHG emissions from the buildings over a 60-year period time period is shown in Figure 6. The results revealed some interesting relationships.

Firstly, although the expected energy consumption is very low (45 to 50 kwh/m^2), in-use energy consumption still is responsible for more than 50% of the total emissions over a 60-year period. This finding suggest that a continuous focus on the reduction of the in-use energy demand – as well as a decrease in carbon intensity of the electric grid – is of outmost importance. Thus, the reduction in energy demand from dwellings, will have a double effect. This because a lowered demand for electricity in turn will eliminate the need for the least effective (most expensive) and most polluting power plants.

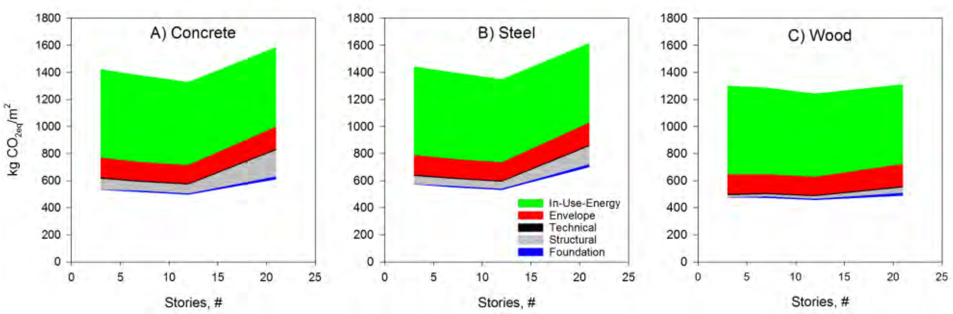

Figure 6: Total emissions from buildings versus building height over a 60 period, for A) Concrete buildings, B) Steel frame buildings and C) Timber buildings

Secondly, there is a significant opportunity for GHG emissions to be harvested by better use of construction materials. This especially concerns the increased use of wood as structural material and in the façade, which would significantly reduce GHG emission from buildings.

Lastly, the figure clearly suggests that there is an optimal building height. According to the figure, this optimum is to be found somewhere between 10 and 20 stories. This result, however, has to be verified with a larger empirical study.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. CONCLUSION

The analysis presented in this paper indicates that there exists an optimum for building height somewhere between 10 and 20 stories regardless of construction technologies. For all the investigated building heights, wood will significantly reduce the embodied emissions from the building. Within all the scenarios presented in this paper, there is a significant discrepancy between the worst-case and the best-case CO_2 emissions. The most accessible gains stem from addressing façade and avoiding energy input to the building. Further research: the study presented in this paper does not include the potential effects of carbon storage of the building. Such effects will prominently appear in timber structures, and will potentially have significant GHG emission reduction effects.

Although the results presented in this paper indicate an optimal height of buildings (in the range between 10 - 20 stories), this can change within an analysis that include a broader scope. If, for instance, the system is expanded to include transport systems and networks, the potential seems to exist for permitting building heights of more than 20 stories. This will be explored in future papers.

ABSTRACT

As long lifetime products, the buildings will stand several decades. The current existing buildings is the dominate part of buildings stock. To improve the existing buildings energy performance is one of key for building sector to meet the goal of global warming mitigation. However, how to do deep renovation in good way, specific with comprehensive considering the environmental impact and cost, is well studied yet. This paper develops a framework to identify the optimized solutions for the deep renovation for less environmental impacts and better cost effective with integrating BIM, life cycle assessment, life cycle costing and multi-objective optimization technologies. A family house built in 1966 in Oslo in Norway is applied to be a case study for this paper. The results indicate that: 1) the renovation of housing itself with better insulation will be more cost-effective than the installation of PV panel; 2) the reduction of greenhouse gases is not as significant as energy saving of renovation because the electricity supply in Norway is mostly from hydropower.

Keywords: deep renovation, LCA, BIM, optimization, Norway

1. INTRODUCTION

Buildings consumed 33843 TWh of energy in 2010, which is 30% more than the level in 1990. By 2050, energy use for buildings is expected to be doubled due to a global rise in floor area of around 130%. Most energy used for buildings today are from fossil fuel, which causes greenhouse gases emissions. Building sector, so-called 40% sector to the global warming potential, is identified as one of the key sector for global warming mitigation. Moreover, as long life products, the existing building are anticipated to still accounting for more than 50% of the global building stock in 2050; in the OECD countries, this figure is closer to 75%. One of main element of contemporary sustainability discourse is that human beings must keep the level of CO2eq in the atmosphere below 450 parts per million (ppm) in order to have a 50% chance of staying below a catastrophic global average temperature rise of 2 ˚C above pre-industrial levels. If such greenhouse gas emissions (GHG) emission objectives are to be met, it is necessary to do deep renovation on buildings to reduce carbon emission considerably.

The life cycle assessment (LCA) is proved as a well suitable tool for obtaining the full picture of the environmental implications of running buildings. Numerous studies has analysed the environmental impacts of buildings/dwelling with life cycle perspectives. Equally, economic is one of three dimensions of sustainable development. The cost-effectiveness is one of the key components of the building design. The life cycle cost (LCC) analysis, working as the effective tools, looks at the economic over the life of building. However, finding solutions to support the progress in the environmental friendly and cost-effective is not easy. The studies, which combine the life cycle assessment and life cycle costing to seeking the sustainable buildings, is relative recent, for example. These existing studies concentrate on the energy efficiency of new design residential buildings. As one of main issue for OECD countries, renovation of current buildings are not well studies. As the consequence, the knowledge on deep renovation with optimising way, specific with comprehensive considering the environmental impact and cost, is not enough. This study tries to add the knowledge of environment impacts and cost caused by deep renovation of buildings, especially to identify the optimizing solutions for the deep renovation for less environmental impacts and more cost effective. In order to identify the goal, this study conducts a decision-making framework, with integrating BIM, life cycle assessment, life cycle costing and multi objective optimization for buildings. A detached house in Norway built in 1966 will be used for case study.

2. METHOD

2.1 BIM modelling

Over the past decades, there had been a growing interest of the construction sector in using Building Information Models (BIM). BIM modelling is approved to be an effective tool to manage accurate building information over the whole life cycle. This study conducts the BIM model for the existing building for the life cycle assessment by onsite survey and interview. The BIM model is processed in the Revit software.

2.2 Life cycle assessment

The LCA in this framework follows the ISO 14040/44 methodology. The ReCiPe Midpoint (H) V1.1 method has been used to estimate the environmental impacts.

- Goal, scope and reference unit

The goal of the LCA study is to estimating the life cycle environment impact due to the deep renovation of the buildings in Norway. While some LCA studies on buildings defines 1 m^2 floor area or 1 m^3 gross volume as functional unit, EN15978 uses the whole building as a functional equivalent. Since the function is delivered by the building as a whole, and not by the floor area/gross volume, the study use the whole building as function unit for the LCA. Thus, the reference unit in this study is defined as "the off-site preparation, on-site renovation, use and demolition of one building over the lifetime of 50 years". The lifetime of a building is a difficult parameter to standardise since it depends on many factors. This study assume the lifetime as 50 years after deep renovation. The off-site preparation stage involves the extraction and manufacture of construction materials and fuels, transportation through the supply chain and to the building site. The renovation stage consider the on-site energy use for necessary demolition and installation. In this study, the operation stage considers energy used by occupants for space cooling, lighting, hot water, and appliances. The energy for demolition is difficult to estimate due the unknown future technology and impossible sorting between original part and renovated part. Therefore, the demolition stage considers waste. The demolition waste off renovated building only refer to the waste from the materials used for renovation. The waste from original part are excluded. Due to the data access, the treatment of waste produced during renovation and demolition are excluded, while the transportation of such waste to the disposal site are included.

- System description, assumptions and data

The system boundaries, the assumptions made for and the data estimated are mainly depend on the renovation projects. The consumption of materials for renovation will be calculated from the information dig outing from the BIM. Moreover, there is common assumption in the framework. Machines and tools for the renovation are used for more than one site. Thus, this study does not consider the consumption of machines and tools. The on-site daily energy consumption are used to calculate the energy consumption for equipment operation and transport on the site. It excludes the transportation of construction machines, equipment and tools to the site. The background inventory data are from EPD Norge and Ecoinvent database.

- Impact assessment

The ReCiPe Midpoint (H) V1.1 method was used to estimate the environmental impacts. The following midpoint impact categories are used: Climate change (GWP) and Particulate matter formation (PMFP). The environmental impact, Ei, is calculated by following the logic of total environmental impact $(\boldsymbol{E}_{i_{tot}})$, equation 1, but where system boards are placed in such way that the end-of-life stage only consider the transportation of the waste;

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

$$E_{i_{tot}} = \sum_{E_i} (E_{i_{ot}} + E_{i_r} + E_{i_o} + E_{i_d} + E_{i_e})$$

Where tot = total impact, ot = off–site preparation (including extraction of materials, production of construction materials, transport), r = on-site renovation process, o = operation, d = deconstruction and e = waste handling and end-of-life activities.

Equation 1

2.3 Life cycle cost

The life cycle cost analysis estimates the relevant cost throughout the life of buildings. The determination of the cost of building is a challenge task, due to the long lifetime of buildings. The price of labour, fuel, material and component can be significantly different from year to year and depend on the location, market and quality. The value of money today and in the future are not equal, because of inflation. Most of the exiting LCC studies follows the method developed by , which eliminated inflation from all escalation and discount rates. However, the inflation rate is difficult to estimating for several decades. To decrease such uncertainty, this study follow the study to use the undiscounted cost. This study assume that the technology and cost for operation in future is same to today. Equally, all cost here are calculated as 2015 price. Moreover, this study does not consider the mortgage. In this study, LCC corresponds the system boundary of LCA. The cost for renovation consider the potential payment paid by the owner. The cost for operation considers the payment for energy bill. At the end of life, the residual value is normally not considered in the demolition. Thus, the end of life stage only consider the cost for the transportation of the waste. In this study, the database in Holte (following the Norwegian standard NS3450) are mainly used. Tax is not included.

The life cycle cost, C, is calculated by following the logic of the cost $\boldsymbol{C}_{\ tot}$) as equation 2.

$$C_{i_{tot}} = \sum_{E_i} \left(C_{i_{ot}} + C_{i_r} + C_{i_o} + C_{i_d} + C_{i_e} \right)$$

Equation 2

2.4 Optimization

The optimization problem here is multi-objective optimization as follows:

$$MinLCC, MinLCEI, MinLCE_c, \& MaxLCE_p$$

Subject to:

$$0 \le LCC \le C_c$$
$$0 \le LCEI \le C_{EI}$$
$$0 \le LCE_C \le C_E \,/\, LCE_P$$

Where, LCC = life cycle cost, LCEI = the life cycle environment impact, LCEc = life cycle energy consumption, LCEp = life energy production. If the deep renovation aims to be nearly zero energy building with renewable energy production on-site, the LCEp will consider.

To simply the optimization of problem and involve the property owners/users perspective. This study follow the literature with solving a multi objective optimization problem with the objective functions for a given weighted vector wi yields a single optimised solution. Analytic hierarchy process (AHP) can decompose a complex decision problem into several sub-problems in terms of hierarchical levels, where each level represents a set of criteria, sub-criteria, or attributes related to each sub-problem. AHP is proved to have some of its advantages over other multi criteria decision making (MCDM) tools. AHP has been chosen for this study to identify the weighting of indicators.

Level 1	Level 2	Level 3	Leve4
Deep renovation optimization solutions	Theme	Criteria	Indicators
	Environmental impacts (life cycle perspective)	Local impacts	PM10 Emissions
		Global impacts	GHGs emissions
	Resource	Energy	Energy production
			Energy consumption
	Cost	Life cycle cost	Life cycle cost

Table 1: The assessment indicators for the deep renovation

The optimization here will be processed by Linear Programming (LP) algorithm. Thus, the LP model of single objective optimization form as:

$$MinY = \sum_{i=1}^{I} w_i(z_i x_i)$$

Subject to:

$$0 \le X_i \le C_i, \mathrm{i} = 1,2,3 \ldots \mathrm{I}$$

Where, Y= objective function, x_i = the output of indicators, $z_i x_i$ is the normalized value of the indicators. w_i is weighting and the sum of weight will equal to 1.

The Matlab software will be used for the optimization.

3. CASE STUDY

A detached house (226 m^2) located in Oslo built in 1966 is selected to be a case study for the project. The figure 1 presents the 3D models of the building.

The house has U-value 0.5 for roof, 0.82 for the façade and 2.4 for windows. The renovation aims to make this old house as nearly zero energy building. The house use annually around 47000 kWh for heating and ventilation, 14000 kWh for hot-water, lighting and appliance, etc. It is supposed to be two part: 1) to renovate it following the existing building code in Norway (TEK10), 2) to install the solar PV panel to produce the enough electricity for the building. The solar resource is much more in summer than in winter in Norway. The electricity produced by buildings is not allowed to sell now, but it will be possible in the future. Therefore, it is supposed to use the electricity for car charging in the summer time. In the winter, the house still need to buy the electricity from the grid. It is supposed that the electricity used for car charging will cover the electricity bought from the grid. The average sunlight hours in Oslo area are 1632 hours annually. The installation of solar PV will get the 10000 NOK (Norwegian kroner) and 1250 NOK per kW (up to 15 kW) subsides from ENOVA. The average cost of installation of Solar PV is 13NOK per Watt. The PV panel is assumed to be renewed after 25 years. The electricity get from grid is estimated as one NOK per kWh according the current bill information.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 1: 3D model of the house from south-west

After analysis, the house will have two options on the renovation; the difference of two options is shown in the table 2.

Solutions	energy saving after renovation (kWh/year)	energy production requirement (kWh/year)	GWP (ton CO_2eq)	PMFP(kg PM10 eq)	LCC(million NOK)
Option 1: Change roof, facade, and window+ install the solar pv	25306	35780	56.13	282.75	1.04
Option 2: Change roof (not increasing the insulation quality) facade, and window+ install the solar pv	20507	40579	62.69	48.59	1.06

Table 2: Main results for two options

The users' perspective is indicated as weighting for optimization according their willing to pay. The result of optimization showed that the option 1 is selected because the owner want to priority on energy saving, life cycle cost and GWP.

4. DISCUSSION AND CONCLUSION

This study concentrates on the users' perspectives, environmental requisites and cost as the study framework for identifying, analysing and assessing the solutions for the deep renovation. It explore and develop an assessment and optimization by using the BIM, life cycle assessment, life cycle cost analysis and multi-objective decision making technology for the deep renovation of buildings. The case of a family house built 50 years ago in Norway is used for analysis.

It is found that the saving of energy for the renovated to be current building code on roof, façade and windows will save energy use around 25 MWh annually and 1.3 million NOK energy cost in total life. The most cost effective renovation part is the façade. It costs around 0.25 NOK to get 1 kWh energy saving. The installation of PV panel on the roof is also a good options for cost saving (investment with 1 NOK will get around 3 NOK payback). However, the renovation of housing itself will be more cost-effective than the installation of PV panel. The saving of the GWP of the renovation is not as significant as the energy saving and life cost saving. The renovation will cause more local PMFP. This is mainly because that the 99% of current electricity in Norway is from hydropower which is already is renewable energy.

There are some uncertainty of the results. Firstly, the material consumption data is from the BIM model, but the energy use data is from simulation. The simulation will create some uncertainty of the results. So the post renovation evaluation will conducted later to improve the reliable of the results. Secondly, the buildings is long life products. The life cycle scenario, including the lifetime, end of life treatment, etc., will impact the results. This require future studies on analysing the uncertainty of life cycle scenario of building in details.

ABSTRACT

The Hong Kong Housing Authority (HA) implement a public housing programme which cover all stages of development, from planning to design, construction and facility management. Building sustainably has always been one of our main objectives, and to this end, we continue to drive for innovation to improve the environmental performance of our development. In the past decade, we have devoted ourselves to integrate the use of Building Information Modelling (BIM) to enhance design efficiency, improve environmental performances, and advance the quality and safety of our work for the entire building development life cycle. We have successfully integrated BIM at all stages of our work, including:

- Feasibility and planning stage – Integration of BIM and geographic information system (GIS) to facilitate a variety of studies, including visual impact assessments, ridge line, vantage point and shadow analyses as well as site appraisal studies.
- Scheme design stage - Use of BIM for site specific design and value management
- Detail design stage - Use of BIM to enhance design efficiency and achieve energy saving.
- Construction stage - Use of BIM for site safety and construction planning.
- Post completion stage - Use of BIM for facilities and asset management.

BIM is transforming the construction industry worldwide and it can also contribute a great deal in sustainability. This paper will explore this subject in detail citing HA's experience as a reference.

Keywords: building information modelling, building performance analysis, sustainable design

1. INTRODUCTION

Established in 1973 under the Housing Ordinance, the Hong Kong Housing Authority (HA) develops and implements one of the largest public housing programme in the World. Today, about 30% of the Hong Kong's seven million population is living in about 750,000 flats in public rental estates. Another 15% of our population is living in subsidized sale flats. In support of the Government policy on housing, HKHA plans, builds, manages and maintains different types of subsidized public housing in meeting the housing needs of those who cannot afford private housing in Hong Kong. According to the latest update to the Long Term Housing Strategy as contained in the Policy Address 2016, the Government has further adjusted the projection of housing demand for the 10-year period from 2016/17 to 2025/26, and the public housing supply target will comprise 200,000 public rental housing units and 80,000 subsidized sale flats. With such a sizable programme to implement whilst ensuring quality, safe and healthy living in such a high density compact city as well as for people of all ages and abilities, it is quite a challenging task to accomplishInvalid source specified..

Building sustainably has always been one of our main objectives, and to this end, we continue to drive for innovation to improve the environmental performance of our public housing developments. In the past decade, we have devoted ourselves to integrating the use of Building Information Modelling (BIM) to enhance design efficiency, improve environmental performance, and advance the quality and safety of our built environment for the entire life cycle. With the concerted effort by staff at all levels, HA has, over the years, embarked on a number of innovative research and developments in BIM. We have achieved great success at many fronts and have applied it to good use in our projects. In this paper, we will highlight how we apply these innovations at different stages of our work, from planning to design, construction and facilities management.

2. INTEGRATING BIM FOR SUSTAINABLE PLANNING, DESIGN, CONSTRUCTION AND FACILITIES MANAGEMENT

2.1 Feasibility and planning stage

2.1.1 Integration of BIM and geographic information system (GIS)

Traditionally, BIM and GIS are two separate platforms which operate independently. Since 2009-2010, we saw the need and benefits in integrating the two systems to assist in the planning and design of our estates. In 2013/14 our colleagues have developed a data transformation tool which allows BIM models to be imported into the 3D GIS platform. The successful integration of BIM and GIS has been a significant breakthrough which facilitates a number of useful applications in the planning and design of public housing development, including visual impact assessments, ridge line, vantage point and shadow analyses as well as site appraisal studies. (Figure 1)

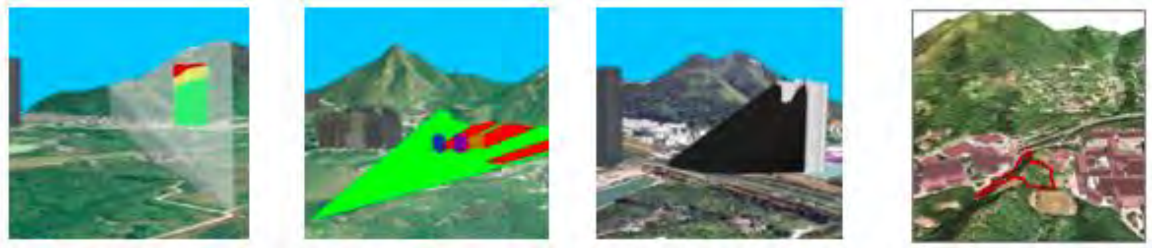

Figure 1: Left to right: Ridge line analysis, vantage point analysis, shadow analysis, site appraisal study

The 3D GIS platform contains accurate geo-spatial data on features such as the terrain, orthophoto, existing buildings and infrastructure of Hong Kong. By importing BIM models of our proposed public housing developments into the 3D GIS platform, our planners and architects can perform accurate visual impact assessments that was not possible before. It replaces the traditional method of taking photos at specific locations to create photo montages for visual assessment which are considered to be less accurate.

In addition, the integrated BIM and GIS platform is also very useful for carrying out site appraisal study as it provides a much clearer understanding of the site, its surrounding and the vicinity area in a 3D environment when compared to the traditional method of using 2D site location plans. We have successfully used the integrated BIM and GIS platform to carry out more than 60 site potential studies and visual impact assessments since 2014, as a standard application for all projects.

2.2 Scheme design stage

2.2.1 BIM for site-specific design

Given the challenges posed by individual site constraints, characteristics and environmental concerns, in 2008 HA developed a library of Modular Flat Design (MFD) to form a basis for creating site-specific block designs. BIM was used in the development of the Modular Flat Design. The precise geometry of a 3D BIM model allows for detailed refinement of the design and construction details of the Modular Flat Design. This enables us to enhance precasting and reduce material consumption for each flat on one hand, and optimizing the dimension of internal space for human comfort on the other hand. With the 3D BIM models of the Modular Flat Design, project teams can quickly assemble and create site-specific blocks and test out different designs options. It also facilitates preliminary environmental studies such as daylight analysis, and assists project teams to select the best design option to meet environmental performance targets. (Figure 2) Applying BIM to Modular flats, we are now exploring the use of BIM for quantity take-off and Statutory Submission of General Building Plans for building control.

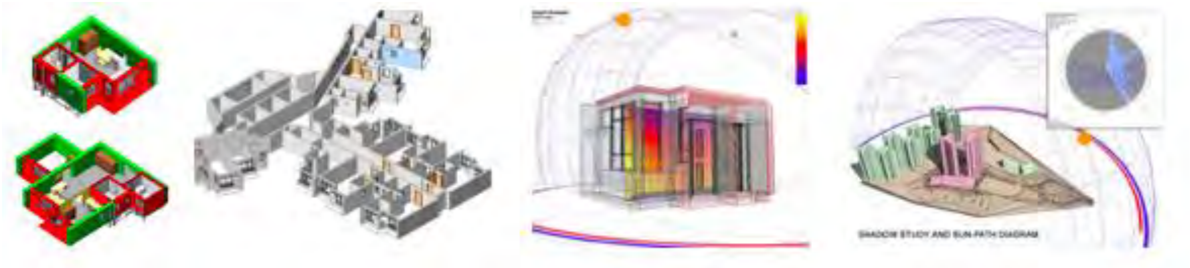

Figure 2: BIM for site specific design. (From left to right) MFD BIM models, assembly of site specific block design, daylight analysis for MFD, daylight analysis for site specific block design

2.2.2 BIM for Value Management

BIM has also been used as a Value Management tool at scheme design stage. For our project at Hin Tin Street in Shatin, we have used BIM for value management to compare the merits between a six-flat and an eight-flat per floor design option, as well as other structural design options to achieve optimum time and cost efficiency. This was made possible by integrating BIM with a construction management software to compare the construction time required between different options; and also by comparing the construction cost by extracting the quantity and materials of the building elements for comparison. (Figure 3)

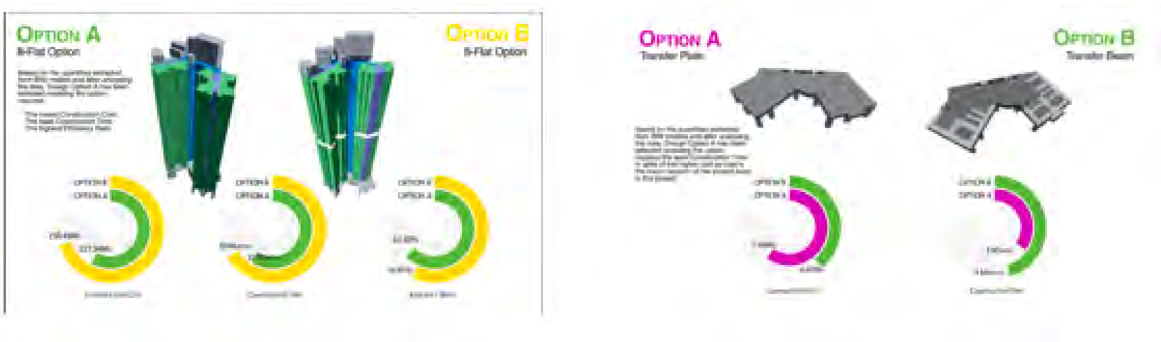

Figure 3: BIM for value management at Hin Tin Street

2.3 Detail design stage

2.3.1 BIM for environmental analyses

Through the integration of BIM with other environmental analysis software, we were able to carry out detailed environmental and technical analyses at detail design stage, including lighting simulation, daylight and solar radiation analyses.

In 2014, we successfully integrated BIM with a lighting analysis software to perform lighting simulation for our project at Sheung Shui Area 36. Our colleagues discovered a way to import BIM models created in Revit® into Dialux®, a lighting simulation software, to carry out lighting analysis and calculations. The successful integration of the two softwares was a significant step forward in the area of integrating BIM for sustainable design to reduce energy consumption. (Figure 4)

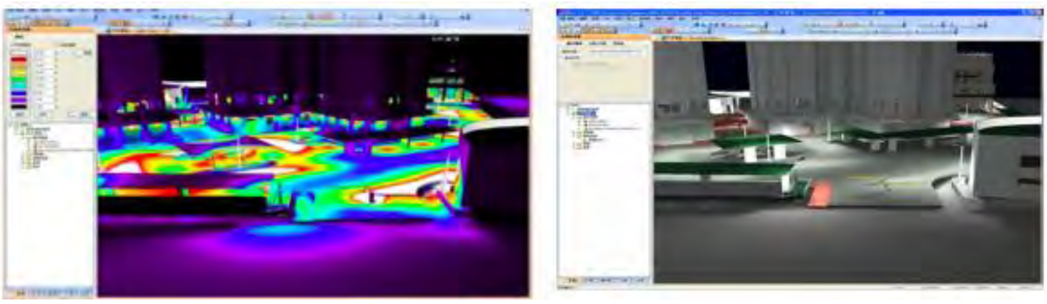

Figure 4: Integrating BIM with lighting analysis software

With the rising cost of energy and increasing environmental concerns, there is tremendous potential in the area of integrating BIM for environmental analyses. As more and more companies are launching new software to meet increased demand for building energy and environmental performance analysis, we continue to search for suitable software to widen our application of BIM. (Figure 5)

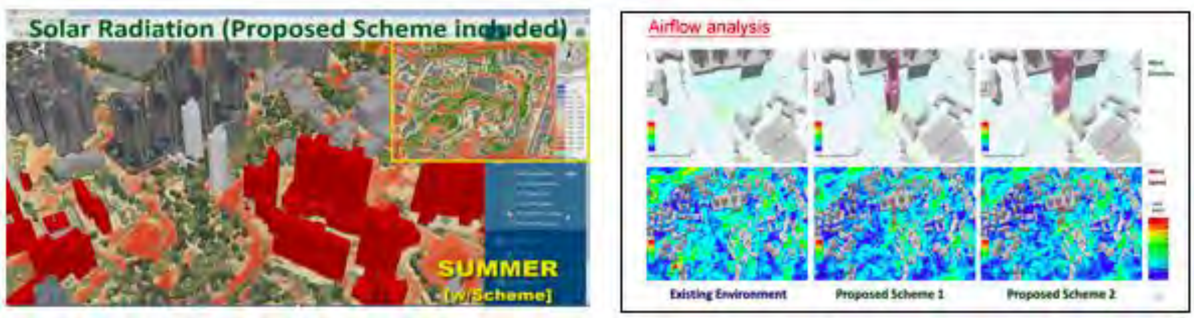

Figure 5: Testing of new software for solar radiation analysis and airflow analysis

Currently, we have integrated BIM to facilitate a number of different assessments at various stages. In the future we hope to apply BIM to facilitate more assessments, including some that may assist BEAM accreditation. (Figure 6)

Twenty five different studies to be carried out at various stages

Potential use of BIM to facilitate assessment

Figure 6: BIM facilitates a number of different studies and assessments at various stages

2.4 Construction Stage

2.4.1 BIM for site safety planning

Safety in construction is our top priority. In the last few years, HA have been working with contractors to use BIM extensively for site safety planning to identify and resolve potential risks and problems prior to carrying out actual work on site. For the demolition of Lower Ngau Tau Kok (LNTK) Estate in 2010, our project team and contractor used BIM to create a video to plan the entire demolition process. The buildings to be demolished in LNTK were our earliest buildings with precast concrete elements. The demolition work requires careful planning in terms of the sequence of demolition and safety precautions. With the video, workers and supervisors were able to visualize and rehearse the demolition procedures safely in a virtual environment and then carry out their work subsequently on site in a precise manner. The outcome was outstanding and resulted in zero accident. (Figure 7)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 7: Site safety planning for demolition of Lower Ngau Tau Kok Estate

2.4.2 BIM for construction planning

Tung Tau Cottage Area East was a project with complex topography which comprised three platforms with significant level difference, and it is our first project using BIM at the design stage. Thereafter, BIM was used to create a detailed 4D virtual construction simulation of the entire construction sequence, from site formation to foundation and superstructure. The objective was to verify the viability of the design as well as enhancing the effectiveness of the proposed construction sequence. The construction simulation was subsequently used at construction stage to monitor and compare against actual site progress. The project was completed on time and with enhanced productivity. (Figure 8)

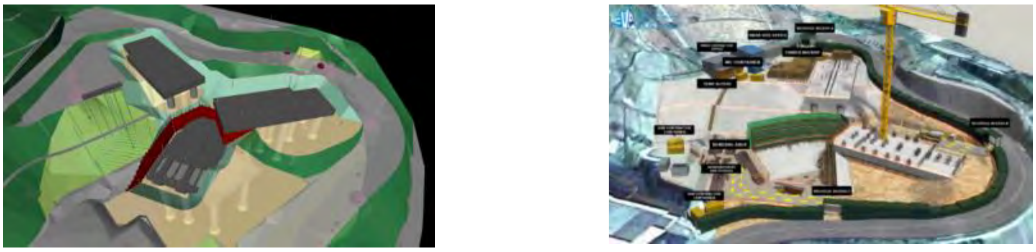

Figure 8: Construction sequence planning for Tung Tau Cottage Area East

2.4.3 Integrated use of BIM and Radio Frequency Identification (RFID)

In 2014, HA collaborated with the University of Hong Kong (HKU) and Hong Kong Polytechnic University (PolyU) to create a consolidated BIM and RFID platform for our project at Tuen Mun Area 54 Site 2. RFID tags were embedded into selected precast building components to track the fabrication, delivery, storage and installation of the precast building components. The successful integrated use of BIM with RFID technologies may extend to other prefabricated elements in both public and private construction projects to enhance the efficiency of logistics and supply chain management. (Figure 9)

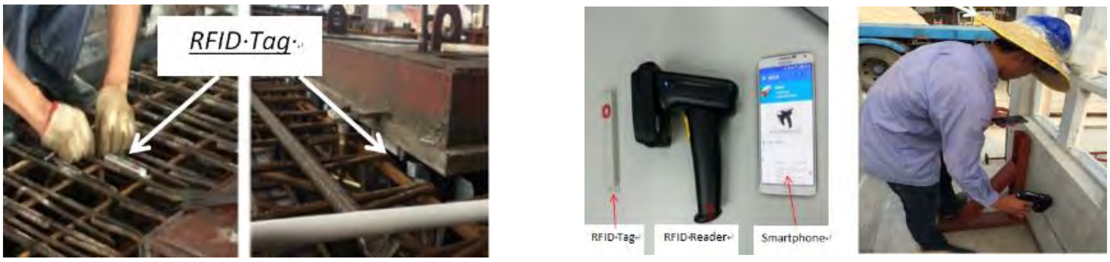

Figure 9: Installation and scanning of RFID tags embedded in precast concrete elements.

2.5 Post Completion Stage

2.5.1 BIM for facilities and asset management

To fully utilize the benefit of BIM, it is important that all the information and parameters captured in the BIM model during design and construction stages be carried forward for facilities and asset management at post completion stage.

For "Domain", our Shopping Centre development at Yau Tong, a data rich model was created at construction stage which contains information such as construction drawings, product certificates and warranties. This data rich model is useful to our facilities managers for storage and retrieval of integrated building, maintenance and management data for future facilities management. For our project at Sheung Shui Area 36, the complicated and dense network of underground utilities and pipes were carefully documented in the BIM model during construction stage which will be very useful for carrying out future maintenance work. (Figure 10)

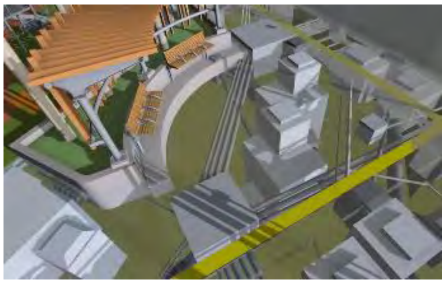

Figure 10: Data rich as-built model for Domain Shopping Centre for facility management (Left)
Underground utilities at Sheung Shui Area 36 for future maintenance (Right)

3. CONCLUSION AND WAY FORWARD

HA has successfully integrated BIM at all stages of our work from planning to design, construction and facilities management and we have seen significant improvements in all areas of our work. This integrated application of BIM has enabled us to achieve social, economic as well as environmental benefits. We have been constantly extending the use of BIM to enhance the quality and efficiency of our work towards sustainable development. Looking forward, we plan to venture into other areas of BIM research and innovation including environmental analyses, statutory submission and material specification. We strongly believe that BIM will play a major role in the construction industry in the future and HA will continue to drive for innovation in this area and put ideas into action.

ABSTRACT

The zero-energy house manages to reduce the energy consumption during its usage phase by using high-performance containment and equipment systems, accompanying with the solar photovoltaic modules and other renewable energy utilization system. It also puts forward higher requirements to the production, construction, maintenance and replacement of building components. Therefore, its embodied energy consumption and environmental impact are usually higher than the general building. It is necessary to analyze these aspects from the perspective of life cycle assessment.

The zero energy building has a higher demand for long-term maintenance and component replacement due to the complexity of its construction and equipment system. Building information model (BIM) provides a sharing data platform for multi-disciplines during the construction and post-operation phase of projects. In this paper, the BIM-LCA method is used to analyze the environmental impact of building materials' whole life cycles. The Global Warming Potential (GWP) and Primary Energy (PE) of a small scale residential building under common energy-saving and zero energy consumption scenarios are compared and analyzed. The environmental impact analysis method based on BIM-LCA of the zero-energy house is discussed.

Keywords: life-cycle assessment, BIM, zero energy house

1. INTRODUCTION

In order to reduce carbon emissions and fossil fuel combustion, the international community has proposed the definition of "zero energy building" to carry out technical research since the 1970s. The definition of zero-energy building by the Department of Energy of the United States is that "an energy-efficient building where, on a source energy basis, the actual annual delivered energy is less than or equal to the on-site renewable exported energy".

In different contexts, the definitions of the boundary division, measurement index, conversion coefficient and balance period of the zero-energy building have not reached a same standard. But most of the definitions for the energy consumption stay at the building operation phase, but not include the production of building materials and the energy consumed by the recycling phase. Therefore, some scholars put forward the concept of Life Cycle Zero Energy Building (LC-ZEB). For example, the study of Maurizio and others introduces the concept of life cycle zero-energy consumption. They calculate the following factors: final energy as metric, primary energy as metric, life cycle energy driven energy balance under the condition of energy balance in order to emphasize the importance of considering the energy content of building materials in the study of the zero-energy building. Hernandez introduces the definition of "life cycle zero energy building" with a simplified calculation formula: Annual Life Cycle Energy (ALCE) =Annual Energy Use (AEU) + Annual Embodied Energy (AEE) = 0. A more objective evaluation of LC-ZEB can only be made by a comprehensive consideration of AEU and AEE (Table 1).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

	Formula	Definition
Operational zero energy building	AEU = 0, AEE > 0, ALCE > 0	Refer only to the energy that is used in the operation of the building.
Life cycle zero energy building	ALCE = AEU+ AEE	Accounting for the embodied energy of building components together with energy use in operation.
Energy producing building	AEU is negative, │AEU│> AEE, ALCE	

Table 2

The Sunflower zero-energy house discussed in this paper is analyzed of the environmental impact of buildings in the context of life cycle based on the zero energy consumption during use stage.

2. METHODOLOGY

In this paper, a small-scale zero-energy solar house – "Sunflower" – is selected as a case to analyze its energy consumption and life cycle environmental impact. As the general energy saving house used to compare with the Sunflower, its structural system, internal and external decoration, home appliances, building exterior shape, window and wall ratios are all the same as the Sunflower. Its energy system design parameters, heat transfer coefficient of transparent structure are both following the latest version of Tianjin's Design standard for energy efficiency of residential buildings.

	General energy-saving house	Sunflower
U-value of exterior doors and windows	≤1.5 (U = 1.46 [W/(m^2·K)])	≤1.0 (U = 0.814 [W/(m^2·K)])
Source of electricity supply	Urban power network	PV power generation system
Heating system	District heating boiler (Gas)	Solar radiant heating
Cooling System	Electric air conditioning	Radiant sky cooling system

Table 2

At this stage, most of the residential buildings are still using the urban power network, electricity air-conditioning for cooling and gas fired boiler for heating, so the general energy-saving building should also follow the above energy system while calculating its energy consumption in use stage and environmental impact of equipment and materials (Table 2).

The environmental impact at all stages of the life cycle can be calculated by modeling a detailed (including envelope structure, decoration materials, and energy systems) model in Revit of which the information can be read in Tally. At the same time, the Sunflower model is established in the Design Builder energy simulation software to calculate the energy consumption of the use stage. Through the above data, in the context of the life cycle, the zero-energy house's Global Warming Potential (GWP), and Primary Energy (PE), non-renewable primary energy consumption (NPE) are discussed.

2.1 Life cycle standards and system boundary

In this paper, the life cycle assessment of the solar energy zero-energy house takes into account two key indicators: total primary energy consumption, and global warming potential (GWP). Energy consumption during the operation phase include heating, cooling, lighting, domestic hot water (DHW), and equipment energy consumption (Figure.1). By using Tally for the calculation of life cycle environmental impacts, the default system boundary of the building products is set to include the manufacturing, transportation, construction, maintenance, replacement, demolition and recycling stages. Therefore, in this study, the transportation process is only considered in the material manufacturing stage. The transportation to and from the site in the construction and waste disposal stages are not included.

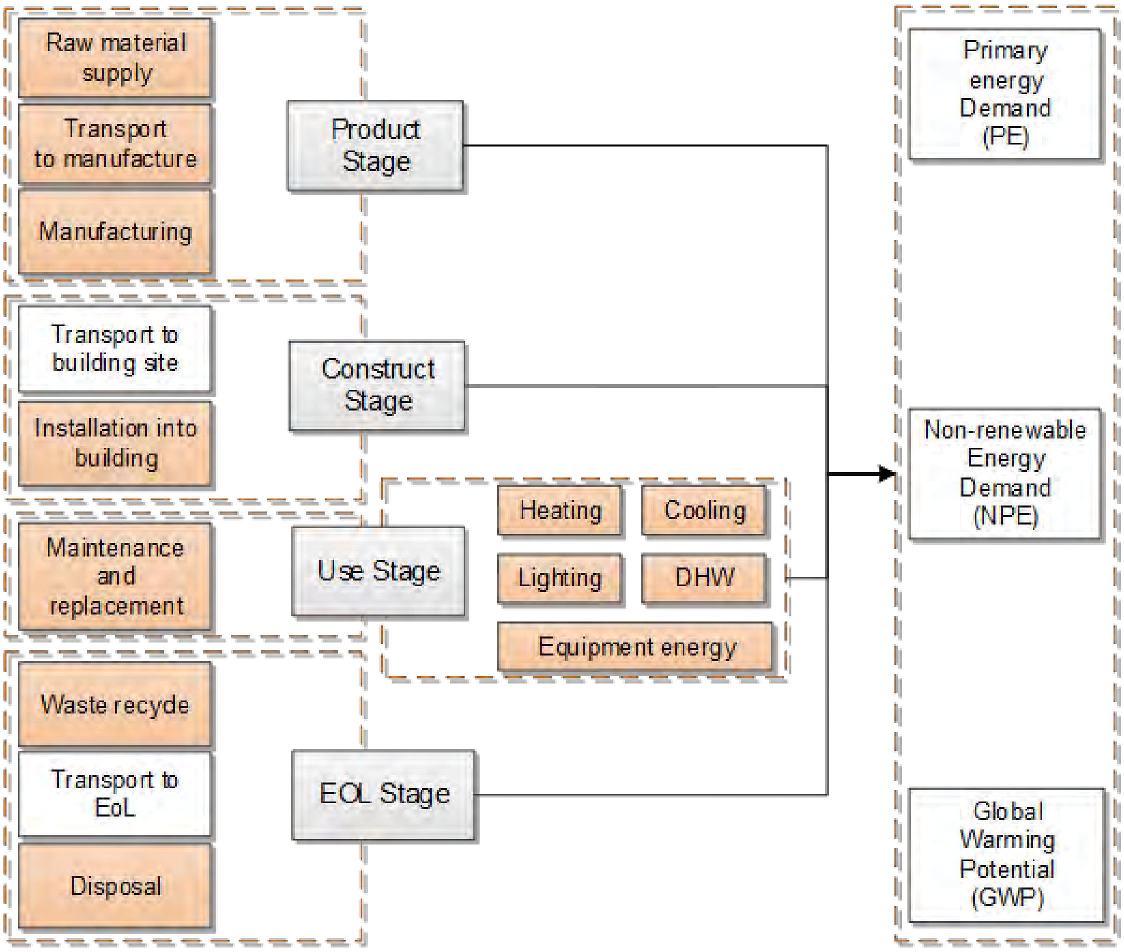

Figure 1: System boundary of the study (The orange box indicates the boundary of LCA)

2.2 Tools and indicators

In this study, Revit is chosen as the BIM/Revit tool to describe the structure and material of the building. The add-in Tally is chosen mainly for the life cycle assessment. Tally is able to link the detailed construction layers of the building model to obtain the geometrical and material information from it. In the meanwhile, Tally's building material LCI data is derived from the GaBi database and its lifecycle impact assessment is based on the TRACI 2.1 standard.

Most of the life-cycle inventory data for building material applied in this study are based on Tally's default database. A small amount of the missing data are quoted from the Ecoinvent and Ökobau.dat databases. At present, China has not yet established a complete building life cycle inventory database for building products which can have good interoperability with the BIM software. Although the use of European and American databases for China's domestic building case study will lead to some biases in the absolute values of the results, the outputs can still provide evidence with the relative values in the comparison of the solutions with different the energy-saving levels on the same building prototype. Table 3 shows the LCI data sources for the major materials applied in the case study and the rate of recovery in the end-of-life stage.

This study mainly focus on the examination of primary energy consumption and greenhouse gas emissions. Other environmental impact types, such as Ozone Depletion Potential (ODP), Acidification Potential (AP), etc., are not discussed in this paper.

Material's name	Database	End of Life
Steel	GaBi(Tally)	98% recovered 2% landfilled (inert material)
wood	GaBi(Tally)	14.5% recovered (credited as avoided burden) 22% incinerated with energy recovery 63.5% landfilled (untreated wood waste)
glass	GaBi(Tally)	100% to landfill (inert waste)
PV system	LEGAP(Ecoinvent)	3.7% landfilled 27.2% recovered 69.1%heating and regenerative cycle

Table 3

Figure 2 shows the mind processes of this article. The energy consumption data of building used in different scenarios simulated by Design Builder is imported into Tally, and the LCA results are output. Then the Global Warming Potential (GWP) and Primary Energy (PE) of the building under common energy-saving and zero energy consumption scenarios are compared and analysed.

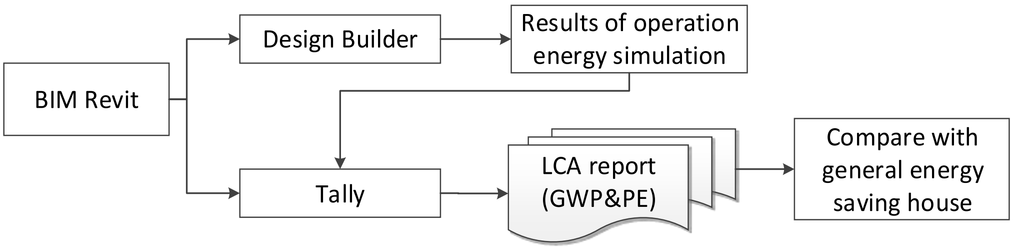

Figure 2: Technical roadmap of the methodology

3. CASE STUDY

3.1 Building model (Site)

Table 4 reports the main site Geographical and climatic data, as well as some building features.

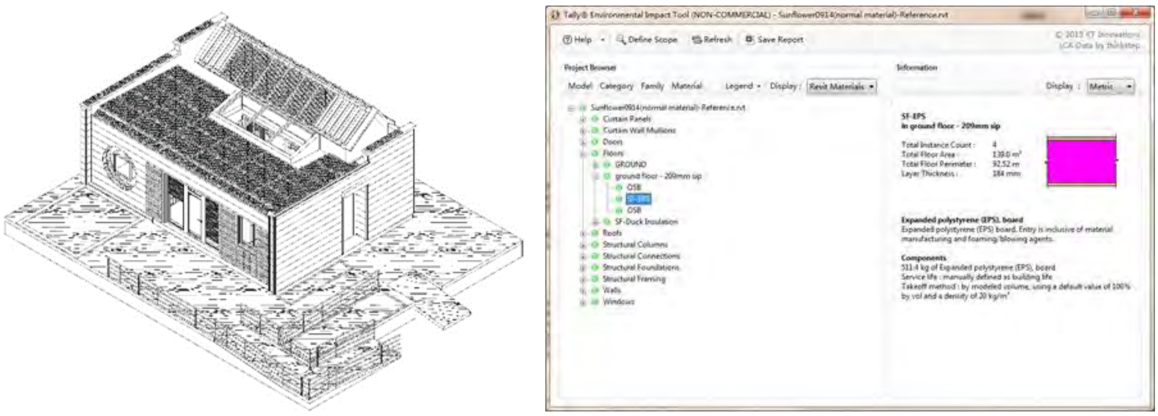

Figure 3: The image of the interface of Tally and the Revit model of Sunflower

3.2 Description of the building

Sunflower is a small single-story residential house with a light atrium in Tianjin, China. It has a steel structure based on an independent basis, mixed with light timber framed beams by Parallel strand lumber (PSL) and the Structural Insulated Panels (SIP) system.

The house is occupied by 3 people. The glazing area to the gross wall surface ratio is 30.7% for the south facade, because of the glass door in the east, the east window-wall ratio is 26.64%.and 4.35% for the north one.

3.3 The building envelope

In order to meet the design standard of the zero-energy house, the design of "energy control" must be done. Before using renewable energy, the standard of low energy consumption should be achieved through strengthening insulation and improving energy efficiency. Table 5 reports the material and their thermal performance respectively. The heat transfer coefficients of the house's envelope structure are all under the requirements of Design standard for energy efficiency of passive low-energy residential buildings. Table 5 presents the thermal properties and the material composition of the building envelope.

External structures	U-value	External structures	U-value
External wall	0.15	Window	0.8
Ground	0.15		
Roof	0.15	Door	1.0

Table 5

3.4 The building service

Sunflower uses the composite energy system basing on radiant panels. The energy of domestic heating water (DHW) comes from solar through the tubular solar collector which locate at the south and north slopes of the roof. The functioning area of the tubular solar collectors is 2.08m^2.

The lighting system of the house is designed to minimize the energy consumption while meeting the specified demand of the rooms. The lighting fixtures are Compact fluorescent lamps (CFLs). The lighting power is set to 5W/m^2.

The electric power of the house comes from the solar photovoltaic system by the solar photovoltaic cells which locate on the roof and walls. The Mono crystal silicon battery module's efficiency which placed at the sloping roof, flat roof, and parapet can reach 15.9% in the standard measurement state, the ones at the east, west and south façade can reach 14.8%.

The main parameters in Design Builder: Winter: 20°C, Summer: 26°C; Relative humidity: 40 - 55%; Fresh air volume: 30m^3/h/p; Cold air infiltration: 0.4 ach/h.

4. DISCUSSION OF THE RESULTS

4.1 Comparative analysis of the use stage

4.1.1 Energy consumption of the general energy-saving house

After entering the climate parameters of Tianjin in energy consumption simulation software and setting the transport efficiency of the gas boiler heating system to 0.9, the COP of air-conditioning to 4.0. It comes with the result that the consumption of gas is 2870.94kwh, of electric power is 6375.54kwh. These results then are imported into Tally, converting to the GWP of 412062.3kwh, primary energy of 5011316.45MJ.

4.1.2 Energy consumption of the Sunflower during the operation stage

The energy consumption of Sunflower during its use stage mainly from the electric power except the solar power used by heating, cooling and hot water. PV panels on the roof along with facades of buildings can provide adequate electric power for the building. According to the statistics of PV power generation in Design builder, the annual output power from photovoltaic panels is 7221.9Kwh/a. The net balance of electric power by PV is 3666.03kWh/a. Figure 4 shows the relationship between electricity production and consumption for the whole year. The spare electric power can be stored in the battery and also be delivered to the urban power grid through the inverter.

Viewing from the results for annual energy balance, PV plates' power generation is significantly greater than the building's power consumption. Therefore, we assume that the excessive electricity would be transferred to the urban power grid. If less PV modules were applied and the annual energy balance is near zero, then the off-grid solar power system could apply. However, it must be equipped with batteries, which will cost up to 30% - 50% of

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

the whole power generation system. As the common domestic batteries' lifespan is 3 - 5 years, the replacement will lead to additional costs and embodied impacts.

4.1.3 Comparative analysis of the primary energy

The electric power consumption of Sunflower during its use stage mainly comes from the PV panels except for a small part of December from the urban power grid. So the spare electric power generated by the PV panels can be delivered back to the grid and used by other buildings. The GWP and primary energy calculated from transmission electric power are negative. Table 6 and Figure 5 shows the comparative analysis of the GWP and primary energy between general energy saving building and Sunflower.

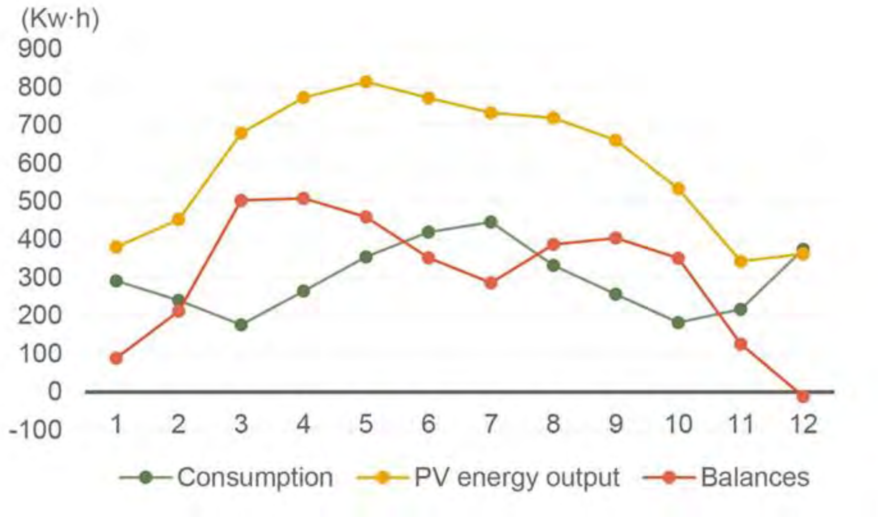

Figure 4: Sunflower's power consumption, PV energy output and power balances (Monthly)

In order to maintain the uniformity of database sources, the calculation method of primary energy consumption and GWP used in this article is derived from Tally's average conversion coefficient of China's electricity and gas. In the calculation of the delivery of power from PV panels to the urban power network, the loss rate of China Power network is 6.64% as published.

	GWP(kgCO2eq)	PE (MJ)	NPE (MJ)
General	412062.30	5011316.46	4741124.87
Sunflower	-196220.12	-2318219.83	-2179992.07

Table 6

4.2 Comparative analysis of the LCA of building materials

It can be read from the figure.6 that the PV panels take the largest part of the environmental impacts of Sunflower, although their power generation capacity can override the embodied energy and carbon. The PV panel not only has a large environmental impact at the construction phase, it also needs replacement during the usage phase due to its operation life is around 15 - 25 years. This article does not consider the improper cleaning and maintenance, resulting in the annual damage and impact during the service life of the PV modules. Therefore, the power output of the PV system might be over-estimated under the actual situation, and the earlier replacement could lead to greater environmental impacts. In addition, the replacement of the building's out doors and windows will also cause an increase in the value of material environmental impacts.

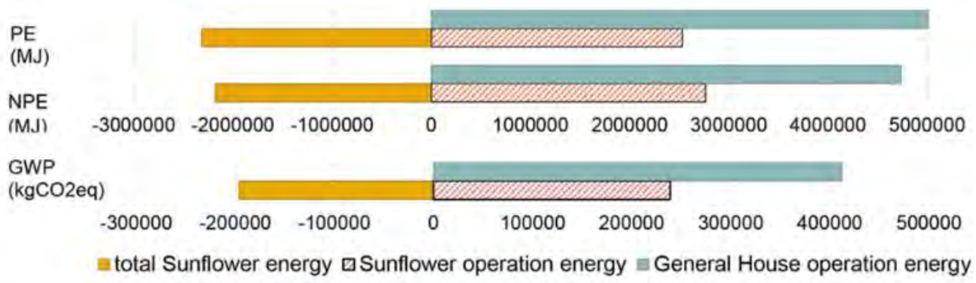

Figure 5: Comparison of PE, NPE, and GWP of operation energy consumption between Sunflower and general energy saving building

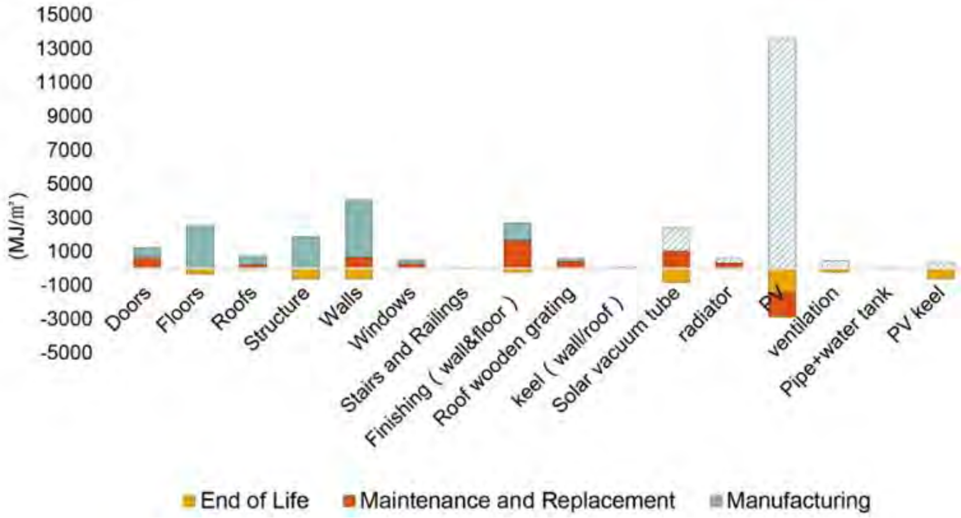

Figure 6: Life cycle primary energy demand of Sunflower's material

4.3 Analysis of total life cycle energy consumption

Although the environmental impact of Sunflower's materials is greater than that of the general energy saving building, the energy of the materials takes a small part of the whole life cycle energy consumption and this difference value can be covered by the electric power generated by the zero-energy house. So from this life-cycle perspective, Sunflower's energy consumption is still close to zero (Figure 7).

Figure 8 shows the cumulative GWP value of Sunflower over time. There is a significant increase in carbon emissions in the 20th and 40th years when the PV panels require replacement. At the end of the life time, PV panels can be recycled after replacement or demolition, and the life cycle impacts of the building can also be reduced. The reduction of GHG emission from material recycling is included in the value of 'maintenance and replacement.

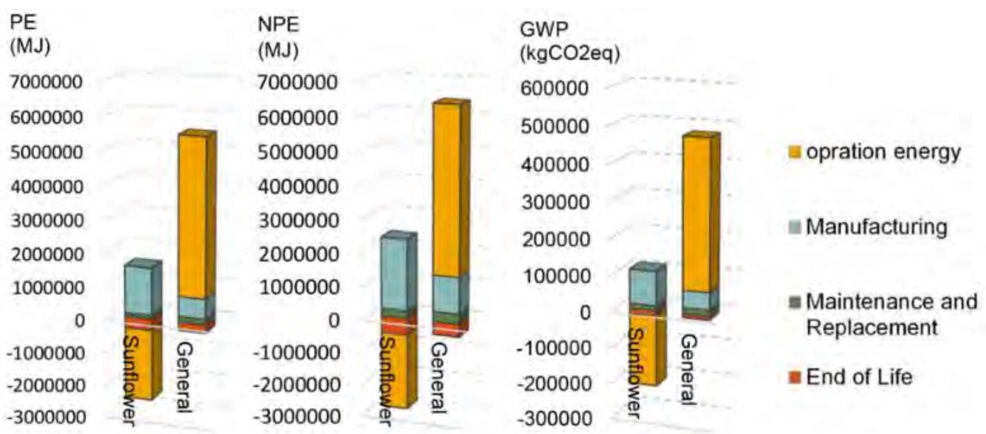

Figure 7: Comparison of the life cycle environmental impacts between Sunflower and general energy saving building

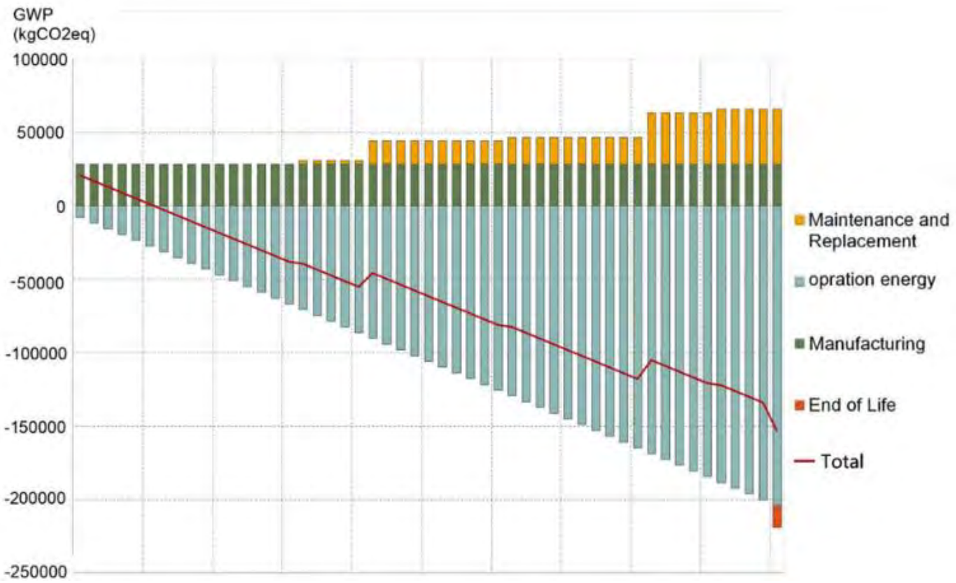

Figure 8: Cumulative GWP value of Sunflower over time in building's life cycle

5. DISSCUSION AND CONCLUSION

By using the BIM enabled LCA calculation method, the life-cycle energy consumption and GWP of a small scale residential building at the general energy saving standard and positive energy level are analysed and compared. The conclusion is that in order to understand the environmental performance of the "zero-energy buildings" comprehensively, it is necessary to consider their energy consumption and environmental impacts during the whole life-cycle.

In this study, a detailed model with the building construction system and equipment system is established in the BIM model, adopting with the LCA tool Tally, which is compatible with Revit. The result shows that it is necessary to carry on the analysis at the BIM standard data platform which shares data through multiple disciplines and phases due to the complexity of the envelope construction and the renewable energy system of the zero-energy buildings.

Despite the interactivity between Design Builder and Revit, the Revit model cannot be easily docked with the original model. Therefore, during the process of energy simulation, the model was rebuilt in the Design Builder to ensure the accuracy of energy consumption simulation results.

Although the results show that the positive energy scenario have obvious ecological benefits, it costs much higher in the new construction stage. In the future study, the life cycle cost of the building will be included in the scope of the study, aiming at a more comprehensive evaluation of zero-energy buildings.

ACKNOWLEDGEMENT

This contribution is supported by Project 51478294, 51628803 funded by NSFC, the Program of Introducing Talents of Discipline to Universities (B13011), and by the International S&T Cooperation Project 2014DFE70210 funded by the MOST. The reviewers had provided valuable advices on the revision of the contribution.

The Use of FTA (Fault Tree Analysis) to Evaluate the Contribution of BIM Platform to The Environmental Quality on Rehabilitated Buildings

Fabiana DIAS DA SILVA[a], Monica Santos SALGADO[b]

[a] *Petrobras, Brazil, fabyds@gmail.com*
[b] *Federal University of Rio de Janeiro, Brazil, monicassalgado@ufrj.br*

ABSTRACT

Several studies recognize the potential of interventions in existing buildings that ensure sustainability and improve the environmental quality of cities. The rehabilitation of these constructions reduces the consumption of natural resources and the intervention in new lands. In the context of sustainable design, the use of tools that support the integrated and collaborative work as Building Information Modeling (BIM) offers a great potential to identify and propose interventions that implement sustainable practices both in new buildings as in rehabilitation of existing buildings. In order to evaluate the possibilities of the use of BIM Platform in a building environmental performance analysis a case study on the head office of an important Brazilian company at Rio de Janeiro was performed. The original design of the building is a result of a national design contest and its construction was performed in the 70's. Improving the environmental performance of the building was one of the principals of the rehabilitation design, which used AQUA HQE environmental assessment and the Brazilian energy efficient performance PROCEL as its parameters. The company design team defined the environmental quality profile for the rehabilitation, later; they hired a design office to develop the design using BIM Platform. The design office developed a digital model that could work in an integrated and multidisciplinary manner. However, there has been little integration between the definition and verification of categories and environmental targets of AQUA HQE method and the employment of BIM model. This article is part of a PhD Thesis, and presents the results of the analysis of the potentialities of BIM Platform through the use of FTA – Fault Tree Analysis Method. The results suggest that the use of BIM model since the beginning of the rehabilitation design process could brought more dynamic and integrated design solutions. Therefore, one must review the practices of design process that aims for integrated design solutions through collaborative work.

Keywords: rehabilitation, environmental quality, BIM

1. INTRODUCTION

Since the 1990's, the civil construction industry is facing different challenges regarding innovation in both design process and construction management. In this period, the increment in the discussions concerning sustainability in the construction production was observed, as well, as the spread of different certification systems for "green" constructions. In general, the tools are attempting to: achieve continuous improvement to optimize building performance and minimize environmental impact; provide a measure of a building's effect on the environment; and set credible standards by which buildings can be judged objectively. [3]

In this scenario, the rehabilitation of buildings enables the extension of the buildings' life cycle through the improvement of energy performance and comfort conditions for occupants. Therefore, the rehabilitation becomes an opportunity to achieve sustainability requirements, through taking into account the needs of current users and ensuring the extension of building's life cycle for future generations

Thus, this paper submits a case study where the BIM platform had been used for the rehabilitation of an existing building, aiming to facilitate the design management process and the inclusion of the requirements of AQUA environmental certification. The AQUA certification is an adaptation of the French method HQE – High Environmental Quality.

This paper is part of an ongoing doctoral research. The first results have been presented on WSB 14 Barcelona. The final part – presented on this paper – includes the use of FTA (Fault Tree Analysis) to evaluate the faults during design management process for the development of sustainable buildings.

2. ENVIRONMENTAL CERTIFIACTIONS

Environmental certifications are tools that seek to evaluate and measure the environmental performance of buildings. Each country has developed its environmental reference, considering the specific characteristics of the different regions. Reed et al. [3] point out that the systems of assessment of environmental performance aimed at promoting continuous improvement to optimize building performance, minimize environmental impact and to establish reliable standards by which buildings can be evaluated objectively.

Only recently, Brazil has given its first steps towards the discussion and the adoption of methodologies that might help the production of building with high environmental quality. Among the foreign methods that arrived in the country, it is possible to highlight the LEED ™ North American system (Leadership in Energy and Environmental Design), the French method HQE® (Haute Qualité Environnementale) which was adapted to the Brazilian reality into AQUA HQE process, the British method BREEAM and SBTool, developed by iiSBE. The first two methods have been adopted by Brazilians constructors, particularly on the Southeast region of the country.

It is important to highlight the role of the environmental certifications regardless the preference provided by stakeholders. It is understood that the main merit of proposals is in helping architects and engineers to re-think the design process aiming at the incorporation of solutions that may contribute positively for the environmental quality of the building.

Chart 1 presents a comparison among the main certifications adopted in Brazil. Through this analysis, it is possible to point out that AQUA HQE and SBTool methods have some advantages in comparison to BREEAM and LEED, as they offer greater flexibility and a demand for an integrated design process. Solutions and practices adopted will depend on the context of each architecture design and each phase of the project, and should be consistent with the previous step and the intended goals which must be defined early in the design process. Thus, there is no prompt model that can be used without analyzing the specificities of each demand.

Certification		BREEAM (1990)	LEED (1998)	SBTool iiSBE (1996)	HQE (1996) AQUA-HQE (2008)
Method	Country of origin	United Kingdom	United States	International group	France/Brazil
	Categories	Management; Health and wellness; Energy; Transport; Water management; Materials; waste; Land use and ecology; Pollution and contamination; Innovation	1-Integrative think; 2 Energy; 3- Water; 4 Waste; 5- Material; 6 Location and transportation; 7 Sustainable sites; 8- Health and human experience; 9- Regional impacts; 10 –Global, regional and local; 11- Innovation	Presents numerous requirements of the three dimensions of sustainability: environmental, social and economic.	4 groups which are divided into 14 targets and about 160 aspects related to: Eco construction, eco-management, comfort and health
	Evaluation	Percentage over the total achieved and classification level: correct, good, very good, excellent and outstanding.	By points from a checklist. which classifies the building into four levels (from certified to platinum)	Presents 9 categories and 44 parameters related to both qualitative and quantitative issues.	Certifies the process and the product through Project management system (SGE) and Environmental quality framework (QAE)
	Performance analysis	Sum of points obtained in 10 categories and applications the environmental weighting factor	Prescriptive: the points are obtained meeting the requirements of credits.	Rating the performance	Rating the performance

Chart 1: Comparison among environmental certifications

2.1 BIM and sustainable design

Among the possibilities offered by the information technology aiming to facilitate this process, the BIM platform – Building Information Modeling – is highlighted, since it allows the conjugation of all aspects involved in the design process and verification of the impact of design decisions identifying incompatibilities.

The Building Information Modeling (BIM) is an anticipation of the reality that deals with developing a set of representations (models) of the construction information. Thus, a database is built which may be used and updated during all its life cycle. The "BIM" platform emerged at late 1970´s in the United States and Europe, mainly in Finland [4]. The migration for the "BIM" platform is relatively slow in Brazil, and still passes through an acceptance process by the offices.

In this sense, it must be highlighted the research developed by Olin´s et al [2] informing the potential of BIM platform as a cooperation instrument, that can be used for both the management of documents and information, for project management, budgets control, planning, schedule, environmental simulations and to analyze variables related to feasibility, costs, energy and environmental performance. The authors add that BIM advantages are not limited to the conception phases of the design and construction, and they may be useful throughout all life cycle of the building such as maintenance, rehabilitation, analysis of space usage and environmental management as well as costs of the operational performance.

3. CASE STUDY

To provide continuity to the survey about the possibilities of the use of BIM Platform in a building environmental performance analysis, a case study was accomplished in a company headquartered in the city of Rio de Janeiro. The original design of the building that lodges the company was chosen by means of a competition organized by the company through the Institute of Architects of Brazil (IAB-RJ), in 1967. The building conception includes precepts of bioclimatic architecture, which should follow the main requirements defined in the official announcement: the maximum occupation of the land with minimum of vertical circulation; the valorization of the social contact in pleasant environments and the desire of becoming a landmark in the city's architecture, highlighting its landscape, but integrated with its surrounding. [1]

Photo 1: Construction and its surrounding

Around 2008, remodel works were performed in the area of air conditioning aiming at increasing the energy saving. To check the efficiency of those new systems, the works were performed in the 6th floor, which has been totally reformed [1]. The enhancement in this floor has oriented the development of the Basic Design for the other floors and, in 2013, the rehabilitation design has been initiated, aiming at the adequacy to the current and future needs of the construction.

3.1 AQUA HQE and BIM platform for rehabilitation process

The development of the renovation/ requalification design was divided into four stages: Conceptual Design, Basic Design, Detailed Design and Construction. Firstly, the Conceptual and Basic Design Phases were accomplished, using the conventional 2D software for design. The option of making models using BIM platform took place in the Detailed Design due the complexity of the design. Moreover, the interest in adapting the building to meet the requirements of AQUA process justified even more the production of the model in BIM. In relation to the environmental certification, an option was made by the AQUA process in light of its resilience, as the stakeholder must prepare the Environmental Quality Profile (QAE) according to the specificities of the construction. [5]

One of the main issues that led to the decision of BIM model construction was the possibility of creating a database of the project. This will facilitate the operation and maintenance activities of the building as well as the accomplishment of future reforms. Therefore, it is necessary to enable and to familiarize the professionals that are responsible for the building maintenance with the use of this tool, in order to keep the database always updated.

Regarding AQUA certification for existing buildings, it is worth adding that there is no need to perform simulations, only the proof by calculation, reports, standards and inventories. In the case studied, nevertheless, considering the parametrical modeling, it would be even possible to perform such simulations.

3.2 The use of fault tree analysis

The Fault Tree Analysis, according to Vesely et al [6] is a systematic method for information on a system. The proposal is a deductive analysis to resolve an unwanted event exhaustively searching for the causes of failure, thus clearly showing all the different interfaces that are necessary to reach the undesired event (top event). The method can be used to evaluate a proposed project according to its safety and reliability, optimize test and maintenance, quantifying the probability of failures and also identify the weaknesses of a system, the effects of human error and effective improvements to a system. Figure 1 shows schematically the symbols used for the construction of a fault tree.

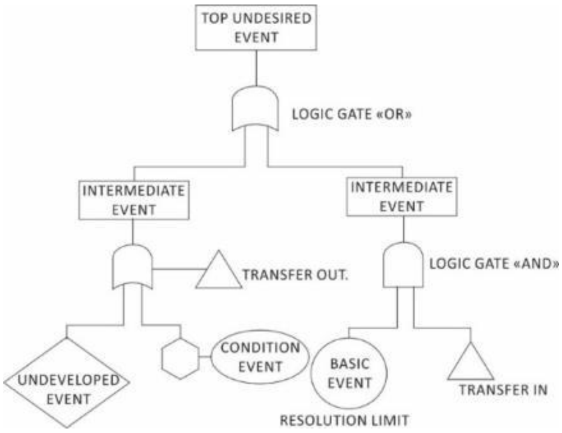

Figure 1: Example of a fault tree

The undesired top event that was explored is: "The project environment quality profile has not been established in a collaborative process".

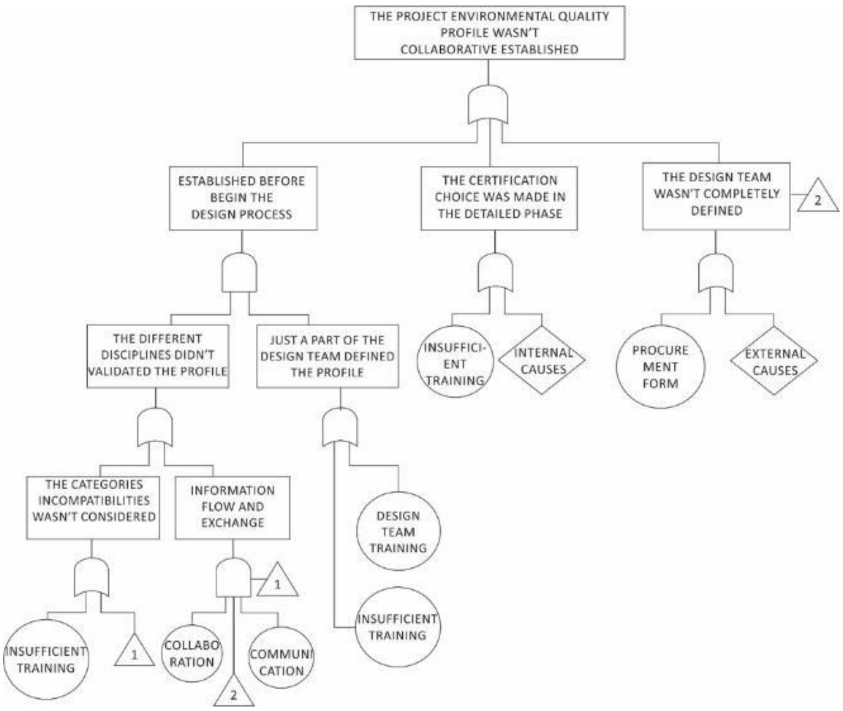

Figure 2: Fault tree construction

From the top-event, began the construction of the FTA, as shown in Figure 2. Among the evidences of the first level of the tree, two intermediate events should be highlighted: environmental profile has been established before the beginning of design process and the design team wasn't completely defined.

The application of FTA on the case study has revealed four aspects to be considered in order to improve BIM implementation: (1) The lack of qualification in the potential offered by BIM Platform; (2) insufficient training; (3) the working method used by the design team to develop projects; and (4) the obstacles to design projects with high environmental quality.

4. DATA ANALYSIS AND CONCLUSIONS

In this case study BIM has not been adopted aiming the improvement of the environmental performance of the rehabilitated building. The case study analyzed through FTA method revealed that, in fact, the use of BIM has been adopted exclusively for its potential in use-operation and maintenance phase and to overcome in the design phase the complexity of the facilities design.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

If BIM Platform had been considered since the beginning of the rehabilitation process it probably would bring more efficiency and transparency to the process, not only in what refers to meet the sustainable requirements as to the preparation of the necessary documentation for certification.

The application of FTA method allows the evaluation of unwanted events as result of aspects related to the design process management approach adopted in this project, which needs to be revised for the realization of new projects. The most important lesson learned with FTA analyses is the necessity to overcome the sequential view of the design process with high environmental quality.

ACKNOWLEDGMENT

The author thanks National Council for Research and Development – CNPq – and Brazilian Petroleum Corporation - PETROBRAS – for the financial support of this research.

Sustainable Buildings with BIM

Peter KONCZ[a]

[a] *GRAPHISOFT Asia Ltd., Hong Kong SAR, pkoncz@graphisoft.com*

ABSTRACT

In today's world, cutting the design and construction cost of a building is not enough to make it a sustainable project. Clients and developers need to think of the operation phase, where a lot of resources are spent to maintain the internal comfort requirements dictated by regulations or the occupants. Cutting operation cost by optimization of energy consumption is one of the key ways to make a truly lean project and increase the return on investment for building owners.

There are two main approaches to cut energy consumption. One is using expensive, but high-end building systems to meet internal requirements, although this requires some time to return the extra dollars. Another way is to design buildings that uses low-carbon materials and demand less energy, therefore lower performance systems can be used, decreasing the overall environmental footprint of the project. A smart building design with good materials can even result in zero energy balance.

Building Information Modeling is a method, where instead of 2D drawings, 3D, information-rich models are used to design and execute projects. This allows more coordination, earlier decision making and less errors, resulting in a lower project cost in general. The very same BIM model can be used to analyze and compare design variations, giving feedback to both designer and developer about the expected building performance in the very early design phase.

GRAPHISOFT® ignited the BIM revolution in 1984 with ARCHICAD®, the industry first BIM software for architects. GRAPHISOFT continues to lead the industry with innovative solutions such as EcoDesigner STAR, the world's first fully BIM-integrated "GREEN" design solution.

Clients and architects can work together to build better buildings that are more sustainable, demand less energy or even none and use our world's resources in a more efficient way.

Keywords: BIM, analysis, sustainability

1. INTRODUCTION

In the following paper will explain the fundamentals of BIM, how BIM models are used for energy analysis and introduce 3 case studies, where such software was used to make better decisions, validate design concepts or design a more sustainable building.

1.1 About BIM

Building Information Modeling is a buzzword these days which is often misused or represents only a small subset of the whole concept, in many cases limited to 3D models of buildings. 3D modelling is not a new thing, we have been able to create visualization of buildings for decades. What differenciates BIM from 3D modelling is the information contained in the elements and it's special relationship with the technical drawings produced from the 3D model. This information, embedded in the elements of a virtual building model, can be utilised by many stakeholders of the project from start to completion to make more informed decisions, reduce risk and increase transparency, ultimately resulting in a project delivered with accurancy on time and within budget.

In a broader view, BIM not only represents the model itself, but the methodology of how it is used within a company. As opposed to 2D drawing based project delivery, BIM brings new methods for delivering projects. 2D drawings are an abstract representation of something that is in three dimensions, so it involves a double abstraction process. The architect needs to translate the 3D design idea into 2D and the users (client or contractor, manufacturers) need to translate this 2D abstraction back to real building elements. Eventually, the vision of BIM is to eliminate 2D drawings and the process of abstraction by allowing designers to directly, contractors to assemble the building

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

and operators to maintain the building by using the BIM models developed during this process. Since the whole process is built upon the virtual 3D representation of the future building, enriched with all the same information, which can be found in reality, it becomes extremely efficient, transparent and safe.

1.2 About ARCHICAD

ARCHICAD is the leading Building Information Modeling (BIM) software solution for the architecture and design industry. All creative work and design documentation happens in 3D, so you can make design decisions and see the results in a project's real, 3D environment. Designers work on a single building model to create, document, and construct their ideas -- changes are fast and automatic. Automatically updated, one-click documentation makes even the most tedious tasks fast and easy.

1.3 About EcoDesigner STAR

EcoDesigner STAR is built to serve highly energy-efficient building design by turning ARCHICAD Building Information Models (BIM) into multiple thermal zone Building Energy Models (BEM). Architects can now enjoy the benefits of high-end building energy performance simulation and reporting without leaving ARCHICAD. Low and net-zero energy building design is made easy for architects worldwide with EcoDesigner STAR's standard compliant energy simulation engine, advanced energy model visualization and documentation.

In addition to the integrated energy simulation functionality, EcoDesigner STAR's advanced BEM export interfaces (such as gbXML and PHPP) allow full collaboration workflow with building energy consultants and enable data export from ARCHICAD to local building energy code compliance calculation applications.

1.4 About whole building energy efficiency optimisation

Software tools only give us the technology to achieve good results, but they aren't enough alone. A good workflow is the key to make use of the tools at hand. Tools like ARCHICAD or EcoDesigner Star allow professionals more than just analyzing the buildings at once. In fact, they allow continuous feedback and supply real data at various stages of design.

The final requirement of such analysis is, of course, cost. Professionals want to know how much money will they have to spend on an annual scale on utilities. Patrick MacLeamy says that for every 1 dollar spent on design, 60 more dollars will be spent on the operation of the building. This includes management cost, but amongst all it it energy consumption.

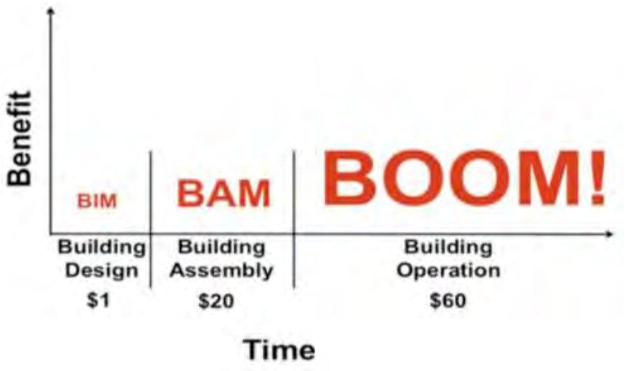

Figure 1: BIM, BAM, BOOM by Patrick MacLeamy, BuildingSmart International

If future building owners can estimate and compare energy consumption cost of different design options in a relatively early stage, they can significantly reduce their expenses later on. Architects can be the execution of this analysis, as even the architecture of the building can contribute to its energy demand.

According to the Environmental Bureau and EMSD, electricity generation is the largest source of local green house gas emissions, accounting for about 68% of the total in 2012 and the single largest category of electricity consumption in Hong Kong in both the commercial and the residential sector is in air conditioning.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

In the 2016 Policy Address, the Government committed a reduction target of 40% in energy intensity by 2025 in the Energy Saving Plan for Hong Kong's Built Environment 2015~2025+.

It is quite clear that not only for new buildings, but for the existing built environment of Hong Kong, air conditioning is one of the major factors that affect the environment and account for the majority of the building energy consumption related costs. It is clear that reducing air conditioning cost for existing buildings and minizine estimated costs for new buildings not only complies with these trends, but yields tangible economic benefits. In following few paragraphs I will elaborate how this can be estimated with software aided workflows.

1.4.1 Climate analysis

Energy evaluation software is not only purposed for the final examination. A careful analysis of the local climate is also possible. By constructing a virtual space with zero thickness walls and 100% transmission rate (called "paper box") for external structures, we create a room in which the same internal requirements occur as in the external spaces. The concept of this space is to serve as a boundary to define an interior space. The software allows us to examine the internal conditions and draw the conclusions for the best low energy design strategy for our building.

This information is present in climate files that can be downloaded from the internet. The software allows us to visualize and extract that data by analyzing the space inside the "paper box". In the evaluation report, we can get the Degree Days and Unmet Load Hours. The Heating and Cooling requirements for a given structure at a specific location are considered to be directly proportional to the number of "Degree Days" at that location.

Unmet Load Hours are the number of hours during a year when the internal temperature is out of the comfort range defined in the operation profile. Operation Profile is practically a schedule that records human activity in different types of spaces, providing data, such as Hot Water requirements, humidity generation and electricity requirements due to lighting and equipment usage. Unmet Load Hours can also be visualized in the Daily Temperature Profile diagrams for typical days of different seasons.

1.4.2 The low energy architectural solution set

There are different levels of energy analysis within the project. At first, we need to specify the internal comfort requirements, such as temperature, humidity level or hot water need. These internal requirements will be related to the heating, cooling and electricity needs of a project. Then we can already start the application of analysis, as the architectural design has effect on the final energy consumption of a building. A common practice is that buildings are designed solely to maximise commercial benefits and increase the rentable areas. This results in large, glassed surfaces, facing west and south that need a lot of air conditioning. This huge air conditioning need can only be balanced by large performance coolers, which in addition to the large cooling requirement also consume a lot of electricity. Using higher quality equipment is sure helping to reduce final consumption, but a smarter architectural design can reduce the cooling requirement on the first place. Using software solutions like BIM, architects and investors can now exactly estimate the affects of picking the right architectural solutions to optimize the design. It is called Project Specific Low Energy Solution Set. The solutions are chosen by a careful analysis of each architectural solution compared to a Baseline Design, which is the Sensitivity Analysis. After the analysis the final solution set can be selected. In a practical example, the quality of the window glasing and frames can affect the cooling need by reducing the heat gain from direct sun radiation. Comparing the calculation results of a Baseline Design using single glased panels and metal frames with an improved design, using triple glased panels and plastic frames, it is possible to see the reduction in the cooling need, which is in direct relationship with the future costs. It is easy to compare the cost savings with the required investment of such improved fenestration, so owners can make a well informed decision about these important design options. Architects can also justify their intentions with real data, which is benefit for both parties.

1.4.3 Energy consumption levels and optimisation

After we have optimized the architectural design by selecting the appropriate solutions that are justified by analitic results, we can select the suitable building systems.

Building Systems can be selected based on their output performance that is needed to balance the heating and cooling requirements in a building. This is called "Energy Demand" and it can be calculated by adding unspecified building systems that show us how much raw energy is needed to be balanced. The problem with building systems is that they also use energy, mostly electricity, during operation. So the building's energy consumption equals the energy demand, plus the consumption of the selected Building Systems. In this stage, energy consumption can further be reduced by selecting highly efficient Building System hardware.

After the energy consumption of the building is selected we also have to consider, how this energy is supplied. It makes a huge difference for example, if the electricity is produced from renewable energy like wind or water or by burning fossils, for example coal. In the latter case, the building's Carbon Footprint is indirectly increased by the result of coal burning that is needed to supply the electricity need.

Speaking of Carbon Footprint, it is also essential to understand the concept of Embodied Energy of building materials. Each type of building material represents a sum of energy that was used to produce it from nature. Clay for example is very low energy as it is natural, while aluminium represents a higher energy level, as it is quite expensive to produce. The way these materials were produced also affects indirectly the environmental impact of the building. This is the highest level of the analysis, which is called Fuel Consumption. It can also be understood as environmental impact.

2. CASE STUDY – ECODESIGNER INFORMATION KEY TO GAINING PLANNING CONSENT

2.1 Introduction

2030 Architects Ltd works throughout Cumbria and the North West to create high quality Low Carbon buildings and environments for existing and future generations. We use GRAPHISOFT® ArchiCAD® as our BIM design system as well as more traditional methods of drafting. Our approach is inclusive and contextual, whether working for an individual householder, community or corporate client to create buildings and places of quality in harmony with the natural environment.

2.2 About the practice

We work regularly with a range of local consultants and find the ease with which information can be communicated via the BIM model to have great commercial value. GRAPHISOFT EcoDesigner™, which is tightly integrated with ArchiCAD, is used in conjunction with SAP and SBEM calculations, and we also use the PassivHaus spreadsheet for fine tuning of designs. The speed with which EcoDesigner can provide feedback is the key to making strategic early design decisions. Experience gives us a feel for what can be achieved on a site, but having the confirmation of the EcoDesigner evaluation from concept stage onwards is extremely valuable.

The use of ArchiCAD in our practice means that we can communicate 3D visualisations of the scheme from day one. We can also confirm the general standards of energy efficiency that we are aspiring to by using EcoDesigner as an additional tool. This gives us, and clients, confidence in developing the detailed designs knowing that we will be able to achieve the desired results without having costly and time consuming planning amendments.

2.3 Creating sustainable new holiday lets, Cumbria

The evaluation information from EcoDesigner has been extremely useful in demonstrating the effects of different glazing options, particularly as we are developing an existing planning approval which had a far more conventional appearance. The current scheme is a radical departure from the existing consent and the use of 3D modeling and justification of the environmental concepts have greatly assisted discussions with the planning authority resulting in a new approval for the current design. Environmentally we have achieved a double A SAP rating for both energy and environment categories whilst using electric heating combined with a large Photovoltaic array and a superinsulated concrete block construction. All of the major design decisions, whether to go timber frame with low thermal mass or conventional build with heavier mass have been checked using EcoDesigner because it is so easy and quick! Because we can run these checks as part of the modeling we use them a lot, as opposed to the other alternatives, which we only use at the critical stages having once established the broad performance criteria.

The overall form of the design is intended as an interpretation of the local barn vernacular; it has a simple rectangular footprint with a pitched roof. The scheme takes advantage of the spectacular views across open fields to the South and East with large areas of glazing, which also serves to provide passive solar gain. The precise

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

areas of glazing were modeled at an early stage using EcoDesigner to ensure that we did not suffer from too much heat gain or heat loss. The ability to analyse the whole design very quickly and set target U values for the structure is something that we use all the time in early conceptual models.

As the site is rural with no mains gas we have explored the potential for an all electric building and found that with careful design we can achieve the desired SAP ratings. Subject to confirmation these dwellings will also achieve a CSH rating of 4, and all… or at least mostly due.to careful use of GRAPHISOFT EcoDesigner.

3. CASE STUDY - THE RURAL REGENERATION CENTRE IN KENT DESIGNED USING **ARCHICAD IS THE UK'S FIRST CERTIFIED PASSIVHAUS EDUCATIONAL BUILDING [3]**

3.1 Introduction

The drive for sustainable architecture is pushing architects to develop designs that not only deliver on appearance but also take account of energy consumption, carbon emissions and operational costs. This requires the modelling of intricate detail, with sustainable design choices made in one area of a building significantly impacting other aspects of the design. This is further compounded when taking the design to the standards outlined by Passivhaus.

3.2 About the project

Designing to this level of detail requires software that can not only support the development of the model using BIM but also integral sustainability tools that can tell, even from early stage design, the energy output of the building.

Therefore when it came to designing The Rural Regeneration Centre at Hadlow College in Kent to Passivhaus standards, James Anwyl, Director of EUROBUILD used ArchiCAD® together with its integrated thermal performance module – EcoDesigner - to evaluate the energy consumption of the design and MEP Modeller to co-ordinate the services within the building.

The result is that the Rural Regeneration Centre at Hadlow College is a showcase of low carbon and renewable technology. One of the top three agricultural colleges in the UK, Hadlow College's new Centre will use just 10% of the typical energy consumption of a modern building and is the first such building in the UK to be constructed using prefabricated materials.

The Rural Regeneration Centre is a sympathetic conversion and extension to redundant cow sheds (over 95% of the original shed structure was retained on site) on the College's fully operational dairy farm. Built using prefabricated structural insulated panels, the centre was planned using Building Information Modelling (BIM) by ArchiCAD and assembled in just three days. In under 10 days overall, the structure was airtight to a very high standard of 0.34h-1.

A number of sustainable technologies have been implemented throughout the centre including a super efficient mechanical ventilation system, triple glazed windows, and a ground source heat pump for heating and cooling. The sanitary rooms all have waterless urinals, low flush toilets, timed water-saver taps and moderated flow showers. Low energy T5 lighting is used through-out the carefully planned building.

The Rural Regeneration Centre is also a great example of marrying a strong architectural design with sustainability and the Passivhaus requirements. For example, the building has a full-height, north-facing window to provide plenty of light to the main seminar room. However this feature provides problems when running it through the Passivhaus planning package and has required thoughtful design in other areas of the building to make up for it. This has included designing in a lot of solar gain to the south and south west elevations and from the skylights, as well as upping the insulation in the walls from the usual 300mm to 400mm. These carefully considered design improvements were modelled in ArchiCAD to assess their visual impact and thermal performance.

Another challenging design issue was ventilation, which needed to meet the requirements of fresh air rates for teaching spaces (Building Bulletin 101) but yet balance this against the energy consumption of the fans. To achieve this, the most efficient mechanical ventilation system that is certified for Passivhaus use has been implemented – a Drexel and Weiss Aero Centro unit. The unit provides background ventilation daily and also allows the ventilation

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

rates to be boosted in the teaching spaces to just above 8 l/ s/ person when they are at full capacity to meet the necessary requirements.

Anwyl sums up the success of this project quite simply,"Designing and building Hadlow College to certified Passivhaus standard, at less than £1,500/ m2, was only possible using the right BIM software and the right prefabricated system."

To date the Rural Regeneration Centre has been awarded Passivhaus certification, the first educational establishment to achieve this accolade and has won the Environmental Project of the Year at the Construction Computing Awards. Anwyl is continuing his passion to marry aesthetically pleasing designs whilst delivering low energy buildings with a number of Passivhaus projects in the pipeline. Through his firm's deep knowledge of the fine detail required to design the most sustainable buildings, and the ability to model and test designs with ArchiCAD, EcoDesigner and MEP Modeller, EUROBUILD is delivering beautiful, energy efficient buildings at speed and scale.

And the enthusiasm Anwyl exudes for Hadlow is also shared by the Client. Mark Lumsdon-Taylor, Hadlow College Finance Director, comments "EUROBUILD delivered a fantastic, innovative sustainable design that has won numerous awards – exactly what we asked for and more - and investing in the early stage design development really paid dividends during the construction phase."

4. CASE STUDY - MAKING OLD BECOME NEW AND EFFICIENT

4.1 Introduction

Constructive Thinking Studio, based in Liverpool, is a design-led practice which has quality of design at the heart of its role. Very experienced in sustainable design the Practice is fully accredited Code for Sustainable Homes, On Construction Domestic Energy Assessor (ONDEA), and advises on early-stage energy strategies.

4.2 About the project

This project is the reinstatement of a pair of three storey Victorian terraces under Registered Social Landlord (RSL) control. The properties had been converted into six 1-bedroom apartments in the 1970s. Our goal was to bring the terraces back to individual houses and, in doing so, adhere to good conservation principles whilst enhancing their environmental performance.

The development forms part of the Technology Strategy Board's Retrofit for the Future competition. Our entry proposed a series of low-carbon measures designed to enhance thermal performance, increase air-tightness and supplement the heating and electrical load with the introduction of energy-saving technologies.

Our aim was to suggest a palette of measures that could be selected from on an ad-hoc basis to apply to all similar conservation area dwellings. At inception (stage 1) we had not identified a property so we modeled (in GRAPHISOFT® ArchiCAD®) a typical 3-storey Liverpool terrace with an east-west orientation. We assumed the property to be of solid wall brick construction, single-glazed sash windows, an un-insulated slate roof and timber suspended floors with basements under the main plan of the house. We then used GRAPHISOFT EcoDesigner™ to analyse the structure and estimate energy use. Working in ArchiCAD and EcoDesigner it was possible to model a series of scenarios to test the efficacy of changing windows, enhancing thermal performance to the roof, incorporating internal and external wall insulation and improving the air infiltration rate.

We modeled the existing properties and tested the energy usage using EcoDesigner. We were able to estimate the effects of MVHR (mechanical ventilation and heat recovery) and Solar HW (hot water). Our energy calculations were then adjusted to take into account the PV (photovoltaic) slates. Having this as a 'live' working model allowed us to trial varying solutions and to tweak the design on the fly. Of particular use at early stage design was the ability to override the U-values (thermal efficiency) of elements (within certain parameters) as we have a stock selection of wall solutions already calculated. We have returned to use EcoDesigner at later stages in order to compare the control and augmented project. In early stages, the actual returned values from EcoDesigner were in the same proportion as those from our SAP calculator (in excess of a 60% reduction in energy use.) This gave us the confidence that we needed to use the software as a design tool.

As architects we use the Building Information Model (BIM) for all of ourprojects. ArchiCAD allows us to produce fully coordinated drawings, details, schedules and quantities, as well as share information with other members of the design team. Moreover, our workflow is improved by the automatic (controllable) update of drawings when making changes to the model.

We made use of many other ArchiCAD features in this project. As we have a large client body we produced interactive presentation files from GRAPHISOFT BIM Explorer™ (BIMx) to illustrate the construction work-flow and, on site, to explain working details to the Building Inspector via iPad. We used 3D document to show 3D details to the contractor during the tender process. In the studio we were able to use BIM for clash detection and for designing plumbing runs with the heating engineer. We have also used interactive scheduling to assist the contractor and for cost control.

It is very evident to this Practice that using ArchiCAD BIM to create a virtual building model not only has great benefit to us in expressing our ideas to clients but it is also hugely helpful in conveying design intent and detail to the other parties involved in design and construction. Our strong focus on sustainability, as illustrated by the certifications we hold, means we are able to assess quickly the value of building performance software. EcoDesigner has proved to be an extremely valuable tool in helping us refine and test our ideas throughout design, from early concepts to documentation.

5. CONCLUSION

BIM is becoming the new industry standard and traditional trades of design and construction will have to transfer to the use of model based information databases more and more.

Beyond the fundamental benefits of BIM, energy analysis can deliver additional earnings for all parties within the projects. Designers can validate their design decisions towards clients and authorities. Builders can vertify their choice of materials and equipment to ensure lower energy consumption. Building owners can significantly cut final utilities cost by estimating the future energy consumption of the buildings and urgning designers and builders to use more environmentally friendly materials and solutions when planning and realizing the project.

BIM based energy analysis is faster and more accurate than traditional manual calculation as it is using the same virtual building models as other stakeholders. As models with the required level of detail are already available in the early design stage, it becomes possible to start thinking about the future early and perform multiple iterations of energy analysis even before the detailed design is complete. In traditional methods, energy analysis is an isolated trade, which gathers input for its calculation manually from 2D drawings. BIM based analysis is built on top of the virtual building model, so there is much less loss of information.

Session 4.11: BIM for Sustainability (2)

Assessment of Different Data Collection Methods for the Creation of BIM Models for Existing Buildings

Bjoern Arild GODAGER[a], Guri KRIGSVOLD[b]

[a] Norwegian University of Science and Technology, Norway, bjoern.godager@ntnu.no
[b] Norwegian University of Science and Technology, Norway, guri.krigsvold@ntnu.no

ABSTRACT

This article focuses on the important considerations related to some actual data collection methods in conjunction with the development of Building Information Modelling (BIM) in existing buildings. The interest associated with creating such models is increasing steadily, in line with better equipment and methods, lower costs and more maturity in the market. Building owners around the world see this as an increasingly sustainable commitment. However, there are some pitfalls, and the paper has devoted some attention related to knowledge about requirements of ordering such a BIM. The most focused data collection methods in the article are terrestrial laser scanning, drone and mobile BIM measurement systems. The last two methods are quite new, and they are exciting additions, which tend to work together with other methods such as scanning. In addition, these methods are significantly cheaper than conventional scanning. The article shows examples of case studies of these methods and connects the results to selected "state of the art' articles, guidelines and tutorials.

Keywords: sustainable creation of BIM in existing buildings, data capture methods, deep building renovation

1. INTRODUCTION

Today we are moving towards a world where 3D is the expected format, whether it is in games, the cinema or world of construction and surveying. The scope of all the BIM technology will be a catalyst for many new and more effective ways of working in all stages of the life cycles of the construction project.

Volk et al. (2014, p.109) wrote: “Results show scarce BIM implementation in existing buildings yet, due to challenges of (1) High modelling/ conversion effort from captured building data into semantic BIM objects, (2) Updating of information in BIM and (3) Handling of uncertain data, objects and relations in BIM occurring in existing buildings.”

The challenges are not solved yet, however the technology is in good progress, and more and more owners or shareholders want to create and use BIM in their existing buildings, because they realize it is sustainable of many reasons (Eastman et al. 2011, p.151-155).

To model existing buildings with BIM, it is important to have clear goals and thoughts about how to take advantage of this. The model specification defines how the modelling requirements should be performed, geometric accuracy and what level of detail it should have. Many major building owners want BIM models in their existing buildings, but they often have a lack of BIM knowledge within their own organization. (Eastman et al, 2011) focuses on how the owner can increase their knowledge and thus get a better claim document and thereupon a better and customized intelligent "BIM". However, many existing Facility Management (FM) software are still far from being good at implementing BIM. The main focus within BIM has for many years been on the earlier building phases in front, while knowledge, standards and guidelines related to FM have not been as much a priority. However, there are some American and British guidelines. Anyhow, it is perceived an increasingly focus on the modelling of existing buildings in recent years. GSA (GSA BIM Guide for 3D Imaging) have guides, and there are others like PAS 1192-2 and PAS 1192-3 (BSI: 2013, 2014).

In rebuilding or in further development of existing buildings, architects often rely on construction or as-built drawings of existing structures as a basis for design. However, there are often discrepancies between the as-built drawings and "as-is". These differences often lead to structural problems, and this can lead to costly and delaying modifications or design changes (Reginato, 2014).

There is a lot of available information about several data collection methods used to perform modelling in existing building. This paper will consider some very relevant data collection methods and 3D imaging technologies (Chapter 2) for this modelling.

The paper has a special focus on the combination of data acquisition with terrestrial laser scanning (TLS), inexpensive drones and Mobile BIM Measurement Systems. Data collection from simple measurement, as well as from existing analogue or digital drawings are less treated here, but they are important nevertheless. The work is based on various case studies with TLS and one study in 2016 with a drone at Campus NTNU in Gjoevik, combined with literature search. The aim has been how to create a "SLIM BIM" in a rational and satisfactory manner with respect to geometric accuracy and with relevant building information. To create a SLIM-BIM is the first step to make a complete 3D model of a building. The discussion related to use of drones is based on a bachelor thesis (Obrestad and Soerensen, 2016).

The model will give many benefits, for instance improved management of buildings, ability to connect a Facility Management system (FM), basis for planning tools for repackaging/ change in existing buildings and basis for later, new adjacent developments.

The studies had both existing, 2D digital drawings, TLS and measurements with drone. The aim was to find out how a simple drone can help improve the geometric model, so in fact we had to combine TLS and drone data. The models are georeferenced, although it was not necessary in this project. The objective of this article is to consider the combination of data from drone and laser to BIM purposes.

2. DATA COLLECTION METHODS

Data collection normally constitutes the greatest part of the total cost by the creation of a Building Information Model in existing buildings, so there are good reasons to approach such a work with good plans. The work can be determined in several ways, but the choice of method will depend on what is available and possible, subscription or model material, accuracy requirements, expertise, available software, equipment and existing guidelines. Anyhow, independent of data collection methods it is important to perform accurate georeferencing at the very beginning.

A BIM survey challenges the surveyor to collect much more information about the building due to the parametric tools of the software and a basic understanding of how the model is physically built.

The resultant survey model will be a combination of detail and information, and it will be a mix of graphical and non-graphical content. This will be considered as the overall Level of Development (Plowman Craven 2015).

It will normally be a good solution to use a combination of several data capture methods. If a building has existing drawings, it will be of great benefit and be a natural starting point in the process. Anyhow, drawings are only drawings and do not necessarily coincide with what it is actually built. Existing buildings often have a lack of good as-built documentation, and it typically leads to a certain need for surveying. This chapter will focus more specific on 1) TLS, 2) Drone and 3) Mobile 3D-Measurement-System.

2.1 Terrestrial Laser Scanning (TLS)

The speed and quality of the scanners increase, while equipment and labor cost decreases, and this allows the value-proportion for using 3D scanning technology clearer than ever (Randall, 2013, p.3).

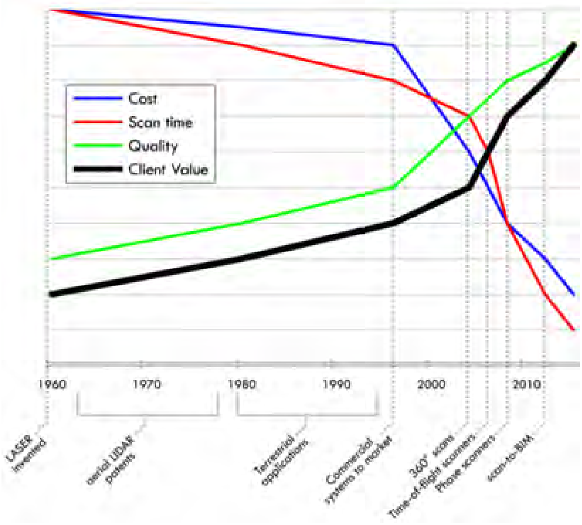

Figure 1: Timeline of 3D scanning development (Randall 2013, p.3)

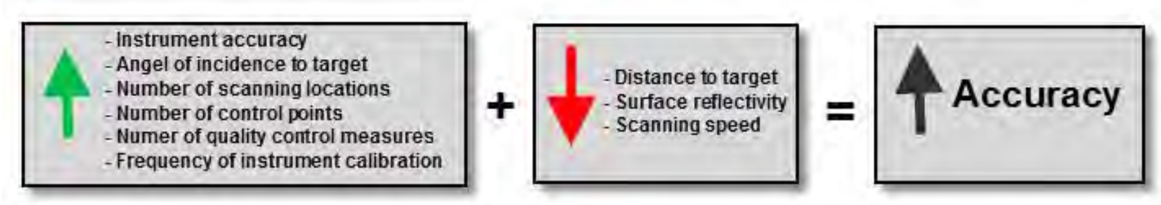

Figure 2: General rules of thumb for achieving higher accuracy, designed with inspiration from Randall (2013, p.5)

BSI (2013, 2014) has specifications for information management for the capital/delivery phase of construction projects using building information modelling. It offers guidance on the use and maintenance of the asset information model (AIM) to support the planned preventative maintenance program and the portfolio management activity for the life of the asset.

The Reference Guide from Plowman Craven (2015) is one of many good guidelines. These guides could be some very important key points on the journey to make a "SLIM BIM", which is the first step to build up a more complete 3D BIM.

Anil (2011, p.4) wrote “We identified five main concepts that are unique to "as-is" BIMs and are not represented with existing BIMs. These characteristics are point density, noise, occlusions, model deviations, and the links between the points and building components.” This means there is a need for further research and development in this field.

The last part of this chapter is a summary of methods used in the case studies:

- "Targets" or benchmarks points were optimally located and measured prior to scanning by a combination of traverses and a fixed network
- A total station was used to measure the targets in front of the scanning area.
- The targets were calculated in a selected datum/ coordinate system
- The point resolution was selected before the scan started.

Becerik-Gerber (2011, p. 649 - 658) has argued more specific related to assessment of target types and layouts in 3D laser scanning for registration of accuracy.

After completing the scanning, unwanted point clouds were deleted, the stored images were draped into the 3D model, and measures from each position were linked to the model, first by storey, afterwards collected. It generated a TrueView, allowing the user to move freely around the model. The finished X, Y and Z data was imported into 3D software (Leica Cyclone), displayed as a point cloud and modelled. The model was exported from Leica

Cyclone and linked to two programs with more BIM functionality (Autodesk Revit Structure and ArchiCad). The dimensions of the Revit model were compared with existing buildings, as well as the previous ArchiCad model of the building. The composite model was exported as TrueView and PTS file was used for modelling of a BIM model. The modelling was carried out in Revit Structure.

Existing analogue and digital drawings were then included into the scanned model, and adjusted as necessary. Each single room has not been scanned.

2.2 Data capture with drone

How can UAV Data Fit into the Scan to BIM Workflow? UAVs are an alternative solution that readily addresses the need to capture inaccessible areas such as roofs. In the study the external TLS data for the building was merged with the point clouds taken from the drone, to produce a complete point cloud of the exterior building. The drone is not suited for indoor mapping, because of its size and speed, so it will still only be an outdoor supplement. It is experienced, even with a simple and cheap drone, how point clouds from an UAV survey also provided images of a building from every angle we wanted, and this provided a much better information than could be achieved from only ground based scanning techniques (Figure 3).

The TLS data is taken an earlier year, so the accuracy considerations is based on comparison of distances measured with a laser and distances in the point cloud (Figure 4).

How can UAV Data Fit into the Scan to BIM Workflow? It is a lot of available photogrammetry software here, but in this study Pix4D was used. Research shows that it currently is very little standardisation of requirements and processes. This varies from project to project, but the various companies seem to make their own rules, as long as this is not standardized. However, there are some guidelines which are mentioned in this chapter.

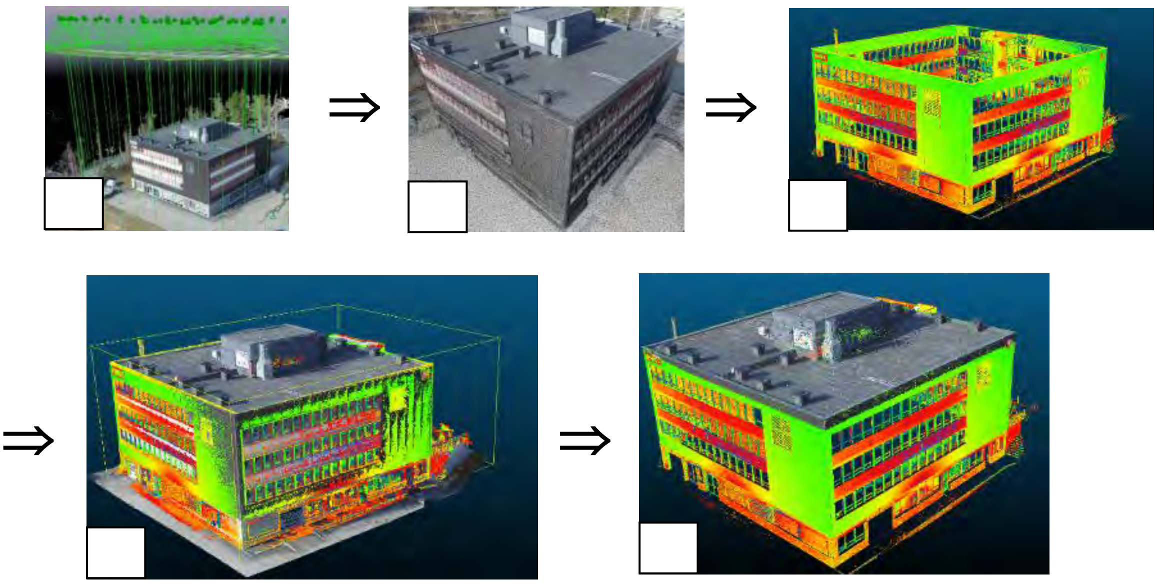

Figure 3: Different steps in combining Drone data and TLS data. 1) Photo/ data capture positions from Drone 2) Triangulated model from Drone, 3) TLS Data 4) Combination of TLS data and drone data 5) Drone data on the roof, TLS in areas with colours

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Photogrammetric point clouds are missing normals at the points. Therefore, we do not know which way is pointing outwards. This can partly be calculated in the software afterwards, but intensity, number of return pulses, placement of scanner etc. will never be able to get in a point cloud of drone data. Since this is information that makes it easier to sort a point cloud and automatically identify objects, a point cloud generated by photogrammetry will never be worth as much as a laser scanned point cloud in a "Scan to BIM" process.

The main question here is: Will the data from the photogrammetric point cloud be accurate enough to BIM? Due to an equipment request which was cancelled, there were challenges of merging test data from drone and data from the laser conducted with an older laser scanned point cloud. Table 1 gives the specific results from selected comparisons between the two data sets. The differences are showing +/ - 5 - 10 cm with the selected resolution. Drones with higher resolution cameras can provide higher accuracy. The resolution in the camera part is important for the accuracy.

	Measured area	Measured with laser	Measured in point cloud (m)	Difference (m)
1	Short side	3.765	3.712	0.053 m
2	Distance between corner and door frame	22.170	22.171	0,001 m
3	Distance between corner and door, long side	18.179	18.188	0.091 m
4	Length partition ceiling	9.524	9.509	0.015 m
5	Distance between two ventilation towers on roofs	25.941	25.810	0.131 m
6	Length long side of the building roof	10.396	10.381	0.015 m
7	Length short side of the building roof	6.841	6.891	0.050 m

Table 1: Shows distances measured with laser and in Recap

In addition to the drone resolution factors like lighting conditions, altitude, overlapping, supplemental control points (pass points) will influence the accuracy.

2.3 Measuring systems with integrated, manual data capture and modelling software inside

The market now offers measurement systems with integrated, manual data capture and modelling software. It becomes like a surveying equipment that connects directly to the PC and can be used for quality assurance of existing drawings or to create all models from scratch to get the proper basis for further planning. The solution appears to be suitable measuring key points for walls, floors and ceilings. Manually selected points outside or inside a building can be measured, drawn and modelled completely in one operation. The use of conventional TLS can be perceived as a bit "overkill" in some situations, and suppliers of less costly equipment of this type is expected to increase, and get a niche.

The geometric accuracy of this method will depend on the measurement plan and the quality of the measurement equipment. How this is carried out with regard to adhering many measuring positions and spaces could follow the same basic manner as the TLS.

This kind of equipment is not used in these case studies, but the author knows one type (Flexijet) used in some hospital projects in Norway. This method is included in this article to show a short summary of its possible use.

3. CONCLUSION AND FUTURE WORK

The study has looked at some selected measurement methods to create a BIM in existing buildings and shows that in many cases it will make sense to combine two or more of the described methods. When establishing 3D models of existing buildings, geometric accuracy requirement may not always be the most important. However, it is perhaps more important that the building is complete. These are factors that building owners must decide for themselves. There is no doubt that TLS is more accurate than a model generated from photogrammetry, especially when using inexpensive equipment.

A TLS normally would be used, when high accuracy is wanted, drawings are inadequate, and the model have to be georeferenced in a nationally adopted reference system.

TLS will anyhow often leave some bad mapped or missing areas. Our study wanted to test how a simple drone can help improve the geometric model. The study has shown it is possible to combine those two methods. The study also wanted to consider the geometry accuracy a drone could provide (Figure 4), but it seems to be a need for more studies to say something clear about the geometric accuracy. The research anyhow shows that even with an inexpensive drone, an accuracy of a few cm is possible.

With improvements in positioning accuracies, developments with software and a continual improvement in understanding from drone operators, point accuracies have now been demonstrated and validated down to just a few millimetres. Of this reasons we will see much more research and documentation in this area in near future.

The study has showed that UAV survey will provide clients accurate point cloud data, which can be processed and imported into actual BIM software to create an intelligent 3D model in existing buildings.

TLS or measuring systems with integrated manual data capture and modelling software inside could both be used inside the buildings.

The embracing of information rich BIM technologies will be a catalyst for new and more efficient ways of working at all stages of the sustainable building project lifecycle, and the operations and maintenance part (O&M) looks very interesting in the future. In this development, it also seems very necessary that building owners increase their expertise, and contribute to better coordination of requirements that should apply when establishing BIM models in existing buildings.

ABSTRACT

Building performance only can be developed in the long-term perspective with holistically constructed instruments in place. In Switzerland the use of the adapted DGNB certification system enables major projects such as hospitals, research laboratories or shopping centers being optimized in a holistic and sustainable way despite a high level of complexity. The use of BIM will play a key role: In 2016 five of the largest national portfolio holders have jointly decided to use BIM from now on.

The DGNB rating system assesses a building on level «pre-certification» (valid until completion) and «certification» (unlimited from start of operation/use) with more than 40 criteria and 120 sub-indicators. A big success factor for an optimized sustainable design is the usability of the evaluation system in early planning stages because changes are significantly cheaper than in later stages. The project can be rated «As-plannend» at this time based on a «digital model». To increase the validity of the evaluation, the virtual building modeling must be precise and enriched with information (e.g. materialization of the building), which are usually not available at this stage of planning. This challenges planners and architects.

The presented research will show, which criteria and sub-indicators of the DGNB system can be tested BIM-based. By analysing current certified DGNB projects (on level «pre-certification») in Switzerland it will be shown which types of BIM tools are already being used and how their distribution in projects is right now. The final chapter will outline the potential of BIM, if used in a consistent way in the sustainability certification process, and the necessary steps of development to achieve the goal of a 100%-BIM-based certification by 2020.

Keywords: BIM, sustainable building rating systems, life cycle management

1. INTRODUCTION

In practice, but also in science Green Building rating system and Buiding Information Management (BIM) as a method are still largely perceived as separate tools. However, a more integrated viewing should open up in future new possibilities and value creation models, both instruments will mutual benefit from.

1.1 Green building rating systems in Switzerland

The international map shows a variety of rating systems used for assessing the sustainability of buildings. In Europe are primarily three systems in place: the British BREEAM system (UK BRE Environmental Asset Method) for existing buildings, the American LEED system (Leadership in Energy and Environmental Design), known for office buildings and tenant improvements and the German DGNB - Certificate of German Sustainable Building Council. In in addition to these «big three» systems there are several country-specific systems available, such as the French HQE-system or the TQB-system in Austria, which are negligible in terms of their distribution in Switzerland.

In Switzerland today we are facing a microcosm of Swiss instruments, in a co-existance with international developments over the past 10 years. Actors have been universities (ESI – Economic Sustainability Indicator by University of Zurich), cities (energy cities label, swiss cities organisation), financial institutes (Green Property Label by Credit Suisse), federal offices and NGOs (e.g. SNBS - Swiss Sustainable Building Standard; Federal Office of Energy) as well as large construction companies (e.g. GENAB – Building Sustainable Construction by Implenia). Since 2009 the Swiss Sustainable Building Council (SGNI) fully adapted the german DGNB rating system and led it successfully into the market. As a result Switzerland has already a wide experience at rating sustainable buildings.

1.2 Swiss BIM definition

BIM may have several meanings, depending on a stakeholders view. The Swiss understanding of BIM reflects best in newly developed SIA leaflet PRSNR 59205 (2016, in consultation) 2016 on the application of BIM method: "Building Information Modelling (BIM) is a method which utilizes digital building models. Models are databases of information about the building and its immediate landscape. The method supports the cooperation and data exchange between all stakeholders during the lifecycle of a building." Thus it is not the aim to map a building digitally as detailed as possible. In fact, building data should be processed, used and made available to all project partners in accordance with the discrete project goals/steps. This understanding is also in line with international definitions such as «The National BIM Standard-United States (NBIMS-US)». In connection with sustainability certification the following working definition shows the understanding of BIM for the research presented here:

SUSTAIN BIM is a method to use digital building data models within the process of sustainability ratings of buildings and areas. This method supports the cooperation and the exchange of data during the complete certification process.

2. METHODOLOGY

As a basis for the research is used the DGNB-system version Office and Administrative Buildings “NBV2015”. The system architecture is as follows:

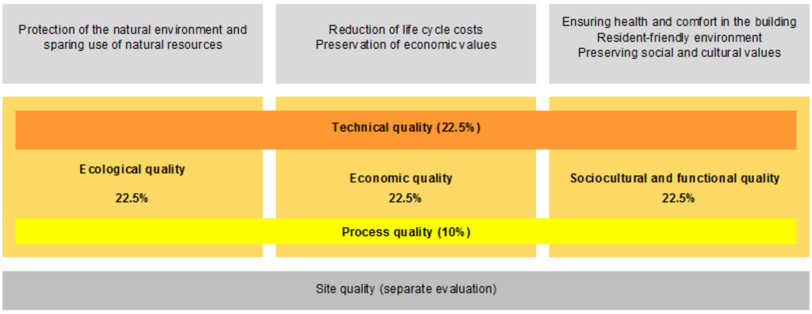

Figure 1: DGNB system architecture (BIM scope in colour)

This study only takes the building-related quality criteria into conclusion, which have direct impact on the rating results. Criteria regarding the location of a building are indirectly included in the evaluation (DGNB-System, version 2012/15, criteria “ECO 2.2 marketability” (see Table 1), but with a small proportion of 3.2 percent of the total weighting. The clustered process criteria rate the quality of planning and construction of a new building. For existing buildings processes related to operation are rated and therefore not based on the "the building as a product" and were therefore not considered in the follwing analysis. Using BIM-based instruments for building operation in the future, it would be benefitial to incorporate these processes into the framework for future studies.

Besides the investigation of the Swiss DGNB rating system itself, a literature review and six expert interviews (with people involved in projects which are already certified or on their way) have been carried out for this study.

3. APPROPRIATE CRITERIA FOR BIM-BASED CERTIFICATION

The Swiss DGNB-System is a performance orientated rating system, which takes all aspects of sustainability into consideration, whenever posssible via simulated or predictable aspects. Also the German Sustainable Building Council (DGNB) aims for restructuring their ratings system in balance with the BIM-methodology and their tools in the near future.

Basically, three types support levels can be distinguished from in the Swiss DGNB-system`s criteria (see Table 1):

- Criteria rating punctually supported (e.g. via BIM predictable characteristics, ratios)
- Basic data support and partially supported (e.g. consistent quantity structure derived from the 3D model)
- Fully or mostly automated (e.g. use of BIM tools such as REVIT or LESOSAI (CH) for automated calculations, verification and reporting)

Table 1: Weighted shares of the three criteria types

The overview shows that 86.8 percent of the global criteria are supportable with BIM. Exception is only «indoor air quality», because it is based on real measurements.

Today there are three types of tools used in practice:

- Virtual Building Model Software
- Model Checker Software (rule-based conformance testing)
- Simulation Software

It could be shown that 76.5 percent (of the total weight) of criteria can be supported by using data coming from the virtual building model, 59.7 percent via automated checks with rule-based instruments and 48.8 percent can be supported by using simulation software. (Basis NBV15-GER)

Based on experience from recently done and running Swiss DGNB certification projects, we identified about 20 BIM-related instruments being used for different purposes by architects and engineers working with the Swiss

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

DGNB rating system. The LESOSAI software enjoys a special status, because it is used today for a full assessment of three criterias and potentially can be used for rating three more. In terms of a systematic review of sustainability aspects the use of model checker software is not apparent from the documents to be delivered for certification. Overall, the real use of BIM software currently covers approximately 67.5 percent of the criteria (total weighting). Almost all of the evaluated BIM software products use shared data about the characteristics of building materials and products. Compared to other international and national certification schemes the Swiss DGNB system attaches great importance to the characteristics of building materials and products. Their characteristics are very comprehensively accounted and influence the results of a Swiss DGNB rating, direct and indirect, somewhere between 50 - 75 percent, without considering process criteria. (Basis NBV12-CH)

In the more recent DGNB version 2015, the proportion even increased further, as shown in the following table. The impact on the costs of a certification is correspondingly high (see Table 2).

DGNB Office Version 2015							
topic	citeria group	no.	%	criterion	impact	min	max

Table 2: Building and construction materials relavant to DGNB criteria (NBV15-GER)

4. HOW TO IMPLEMENT BIM INTO THE CERTIFICATION PROCESS?

The Swiss DGNB certification process is currently divided in the following sub-phases (see Table 3): 1) pre-assessment, 2) pre-certificate ("as-planned") and 3) certificate ("as-built"). The sub-steps are carried out in coordination with the general outline phase based on the SIA Standard 112 of the Swiss engineer and architect association.

no.	SIA phases	no.	SIA sub-phases	Phase SGNI		Description of services in the accompanying project audit
1	Strategic planning	1	Definition of needs, solution strategies		Pre-assessment	Kick-off workshop with client
2	Preliminary studies	2.1	Project definition, feasibility study			Quick check
		2.2	Selection procedures			Participation in planning competition / study contract
						Pre-check
						Definition of sustainability goals
3	Project	3.1	Preliminary project	Calculation	Pre-certificate	Beginning of pre-certification process
						Monitoring of planning process with a focus on certification
		3.2	Construction project			Project optimization (including virtualization and simulations)
						Preparation of pre-certification documents
		3.3	Permit-obtaining procedure / submitted project			Submission of pre-certification documents / awarding of pre-certificate (in SIA phase 3.3.2)
4	Invitation to bid	4.1	Invitation to bid, comparison of quotations, application for contract awarding	Verification	Building-certificate	Beginning of certification process for new buildings
						Assistance with tendering and awarding
5	Implementation	5.1	Construction project			Verification
		5.2	Implementation			Control of construction process
		5.3	Commissioning, completion			Preparation of certification documents (certificate for new buildings)
						Submission of certification documents > Awarding of certificate
6	Management	6.1	Operation			
		6.2	Maintenance			

Table 3: Allocation of certification levels to the general planning and construction phases according to SIA

The Swiss DGNB pre-certificate "as-planned" is being used in practice on the one hand side as a marketing tool for e.g. tenant search and on the other hand by the builders as quality assurance tool for creating a high planning predictability. The main problem in practice today is that the specific materialization is usually fixed in later planning stages. Many important core criteria (LCA, LCC, etc.) for pre-certification cause therefore huge uncertainties concerning the achievement of assigned quality targets (silver, gold, platinum). To solve this problem, two approaches are currently being pursued in Switzerland:

- Simplified calculations as of the average characteristics of whole products classes contained in e.g. EPD's (environmental product declarations) or use of general product class data bases (e.g. KBOB list for LCA)
- Early BIM-based materialization in coordination between client and architect

Based on the analysis of current Swiss DGNB projects, the first approach is currently the most preferred. Aiming for a full BIM-based certification this must be considered, however, as an interim solution. The second approach is currently applied only partially in Switzerland since it also implies changes in the existing status quo of Swiss planning culture. For a future fully BIM-based certification process therefore the following model is proposed:

no.	SIA phases	no.	SIA sub-phases		Phase SGNI	Description of services in the accompanying project audit
1	Strategic planning	1	Definition of needs, solution strategies	Pre BIM	Pre-assessment	Kick-off workshop with client
2	Preliminary studies	2.1	Project definition, feasibility study			Quick check
		2.2	Selection procedures			Participation in planning competition / study contract
						Pre-check
						Definition of sustainability goals
3	Project	3.1	Preliminary project	BIM model	Planning certificate	Beginning of pre-certification process for planned project (= building as planned)
						Monitoring of planning process with a focus on certification
		3.2	Construction project			Project optimization (including virtualization and simulations) Verification (including model checking)
		3.3	Permit-obtaining procedure / submitted project			
4	Invitation to bid	4.1	Invitation to bid, comparison of quotations, application for contract awarding			Preparation of pre-certification documents (planning certificate)
5	Implementation	5.1	Detailed construction project			Submission of pre-certification documents / awarding of plannung-certificate (in SIA phase
		5.2	Implementation	BIM method	Building certificate	Beginning of certification process for new buildings (= building as planned)
						Assistance with tendering and awarding
						Control of construction process
		5.3	Commissioning, completion			Preparation of certification documents (building certificate / "as build")
						Submission of certification documents > Awarding of certificate

Figure 2: Fully BIM-based certification process

It will be appreciated that the timing of the pre-certificate has been rearwardly moved to phase 5.1 «preliminary project». In the future, a "key-ready" project hand over as-planned will be possible. It will help to prevent cancellation of the certification by the client due to uncertainty of achieving the aimed for quality level.

5. FULLY BIM-BASED CERTIFICATION

Based on the previous findings three development stages are proposed on the road to a fully BIM-based certification:

Level 1 includes all product-based core criteria of material and energy LCA, life cycle cost, recyclability and risk evaluation. Together they display about 30 percent of the evaluation and impact the achievable quality level of a building significantly. A one-stop solution, as the BIM-based Lesosai software (CH) represents, proofs to be enormously helpful, because each product used has different advantages and disadvantages with respect to the adressed core criteria. An integral solution is also desirable because in larger projects hundreds of building materials and products are used in different quantities. Tracking the impact of changes in metarial or product selection on overall evaluation can be determined as very cumbersome. The time factor is, at the stage where it comes to the choice of materials, very significant.

The European green building councils are currently striving to formulate six core criteria which are to be valid for all three major certification systems, BREEAM, LEED and DGNB, which should also be anchored in European policy and standardization. If this project is to be successful, it can be expected that the objectives of level 1 will be achieved in common for all international systems.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Level 2 includes all criteria, which are used for evaluating the building as a product, (process criteria related to planning and construction excluded). A coordinated tool-environment, standardized interfaces and the general use of the IFC format could deliver many benefits. A set of fully operationalized predictable criteria could be a base. With the newer DGNB-System Version 2015 this target seams relatively achievable. However, many criteria show two ways of evaluation. Firstly, the calculation of performance via simulations and measurements for the pre-certificate and secondly, the assessment of compliance with certain criterion-related requirements, which can be checked using a model checker.

Level 3 also includes the process criteria during planning and construction for project development as well as for buildings in operation. In order to assess the appropriate process quality BIM-based, a high level of transparency and operationalized documentation of the entire flow of information is necessary with respect to different parts of the phases (located temporally and spatially).

Based on the research results and expert interviews carried out by the authors it can be expected to achieve stage 1 in Switzerland in the next 3-4 years. Even stage 2 is within reach (next 4 - 6 years). Just stage 3 (evaluating process criteria BIM-based) needs a longer development period of approximately 6 - 10 years, obstacles like e.g. data protection issues can be expected in practical implementation and application.

6. CONCLUSION

The presented study results lead to the following conclusion: To achieve stage 1 (core critera tool) of a BIM-based certification process, it is necessary to develop a comprehensive integrated tool solution. In Switzerland, this is could be the LESOSAI application (Swiss solution), which has the capability to cover LCA and LCC related criteria evaluation. To achieve stage 2 (BIM-based "building as a product" -criteria) the already existing simulation tools need to be supplemented with intelligent model checker tools, which can cover the operationalized criteria contained in the DGNB system in a BIM-based way comprehensively. Corresponding rulesets in model checker applications (e.g. Solibri) need to be developed fo this purpose, due to the fact that few rule sets are accessible today (often for single purposes e.g. accessibility or for specific business needs or countries). To achieve stage 3 (BIM-based process criteria) major adjustments have to done for system-related criteria requirements as well as advanced BIM applications are necessary in the medium term. Following this study the ZHAW Institute of Facility Management is in preparation of more research activities.

The results of this study show, that a lot of the material and product-related data needed for certification by Swiss DGNB can be drawn from BIM-based planning and construction processes, as some kind of a by-product. This will help to avoid "additional costs" may be caused by a sustainability certification. Assuming that building certificates will have more significant impact on the property value, a combination of sustainability certification with the use of BIM will make the investment for the appliance of BIM even more valuable on the longterm.

The result is a sustainable win-win situation both technologies can mutually benefit from, and environment and society as well.

ABSTRACT

The Architecture, Engineering and Construction industry has many times been criticized for lack of control and management of its environmental impacts. In an attempt to monitor and minimize these impacts, the method of Life Cycle Assessment is being used more and more often during the design process of construction projects. Nevertheless, the whole process of performing a building's LCA is considered time consuming which sometimes prevents the design teams from using it more than once in the end of the design as a way to assess the impacts of their final design. The aim of this study is to suggest a method which will render LCA a design tool used during the whole design process. The study focuses not only in creating a tool that will be able to assess a building's environmental impacts, but will also be an analysis tool which will help the design teams make the right decisions and help them minimize their design's environmental impacts. To achieve this, this study evaluated the potential of integrating LCA into BIM, developed and proposed an Integrated Dynamic Model using Revit, Dynamo and Excel. The Integrated Dynamic model was used in case studies the results of which were compared with the respective ones from other established LCA software. The results showed that the integrated dynamic model can create results of equal quality and precision with other specialized software while demanding significantly less time. The ease of use of such an integrated dynamic model and the instant creation of results could render it a decision-making tool in respect with LCA.

Keywords: Life Cycle Assessment, Building Information Modelling, design process

1. INTRODUCTION

Recent studies have shown that buildings are responsible for 30 - 40% of the energy consumption in Europe (Zabalza Bribián et al. 2009) and 40 - 50% of the greenhouse gas produced globally (Abd Rashid & Yusoff 2015). Increased awareness on the fact has led to the conduction of studies on how to reduce the environmental impacts of buildings. Life Cycle Assessment (LCA) which is one of the methods that have been developed and used to quantify the environmental impacts of a process or product (European Commission -- Joint Research Centre -- Institute for Environment and Sustainability 2010) is used in the building sector since 1990 in order to assess the environmental impacts of buildings (Ortiz et al. 2009). On the other hand, the building industry continuously aims for cost reduction and simultaneous increase of the projects' quality (Tao & Tam 2013). Therefore, methods that can lead to more sustainable design of buildings while assisting in keeping the total budget low are of high interest in the last few years.

Various tools and methods have been developed till today that can assess a building's environmental impacts (Liu et al. 2015) but few have been done to assist the architects and engineers to make the right choices in the early design stage of a building. Considering that the early stage of a building design is the stage when environmental matters are best arranged and given the fact that making good design decisions at the initial stage plays an important role in reducing a project's cost and completion time, the development of such a tool is considered necessary. The emerge of Building Information Modelling (BIM) concept, the wide use of it in the Architecture, Engineering and Construction (AEC) industry and the benefits of its use in respects with the information enrichment and visual representation of a building (Eastman 2011), dictates that such a tool should also be able to be integrated and interact with the most popular BIM software in the AEC industry.

This study aims to develop an Integrated Dynamic Model (IDM) (Negendahl 2015) that would enable design teams to assess the environmental impacts of their design from the early stages of the design through the end of it. The developed model is built to function as a design tool for the design team and offer useful feedback regarding the environmental impacts.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The IDM developed during this study consists of Revit (Autodesk 2016), Dynamo (Autodesk 2015) and an external Life Cycle Impacts (LCI) database. The results of this IDM are produced in a material level and exported in an excel sheet enabling the analysts perform hotspot analyses in a material level, construction type level or construction category level.

2. LCA IN CONSTRUCTION INDUSTRY AND BIM

The recognition of LCA as a factor of sustainability assessment of buildings has led to the increasing use of it in the construction industry. The way it is usually performed though, differs from LCAs performed for other products. The fact that buildings are not industrialized products in their majority makes a detailed LCA hard and time consuming. For this reason, in most of the cases these assessments are based on a material database that contains various generic materials' impacts per specific quantity unit. These impacts are then multiplied with the quantities of the construction's materials to give the total impacts of the construction.

The emerge of BIM concept, the wide use of it in the AEC industry and the benefits of its use in respects with the information enrichment and visual representation of a building (Eastman 2011), dictates that BIM models could be the source of all relevant information needed for a project's LCA.

The integration of projects' LCA studies in BIM will not only make LCA analysis faster but by using the graphical interface of BIM tools, the results from the LCA analysis will be communicated better among the different engineering disciplines and architects. This better communication of results could lead in more sustainable solutions for the studied buildings and projects (Jensen & Nielsen 2011).

3. PROPOSED METHOD (INTEGRATED DYNAMIC MODEL)

The proposed method consists of an Integrated Dynamic Model where the connection of Revit is used with an external material LCI database and the Visual Programming Language (VPL) Dynamo. The LCI database is the source where VPL gets the environmental impacts of the used materials from. The database consists of all common construction materials and their environmental impacts per a specific functional unit (m^2 or m^3).

The basic concept of the proposed model is that there is a permanent link between the Revit materials and the Database materials resulting to zero input from the user every time they want to perform an LCA. To achieve this permanent link, a unique material ID is employed which is the same in both the Revit material library and the LCI database.

Given the material linkage, a script developed in Dynamo is able to automatically read and understand each Revit material's environmental impacts from the LCI database. Getting the material take-off from the BIM model in the same script, it is possible to calculate the total life cycle environmental impacts. Finally, the results are formed accordingly and exported in a new excel sheet which generates all the necessary graphs and charts.

As shown in the model's overview in Figure 1, an advantage of calculations actually happening in the BIM environment itself is the graphical feedback of the results. The use of Dynamo for the entire calculation means that the model can also take advantage of the colour override functionalities it offers. The final results are interpreted visually in the BIM environment and numerically by being exported in an excel sheet where analytical charts are produced.

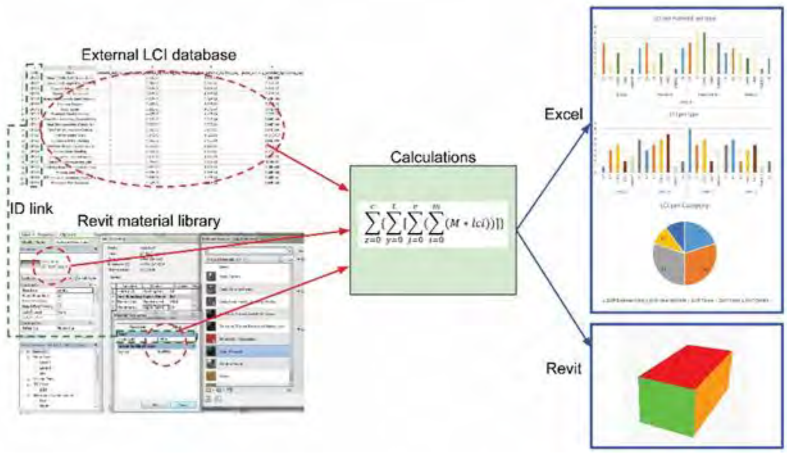

Figure 1: Overview of the proposed model for LCA integration to BIM

3.1 Life cycle impacts database structure

The Excel based database (Figure 2) contains the life cycle environmental impacts of a number of predefined construction materials for specific impact categories. The materials' functional unit was chosen to be m^2 or m^3 since these quantities can be extracted from the BIM model. The materials that are modelled in Revit as membranes are stored with their impacts per m^2 while all the rest as impacts per m^3.

Figure 2: LCI database structure

The environmental impacts are divided into manufacturing impacts and End-of-Life (EoL) impacts to enable the organization of the final results into the respective life cycle categories. For validation reasons information like the functional unit, the density and the source for each material are also stored in the database. The life expectancy of each material is given in three different values to enable the lifetime estimation of each material in the BIM model according to its exposure to the exterior environment. This way, the same material can be considered with different lifetime whether it is placed on the exterior of an exterior wall, on an interior wall or in the core of a wall.

3.2 Datasets and material linking

The unique ID which serves as the link between the database materials and the BIM materials is stored both in the database (Figure 2) and the BIM model. In the BIM model the material ID is stored as a material property which can be read by the VPL that will then identify and link it with a dataset. This way, a permanent link is created between the LCI database and the BIM material library reducing the time needed for a whole LCA performance since the user is not called to link the materials one by one as in most of the LCA applications. In this method, the link is performed only once when the LCI database and the BIM material library are formed. After this and for every new project the BIM material library will always contain the "key" (Figure 4) to its materials' respective datasets in the database.

3.3 Classification system

Although in most BIM applications the elements that can be used are sorted per categories like beams, walls, columns, etc., there are a lot of cases where elements have to be modelled as generic models. Regarding this specific application, this means that these elements and their respective environmental impacts cannot be included in a category in the interpretation of the results. By employing a classification system, these elements can be given a code which specifies what kind of element they are. Then, VPL, by reading these codes sorts the final results by code. This way, in the final results, in the beams' impacts not only the elements that were modelled as beams will be included but also elements modelled as generic models and used as beams.

In this specific application, the BIM7AA encoding system (BIM7AA 2015) is used because it is simple enough to use and provides all the functionalities needed. Similarly, other encoding or classification systems can be used according to the developer's or user's preference.

3.4 Dynamo script

For the proposed IDM, the VPL works not only as the medium to translate and transfer the data to the Building Performance Simulation (BPS) tool, but as the BPS tool itself. Subsequently, the Dynamo script (Figure 3) contains coding for both reading-gathering data from the design tool (Revit) and the database and performing the calculations. The Dynamo script can be "divided" in parts-steps that undertake different functionalities. These functionalities can be divided to Material take-off, database reading, materials-datasets matching, LCI calculation and communication of results.

The material take-off gets all the materials' quantities in m^2 or m^3 depending on if they are modelled as membrane or regular materials. The database reading results in importing of the excel database into Dynamo and the sorting of the data into appropriate lists which facilitate the calculation thereafter. The materials-datasets matching actually links every material with a dataset by creating a list of keys which is of equal size with the materials' list and leads to the corresponding datasets (Figure 4).

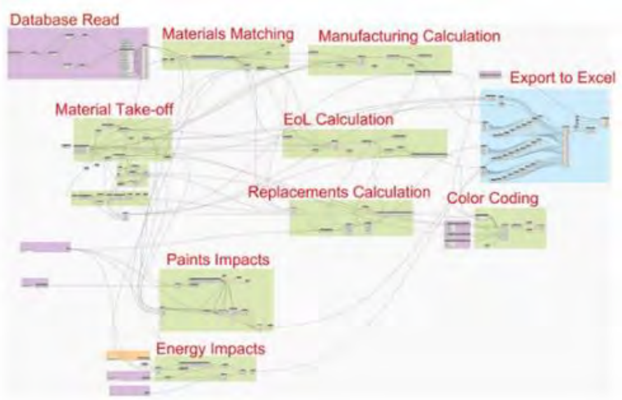

Figure 3: Dynamo script overview

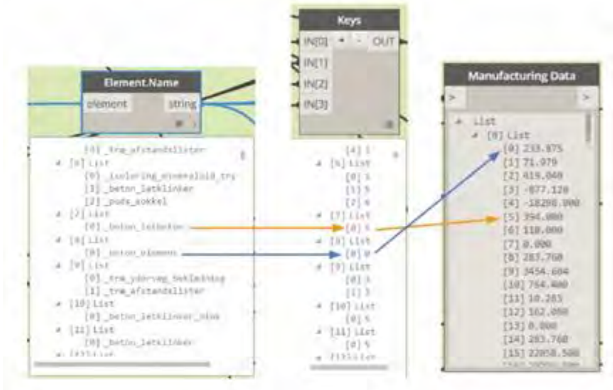

Figure 4: Revit material linkage with LCI

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The LCI calculation takes under consideration the manufacturing, the EoL and the use stage of each material. The use stage is considered by the number of replacement of each material during the building's lifetime. This is achieved by estimating each material's lifetime according to its exposure to the exterior environment and the lifetimes provided in the database. Furthermore, the impacts of the paints and the energy used are also included. The paints are treated differently since it is a common practice not to be added as materials in the BIM model but as a graphical representation or text information. For this application, the paints information is added as text information in the material which is then recognized by the script that can treat it as a regular material. The energy impacts are included in order to make the final report more complete. Ideally the energy consumption would be calculated in the design tool itself being automatically accessible by the VPL.

Finally, after the calculation of the impacts, the communication of the results occurs both analytically and visually (Figure 5). VPL, taking the advantage of producing the results in the BIM environment, color-codes all elements in the geometrical model according to their contribution to the final impacts. This color-coding can be performed for any impact category or element category (walls, roofs, etc.) according to the user's preference. The elements can also be color-coded according to some predefined reference values or relatively to each other.

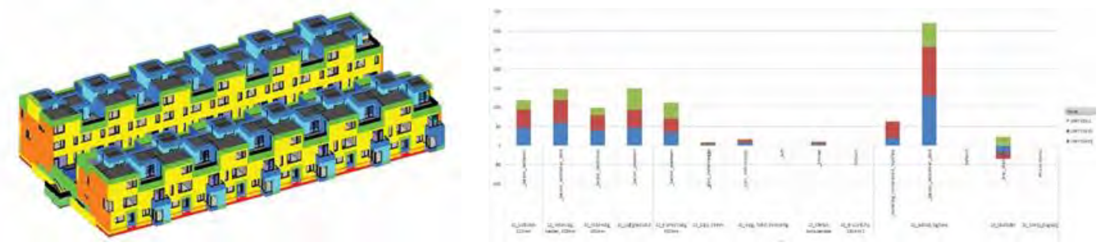

Figure 5: Visual (left) and analytical (right) representation of results

As for the analytical results, these are exported to an Excel sheet sorted by material, family type, classification number and life cycle stage. This detailed production of results enables better comparison of design options by using charts that are produced automatically in Excel.

3.5 Pre-check

The accuracy of the produced results by the proposed LCA IDM depends on the accuracy of the datasets and the accuracy of the information of the Revit model. To ensure that all needed information are included in the Revit model, a new IDM is used to check the BIM model before the LCA IDM is run. This IDM performs various checks before it approves that the BIM model is ready to be used to the LCA IDM. Of course, the LCA IDM is built in a way that it surpasses and ignores (but reports) any potential errors so that it gives a final result. This pre-check IDM's purpose is to enhance the accuracy of the LCA model's results by informing the modeller what is not modelled correctly. The checks performed by this IDM include missing classification codes, missing or invalid material IDs, wrong material links and elements with no materials assigned. The results of these checks are communicated by text in the VPL environment and visually by color-coding the problematic elements in the BIM model.

4. EVALUATION OF THE LCA INTEGRATED DYNAMIC MODEL

The proposed IDM was evaluated in terms of accuracy of results and time needed for a full LCA analysis. This was done by performing a building's assessment with the developed IDM, LCAbyg (Statens Byggeforskningsinstitut Aalborg Universitet 2016) and tally (KT Innovations et al. 2015). LCAbyg was chosen because it is among the most popular LCA tools for assessing buildings in Denmark and its results were used for assessing the accuracy of the developed IDM. As for tally, since it uses an American database and a different LCA method than the custom LCI database, a deviation was expected between its results and the results of the IDM. It was chosen though mainly for comparing the efficiency of the two methods in terms of time needed for a full LCA assessment. For the same case study, the Global Warming Potential (GWP) results are presented at Table 1.

Tool/Method	GWP (kg CO_2 Eq.)	Deviation
Integrated Dynamic model	1,38E+06	0%
LCAbyg	1,44E+06	+4%
Tally	2,84E+06	+51%

Table 1: GWP results of case study

Regarding the time needed for a full assessment, the proposed IDM created results in less than one minute while using tally this time was more than two hours since all materials had to manually be linked with datasets one by one. The IDM's strongest advantage though, is the fact that it is a tool that can be easily modified by the user to meet any specific requirement. By modifying the custom LCI database and adding new "equivalent" datasets the practitioner can overcome issues like including elements that are not modelled in the BIM model (screws, foils, tapes etc.), including non-conventional materials and in general to adjust the whole process according to the standards the BIM model is produced.

5. DISCUSSION

After the evaluation of the developed IDM, it appears that it could potentially be useful for engineers and architects who try to monitor and minimize the environmental impacts of their design in all stages, from the pre-conceptual to the end of the detailed one. Nevertheless, there are factors that can affect the validity of the results of the developed IDMs. These factors include the precision of the BIM model, the material take-off precision and the accuracy of the database. The BIM model precision is related with the geometry modelled by the modeller, while the material take-off is related to the software itself. For the purpose of this study it is assumed that the material take-off produced from Revit is accurate enough for use in LCA. As for the database, since it is custom made by getting datasets from other databases or by creating new ones, its accuracy can strongly affect the final results. For this reason, it is recommended that the database's datasets come from the same source.

Furthermore, the same concept with the developed IDM can be used to perform Life Cycle Cost (LCC) assessments of buildings. Similarly with the LCA IDM, an LCC IDM can use a cost database of materials or elements and thus estimate the cost during the building's life cycle.

6. CONCLUSION

The case studies of the proposed IDM showed that such a model could facilitate the assessment of a building from the early stages of design and provide useful feedback in a short amount of time. The level of detail of the produced results facilitates the further analysis by the LCA practitioner. The results can be interpreted in material, construction type and construction category level, helping the practitioner perform a hotspot analysis, detect materials and constructions causing higher impacts and perform the necessary changes. The visual representation of the results directly in the BIM environment by color-coding of the building elements is also a feature that is helpful in terms of quickly detecting the hotspots in the construction type level.

Regarding the complexity, the use of IDMs for LCA is considered not more complicated than the use of conventional simplified LCA tools. The complexity in this case has mainly to do with the use of the VPL language. The practitioner must have some basic knowledge in VPL while at least one practitioner in the design team should be able to verify the final results and maintain the LCI database. On the other hand, the assessments are performed much faster in the IDM while LCA knowledge is not a prerequisite for a practitioner to perform them. This, combined with the fact that the inventory is automatically updated when changes occur in the geometrical model, enables the production of more results with a lot of iterations in considerably less time and leaves the LCA specialist more time to analyse the results instead of creating them and then analyse them. In the same time the modeller can use the time saved for more iterations or other tasks more relevant to their discipline.

To conclude with, this study showed that the use of LCA IDMs can help towards the integration of LCA in the design process and the design of more sustainable constructions in terms of environmental impacts. The developed IDM, with some further development and improvements could be used by design teams while they could be the basis for development of new more stable and precise LCA IDMs.

ABSTRACT

Against the background of changing societies and our planet's changing climate, the project presented deals with the various aspects of sustainability and tries to envision a democratic and sustainable design process supported by technology.

To identify the purpose and objectives for the project, a participatory design process with a co-housing group was conducted to define the group's common vision and requirements towards a residential project. Through several workshops these were elaborated and shaped into first conceptual designs. To assess and improve the environmental performance of these concepts and support fact-based design decisions, a variety of scenarios for building materialisation, energy standard and energy supply mix were compared through the application of Life Cycle Assessment (LCA). Working towards the integration of LCA into the architectural design and planning process, a prototypical workflow to combine LCA with the planning method of Building Information Modelling (BIM) was developed. Through the application of visual scripting, essential steps of LCA could be integrated into a BIM workflow and innovative methods of communicating assessment results using the digital building model could be shown.

Keywords: life-cycle assessment, Building Information Modelling, embodied energy

1. INTRODUCTION

In a rapidly evolving and energy demanding present, sustainability is gaining ever more relevance in designing new buildings and infrastructure as well as retrofitting the existing building stock. The sheer number of stakeholders involved in the highly interrelated building design and planning process emphasizes the need for clear communication among all parties involved on how to improve the environmental performance of the built environment.

To evaluate the environmental performance of buildings over their life cycle, the method of Life Cycle Assessment (LCA) has been widely accepted, standardized and is increasingly applied to assess the built environment. LCA is commonly used to assess and improve upstream processes, like material sourcing and production of construction products through Environmental Product Declarations (EPDs). Comprehensive LCA of buildings is mainly applied to evaluate and document existing buildings but is hardly implemented in the building design process.

At the same time, state-of-the-art planning and building management methods like Building Information Modelling (BIM), follow an object-oriented modelling approach and provide potential to integrate life cycle information and LCA during the design process. The increasing standardization of BIM in terms of building element structure, Levels of Detail in modelling (LOD), and intended purpose of the building model in different planning stages furthermore supports a transparent and comprehensible application of BIM for LCA.

In order to tackle the outlined challenges and support the integration of comprehensible LCA during the building design process, we build on the advances mentioned and integrate information on embodied impacts into BIM. This enables us to use the model to evaluate the sum of embodied impacts using predefined construction profiles to test different materialization options by linking the process with an existing assessment tool. Furthermore, we present a prototypical method to visualize the embodied impacts using the BIM model, to support intuitive optimization and the communication of assessment results throughout the planning process.

2. METHODOLOGY

The environmental design process presented is based on requirements and a building design developed throughout a participatory design process with future inhabitants of a residential co-housing project.

To assess the environmental performance of the architectural concept in various stages, we perform a simplified LCA through application of the district evaluation spreadsheet tool (DEST) of the Swiss 2000 Watt society, comparing the results to the underlying benchmarks of the 2000 Watt society model. A first assessment comparing different materialization options is based on the program and requirements of the participatory process and serves as an estimate result to further develop the conceptual building design.

The developed design is then assessed using actual element quantities of the BIM model to refine the Life Cycle Inventory (LCI). Within the DEST the LCI is by default structured according to Swiss building element structure eBKP-H which was designed to evaluate building element cost. This element structure was also applied to structure the building elements of the BIM model to serve as a common structure and support data exchange between the DEST and the BIM model. This supported the extraction and transfer of quantities as well as the integration of life cycle information in the BIM model, which was automated through the application of Visual Scripting (VS).

2.1 Tools

Building Information Modelling (BIM) is a contemporary digital planning and building management method. A building information model (BIM model) is a component-specific building database that can be used to hold, update and document information related to the building life cycle. The object-based BIM model is increasingly used for cost management and life cycle analysis. In the present paper BIM is used to extract building quantities for LCA as well as to host life cycle information on the environmental performance of the building elements. The 3D model is also used to visualize information for communication with other stakeholders.

2000 Watt society provides environmental benchmarks for the development of districts and buildings in impact categories of Global Warming Potential (GWP) and Primary Energy Demand (PEDnr and PEDtotal), based on the calculation of a personalized “environmental budget”, which must not exceed 2000 Watt constant energy consumption per capita. The method of LCA is used for the assessment of the building concept, through the application of the 2000 Watt society district evaluation spreadsheet tool (DEST). The tool provides component-specific values for embodied impacts for various (customizable) construction options as well as a simplified calculation of the impacts of operational energy demand based on the building energy efficiency classification. The database used is EcoInvent version 2.2 with calculations based on a building Reference Service Period (RSP) of 60 years.

Visual scripting (VS) provides a graphical scripting interface to manipulate parametrised geometry and alphanumerical data. VS was used to access the BIM model’s geometry and alphanumeric information as well as to exchange data with the DEST using spreadsheet software. The processes automated to support the integrated LCA and communication of results were: a) Extraction of element quantities from the BIM model; b) Transfer of quantities to 2000 Watt DEST; c) Assessment within 2000 Watt DEST based on BIM quantities and scenario settings; d) Extraction of overall results on building performance in relation to established benchmarks; e) Extraction of detailed assessment data and results (component-specific embodied impacts); f) Integration of component-specific impacts into building elements in the BIM model; g) Visualization of component-specific impacts using the BIM model

2.2 Case study and scenarios

To identify suitable solutions for the further design process of the case study building, different scenarios were assessed for a consistent conceptual building design. The assessment scenarios defined and calculated in the DEST are a combination of options for materialisation (construction profiles, CP), envelope quality and technical services (energy standard, ES), as well as multiple options for the energy mix used to supply the operational energy demand (energy mix, EM). CP, ES and EM each comprised three different options – see exemplary options for CP in Figure 1. Following the strategy of improving the building’s environmental performance through efficiency, consistency and sufficiency a total of 27 scenarios was tested.

CONSTRUCTION PROFILE		Overview materialisation
CP1	Massive, concrete	Concrete walls, concrete ceiling and roof construction, wood/aluminum windows, lightweight stud partition
CP2	Lightweight, timber	Wood frame construction walls, wood-concrete composite floor and roof construction, wood/aluminum windows, lightweight stud partition
CP3	Brick-timber (custom)	Perforated brick walls, coffered wooden ceiling and roof construction, wood/aluminum windows, plasterboard partition

Figure 78: Description of options for materialisation (CP), envelope quality and technical services (ES), and energy mix used to supply operational energy demand (EM)

3. RESULTS

In the following, results are first of all presented for the overall performance of the individual building scenarios assessed. Based on these results a group of well-performing scenarios could be identified and investigated in more detail. A best scenario in terms of embodied impacts was identified and the detailed (component-specific) results are presented and discussed in the following. For the refined LCI of this assessment, quantities have been extracted from the BIM model. Detailed LCA results are then presented using conventional diagrams as well as a novel method of visualizing embodied impacts using the BIM model. The three construction profiles are also visually compared to test the visualisation workflow and show its potential for communication of design variants and assessment results to clients and other stakeholders.

The LCA results of the scenario assessments were evaluated in terms of their total environmental impacts regarding the impact categories of GWP and PEDnr. Results are structured into embodied impacts (construction and demolition + replacement), operational (operational energy demand) and building induced mobility. Building induced mobility is a parameter set forth by the 2000 Watt society model, which includes the environmental impacts caused by transfer from or to the building, based on the location of the building and the quality of the connection to the public transit networks. As the site location of the project is fixed, the focus was on identifying suitable building scenarios based on the improvement of the variable parameters of embodied and operational impacts in both impact categories.

In a first step, all 27 scenarios were assessed and the sum of embodied and operational impacts (total impacts) analysed regarding the fulfilment of the target values for PEDnr and GWP. The mapped data shows three clusters (green, orange, red), which result from the energy mix chosen for the scenarios. (see Figure 2)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

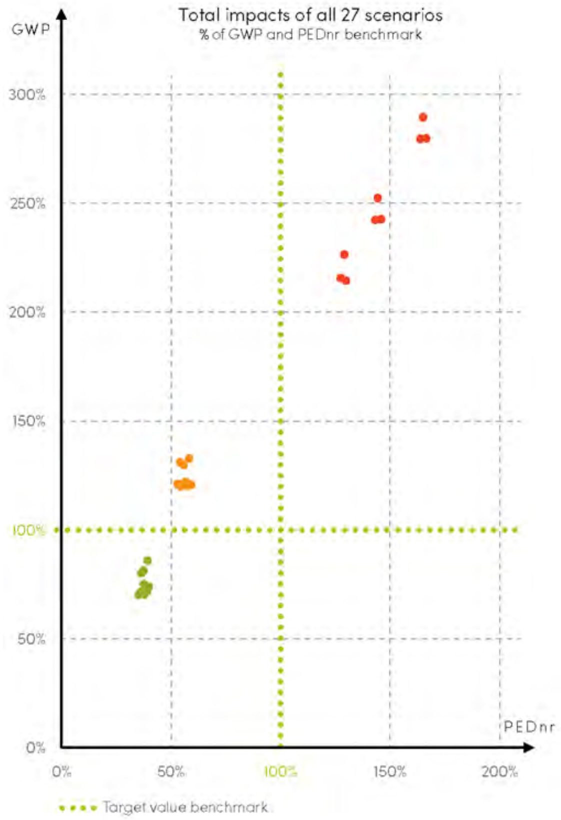

Figure 2: Graph showing the fulfilment of target values for the total impacts of each scenario in impact categories PEDnr and GWP. Clusters of the scenarios resulting from chosen energy mix (EM) can be clearly identified.

- Red cluster: Scenarios 1 - 9, (which apply EM1) are not able to meet either GWP nor PEDnr target values, due to the high impacts caused by building operation.
- Orange cluster: Scenarios 10 - 18 (all applying EM2) are able to meet requirements of PEDnr, however fail to fulfil GWP benchmarks.
- Green cluster: Only the scenarios 19 - 27, which apply energy mix EM3, manage to fulfil the target values in both impact categories, PEDnr and GWP.

Scenario results showed the green cluster of scenarios 19 - 27 should be further investigated. Based on the premise of reducing embodied impacts - and as scenarios 19 - 27 are all applying EM3, which is the best performing, renewable energy mix scenario - scenarios 20 and 21 (CP2 and CP3, each with ES1 and EM3) can be considered suitable construction profiles for the further design process.

Based on a specific construction profile and energy standard – in our case scenario 21 was chosen as the best performing case – the impacts per building element and the contribution of different component categories to the sum of embodied impacts can be identified. Using quantities of the actual building design, e.g. when directly extracted from the BIM model as in our case, the share of an element category of the total embodied impacts can be put in relation to the share of the total quantities assessed to identify the dominance of a certain element category (see Figure 3). High dominance indicates that certain element categories, or individual building elements for that matter, have higher contribution to embodied impacts than to the sum of areas quantified. Focusing on these elements therefore provides high potential for effective improvement of embodied impacts. Especially element categories C 2.1B (external walls above terrain) and E3 (windows and doors) show high dominance and thus potential for improvement in the further design process.

	GWP [%]	m² [%]	GWP / m² [%/%]
Seperation walls	13,7	31,7	0,43
Windows (wall/roof)	17,2	9,1	1,90
Roof construction	10,0	10,3	0,98
Floor construction	12,0	19,9	0,60
Ext. wall above ground	36,9	17,4	2,13
Foundation	10,2	11,6	0,87

Figure 3: Dominance analysis of element categories. Calculated by comparing an element category's share of total embodied impacts to its share of the total element areas assessed. Values for CP3 (Scenario 21).

4. VISUALIZATION OF IMPACTS

In order to present results and support further development of the design, component-specific embodied impacts can be visualized in different ways. Using the 3D BIM model to present results in a comprehensible way helps to inform designers during the process and to communicate design decisions to clients and other stakeholders. Figure 4 shows possible applications of this visualization workflow to present information on embodied impacts.

This can serve the visualisation of, for example: a) Embodied impacts per unit (m^2, m^3 or per piece) of components; b) Share of the element category of the total of embodied impacts; c) Share of an element category of the totally assessed element quantities, as well as; d) Dominance of a certain element category in the total embodied impacts. The latter highlights areas and elements suitable for effective improvement of embodied impacts (see also Figure 3). Thus, a visual comparison of different construction profiles can help identify strengths and weaknesses as well as potential for improvement in the building design. This may also support the future development of BIM integrated LCA processes.

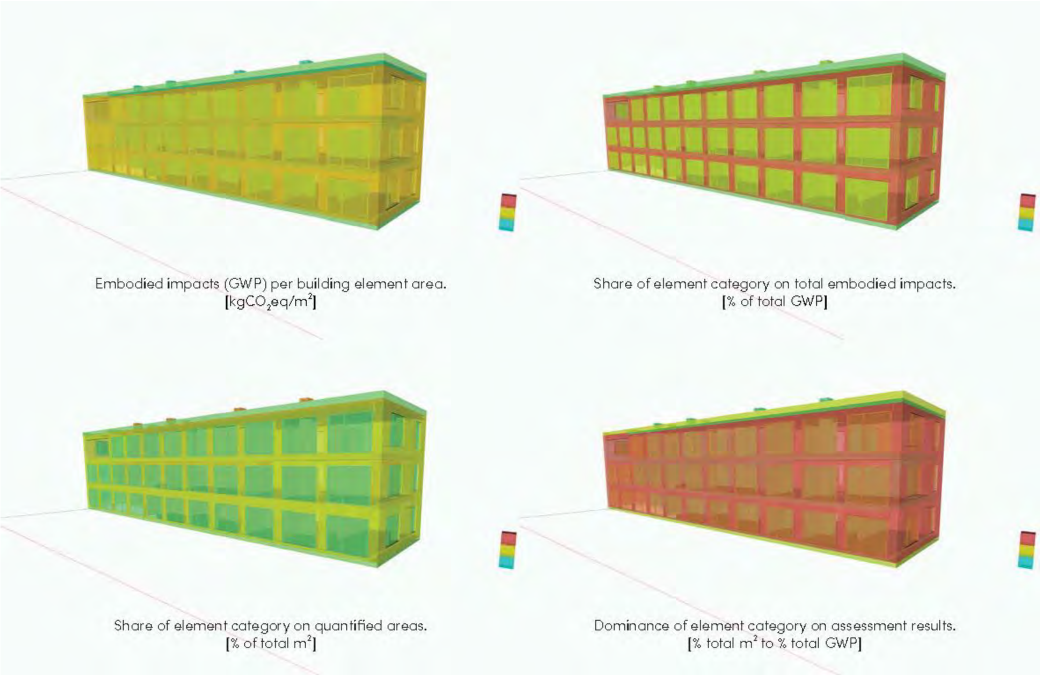

Figure 4: Visualisation of different aspects and results of LCA for scenario 21. Embodied impacts (GWP) per element area, the share of an element category of the total impacts as well as on the areas quantified for the LCI. Combining these shares one can identify the dominance of a certain element category, to highlight elements with improvement potential. The dominance illustration clearly shows external walls and windows in red being the dominating elements categories.

5. DISCUSSION AND OUTLOOK

In the analysis of the scenarios the high dominance of the energy mix could be shown, as in EM3 all construction profiles and energy standards were able to meet the benchmarks. This highlights the importance of choosing a clever energy mix for buildings, which should be based on renewable energy sources wherever possible. For construction profiles (CP) and energy standards (ES) tested, the ES chosen for high energy efficiency during operation also showed higher embodied impacts, due to more insulation and technical systems. This again highlights the possible advantages of reducing embodied as well as total impacts through low impact construction materials and a clever energy mix. The conducted scenario analysis and identification of suitable options can improve design decisions throughout the process and support sustainable building design based on a process-integrated assessment.

For the BIM based quantification, plausible values and results could be shown, supporting the applicability of BIM quantity extraction for LCI in future LCAs. Furthermore, the integration of impact data into the BIM model using the same element structure allowed for a component-specific visualization of impacts, independent of the assessment results. Meanwhile, the validity and completeness of an assessment performed on the basis of component-specific ("per component area") impacts should be subject to further research through the comparison with complete conventional LCAs on a considerably large number of case studies.

The presented visualization of embodied impacts could promote understanding of the embodied impact concept amongst designers as well as the communication of LCA with clients, planners and other stakeholders. In the future, integration of embodied impacts into BIM combined with building energy simulation towards a process-integrated LCA could enable real-time assessment and a constant visual feedback of the building performance in terms of embodied and operational impacts. The application of visual scripting for that matter is to be further investigated and can support the development of such processes.

Current developments of BIM towards the integration of EPDs through the link to external property and product databases may provide potential to include building and element specific environmental benchmarks to be used during a BIM supported building design process. These developments should be closely monitored and influenced where feasible to improve the integration of LCA and BIM and support sustainable building design processes in the future.

ABSTRACT

Buildings use about 40% of global energy and they emit approximately one-third of GHG emissions. Having such high impact on global sustainability indicators, buildings have greatest potential to reduce this impact. The key to reduce this impact is by quantifying the impact caused during different phases of the life cycle of building (design, construction and operation) and prioritizing the impact mitigating strategies. Life Cycle Analysis is the most adopted methodology for quantifying the impact, however to suggest the impact mitigating strategies is quite cumbersome as multiple software tools are used to conduct such analysis and the reports generated are static. BIM has the potential to keep this data dynamic and enable real-time analysis of these parameters thereby offering intelligent solutions. Previous researches conducted did not utilized the full potential of BIM in integrating life cycle analysis with BIM as most studies exported the model from the main BIM authoring tool and do not consider bringing back the results to the BIM model thereby making the effort useless for incorporating changes in the model.

A novel framework to conduct the analysis within the BIM environment is proposed in this paper focused on both embodied and operational Energy & Carbon as it constitutes a major portion of Life Cycle Analysis of a building. This framework has four steps: i) Data Collection which includes both the design data required for simulations and actual data from the sensors, ii) Data Mapping ensures the proper input of data into the model in a suitable format and at a reasonable memory location by creating content space, iii) Data Analysis comprises of Whole Building Energy Simulation, Life Cycle Energy Analysis and comparison between Simulated and Actual Energy consumption and iv) Alternatives Provision guides the designers to implement effective solutions for reducing the total energy consumption and carbon emissions.

Keywords: building sustainability, BIM, lifecycle evaluation

1. INTRODUCTION

Sustainability has been a high priority goal for the current construction projects; to evaluate and rate the alternatives some common parameters needs to be established to compare them. Life Cycle Energy and Carbon Emissions are the most effective parameters based on which the alternatives can be compared. Quantification of these parameters require a standard method for calculation as well as the data that will act as the input for this method. The process for collecting this information and evaluating the building faces two major challenges: First is the fragmented nature of the construction industry and second is Temporal data that is needed to perform analysis such as Material Wastage, Energy Consumption Data, Air Quality Management, Commissioning and Post Occupational Activities.

The first challenge of fragmented nature of the construction industry brings forward the issue of specialized software that are adopted by experts of a certain phase (such as design) which are not interoperable with other phases there by forcing re-input of data for the subsequent phases which in-turn breaks the virtual chain of building construction process. To address this issue IFC file formats are utilized which allow the interoperability between software products of different vendors but with limitations.

The second challenge of the collection of temporal data brings forward the effort needed to collect the data and the accuracy of the data collection process. A Real-Time Location System (RTLS) is proposed to ensure the accuracy of the spatial position of the sensors. Energy consumption data is collected using a sensing system and energy consumption patterns are analysed based on the spatial division in the building. An expert system is developed to forecast and diagnose energy consumption and achieve energy efficiency by providing corrective measures. Building Information Model acts as a database that can hold all the relevant information for every phase of construction if the templates of the BIM authoring tool are designed as such.

2. LITERATURE REVIEW

Policies, laws and regulations around the world are pushing the construction sector to adopt sustainable innovation in terms of products and processes (Hellstrom, 2007; Steurer, 2011). Building sustainability refers to a building structure and the processes for its use that are environmentally responsible and resource-efficient throughout the building's life-cycle: from siting to design, construction, operation, maintenance, renovation and demolition (UEPA, 2011). This encompasses efficient utilization of resources (energy, water etc.), reduction in environmental degradation due to pollution & waste and regeneration of resources through onsite mechanisms & treatment plants. Sustainability assessment can be defined as the process of identifying, predicting and evaluating the potential impacts of initiatives and alternatives (Devuyst, 2000). Achieving sustainable buildings is possible through a broad range of products and services like heat pumps, solar collectors, insulation systems, shading devices, phase-change materials heating and cooling equipment, photovoltaics, sensor systems for intelligent energy management and energy control and monitoring systems (Kolokotsa, 2011). Therefore, to make a particular building sustainable stakeholders need to do market search and comparison of various solutions based on sustainability criteria, such as return-on-investment, CO2 emissions, the potential for reducing energy consumption etc. Forecasts of the EIA (2010) show that energy consumption in buildings is increasing at a rate comparable to those of the industrial and transportation sectors. Interestingly, the building sector has the highest energy saving and pollution reduction potential, given the flexibility of its demands (Ipcc, 2007). An information intensive process is necessary to consider the phenomenal number of high-end technology solutions and their suitability for the particular project. By applying sustainable techniques and methods over a period, there should be a considerable amount of change resulting in reduced environmental impacts not only within the built environment but also on a larger ecological scale (Bynum et al., 2013).

In order to measure the building performance sensing system is needed to monitor, collect and transmit the data for analysis. Different sensors, monitoring and control equipment used in various researches are:

- iMeterRail (Electricity meter for electric switch boards): The sensor monitors the consumption of an electrical circuit to deduct the level and kind of activity in each moment.
- Power Plug (Measurement of electrical consumption and control of electric devices): The sensor monitors the consumption of an electrical device
- Clamp (Measurement of electrical consumption of circuits): The sensor monitors the consumption of a building's section to deduct the level and kind of activity in each moment.
- Air monitor (Indoor Air quality modules with 4 different sensors: temperature, relative humidity, CO2 and CO): The sensor monitors air quality of a space to deduct the people density in that space.
- Gateway 1 (Receives data from RF 868 MHz and RS485 devices and send over a TCP/IP connection): The device acquires the data from several devices.
- Gateway 2 (Receives data from ZigBee sensors and sends over a TCP/IP connection): The device acquires the data from several devices.
- RFID Receiver (Equipment to track RFID cards passing by): Track Individual occupants carrying RFID cards.
- RFID Cards (Radio Frequency Cards to be tracked by RFID Receivers): To be carried by Individual Occupants participating in Individual-Based scenarios.
- RFID Reader (Module used to detect the proximity of a RFID tag): The reader is used to track the position of a person or equipment inside the pilot's buildings.

As far as building energy is concerned, Embodied energy (EE) and Operational energy (OE) together constitutes a building's life cycle energy (LCE). EE involves the initial energy of the construction (material and burden associated with material consumption in buildings) and OE reveals the energy utilized in operating phase (Praseeda et. al., 2016). There are two more types associated with building energy namely demolition and disposal energy but these are rarely addressed as they together form less than 1% of life cycle energy (Sartori and Hestenes, 2007; Ramesh et. al., 2010).

Both primary energy or secondary energy can be considered for LCE. Primary energy is the raw fuel that is used to create heat and electricity, such as natural gas, coal, or fuel oil while secondary energy is the energy product created from a raw fuel, such as electricity purchased from the grid or heat received from a district steam system (Asif et al., 2007; Atmaca, 2016).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

There are three methods used in life cycle analysis: process analysis, input–output (I–O) analysis and hybrid analysis. Due to the complexity of the upstream requirements for goods and services, the process analysis which is used widely has some disadvantages. The second method, I–O analysis, uses national average data for each sector of the economy and is considered by many researchers to be more comprehensive than process analysis. On the other hand, I–O analysis is usually used as a “black box”, with little understanding of the values being assumed for each process (Crawford, 2008).

BIM consist of three words Building, Information and Modelling. Building: any structure like residential/commercial buildings, Hospitals and different Infrastructures. Information: the complete information about the building like cost, quality management, safety measures, risk management, structural elements, architectural information. Modeling: a complete 3D representation (Azhar et al., 2012). BIM can be applied in sustainability analysis widely while considering for example building orientation, building envelope, and construction materials. With the introduction of BIM, different attributes of the building envelopes can be recorded in the digital database, for instance carbon dioxide emission, which facilitates the automatic sustainability assessments of buildings.

A framework for utilizing BIM for sustainable building design is proposed by Zhang et. al., 2014). In this study a rule-based system is proposed for checking building model against the building codes and provide instructions on sustainable design practice. Rules are developed as per the LEED standards and Revit is as used as BIM authoring tool. A plug-in is developed to assess the building as per LEED. Another study conducted by Jalaei and Jarade (2014), proposed BIM for assessing sustainability of Buildings. Anton and Diaz (2014) studied the integration of Life Cycle Assessment in the BIM environment highlighted a missing link between the Environmental Information (such as Embodied energy and Carbon) with the BIM objects.

The lack of integration between environmental analyses and the main BIM simulation processes may lead to inefficient afterward modification to meet certain environmental criteria. Another feature which is common to all environmental analyses system is that they demand large amounts of design and construction data in different formats, and the accuracy of analysis depends on the quality and availability of data from all phases of the project (Alwan et al., 2015).

3. MOTIVATION

A lot of research has been conducted on evaluating the building design based on embodied and operational energy consumption as well as carbon emissions but such studies are case-based i.e. the outcome is usually a static report that show the statistics of that particular project. The data entered and processed are lost due to a disconnect between the different applications used in the process. The very nature of this process is iterative but due to the limitation of the existing frameworks slight changes cannot be incorporated and needs a complete cycle of steps performed on it before any meaningful results are obtained. Interoperability and reusability of life cycle sustainability data has been the prime focus of this research paper.

4. PROPOSED FRAMEWORK

Figure 1 below shows the framework for Lifecycle Evaluation of Building Sustainability. It has four steps namely Data Collection, Data Mapping, Data Analysis and Alternatives Provision.

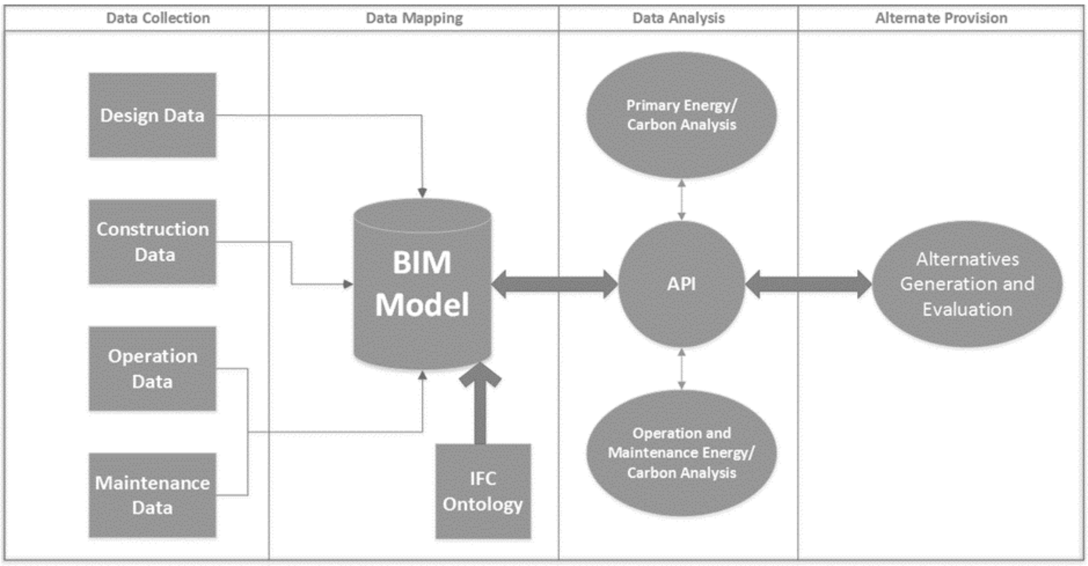

Figure 1: Framework for lifecycle evaluation of building sustainability

Data Collection: In order to evaluate the primary energy consumption all the direct and indirect processes associated with building over its lifecycle are to be quantified which includes all activities from material extraction, manufacturing, transportation, construction, refurbishment and replacement, and disposal activities at the end of the building's life. The data collected can be further divided into two categories. First category includes data that is associated to design and other category includes temporal data collected during the construction and operation stage. The design data encompasses the geometry of the buildings, properties of the building elements, location and orientation of the building, the embodied energy of the construction materials (The values of the embodied energy can be linked to any suitable database that can holistically estimate the impact such as Inventory of Carbon and Energy (ICE) (Hammond et al., 2008)). The temporal data that needs to be collected is the amount of energy consumed during construction (both direct and indirect), wastage of building materials, energy consumed in transportation of material from plant to site, operational energy consumed during the operation phase and the energy consumed on maintenance over the life span of the building. The operation energy can be divided into heating/cooling load, building services and electrical appliances. A real-time location system will be incorporated to make the data location wise intelligent to provide basis for break down analysis. The operation and maintenance energy will also be estimated through whole building energy simulations with standard occupancy schedules and considering standard maintenance schedules. BIM will act as a platform to integrate all the data which will be discussed in the next phase.

Data Mapping: A typical BIM authoring tool has provisions for assigning geometry and location data as well as element properties but does not provide content space for embodied energy of materials, construction energy, material transportation energy, operation energy and maintenance energy. As mentioned previously in the data collection step that this data is of two types thus require different types of content space. First type includes data available during the design stage; this can be further divided into single value data such as Embodied Energy (MJ/Kg) and the other type includes expected occupancy schedules and estimated maintenance schedules. The second type i.e. temporal data includes wastage of building materials, construction energy, energy consumed in transportation of material from plant to site, operational energy consumed during the operation phase and the energy consumed on maintenance over the life span of the building. To make all this data interoperable a standard data exchange protocol needs to be set up. IFC acts as a standard data exchange protocol for construction data but is limited to the conventional BIM entities so it needs to be extended as explained in the next section.

IFC Ontology: An IFC export from any BIM authoring tool generally exports standard entities present within the model and does not export any additional attributes that may be input into the model. Since some additional parameters are input in the last step, there is a need to establish a relationship between standard project entities and these newly added parameters. IFC Ontology will be developed by using any suitable environment to map this data in the IFC format which will make this data interoperable among different IFC enabled software suits with a variety of applications.

Data Analysis: Whole Building Energy Simulation will be based on LEED and will account for Minimum and Optimized energy performance credits. It will take into consideration the building geometry, location and orientation as well as properties of the building elements to perform solar gain, total energy gain, and Lighting Analysis. Occupancy schedules will help to simulate the heating/ cooling loads. Life Cycle Energy analysis (based on MR credit: Building life-cycle impact reduction) will take into account the embodied energy, construction energy, material wastage and maintenance schedules to calculate the whole life cycle energy. The actual operational energy will be calculated by sensor data which will be based on Building Level Energy metering credits. A comparison will be made between the simulated loads and actual values.

Alternatives Provision: Provision of alternatives and their evaluation is the prime goal of life cycle evaluation. An API is developed to link up all the data provided for a single alternative and enable the designer to change the material configuration of the model and compare with the base model in real time. A report will be generated based on the selection of material configuration describing the life cycle impact of different alternatives and highlighting the most effective solutions.

5. CONCLUSION

Today's construction projects need extensive simulations with regards to sustainability aspects. This framework is intended to cater two very critical needs of these projects. First is incorporating data for various alternatives as well as their simulated reflections on the sustainability aspects in a single model database. Second is recording and mapping of the actual consumption patterns as well as enabling comparison with the simulated values to record the impact of sustainable measures taken during the design, construction and operation phase of the building project. The most important advantage of this framework is that it allows all its activity within the main BIM authoring tool thereby saving time and effort to generate and compare alternatives in addition to accommodating changes in the building geometry.

ABSTRACT

Facing the expansive growth of cities and the wasteful consumption of resources, cities must be measured in its immense complexity, and its parts and layers must be observed so as to assess its ability to support such pressures. Cities should look at themselves and define how far away they are from a sustainable model, which means a greater sense of community, mixed uses, higher densities, better public space, higher quality of life, less energy consume, among others. This paper presents a toolbox for assessing sustainable urban densification using Geographic Information Systems (GIS). The toolbox uses spatial analysis and cartographic representation techniques to characterize and analyze the spatial distribution of a set of indicators using an orthogonal grid. The toolbox includes the automatic computation of 20 indicators of urban sustainability organized in four themes: compactness, diversity of uses, urban green, and socio-spatial integration. It also computes a Sustainable Urban Densification Index for each cell of the grid allowing to explore and discover spatial patterns of urban sustainability. The toolbox includes options for parameterization of both the indicators and the index, offering flexibility for adapting it to different realities and needs. These features allows the application of the toolbox for a wide variety of studies, such as comparative analysis of different cities or urban fabrics, monitoring of performance of urban policies, assessment of the impact of urban densification and urban sprawl, and future scenario evaluation. The toolbox is publicly available to researchers, practitioners, urban officials, technicians and students interested in urban sustainability.

Keywords: urban indicators, spatial analysis, sustainable neighborhood

1. INTRODUCTION

"Measure what is measurable, and make measurable what is not so"

Galileo Galilei

The city is, among other definitions, a spatial and relational phenomenon, the most comprehensive work of human activity (Whitman cited in Chueca, 2011, p.19). It is a scene of life, so that understanding it means approaching its inhabitants. Therefore, the desire to study the city represents an act that involves tackling its immense complexity, observing its parts and abstracting the different layers that constitute it. La ciudad es esto (Hermida et al., 2015a) proposes a tool for measuring and comparing urban sustainability taking as a main issue housing densification and intensification of uses. Besides, this tool considers the different variables that affect urban life and mobility, green infrastructure and social cohesion (Hermida et al., 2015b, p. 29). In fact, compact city is assumed as a sustainable urban model and densification as a key variable for analysis.

1.1 The abstraction of the city

Due to the expansive growth of cities and their wasteful consumption of resources it is necessary to measure their ability to face these pressures (Cabrera *et al.*, 2015). The dispersed city has failed as urban model (Arbury, 2005) and its effects require a change of course. For this reason cities should look at themself to assess how much they have deviated from the compact model, which defends cities with a greater sense of community, mixed and walkable uses, higher densities, more space for its inhabitants and less for the car (Lehmann, 2010). It is necessary to measure how the city resembles the compact and diverse model and thus demonstrates urban sustainability (Rueda, 2008). With this in view techniques of spatial representation GIS (geographic information systems), that integrate mapping and information resources allowing the organization, storage, analysis and modeling of large amounts of geo-referenced data (Olaya, 2011) are used. Drawing on these data it is possible to create indicators represented in layers of geographic information that may overlap to measure urban sustainability addressing spatial heterogeneity.

While GIS tools are useful and maps are essential to navigate and locate boundaries and landmarks, some representations are inefficient to visualize and communicate information as the visual impact of data displayed in a spatial way is influenced by the way space is divided (London Data Store, 2015). Irregular divisions of cartographic maps carry the "modifiable area unit problem" MAUP (Openshaw, 1981) due to the variability of spatial boundaries and the lack of a regular unit area which present spatial and statistical calculations (densities, proportions, etc.). To reduce the visual impact and to maintain possibilities of comparative analysis a regular grid is chosen. This divides the territory analyzed in uniform cells (Figure 1). The grid is dimensioned according to the average area of a city block and its cells contain at least 4 blocks. In the case of Cuenca-Ecuador, the cells are sized 200m x 200m (Hermida *et al.*, 2015a, p. 35).

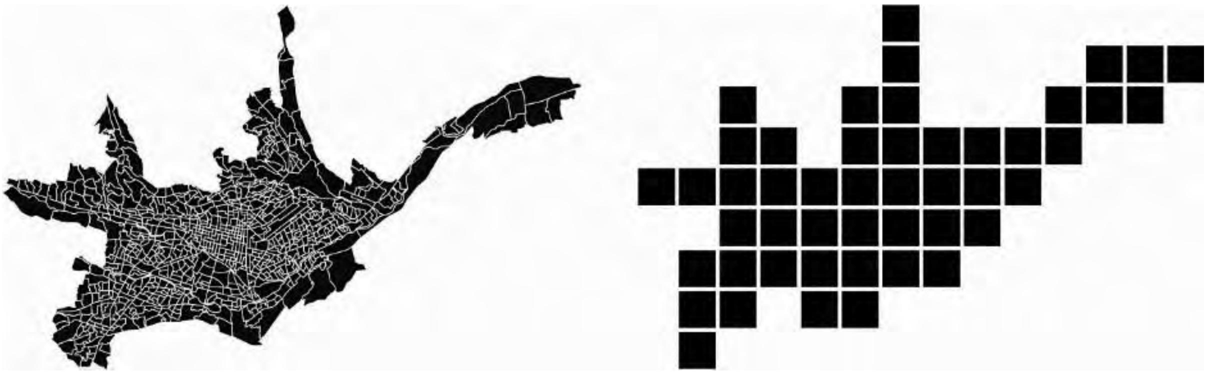

Figure 1: Division of the urban fabric through a square grid

2. INDICATORS SYSTEM

The construction of this system uses at a starting point 52 indicators extracted from the indicator system for large and medium-sized cities (Agencia de Ecología Urbana de Barcelona and Red de Redes de Desarrollo Local Sostenible, 2009), and the environmental sustainability indicators plan of Seville (Rueda, 2008). From these studies 20 indicators are proposed, which are adapted to the city of Cuenca and organized into four axes: 1) compactness, 2) diversity of uses, 3) urban green, and 4) socio-spatial integration (Table 1) (Hermida *et al.*, 2015a, p. 36). The criteria for the selection and development of these indicators are based primarily on relevance, cost of production and information value. In this sense the existence of updated cadastral data to reduce the cost in obtaining information becomes fundamental.

Code	Name	Description
Axis 1: Compactness		
01	Urban housing density	Housing net density per hectare. It evidences consumption of residential land.
02	Inhabitants density	Inhabitants net density per hectare. It is complementary to the previous.
03	Absolute compactness	Building intensity, equivalent to building volume on a given surface.
04	Percentage of pedestrian road	Percentage of public road intended foot citizen.
05	Alternative transportation proximity	Percentage of population with access to three or more modes of transport other than the private car.
06	Pedestrian accessibility	Degree of accessibility on foot for the public road.
07	Percentage of closed condominium	Percentage of area destined to gated communities.
08	Empty lots area	Percentage of unused land or buildings on the block.

Axis 2: Diversity of uses		
09	Urban complexity	Diversity and frequency of uses. It evidences the mixture of activities.
10	Ratio of activity and residence	Ratio of commerce activities and the amount of housing.
11	Daily commerce activities	Simultaneous coverage of day-to-day commerce activities.
12	Spatial and functional continuity of corridor	Street interaction in relation to percentage of pedestrian road and complexity of uses.
Axis 3: Urban green		
13	Permeability of public land	Degree of permeability public land.
14	Green area per capita	Ratio of public green space and the number of inhabitants.
15	Volume of green in public space	Percentage of volume street occupied by vegetation.
16	Proximity to the nearest green area	Closeness of the population walk to the nearest green area.
17	Simultaneous proximity to three types of green areas	Closeness of the population walk to three types of green areas.
Axis 4: Socio-spatial integration		
18	Provision of infrastructure	Simultaneous coverage of different types of infrastructure.
19	Percentage of households in quartile 1	Fraction of households cataloged in quartile 1.
20	Socio-spatial segregation	Percentage of low-income population, measured in quartiles.

Table 1: Indicators system proposed

2.1 A synthetic index of sustainability

After the building of these 20 urban sustainability indicators, the Sustainable Urban Densification Index is proposed by obtaining four sub-indexes (Table 2). These in turn are built from 9 of the 20 indicators.

Sub-index	Indicator	Optimum value
Housing and diversity of uses	Urban housing density	>40 dwellings/hectare
	Urban complexity	>4
Pedestrian accessibility	Pedestrian accessibility	>75%
	Alternative transportation proximity	100%
Urban green	Green area per capita	>15m^2/inhabitant
	Volume of green in public space	>30%
	Simultaneous proximity to three types of green areas	100%
Socio-spatial integration	Percentage of households in quartile 1	25%
	Socio-spatial segregation	0,76-1,25

Table 2: Sub-indexes for calculating the synthetic index

The Sustainable Urban Densification Index represents the relative valuation of sustainability in terms of density and composition through the four sub-indexes, allowing a global reading and facilitating comparisons. Additionally, the results are normalized to values from zero to one, with zero being the lowest and 1 the highest value of sustainability (Hermida *et al.*, 2015a, p. 123). The index and the values of these indicators are represented through the regular grid of 200x200mm (Figure 2).

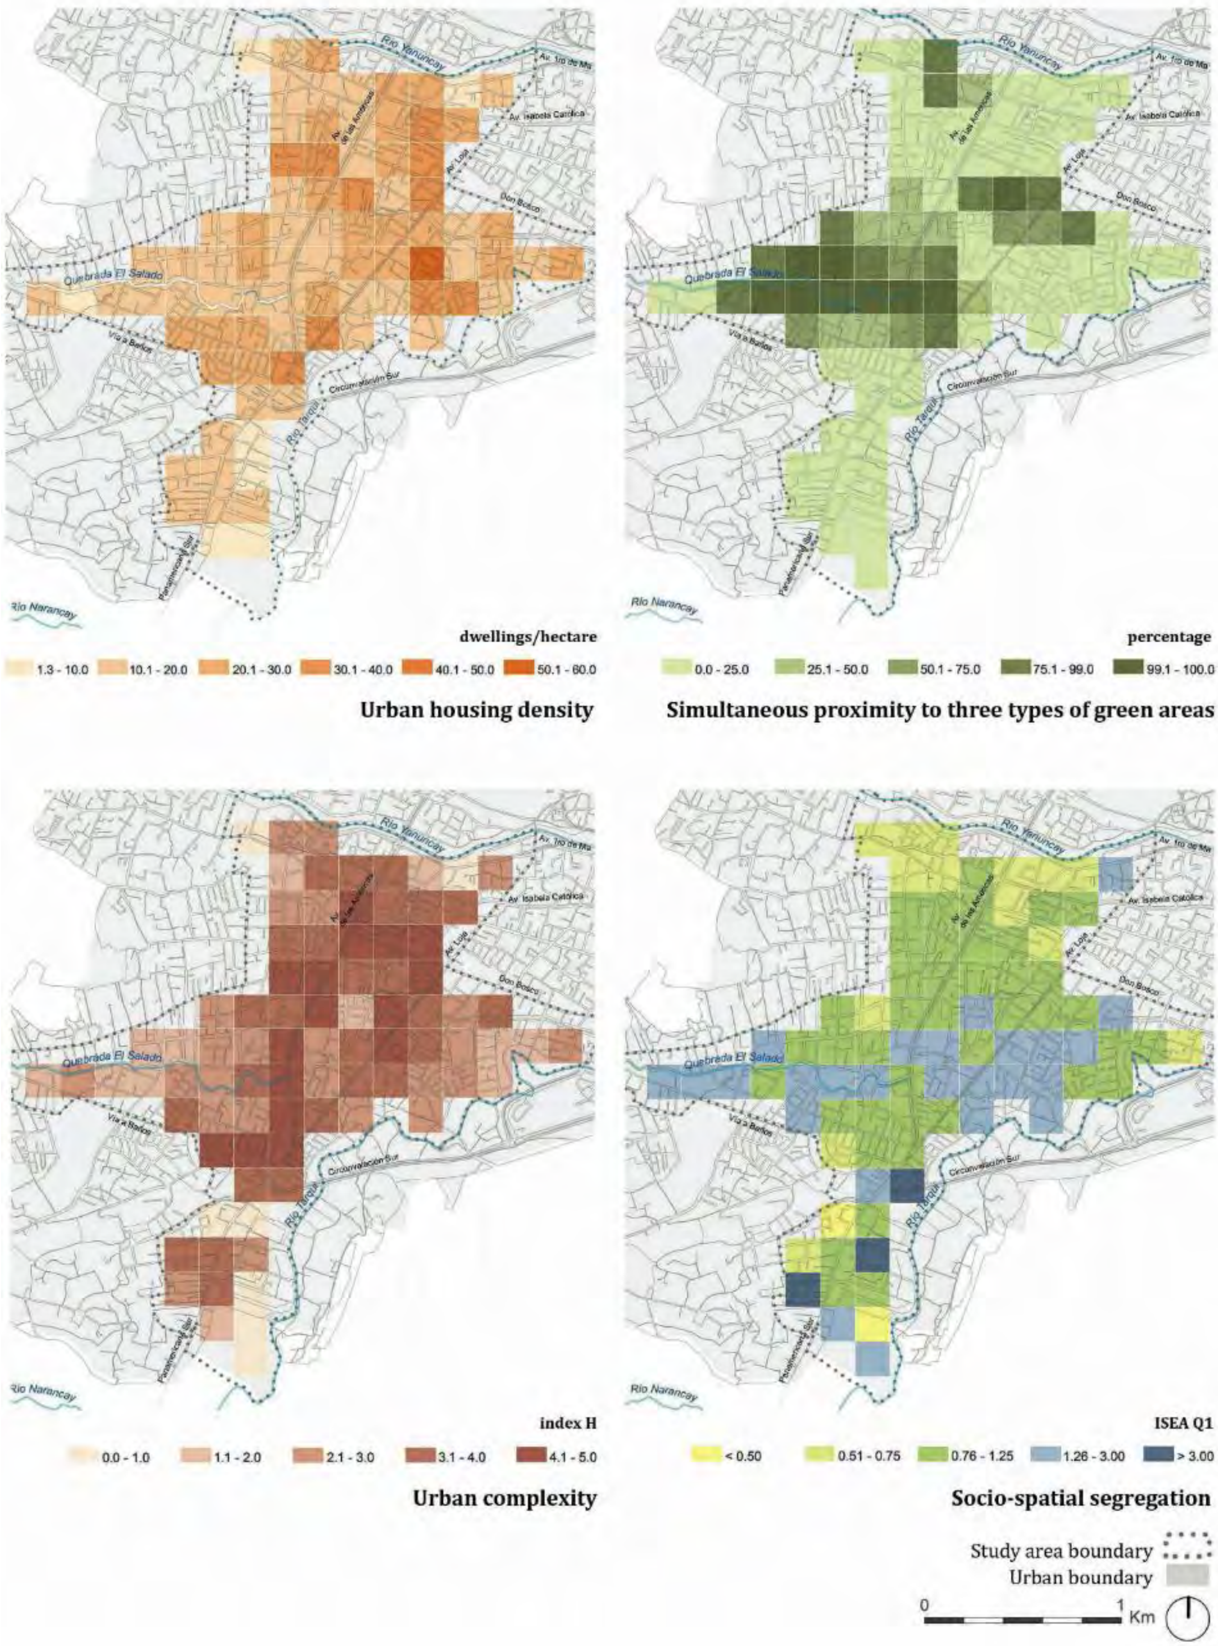

Figure 2: Spatial representation of indicators

3. AUTOMATION

The calculation of the indicators and the index is automated within GIS, using process flows that take data entry, stored inside geographic layers and tables, perform spatial aggregation operations, overlay, execute statistical calculation and produce results which are referenced to each grid cell (Figure 3). A tool for calculating each indicator and a tool for calculating the Sustainable Urban Densification Index using ArcGIS 10.3 has been implemented. These tools are clustered in a "Toolbox" and can be executed through a friendly graphical user interface or through a command line that allows greater flexibility.

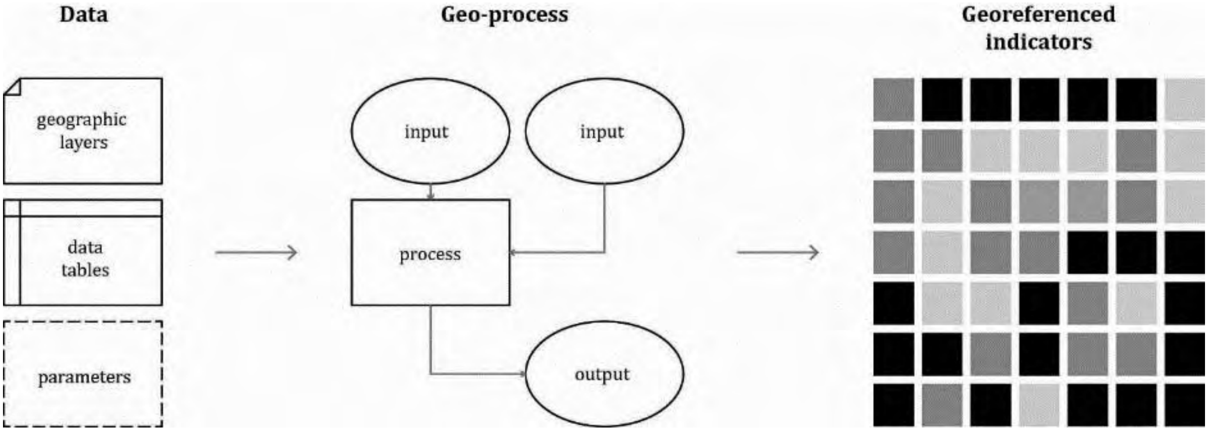

Figure 3: Schematic of process automation

To use the tools, a data structure is required so the names and locations of the input files should be standardized according to a table in the Toolbox. Table 3 shows an example of the input data required for the calculation of an indicator.

Indicator	List of data needed with the required name	Description
Percentage of households in quartile 1	Malla_200x200.shp	Shape with the grid of 200x200m. Each cell must be assigned with a code.
	Manzanas_Condiciones_Vida.shp	Shape with blocks, whose attribute table contains the number of total households and the number of them in quartile 1, considering four elements: construction quality, access to public services, education and health services affiliation (Orellana and Osorio, 2014).

Table 3: Required information for calculating the indicator "Percentage of households in quartile 1"

The files generated by each tool are automatically placed in a folder output structure depending on the indicator or index, which includes: a) the original files of each indicator; b) the intermediate files generated by geo-processes; and c) the final file that corresponds to the spatial representation of the values obtained for each indicator (Figure 4).

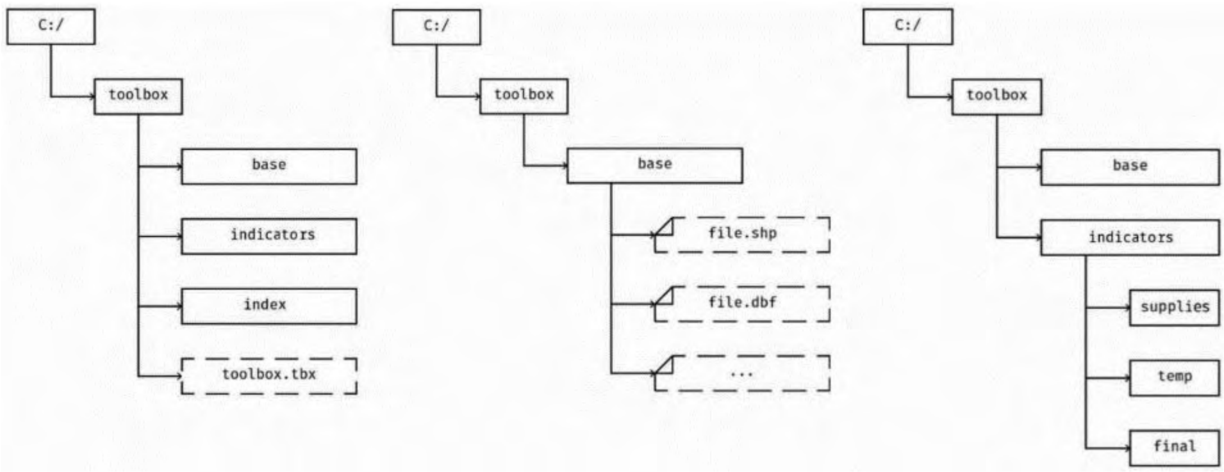

Figure 4: Organization of the information required for automation

To calculate the index, results of 9 indicators are required; therefore it is necessary to run the tools to calculate each indicator first. In order to facilitate the use of the Toolbox, each automation process is accompanied by a management protocol -a detailed explanation of each indicator and suggested representation ranges-.

4. CONCLUSIONS

This automation process by using geographic information systems, aims to facilitate the evaluation of urban sustainability in terms of densification in different cities, using the same methodology, which allows comparison between different cities or different areas within the same city. The most important requirement of the proposed approach is the availability of the necessary input data, so the indicators intend -as far as possible- to use secondary sources available in local government, to avoid obtaining data in field. Therefore the result is partly dependent on the quality of information available, which is highly variable for Latin American cases.

The proposed Toolbox has been developed in such a way that allows the parameterization of the calculations and representation ranges, enabling the adaptation of the optimum values for different assessment approaches. This feature makes it a useful tool for a well informed and evidence based debate about different ways of assessing the parameters that affect sustainability, especially in terms of densification.

The Toolbox, a set of demonstration data, a tutorial and research documents are publicly available to all individuals and institutions. The next step in this line of work consists of the implementation of this tool in open source software as an effort to democratize access and use of information and public debate on the decision-making around our urban spaces.

ABSTRACT

The environmental conditions of urban areas are directly affected by the operation in their road intersections and by the amount of vehicles and its dispersion throughout the day. To measure these conditions, the present study aims to propose a Traffic Quality Index (TQI) applicable to urban intersections and for comparing traffic performance, bringing a comprehensive methodology about the parameters involved in intersection quality. To prepare the TQI, it was used the Delphi methodology, through opinion of traffic experts. The results supported the selection of a group containing five parameters, namely: delay per vehicle; stops per vehicle; average speed; fuel efficiency and queue size. The formulation of the TQI has been established based on the values of parameters scored and their respective weights and evaluated for use of sum or product. Aiming at its validation, the TQI was applied to four intersections (two of them non-signalized and the other two signalized), simulated by Synchro Studio 9 software, and the results were compared with those obtained by the HCM (Highway Capacity Manual) and ICU (Intersection Capacity Utilization). It was found that the TQI product is more sensitive to roads changes and is a tool to assist the development and evaluation of urban road design and traffic planning, and that its use is complementary to the HCM and ICU methodologies.

Keywords: policy and regulation, traffic quality Index, traffic simulation.

1. INTRODUCTION

The environmental conditions of urban spaces for vehicles are directly affected by the operation at their intersections, the number of vehicles traveling on the road network and its dispersion throughout the day. With the growth of cities and the consequent increase in the amount of circulating vehicles, public agencies responsible for the planning of cities have required impact studies road of new projects. These studies are aimed, among other things, assess the current quality of road intersections and estimate the future quality in a pre-established horizon.

There are several methodologies that can be used in studies of intersections, such as the Webster Method (Webster and Cobbe, 1966) and Percentile Method (Trafficware LLC, 2014). The most widespread is the Highway Capacity Manual - HCM (Transportation Research Board, 2010). The HCM has the criterion for evaluating the identification of delay per vehicle intersection or approach, measured in seconds per vehicle. Another very common methodology is Intersection Capacity Utilization - ICU (Husch and Albeck, 2003), which compares the volume of active traffic at the intersection with a traffic capacity.

However, the available methodologies are not yet able to predict the quality of traffic through a broader approach that considers a set of more comprehensive variables related to the quality and fuel efficiency, like delay per vehicle and capacity of the intersection, as mentioned, and number of stops, vehicle emissions, among others. In this sense, this paper proposes a Traffic Quality Index - TQI, whose determination was based through transport specialists opinion and quality indicator variables that could be measured by applying traffic simulation.

The formulation of TQI was based on procedure adopted by studies using the Delphi Methodology (Dalkey and Helmer, 1963) to obtain the opinion of experts to identify variables related to quality indexes. The final selection of the parameters was the result from consensus opinions obtained in feedback round.

The establishment of a Traffic Quality Index is of great importance for road impact assessments and can support decisions on physical and operational changes on urban roads. In this context this study is innovative because it provides a more comprehensive approach to assessing the quality of traffic that presented by the most known methodologies available.

2. TRAFFIC QUALITY INDEX DEFINITION

In this section the details of the Traffic Quality Index (TQI) definition are presented, such as the steps used, its formulation, questionnaire application, scoring criteria, traffic simulation and sensitivity analysis

2.1 Steps considered for the TQI

The TQI setting method is divided into sequential steps, being necessary, firstly, the formulation of the index, followed by traffic simulation, sensitivity analysis and validation. It is important to note that in the simulation stage were modeled intersections in two versions to enable sensitivity analysis. The version "A" shows the simulation of the real traffic volumes collected, whereas version "B" shows the simulation of half traffic volumes.

2.2 Election of study case

Following Delphi methodology (Dalkey and Helmer, 1963), two questionnaires were applied to experts who works with traffic planning or operation, one in each stage of the research. In the first stage, the Questionnaire 1 had variables related to quality indicators and participant should choose which would be included in the general equation and establish a weight of 0 to 100. Nine variables that indicates the quality of movement or environment and that can be obtained by traffic simulation were evaluated. They are: delay per vehicle (s); stop delay per vehicle (s); stops per vehicle (stops/veh); average speed (km/h); fuel efficiency (km/l); vehicles with denied entry to the road network (veh); maximum queue lengths (m); average queue length (m) and 95th percentile queue length (m).

Once these variables are measured on different scales and units, it was also necessary to establish, in the first stage, scoring criteria able to parameterize the values for variables in a predetermined range.

In the next step, the second questionnaire was applied showing the statistics based on the previous questionnaire answers. This way the participants could re-evaluate their answers based on the previous opinion of the group and, thus, allow the convergence of the results.

After completing the steps of selection of variables, assigning weights and scoring criteria, was made a sensitivity analysis of the index using the forms of sum and product operators, as the following equations (Equation 1 and Equation 2). These formulations represent two forms of aggregation of subindices commonly used to obtain a final index (Abbasi and Abbasi, 2012).

$$TQI_S = \sum_{i=1}^{N} W_i Q_i$$

Equation 1

$$TQI_P = \prod_{i=1}^{N} Q_i^{W_i}$$

Equation 2

where, $\mathrm{TQI_S}$ = Traffic Quality Index – sum formulation; $\mathrm{TQI_P}$ = Traffic Quality Index – product formulation; W = weight assigned to each variable; Q = score of the intersection for each selected variable, according scoring criteria developed; i = each variable included in the calculation; N = total number of variables included in the calculation.

2.3 Delphi questionary application

Questionnaire 1 was sent to a group of about 40 experts obtaining 23 valid responses, of which 18 have continued to research by completing the questionnaire 2. There is no consensus in the literature on the number of participants used in Delphi studies (Hsu and Sandford, 2007), however most of them uses between 15 and 20 responders (Ludwig, 1997).

The profile of respondents is made up of independent professionals, consultants , civil servants and academics who work with urban and transportation planning and traffic control in the brazilian states of Espírito Santo, Rio de

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Janeiro, Ceará , São Paulo, Rio Grande do Sul and Brasilia. Table 1 shows the results obtained regarding the inclusion of variables.

The results show that the variable 9 (95th percentile queue length) was not a relevant factor for calculating the TQI, according to the opinion of the respondents.

Nº	Variable	Measurement	Answers (%)		
			Include	Not to include	Undecided
1	Delay per vehicle	Seconds	94.4	5.6	0.0
2	Stop delay per vehicle	Seconds	83.3	16.7	0.0
3	Stops per vehicle	Stops/veh	72.2	22.2	5.6
4	Average speed	Km/hour	83.3	16.7	0.0
5	Fuel efficiency	Km/litre	83.3	16.7	0.0
6	Vehicles with denied entry to the road network	Units	66.7	33.3	0.0
7	Maximum queue length	Meter	83.3	16.7	0.0
8	Average queue length	Meter	100.0	0.0	0.0
9	95th percentile queue length	Meter	44.4	33.3	22.2

PS: Highlighted the highest values

Table 1: Results obtained in the Questionnaire 2 – Variables inclusion

The final responses were evaluate for inclusion rate, which was calculated for insertion into the TQI formulation to include divergent views of the respondents. Its value is equivalent to the percentage of inclusions to the total of valid responses, considering only the results "include" and "not to include". Regarding the weights of the variables, it took the median of the results in order to avoid the influence of extreme points. It arbitrated that the sum of all weights should result in one (1), thereby yielding the final weight used at the general TQI equation. Table 2 shows the results obtained. Variables with inclusion rate lesser than 70% were excluded (variables 6 and 9). Variables 2 and 7 were exclude to avoid redundancy since they have lower inclusion rates than the variables 1 and 8, respectively. Variable 4 was exclude because the delay is dependent on vehicle average speed, among other factors.

Nº	Variables	Resposes		Incl. rate x Weigth	Final weigth
		Inclusion rate	Weigth		
1	Delay per vehicle	0.9444	7	6.61	0.2778
2	Stop delay per vehicle	0.8333	8		
3	Stops per vehicle	0.7647	7	5.35	0.2250
4	Average speed	0.8333	5		
5	Fuel efficiency	0.8333	7	5.83	0.2450
6	Vehicles with denied entry to the road network	0.6667	5		
7	Maximum queue length	0.8333	8		
8	Average queue length	1.0000	6	6.00	0.2522
9	95th percentile queue length	0.5714	5		
			Sum	23.79	1.0000

Table 2: Inclusion rate, median and final weight of the variables evaluated in the questionnaires

2.4 Scoring criteria development

The selected variables were scored according to the classification given by the traffic simulator (Husch and Albeck, 2003), except “queue size” that was given by expert opinion because the software does not classify this variable. Thus, graphics were produced by correlation between the results ranges presented by the software to "delay per vehicle", "stops per vehicle" and "fuel efficiency" and standardized scale ranging from 0 to 10. These are graphs presented in Figure 1. It was used polynomial correlation because its greater adherence to the collected data.

The development of scoring criteria for the variable "queue" dismissed the outliers. A correlation was make between the valid responses from the questionnaires and the standardized scale. Note that the sensitivity of queue size decreases as increase its size.

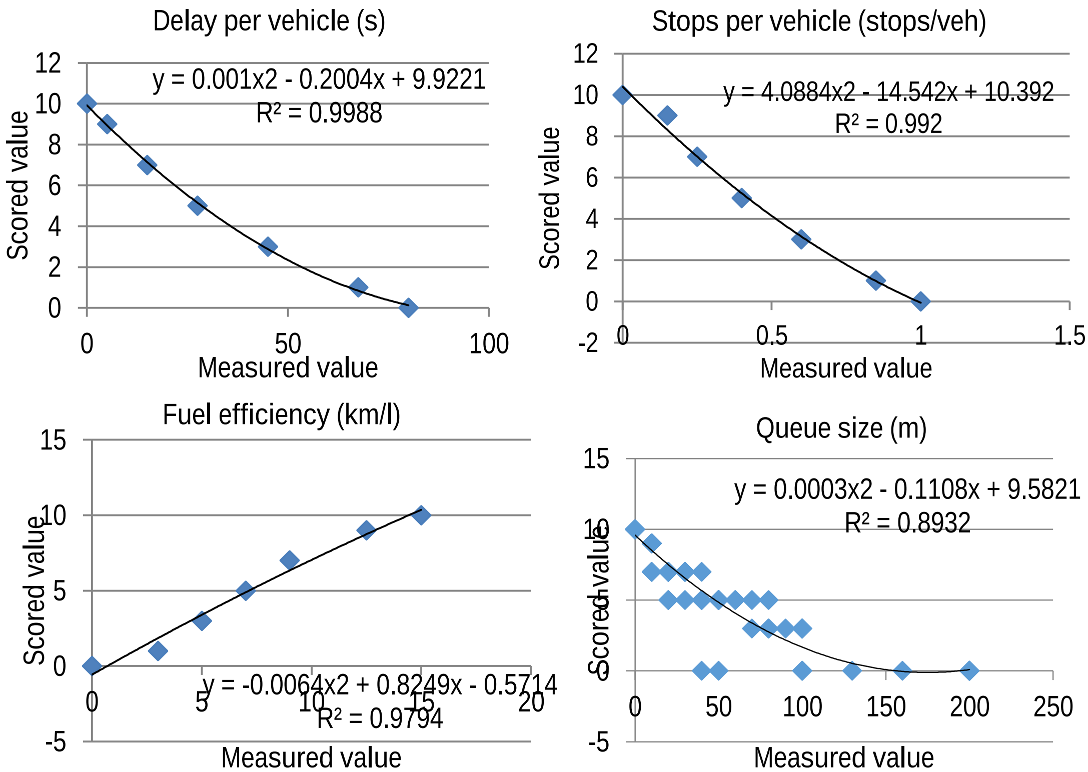

Figure 1: Score criteria to "delay per vehicle", "stops per vehicle" and "fuel efficience" variables

Thus, the equations that defines the traffic quality variables for TQI are represent by the following linear regression equations.

$$A = f(x) = 0.001x_a^2 - 0.2004x_a + 9.9221$$

Equation 3

$$P = f(x) = 4.0884x_p^2 - 14.542x_p + 10.392$$

Equation 4

$$E = f(x) = -0.0064{x_e}^2 + 0.8249x_e - 0.5714$$

Equation 5

$$F = f(x) = 0.003x_f^2 - 0.1108x_f + 9.5821$$

Equation 6

where A = Scored delay per vehicle (s); x_a = Measured delay per vehicle (s); P = Scored stops per vehicle (stops/ veh); x_p = Measured stops per vehicle (stops/ veh); E = Scored fuel efficiency (km/ l); x_e = Measured fuel efficiency (km/ l); F = Scored queue length (m); x_f = Measured queue length (m).

2.5 Traffic simulation

Equations 3 to 6 were applied in the quality evaluation of four intersections that has different flows, geometries and operational logistics, considering the peak vehicle volumes and its reduce it by half, in order to analyze the sensitivity of the formulation to the same geometric and operational characteristics. These intersections were modeled and simulated using Synchro Studio 9 (Husch and Albeck, 2003) to enable the achievement of results of TQI variables and to compare it to the ratios obtained for HCM and ICU.

Currently, there are several softwares used for traffic simulation, such as Vissim, Rodel and Sidra, highlighting to SimTraffic, Corsin and Aimsun. Simtraffic from Synchro Studio 9 package was used in this research (Husch and Albeck, 2003), since that is the most used in the city under study and the database of the intersections was accessible. The information is initially created through mesoscopic analysis in order to be simulated through the microsimulation and animation traffic.

The intersections selected for the simulation was a roundabout (intersection 1), a unsignalized (controlled by signal "stop" sign - intersection 2) and two pretimed (one with 3 and another with 4 branches - intersections 3 and 4). To sensitivity analysis, for each intersection was simulated an "A" version, with peak hour volumes, and a "B" version, with the volumes of the first version reduced by half.

The traffic simulation was performed with the software standard configurations and the total simulation time was 10 minutes. The results for delay and ICU are shown in Table 3 with their respective levels of service. The qualitative scale used to quantify "delay" level of service is the one presented by the Transportation Research Board (2010), while to quantify the "ICU" level of service is the one presented by Invalid source specified..

Intersection	Delay (s)		ICU	
	Measurement	Level of service	Measurement	Level of service
1A	43.4	E	0.99	F
1B	7.5	A	0.55	A
2A	12.3	B	0.68	C
2B	3.5	A	0.41	A
3A	68.5	E	0.77	D
3B	19.1	B	0.44	A
4A	20.6	C	0.84	E
4B	10.8	B	0.47	A

Table 3: Simulation results – delay and ICU

The results measured for input variables from TQI are shown in Table 4 with the respective scored values resulting from the application of the Equations 3-6.

Intersection	A		P		E		F	
	ME	SC	ME	SC	ME	SC	ME	SC
1A	7.4	8.49	0.25	7.01	4.6	3.09	27.45	6.77
1B	2.6	9.41	0.27	6.76	8.4	5.91	10.85	8.42
2A	2.8	9.37	0.30	6.40	11.9	8.34	10.98	8.40
2B	1.5	9.62	0.21	7.52	13.2	9.20	5.63	8.97
3A	18.8	6.51	0.48	4.35	4.0	2.63	38.30	5.78
3B	14.3	7.26	0.50	4.14	5.7	3.92	18.96	7.59
4A	17.2	6.77	0.36	5.69	2.0	1.05	39.14	5.70
4B	14.3	7.26	0.50	4.14	5.7	3.92	27.15	6.80

Note: ME = measured value; PN = scored value.

Table 4. Results for measured and scored variables

Then the TQI formulations were obtained through application of the final weights of the variables shown in Table 2 to Equations 1 and 2, resulting in Equations 7-8 listed below.

$$TQI_S = 0.2778A + 0.2250P + 0.2450E + 0.2522F$$

Equation 7

$$TQI_P = A^{0.2778} \times P^{0.2250} \times E^{0.2450} \times F^{0.2522}$$

Equation 8

where $\mathrm{TQI_S}$ = Traffic Quality Index – sum formulation; $\mathrm{TQI_P}$ = Traffic Quality Index – product formulation; $\mathrm{A} =$ Scored delay per vehicle (s); $\mathrm{P} =$ Scored stops per vehicle (stops/ veh); $\mathrm{E} =$ Scored fuel efficiency (km/ l); $\mathrm{F} =$ Scored queue length (m).

2.6 Traffic simulation

The scored values were applied to Equations 7 and 8 to obtain the values of TQI_S and TQI_P, respectively, from intersections. These results are shown below in Table 5 by intersection groups (A = traffic volume obtained by counting, B = traffic volume obtained by counting halved).

Intersection	TQI_S			TQI_P		
	A	B	B-A	A	B	B-A
1	6.40	7.71	1.31	6.00	7.58	1.58
2	8.20	8.88	0.68	8.13	8.84	0.71
3	4.89	5.82	0.93	4.62	5.56	0.94
4	4.86	5.62	0.76	3.95	5.41	1.46

Table 5: Results for TQI_S e TQI_P

Observed up through the columns "B-A" that TQI presents best results with volume traffic reduction, even with sum or product formulation. Furthermore, it notes that the values of the TQI_P column "B-A" are larger than the corresponding TQI_S, indicating that the first index is more sensitive to changes attributed.

Table 6 presents a comparison values obtained for TQI with HCM and ICU, both indexes commonly used in traffic analysis. It is observed that TQI large variations not necessarily imply ICU and HCM large variations.

Intersetion	TQI_S	TQI_P	ICU	HCM
1A	6.40	6.00	F	E
1B	7.71	7.58	A	A
2A	8.20	8.13	C	B
2B	8.88	8.84	A	A
3A	4.89	4.62	D	E
3B	5.82	5.56	A	B
4A	4.86	3.95	F	F
4B	5.62	5.41	A	B

Table 6: Comparison values obtained for TQI with HCM and ICU

The values obtained by TQI did not follow those obtained by the ICU and the HCM. The simulation results show ICU values with classification F with TQI_S ranging between 4.86 and 6.40 and TQI_P ranging from 3.95 to 6:00, that represents a very high amplitude. This fact occurs as two intersections with the same capacity utilization may have different values for TQI input variables (delay per vehicle, stops per vehicle, fuel efficiency and queue length).

Another example is the existence of intersection with E classification to HCM showing its TQI_S ranging between 4.89 and 6.40 and its TQI_P between 4.62 and 6.00. The explanation for this is due to the fact that the TQI considers a wider range of variables in its composition to describe the quality of traffic. In addition, "delay per vehicle" values from TQI are obtained by simulation, while the HCM is calculated by its own methodology (Transportation Research Board, 2010).

3. CONCLUSIONS AND RECOMENDATIONS

The proposed index consists of indicators commonly observed in transport planning routine through computer simulation. This allows its use as a tool for assessing quality of traffic and can be applied as a criterion in the process of projects and transportation planning.

The design of the TQI based on the opinion of the expert group covered in this research indicates that the quality of the traffic of an urban intersection can be better analyzed if include in the formulation stops per vehicle, fuel efficiency and queue length, than just the delay per vehicle variable. Thus, although the ICU and HCM are used to analyze the quality of traffic, TQI covers better this concept because includes the other parameters, all of them directly related to the traffic quality.

About its formulation, the TQI application to the simulated intersections of this study showed greater susceptibility of the product equation to the traffic volume change effects, and it is recommended this as an assessment tool format.

It is important to state that the index should not be static, because as the computational simulation tools allow obtaining new variables with reliable results, the formulation of TQI should be reevaluated.

ABSTRACT

Urban noise is a major nuisance and health hazard in Hong Kong. Existing assessment methods are limited in their capacities; many do not apply to high-density cities. We developed a numerical model capable of assessing individual or household noise exposure in high-density cities. The purpose is to provide a tool for population-based health research and to inform urban planning decisions. The model is based on ray-tracing techniques. It takes into account geometric spreading, air absorption, material reflection coefficient and scattering properties of surfaces. The model is being evaluated in lab experiment and field measurement while the balance is held between accuracy and computing efficiency. Results showed that the new model allows us to assess noise exposure for individuals and households in high-density cities.

Keywords: design process, acoustic simulation, urban noise environment

1. INTRODUCTION

Noise is a major pollutant and health hazard in dense cities. Excessive exposure to noise disturbs concentration and sleep, violates intellectual activities, and engenders adverse health effects (Basner et al., 2014; Berglund et al., 2000). Residents of high-density cities are more likely to suffer from a variety of noise sources due to the complex spatial configuration (Lam et al., 2013). It is important to understand urban noise environment and investigating noise-related health impacts (van Kempen & Babisch, 2012). Hong Kong is an exemplar of high-density city for Asia and the rest of the developing world, where, road traffic is the dominant source of urban noise. Existing researches found road traffic noise associated with adverse health impacts (Lam et al., 2012; Lam & Chung, 2012; Environmental Protection Department, n.d.; GovHK, n.d.). Existing study (Tang & Tong, 2004; To et al., 2002; Mak et al., 2010) applied LimA, a commercial noise-mapping software capable of calculating noise propagation (Brüel & Kjær, n.d.; Law et al., 2011) in combination with Calculation of Road Traffic Noise (CRTN) algorithm (Brüel & Kjær, n.d.; Department of Transport Welsh Office, 1988, Lam et al., 2012), a U.K-developed standard for road traffic noise.

Existing noise-mapping techniques are limited when applied to high-density cities. Most software is developed in European or North American context where building types and traffic profiles differ from those in Asian cities (International Organization for Standardization, 1996; Salomons et al., 2011). Most are "black-box" software with little flexibility for customized data input. Many are developed for stand-alone PCs and incompatible with cluster computers. Further, these softwares are difficulty for urban planners to operate and understand (Brüel & Kjær, n.d.). There is a need for an efficient tool that can be applied in dense cities and understood by urban planners (Ding et al., 2014, Pai, 2006).

We propose a novel numerical model to simulate the impacts of road traffic noise in complex spatial configuration or high-density cities. A pilot study was conducted in Sai Ying Pun neighbourhood in Hong Kong. This model returns the intensity of sound energy in 3D urban space. Results can be visualized to enhance understanding of noise environment for non-experts. This model is designed to be able to exchange data with urban planning software such as ArcGIS, Rhinoceros, and SketchUp Pro. It has the potential to serve as a planning and design tool. It would also support population-based health studies by linking traffic noise exposure and health outcomes at household levels.

2. A NUMERICAL MODEL FOR NOISE SIMULATION

This numerical model is proposed to assess household noise exposure in high-density cities. It consists three major sectors: 1) Identifying sound propagation paths with ray tracing; 2) Calculating sound energy attenuation along a propagation path; 3) Synthesizing echogram contributed by each path. The calculation process is concluded with noise exposure at receiver point.

2.1 Ray tracing

We applied backward ray tracing technique to simulate sound propagation in complex spatial configuration. Ray tracing has long been adopted for simulating sound propagation with multiple reflections. It traces the route and reflections of emitted rays for intersection with pre-located detectors (Krokstad et al., 1968; Kulowski, 1985). Seeing the difference between urban scale and wavelength of sound, we employed rays to represent sound propagation paths in high-density cities. We utilized the ray tracing engine of RADIANCE, a state-of-the-art day lighting simulation tool (Radiance-online n.d.). This tool has been extensively validated in many day lighting researches, yet to be applied for acoustic studies (Mardaljevic, 1995; Reinhart & Walkenhorst, 2001). It supports the manipulation of backward ray tracing, and facilitates efficient and accurate calculation of ray paths (Ward et al., 1988; Ward, 1994). We adopted this ray tracing engine for acoustic simulation through handling material characters, receiver parameters, noise source attributes, geometries, etc. In the ray tracing process, rays are randomly emitted from receiver points and intersection points following the Monte Carlo function. Through one or more times of reflection, they would end somewhere in the geometry. Only part of the rays, amongst all, is able to build connection between receivers and resources. These valid rays were then sorted out for ensuing calculation of attenuation through propagation (Figure 1).

(a) (b)

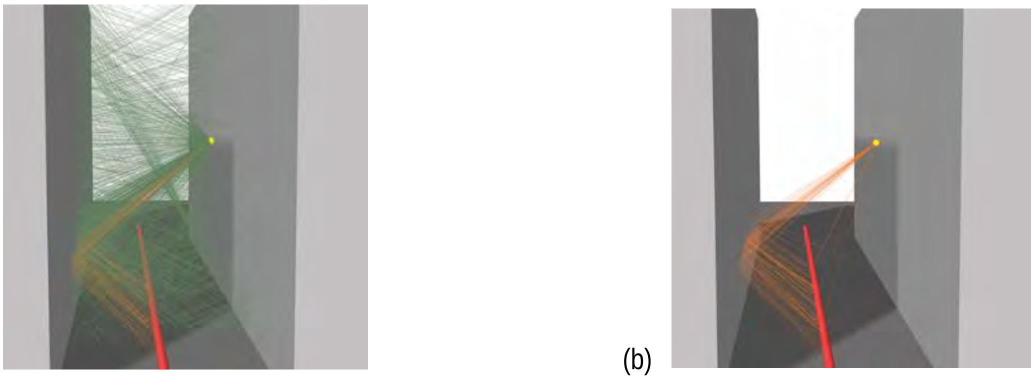

Figure 1: a) Rays are emitted from receiver point (yellow point) into space, including both valid (orange) and invalid (green) rays b) Only valid rays (orange strings) are able to build connection between sound source (red pipe) and receiver point through direct connection or reflections

2.2 Propagation attenuation

In high-density cities, where spatial configuration is highly complex, the propagation of sound rays is limited in horizontal direction. The propagation paths extend in vertical direction with multiple reflections. Therefore, in addition to attenuation in free field condition, the loss of sound energy upon reflection is considered prior to other types of excess attenuation in our model. Each valid ray contributes an echogram to a receiver point. This echogram is calculated with sound intensity at source and attenuation through propagation. The computation of propagation attenuation (AttenP) takes into account the characters of each ray and 1) Geometric spreading loss (Attengeo), 2) Air absorption (Attenair), 3) Reflection (Attenrefl) and 4) scattering (Attenscat) at reflection surfaces along all segments of each ray path, as expressed in Equation (1). Attengeo and Attenair account for attenuation along transmission in free field condition; and Attenrefl and Attenscat calculates sound energy loss upon reflection. Road traffic noise is calculated with local standard, i.e. the CRTN type of equation (Tang & Tong, 2004).

$$Atten_P = \sum_{k=0}^{n} f\left(Atten_{geo}, Atten_{air}, Atten_{refl}, Atten_{scat} \right)$$

Where n is the total segment number of the ray path

Equation 1

For road traffic noise calculation, cylindrical equation is adopted to calculate geometric spreading loss. Sound intensity attenuates in inverse proportion to the increase of propagation distance, independent from frequency (Attenborough, 2007). Air absorption varies with temperature, humidity, pressure, frequency, and transmission distance according to ISO 9613-1 (International Organization for Standarization, 1993). Energy loss due to multiple reflections is estimated with materials characters of reflecting surface. It includes noise reduction coefficient (NRC) and scattering coefficient, and is frequency-dependent. NRC accounts for the reduction of total sound energy upon striking a surface. Scattering coefficient calculates the distribution of energy in specular and non-specular directions. The angular energy distribution of scattered rays is calculated according to Lambert's cosine law (Kang, 2007). Figure 2 illustrates the attenuation of sound intensity at 1000 Hz along a random three-segment valid ray path in Figure 1.

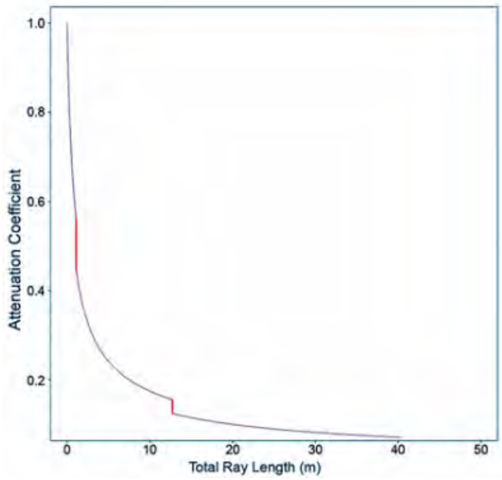

Figure 2: Attenuation of sound energy along single ray path
Blue curve depicts attenuation along propagation; red segment illustrates attenuation upon reflection
Meteorological and environmental parameters include: temperature: 23 Degree Celsius; humidity: 78%; atmospheric pressure: 101.3 Kpa; NRC of all surfaces: 0.2; and scattering coefficient: 0.2

2.3 Acoustic characters at receiver point

Final sound energy histogram at a receiver point is obtained from gross energy contributions of valid ray paths. Each ray path is connected with the geometry of noise source at one point, representing the intersection with traffic flow. Some intersection points are too closely located from another that their contribution cannot be considered independent. In that case, we applied a well-validated data clustering technique, density-based spatial clustering of application with noise (DBSCAN), to handle the intersection points. DBSCAN assembles closely agglomerated intersection points into clusters with a controlled distance ε (Chakraborty et al., 2011; Dai & Lin, 2012; Ester et al., 1996). Each cluster represents an independent vehicle (Figure 3). Contribution from direct rays, specular rays, and scattered rays are weighted and summed within the cluster. This process calculates the final sound intensity in spectrum at each receiver point. The output could then be transformed into sound pressure level or A-weighted sound pressure level.

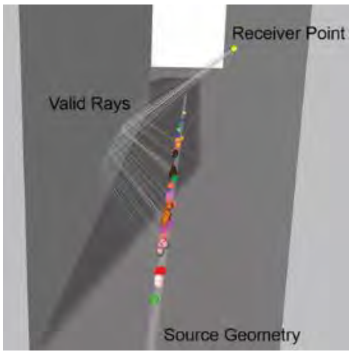

Figure 3: DBSCAN clustering technique; Clustered intersection points represented by Sphere Groups in different colour

3. PILOT STUDY AND DISCUSSION

3.1 Pilot study

This numerical model was tested with a road traffic noise simulation practice in a 200m * 200m area of Sai Ying Pun, Hong Kong. This area is representative for the complex spatial configuration in Hong Kong. Urban model was constructed with Rhinoceros 5 (Figure 4). To simplify, we assumed that surface material of buildings and ground is concrete, with NRC of 0.35 and scattering coefficient of 0.16 at all frequencies. An idealized road traffic noise was calculated with adjusted CRTN type of equation (Tang & Tong, 2004). It endowed a uniformed value: 70 dB(A) to all road segments, representing A-weighted equivalent sound pressure level per day ("L" _"Aeq,1d"). Source geometry was set as cylinder (r = 0.5m) sitting along road centre line on the ground. We referred to average weather condition of March and April in Hong Kong. The parameters are: 23 Degree Celsius; humidity: 78%; atmospheric average pressure: 101.3 Kpa. Number of scattered rays generated upon each reflection was 100; and maximum reflection time was 2.

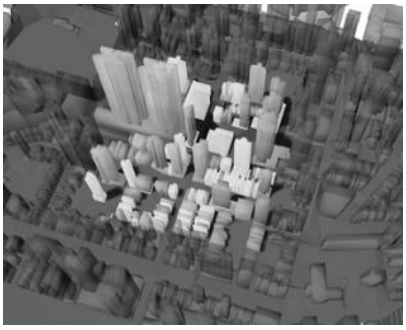

Figure 4: 3D Urban model of selected area in Sai Ying Pun, Hong Kong

A 20 * 20 point array, with an axial distance of 8m in both x- and y- axes, was fitted in with the geometry at the centre of the model area (Figure 5-a). This array was elevated 2m, 5m, 15m, 25m, 35m, and 115m above ground to examine the impact of traffic noise at different elevation. At each elevation, some points were covered by buildings; while others were exposed in urban open space (Figure 5-b). Those exposed points were valid receivers, which will be endowed acoustic characters at the end of the simulation process.

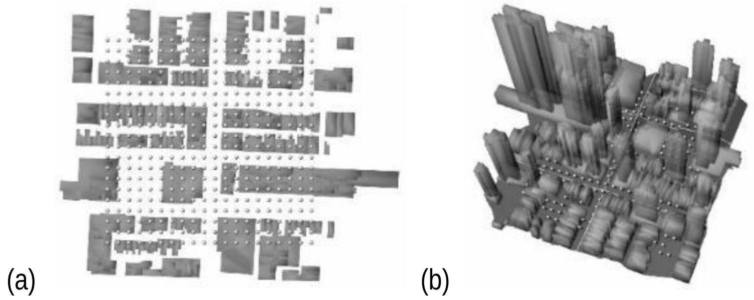

Figure 5 Receiver Array (Represented by Spheres) in Model
*(a) A 20 * 20 point array in the centre of the model*
(b) Point array (white balls) elevated at 5m above ground; white lines represent road traffic

3.2 Results and discussion

Simulation output were visualized as raster images, depicting sections of traffic noise impacts on respective elevations (Figure 6). Variation of traffic noise exposure was illustrated. Sound pressure level fluctuation of points on the same section became moderate while elevating the section upward. Meanwhile average sound pressure level turned moderate from ground level to the roof level of low-rise buildings (e.g. tenement buildings) (Figure 6-a, b, c), and increased afterwards (Figure 6-d,e,f). Results of Sai Ying Pun study contribute to better understanding of 3D urban acoustic environment. Being able to assess noise exposure at individual level in urban scale, our model may support population-based studies on the health impact of road traffic noise. It also suggests a potential of the model to serve as an urban planning and design tool.

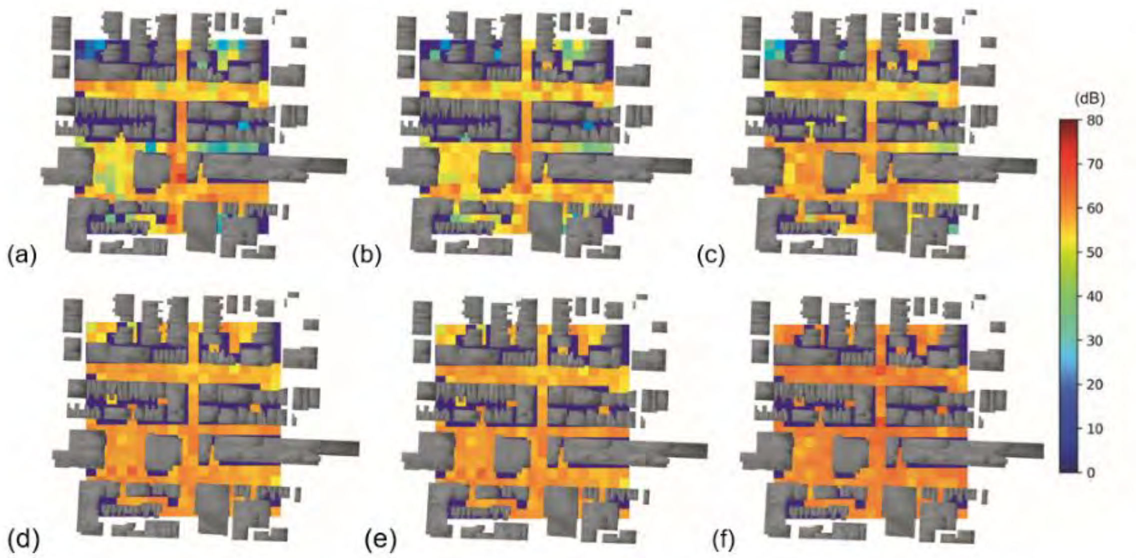

Figure 6: Acoustic sections of $L_{Aeq,1d}$ above ground at (a)2m, (b) 5m, (c)15m, (d)35m, (e)55m, (f)115m

There are several limitations in our numerical model. The time domain of propagation is not yet included, seeing that road traffic noise is expressed by time-averaged equivalent sound pressure level for calculation with CRTN model. We have neglected the wave character of sound by adopting ray tracing technique and geometrical acoustics. Compared to conventional engineering models, characters including diffraction, ground impedance, atmospheric refraction, and atmospheric turbulence are not yet considered. Validation study with lab experiment and field measurement is being scheduled.

4. CONCLUSION

In this paper we proposed a novel numerical model to simulate individual exposure to road traffic noise in high-density cities. We employed ray tracing, geometrical acoustics, and clustering technique in the algorithm. A pilot study in Sai Ying Pun, Hong Kong was conducted. Results presented the impact of traffic noise in 3D urban space

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

with different elevations. This model has a potential to assist population-based studies for uncovering health impacts of road traffic noise. It may also serve as a planning and design tool, and facilitate efficient knowledge sharing among planners and designers, also with other stakeholders. Lab experiment and field measurement is being scheduled.

ABSTRACT

Nowadays, sustainable building is a relevant research area by the current global trend to apply science in order to improve the life quality of the ever-growing populations. It is hard to develop a prior complete plan to ensure the best use of materials, energy, hard-working and then less environmental pollution once a construction is finished. To help in these projects there are several approaches from different disciplines using a broad set of search techniques or heuristics combined with some computer assisted simulators and programs where the goal is to find the best match between design and sustainability.

In this work we will use a new approach of populational heuristics: the Quantum-Inspired Evolutionary Algorithm (QIEA-R) and the SBTool rating system. Although traditional evolutionary algorithms have demonstrated good outcomes when applied in several models of sustainability in buildings, there are some drawbacks that make them not good at all. To avoid these difficulties, we propose to use the QEIA-R to find the best combination of building criteria.

This algorithm uses the quantum mechanical foundations of superposition of states to improve speed and less computation to find best solutions. Also the QIEA-R can search solutions over continuous domains and, the building problems need a continuous solving approach. The effectiveness of our work will be proved using the SBTool rating system and a sustainability criterion set suitable to Arequipa City in Peru. Thus, in this work we will present a case study over the city of Arequipa. Results will demonstrate efficiency in computational time and resources, and open a new research line in the field of quantum algorithms applied in optimization of sustainable buildings.

Keywords: green infrastructure, evolutionary algorithms, quantum-inspired

1. INTRODUCTION

Sustainable Building (SB) as a research and development area have changed the way of conducting building projects all over the world. Countries are experimenting a fast population growth, and some resources are now not available at all. The need of spend less money, time, energy and resources in a building project have carried a big set of approaches in different areas. The common goal is to develop the best plan in order to have the best match among the building functionality and sustainability.

Computer Science (CS) have widely opened a research area in SB. Algorithms can speed up any kind of process, and buildings use a big set of data to be processed and help professionals to take decisions. Several CS approaches to SB have been placed promoting solutions around metrics, statistics, heating ventilating and air conditioning systems (HVAC), topography and so. Most of them use optimization methods to achieve their goals (Baños, et al., 2011). Heuristics Methods (Somayeh, et al., 2014) include a set of search algorithms, and includes the Evolutionary Algorithms (EA) which is base of our work. Almost all of these algorithms work under a discrete domain. Although some problems can be modeled under discrete domains, and heuristics and evolutionary algorithms have demonstrated good results, we found out that in SB the discrete scenarios are just a bit of the problem.

In this work we will demonstrate the efficiency of the Real Coded Quantum Inspired Evolutionary Algorithm (Abs da Cruz, et al., 2007) (QIEA-R), which have been constructed to work with continuous values. The QIEA-R takes advantage of the principles of Quantum Computing (Hey, 2002) (QC) to construct a population that simulates superposition of states. We apply this approach to a building case study over the Arequipa city in Peru. Finally, we will validate the results using the SBTool rating system.

Our motivation is to open a new branch of SB studies, promoting the use of all the SB benefits in Peru and to achieve the goal of sustainable countries. This paper is divided as follows: section 2 the related work, section 3 the QC basis, section 4 the QIEA-R algorithm, section 5 the experiments, finally in section 6 the conclusions and future work.

2. RELATED WORK

Building projects are being executed all over the world since memorial dates, human and natural resources are the main components in every project. Over the last decades, science and technological development have provided help to humans in performing projects using less energy (Rivard, 2006). Unfortunately, at the opposite site, this faster global growth has increased an unconscionable use of natural resources (Schultz, et al., 2016). Another concern is the building final product, once a construction is finished it produces pollution and needs energy to satisfied human daily needs

SB enforcement brings a new era in conducting building projects (Happio, et al., 2008). Different research areas promote the application of their techniques to spend less time, resources, pollution and energy. CS uses a good set of algorithms and programming techniques to achieve SB goals. Our approach is novel, but we present the following related works.

Multi Agents Systems in HVAC systems (Wang, y otros, 2011) are the easiest sample to understand that a building needs constantly carry energy to several power devices to ensure human wellness. Multi Objectives approaches solve problems when several objectives are needed (Yao, 2014). Genetic algorithms (Rowe, 2012) are a subset of Evolution Algorithms (Sarker, et al., 2002), which simulate Darwinism evolution theory.

In (Caldas, et al., 2003) Caldas and Norford use Genetic Algorithms (GA), their work focuses on HVAC control to achieve energy optimization, and perform a building envelope simulation to improve the lightness in rooms. They use a Pareto and non-Pareto basis approaches. One of the drawbacks of GA is the fact to define a good fitness function; another one is that GA can suffer of stagnation due to local maximums.

Shea et al. (Shea, et al., 2006) define the Multicriteria Ant Colony Optimization method (MACO) that uses a Pareto filtering. The task is to improve building envelopes for lighting performance. This Pareto approach do not search the best result among all criteria, it eliminates solutions and evolve just a few set of individuals.

Wu and Thomas (Wu, et al., 2012) use a GA putting in surface the three well-know objectives in SB which are economical aspect, energy performance and end-user comfort. They use a building simulating program called EnergyPlus. Fuzzy logic is carried out to define the best temperature of any ambient. The GA is developed using a Multi Objective approach which have three objectives functions mentioning the SB objectives.

3. QUANTUM COMPUTING

Since many years QC (Hey, 2002) is taking more and more enforcement. The reason is quite simple; the idea of faster data computing opens a new way of think about computers. Actually, we all know computers use binary bits as the minimum element to store information. Binary bits just can store 1's or 0's. In QC the bit now is represented as a Q-bit, that can represent not only 1 nor 0, but any combination of them. The common representation of the Q-bit is:

$$|\Psi\rangle = \alpha\,|0\rangle + \beta\,|1\rangle$$

Equation 1

where "Ψ" represents the state of the Q-bit, α and β are complex numbers. The Q-bit instead of the well-known binary bit, can contain more information letting computers perform more computations, improving the computation cost and breaking some barriers that binary computers cannot.

Although quantum computers are not commercially available yet, studies have demonstrated good results in simulating QC basis over binary computers (Grover). Our work promotes the evolution algorithms using a quantum inspiration where they key is the manipulation of the Q-bit.

4. THE REAL CODED QUANTUM INSPIRED EVOLUTIONARY ALGORITHM

Abs da Cruz et al. (Abs da Cruz, et al., 2007) define an EA for real numbers using a QC approach. Their work focuses in numerical optimization. The motivation of our work is to demonstrate the efficiency of the QIEA-R applied to SB, due to the need of a continuous domain. The algorithm follows these steps:

Algorithm 1 Real Coded Quantum Inspired Evolutionary Algorithm

```
t ← 1
generate quantum population Q(t) with N individuals and
  G genes
while (t <= T) do
  E(t) ←generate classic individuals while observing
  quantum individuals
  if (t=1) then
    C(t) ← E(t)
  else
    E(t) recombination with E(t) and C(t)
    evaluate E(t)
    C(t) ← K best individuals of [E(T) ∪ C(t)]
  end if
  Q(t+1) ← Update Q(t) using best individuals of C(t)
  t ← t+1
end while
```

Figure 1: Algorithm steps

4.1 The quantum population

In the same way a binary bit represents a binary population, the quantum population is made of Q-bits which represent the superposition of states (Hey, 2002). So the quantum population is made up of N quantum individuals q1 = (1, 2, 3, ..., N). Each quantum individual q1 is made up of G genes gij = (j=1, 2,..., G) and finally each gene is associated to a function that represents a probability density. The formal representation is:

$$q_i = [g_{i1} = p_{i1}(x),\ g_{12} = p_{12}(x),\ g_{iG}(x)\ ]$$

Equation 2

where i = 1,2,...,N, j=1,2,...,G , and pij represents a probability density function that is the probability of observing a value for a quantum gene when is under superposition. A gene is a pulse in a continuous domain and for our case represents a square shape. In the Figure 2 a pulse is created, it has a center point (μ), and a length (σ). So the task is to create a set of quantum individuals, each one with a set of quantum pulses. In Table 1 shows two individuals and two genes each one.

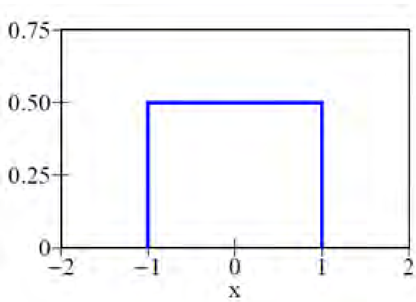

Figure 2: Quantum gene

Individual	Genes
q_1	g11 = (μ =-5, σ = 20), g12 = (μ =0, σ = 20)
q_2	g12 = (μ = 5, σ = 20), g22 = (μ =5, σ = 20)

Table 1: Example of individuals and genes

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4.2 Classic individuals

The next step creates the classic individuals for each gene, which are the real values in the space. The probability density function and a random number generator are needed for this step. The authors use a line function as a probability density function. Having the random number r in the [1] interval, we use the line formula:

$$x_{mj} = r_{mj} * \sigma_{ij} + (\mu_{ij} - \sigma * 0.5)$$

Equation 3

Once the classic population has been created, we need validate it using an optimization function. Abs da Cruz et al. (Abs da Cruz, et al., 2007) use the QIEA-R for function optimization. In our work we define a domain with continuous values to optimize; the more the values close to a desired point, the best optimization we get. After the validation step, the evolution process begins. Abs da Cruz et al. propose 4 possible approaches to replace or update the last population: replacing the old population with the new one, replacing the old population but preserving the best one, replacing the n worse individuals with the n best individuals of the new population and replacing the n worse individuals with the n whichever new individuals.

4.3 Quantum population update

To achieve the evolution approach each quantum individual must be updated. As we are working under a continuous domain, the main criterion is to ensure the candidates to suffer modification to enclose them to the answer. For each gene the μ value must be relocated and the σ value increased or decreased. Abs da Cruz et al. use the 1/5 rule (Michalewicz, 1996), which is a heuristic to modify the individuals boundaries. If the amount of individuals that have been replaced by others of the new generation is greater than the 20%, σ is divided by a random value δ in the interval]0,1[. If it is lower than the 20%, σ is incremented. Otherwise there is no change. In Figure 3 the complete algorithm schema.

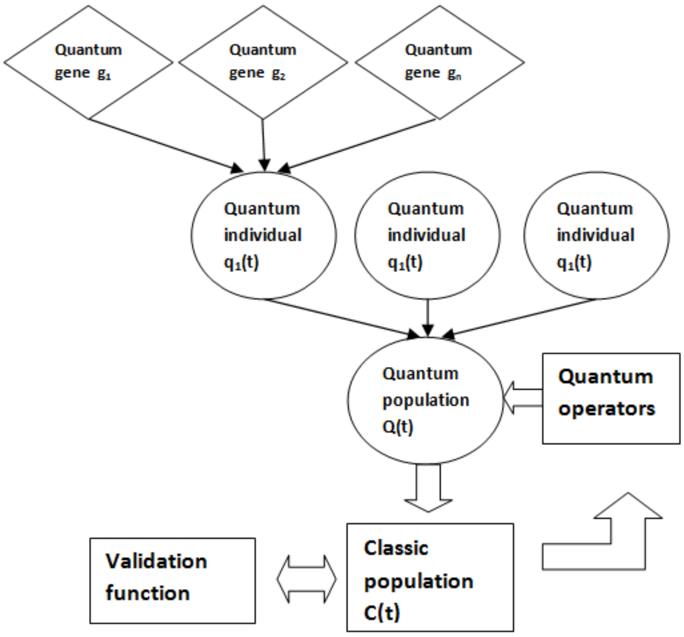

Figure 3: Algorithm schema

5. EXPERIMENTS

The novelty of this work is to use the QIEA-R in a real building case study to get the best score in sustainability using the SBTool as a rating system. We work hand by hand with a research group of architects that validates SBTool input data and score. This last due to this paper is part of a government research project.

5.1 Using the SBTool rating system

The International Initiative for a Sustainable Built Environment (iiSBE) developed the Sustainable Building Tool (SBTool) (Larsson, et al., 2012). It is a framework that can be calibrated by region depending the conditions and needs. We rate our work using the SBTool criteria. Table 2 shows some highlights of Arequipa conditions set in SBTool. As an important note, Arequipa city has the title of Cultural Heritage of Humanity by the United Nations Educational, Scientific and Cultural Organization (UNESCO). In Table 3 the SBTool criteria used is showed. This work uses these data as input for the algorithm and then brings the best rate possible.

Item	Descriptors of Condition
Ecological Sensivity Classification	High: Areas that contribute to regional biodiversity but lack critical habitats for at risk species. Development should generally avoid these areas.
Flooding Risk Classification	Location is a Medium-Low Risk Zone for flooding
Site location with respect to earthquake risk classification	Site is located in a High Risk Zone, with soil capacities <0.7 kg/cm2, a period of vibration of 0.52 sec. and a high probability of liquesfaction
Volcanic risk classification	Location is in a High Risk Zone
Availability and enforcement of urban planning regulations, including zoning of land uses, occupancy types and building heights	The content or geographical coverage of regulations covering zoning of land uses, occupancy types or building heights provides a high degree of guidance for future growth
Availability and adequacy of municipal water supply in the urban region	The municipal system has some quality and/or supply problems
Public transport system in the urban area	There is no public transport system, and private services are poor.

Table 2: Arequipa city context information

SBTool Issues	SBTool Categories
A Site Regeneration and Development	A1 Site Regeneration and Development, A2 Urban Design, A3 Project Infrastructure and Services
B Energy and Resource Consumption	B1 Total Life Cycle Non-Renewable Energy, B2 Electrical peak demand, B3 Use of Materials, B4 Use of potable water, stormwater and greywater
C Environmental Loadings	C2 Other Atmospheric Emissions, C3 Solid and Liquid Wastes, C4 Impacts on Project Site, C5 Other Local and Regional Impacts
D Indoor Environmental Quality	D1 Indoor Air Quality and Ventilation, D3 Daylighting and Illumination, D4 Noise and Acoustics
E Service Quality	E1 Safety and Security, E2 Functionality and efficiency, E3 Controllability
F Social, Cultural and Perceptual Aspects	F1 Social Aspects, F2 Culture and Heritage
G Cost and Economic Aspects	G1 Cost and Economics

Table 3: SBTool manipulation data

5.2 Using the QIEA-R with SBTool input data

We follow the steps of the algorithm in Figure 1. We define a quantum individual for each SBTool criterion, each quantum individual is made up for a variable number of genes. We use the line function as probability distribution. We use the SBTool score to optimize the population. For updating we choose to replace the worst n individuals with the n best ones. In figure 4 the evaluation step uses the SBTool as engine to get the highest score per criteria and overall score.

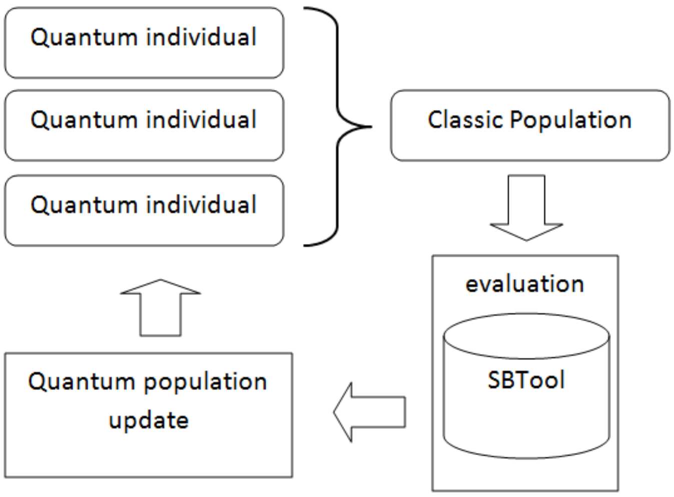

Figure 4: Algorithm steps

We encourage the use of a minimum number of genes per individual and a small number of individuals. In Table 4 we evaluate a population of 1000 individuals with a different set of genes per individual. The best score is 3.74 and the worst 3.70 meaning a big number of genes per individual are not necessary see Figure 5. So we proceed to work with different number of individuals and just one set of genes per individual. Table 5 shows a pretty similar best score using a really different number of individuals with the same number of genes. See Figure 6.

The quantum approach of superposition of states demonstrates the effectiveness of the algorithm. Having a small number of individuals is enough to reach the best result. We perform 100 iterations in every evaluation, over that number the result remains the same. The quantum algorithm converges fast.

Individuals	Genes per Individual	Overall Score
1000	500	3.74
	250	3.74
	150	3.74
	100	3.72
	50	3.72
	25	3.70
	10	3.70

Table 4: Quantum population with different genes per quantum individuals

Individuals	Genes per Individual	Overall Score
5000	20	3.74
2000		3.74
1000		3.73
500		3.73
250		3.72
100		3.72
50		3.70

Table 5: Different number of quantum individuals using a same number of genes

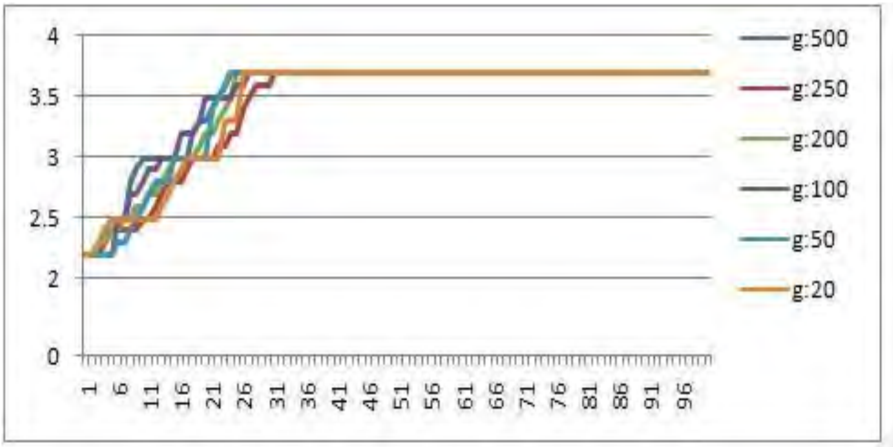

Figure 5: 1000 Individuals and a set of different number of genes

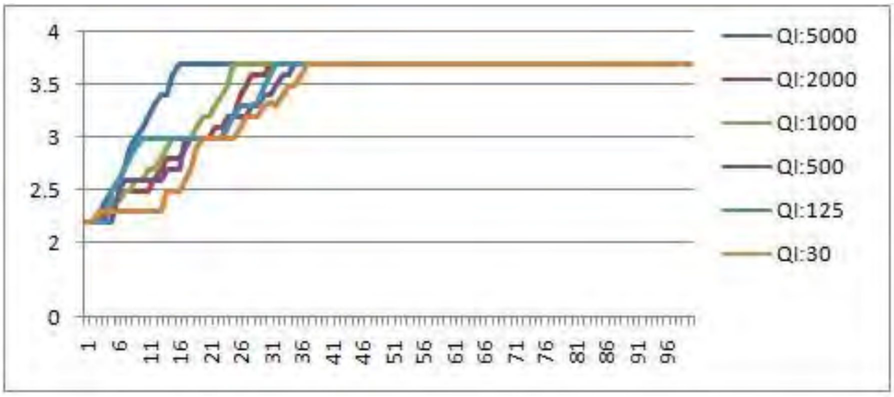

Figure 6: 20 Genes with different number of quantum individuals

5.3 Case study

We perform the design simulation of a building project. The structure is a dwelling house with a total of 120m2, total built area 36.83m2, no built area 83.17m2, 2 floors, 3 bedrooms, 2 bathrooms, 1 dining room, 1 kitchen. Figure 7 shows the rendering of the structures. In Figure 8 a screenshot of the SBTool results B+ that represents a Good Practice or better, and in Figure 9 the table screenshot of the weighted criteria and the project score 3.74.

Figure 7: Building rendering

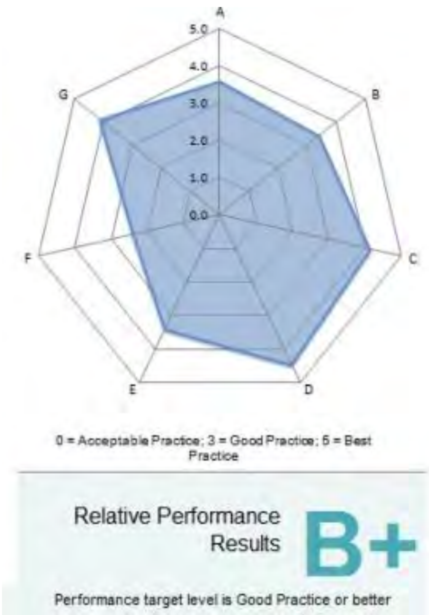

Figure 8: SBTool relative performance results B+

A	Site Regeneration and Development, Urban Design and Infrastructure	10.5%	3.6
B	Energy and Resource Consumption	33.9%	3.4
C	Environmental Loadings	39.0%	4.2
D	Indoor Environmental Quality	4.3%	4.5
E	Service Quality	5.7%	3.4
F	Social, Cultural and Perceptual Aspects	4.5%	2.4
G	Cost and Economic Aspects	2.0%	4.1
	Weighted project score		**3.74**

Figure 9: Weighted project score 3.74

6. CONCLUSIONS AND FUTURE WORK

We use the QIEA-R for a continuous SB approach. We used the SBTool as a simulator in order to get the best sustainable score in the building project. Using the benefits of the SBTool we can choose for example the best geographical point to place the building before any kind of work. Also, is possible to define a set of materials, comfort devices and so depending of the changing conditions that the algorithm can set on the march.

The effectiveness of the algorithm has been demonstrated speeding up the evolution process and using less resources. A professional approval is done under the supervision of the project expert group we work with. As a future work we will compare traditional GA and EA against the QIEA-R. Finally, the Sustainable Building research and development area will be deeply introduced to the Peruvian reality. This is one of the goals of this government-funded project. Sustainable Building is a need for everybody; we must enforce populations in every project to conduct their tasks using SB principles.

ACKNOWLEDGMENT

The authors would like to thank the San Pablo Catholic University of Arequipa Peru and the National Council for Science, Technology and Innovation (CONCYTEC) of the Peruvian government for funding this project.

ABSTRACT

The traditional approach to energy efficiency in building retrofitting brings poor results in terms of urban sustainability, resource efficiency and economic return. In order to fulfill the EU-targets for 2030 and 2050 and to support the necessary building-retrofit market, the European project FASUDIR was established under the framework of a FP7 R&D program. FASUDIR provides an Integrated Decision Support Tool based on a new methodology supported by a software tool that will help decision makers to select the most suitable energy retrofitting strategy to increase the sustainability (economic, social and environmental) of a whole urban district. The Decision Support Methodology developed in FASUDIR guides planners of neighbourhood retrofitting projects in a structured way through several phases of the project. The Methodology starts with the preparation phase comprised of data collection and data entry. The diagnosis phase demonstrates planners and stakeholders the current state of the neighbourhood in terms of sustainability and overall energy efficiency. The decision-making phase helps planners to create optimized energy retrofitting variants for the neighbourhood. It allows considering the neighbourhood as a global energy system by assessing heat and electricity related synergies and interactions between buildings. Based on the results the planners are able to design heat networks and to plan the inclusion of renewable energy sources taking into account smart grids and energy storages. The created energy variants can be assessed and ranked with regard to their sustainability by a MCDA approach and the use of several simulated Key Performance Indicators (LCA, cost, energy, social aspects).

Keywords: urban district regeneration, sustainability, energy, holistic decision-support, software tool, neighbourhood

1. INTRODUCTION

The current results of retrofitting interventions on building scale have shown that the effectivness of building retrofitting can be increased significantly through considering each building as a part of a global energy system in a district [6] [7]. This follows the approach of considering all buildings located in the same district as an entity. In this case the application of retrofitting measures is not limited to single buildings only but can be applied on district level through exploiting synergies and interactions between buildings and their surrounding infrastructure and environment. While planning retrofitting concepts for single buildings is a challenging task the complexity and work intensity for planners on district scale increases significantly. While acting on district scale planners have to consider how implemented measures on single buildings may affect the implementation of measures for other buildings located in the same district. Retrofitting measures on single buildings even may have negative impacts for other buildings or the whole district sustainability performance if they are not planned proactively. For instance, the feasibility of establishing heat networks between buildings is strongly depending on the available heat demand density in an area. Thus, planners in district retrofitting projects have to assess if retrofitting measures on single buildings like improving the building envelop are more sustainable than connecting the buildings to a renewable driven heat network. In order to find the optimum solution in terms of sustainability for a whole district planners have to consider several criteria like the total impacts on the environment, the life cycle costs, the return of investment as well as social impacts of the planned measures. Moreover, in order to gather all the needed information for a sensible planning process and to achieve the most effective results planners have to cooperate with all involved stakeholders in a well-coordinated and structured way. Among others, representants of the municipalities, building owners, tenants, financing bodies and energy supplying companies have to be involved in all phases of the planning and implementation process. This presents a major challenge to planners of district retrofitting projects and can only be solved following a well-structured and thoughtful methodology which guides the planners and all involved stakeholders through the different phases of the project. To facilitate the planning on

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

district scale and to improve the effectiveness of the planning and implementation process of energy retrofitting measures the use of an advanced and integrated planning and decision-support tool (IDST) is indispensable.

2. FASUDIR METHODOLOGY AND DESCRIPTION OF THE INTEGRATED DECISION-SUPPORT TOOL (IDST)

2.1 The FASUDIR decision-support methodology

The execution of district retrofitting projects is a very multifaceted task for planners and all involved stakeholders. Compared to building level projects the complexity on district scale grows exponentially while the data availability declines. So, planners need a sophisticated decision-support methodology to handle the complexity in an appropriate way. Therefore, the FASUDIR Methodology divides district retrofitting projects into four main steps which planners can work off in a structured work process. The four steps are defined as followed:

- Preparation Phase
- Diagnosis Phase
- Decision-Making Phase
- Implementation Phase

2.2 Project preparation phase

The preparation phase is the foundation of each district retrofitting concept. In this phase all necessary data to create a citymodel for the use in FASUDIR is collected from several sources (GIS, CityGML, on-site inspection, owner and occupant surveys, etc.). The FASUDIR IDST supports planners in collecting the data by involving all stakeholders that may be able to provide needed data via an e-collaboration platform. Hence, planners are able to request data from different data providers in a structured data collection process. Stakeholders are able to share digital data or to respond on the requests of the planners. E.g. owners, ESCOs or representants of municipalities are able to upload geodata files on the platform which can be utilised by the planners or a data manager. Owners and tenants can fill an online-survey which asks them several for the building characterisation necessary data, that cannot be obtained from default data or on-site inspection from the outside of the buildings (heating system, average number of occupants, measured energy data, etc.) [4]. Planners use the e-collaboration platform as a supporting tool in the preparation phase. It supports them in acceleratíng the data collection by an improved information flow between planners and other stakeholders.

2.3 Project diagnosis phase

The next phase in the FASUDIR Methodology is called diagnosis phase. In this phase an evaluation of the current sustainability state is conducted and the useful targets for a district retrofitting project are defined. After the data entry process has been completed all necessary data to run a first simulation for assessing the current state of the whole district and all buildings in the district is available in the IDST Citymodel. The current state is analysed according to its global sustainability by the use of Key Performance Indicators (KPIs) which have been defined in the FASUDIR Methodology on building and district level [5]. To assess the current sustainability state of the district and each building the following in Table 2 listed KPIs are used:

Thus, all KPIs are calculated by the IDST based on the simulation results. Additionally, each KPI is compared to a defined benchmark from the methodology which allows evaluating the KPI result compared to a sensible average value. This allows the user of the IDST to identify the strengths and weaknesses of the district in terms of sustainability. A low KPI value in this case means that the sustainability issues which the KPI addresses must be improved. To support the visualization of the KPI results to the user the IDST provides a special KPI Analysis Tool which is used every time the user wants to check KPI results. The KPI analysis tool also is used to assess the created energy variants in the decision-making phase. Moreover, to enable a detailed evaluation of the district's and building's results the user has the possibility to display selected raw data of the simulation results. These for example are the direct simulation outputs which are stored in the building and district result records of the Citymodel. The user therefore is able to access and display all data that is stored in the city model databases on a map. Thus, the user also has the possibility to export the data generated in the current state evaluation for further purposes beyond the FASUDIR IDST.

2.4 Project decision-making phase

The decision-making phase is the third phase in the FASUDIR methodology. The decision-making phase enables the decision makers to define the district retrofitting project through the selection of the most sustainable retrofitting solution in terms. To achieve these objectives a structured methodological approach to fulfil all the needs has been developed. At the beginning the planners are able to create scenarios representing a district retrofitting project which are defined by setting measurable targets and objectives for the improvement of the KPIs. The target definition is based on the current state evaluation of the KPIs and is also linked to the e-collaboration platform. All involved stakeholders therefore can participate in the target definition process by giving votes on their targets and priorities.

2.5 Conception of retrofitting variants

After the main objectives for a project have been defined the planners are able to create different retrofitting variants. Therefore, it is possible to select different retrofitting measures on building and district level from a pre-defined selection list. In order to apply only useful and technically feasible retrofitting measures on buildings it is essential to know which retrofitting measures work well or may not work for the buildings or whole groups of buildings. Even though planners of retrofitting variants may have a good knowledge about the feasibility of different retrofitting measures the Methodology supports and guides them in the selection process. Therefore, the IDST provides a comprehensive tool box with several useful analysis functions that help planners in evaluating the feasibility of different solutions. The main challenge for planners in creating energy retrofitting variants for urban districts is to evaluate the impacts of different solutions onto the buildings and the energy supplying infrastructure in the district. Those synergies and interactions between buildings and the district were analysed deeply in the methodology development and can be assessed using the IDST. The provided retrofitting interventions in the IDST repository of technologies are classified according the following categories:

- Reduction of energy consumption (consumer-driven)
- Increasing the efficiency of the energy supply
- Inclusion of renewable energy production

All categories contain several traditional off-the-shelf retrofitting measures as well as new innovative ones at building and district level. On building level, it is possible to apply several envelop improvement measures (adding insulation, replacing windows, etc.), replace HVAC systems by more efficient ones, increase the efficiency of electrical appliances and to include renewable energy sources (photovoltaics, solar thermal systems, CHP, biomass fuel, etc.). On district scale, users can apply improvement measures in the fields of street lighting (LEDs), heating and cooling networks as well as renewable district energy systems (wind turbines, photovoltaic farms) and further. Moreover, planners have the possibility to assess the improvement of non-energy related measures in a scenario like increasing the green spaces in the district or improving the accessibility to public transport stations. The KPIs are simulated and assessed for each variant representing the different applied retrofitting interventions.

2.6 IDST analysis tools and functions

Following special analysis tools and functions to support the variant creation are provided within the IDST:

1. Analysis tool assessing the energetic weak points of buildings

In order to prioritize different retrofitting measures to reduce the energy consumption and to increase the energy efficiency of a building it is necessary to know which represent from an energy view the weakest points of a building. This means the FASUDIR IDST supports the users in identifying the building components or systems which cause the highest energy losses and therefore, have with high probability the greatest energy saving potential. Hence, with the Energetic Weak Points Tool the FASUDIR user is be able to plan the retrofitting measures in a way that allows exploiting the most effective energy savings.

2. Tool assessing the feasibility of heat networks

The FASUDIR IDST provides a function that allows planners to assess the correlation between different retrofitting measures and the capability of heat networks for groups or the whole district. The function in the IDST calculates

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

for user defined building groups or areas of the district a heat demand density map and visualizes it in 2D and 3D maps. By setting user defined thresholds the function shows the user the areas of a district or a city in which the construction of a heat network can be feasible.

3. Analysis tool for the assessment synergies and interactions between buildings

The functions show the user the time-based load curves of the electricity consumption and the electricity generation (CHP, PV, Wind) of a group of buildings or the whole neighbourhood. Moreover, it allows the user to assess how much electricity surplus is generated at which times to plan smart grids and electricity storages (charge e-vehicles, intelligent appliances).

4. Analysis Tool Assessing Solar potentials of Surface areas on Buildings and free spaces

The function shows the user for each building in the neighbourhood the suitability of roof and façade areas for photovoltaics or solar thermal systems (solar potential).

5. E-Collaboration Platform

The e-collaboration platform in the FASUDIR IDST is the central hub between the planners of a district retrofitting concept and all involved stakeholders and guests. The e-collaboration platform provides the framework to support the stakeholder involvement in each phase of the FASUDIR methodology. The platform is accessible via the main created project website of a district retrofitting project. Therefore, the e-collaboration platform enables the following features for the users:

- Online-Discussion-Forum (Citizen Participation, idea collection, etc.)
- Online Retrofitting Questionnaire (Owners, Tenants)
- Online cloud-based data storage for file exchange
- Front-page for announcements (News, Dates for Physical Workshops)

2.7 Variant assessment for holistic comprising purposes in the decision making process

After planners have created variants the IDST is able to compare the variant to identify the most suitable one according to the set priorities of the decision-makers. In the assessment step of the methodology the users are supported by a decision-support tool. In this function all gathered information, conducted upstream analysis and generated data outputs in the different steps of the variant creation are finally stored in a database. The main input of the variants in the decision-support function is in the form of the KPIs results. The KPI results afterwards are used as core criteria in a value assessment to rank the different retrofitting variants according to the preferences of different stakeholders and decision-makers. Thus, planners of retrofitting concepts have a powerful and logic feature to support the complex decision-making process in energy retrofitting projects for urban districts. In order to be able to conduct a value assessment based on a Multi-Criteria-Decision-Analysis (MCDA) approach the valid variants are ranked according to the preferences and priorities of the decision-makers. For all created retrofitting variants, the different KPIs are simulated by the IDST. To set the priorities the IDST provides a Decision Support Tool which allows the FASUDIR Users to enter their priorities from a list through a plain language entry mask. The plain language entry mask translates priorities in a weighting system. Hence, the weights for the different KPIs in the value assessment are adjusted automatically.

2.8 Project implementation phase

The implementation phase is the last phase of a district retrofitting project in the FASUDIR Methodology. In the implementation phase the best ranked variant of the district retrofitting concept has to be practically implemented. Therefore, it is the longest phase in a district retrofitting project and can last from 2 years up to 20 years or even longer depending on the motivation of the stakeholders and owners. The focus of the FASUDIR Methodology therefore is not the complex work of planning the detailed retrofitting construction process. This task should be done by a retrofitting manager who has the final responsibility for the coordination of the retrofitting construction process. However, FASUDIR supports the complex work of the retrofitting manager by the IDST and the related supporting tools. To achieve this, the IDST provides an update and monitoring function which allows updating and monitoring the current state of the district according to the already implemented retrofitting measures by the owners.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The updated current state can be compared to the targets that have been defined in the scenario. Thus, the retrofitting manager and the represents of the municipality have the possibility to check the current progress during the whole implementation phase. This is very important in order to control the retrofitting progress and to identify obstructions which have negative impacts of the retrofitting work. Based on the results the retrofitting manager is able to develop suggestions for improvements (e.g. new grants, change of the variants) and to recommend them to the stakeholders. Moreover, the achieved successes in the retrofitting project can be shown and demonstrated to politicians, stakeholders and citizens by using the IDST. Furthermore, the IDST supports the retrofitting manager in improving the communication flows between the stakeholders in the implementation phase through the e-collaboration platform. Hence, the retrofitting manager is able to contact all stakeholders in an optimized way via the internet. This facilitates the mediation between different stakeholders which is very important in the implementation process of district solutions.

3. DISCUSSION

In fact, it is very difficult to assess the uncertainties that may occur in district retrofitting concepts. However, the goal of district retrofitting concepts and the district approach in general is not to provide as detailed results and calculations as possible but to help planners and stakeholders to find the right direction for the whole district. As the data collection in a district is not as detailed as for building retrofitting concepts the uncertainties are higher on district level. However, the time effort for the data collection can be reduced by up to 80 % compared to a detailed data collection. Therefore, the Pareto principle states those, for many events, roughly 80% of the effects come from 20% of the causes. If the Pareto Principle is applied to the data collection process for buildings and districts 80 % of the accuracy can be reached with 20 % of the time and cost effort. If the planners need to have 100 % accuracy the time effort for the data collection will be increased by 80 %. FASUDIR therefore is created as a tool for high level insights and therefore takes advantage of the Pareto Principle.

4. CONCLUSION

Besides the planning of concepts, the practical implementation of the measures cannot be done by software tools as a deep interaction and communication between all involved stakeholders is necessary. Hence, the planning and practical implementation of district retrofitting projects is a task that is due to its high complexity still strongly dependent on the human intelligence of professionals and experts. However, the professional planners can take advantage of structured approaches and supporting software tools to make their work more efficient. Against this background the Decision-Support Methodology must be regarded as a stand-alone approach which is not directly coupled to tools or software. This means, that the FASUDIR Decision-Support Methodology in general is applicable without the use of the FASUDIR IDST. However, to follow all steps included in the different phases may need a lot of time and partially be not effective without using appropriate support by the IDST. Vice versa the IDST also cannot be seen as a stand-alone tool. Using the IDST in an appropriate way needs to follow the structured Decision-Support Methodology in order to achieve meaningful and resilient results. Only the joined use of the Decision-Support Methodology and the IDST ensures an efficient work flow and increases the probability for a successful completion of district retrofitting projects. The development of the FASUDIR Decision-Support Methodology and the IDST will significantly improve the currently used methods of operating in district retrofitting projects and facilitate keeping the EU's "40-27-27" targets for the building sector.

ABSTRACT

A systematic procedure for calibrating building energy simulation models has been developed. The proposed method combines analysis of building plans and documentation manufacturers' specifications, data from building sensors and results from EnergyPlus simulation. This paper describes the calibration method that was developed and demonstrates the use of the calibration procedure by applying it to an office building located in Kawasaki, Japan. Data collection took place between July 2015 and February 2016. Data from the months of August November and February were used as test data and used to determine the model's CVRMSE and NMBE. These months were selected to be representative of summer, autumn and winter periods in Japan respectively. The remaining months were used for model training and to determine model inputs. This separation (training and testing data) was done to prevent bias when evaluation the model. Comparison of the simulation results with hourly measured data gave coefficient of variation of the root mean squared error (CVRMSE) values of 14%, 11% and 11% for lighting, equipment and air handling units (AHUs) energy consumption respectively, all of which are below the 30% threshold set by ASHRAE Guideline 14 (2002). In addition, the calibrated model also shows normalized mean bias error (NMBE) values less than 3% when compared with hourly lighting, equipment and AHUs energy consumption.

Keywords: BEM, calibration, model

1. INTRODUCTION

The building sector accounts for approximately 40% of total energy consumption in the United States (U.S. DOE, 2012) and the world (Sisson et al., 2009). Thus, retrofitting existing buildings provides one of the biggest opportunities to reduce energy consumption and CO2 emissions. Over the past decade, building energy models have been increasingly used in measurement and verification (M&V) for the evaluation of energy conservation measures (ECMs). However, before any ECM can be evaluated, the model needs to be calibrated. With increasing emphasis on the integration between Internet of Things (IoT) and buildings, installation of sensors in buildings is becoming increasingly common, collecting large amounts of information that can be used for controls and retrofit analysis. Significant discrepancies between simulated and actual measured consumption of buildings has also brought about a movement to uncover these discrepancies by analyzing data collected through extensive sensor networks.

In this paper, we present the calibration of an EnergyPlus whole building simulation model using available measured data. The calibration is validated using hourly measurements. The objective of this study is to propose an evidence-based stepwise approach that is deeply related to the collection and analysis of high-resolution data for the model calibration process.

2. METHOD

2.1 Overview

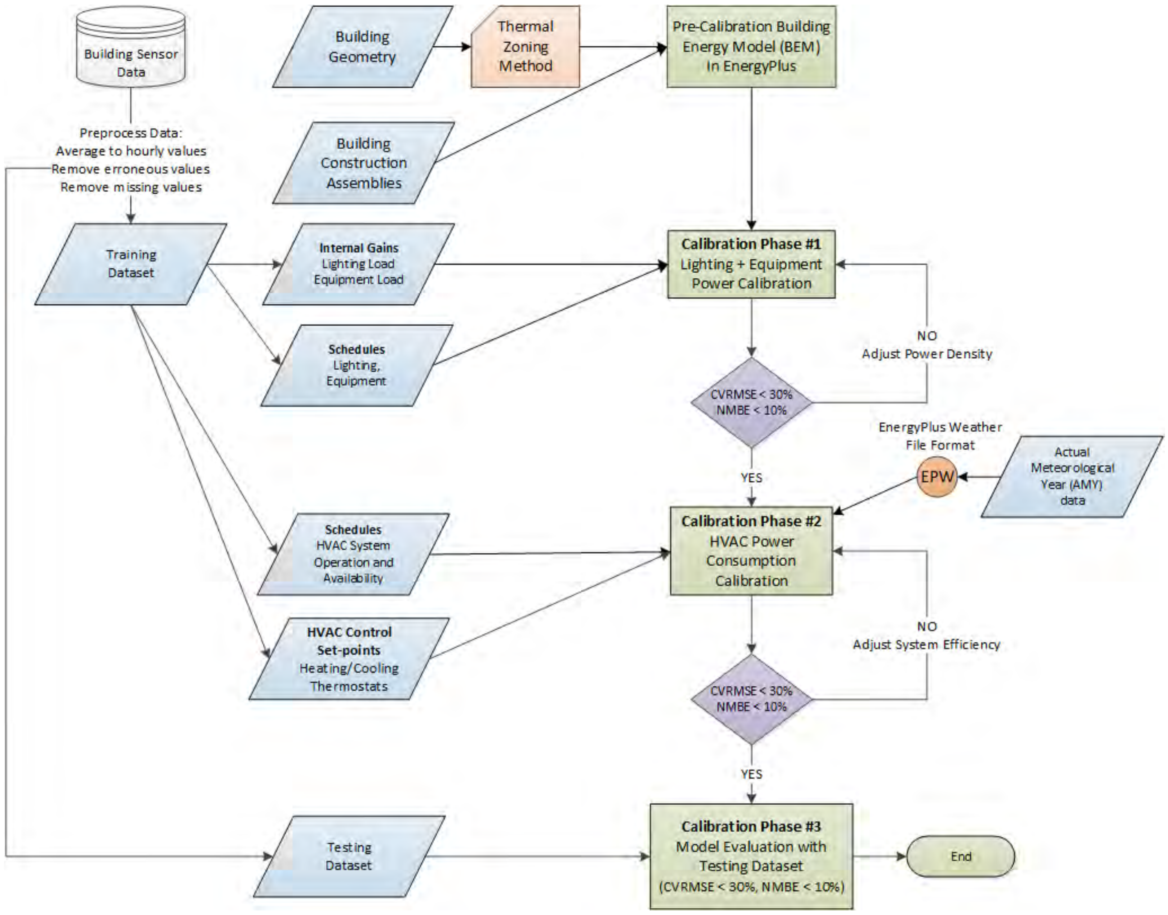

Figure 1: Overview of calibration framework

Figure 1 shows an overview of the proposed calibration framework and is based on the calibration of an EnergyPlus model. The process begins with the standard procedure of building an energy model based on construction documents, design specifications and following the guidelines for a design model Table G3.1 of ASHRAE Standard 90.1 (2010). Before any model calibration, the dataset was preprocessed by removing instances that contains erroneous values to yield "complete" data sets. These include instances containing missing values, negative power consumption and temperature beyond reasonable values. To over-fitting the energy model and reduce bias in the calibration process, the processed dataset is split into two sets; a training dataset for building the model and another testing dataset for validating the accuracy of the trained model.

The calibration process can be separated into three phases, (1) calibration of internal loads, (2) calibration of HVAC system, and (3) model validation with testing data (Figure 1) and can be summarized as follows:

- Calibration of internal loads (lighting and equipment power consumption)
  - Analyze hourly power consumption of internal loads to determine resolution of schedule to set for each component of the internal loads
  - Determine maximum power consumption from data collected
  - Use analysis from (1a) and (1b) to set the schedule and the design power consumption
  - Iteratively tune design power consumption until CVRMSE and NMBE for internal load energy consumption is less than 30% and 10% respectively (ASHRAE Guideline 14, 2002).

- Calibration of HVAC system
  - Identify inputs to the EnergyPlus HVAC object. For calibration of HVAC systems, it is important that actual meteorological year (AMY) weather files be used. AMY files contains hourly weather data over the time period of the calibration and should be obtained from a weather station that is closest to the building of interest.
  - Use documentation of the simulation tool to determine how the measured data could be used to derive inputs to the energy model. Two typical inputs to an EnergyPlus HVAC object are performance curves, which give the systems efficiency at off-reference conditions, and availability schedules which can be used to model the system's operation. For performance curves: apply least square regression to measured data to derive coefficients that would be used as inputs to the energy models.
  - If measured data is not available, extract required information from construction documents and design specifications
  - Iteratively tune HVAC system efficiency until CVRMSE and NMBE for HVAC energy consumption is less than 30% and 10% respectively (ASHRAE Guideline 14, 2002).

Validate the calibrated model by computing the model's CVRMSE (Equation 1) and the NMBE (Equation 2) on the testing dataset. The model is considered calibrated if CVRMSE and NMBE meets the threshold of 30% and 10% respectively (ASHRAE Guideline 14, 2002).

$$CVRMSE = 100 \times \left[\sum (y_i - \hat{y}_i)^2 / (n-p)\right]^{1/2} \bar{y}$$

Equation 1

$$NMBE = \frac{\sum(y_i - \hat{y}_i)}{(n-p) \times \bar{y}} \times 100$$

Equation 2

2.2 Building description

As an illustrative example, we apply the calibration method to the 9th floor of a building located in Kawasaki, Japan. The calibration would be demonstrated for the internal loads (lighting and equipment energy consumptions) and the air handling units (AHUs). The 9th floor of the building is mainly made up of an open floor office and can be divided into 9 zones (Figure 2). Each zone aside from the core is also installed with sensors that measure, zone temperature, lighting, plug and process loads. Ventilation is supplied to each zone (except the core and IS zone) by individual variable air volume (VAV) AHUs. No ventilation is supplied to the core zone while ventilation to the IS zone is jointly supplied by the AHUs that supplies outdoor air to the N, S and W zones. Data collection took place between July 24th, 2015 and February 24th, 2016 at 1-minute intervals. The data collected were averaged to hourly values. Data from the August 2015, November 2015 and February 2016 were separated and used to form the testing dataset while the remaining months used form the training dataset. These months were selected to be representative of summer, autumn and winter periods in Japan respectively.

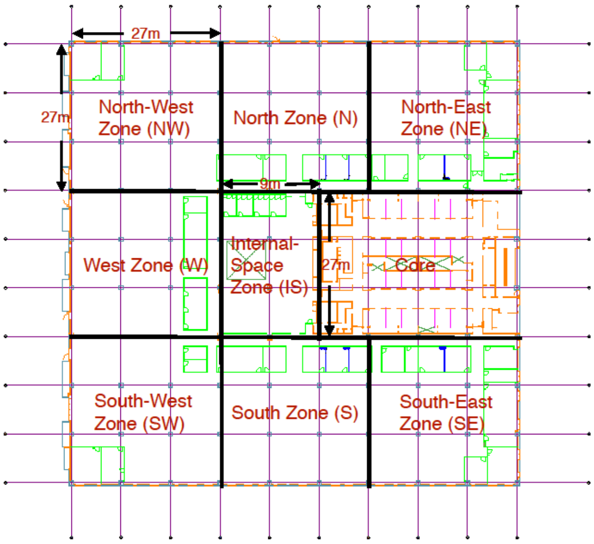

Figure 2: Insert figure of floor plan (9 zones)

3. INPUTS TO MODEL

3.1 Internal Loads

The EnergyPlus objects used for the calibration of lighting and equipment energy consumption are the "Lights" and "ElectricEquipment" objects respectively (UIUC and LBNL, 2015a). Both EnergyPlus objects are similar in that they compute energy consumption by multiplying an hourly schedule by the design power density. A first step in this process would therefore be to determine the appropriate resolution of schedule to set. This is done via data exploration of the measurements for lighting and equipment power consumption of each zone (Figure 3 and 4). Figure 3 shows four distinct trends in lighting power consumption. It can be observed that mean lighting power consumption is highest during weekdays followed by Saturday, Holidays and Sundays. Figure 3 indicates that a 24-hour schedule that represents each of the four trends (weekday, Saturday, Sunday and holidays) would be most appropriate when modeling lighting power consumption in an energy model. On the contrary, from Figure 4 it can be observed that there is a more distinct separation between the weekdays mean equipment power consumption. To better represent this difference, a 24-hour schedule for each day of the week (Monday to Sunday and Holidays) was used. The design power density was computed by dividing the maximum measured power consumption by floor area.

3.2 Air-Handling Units (AHUs)

The main components of the AHU are the variable speed fans and the cooling and heating coil. The EnergyPlus objects used to model the AHU are the "Fan:VariableSpeed", "Coil:Cooling:Water" and "Coil:Heating:Water" objects (UIUC and LBNL, 2015a). Since the target of this model calibration is energy consumption, the focus would be on the calibration of the AHU fan. Equations 3 to 5 shows how fan power consumption is calculated by EnergyPlus (UIUC and LBNL, 2015b). f_{flow} denotes the flow fraction, $\dot{m}$ is the air mass flow (kg/s), $\dot{m}_{design}$ is the design (maximum) air flow (kg/s), ΔP is the fan design pressure increase (PA), e_{tot} is the fan total efficiency, and ρ_{air} is the air density at standard conditions (kg/m3). Table 1 shows the inputs to the Fan:VariableSpeed EnergyPlus object and summarizes how their values were computed using measurements of fan power and airflow rate.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

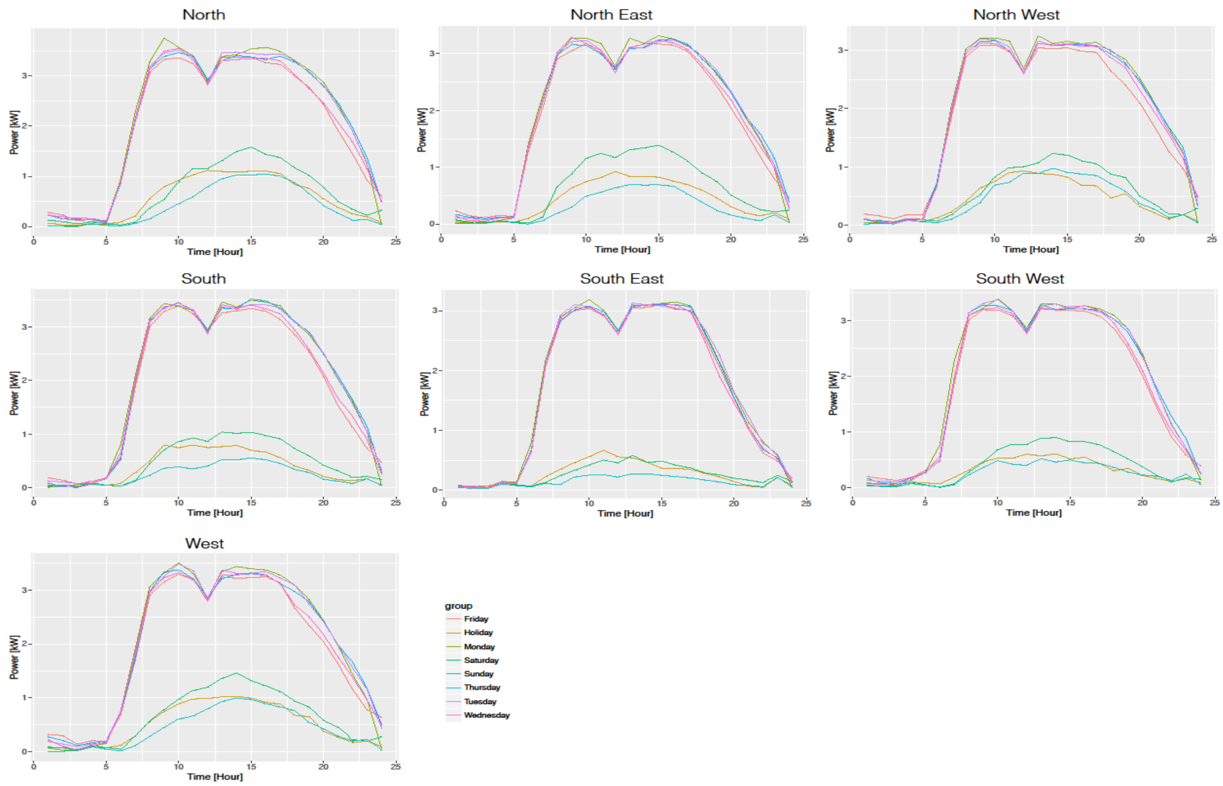

Figure 3: Plot of average (mean) lighting power consumption at different hours across different days

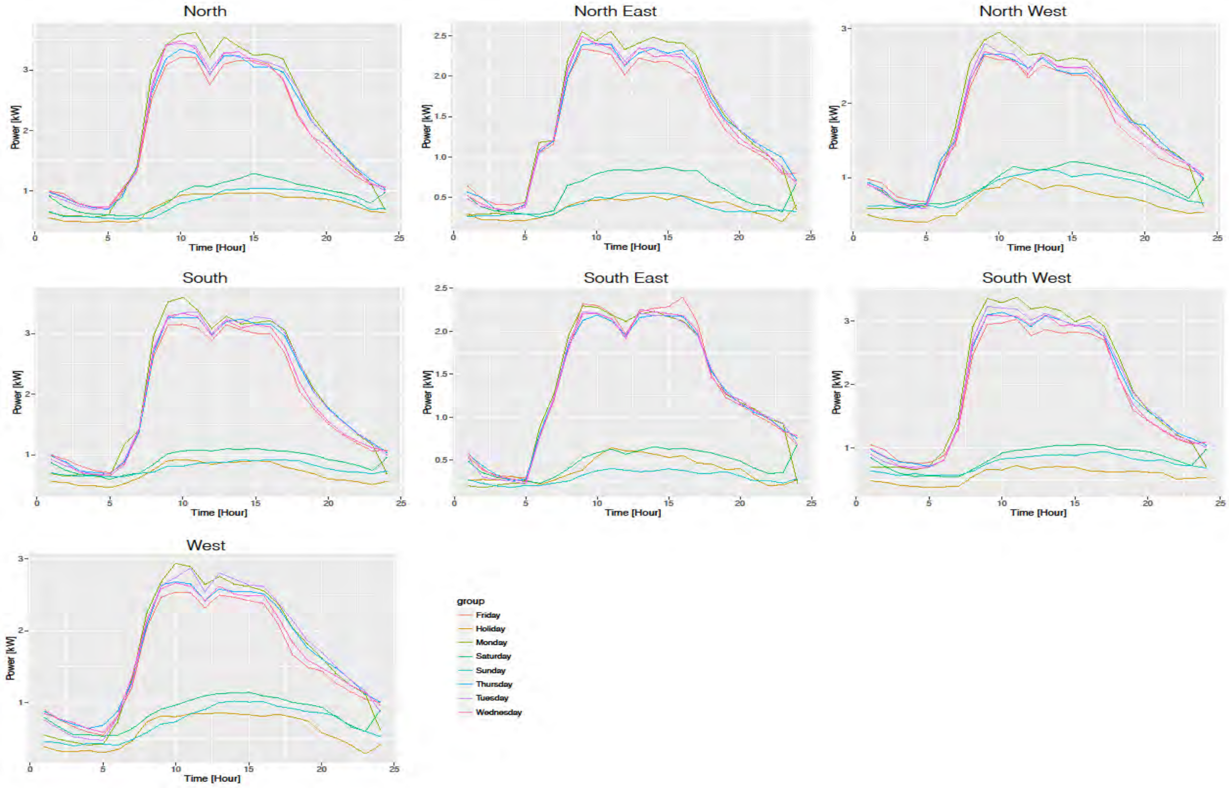

Figure 4: Plot of average (mean) equipment power consumption at different hours across different days

Parameter	Method used to compute parameter value
Fan Total Efficiency	Average fan efficiency computed from air flow measurements, fan power measurements and pressure rise from manufacturer's specification (Equation 5)
Pressure Rise (Pa)	Manufacturer's specification
Maximum Flow Rate (m3/s)	Maximum airflow rate that was measured
Fan Power Minimum Air Flow Fraction	Ratio of minimum measured airflow rate to maximum measured airflow rate
Motor Efficiency	Given value of 1 since motor inefficiencies are accounted for in measurements of airflow and power
Coefficients of Fan Power Curve (Equation 4)	Least square regression using measurements of air flowrate and fan power consumption. The independent variable (f_{flow}) is derived from measured air flowrate as the ratio of air flowrate to the maximum airflow rate. The dependent variable (f_{pl}) was derived from measured fan power consumption as the ratio of fan power to the maximum fan power.

Table 1: Inputs to EnergyPlus Fan:VariableSpeed object

$$f_{flow} = \frac{\dot{m}}{\dot{m}_{design}}$$

Equation 3

$$f_{pl} = c_1 + c_2 \cdot f_{flow} + c_3 \cdot f_{flow}^2 + c_4 . f_{flow}^3$$

Equation 4

$$\dot{Q}_{tot} = f_{pl} \cdot \dot{m}_{design} \cdot \frac{\Delta P}{e_{tot} \cdot \rho_{air}}$$

Equation5

4. EVALUATION OF CALIBRATED MODEL

Two approaches were used for the evaluation of the calibrated model and they are: (1) CVRMSE and NMBE, and (2) hourly time series plot of measured power consumption and predicted energy consumption. We include a graphical time series comparison of measured and predicted energy consumption to identify any possible deviations in hourly patterns that might not be captured by error indices such as CVRMSE and NMBE. Table 2 shows the CVRMSE and NMBE for the total lighting, equipment and AHU energy consumption. CVRMSE and NMBE are computed using testing data to check the model for overfitting and prevent large biases in the calibrated model. It can be observed that CVRMSE and NMBE are below the threshold of 30% and 10% respectively (ASHRAE Guideline 14, 2002). Figure 5 shows the comparison between measured lighting, equipment and AHU energy consumption and model predictions. From the plots it can be observed that there are slight overestimation and underestimation of energy consumption across the testing data. This explains the low NMBE (< 3%) for all components. Figure 5 also provides visual confirmation that predictions by the calibrated model is able to capture the trends in the observations.

Component	CVRMSE (%)	NMBE (%)
Lighting Energy Consumption	14.01	1.47
Equipment Energy Consumption	10.68	-0.005
AHU Energy Consumption	11.48	-2.35

Table 2: CVRMSE and NMBE

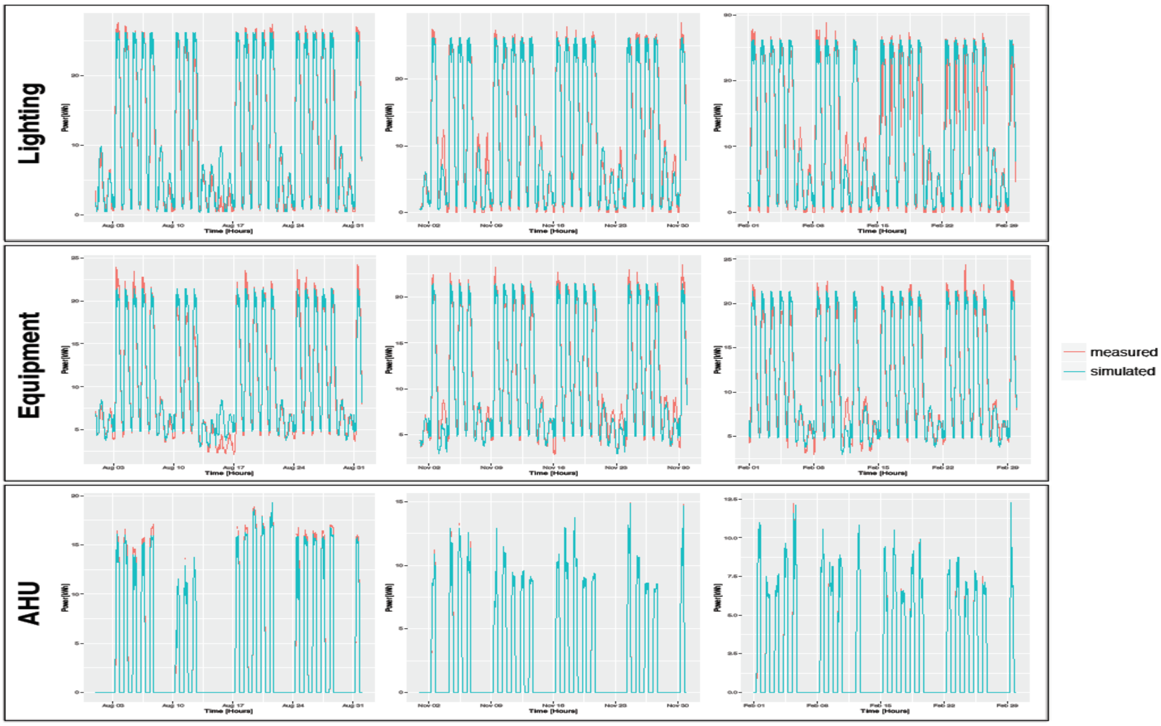

Figure: 5 Comparison of measured data and model prediction using testing data

5. CONCLUSION

This study provides details on the calibration of a whole building EnergyPlus model of a building located in Japan using hourly detailed sub-metered data. The proposed stepwise method starts with the calibration of internal loads, followed by HVAC energy consumption and ends with evaluation of the models accuracy using a testing dataset to prevent overfitting and avoid large biases in the energy model.

The model's prediction was compared to hourly measured data to ensure that the model represents actual building operation more accurately as compared to calibration with monthly data which is more commonly used for the calibration of building energy models. Graphical time-series plots also shows good agreement between the model prediction and the measured data, illustrating that the model is able to capture hourly patterns in the measured data. Overall, the final model shows good agreement with the testing dataset, demonstrating the effectiveness of the proposed method. However, the calibration process is still an iterative manual process that would take considerable time and resource. For practical applications, future work is still needed in the following areas: (1) a systematic framework to sensor installation and measurements in buildings, and (2) automation of calibration process.

ABSTRACT

The open international online database structure for LCA of building materials shall allow open access to EPD (environmental product declaration) data from all participating databases. The way these EPD data can be used, e.g. within certification schemes or for LCA at building level, nonetheless can follow national rules. This undertaking calls for a high transparency of data content and data quality.

In many European member states national EPD programmes in conformity to EN ISO 14025 were established, producing EPDs in conformity to EN 15804. In order to use EPD data for LCA at building level, the EPD data needs to be available in a database in machine readable form. The independent development of these databases brings the risk of a great variety of data formats and thus the danger of incompatibility of data. Additionally, the Product Category Rules (PCRs) differ from one programme to the other, as for some aspects EN 15804 gives only a frame.

In order to overcome these problems, a project has been launched by the German BMUB/BBSR (Federal Institute for Research on Building, Urban Affairs and Spatial Development) which shall demonstrate the concept and implementation of an open international LCA-database network for EPDs. Starting point is the already existing infrastructure around the database ÖKOBAUDAT established within the Assessment System for Sustainable Building (BNB). These existing tools have to be adapted in order to meet the challenges of an open international data network.

The project is based on various precedent projects and will be finished in August 2017. Results of the project are a conceptual framework as well as a concept for the necessary technical applications and a technical implementation on lab level for demonstration purposes.

Keywords: EPD (environmental product declaration), building materials, databases

1. INTRODUCTION

1.1 Motivation

Life cycle assessment (LCA) at building level has become a widely used methodology to assess resource consumption (e.g. primary energy) and environmental impacts (e.g. contribution to global warming) of buildings over their entire life cycle. The basic building product data for such LCA are provided in form of environmental product declarations (EPD). In many European member states, more and more EPDs are produced by manufacturers and trade associations, commonly within a national EPD programme according to EN ISO 14025 [1]. Most of the programme operators in Europe follow also the core rules for construction products laid down in EN 15804. In spite of the considerable standardisation work during the last few years, the product category rules (PCR) differ between programmes, as for many aspects EN 15804 rather provides a framework than distinct specifications. Hence, questions arise concerning the consistency of data in applying EPD in the assessment and environmentally driven optimisation of buildings.

Until now, programme operators run their own information systems for EPD data mainly in form of product lists supplemented by PDF documents. On the other hand, using EPD data in LCA at building level calls for EPD data provided in a machine readable form, which has lead to different initiatives for databases in many member states. As building products are used within the European or global market, it is to emphasise that there is a great interest to use data from different EPD program operators for LCA at building level. The independent development of local databases however leads to the risk of a great variety of data formats and thus possible incompatibility of data.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

A high transparency of data information (such as origin of data, validity of data, applied scenarios etc.) and data quality (e.g., verification, categorisation etc.) is needed to support a sensible use of data in subsequent LCA calculations. Furthermore, a common technical framework is required in order to facilitate data exchange.

1.2 Objectives of the demonstration project

The project launched by the German BMUB/BBSR (Federal Institute for Research on Building, Urban Affairs and Spatial Development) shall demonstrate the concepts and implementation of an international open LCA-data network structure for construction products based on EPD information. This data network structure shall allow the exchange of EPD data and offer open access to EPD data from all participating databases and tools. At the same time, the use of these EPD data (e.g. within certification schemes or for LCA at building level) nonetheless shall be able to follow national rules. This undertaking calls for a high transparency of data information and quality, which shall be ruled by a conceptual framework. Furthermore, a common basis regarding the technical framework is required, e.g. software and interfaces.

Starting point shall be the already existing infrastructure around the database ÖKOBAUDAT which had been established within the Assessment System for Sustainable Building (BNB). These existing tools have to be adapted in order to meet the challenges of an open international data network – in conceptual and technical means.

The project is based on various precedent projects and shall be finished in August 2017. Result of the project shall be a conceptual framework and a concept for the necessary developments concerning the technical applications. The achievements are meant to be a contribution to support ongoing harmonisation efforts on international level and serve as a live example how a data network for EPD data could be implemented and used in practice. The objectives are to make the stack of existing tools fit for international networking with focus on multilanguage and handling of data quality declarations as well as to identify and possibly fix any technical and procedural gaps. In the demonstration phase the data network will be on the ÖKOBAUDAT website but shall be transferred to a common website later on.

2. METHODOLOGY

2.1 Approaches to achieve the conceptual deliverables

An open data network implies a precise definition of mandatory and additional information as well as a common understanding of calculation rules, verification procedures and data quality. Working steps are:

- The conceptual framework developed for ÖKOBAUDAT [3, 4] shall be used as a starting point.
- Differences in the concepts of the cooperating data deliverers and the interpretation options in handling the normative requirements shall be analysed.
- A comprehensive conceptual framework concerning data sources, formats and other aspects of data quality shall be delivered, considering
  - Results from the ongoing UNEP-SETAC Life Cycle Initiative's GLAD network, especially working groups Nomenclature and Metadata descriptors of data quality
  - Requirements of several further database operators and application
- Based on the conceptual framework, a technical system shall be implemented.

2.2 Cooperation – working group "International Open Data Network for Sustainable Building"

In order to develop a harmonised and consistent way of using material and product relevant LCA or EPD data for the LCA of buildings, in March 2015 a working group "International Open Data Network for Sustainable Building (InData)" was founded. The main objective of WG InData is to establish an International LCA data network structure for construction products based on EPD information. Its members are EPD programme operators, LCA data providers, LCA database operators, LCA format developers, federal institutions and building assessment operators. The mode of operation comprises network activities and bi-lateral co-operations. Currently six countries (Austria, Belgium, Denmark, Germany, Norway, and Spain) are represented [5, 6]. The conceptual framework for the data network structure shall be elaborated together with the WG InData.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. DELIVERABLES

3.1 InData survey

A survey has been undertaken beyond the members of the WG InData in order to find a common understanding of aim and actions of the group [7]. 20 representatives were invited to take part, 8 questionnaires from 6 member states (Germany, Austria, Belgium, Denmark, Spain and Norway) came back. The posed questions concerned conceptual approaches and status quo in the represented countries. The survey brought about that a combined nearly 4000 datasets could be delivered by five InData members (IBU, BBSR, baubook, IETCC, EPD Norway). The methodologically motivated questions lead to a decalogue [5] actually consisting of 12 commandments which will guide the future work of the working group and form the basis for the conceptual framework of the data network structure.

3.2 Conceptual framework

The essential elements which have to be covered in the conceptual framework are

- Objective of the open data network structure
- Standardisation schemes to use
- Core information, classification and meta information
- Data quality (options/ scale)

Objective of the open data network structure

The open LCA data network structure for construction products based on EPD information shall allow the exchange of EPD data and offer open access to EPD data from all participating databases and tools. This requires agreements about data format and interfaces in order to ensure compatibility. The system should offer compatibility with subsequent applications and tools such as LCA tools, building information modelling (BIM), and others. Nonetheless, national databases shall be able to maintain their identity. They can use different webpages of information, software database platforms and technology.

Standardisation schemes to use

EN 15804 shall be the common ground to start. It is not the aim to develop additional rules complementing the standards, but complementary information will be defined for classification of products (Generic, average, BIM codes, etc.).

A common approach to product categories and hierarchies is crucial. In consideration of the estimated rapid implementation of building information modelling (BIM), the building smart Data Dictionary (bsDD) shall be used as the reference.

The ILCD data format shall be used as data exchange format (See technical deliverables).

Core information, classification and meta information

All the data involved shall contain at least a common core of information which shall be oriented on EPD data according to EN 15804. All the information shall be available in English and optionally complementary in other languages. National additional information shall be possible, but will not be supported by the network structure.

It is necessary to have a common classification system for specific types of attributes, e.g. the representativeness of EPD data classified as being specific, average, representative, or generic.

Other types of attributes need additional information allowing to estimate the validity of data (e.g. background databases, sources of information, hypothesis, description of procedures and scenarios).

Data quality (options/ scale)

Data quality is a crucial point in the data network structure and shall be identifiable by the user. One option is to guarantee a high level of data quality by qualitative assessment of data as it is carried out by the ÖKOBAUDAT operators. The other option is a transparent communication on the data quality, giving the responsibility to the user of the database to decide which data they prefer and how they use it. For the second option it might be helpful to develop a classification in the sense of level of data quality. Anyhow WG InData decided to define a minimum common quality level of the data. For example, third party verification of data according to EN 15804 shall be mandatory. Competences of the EPD verifiers in the product family, in LCA and in environmental verification (and in the relevant standard) shall be prescribed.

3.3 Technical deliverables

Data format

In the course of a revision of the ÖKOBAUDAT database, its underlying data format has been revised to use the widely-adopted ILCD data format with a few extensions which allow modelling of the information in compliance to the EN 15804 standard. It has to be underlined that the data format itself does not impose any rules with regard to data quality, but merely provides a technical means of storing and transporting information in a structured way.

Multilingual data

In practice, a multilingual dataset will usually contain information in English and one other local language.

Having been designed specifically for data exchange in an international context, the ILCD data format provides built-in multi-language capabilities that allow for storing the textual meta information of a dataset such as process name, general comment, technology description, use advice etc. in an arbitrary number of languages while at the same time yielding only one single physical dataset. In past projects related to the ÖKOBAUDAT database, a set of tools has been developed or adapted in order to cover the entire data life cycle from data generation over data distribution to applications that use the data for building LCA calculations. So far these have only been used with datasets in German. In order to support international data exchange activities, these tools are to be modified in order to support processing multilingual data.

Being designed as a general-purpose tool for distribution of LCA data with native storage of the data in the ILCD data format, the underlying soda4LCA software) already provides a large set of features in order to handle multilingual data. Nevertheless, the networking features of soda4LCA were so far only used in context of one language).

The openLCA software tool which is able to create and export EPD datasets in the format described above is currently limited to a single language at a time. Emphasis within the project with regard to the openLCA software is on extending it in order to support adding information in a second language to a dataset. This would be especially useful in situations where an EPD or a generic dataset which is supposed to be shared on an international level is only available with textual information in a local language and is to be complemented with English translations of the existing textual information.

Simulating data networking on lab level

In order to identify and fix any technical issues, a data network with multilingual data is simulated on lab level. For the lab setup, at least three individual nodes are set up to simulate different data providers (Figure 1). These nodes are then populated with bi- or multilingual datasets which are either synthetically created just for the testing purposes or obtained from interested international partners who provide bilingual data for this project. Defined use cases are then executed, such as locally searching and browsing data on a node and performing a distributed search on the entire network.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

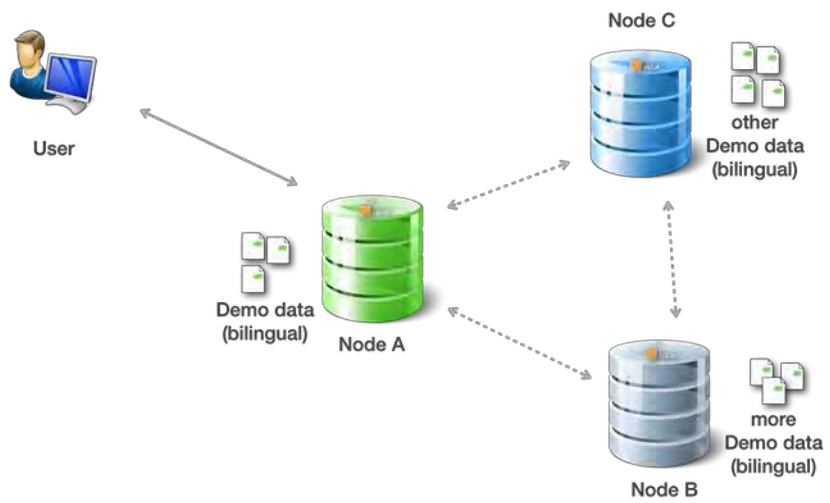

Figure 1: Lab setup for a multilingual data network

Data quality labelling

When datasets originating from different domains are to be shared among a wider audience, it is important that potential users of the dataset can easily identify the original purpose and quality scheme it has been made for as well as optionally other quality schemes it may be compliant to.

In the ILCD data format, a built-in mechanism is foreseen to indicate adherence to one or multiple compliance schemes by simply declaring any applicable compliance systems (which basically is a set rules that the data has to adhere to) within the dataset. This declaration includes a reference to a source dataset representing the compliance scheme which may in turn reference further information such as a document or web site with a more detailed.

For the application scenario of an international data network on EPDs, this mechanism can be used to declare the conformity to EN 15804 and in addition any quality schemes that impose further rules on data quality, such as the BNB system that the ÖKOBAUDAT originally was designed for and which is described in [9]. An example for the declarations that a dataset could carry is given in Figure 2. The declared quality systems can even be disjoint, as long as the dataset actually conforms to each one of them.

Figure 2: Relationships of different compliance schemes

With such declaration in place on dataset level, it easily can be identified which quality schemes a dataset qualifies for. A user interface for a node or for the network search interface can then allow for searching or filtering for specific quality schemes, enabling users to quickly find data that meets their requirements.

4. CONCLUSIONS AND OUTLOOK

In the paper, the development of an open network structure of LCA data for building products based on EPD information is presented. The idea behind the described developments is the vision of an open data network, where independent national databases are linked to each other with open search and use of data with a common data format. Yet, each data provider will have the opportunity to set up own national rules for the use of data in subsequently used LCA tools, or other processes. This is a great chance for the idea of a consistent and comparable establishment of LCA within the context of sustainability considerations in the construction sector.

ABSTRACT

Taiwan High Speed Rail (THSR) has become a major north-south public transportation systems, a day round trip of life style is a growing trend. Due to the business district be vigorously developed which is surrounded and alone rail station, residential building also will develop and become another form of satellite communities. On security considerations facilities and transport quality in the relevant law regulation, the less than 30 meter restriction of construction regulations may be conducted. Noise Environmental impact will certainly affect the subsequent use and operation of the residential building, in order to ensure the future of indoor comfort and health indicators, the present study was to investigate the noise effect in the process of generated from high-speed rail transportation, to plan the corresponding acoustical performance of residential building construction which is in the region of surrounded location at around THSR station, thereby providing future making decisions and reference basis for the architectural design team.

Keywords: high-performance of sound insolation, indoor environmental quality, adaptable design

1. INTRODUCTION

The influence of sound on the space environment and people's emotional perception and reaction is directly mentioned that the environment is a passive energy transmission, it all the time affect the physiological, psychological, cognitive behavior of related senses. Annoying noise interference is actually more serious, when the living environment is not ideal, leading to speech message may not be a good transmission, it will cause displeasure. Sound insulation performance of buildings is usually enhanced through rigidity, resonance, quality, and critical frequency (critical frequency (fc)) and other physical factors to control its performance. Based on the law for conservation of energy, if the energy loss is caused by passive transmission in the critical frequency zone, even if the boards are double-wall or compound structure, the low-frequency sound insulation effect is still limited, especially in ventilated openings. Bao et al. suggest that mass-air-mass resonance in the low-frequency section of a double-wall structure is another type of noise reduction. Resonance effects can often be reduced by using sound-absorbing materials or by increasing damping. Even if the high-performance material made by the micro-perforation principle has been used in the present age, it is not easy to control the double-layer glass facade (low resonant frequency) structure, so the low-frequency part of the sound insulation performance is also poor. General building structure for the sound of low-frequency performance will not be able to effectively isolate the sound energy. In the case of uncertainties in the noise source and the receiving point, the control of the noise propagation path of the high-speed railway line sound source becomes important. In particular, up to 250 kilo meter per hour of high-speed rail train through close to the station may enlarge noise sound by the impact of the perturbed energy which is the main focus of this study. In Taiwan, a regulation on the correspondence between the height of vertical noise walls and the horizontal distance of land transportation has been made. The noise of LAeq (dB) will exceed the ambient volume standard value within 6 meter from the orbit side, and the LAmax (dB) is still 75 ~ 80dB at 40m when the train passes through the building. In addition, the high-speed rail along the noise map, Kriging method can be drawn better results, according to the questionnaire survey pointed out that the high-speed rail from the centreline within 100 meters, is more serious noise interference in the region. To meet the residents of the feelings, the Taiwan high-speed railway LAmax (dB) recommended value of 70dB is more suitable. From the above we can see, such as low-frequency diffraction, vertical and horizontal sound source and high-rise building sound source impact surface, and no consistency discussed. Taiwan high-speed railway was completed in October 2005, the driving speed of about 250km / hr, due to high-speed driving under the noise intensity will increase with the speed increase. Germany's ICE noise peak level is 85 to 93 dB compared to other national standards; France's TGV

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

noise peak level is 97 dB; Japan's Shinkansen has a noise peak level of 85 to 90 dB at 200 kilo meter per hour. The environmental vibration caused by high-speed railway is affected by many factors, and the distance and geological conditions are the main factors affecting the vibration level. At the same time, in order to maintain the living environment of residents in peace along the high-speed railway, high-speed railway set the maximum recommended value, After two years later, high-speed rail operated the noise nuisance petition events still emerge in an endless stream. In the research of Professor Wang found that 80 high-speed rail noise from the monitoring results, eight points of LAmax (dB) exceeded the time standard value, four points of the LAeq (dB) also exceeded the standard, the report pointed out that the use of LAeq and LAmax (mean) Regulation still does not adequately reflect the noise impact of the majority of the petitioners. Sound Exposure Level (SEL) and LAmax (mean) of the difference can be explained. The SEL system considers both the time and energy of the noise event and compresses the time of occurrence and conversion to one second to maintain the corresponding noise level. The peak-to-peak LAmax of the two typical high-speed TGV and Eurostar trains at different vehicle speeds differ by 4 dB (A). When converted to SEL, both are 93.8 dB (A).

In order to meet the high-speed railway station area in the special settings, the region is designated as a specific area of traffic land, land use will play a convenient transportation function as the main objective, the overall planning concept includes high-speed rail transport efficiency, enhance regional transportation condition. Specific area plans include adjacent residential areas, high-speed railway train running on both sides of the railway environment will produce noise pollution, mainly in the surrounding residents of sleep interference, followed by residents of the heart, as well as the interference of learning and work. Therefore, the control of high-speed railway noise pollution for the environment is another important task. The purpose of this study is to evaluate the impact of high-speed railway noise on high-rise buildings in Taiwan, and to explore the noise impact of high-speed rail vehicles, and to provide the basis for the application of noise protection measures and the noise control standards of exclusive high-speed railway. The purpose of this study is the following four points:

- When the high-speed railway through the station body, the noise generated by the impact of sound energy, through monitoring to explore the impact of ambient sound and the sound of the multiplication effect.
- Through the simulation analysis results, corresponding to the combination of wall structure model to provide follow-up study of reference.
- Based on field measurement survey, summarized the sound field distribution around high-speed rail station.
- The research results may provide the basic research data on the noise intensity regionalization and high-performance residential planning strategy for the around the high-speed railway stations.

2. RESEARCH METHOD

According to CNS 7183 noise level measurement method, the noise meter complies with the national standard (CNS 7129) Type 1 or the International Electrotechnical Society standard Class 1, measuring the points of the test points more than 2 minutes of the frequency (20 to 20000Hz) Pressure level, noise The analyzer is set to Fast mode. The sound field focused on monitoring through the instantaneous acoustic energy to a single high speech train, and can outline an equivalent level LAeq (dB) described volatility sound energy. Record result following two evaluation indicators, including the volume of noise can process the event (equivalent) LAeq (dB) and the maximum volume (Maximum) LAmax (dB). In frequency-weighting, this measurement method shall be weighted by A, and the measurement shall be noted with the weighted name used for field measurement. In addition, the dynamic characteristic uses the Fast (F) characteristic in principle, but the Slow (S) characteristic can be used when the sound generated by the sound source is not fluctuant. As indicated by the average sound pressure level shown in Equation (1):

$$\mathrm{L}_{Aeq} = 10\log\left(\sum_{n=20Hz}^{20kHz} 10^{1/10Leq}\right)$$

Equation 1

2.1 Monitoring environmental sound field in the perimeter of Hsinchu high speed rail station

The object of the study is located in the vicinity of Hsinchu High Speed Rail Station, which is located in North Taiwan. For the purpose of prohibiting the construction land from the land within 25 meter from the centre line of the outer track of the high-speed railway, the external noise of the building shall be assessed and the distance from the building wall line shall be 1.5 meter. Indoor measurements shall be made at least 1.5 meter from the interior walls or other major reflecting surfaces. All measuring positions are 1.2 meter from the ground or floor. In order to effectively understand the height of the building in the temporary high-speed railway station building level and elevation location, and the other two near the peripheral area of similar base location to assess. The measurement and measurement are three locations, one is the open space (Site 1), the other two are the commercial (Site 2) building and the high rise residential building (Site 3) respectively. The relative position of the study objects and field pictures are shown in Figure 1.

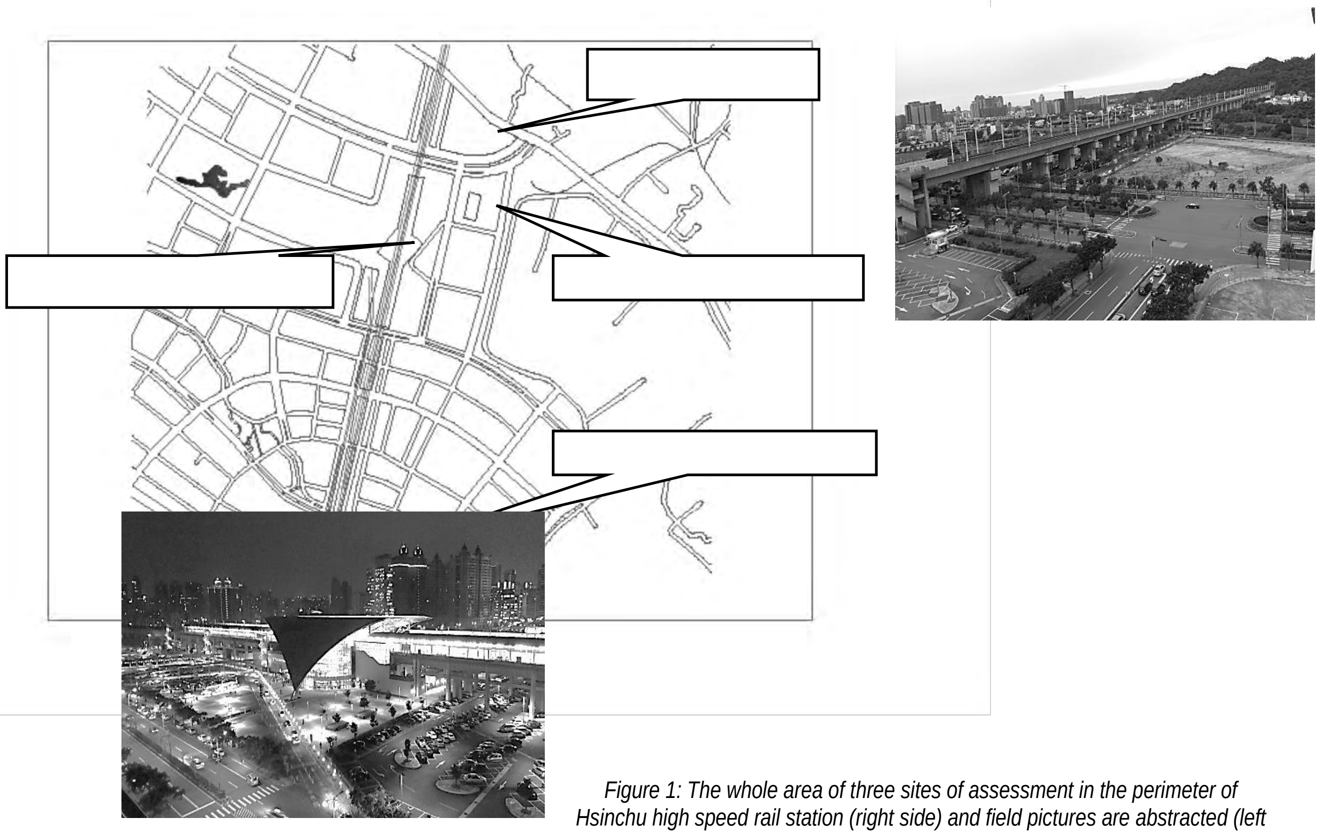

Figure 1: The whole area of three sites of assessment in the perimeter of Hsinchu high speed rail station (right side) and field pictures are abstracted (left side).

3. FIELD MESUREMENT

This study assesses compliance with Taiwan Environmental Protection Agency land transport system noise control standards and high-speed railway environmental volume standards, the main assessment project will develop the relevant noise control program, including the identification of noise source characteristics, base noise and analysis. According to the field analysis of the data measured, the proposed improvement of the proposed program and performance recommendations for the future performance of the field noise performance test.

3.1 Results of environmental sound measurement

The site 1 (Open space) is a 30 meter distance from the station structure which outline of triangle is consisted of three roads (St. A, St. B and St. C). Site shape is shown in Table 1. The distribution of the measurement points includes a total of 18 points around the site of the horizontal dimension, and a total of 10 points in the site. The distribution of survey locations and measurement results of environmental acoustics is shown in Table 1. Around

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

the surrounding site, the average of LAeq (dB) is between 54.1 and 64.8 dB (A). Inside the site, the average of LAeq (dB) is 64.5.

Parameter / Locations	LAmax (dB)	LAeq (dB)
St. A	**60.6**	**54.1**
St. B	**76.3**	**64.8**
St. C	**71.8**	**61.4**
In Site area	**64.5**	**57.2**

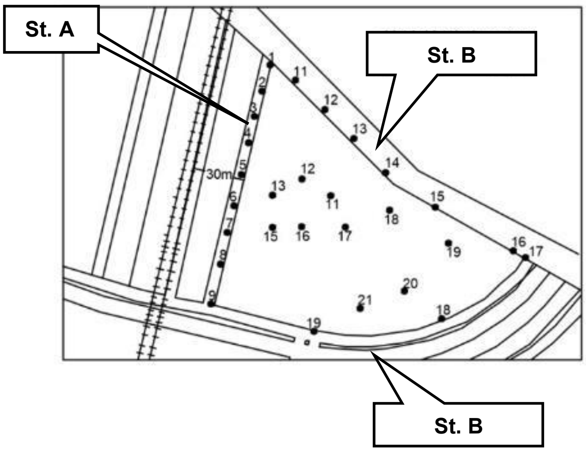

Table 1. The distribution of survey locations and measurement results of environmental acoustics

3.2 Results of noise monitoring for passage trains

When the high-speed train through, the noise was generated by the value of the content of this stage of assessment. Although the noise value may be reduced by the distance of sound source which is from station body, traffic noise LAeq is between 54.1 to 64.8dB (A). However, up to speed of 250 kilo meter per hour through the car close to the high-speed rail station body and pass through the station caused by the impact of the impact of the surrounding area, will make sound noise enlarged. The distance from the centre line of the outer track 50 meter, 1.5 meter above the ground height of the noise measured by one of third octave band frequency of LAeq (dB) values is shown in Table 2. The measurement (THSR) resulted similar to the research of distribution at 1/3 octave band of LAeq (dB) of Korea high-speed railway (KTS) between the station Chunan to Chungwon, as measured in the case of the relative position and elevation measurements, measuring 107 classes of trains to speed of 150 to 300km /hr. Comparison the measurement results of LAeq (dB) between THSR700 and KTS700 are illustrated in Figure 2.

Freq.	63	125	160	200	250	315	400	500	630	800	1k	1.25	1.6k	2k	2.5k	3.15 k	4k
dB (A)	**53.4**	**56.4**	**57.7**	**57.9**	**57.8**	**54**	**52.4**	**58.6**	**53.5**	**59.7**	**60.7**	**66.7**	**68**	**69.7**	**70**	**75.8**	**70**

Table 2. LAeq at 1/3 octave frequency band for High speed trains pass through

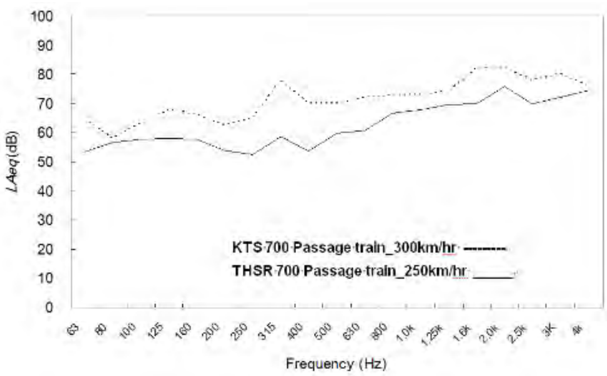

Figure 2: Measurement results of LAeq of THSR (—) in the perimeter of Hsinchu Station at 1/3 octave frequency band compared with the measurements of Korea high-speed railway (KTS) (----)between the station Chunan to Chungwon.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.3 Horizontal distance and vertical altitude for moinitoring of passage trains

The dynamic characteristic uses the fast (F) characteristic in principle which is also conducted by meet the act of environmental standard for high-speed rail traffic noise standards. The average LAmax value is 75.4 dB (A) and is in line with the 85 dB (A) requirement for the maximum volume control zone III of the High Speed Railways. When using the noise meter to carry out various noise assessment parameters of the measurement analysis, select Fast or Slow time dynamic characteristics, will have different results. High-speed rail train through the maximum noise measurement, the choice dynamic characteristic of Fast than Slow module may higher than about 2dB (A). The measurement results (Figure 3) show that the distance from the high-speed train increases, may decrease sound energy LAeq (dB) with the increase of the distance of horizontal sound source. About the vertical direction, when the sound source reaches 40 meter, the sound energy will have the effect of amplification, the maximum sound LAmax (dB) up to 84dB (A).

3.4 Prediction on performance of sound insolation for vertical façade

The sound pressure at the side of the curtain glass (at the window) is 56.7 dB (A), and 80 dB (A) of sound energy can be expected to be blocked under the target setting STC35 for the sound insulation of the curtain glass. In the glazing materials supplied by the curtain glass supplier, if the sound insulation performance of 6mm + 1.52PVB + 6mm cemented glass is selected, the STC is 37 (OITC = 33), the barrier performance can be effectively achieved, and the simulation result has the same performance and consistency .

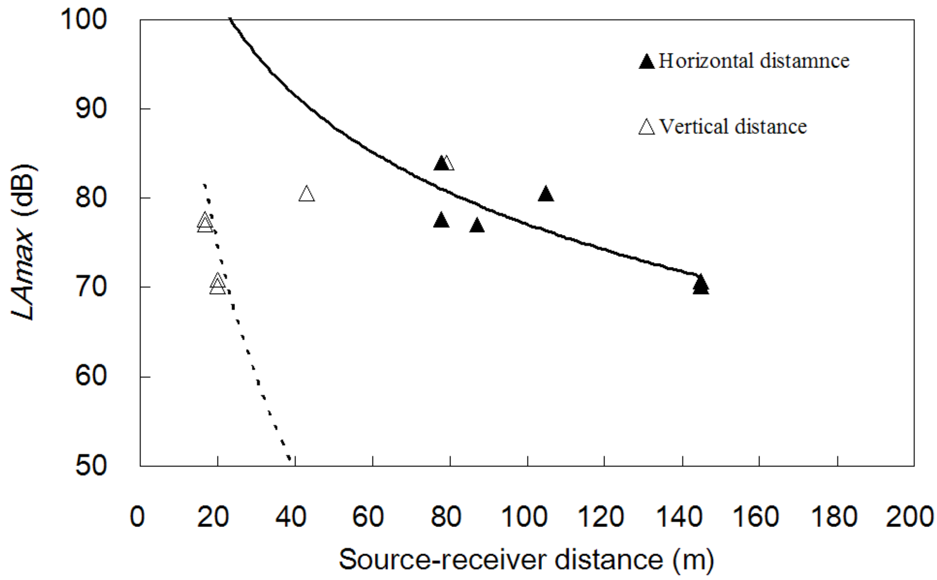

Figure 3: Measurement results of LAmax (dB) shown as a function of source-receive distance of vertical distance (- -) and horizontal distance(—).

4. DISCUSSION

In the high-density urban living environment, the noise environment impact will affect the subsequent use and operation of the building after the development. In order to ensure the indoor comfort and health index of the user, the noise environment will be affected. Assessment results may provide sound performance of architectural tectonic, and provide the improvement basis for project design decisions. The study will develop a noise prevention program that will include identifying the noise source characteristics, noise and analysis within the base. According to the field data analysis and analysis, preliminary results are also abstracted. The conclusions are as follows:

- The site of the study for high-speed railway noise measurement assessment, the environmental noise LAeq (dB) value is between 54.1 to 64.8dB (A), when the high-speed railway vehicles through the station, at 50m away from the outer track centre line at the site, 1.5 meter above ground, the distribution at 1/3 octave band of LAeq (dB) is similar as of the measurements results of Korea high-speed railway (KTS) between the station Chunan to Chungwon, the maximum sound energy LAmax is 70.1 (dB).

- It is found that when the distance between the horizontal sound source and the high-speed train passes, the acoustic energy will decrease with the increase of the distance. The LAeq sound energy is below 72dB (A) and the average maximum sound energy is 80dB (A) The following are in line with the EPD's regulatory requirements. If the sound source is away from 40 meter or more, the sound energy will be amplified, and the maximum sound LAmax (dB) can reach above 84dB (A).
- Considering the above-mentioned results, considering the indoor background noise comfort, it is recommended that the indoor background noise be NC40 _ 48dB (A), considering the maximum sound energy of 80dB (A), the sound insulation performance index STC35 (40) for the external curtain wall of this curtain will be suggested.

The Failures of Initial Commissioning, and its Impacts on Overall Building Performance

Madeline Kathleen PARROTT[a]

[a] *British Columbia Institute of Technology, Canada, maddy.parrott@gmail.com*

ABSTRACT

High-level green buildings aiming for superior targets often fall short of their predicted performance, and there is recent a push in industry to discover why.

This paper discusses the study of three green buildings in British Columbia. Each building was built to exceptional green building standards (LEED or Living Building Challenge), yet all have performance issues reported by owners and operators.

While studies exist on the green building performance gap, the majority of them focus on identifying and fixing the issues causing the gap, rather than trying to eliminate the gap in the first place. There are many design ideologies that try to eliminate the gap, but there is little information on what impact initial design and construction failures have on overall building performance.

The project will be completed by first identifying issues in design and construction that were not caught by initial commissioning. Then, using the calibrated models done in other phases of this project, the impact of each of these initial commissioning failures will be determined by varying the parameter in the calibrated model. A sensitivity analysis will be performed to see which aspects have the biggest impact on overall building performance. A comparison between the three buildings will identify what issues are common across projects, and which issues present themselves on a case-by-case basis.

This information will be invaluable for architects and designers trying to create high-performance buildings in the future. It will show which aspects of building design are extremely important, so that those steps are not glossed over in the design.

Keywords: high-performance building, commissioning, performance gap

1. INTRODUCTION

About 40% of energy usage in Canada and the US can be attributed to buildings, which presents a unique opportunity for reducing energy consumption in this part of the world. If buildings were to strive for higher energy efficiency, they would have a huge impact on North American energy consumption. Due to this, governments, designers, and owners have turned to the increasingly popular green building movement, including building certifications from programs like LEED and LBC. These certification systems reward buildings for sustainable building practices, including efforts to improve efficiency (energy and otherwise).

As green buildings and more stringent targets for buildings become more popular, the emerging problem has become that there is little proof that high performance buildings actually are high-performing. It has been shown that in many cases there are large discrepancies when you compare predicted performance to actual utility bills.

This phenomenon of buildings performing much worse than intended is known as the “performance gap” in green and high performance buildings. It reflects the disconnect between design intent and actual performance, often framed in terms of energy use, water use, occupant comfort, or other measurable outcomes.

1.1 Performance gap

There is plenty of evidence around the globe to support that most high-performance buildings do not perform nearly as well as they were intended to perform. From schools to commercial buildings, high-rise residential apartments to single family net-zero houses, it is very rare that actual performance reflects the anticipated performance. (Norford et al, 1994; Scheuer et al, 2003; Salehi et al, 2015; Fedoruk et al, 2015; Bordass et all, 2004)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

While the majority of studies on buildings agree that the performance gap exists and is a significant problem within the realm of green and high-performance buildings, there is no single confirmed reason for this gap. In some cases, it is due to complicated systems that were not well understood when they were designed, so their actual functionality is much different from assumed conditions (Li et al, 2014). In other cases, the expected performance is an inaccurate number, because the assumptions used to create the original energy models are incorrect (SUN). In many studies, it has been shown that occupant behaviour and schedules can be one of the biggest contributors to variations in performance. (Salehi et al, 2015; Norford et al, 1994; Wei et al, 2015; Demanuele et al, 2010).

Performance gaps are not uncommon in green buildings. There are many different aspects of building performance, and if any of them are not designed, implemented, or used correctly, it can result in the building performing very differently than intended. Often poor design or integration of these sustainability measures end up resulting in substantially higher energy use than predicted. (Li et al, 2014; Torcellini et al; 2006; Dronkelaar et al, 2016; Demanuele et al, 2010; Wilde, 2014; Chu, 2016.)

Green and high-performance buildings often use extremely state-of-the-art ways to attempt to save energy or improve energy efficiency. Such attempts to limit energy use in buildings can be high-performance envelope assemblies, innovative mechanical systems, architectural solutions to problems like daylighting and shading, along with many others. While many of these attempts have been proven extremely effective when implemented correctly, they can have large negative effects on buildings when they are not done correctly (Salehi et al, 2015).

Designers, architects, engineers, and contractors need to have a much better understanding of how their systems work and influence all aspects of the overall building in order to use them effectively. Trying to design these types of systems in a bubble away from other key stakeholders in building design, or without fully understanding how they work, can end up doing more harm than good in the design of a high-performance building meant to be “green.”

1.2 Energy models

In the design stage of buildings, especially high-performance buildings, energy models are used as a way of seeing how all of the different aspects of the building interact with one another in terms of energy usage. Since building systems are incredibly complex, it is hard to see how one decision may affect another. Energy models help with this, by allowing iterative changes that give outputs of overall energy use, to show which parameters have the largest effect on the overall building. This helps influence decisions all across the building, from architectural form to mechanical systems to construction techniques (Harmer and Henze, 2015).

In addition, to determine how well buildings are actually performing after final construction and occupancy, utility data should be compared to the predicted performance of the building. These baseline performance targets most often come from energy models, which provide estimates for building energy use.

High performance buildings almost always use energy models to help in the design process, but the issue with energy models for new construction is that they are almost never accurate in the sense of “matching reality.” The purpose of design-stage models is to “provide relative energy use,” that is, to compare the effectiveness of various methods to be implemented in the building (Dirkes and Weaver, 2016). There are many assumptions made to complete an initial energy model, many of which may not reflect the actual usage of the building and result in performance estimates that can generally range from fairly close to wildly inaccurate (Fedoruk et al, 2015). Despite these performance estimates being generally incorrect most of the time, they are still the performance targets which are referred to throughout the life of the project. The difference between these values and actual utility bills is how the performance gap is explicitly measured.

Since using early design-stage energy models often does not reflect (even roughly) performance, a better usage of energy models is calibrated energy models. Calibrated energy models take actual building usage (from utility bills, etc.) and re-model based on actual performance. The way this is completed is by varying individual parameters one by one until the model mostly closely reflects the actual utility data or data points of those parameters. When individual energy users are determined as accurate reflections, they are combined into an overall building energy model which closely resembles the final constructed building (Salehi et al, 2015).

Calibrated energy models are the closest virtual representations of the building as-is, and can be very useful in several different ways. The process of calibrating an energy model can be very telling, highlighting which areas of

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

the building have the biggest impact on overall energy use and which parts of the existing model are not accurate, showing where the underlying issues are. They can also be used to analyse the effectiveness of various changes to the building (like implementing energy conservation methods), or they can be used to perform sensitivity analyses of what actually has the biggest impact on energy use. (Claridge, 2004; Demanuele et al, 2010)

Energy models are hugely powerful tools when it comes to analyzing the success or failure of high-performance buildings. The problem with energy models is that it is essential that the models are as accurate as possible to aid in diagnosing and fixing issues. If incorrect assumptions are made, energy models will not accurately reflect actual performance.

1.3 Eliminating the performance gap

Since the performance gap has come to light, there have been many strategies suggested to try and eliminate it. For the most part, these strategies fall under two categories: attempting a more integrated design process, or catching and fixing issues by using building commissioning.

1.4 Integrated design process

The integrated design process is a method of building design and construction that aims to ensure no part of a building is completed in isolation. The IDP ensures that there is much cross-disciplinary teamwork which results in a more sustainable building: all problems and issues are dealt with by a whole team, rather than an isolated individual.

The integrated design process is one such method meant to ensure that all of the various aspects of the building work together seamlessly. It is achieved by bringing together disciplines that would not normally work together in the traditional design of buildings. It emphasizes the idea of a building as a complex system where one change can have huge effects on other aspects, and tries to eliminate those effects by addressing them before the changes are made. It also strives to ensure all systems work well together rather than conflict, and prevents redundancies by allowing team members to work together (REED and GORDON). This helps to reduce the performance gap because it allows for systems to be designed properly, without inadvertently interfering or causing issues in other areas of the building. When a building team works together in all aspects of the design and construction of buildings, some

The underlying principle of the integrated design process is recurrent in almost all methodologies trying to improve design: the final design of a building should be seamless and cohesive, not a fragmented and uncoordinated approach as it is in current building practices (Fedoruk et al, 2015).

1.5 Commissioning

One way to ensure the actual performance targets of HPB's are met is through a process called commissioning. Commissioning is a quality assurance process which exists to ensure systems and buildings are meeting their designed performance requirements (Barich, 2007). It can also be used to find and correct a variety of mistakes relating to performance in existing buildings. Commissioning ensures that owners get what they pay for in buildings, and could be one of the most powerful tools for ensuring acceptable performance of green and high-performance buildings. However, commissioning is one of the least understood strategies and as such rarely gets implemented, or is used to highly varying degrees of success from building to building (Mills, 2010).

There are many different aspects of commissioning, meant to address the various stages of buildings- design, construction, and operation.

The first is initial commissioning, which covers the design and construction phases of the building. It is meant to confirm that the performance intent of the building, including requirements for code and various green building targets, have been met in the design of said building. Initial commissioning also exists as a means of confirming that the actual construction of the building and the implementation of systems accurately represents the design, which in turn guarantees that the performance targets are met, assuming the design accurately represents performance goals (ASHRAE, 2012).

After a building is completed, ongoing commissioning is the means by which the building can be checked periodically to ensure the building is continuing to meet its performance goals. Ongoing commissioning is especially useful for finding where systems have started to fail or lose efficiency. It identifies the problems, and if used properly can give clues into how to fix them (Barich, 2007).

Continuing commissioning is an extension of ongoing commissioning, but instead of a periodic check-up on the building, it is a continually monitored process of checking performance. Automated building measurements and systems are the most helpful for continuing commissioning, and can be extremely helpful in triggering alarms or alerting owners when building performance falls outside of an expected range (Harmer and Henze, 2015).

Retro- and re-commissioning are, for all intents and purposes, the same thing. Retro-commissioning refers to the commissioning process applied to a building that has never had commissioning performed. Re-commissioning looks at all the same things as retro-commissioning, but is applied to buildings that were originally commissioned but are now failing. Both types of commissioning help to narrow down the actual reason for generally identified performance issues. Retro- or re-commissioning usually occurs when building owners realize various discrepancies of building performance, and a study is undergone to determine why that is. These studies and re-commissioning projects most often utilize calibrated energy models and extensive analysis of building data, including utility or building monitoring (Schultz and Ayala-Navarro, 2012).

An overview of the types of commissioning can be seen in Table 1 below.

Type	Initial		Ongoing / continuing	Retro- / re-
Role of Commissioning	Ensure design meets performance targets	Ensure as-built building represents designed building	Ensuring building continues to perform as intended	Identify the reasons for performance issues
	QC	QC	QC/Diagnostic	Diagnostic
Why?	Helps to guarantee that architects, designers, and engineers actually realize what they're designing and know/ can prove that the specified systems/assemblies meet requirements	Assuming the design met performance targets, if the built building matches the designed building, then performance targets have been met	Makes sure that the systems continue to operate as they are supposed to, and that issues are caught and dealt with	Fixes issues in existing buildings, when obvious performance deficits have been identified by building owners or users

Table 15: Summary of commissioning

2. THE BUILDINGS

All three buildings are located in southern British Columbia, Canada. Two are located on Vancouver Island, and one is in the City of Vancouver. Each was designed to be a high performance buildings. The two Vancouver Island buildings were aiming for LEED certification- one Gold and one Platinum. The Vancouver project was aiming for full Living Building Challenge certification, a much more stringent process with higher performance targets than LEED. The design of all three buildings included an energy model to predict performance, and all three have some sort of energy monitoring systems to capture information about energy usage across the building.

2.1 Gulf islands national park reserve of canada- operations centre

The Operations Centre for the Gulf Islands National Park Reserve of Canada is located in Sidney, B.C. on Vancouver Island. It is a three storey office building for the operation and administration staff of the park. It was designed to LEED Platinum standards, with an estimated energy consumption of 75% than the baseline Model

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

National Energy Code reference code. There were many innovative systems proposed for this building, including an ocean based geothermal heat exchange system. Additionally, since this was a LEED project, commissioning was a required credit for achieving certification.

2.2 VanDusen gardens visitor centre

The VanDusen Gardens are a 22 hectare botanical garden located in the middle of Vancouver, BC. The Visitor Center is a mixed-use building meant as the first point of entry to the gardens. It has a shop, a café, offices, and flexible rental spaces for events, classrooms, or meetings. This building was designed to meet Living Building Challenge full certification, which involves incredibly stringent targets like creating 105% of the energy it uses and treating all its own storm, grey, and black water. The VanDusen Visitor Centre, in order to meet these very high performance targets, employed several highly unique systems to try to achieve these goals. They employed a mix of passive strategies in addition to active mechanical systems to address energy goals, and a complex water collection and recycling system to address water targets. Living Building Challenge does not require commissioning, unlike LEED, but also unlike LEED, it is a performance driven certification system that requires buildings to prove they meet the targets.

2.3 Vancouver island university- cowichan campus

The VIU project, located on Vancouver Island in Duncan, B.C. is a university building comprised of classrooms, administrative offices, a cafeteria, laboratories, and other educational spaces. It was designed to LEED Gold standards, and entered into an Energy Study Agreement with BC Hdyro as part of the New Construction Program, which aimed to study how to reduce energy consumption of new buildings in BC while still providing owners with added benefits to their building, like higher productivity and occupant satisfaction. Similarly to the Gulf Islands Parks building, aiming for LEED certification meant this project was commissioned as part of the credit requirements. The measures implemented into the building to achieve high energy performance were fairly similar to the other two projects, and included a unique heat exchange system and rainwater collection and grey water recycling.

2.4 Performance issues

Since the buildings have been in operation, there have been significant gaps between predicted and actual performance. These have been determined through a variety of avenues: utility bills were higher than expected, actual energy consumption was higher than expected, occupants have reported thermal comfort issues, the full LBC certification was not achieved due to systems not working as intended, and other issues that have been discovered and fixed over the life of the buildings so far. It is these significant issues in all three buildings that inspired the need for further study.

The purpose of these projects is to determine what the underlying causes of the performance gap are, how to fix them, and how to prevent the same gap from occurring in future buildings. Using calibrated models, general discrepancies will be narrowed down into specific end-uses, identifying the reasons for the overall gap.

3. PROJECT PLAN

Many people will argue that the biggest cause of the performance gap can usually be traced to issues with either occupancy or systems that work improperly. Theoretically, both of these problems are early-stage design issues, as occupancy schedules are normally an assumption made for the energy model and it is always assumed that systems work 100% as they are intended. However, actual increased occupancy rates or inefficient systems both present themselves only after the building is handed over, because it is not until then that the discrepancy becomes apparent.

When it does become apparent, re- or retro-commissioning is performed using calibrated models to determine the problems and identify fixes. Since these measures are taken in a later commissioning step, it is rare that that initial commissioning is blamed for the failure, even if that initial step should have caught the potential mistakes.

Additionally, if a building is handed over to owners with issues to begin with, any further problems caused by anything even as small as wear and tear will only compound the difficulties further, widening the performance gap.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

This would mean that had the problems been caught during initial commissioning, they could be fixed and targets adjusted accordingly, bringing predicted and actual performance closer together.

The purpose of this project is to determine the effects of the failures of initial commissioning on the overall performance of green buildings. In today's construction world, many of the issues associated with initial commissioning failures are accepted as "the reality of the construction world," but it is extremely important to recognize where this first quality assurance procedure goes wrong, and how much of an impact it has on final building performance.

If the building starts off working like it is intended, it will be much easier to diagnose problems when they arise, rather than trying to diagnose the issues of an already flawed system. This is why the focus of this paper is on the initial commissioning of the three buildings, rather than only applying retro-commissioning to identify and fix issues.

By studying the documentation of the building design and construction process, and studying the current state of the building, we will identify two main flaws in the early design process:

1. Parts of the building design that were designed improperly due to lack of knowledge or improper assumptions (ie. U-values of walls much higher than anticipated due to thermal bridging, occupancy schedules were inaccurate, mechanical systems did not function as intended)

2. Parts of the building design that were implemented improperly during construction (ie. air barrier details were installed incorrectly, vents were placed in the wrong spots, flow direction in pumps was opposite of what it should have been, specified product alternates were lower performance)

These two types of issues are those that should be caught during initial commissioning, but often aren't. We will use the documentation available as well as post-occupancy surveys to determine which types of these issues were present in each of the three buildings.

At the same time, other projects are being completed to study other aspects of the performance gap. These projects will be complete with calibrated models of each of the three buildings, to show the most accurate energy and performance breakdown of the buildings.

Using these calibrated energy models, the impacts of each of these failures in terms of total building performance will be analyzed for each building and its corresponding issues. If the impacts on overall performance are noteworthy, a sensitivity analysis will be completed to see which of them is the most critical.

The results of the sensitivity analyses will be compared across the three buildings, to see if the same issues present themselves in the different projects. This will lead to discovering the common, general issues which are prevalent across multiple building types, rather than just studying each building in isolation.

4. CONCLUSION

High-performance buildings often have issues where their actual performance does not match the performance predicted by energy models in the early design stages. Once performance gaps exist, calibrated energy models must be completed to identify and fix these issues.

Some ways to try and eliminate the performance gap in the first place is to implement integrated design processes or building commissioning, both of which can limit the discrepancy between actual and predicted performance.

This project will investigate how much of an impact the failures of initial commissioning have on overall building performance, by examining how much better a building would perform if the design and construction met the performance requirements laid out by the building owner. It will accomplish this by using existing documentation, post-occupancy surveys, and calibrated energy models to perform a sensitivity analysis to see which aspects have the biggest impact on overall performance.

ABSTRACT

Space heating and cooling comprises 40% of the global final energy use. With more energy efficient technologies in heating and cooling, up to 10% of global energy consumption could be saved. In agriculture, poultry sheds are used to shelter poultry (broilers and layers) for the production of meat and eggs, sources of animal protein for most people. The range of acceptable indoor air temperature for poultry sheds is 15°C to 25°C for mature birds, and higher temperatures are required for young birds depending on the stage of growth. It is recognised that the costs of heating, cooling and ventilating poultry sheds constitutes a significant portion of the chicken farm operating costs. Various aspects can be considered to reduce these costs considerably. The potential improvements include better thermal performance of building envelopes, energy efficiency of HVAC systems and operational schedules or timing of the production cycle. This paper aims to reduce the cooling and heating energy consumption by identifying the most suitable operational plan. The heating and cooling demand cycles of a poultry shed in the Central Coast region has been investigated in detail by using building energy simulation software tools. This paper reveals that the operational schedule (i.e. begin dates of the cycles of production) has profound influence on energy consumption. The optimised operational schedule can save an average of 12% of overall energy expenditure and 20% on heating.

Keywords: building energy simulation, energy use, poultry shed

1. INTRODUCTION

The global annual energy consumption is about 13,000 Mtoe (~544 EJ), resulting in nearly 50 Gt CO_2-e Greenhouse Gas (GHG) emissions. It is widely accepted that our future energy sources could not highly rely on fossil fuel such as oil and gas since these resources are finite, and more importantly the majority of GHG emission (65%) comes from them. To provide our next generations with a sustainable energy future, alternative approaches must be adopted as soon as possible.

Space heating and cooling comprises a significant part (40% - 50%) of the overall final energy use, resulting in 20 Gt CO_2-e GHG emissions. By using advanced technologies for space heating and cooling, up to 1,509 Mtoe of global annual energy consumption could be reduced by 2050. In order to develop sustainable buildings and improve energy efficiency in existing buildings, several approaches can be considered, which include improving the thermal performance of the building envelope, increasing the energy efficiency of HVAC system and determining the most suitable operational schedule.

The agriculture sector constitutes a significant part of Australia's economy. In year 2014/15; the overall sector was worth $51 billion, comprising 3% of Australia's total gross domestic product (GDP). However, when considering all the add-on processing industries, the overall contribution of the agriculture sector rises to 12% of the GDP. Among these industries, nearly 600 million chickens are raised every year for producing meat and a typical shed provides about 200,000 chickens annually, which means there are currently around 3,000 poultry sheds for chicken meat production in Australia. The overall costs of heating and cooling for chicken farms are estimated to be $80 million per year.

To raise chicken/ broiler efficiently, poultry sheds are designed to meet the specific requirement for chickens during different growth stages. The indoor temperature is a vital factor for the chicken to grow properly in an effective timeframe. Within each growing cycle, the indoor air temperature requirement changes from 33°C at the beginning to 21°C in the end, which results in a unique heating/cooling load cycle depending on the start date. Since outdoor

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

air temperature changes throughout the year, a considerable amount of energy is sometimes needed to maintain the required indoor air temperature (i.e. to reach 33°C in winter).

Researchers have conducted building simulations for poultry sheds for heating/cooling load cycles in recent years. Kharseh and Nordell (2011) estimated the heating and cooling loads for a typical poultry shed in Syria in order to design a geothermal cooling and heating system for the shed. However, the assumption made for the chicken is not enough to describe the heat generation due to the growth of chicken, which may result in an inaccuracy of the heating and cooling loads. El Mogharbel et al. (2014) developed a 3D computational simulation model for the heating system of a poultry shed in East Lebanon, with various factors taken into consideration. However, this model is based on the solar assisted heating system only. At the same time, no annual data and cooling loads has been reported. Rojano et al. (2015) developed a 3D model using a CFD commercial software package, Fluent. In their study, the heat and mass transfer within a poultry shed in the US is analysed in detail. However, the aim of their work is to analyse temperature, humidity and air quality in the shed. Hence, no heating and cooling loads were reported. Besides, owing to the complexity of this 3D model computational time is long, thus a detailed model for annual heating and cooling loads is unlikely to be feasible. Hamilton et al. (2016) developed a thermodynamic model for the thermal analysis of a poultry shed in Australia. This model contributes to a theoretical analysis of chicken growth, heat generation, and water consumption during the cycle. Validation based on measured data was also made on the model. However, no models were derived in this article and there were no direct data for heating and cooling loads. From the review of the literature, it follows that limited knowledge is available to derived sheds load cycles, particularly of local settings.

Due to the different agricultural standards encountered among countries (i.e. construction materials, operational schedules) and the various climate conditions of the poultry sheds, it is essential to analyse the heating/cooling demands for local conditions, in the case presented herein, for Australia. The aim of this paper is to estimate the heating/cooling load for a specific poultry shed in NSW, Australia, as representative of current practice in the area. The estimated costs base on the current HVAC system is also reported. An optimisation of growing cycle start date for the minimum cost is investigated.

2. BUILDING SIMULATION MODELS

EnergyPlus is widely used for building energy performance simulations. In this paper, an EnergyPlus model was developed for a poultry shed in Central Coast, NSW. Other details of the methodology employed are included in this section.

2.1 Simulation parameters

The poultry shed investigated in this investigation is located in the Central Coast Region, NSW, Australia (approximately at 33°23'49"S and 150°24'09"E). Climate data are essential for the building simulation. A typical meteorological year (TMY) data generated by an algorithm based on 20 years of recorded dataset is widely used to predict the long term performance of buildings. In this paper, the TMY file generated by Meteonorm 7.1 based on recorded climate data from 1990-2010 is utilised. An average error of 6% in year sum comparing with the actual climate can be expected by using this method of hourly data generation.

Time/Days	Weight/kg	Metabolic Weight/w	Power/W	Population of Chicken	Size of Shed	Required Temperatue/°C
1	0.04	0.09	0.68	40,000	Small	33.0
7	0.16	0.25	1.82	40,000	Small	30.7
14	0.42	0.52	3.82	40,000	Small	27.5
21	0.84	0.88	6.43	40,000	Large	24.8
28	1.39	1.28	9.36	40,000	Large	22.0
35	1.97	1.66	12.13	40,000	Large	21.0
42	2.43	1.95	14.21	30,000	Large	21.0
49	2.74	2.13	15.55	20,000	Large	21.0
56	2.90	2.22	16.23	10,000	Large	21.0

Table 1: Poultry shed simulation parameters

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

As shown in Table 1, there are two building models to meet the different space requirements as chickens grow. The small area within the shed is for the first three weeks of growth with dimensions of 18 x 18 x $3m^3$. Later, the bigger chickens are redistributed into a larger space within the shed, with dimensions of 18 x 160 x $3m^3$. The building is constructed with 75mm 'Coolroom' walls (thickness: 0.075m, thermal conductivity: 0.039 W $m^{-1}\cdot K^{-1}$, density: 16 kg m^{-3}, specific heat: 340 J $kg^{-1}\cdot K^{-1}$) with no windows. A chicken usually attains 2.8 to 3kg at the age of 8 weeks. The mass of chicken for the first 35 days is provided by our industry partner (Ground Source Systems Pty Ltd) while the following 21 days data is generated through a quadratic function. Heat produced by a living creature is proportional to the metabolic weight, which is the unit of 0.75 power of kg. The heat rate generated by an adult chicken is 160 kcal d^{-1} w^{-1} (7.75 W w^{-1}).

2.2 Operational schedules

In Australia, it usually takes about 55 to 60 days for a recently hatched chicken to develop fully for the market. Meat broilers reach the mass of harvest at the age of 5 weeks, and partial harvest of chicken happens up to four times in one batch on a chicken farm due to the different demand for light and heavy chicken meat. After that, there are 5 to 14 days for clean-up and preparation for the next batch. The simulation in this paper is based on the operational schedule shown in Table 1.

As shown in Table 1, during the first 21 days, chicks are kept in a small area with controlled temperature inside the shed to save energy. At the 22nd day of each batch, the shed is expanded to the full area. At the 35th day, the average mass of a chicken reaches about 2 kg, meeting the requirement for the market. The first harvest happens in the midnight of the 35th day, when one-fourth of the overall population, which is 10,000 chickens, are taken away. Later, in every following week chickens are taken away at different stages in order to suit the demand of the market. The partial harvesting significantly decreases the internal heat gain, hence influencing the heating and cooling loads. The final harvest happens at the end of the eighth week, followed by two weeks of clean-up and preparation for the next batch.

3. TITLE HEATING/ COOLING LOADS AND COSTS ESTIMATION

By utilising 'Ideal Air Load' option in EnergyPlus, the hourly heating and cooling loads were estimated. The algorithm applied is the third order backward difference method. Estimation of costs based on the current HVAC system has also been conducted.

3.1 Heating and cooling loads for different starting dates

In order to determine the heating and cooling loads for the different starting dates, 52 batches starting at different weeks for one year were investigated. The first week starts at 3rd of January, the first working day in a year in Australia. As an example, Figure 1 and Figure 2 describe a typical eight-week batch starting at the 19th of December. The indoor temperature requirement is set every day to meet the temperature requirement for raising broilers. During this batch, the heating load decreases as a result of increasing heat generated by the chickens. After that growth stage, the cooling load significantly increases during the following first five weeks. After each harvest, the internal gain (heat produced by chicken) reduces, which results in a reduction of cooling loads.

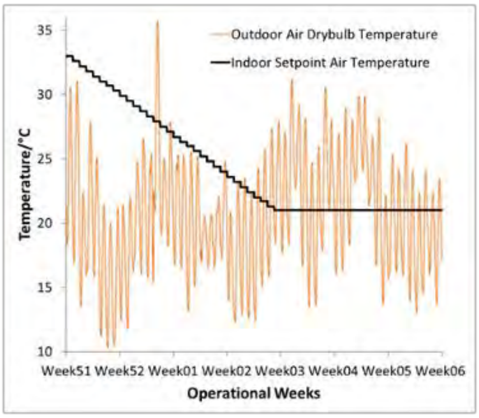

Figure 1: Indoor and outdoor air temperature

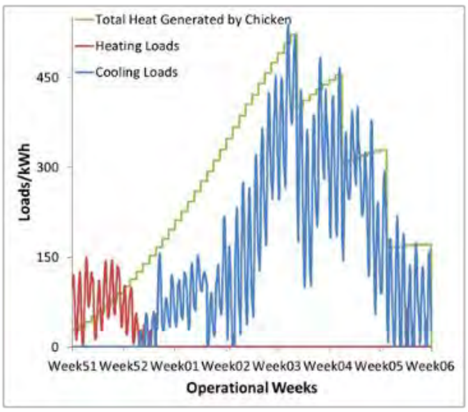

Figure 2: Hourly heating and cooling loads

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

After hourly heating and cooling loads for 52 starting weeks were acquired, the overall energy consumption for each batch was obtained by summing up the heating and cooling loads. As shown in Figure 3, at the beginning of the year (summer), raising a batch requires much more cooling than heating (nearly eight times higher). Later, as the outdoor air gets colder, the heating loads increase while the cooling loads decrease. At the middle of July (winter), the heating load reach the peak (105,108kWh) for one batch, while the minimum cooling load, 23,366kWh, appears in the 24th week. After the coldest periods of the winter, the heating load begins to reduce together with the boost of cooling demand. The highest cooling demand happens at the end of the year, corresponding to the minimum heating demand of only 11,575kWh for one batch.

Figure 3: Loads for different starting weeks

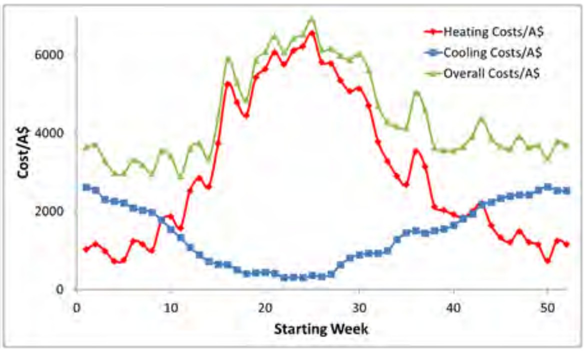

Figure 4: Costs for different starting weeks

3.2 Estimation of costs

Chicken sheds are typically equipped with gas heaters for heating and evaporative coolers for cooling in NSW. The gas heaters were assumed to have an efficiency of 0.85. It was hard to determine the operating efficiency of evaporative coolers because their performance highly relies on the relative humidity and ambient air temperature. However, it is known that evaporative cooling usually saves around 75% of the cost compared with standard air conditioning. This paper assumed one-fourth of the cost of air conditioners with COP of 2.5 as estimation. The prices of energy applied for the analysis are 12.9c/kWh for electricity and 5.3c/kWh for gas.

Figure 4 shows the heating and cooling costs for the different starting week. Corresponding to the loads, the heating cost rises from AU$ 722 to more than AU$ 6,500 in the mid-year while the cooling cost reduces from AU$ 2,614 to AU$ 301. After winter, the heating cost decreases and the cooling cost increases. Since the evaporative cooler is cheaper to operate, the cooling cost is much less than heating in the year total, despite the nearly doubled cooling load's peak. The results also show that raising a batch in winter costs much more than in summer. The most cost-effective period for starting a batch is from late September to early April.

4. OPERATIONAL OPTIMISATION

As fully-grown chickens generate large amounts of heat, i.e. 40,000 chickens in a shed could generate heat up to 600kW, raising a batch in summer consumes a large amount of energy for cooling. In winter, due to the low outdoor temperature and the relatively high initial temperature requirement (33°C on the first day), the heating loads could also be large. By avoiding raising chicks in the coldest time of winter as well as adult chickens during the hottest weather in summer, a suitable yearly operational schedule reduces the heating loads in winter and the cooling loads in summer.

A typical batch takes eight weeks duration. It is almost impossible for a shed to run six whole batches in one year due to the time required for cleaning and preparation. In this paper, five batches were considered for one year. Assuming a minimum break of one week for cleaning and preparation, the possible intervals between each batch are one to six weeks. Assuming at least a one week break between the last batch and the first one, there are overall 3,248 possible operating schedules. In this paper, the costs of all of the 3,248 possible schedules have been estimated using a Matlab code developed.

Figure 5 shows that the annual costs for all operating schedules resemble the normal distribution pattern, with an average of AU$ 22,126 and the standard variations of AU$ 852, which is calculated with the Maximum Likelihood

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Estimation (MLE). MLE is a method that estimates parameters of statistical models based on given data. The distribution has also passed the Kolmogorov-Smirnov test in Matlab, a hypothesis test for normal distribution, at a 1% significance level.

In statistics, for the normal distribution, the three standard deviation (sigma) rule treats the values within the region of the distance of three times of the standard deviation to the mathematical expectation as a practical certainty. By starting at 5th, 14th, 28th, 39th and 48th week of the year, the most economical schedule costs only AU$ 19,514, which is out of the three-sigma region (AU$ 19,570 to AU$ 24,681). This result reveals the significance of the optimisation because it is improbable for a farmer to operate the chicken shed with the minimum cost if the optimised schedule identified is applied.

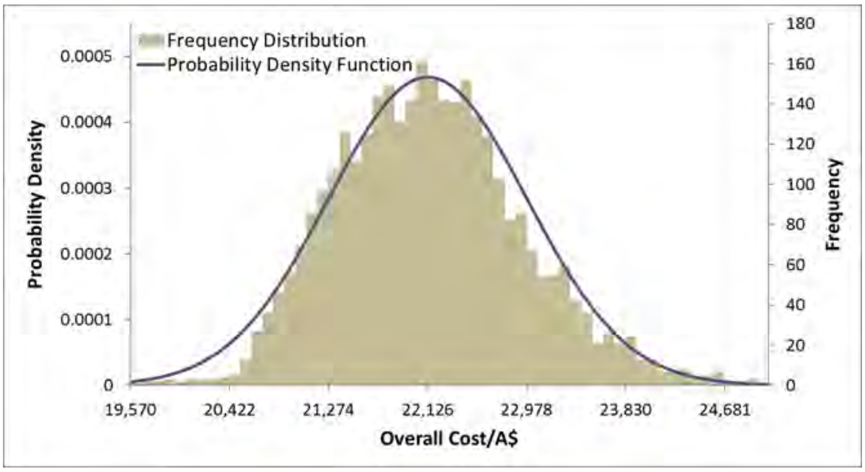

Figure 5: Costs distribution for all operating schedules

More specifically, the optimised schedule costs are AU$ 11,972 for heating and AU$ 7,542 for cooling. Although the cooling cost is 5.5% higher than average, this schedule nevertheless consumes 11.8% lower than the overall average and saves more than 20% on heating. Since gas heaters produce GHG emissions, adopting this schedule would also reduce the GHG emissions. For the typical poultry shed investigated, approximately 10 t CO_2-e would be reduced annually, equivalent to the removal of two cars or the planting of more than 600 trees per year.

5. CONCLUSION

This paper investigated the heating and cooling load cycles of a typical poultry shed in Central Coast Region, NSW, Australia by using EnergyPlus simulation engine. The simulations considered the chicken growth rate and metabolic heat generation, operating schedules, building envelop materials, orientation and climate conditions.

The two vital factors that influence the energy consumptions for heating and cooling the chicken shed are internal gains from the metabolic heat of chickens and the climate conditions. The energy consumption could be reduced by changing the operating schedules. By evaluating the heating/cooling load profiles for batches starting at 52 different weeks throughout a year, the relationship between energy consumption and operating schedule has been discussed. The results reveal that the period from late September to early April is the most economical time for starting a batch.

Considering the estimated cost based on the current HVAC system, an operational optimisation for the minimum cost is suggested. The results show that operational optimisation would significantly reduce the heating/ cooling loads as well as the costs for heating and cooling. By applying the lowest cost schedule, on average 20% of the heating cost and 12% in total cost could be saved.

ACKNOWLEDGEMENTS

The authors would like to thank Mr. Brad Donovan from Ground Source Systems Pty Ltd and Mr. Brad Brown for kindly providing information regarding the poultry house.

ABSTRACT

There has been an increase in demanding environmental performance information of building materials and systems (components) from policy makers, due not only to high resource use but also environmental impacts such as climate change, and from the designers of sustainable or high performance buildings through certification systems. Such information requires life cycle impact dataset with multiple impact indicators and are proposed to be used to assess the sustainability of a whole building. Turkish Construction Materials Life Cycle Database is formed including data from Turkish Life Cycle Inventory Database as well as data from products with Environmental Product Declarations. The database includes product and sector specific primary data sets as well as generic data reflecting Turkish manufacturing conditions. Data quality requirements for the database is very high, i.e. mainly primary data.

This database will be introduced and its relevance to Turkish green building sector will be discussed. The use of the database within the context of assessing the environmental impacts of a real building will be demonstrated. The database's relevance to the development of green building assessment schemes in Turkey as well as to the established assessment schemes will be discussed. Potential benefits of using the database in the Urban Regeneration in Turkey to to assess at least greenhouse gas emissions and its contributions to Turkey's commitment for Kyoto Protocol II for reducing such emissions will also be speculated.

Keywords: life cycle, construction materials, database.

1. INTRODUCTION

Life Cycle Assessment studies are becoming more important in assessing sustainability of buildings due to the sector's huge impacts on climate change and resource use such as materials, energy and water. Over 40% of carbon emissions, 50% of resource use is attributed to the sector. Embodied energy and carbon, which refers to energy and emissions during manufacturing of materials, becomes important part of building life cycle. Although its effects are reduced over the building life cycle due to long life of buildings, its effects are immediate, i.e. when a built is constructed, and will be even more prominent when energy efficient and/ or passive houses becoming more prominent. As such, demolition of a building is also relevant. As the awareness of the topic in the built environment has been increasing and the environmental concerns have been paid more attention to, the construction sector is led to Kyoto Protocol. The EU regulations are also focusing on resource efficiency and energy performance through Energy Performance of Buildings Directive 2002/ 91/ EC.

Several building assessment schemes have been developed in the built environment and construction sector. The well-known schemes are British BREEAM, American LEED, German DGNB. Turkish Green Building Council (ÇEDBİK) also develop the first local scheme for new homes. Each scheme has its own set of methodologies, some common some differs among them, to assess sustainability in a building context. To make such assessment more measurable and comprehensive, Life Cycle Assessment (LCA) is becoming an important element of these assessment schemes.

Embodied energy demand of a building is about one fourth of a total building energy demand. This ratio, however, increases for well insulated homes and for passive houses. As such embodied energy and carbon are becoming an important indicator for the sustainability of buildings. A cradle-to-grave LCA study can present the energy demand, carbon emission for climate change and other midpoint and endpoint impact indicators of a whole building from raw material extraction to manufacturing, construction and the end-of-life phases.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Construction materials with environmental indicators such as embodied energy and carbon is becoming widely available thanks to ISO 14025 Environmental Product Declaration (EPD) for products. An EPD is third-party (external) verified and registered document that communicates transparent and comparable information about the life-cycle environmental impact of products. LCA is always needed to obtain all the indicators required by EPDs.

Database containing life cycle environmental impacts of construction materials manufactured in Turkey have been developed to facilitate the assessment of environmental impacts of buildings. Compliant to international standards and called Turkish Construction Materials Life Cycle Database, it contains not only branded product specific but also generic datasets relevant to Turkey taken from Turkish Life Cycle Inventory Database (TLCID)]. So far with over 200 high quality datasets and growing with daily additions, it is comprehensive enough to become an important element of assessment schemes developed in Turkey. Such database is also useful for international green building assessment schemes that requires calculation of LCA as part of assessment, for example LEED and BREEAM. More importantly for Turkey, the Database will facilitate the calculation of carbon footprint for any Urban Regeneration project to be registered for the Kyoto Protocol II commitments. This paper demonstrates the use of this database to assess the environmental impacts of a multi-storey residential building reflecting the local conditions and makes the assessment relevant to Turkey.

2. METHODOLOGY

A four-storey residential building with 1200 square meter area constructed in Turkey was used for the case study (Figure 1). All the materials and assembly information of the building was taken from an earlier PhD study. The building is divided into the following components:

- Foundation
- Structure
- Coverings
- Internal Walls
- External Walls
- Profiles
- Glazing
- Roof

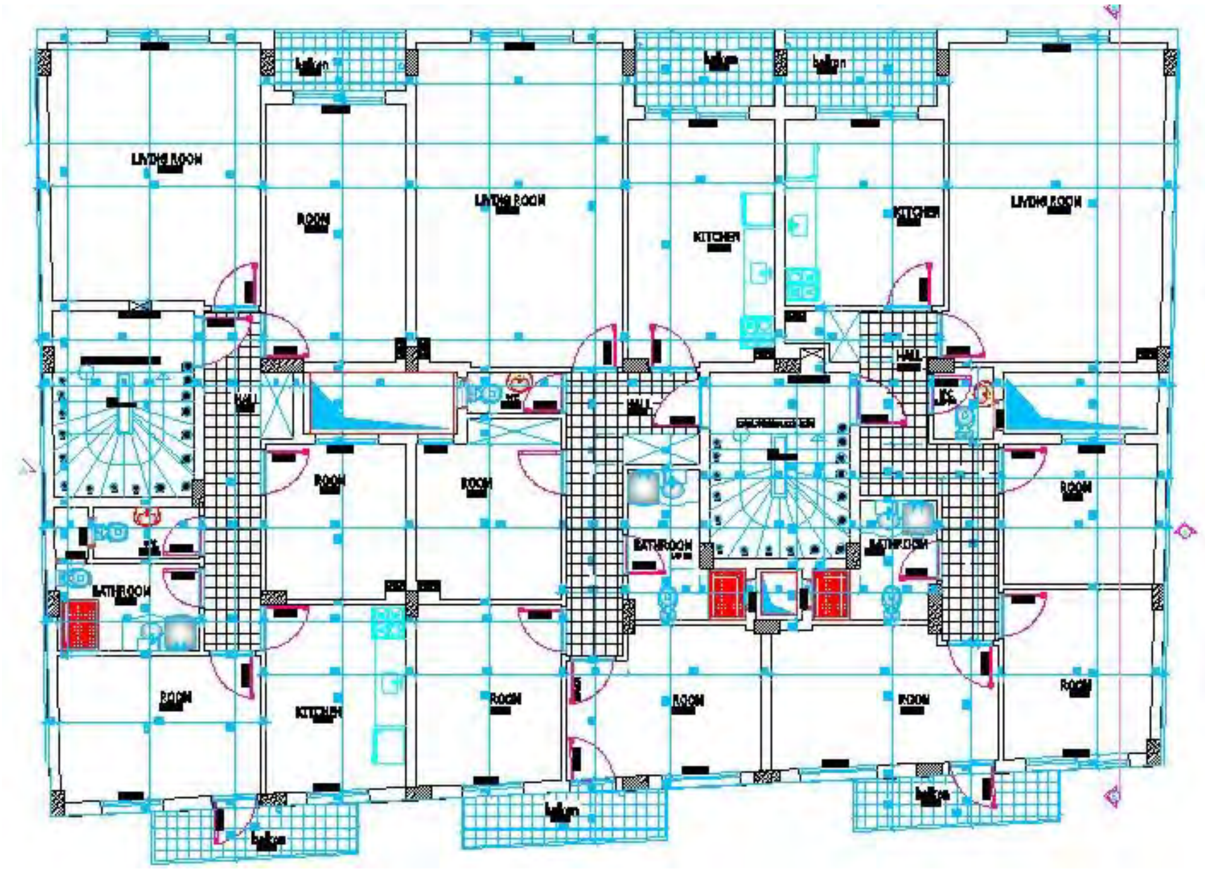

Figure 79: Architectural details of the buildings design used for the study

Building inventory involving all the above components was gathered from the design and insulation reports. The functional unit was considered as the entire building with 1200 gross sq. meters. The system boundary was determined to include the raw materials extraction from the nature, transportation from/ to raw material treatment, transportation to production site, manufacturing, fuel and energy consumptions. Datasets for Turkish electricity mix and natural gas mix is part of the Database taken from the TLCID database.

Many combinations area available for the types of components to use. For example, a flat-roof with tile covering but no insulations which was part of the assessment is shown in Figure 2. The following materials are required to assemble 1 m^2 of such roof:

- 12 kg ceramic tiles
- 2 kg cement based adhesives
- 0.1 kg geotextile felt
- 0.8 kg polymeric modified bituminous water proofing membrane
- 154.14 kg screed for inclined purposes (7 cm)
- 364 kg concrete slab (15 cm)
- 12.6 kg steel reinforcement
- 5 kg gypsum plaster (5 cm)

The rood component shown in Figure 2 can be modified to include insulation materials with various thicknesses such as XPS, EPS, Rockwool, Glasswool etc. Other sections of the component can also be modified per the architectural design requirements. Such flexibility is available for all components of the building highlighted above. Such flexibility gives the designer to do life cycle design study at an early stage of the design and find the best compromise between building cost, environmental impacts and life cycle cost.

All the inputs were inserted into SimaPro LCA software tool with Turkish Construction Materials Life Cycle Database. All environmental impacts are assessed in accordance with EN 15978 norm per total amount and per square meter. Only building materials stage A1-3 (Figure 3) is considered in this study. The other stages can easily be included to complete the full life cycle assessment. For the use phase, energy consumption figures from energy certificates can be used and match with the latest Turkish energy specific impacts from the Database.

Inventory for all other remaining building components were also collected to complete the assessment. Indicators per square meter is calculated.

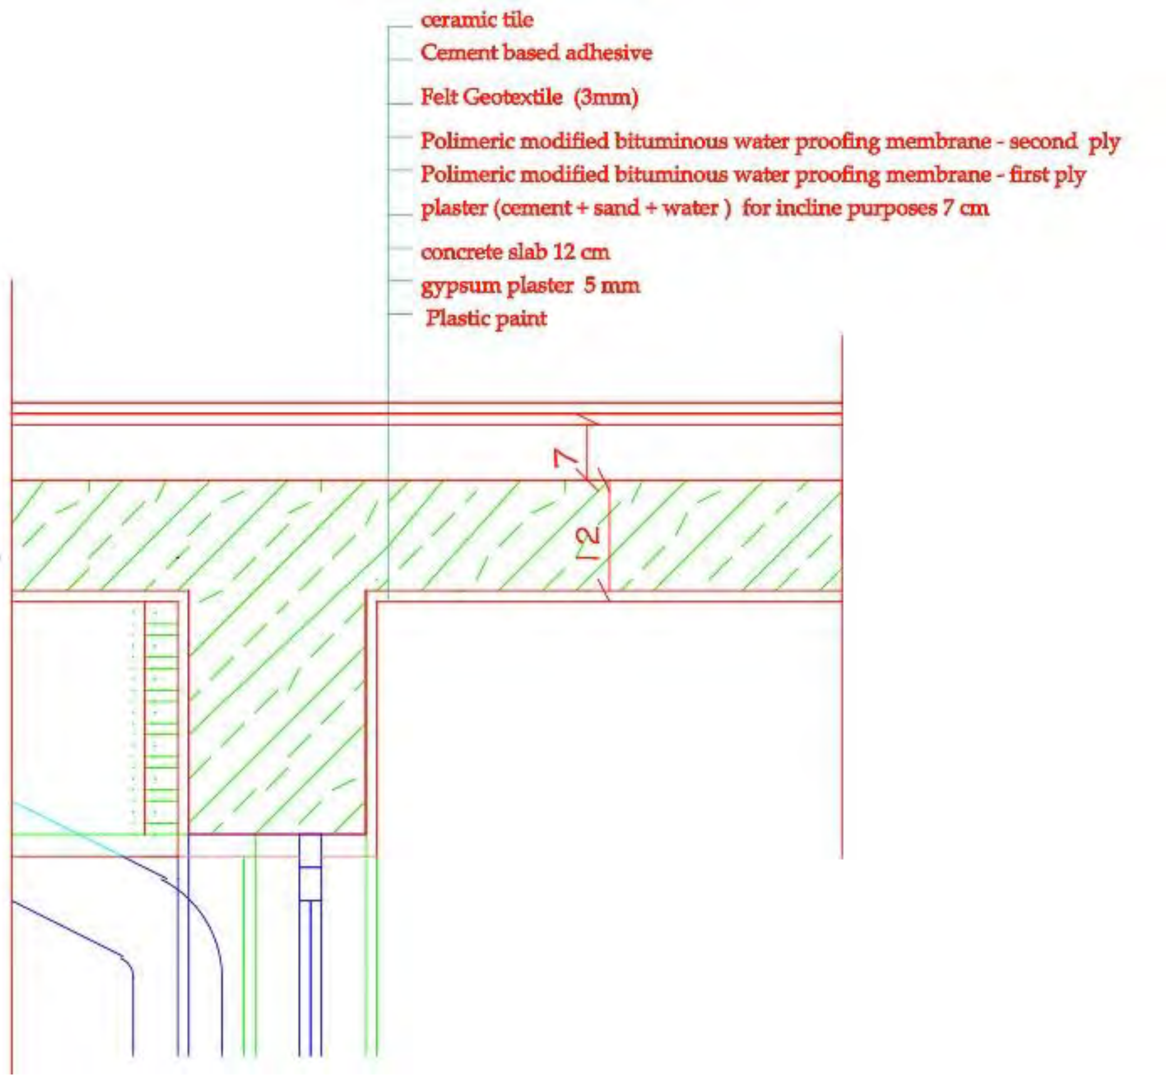

Figure 80: Design detail of flat roof component without any thermal insulation

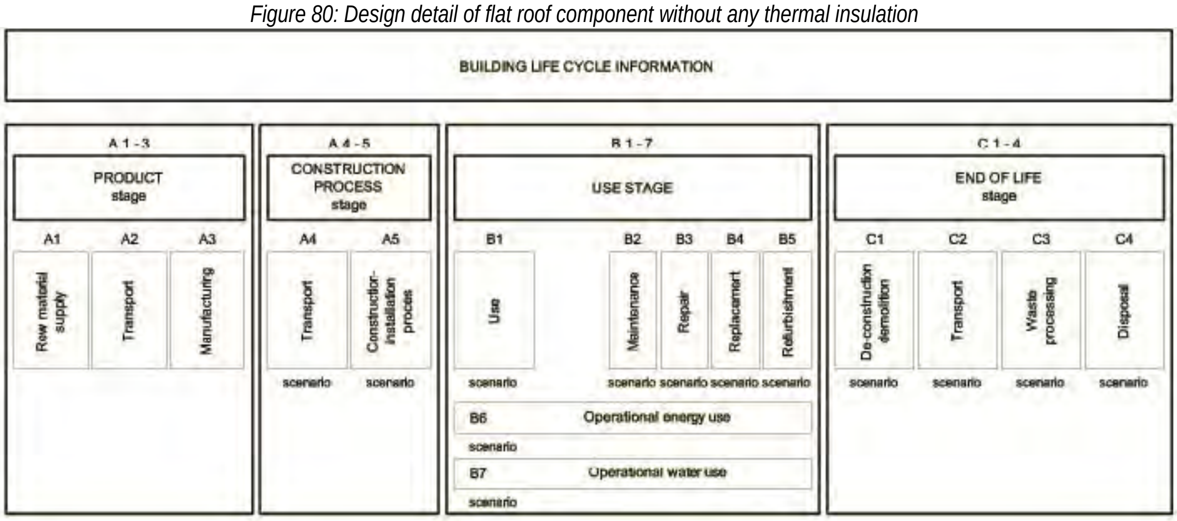

Figure 81: Different stages of the building life cycle assessment according to EN 15978

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 4 represents a system boundary flow from raw materials extraction to end of life stage over a buildings life time in compliance with EN 15978 standard. This LCA study focuses on the Global Warming Potential (GWP) and Energy Demand (CED) because of construction materials use, i.e. embodied carbon and energy demand of the construction materials.

The GWP impact is calculated using IPCC 2013 GWP 100a ver. 1.2 methodology that contains the climate change factors with a timeframe of 100 years. For embodied energy, Cumulative Energy Demand ver. 1.09 methodology is used.

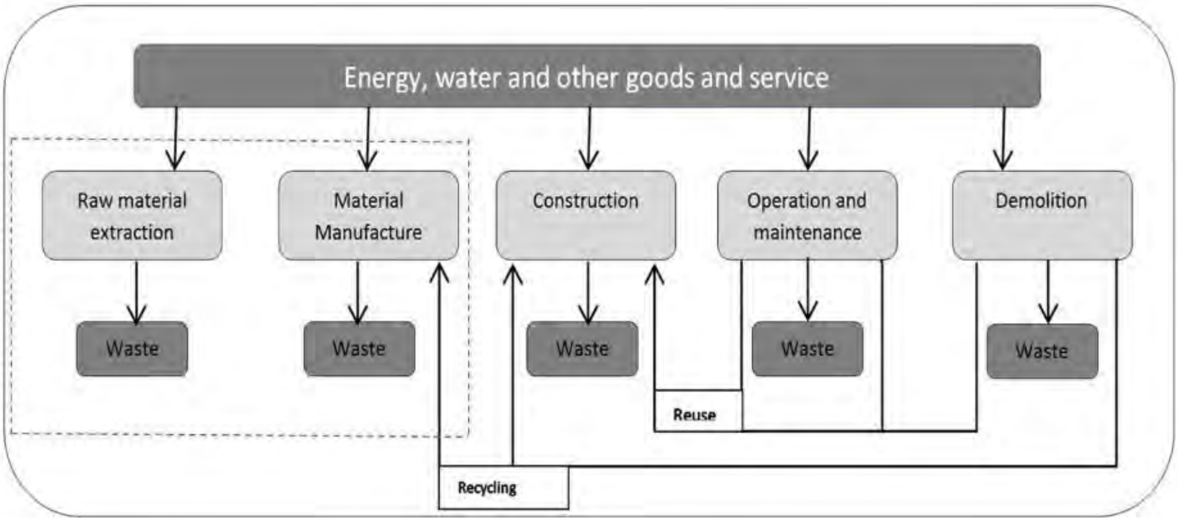

Figure 82: System boundary across the building life cycle

3. RESULTS

The GWP impact of all building components for 1200 square meter building are shown in Figure 5. As seen, structure and foundations are two building components with about 29% and 28%, respectively, the dominant embodied carbon impacts among all building parts. The total carbon impact of the building due to materials use (A1-3) is 476 913 kg CO2 eq. The values and relative contributions of each building components per one square meter of the building is shown in Figure 6. GWP per square meter is about 397 kg CO2 eq.

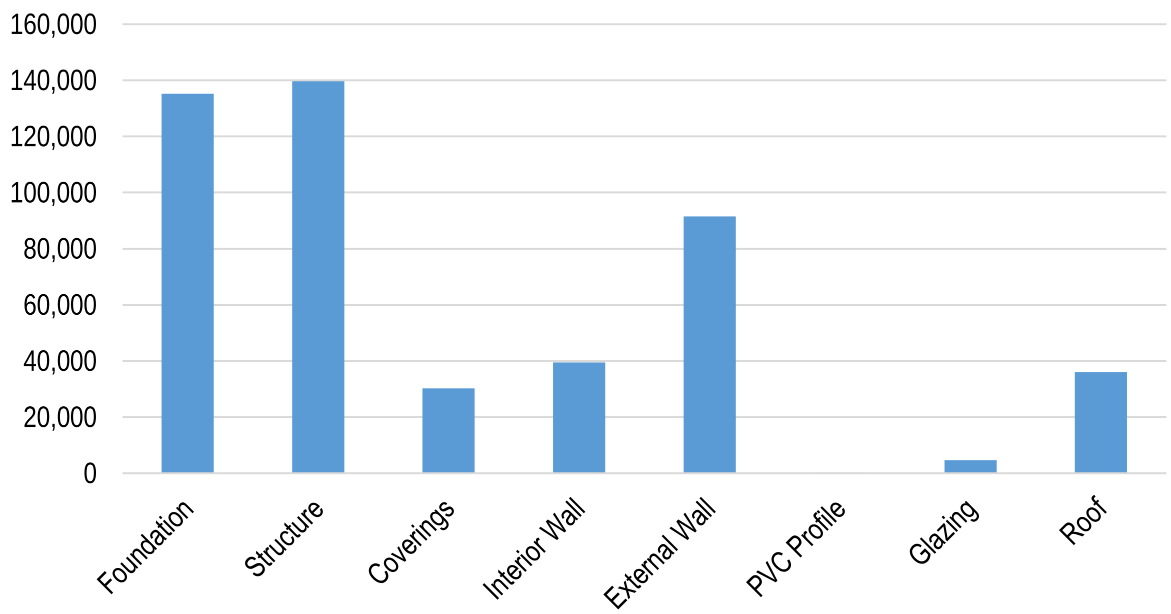

Figure 83: GWP of each building component and their relative contributions to climate change

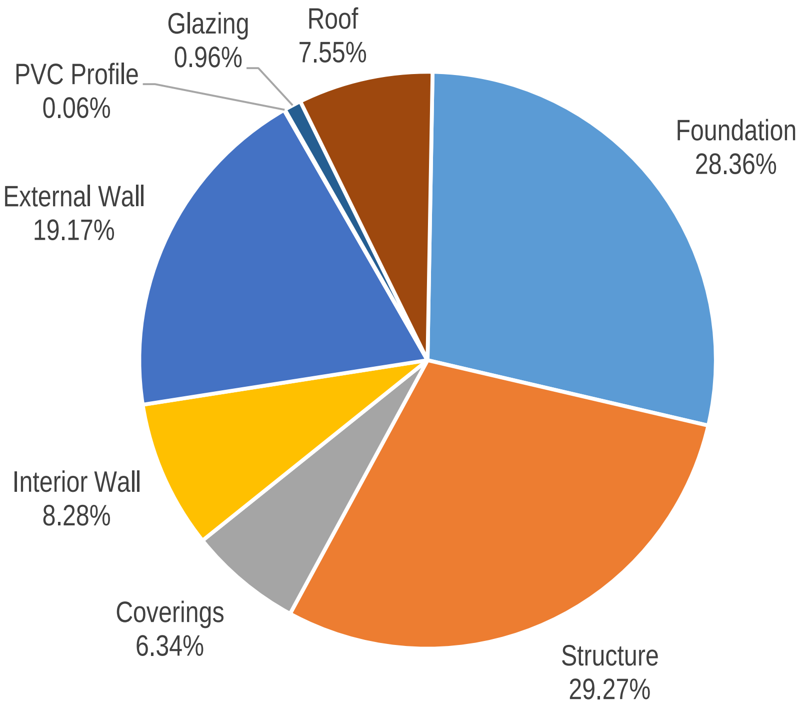

Figure 84: GWP distribution among building components per square meter

When the embodied energy consumption of building was examined, it was found that fossil energy sources are the most prominent (Table 1). Total embodied energy consumption of the building is 5.25E+06 MJ. Per square meter this is calculated to be 4.38E+03 MJ. of which only small fraction of about 315.2 MJ is coming from renewable primary energy resources.

Although this paper is focusing on the embodied carbon and energy, other relevant environmental impacts at building level can also be calculated. This is also the requirement of the EN 15978 building life cycle assessment norm. This is done using a CML-IA baseline methodology (ver. 4.02). The results of the methodology are presented in Table 2.

Parameter	Unit	Building Level	Per sqm
Use of renewable primary energy excluding resources used as raw materials	[MJ]	3.78E+05	315
Use of renewable primary energy resources used as raw materials	[MJ]	0	0
Total use of renewable primary energy resources	[MJ]	3.78E+05	315
Use of non-renewable primary energy excluding resources used as raw materials	[MJ]	4.88E+06	4064
Use of non-renewable primary energy resources used as raw materials	[MJ]	0	0
Total use of non-renewable primary energy resources	[MJ]	4.88E+06	4064
Use of secondary material	[kg]	0	0
Use of renewable secondary fuels	[MJ]	0	0
Use of non-renewable secondary fuels	[MJ]	0	0

Table 16: Whole building LCA results for embodied energy

Parameter	Unit	Building Level	Per sqm
Global Warming Potential	[kg CO_2 eq.]	4.70E+05	391.9
Ozone Depletion Potential	[kg CFC11 eq.]	2.10E-02	0.0
Formation potential of tropospheric ozone photochemical oxidants	[kg ethane eq.]	1.11E+02	0.1
Acidification Potential	[kg SO_2 eq.]	1.49E+03	1.2
Eutrophication Potential	[kg PO_4^{3-} eq.]	5.00E+02	0.4
Abiotic depletion potential for non-fossil resources	[kg Sb eq.]	6.39E-01	0.0
Abiotic depletion potential for fossil resources	[MJ eq.]	4.88E+06	4062.7

Table 17: Whole building LCA results for environmental indicators (CML-IA baseline method ver.4.02)

4. CONCLUSIONS

Turkish Construction Materials Life Cycle Database is developed in compliance to international standards and European EN 15804 construction product norm. The Database contains high quality product specific datasets for Turkish construction materials as well as Turkish electricity and natural gas mix. Therefore, any study conducted using the Database will be highly relevant to Turkey and the results will be more precise contrary to studies using generic databases.

Environmental impacts evaluations of four-storey residential building using life cycle information from materials can be calculated to measurable indicators such as climate change effects. Embodied energy and carbon area two indicators that refers to carbon emissions, climate change effects and resource use due to construction materials. Besides, other environmental indicators are also available to measure if necessary such as acidification, eutrophication and so on.

Existing or future green building assessment schemes in Turkey will be able to utilize the Database. Such schemes will be more valuable when environmental indicators per square meter area provided to the end users is communicated. The Database also provides the opportunity to bring life cycle assessment to non-LCA experts such as architects, green building designers and other engineers.

The Database will open the way to conduct environmental impact assessment of any type building using Turkish specific datasets. As such, measuring carbon impacts from the so called Urban Transformation projects in Turkey will be an excellent opportunity to achieve Turkey's Kyoto II commitments. By doing so, future carbon burden on the industrial sectors will be minimized. This is a life-time opportunity not to be missed by the policy makers and all other stake holders.

[b] *Chair of Sustainable Construction, ETH Zürich, Switzerland, habert@ibi.baug.ethz.ch*

ABSTRACT

The construction sector is the responsible of significant environmental impacts worldwide, such as 40% of natural resources consumption and 40% of total waste generation. Consequently, a change in design and construction is needed to improve sustainability aspects in construction. Digital fabrication represents a feasible solution for the low levels of innovation, efficiency and sustainability present in the sector. Initial sustainability assessments of 3D printing have clearly revealed the potential of digital technologies to achieve environmental benefits compared to conventional processes. However, digital fabrication in architecture presents new formal, technological and material challenges where further demands must be met. Advances in computer-aided design and robotic additive fabrication challenge architects to design and construct non-standardised complex building structures. Nevertheless, complexity has been often considered a negative factor in sustainable construction, responsible of an increase of material, labour and waste in the projects. This paper investigates the environmental potential of digital fabrication methods applied to complex concrete structures. Furthermore, this research studies how formal and structural complexity in architecture influences the environmental performance of a project. With this objective, the Life Cycle Assessment (LCA) method was used for the evaluation of an innovative robotic construction process applied to a wall structure and its comparison with a conventional element with the same function. The results of the assessment demonstrated that digital fabrication becomes a feasible construction technique for non-standard complex structures. In the case study evaluated, digital fabrication provided environmental benefits compared to conventional techniques for the construction of complex structures.

Keywords: life-cycle assessment, digital fabrication, complexity

1. INTRODUCTION

The construction sector is one of the least sustainable industries in the world. Specifically, buildings are responsible for 40% of global energy consumption, 38% of global greenhouse gas emissions, 12% of global potable water use, and 40% of solid waste generation in developed countries (UNEP, 2012). Faced with these environmental problems, the sector has an impressive potential improvement. However, commitments to sustainability in building construction remain weak and fragmented. A change in how we design, construct or use the buildings and their environment will establish a situation of improvement in not only environmental, but also economic and social aspects. Over the last 15 years, the advances in Computer-Aided Design software have enabled the conception of innovative and complex forms in architecture. Architects such as Frank Gehry & Associates or Zaha Hadid have demonstrated the potential of employing digital technologies for the design of high complex structures (Dunn, 2012). However, this shift in the design process has new formal and technological challenges where further demands must be met.

The construction sector is a traditional industry, which requires the implementation of innovative construction processes to face this increased structural complexity in architecture. Contrarily, digital technologies are broadly used in the manufacturing industry and technologies such as 3D printing have become an essential part of modern product development (Hague et al., 2003). The increasing impact of digital technologies in the society has fostered novel research in digital construction processes applied to building systems (Willmann et al., 2016). Digital fabrication processes allow on-site mass-customised construction of complex and unique architectural forms and structurally optimised structures, which would suppose elevate costs in conventional construction. Digital fabrication aims to radically change traditional construction processes with the implementation of innovative methods that potentially reduce material and labour costs, time and improve the efficiency in construction. However, the attempt to implement digital fabrication technologies in the construction sector presents many potential challenges and benefits, such as sustainability issues, that should be analysed.

Over the last years, several studies have addressed sustainability aspects in the building industry (Passer et al., 2012). Specifically, the Life cycle assessment (LCA) methodology is nowadays internationally applied within the sector for evaluating the environmental impacts of construction materials and buildings (Ortiz et al., 2009). However, scarce conclusive environmental assessments of large-scale digital fabrication processes are present in literature. Most published studies related to sustainability aspects in digital fabrication focus on small-scale additive processes. For instance, Kreiger and Pearce (2013) found that distributed manufacturing through 3D printing can reduce the cumulative energy demand by 41–64 % compared to large-scale production. Similarly, Faludi et al. (2015) highlighted the reduction of waste and energy consumption with 3D printing compared to traditional CNC milling. Finally, Gebler et al. (2014) assessed 3D printing technologies from an environmental, social and economic perspective. However, few of these studies were quantitative, consequently, applied research on the environmental implications of digital technologies, particularly at the architectural scale, is required.

Digital design and robotic fabrication developments facilitate an increased complexity in architecture, which implications need to be evaluated. The potential of these new construction processes to improve sustainability in construction is promising (Rahimi et al., 2009), but complexity aspects may affect the environmental performance of the projects. Therefore, the aim of this paper is to understand in which boundary conditions we can expect an environmental benefit from digitally fabricated architecture. Consequently, this research analyses the potential environmental opportunities of additive robotic fabrication compared with traditional construction techniques. Specifically, the paper presents the life-cycle assessment of the case study of a novel robotic fabrication approach applied to a complex concrete wall compared with a conventional structure with the same functional and structural performance.

2. METHODOLOGY

The method selected for the evaluation of the case study is the Life Cycle Assessment (LCA) framework present in the ISO 14040-44: 2006 standards (ISO, 2006a; ISO, 2006b). LCA has been commonly used in many industrial sectors to evaluate and compare the environmental load of processes and products during their life cycle. Furthermore, over the past 20 years, LCA has become a widely used methodology for evaluating the impact of materials, construction elements and buildings (Chen et al., 2010; Damineli et al., 2010; Purnell and Black, 2012). LCA method was applied in this paper to compare the difference in environmental impacts between digital fabrication and conventional construction processes. Specifically, we performed a life cycle evaluation introducing variability on the functional unit with an increased complexity on the structural element. Specifically, we varied the type of formwork in the conventional structure and the volume of concrete and steel in the digitally fabricated to understand in which type of projects digital fabrication brings environmental benefits. The LCA method was implemented in the software SimaPro 8 using the Ecoinvent v3.1 database (Weidema B. P., 2013) and the Recipe Midpoint (H) v1.12 impact method (Goedkoop et al., 2009). The selected impact categories were climate change (kg CO2 eq.), ozone depletion (kg CFC-11 eq.), human toxicity (kg 1.4-DB eq.), terrestrial acidification (kg SO2 eq.), freshwater eutrophication (kg P eq.), terrestrial ecotoxicity (kg 1.4-DB eq.), freshwater ecotoxicity (kg 1.4-DB eq.), water depletion (m3), metal depletion (kg Fe eq.) and fossil depletion (kg oil eq.).

3. CASE STUDY: MESH MOULD

The case study selected for the evaluation is Mesh Mould, a research project from Gramazio Kohler Research, ETH Zürich. This novel construction system is based on the combination of the formwork and reinforcement in a single element. This element is a mesh robotically fabricated in a process of bending and welding steel wires (Hack et al., 2015). Mesh Mould combines two labour intensive processes, installation of formwork and reinforcement, which are responsible for over 50% of the overall economic cost of conventional concrete structures (Robert, 2007). The project studies the potential of these bespoke formworks for non-standard concrete structures, which can be efficiently fabricated on-site. The robotic approach simplifies the building process, while allowing a higher architectural complexity. As a result, the structure is no longer restricted to planarity or single curvature and it can be geometrically complex and individually adapted to the forces that act upon the mesh (Hack et al., 2013). Figure 1 shows one of the recent prototypes of Mesh Mould project.

Figure 1: Robotically fabricated metal Mesh Mould structure

3.1 Definition of system boundaries and functional unit

The case study was focused on the analysis of the production and construction phases of a wall constructed with this system. The cradle-to-gate analysis performed included material extraction and transport, building materials and digital technologies production and robotic fabrication (EN 15978 modules: A1-A3, A5). Operation and end-of-life stages were excluded from the case study evaluation due to the early state of research. The functional unit of the case study was 1 m^2 of reinforced concrete wall with a specific structural performance. In the current evaluation, two systems were compared: a 1 m2 Mesh Mould wall designed and constructed with digital fabrication techniques and 1 m^2 of a conventional reinforced concrete wall system.

3.2 Data collection

The materials and the energy consumption for the fabrication of a wall with the Mesh Mould process and a conventional reinforced concrete wall are studied in the following section. Thereafter, the scenarios for both wall systems are summarised for the later environmental comparison.

Mesh Mould wall

The concrete in the Mesh Mould wall is more demanding than in the conventional technique. Beside the structural performance, the behaviour of the concrete influences the protrusion rate through the outer perimeter and the roughness of the surface. In response to these criteria, the Institute for Building Materials (IFB) at ETH Zürich developed a special concrete mixture with an optimised filling process (Hack *et al.*, 2015). Based on the increased amount of Portland cement (500 kg/ m^3), which nearly duplicates the amount in ordinary C25/ 30 concrete, the compression strength of the ETHZ IFB concrete is higher (Habert *et al.*, 2012). Consequently, an improved scenario with concrete reduction was analysed. The reinforcing steel is formed by metal wires with a diameter of 3 mm form the three-dimensional mesh of the Mesh Mould wall. The steel used was B500A, with the same tension yield strength f_{yk} = 500 N/ mm^2 as a conventional reinforcement, but less ductile material. For the standard Mesh Mould scenario, we assumed the same steel fraction as a conventional reinforced wall, ρ_{MM} = 0.7% of the wall volume (CEN, 2004). Based on the previous value, we established a realistic range with the minimum and maximum reachable reinforcement content.

Additionally to the materials, the embodied energy of the digital fabrication technologies was included in the Life Cycle Inventory (LCI) of the Mesh Mould wall. This included the production of the "In-Situ Fabricator" construction robot and a customised tool for welding, bending and cutting the mesh (NCCR Digital Fabrication). Specifically, the tool has an approximate mass of 10 kg and it is mainly composed by aluminium. The service life assumed for the robot and the tool was a period of 10 years. Finally, the energy consumption during construction was calculated based on the operation time and power supply of the robot. The tool head had a theoretical building speed of 10 h for a prototype mesh of 1 m^2. The construction robot is electrically powered by lithium-ion batteries with a total capacity of 5.1 kWh, which enable the robot to operate for 3–4 h without being plugged in (Dörfler *et al.*, 2016). As a result, the total energy demand E_{MM} for the construction of the wall with the Mesh Mould technique was 17 kWh.

Based on the previous data collection, three scenarios were analysed:

- Best scenario: The optimal performance of the Mesh Mould wall was characterised by the minimal reinforcement steel volume fraction $\rho_{MM,min}$ =0.5% and the thickness of the wall was reduced to $t_{MM,min}$ = 0.1 m, the limit given by the calculation of the slenderness criteria.
- Reference scenario: Wall thickness of t_{MM} = 0.2 m and reinforcement volume fraction of ρ_{MM} =0.7%, same parameters as a conventional wall.
- Worst scenario: The buckling failure might request a wall thickness of t_{MM} = 0.2 m and additional complications with the mesh could lead to a reinforcement steel content of up to $\rho_{MM,max}$ = 1.5%.

The LCI of the reference scenario of Mesh Mould wall is summarized in Table 1.

Flow	Unit	Amount
Construction robot production	p	$1.14*10^{-4}$
Bending/Welding tool, production	p	$1.14*10^{-4}$
Concrete ETHZ IFB, production	m^3	0.2
Reinforcing steel, production	kg	11
Electricity, medium voltage, market	kWh	17

Table 1. Life cycle inventory of a mesh mould wall construction process (1 m²).

Conventional concrete wall

A reinforced concrete wall with a thickness of 0.2 m was taken as a reference. The concrete used was C25/ 30, characterised by its strength compression of f_{ck} = 25 N/ mm². The reinforcement steel was an ordinary, highly ductile B500B, with a tension yield strength f_{yk} = 500 N/ mm². A steel fraction of 0.7% of the volume of the conventional reinforced wall was assumed. The formwork chosen for each scenario varied according to the complexity of the wall. On the one hand, a traditional three-layered laminated board formwork was selected for the straight wall. On the other hand, the double-curved wall was constructed with a free form polystyrene formwork. This system is composed by polystyrene blocks covered by a 5 mm layer of epoxy resin. Moreover, the data inventory included the energy demand for hot-wire cutting the formwork, 30% of waste polystyrene produced, and the landfill deposition after use in the data inventory. The energy demand of the formwork production was calculated based on the speed (1500 mm/ min) and power (600 W) of a 2-axis wire-cutting machine.

Two scenarios were investigated for the conventional reinforced concrete wall:

- Standard scenario: Straight wall of thickness t_{wall} = 0.2 m, where the formwork is reused 10 times.
- Complex scenario: Double-curved wall of thickness t_{wall} = 0.2 m, constructed with non-reusable polystyrene formwork.

4. RESULTS

The range of environmental impacts product of the material dependent Mesh Mould scenarios compared with the complexity dependent conventional wall scenarios are illustrated in Figure 2.

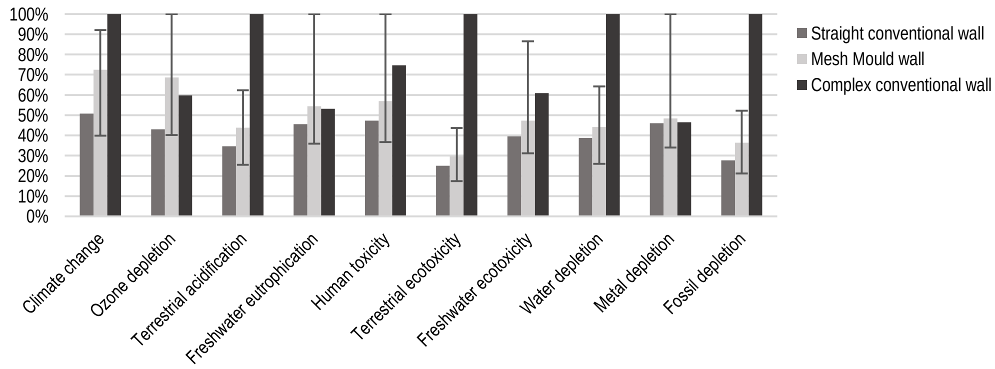

Figure 2: LCA comparison of the Mesh Mould wall with a standard and complex conventional wall. Error bars represent the best and worst scenarios of the Mesh Mould wall

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The previous figure demonstrates that the optimisation of the Mesh Mould wall, with 50% of thickness reduction, leads to less concrete usage and decreases 33% of CO2 emissions compared to the reference scenario. Furthermore, the results show the importance of an efficient steel usage. The environmental emissions of Mesh Mould grow 30% average, compared to the reference scenario, with the maximum steel content. In general, the results indicate that the best scenario of the Mesh Mould wall is responsible for lower environmental impacts than a conventionally constructed straight concrete wall. Specifically, the best scenario of the Mesh Mould wall reduced the emissions by 3-13% depending on the indicator. However, a less optimised Mesh Mould wall (worst scenario) is clearly less environmentally performant than a conventional straight wall.

The results graphically depicted in Figure 2 prove that the reference Mesh mould system brings currently environmental benefits compared to the double-curved concrete wall constructed with conventional techniques. Only in three midpoint categories, the reference scenario of Mesh Mould shows greater impacts than the complex conventional scenario, but the difference is negligible (1-9%). This result is mainly due to the use of polystyrene formwork for the construction of complex walls, which increases the impacts. Finally, we observe that the worst scenario of the robotically fabricated wall can still environmentally compete with the complex conventional wall in categories such as Terrestrial acidification and Fossil depletion. Consequently, the complexity is a key factor to consider during the comparison with conventional construction since the environmental impact of the Mesh Mould process does not grow with the uniqueness and complexity of the architectural form.

5. DISCUSSION & CONCLUSION

In this paper, we evaluated the environmental potential of an innovative digital fabrication process for the construction of high complex concrete structures. The LCA performed allowed its comparison with conventional construction. Furthermore, we analysed how formal and structural complexity in architecture influences the environmental performance of a project. Complexity is an architecture characteristic, which costs and value creation has been often discussed. In the last few years, technological advances challenged architects to design increasingly complex architectural structures. However, complexity has been often considered a negative factor in sustainable construction, responsible of an increase of material, labour and waste in the projects.

The Mesh Mould system allowed higher structural complexity while simplifying the construction process. The study demonstrated that robotic fabrication becomes a feasible construction technique for non-standard structures. But most important, the results highlighted the importance of digital fabrication to achieve environmental benefits in complex structures. Contrary to conventional construction, the impact of the Mesh Mould process did not change with an increase of the uniqueness and complexity of the architectural forms. Therefore, the environmental potential of this digital fabrication process increased proportionally to the required effort relative to the conventional technique. The study demonstrated that the current Mesh Mould system can environmentally compete with conventional structures when both have a high degree of formal and structural complexity. Simultaneously, the results highlighted the need for improvement to compete at a lower degree of complexity. The digitally fabricated wall required material optimisation (thickness reduction) to achieve environmental benefits compared to a standard reinforced concrete wall.

ABSTRACT

Air pollutants from traffic in highly dense urbanized cities such as Hong Kong have negative impacts on human health. Without adequate ventilation, these pollutants would accumulate within street canyons formed by high rise buildings, an issue of great concern to the public. To create a healthy, liveable environment, collaborative efforts from environmental scientists, architects/town planners and developers are required to develop innovative building designs that reduce pollutant accumulation within street canyons. One recent design approach is the use of the 'Dragon Hole': a large void around the center of tall buildings that extends from pedestrian level to around half of the building height.

To assess the effectiveness of the Dragon Hole design concept in Hong Kong, we conducted a sensitivity study of the level of pollutant accumulation within the street canyons due to changes in building permeability by varying the size and location of the 'Dragon Hole'. Computational Fluid Dynamics (CFD) with the Shear-Stress-Transport $k-\omega$ turbulence model was used to model an idealized urban area with traffic emissions, and six cases with different permeability of the "Dragon Hole" building varying from 0% to 30% were investigated. Model validation was carried out by comparison with the wind tunnel experiment data from the Tokyo Polytechnic University. The amount of pollutant accumulation at the source canyon was calculated and pollutant concentration profiles plotted under different cases within the source street canyon. Some discussion and recommendations will be presented for adoption of 'Dragon Hole' design in Hong Kong and similar cities.

Keywords: sustainable neighbourhood, adaptive design, air ventilation, pollutant dispersion, CFD turbulence model

1. INTRODUCTION

Pollutants accumulated within street canyons due to traffic emission have raised concern from the public living in high-density cities (WHO, 2008). Apart from controlling the pollutant emission amount, sustainable building designs have been suggested as another way to solve the pollution problem within urban regions (Yuan et.al, 2014). The "Dragon Hole" building design, with a large void extending from pedestrian level to around half of the building height, is an innovative building design not only beneficial for maintaining building connectivity, satisfying visual and geomantic concerns, but also for providing air ventilation corridors and possibly avoiding pollutant accumulation.

Computational fluid dynamics is a capable technique for understanding momentum and mass transport mechanisms within urban areas. Extensive studies have been conducted in understanding the wind flow patterns within both idealized and real cities by applying various turbulence models (Baskaran and Kashef, 1996; Blocken et al., 2009, 2015). Ng et al. aided in the development of Technical Circular No.1/06 for the industrial assessment of air ventilation performance in Hong Kong, in which air ventilation assessment has been implemented as a prerequisite for urban development and renewal. In addition, there are well established guidelines (Franke et al., 2004; AIJ, 2007) for carrying out robust CFD studies of urban wind environment. However, there are comparatively fewer studies on pollutant dispersion by application of the CFD technique compared to wind flow simulations. Most research has applied $k-\varepsilon$ family turbulence models (Cheng et al., 2008; Salim et al., 2011) which produce less satisfactory predictions compared to the more computational costly unsteady models. Furthermore, the industrial applications of CFD in prediction of pollutant accumulation are still limited due to uncertainties in the choice of turbulence models and methodologies.

This study aims to put forward a sustainable building design to enhance air ventilation and quality, at the same time conducting a parametric study to explore the relationship between building permeability of the innovative "Dragon Hole" building design and level of pollutant accumulation. Furthermore, the study demonstrates the usage of a relatively robust and industrially affordable turbulence model in carrying out assessment of pollutant dispersion via the CFD technique.

2. METHODOLOGY

2.1 Model geometries

An idealized urban area in Figure 1 is formed by five surrounding sub-sites, each consists of 16 identical building blocks with length and width of $2W_s$, height $6W_s$, where $W_s = 10m$ being the width of streets. The sub-sites semi-circled the simplified "Dragon-Hole" building located at the upwind region. The targeted building has a width of $3W_s$, length of $11W_s$ and height of $12W_s$, with an opening extending from pedestrian level to a height of $6W_s$. Six different cases (Cases A to F) with varying width of opening corresponding to building permeability of 0%, 5%, 10%, 15%, 20% and 30% respectively are evaluated in this research on the pollutant removal and air ventilation performance within the street canyons by the use of ANSYS CFD package. Line sources representing traffic emissions releasing NO_2 tracer gas of 1ppm concentration with exit velocity of 0.5m/s are located at the main streets. The prevailing wind in this study is kept perpendicular to the permeable building in order to achieve the maximum performance of the "Dragon Hole" in each study case.

2.2 Turbulence model description

The SST $k-\omega$ turbulence is a two equation eddy viscosity turbulence model which employs Wilcox's $k-\omega$ model at the near wall regions and switches to a $k-\varepsilon$ formulation outside the boundary layer through the application of two blending functions. These combined features have proved beneficial in the prediction of adverse pressure gradient and flow separation. Detailed formulation of the SST $k-\omega$ model has been documented in Menter, 1993. Therefore, only the main closure equations and its eddy viscosity definition are provided here. In addition to the typical Reynolds averaged Navier-Stokes equation, the k and ω closure equations are defined as:

$$\frac{\partial k}{\partial t} + u_j \frac{\partial k}{\partial x_j} = \frac{\partial}{\partial x_j}\left[\left(v + \frac{v_t}{\sigma_k}\right)\frac{\partial k}{\partial x_j}\right] + P_k - \beta_* k\omega$$

Equation 1

$$\frac{\partial \omega}{\partial t} + u_j \frac{\partial \omega}{\partial x_j} = \frac{\partial}{\partial x_j}\left[\left(v + \frac{v_t}{\sigma_\omega}\right)\frac{\partial \omega}{\partial x_j}\right] + \alpha S^2 - \beta\omega^2 + 2(1-F_1)\sigma_{\omega 2}\frac{1}{\omega}\frac{\partial k}{\partial x_j}\frac{\partial \omega}{\partial x_j}$$

Equation 2

with eddy viscosity definition $\mu_t = \frac{\rho a_1 k}{\max(a_1\omega, SF_2)}$, where $a_1 = 0.31$ and S is the strain rate magnitude. The other model constants α, β, σ_k and σ_ω are blended across different regions through the blending functions F_1 and F_2 by $\varphi = F_1\varphi_1 + (1-F_1)\varphi_2$ where φ_1 and φ_2 being the corresponding constants for the inner and outer regions respectively. The default values of the SST $k-\omega$ model are more suitable for aerodynamics applications

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

rather than urban flow problems. As pointed out by Richards and Hoxey, a smaller value of β_* is often observed in field measurements of atmospheric boundary flows. Therefore, a reduced value of $\beta_* = 0.03$ is applied in this study. There is also modification in the diffusion constant of the outer region for the SST $k-\omega$ model as Poroseva and Iaccarino emphasized the importance of turbulence diffusion in unbounded flows and suggested to set $\sigma_\varepsilon = 1.5$ for the $k-\varepsilon$ model. The value of β_1 in the inner region is chosen to satisfy the ratio $\beta_*/\beta_1 = 1.27$ based on isotropic turbulence calibration. For the value in outer region, the relationship $\beta_2 = (C_{\varepsilon 2} - 1)\beta_*$ where $C_{\varepsilon 2} = 1.92$ should be satisfied. Furthermore, the simulations are carried out with a turbulent Schmidt number value of 0.7.

2.3 CFD model parameters and setup

The computational domain is rectangular in shape with size in compliance with the minimum recommendations documented in available CFD guidelines (Franke, 2006; Tominaga et al., 2008; Mochida et al., 2002; Shirasawa et al., 2003). There are approximately 18 million rectangular structured grids for each of the cases with the near wall meshes relatively fine to maintain a reasonable small dimensionless wall distance value. Other settings of the model are stated in Table 1 which followed those recommended in the COST Action C14 (Franke et al., 2004) and the Architectural Institute of Japan (AIJ) guidelines (Tominaga et al., 2008; AIJ, 2007).

The inflow wind and turbulent kinetic energy profiles for the CFD simulation cases adopted from Yuan et al., 2014 are shown in Figure 2. For the SST k-ω turbulence model, apart from the inflow TKE profile, another inflow specific dissipation rate profile defined as $\omega = \varepsilon / C_\mu k$ (ε is the turbulent dissipation rate, k is the turbulent kinetic energy and $C_\mu = 0.09$) is required for closure.

Normalized concentration (C_+) defined as $C_+ = c/c_0$ where c is the simulated result of the averaged concentration of NO_2 and c_0 is the reference emission concentration is adopted as the indicator to analyse the effects of different "Dragon-Hole" building permeability on pollutant dispersion within street canyons. From the definition of C_+, one can observe the smaller the value of C_+ the less the accumulation of pollutants within the street canyon while the higher the C_+ value, the higher is the pollution level.

3. MODEL VALIDATION

Wind tunnel experiment data under isothermal condition is available from an experiment on flow and tracer gas dispersion around a single block building conducted in the wind tunnel (cross section at measurement part: 1.2 m × 1.0 m) of Tokyo Polytechnic University (Tanaka et al., 2006). The wind tunnel experiment has been described in detail on the webpage of Architectural Institute of Japan, therefore, only the main features are presented in this paper. As illustrated in Figure 3, the model building has a dimensions of 0.2m in height, 0.1m for both width and depth (H:W:D = 2:1:1) situated in a turbulent boundary layer with power law index of approximately 0.25. A small area gas source was set on the floor 0.25H away from the leeward side of the model building releasing ethylene (C_2H_4) as a tracer gas at a volume flow rate of $5.83 \times 10^{-6} m^3/s$.

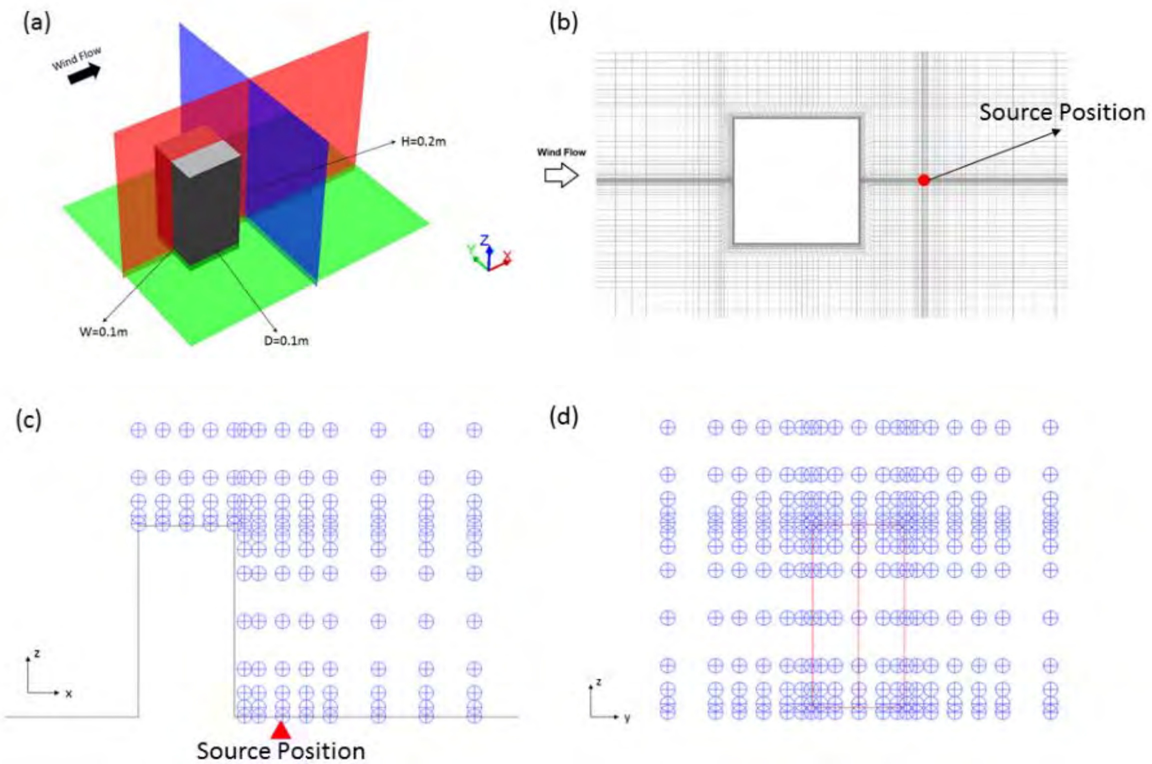

Figure 3: (a) Geometry; (b) Mesh; (c) X-Z measurement locations; (d) Y-Z measurement locations

Result Data from the CFD model simulation are compared with the experimental data on the X-Z, X-Y and Y-Z planes at measurement locations shown in Figure 3. As pointed out in Section 2.2 above, the default parameters for the SST k-ω turbulence model has been set to achieve best application for the aerodynamic flows while this set of model constants is not capable to produce best simulation results in match with experimental data for urban flow and dispersion problems.

By applying the set of modified model constants stated in Section 2.2 together with a turbulent Schmidt number value of 0.77, the CFD results from the SST model generally match well in both shape and magnitude with the experimental wind data downwind from the building obstacle as illustrated in Figure 4. The CFD simulation predicts relatively better within the near wake region compared to the far wake. In the far wake region, the velocity deficit from CFD simulation has a slower recover rate compared to the wind tunnel experiment.

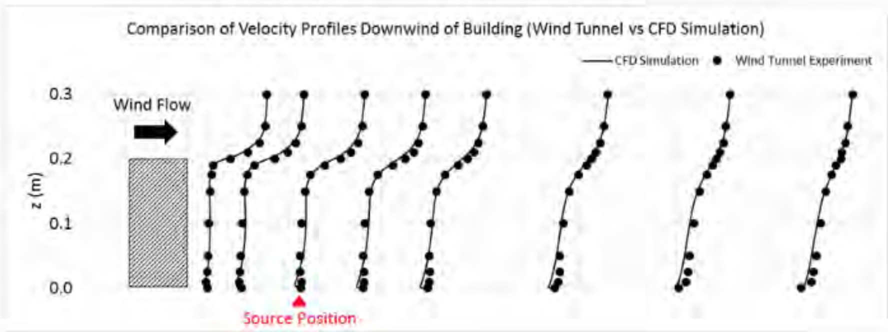

Figure 4: Comparison of wind velocity profiles between CFD and experiment downwind of building

Similar to the wind field prediction, a rather promising result between the wind tunnel experiment data and CFD simulation results has been achieved for the pollutant concentration prediction. From Figure 5, it is observed the pollutant concentration profiles are well predicted on the X-Y plane. There are a few test points (around 10% of the total amount of test points) in which the SST model over-/under-predicts the wind tunnel experiment with a percentage difference of several tens. It is noticed that the over-/under-prediction phenomenon of pollutant concentration by steady state CFD models has also been reported in previous studies (Gromke and Ruck, 2012; Yuan et al., 2014). However, the CFD results are able to achieve good correlation with experimental data with value of around 0.8 and 0.7 on the X-Z and Y-Z plane respectively. In addition, majority of the test points' values achieve an approximate deviation of +/-20% compared to wind tunnel experiment. Furthermore, Willemsen (2002) reported that wind tunnel experiment conservatively could have a standard error of 20% in measurement. Therefore, it is also worthwhile to take note that wind tunnel data also includes uncertainties to some extent.

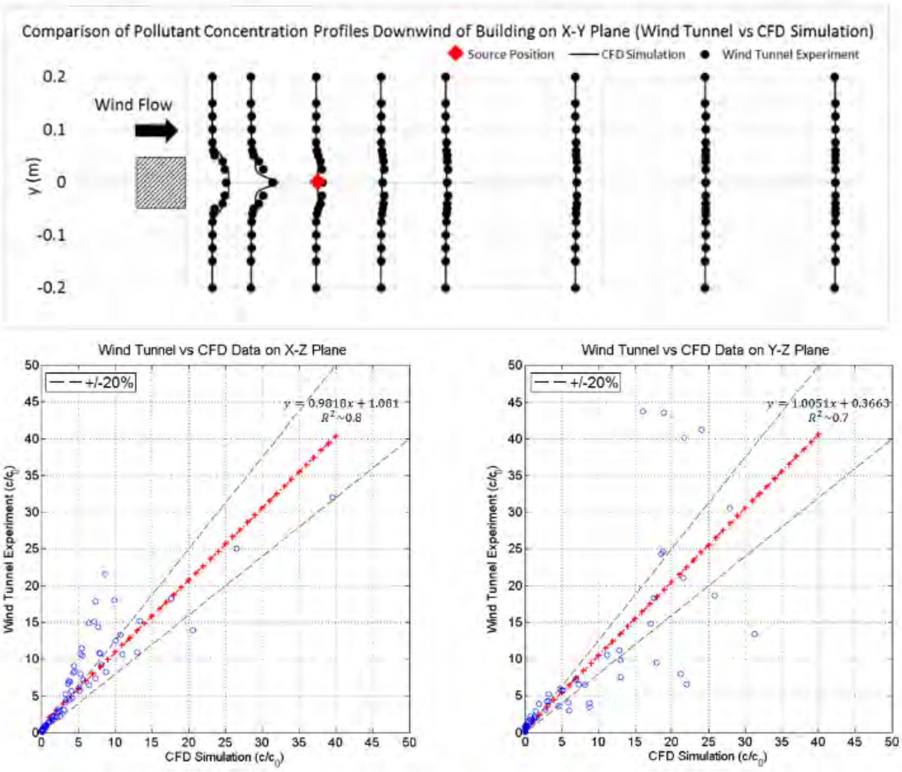

Figure 5: Comparison between CFD and wind tunnel on pollutant concentration (Upper) profiles on X-Y plane; (Lower-Left) data on X-Z plane; (Lower-Right) data on Y-Z plane

To summarize, the SST $k-\omega$ turbulence model with modified model parameters generally produce relatively robust predictions in both the wind field and pollution concentration field which is appropriate for application to urban and industrial flow/dispersion problems. Nevertheless, it is inevitable that there are locations with certain discrepancies between the simulation results and the real physical situation which might be due to the eddy viscosity hypothesis of steady models and the over-production of turbulence levels in stagnation regions behind bluff body by the SST $k-\omega$ model.

4. RESULTS AND DISCUSSION

This study has investigated the effectiveness of “Dragon-Hole” design buildings with different permeabilities in reducing pollutant trapping within downwind street canyons bounded by three control volumes (See Figure 1). From the comparison plots in Figure 6, showing the total amount of accumulated pollutant of the studied cases, the results reveal there is a 12% difference in total pollutant accumulated for Case B compared to the impermeable case (Case A) in which it is discovered that a 5% building permeability design (Case B) is far from sufficient in carrying away pollutants within the Control Canyon C1. For Cases C and D with increased permeability, more satisfactory results are achieved. There is more than 50% decrease in NO_2 for these two cases as compared to Case A. The reduction in pollutants within Control Canyon C1 becomes even more observable (i.e. reduced down to about 20% of the total amount of pollutants trapped in Control Canyon C1 in Case A) when the permeability is increased to more than 20% (Case E and Case F). The first point to be mentioned is that the “Dragon-Hole” building design is effective in removing pollutants trapped within an immediate downwind canyon, provided that at least 10% building permeability is achieved for the permeable building.

By referring to the pollutant accumulation at further downstream canyons (Control Canyons C2 and C3), Cases B, C and D result in an increased NO_2 accumulation compared to the impermeable case (Case A), with amount trapped in Control Canyons C2 and C3 of Case C being twice the impermeable case. However, a significant drop is observed in Cases E and F compared to the impermeable case. Furthermore, when considering the volume averaged concentration of NO_2, Case A, B and C slightly exceed the NO_2 limit of $200\mu g/m^3$ documented in current AQO guideline. Case D (15% permeability design) bordered the requirement limit within Control Canyons C2 and C3. Meanwhile, Cases E and F (with more than 20% permeability) maintained a low NO_2 concentration level in all Control Canyons. The second point to note is that if a “Dragon-Hole” building design is to be adopted, it is necessary to maintain building permeability of 20% or above to alleviate pollutant accumulation within urban areas.

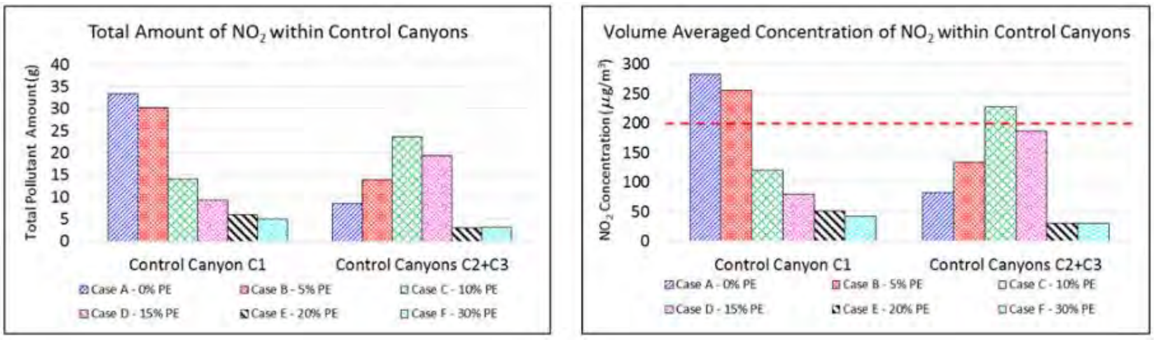

Figure 6: (Left) total amount; (Right) volume averaged concentration of NO2 within control canyons

Normalized concentration profiles in Figure 7 show horizontal and vertical distribution of NO_2 within the source canyon. From the horizontal concentration profiles, low concentration of pollutants behind the “Dragon-Hole” opening at pedestrian level is observed and the pollutant concentration starts to rise at locations departing from the opening location. In general, Cases C, D, E and F maintains a relatively lower horizontal concentration level as compared to Cases A and B. On the other hand, from the vertical concentration profiles, it is shown that above the height of $z/H_B = 0.5$ (i.e. the height of “Dragon-Hole”), the NO_2 concentration decays to almost zero for Cases B to F, while there still appears to be a small amount of pollutant above that elevation in Case A. In addition, Cases C to F acquired vertical concentration profiles of faster decay rate and smaller pollutant magnitude compared to Cases A and B, indicating pollutant removal effectiveness would be enhanced by an increment of building permeability. In summary, “Dragon-Hole” building permeability of more than 20% produces best performance among all cases.

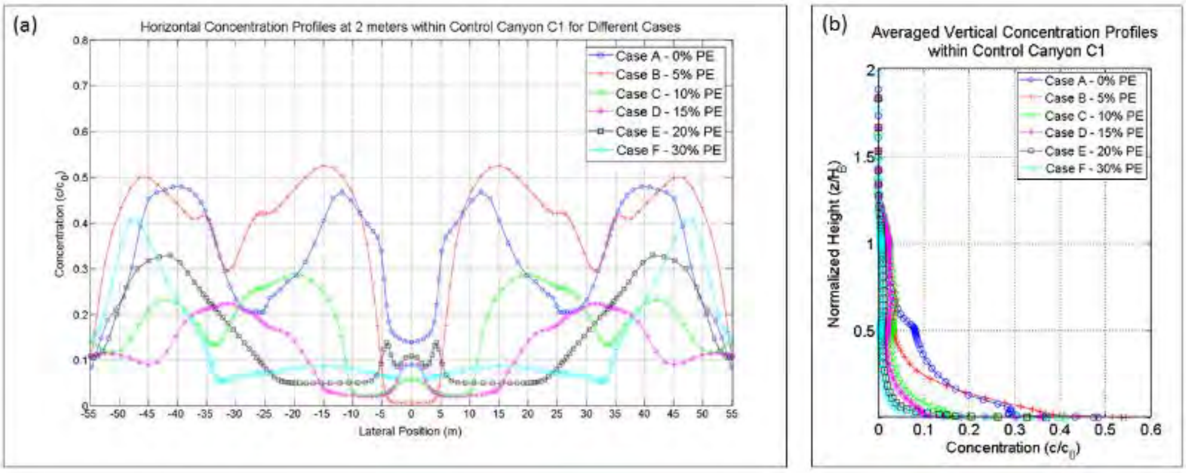

Figure 7: (a) Horizontal concentration profiles at 2 meters; (b) Vertical concentration profiles

5. CONCLUSIONS

This paper has demonstrated the usage of a well validated and industrially affordable turbulence model in carrying out assessment of pollutant dispersion within an idealized urban area via CFD technique. A parametric study has been conducted to investigate the relationship between building permeability of the “Dragon Hole” building design and the effectiveness of pollutant removal within street canyons.

There is evidence that the “Dragon-Hole” building design concept is effective in reducing pollutant accumulation provided that a sufficient opening size is achieved. This result accords with the requirement of maintaining at least 20% building permeability to maintain good ventilation performance, as stated in the Sustainable Building Guideline. Moreover, it is shown that a low permeability of less than 5% would not be sufficient to disperse pollutants trapped within street canyons.

Environmental scientists and modellers may follow the methodology in this paper when performing pollutant dispersion assessments via CFD technique to acquire a cost effective and robust result. Meanwhile, developers/architects may take into consideration the “Dragon-Hole” concept during the building design stage.

ABSTRACT

Due to multi criteria related decision making processes during the construction of sustainable buildings, the operationalization of holistic building performance is becoming increasingly challenging. The realization of sustainability aspects in current construction practice calls for - next to precise stakeholder requirements - an integrated and life cycle oriented approach. Current challenges regarding the operationalization of holistic planning and construction processes are mainly caused by vague stakeholder requirements and by the current lack of appropriate methods for the required life cycle processes management. The holistic quality of the expected technical and functional performance of a building is closely and strongly related to the fulfillment of all processes (technical and organizational), which occur over the building's life cycle. In this context comprehensive sets of sustainability criteria and possible interdependencies between these criteria increases the risk of disregarding crucial life cycle processes and can lead to wrong decisions. This article presents the application of maturity assessment method based on a systemic approach, in order to achieve the expected building performance and stakeholder satisfaction simultaneously.

Causal loop analyses of several sustainability criteria aid visualization of different optimization strategies' tradeoffs and synergies. Depending on the building's predefined quality targets, relevant construction processes can be identified – through a systemic perspective. Management and assessment of these processes during the planning and construction phase is based on maturity assessment method. Thereby, a number of "basic" and "generic" practices (assigned to each process) are evaluated and thus define the capability level for each process. The final aggregation of each process's evaluated practices leads to a specific "maturity level" which indicates the fulfillment level of the previously defined sustainability targets on the validation date.

Maturity assessment based on a systemic approach is an appropriate method to ensure the holistic management of life cycle processes for sustainable construction.

Keywords: sustainable construction, maturity assessment, process optimization, systemic approach, design process, green building management

1. INTRODUCTION

Sustainable construction implementation is driven forward by harmonized International and European standards (ISO EN) and voluntary instruments, such as the ISO 14000 series – environmental management or building sustainability rating system. In 2008 the ISO 15392 – Sustainability in building construction – General principle already created the basis for a common understanding of sustainability in the construction industry. Whereas an increase of building performance can only be reached with the implementation of sustainable targets in early design stages and with their assessment after completion. Accordingly, in each project stage numerous processes are interacting. Therefore, two approaches are necessary to evaluate their influence - a systemic approach and a maturity assessment approach.

In the following contribution a "process" represents a set of interrelated or interacting activities that transform inputs into outputs. Whenever the processes quality has strong influences on the product's quality, it makes sense to focus on the capabilities and the maturity of the processes. Processes on a higher capability level are more reliable to deliver the expected results, are less prone to risks and to a certain degree, are well predictable within time, budget and quality. Processes on a lower capability level are often performed "ad-hoc", are not well planned

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

and often don't deliver the expected results or need some reworking in order to satisfy the needs. Time, budget and quality are at risk. Additionally, the amount of hidden flaws and problems – which will be detected in the future – is hard to estimate, but probably significantly higher compared to processes on higher capability levels.

The quality premises and the associated ideas about process capability are an integral part of the industrialization in our world: it is not only used in mass-production, it is also used for individual projects (like development of software and systems in different industrial sectors) but also for service oriented business (like banking, insurance, health, communications, etc.).

In this case the application of maturity assessment methods in the construction industry can help to optimize construction processes, because the capability of the performed processes indeed has big influences on the quality and sustainability of the building respective construction. This optimization concerns two important conditions of a successful project progression. On the one hand it is possible to prevent insufficiently planned processes and inform the stakeholders in an early project stage, and on the other hand it is a first important step towards risk management, which could minimize claims after the projects.

2. METHODS

When operationalizing maturity assessment in sustainable construction, first, stakeholders integration in the planning process must be dramatically increased. Further, a methodology for holistic consideration of synergies and trade offs that probably occur in life cycle oriented planning processes must be provided. In this article, on the one hand causal loop analysis is applied to identify crucial life cycle processes based on specific stakeholders goals. On the other hand, the subsequent assessment in how each sustainability process is embedded within the integral planning process is implemented by maturity assessment method. By combining these methods, the fulfillment level of life cycle processes can be highlighted, and strengths and weaknesses can be visualized. First approaches concerning maturity assessment in sustainable construction are currently developed in the research project "UNAB-Sustainable Designprocess and Integrated Facades" at the Technical University of Graz. This paper presents the project's intermediate results.

2.1 Systemic approach

Assessment of building sustainability using building certification systems (e.g. BREEAM, LEED, CASBEE, DGNB/ÖGNI, etc.) is increasing. Due to multi criteria assessment, dynamic stakeholder goals and enlarged system boundaries decision making, especially in early planning stages, are getting increasingly complex. Using building certification methods the holistic life cycle oriented consideration of sustainability criteria is operationalized by a full set of criteria with appropriate weighting. This method allows impacts' quantification and identification of the individual optimization potential for single assessment criteria. However, because of sustainability criteria interaction, trade offs and synergies may occur by implementing technical measures. Acknowledgement of these system interdependencies is of high importance for a balanced improvement, which is claimed by the sustainability concept of CEN/TC 350 requirements . Depending on the individual stakeholder preferences, different criteria groups must also be optimized within the planning process. Therefore, building certification systems are only partly suitable for holistic building improvement. They do not permit an optimization approach covering both estimation of single measure influence on overall building sustainability and stakeholder objectives by highlighting their system interdependencies. By applying causal loop analysis based on the assessment concept of building certification, the improvement potential and furthermore the identification of appropriate processes in order to achieve high building sustainability can be transparently visualized.

2.2 Maturity assessment

The achievement degree of the expected outcomes and a company's processes efficiency can be assessed on the basis of capability levels (CL). The description of the next higher capability level (CL) can be used as a guideline to improve the process.

The characterization of capability levels is generic to all kinds of processes.

CL 0: A process on SPiCE Capability Level 0 is considered as an incomplete process, which is not capable to achieve its expected outcome. By definition, a process, which is not done at all, gets also a CL 0 rating.

CL 1: A process on SPiCE Capability Level 1 is called a performed process, because it (obviously) is performed and it achieves its expected outcomes. There is no word about how good or fast the process is done or which means were used to get it done or whether the process was planned appropriately or not.

CL 2: A process on SPiCE Capability Level 2 is called a managed process. It builds upon a performed process (CL 1) so it achieves its expected outcomes. Beyond that, the process is planned in a proper way: the expected outcomes are defined and described, the activities and tasks are defined and assigned, and estimates about effort and cost are aggregated. During the execution of the process, the activities are monitored and controlled to assure adherence to the plan. Additionally, quality assurance activities are performed, to ensure the correct application of the processes and to ensure the process's results quality – so that they fulfill the defined expectations.

CL 3: A process on SPiCE Capability Level 3 is called a defined process. It builds upon a managed process (CL 2) so it achieves its expected outcomes, is planned, monitored, controlled, and quality assured. Beyond that, the process is derived from the set of standard processes of the organization. So the organization needs to have done this process several times before, learned from doing it and consolidated these experiences into a "standard process description". Typically, an organization provides templates, methodology descriptions, rules for estimation and other resources to be able to perform the process routinely. On the other hand, it is expected that the process – whenever it is performed – also provides valuable feedback to the organization to answer the following questions: Did the standard process work out as expected? Were the process descriptions comprehensible? Were the rules for estimating appropriate? Which things can be improved? The answers to these questions are used to maintain the organizations' set of standard processes.

CL 4: A process on SPiCE Capability Level 4 is called a quantitatively controlled process. It builds upon a defined process (CL 3) so it achieves its expected outcomes, is planned, monitored, controlled, quality assured, derived from standard processes, and provides feedback. Beyond that, quantitative measures are used for planning, monitoring, and controlling the process and statistical methods are used for estimating and managing quality aspects of the process's results.

CL 5: A process on SPiCE Capability Level 4 is called an optimizing process. It builds upon a quantitatively controlled process (CL 4) so it achieves its expected outcomes, is planned, monitored, controlled, quality assured, derived from standard processes, provides feedback, and is managed using statistical techniques. Beyond that, the results from statistically managing the process execution are used to predict potential improvements, which are piloted and then after evaluation deployed to the organization again.

3. RESULTS AND DISCUSSION

A systematic procedure was developed in order to apply maturity assessment for sustainable construction (Fig.1). Based on stakeholder defined goals and on building certification system DGNB/ÖGNI, functional requirements for both are determined. Causal loop analysis highlights systemic behavior of base practices in order to optimize technical measures that are suitable for the improvement and achievement of the pre-defined stakeholder goals. Furthermore, the cause and effect chain is modeled for each base practice. Possible interdependencies within the optimization process are highlighted.

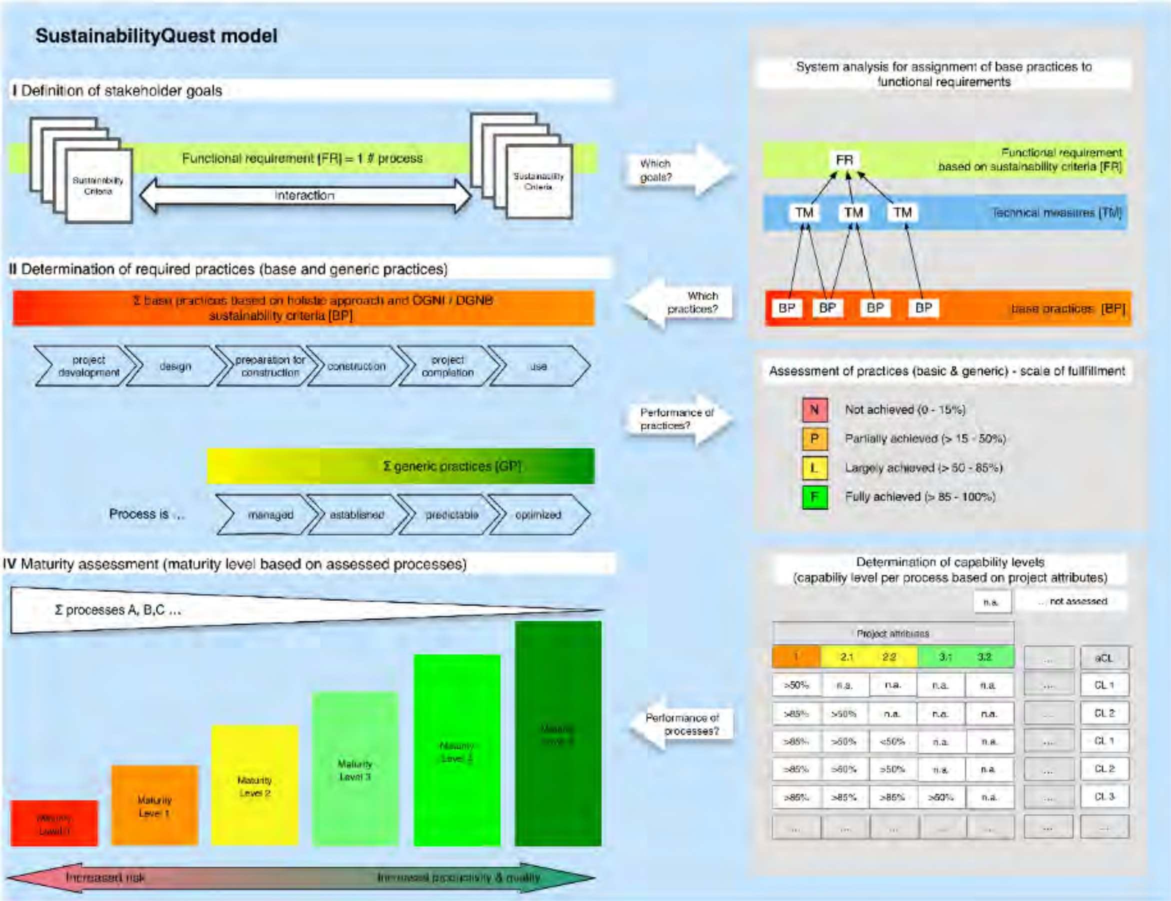

Figure 85: Assignment of processes

Figure 2 exemplary pictures the sequence of several base practices for stakeholder goal "slender design of building envelope". These sequences of base practices may vary when modifying stakeholder requirements.

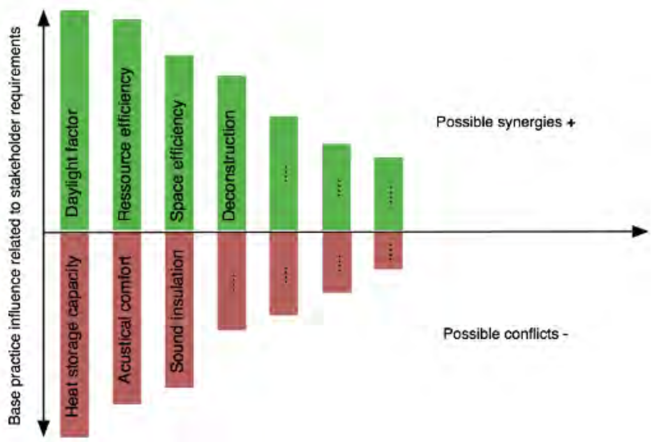

Figure 86: Synergies and conflicts for stakeholder requirement "slender design of building envelopes"

The process model approach allows stressing base practice influence as well as synergies and conflicts for several stakeholder requirements and provides therefore important information for integral planning processes. System interdependencies induced by implementing base practices can support decision makers during the integral planning process.

After identifying major practices to be implemented with regard to predefined and prioritized stakeholder goals, the fulfillment of these practices by consideration of all life cycle stages that are relevant for selected base practices is evaluated. Next to base practice, the fulfillment of generic practices is also assessed. For visualizing the optimization potential, the practices based on the assessment method from SPiCE must be assessed. Each practice will be assessed and rated using the N-P-L-F scale. Finally, the determination of the processes' achieved capability levels can be conducted. Base practices result in the process attribute "process implementation", which is equivalent to SPiCE Capability Level 1. The other process attributes are the results of the generic practices' assessment, which make up SPiCE CL 2 to 5. Due to SPiCE's rating and aggregation mechanism, the capability level calculation for each process attribute is possible. Based on pre-defined project attributes (assigned to different capability levels) and their scale of fulfillment according to the pictured evaluation algorithm in Fig. 1, capability levels for processes can be identified. Finally, the performance of all necessary processes is aggregated to a specific maturity level depending on the performed clustering.

The assessment result is usually displayed as a capability level profile, which is compared to a maturity level. The maturity level is a target capability level profile, so it is set up as a collection of processes, which each need to fulfill a defined capability level to satisfy the defined maturity level.

In a joint meeting with the decision makers, it is possible to identify optimization potential based on the assessment results in respect to pre-defined objectives and the expected maturity level. Thus, necessary countermeasure can be implemented in the early project stages. Using the following approach, it is possible to show the interactions on the stakeholders' specified target requirements in reasonable time.

4. CONCLUSION

This paper presents a new methodological approach for maturity assessments application for sustainable construction. Results clearly demonstrate that the combination of cross loop analysis and maturity assessment method allows the holistic management of life cycle processes regarding sustainable construction. Synergies and conflicts' visualization when implementing construction measures shall support decisions makers (investors, architects, planners, etc.) in the early planning stages of construction projects. By applying SustainabilityQuest model, sustainable construction processes can be monitored based on a systemic perspective. Alterations or deviations from the agreed quality goals can be covered in a timely manner and thus lower project risks.

ABSTRACT

To drive the research and development of energy-efficient building technologies in the tropics, an advanced rotatable testbed, BCA SkyLab, was developed in Singapore in collaboration with Lawrence Berkeley National Laboratory (LBNL). As world's first high-rise rotatable testbed for the tropics, this facility is an outdoor testbed sitting atop a 7-storey building, with a rotatable platform that can simulate various orientations of building. The testbed allows testing and evaluation of performance of various technologies in the tropical urban environment, including lighting, air-conditioning, facades, shades and control systems. Performance in visual comfort and potential in deeper energy savings of an integrated auto-dimming lighting with automated blinds system was investigated in the SkyLab. This system was installed and tested together with a conventional baseline system in the two cells in the SkyLab. This integrated system uses auto-dimming control based on outdoor illuminance level through the Digitally Addressable Lighting Interface (DALI), and the automated blinds incorporates a two-section daylight-redirecting design to introduce maximum daylight while minimising Daylight Glare Probability (DGP). The system performance of energy savings and visual comfort were investigated with an innovative control algorithm developed in-house. It was found that the automated blinds effectively eliminated glare discomfort, and with the automated blinds working in conjunction with the auto-dimming, up to 74% of lighting energy savings is achievable without compromising the illuminance level at the working plane.

Keywords: auto-dimming, automated blinds, daylight redirecting

1. INTRODUCTION

Lighting system with automatic dimming is gaining popularity as a green building technology. Studies have shown high potential for lighting energy savings by automatic dimming system when sufficient daylighting is available. Galasiu et al. (2007) reported 10-20% savings by using daylight-linked dimming over one year in an office building located in Burnaby, Canada. Fernandes et al. (2014) found that daylighting-based dimming controls integrated with set point tuning can reduce lighting energy by about 20%, compared to the recommended 12 W/m^2 in ASHRAE 90.1-2007 for day-lit zones in New York Times Headquarters Building. Delvaeye et al. (2016) reported that 46% of lighting energy savings can be achieved by an open loop system with Digitally Addressable Lighting Interface (DALI) control in an one-year measurement conducted in a classroom in Belgium. These studies used either T5 or T8 fluorescent lamps. Switching from florescent lighting (e.g., T5 and T8) to LED could also bring energy savings, as some studies showed. A study conducted in an eight-story office building in the UK (Department of Energy & Climate Change, 2014) reported 30% of electricity savings due to replacement of T5 lighting with LED lighting and upgraded BMS system. Richman et al. (2011) conducted a laboratory evaluation of LED and T8 lamp products, and reported that 3-24% of lighting energy savings can be achieved by LED depending on fixture type, compared to T8.

Window blinds system is usually used in conjunction with indoor lighting system to modulate daylight and reduce glare. The lighting and blinds systems may operate independently or as an integrated system. Lee et al. (1998) performed a full-scale test bedding of an automated Venetian blind with T8 dimmable lighting system in two unoccupied, private offices in Oakland, California. For an office with Southeast-facing façade, 1 – 22% lighting energy savings can be achieved by the dynamic system (automated blinds plus auto-dimming lighting), compared to fixed blinds partly closed at 15o with auto-dimming lighting. Daily lighting energy savings of 22-86% were obtained with the dynamic system compared to a static system (fixed blind set at any tilting angle plus non-dimmable lighting). Lee et al. (2009) conducted another experimental study in an 88.4-m^2 window system testbed facility located at Lawrence Berkeley National Laboratory (LBNL). A system consisting of automated daylight-redirecting blinds and auto-dimming lighting saved 69% of lighting energy comparing to a system with manually-operated Venetian blind and non-dimmable lighting. These savings are based on an average daytime of 6 am – 6 pm. Mettananta & Chaiwiwatworakul (2014) reported that more than 24% of lighting energy savings can be obtained from a system consisting of auto-dimming lighting and automatic vertical blinds in a laboratory room with North-west facing façade in Thailand. Chaiwiwatworakul et al. (2009) reported a lighting energy saving of 80% in an office building in Thailand, which is equipped with an automated blinds system and an auto-dimming ballast lighting system with an optimized operation scheme developed through simulations.

Lighting energy savings by daylight-responsive auto-dimming and automated blinds system can be affected by a few factors: 1) daylight availability affected by location and orientation, and 2) shading configurations including type, material, control strategies, etc. This study investigates the performance of an integrated system consisting of auto-dimming lighting and automated blinds. The automated blinds system is a split system with the top part featuring daylight re-directing functionality and the bottom part for glare control. Experiments were conducted in the newly established BCA SkyLab facility, which is a rotatable outdoor test bed subjected to the tropical climate in Singapore. The facility has two side-by-side, identically configured test compartments with interior simulating an office environment facilitating well-controlled comparative studies. The results shall provide new insights into the operational characteristics and energy savings potentials of an integrated auto-dimming lighting and auto blind system in the tropical context.

2. METHODOLOGY

2.1 Configuration of the BCA SkyLab test facility

The test facility is constructed on an outdoor 360o rotatable platform enabling tests to be carried out at any orientation under the exposure to real weather conditions. In addition, it adopts a plug-and-play concept, allowing quantitative assessment of technologies in individual or combined configurations. The facility is situated atop a 7-storey-tall building to avoid shadow casted by neighbouring buildings. The facility has two configurable test compartments (the reference cell and the test cell) side-by-side and a control room located behind the test compartments. The two compartments are identical in dimensions (8.41 m L × 5.54 m W × 3.47 m H) and orientation, enabling comparative studies of the performance of design solutions and technologies in the test cell against a baseline setup in the reference cell. The control room holds the Building Management System (BMS), data acquisition system (DAQ) and other monitoring systems.

The exterior walls are built from 257-mm-thick aluminium composite panel and plasterboards with insulations. The U-value of the exterior wall is 0.2 W/m^{2}K. One of the sidewalls is a full-height window façade. The window is made of double-pane low-E glazing with aluminium frame and thermal block insulation. The window façade has a U-value of 1.54 W/m^{2}K and a shading coefficient of 0.30. The roof is made of 100-mm-thick concrete slab and 50 mm of ultra-foam insulation. The floor is carpeted. There are 4 typical office work stations in each cell. A thermal dummy (0.3 m in diameter and 1.1 m tall) made from galvanised steel sheet is put at the seat position of each work station. Each thermal dummy is providing up to 180 W of sensible heat. Each cell is served by a fan coil unit (FCU) with an indoor temperature set point of 22°C. Indoor relative humidity is maintained at 65%. Figure 1 (a) shows the schematics of the experimental setup.

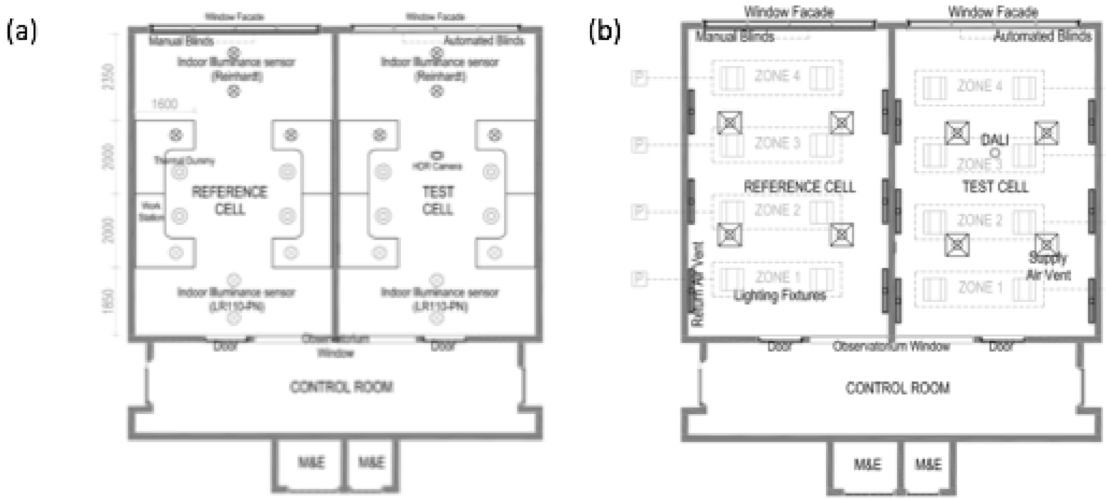

Figure 1: Experimental Setup. (a) Cell Arrangements; (b) Ceiling Installations

2.2 Lighting system

Each cell is fitted with 8 lighting fixtures. The lighting fixtures are mounted on the false celling at the height of 3.47 m from the finished floor. Each lighting fixture is 0.60 m long and 0.60 m wide. Two representative types of lighting are covered in this study: T5 fluorescent lamp and LED. The electrical power drawn by each lighting fixture is 51.75 W (T5) and 46.00 W (LED), at their respective maximum outputs. The lighting power density in the cell is 7.9 W/m^2 for T5 and 6.1 W/m^2 for LED.

Prior to the experiments, a lighting distribution test was carried out in both cells with all lighting fixtures set to maximum output. The test was conducted at night time with all windows blocked by papers to minimize external lighting disturbances. Illuminance measurements were made in a pre-defined grid of 1.07 m x 1.07 m per grid point covering the entire cell at the working plane height (height of work desk table top, 0.73 m above the floor) with a portable handheld lux-meter (Tenmars TM 202 Lux/FC). The test was conducted twice, once with T5 and once with LED. The average horizontal illuminance level at working plane height is 540.8 Lux with T5 lamps and is 538.9 Lux with LED. It is in compliance to the recommendation in SS531: Part1: 2006 (2013) of above 500 Lux at the working plane. The uniformities of illuminance in task area and surrounding area also conform to the recommendations in SS531: Part1: 2006 (2013) (task illuminance shall not be less than 0.7 and that of the immediate surrounding areas shall be not less than 0.5).

DALI dimming control (Lutron) was installed to provide auto dimming functionality to the lighting system. The DALI control system provides 4 settings: OFF, 25%, 100% and daylight responsive. The first 3 settings are manual overrides and the daylight responsive setting provides the auto dimming function. A daylight sensor is mounted on the ceiling 3.5 m away from window façade to detect the daylight conditions, providing the control feedback to the DALI system. The eight lighting fixtures in each cell are divided into 4 control zones as shown in Figure 1 (b). Zone 1 and zone 2 are individually controlled whereas zone 3 and zone 4 are controlled as one zone.

2.3 Blinds system

Conventional manual blinds, were installed inside of the reference cell. In the test cell automated daylight-redirecting blinds are installed. Both blinds systems are of Venetian type. The automated blinds were divided into two sections: the upper one-quarter-height portion consists of mirror-finish daylight-redirecting slats (50 mm wide, reflectivity: 0.91) and the lower three-quarter-height portion consists of mat-finish slats (25 mm wide, reflectivity: 0.56). The conventional manual blinds have the same mat-finish slats for full height. An in-house developed control algorithm was applied to control the automated blinds. The algorithm controls the lower portion such that the DGP of the person sitting at the work station closest to the wind façade will not exceed 0.35. The upper portion is controlled to allow maximum daylight penetration below the maximum threshold of 1,200 Lux of daylighting at the working plane. The manual blinds system is set at a predefined position (close/ open/ retracted) manually depending on experimental need.

2.4 Instrumentation

In each cell, horizontal illuminance at working plane height is measured by 8 illuminance sensors (4 further away from the window façade have a range of 0-10,000 lux (LR-110 PN), and the other 4 closer to the window façade have a range of 0-150,000 lux (Reinhardt)). One illuminance sensor (Reinhardt) is placed on the top of the roof to measure the outdoor horizontal illuminance at rooftop level. Glare in the test cell is measured using a High Dynamic Range (HDR) camera setup. Zonal lighting power is monitored by power meters (PowerLogic iEM3155). All sensors are reading and data-logging at 1-min intervals through the central DAQ of BCA SkyLab, apart from the HDR camera which used a 5-min interval due to the heavy processing power demand of imaging data. The sensor setup is shown in Figure 1 (b). Before the experiments, all the sensors and instrumentations have gone through systematic calibration and verification. The lux sensors have also been subjected to zero offsetting with their sensing elements closed using the factory-provided covers. Further, sensor signal noise is analysed by comparing the 2 × standard deviation of readings and noise-to-signal ratio with the documented accuracy of the sensors. The analysis ensures that the sensor signal noise does not exceed the documented accuracy range.

2.5 Experimental setup

Four tests were designed to study the performance of T5 vs LED, auto-dimming system, automated blinds system and the combined system. Each test runs from 9:00 am - 6:00 pm per day, following a typical office working schedule, for 3 days in May and Aug 2016. Table 1 summarizes the configurations of the four tests. Test 1 and Test 2 are conducted at blinds retracted condition to isolate the lighting energy savings potential of the auto-dimming system and the LED lighting. In Singapore, buildings are recommended to minimize façade exposure to the East and West orientations (Building and Construction Authority, 2010) and, thus, the North represents a typical façade orientation setting in Singapore. Test 3 and Test 4 study the integrated system consisting of auto-dimming lighting and automated blind. Test 4 has the same settings as Test 3 except that the façade orientation changes to East to investigate its impacts on energy savings potential of the integrated system.

Tests	Reference Cell	Test Cell	Façade Orientation
Test 1	Lighting: T5, Auto-dimming: No Blinds: Retracted	Lighting: T5, Auto-dimming: Yes Blinds: Retracted	North
Test 2	Lighting: T5, Auto-dimming: Yes Blinds: Retracted	Lighting: LED, Auto-dimming: Yes Blinds: Retracted	North
Test 3	Lighting: T5, Auto-dimming: No Blinds: Close	Lighting: LED, Auto-dimming: Yes Blinds: Automated	North
Test 4	Lighting: T5 Auto-dimming: No Blinds: Close	Lighting: LED, Auto-dimming: Yes Blinds: Automated	East

Table 1: Test cases

3. RESULTS

3.1 Auto-dimming lighting control

Table 2 summarises the lighting energy consumptions and energy savings achieved in the Test cell compared to the Reference cell. In Test 1, about 56.80% of lighting energy savings is achieved. Test 1 was conducted with both cells using T5 lighting fixtures and, thus, the energy savings obtained from this test reflects the energy savings due to auto-dimming.

	Lighting Energy Reference Cell(1)	Lighting Energy Test Cell (2)	Lighting Energy Savings (1) – (2)	Lighting Energy Savings [(1) – (2)]/(1) x100%
Test 1	9.90 kWh	4.28 kWh	5.62 kWh	56.80%
Test 2	3.52 kWh	2.06 kWh	1.46 kWh	41.52%
Test 3	9.79 kWh	2.51 kWh	7.28 kWh	74.35%
Test 4	9.87 kWh	3.66 kWh	6.21 kWh	62.92%

Table 2: Measured lighting energy consumption and savings

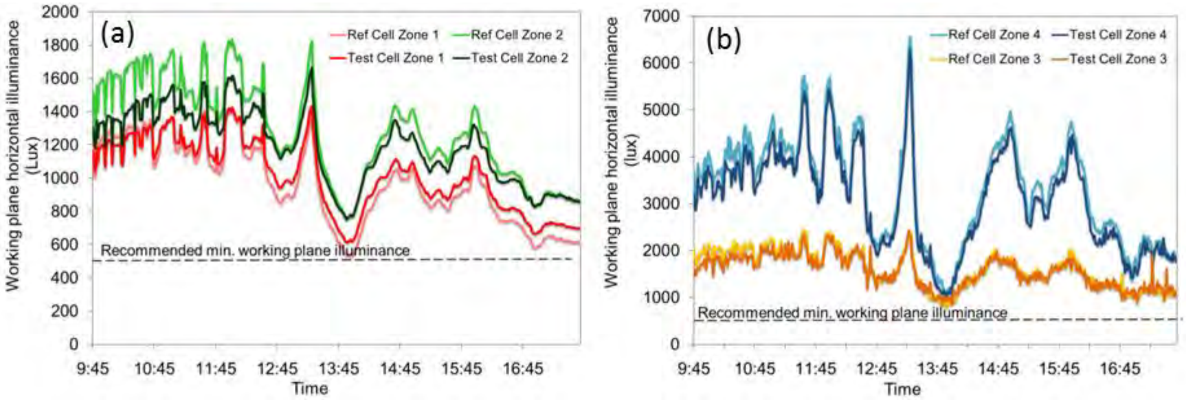

Figure 2: Working plane illuminance at each lighting zone for 1 day of Test 1

The horizontal illuminance at working plane in all lighting zones is maintained at over 500 lux during testing period, as depicted in Figure 2 (a) and Figure 2 (b). The high illuminance in zone 4 could be largely attributed to daylight penetration through windows.

3.2 T5 fluorescent lamp vs LED

Test 2 shows that about 42% of lighting energy savings is achieved by LED, compared to T5 lighting. Since this test is conducted with auto-dimming enabled in both cell, this saving by LED is achieved on top of the saving by auto-dimming. This could be due to the difference in dimming effects between LED and T5 as the two types of lamp has different lighting efficacy. The horizontal illuminance at the working plane is maintained at over 500 lux during testing period, in both cells.

3.3 Combined system

There is substantial lighting energy savings potential in an integrated system with auto-dimming lighting, automated blinds and LED. About 74% lighting energy savings was attained when the façade is facing North (Test 3). The working plane horizontal illuminance in both cells are maintained at above 500 lux as shown in Figure 3 (a) and Figure 3 (b), suggesting that the savings are obtained without compromising working plane illumination. The illuminance of zone 3 and zone 4 in test cell is higher than that in reference cell, indicating daylight penetration from automated blinds in test cell.

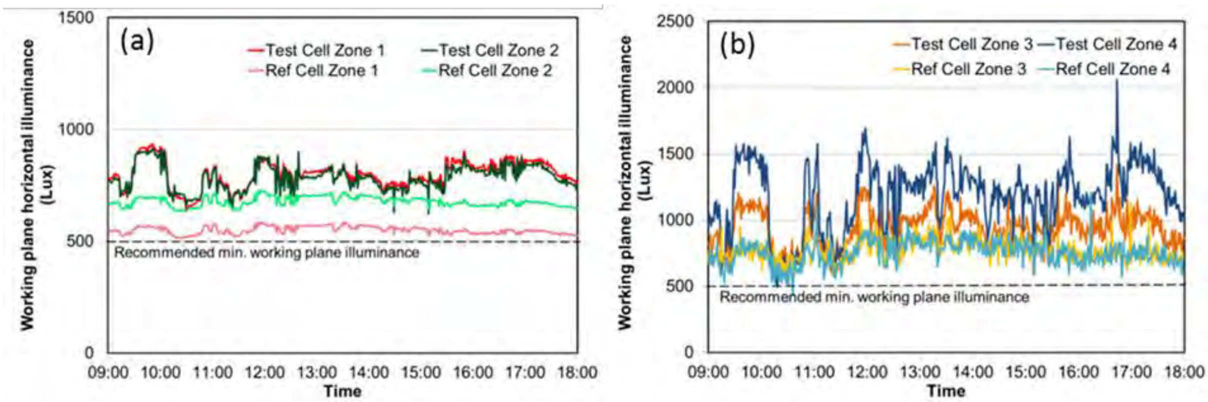

Figure 3: Working plane illuminance at each lighting zone for 1 day of test 3

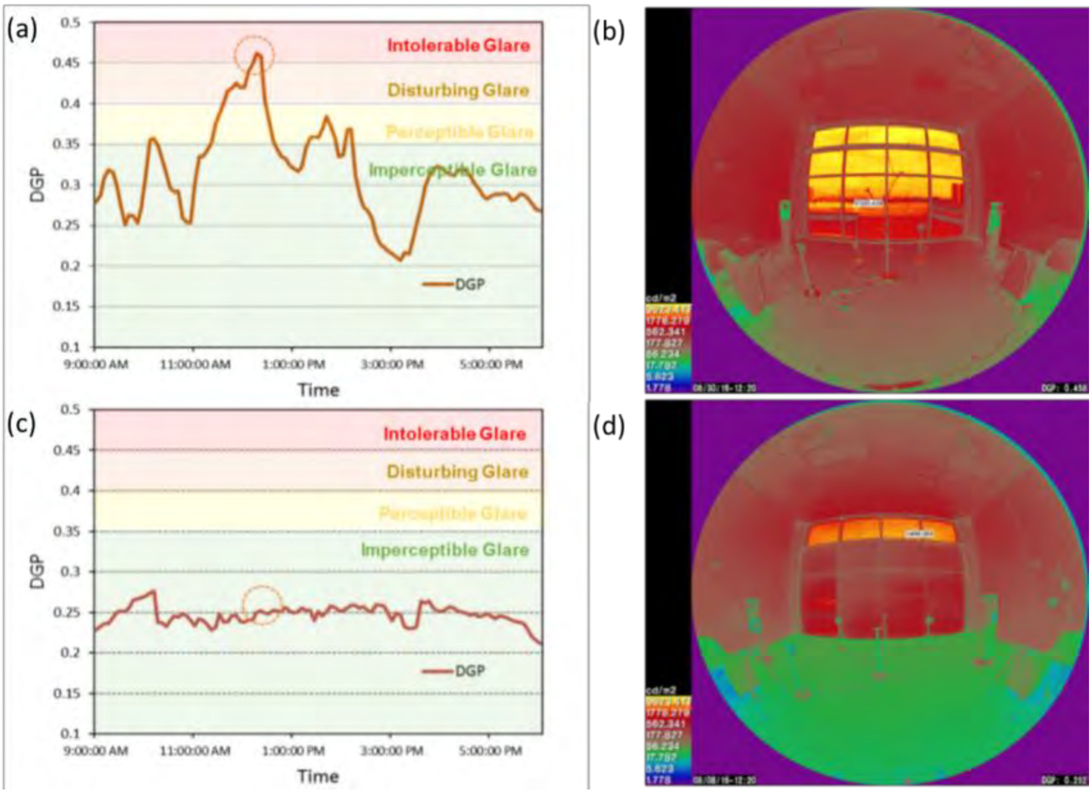

Figure 4: (a) DGP Profile of Test 1 (Blinds Retracted); (b) HDR Image at 12:20 pm during Test 1; (c) DGP Profile of Test 3 (Automated Blinds); (d) HDR Image at 12:20 pm during Test 3

While maintaining adequate horizontal illumination at the working plane (at above 500 lux), the integrated system maintains the Daylight Glare Probability (DGP) to be below 0.35 during the testing period, as shown in Figure 4 (c). It indicates that the automated blinds have successfully controlled glare according to the glare level classification in Jakubiec & Reinhart (2012). The DGP profile of Test 1 (blinds retracted) is shown in Figure 4 (a) for comparison. In Test 1, DGP exceeds 0.35 (threshold for perceptible glare) at certain time of the day and reaches a maximum of 0.46 (intolerable glare) at 12:20 pm. DGP at the same time of the day in Test 3 is 0.24.

The impact of facade orientation is examined by running the same test but with façade orientation adjusted to facing East (Test 4). The Test cell consumes significantly more lighting energy in Test 4 compared to Test 3 (see Table 2), suggesting that the East façade orientation has less daylight availability (and potential for dimming) than the North orientation. This could be due to the fact that although there is ample amount of daylight available in the morning in the East orientation, the East-facing façade is under the shadow of the lab itself in the afternoon and, thus, less daylighting potential compared to North on a daily basis. This is reflected in the system's ability to save lighting energy consumption. The same integrated system saves only about 63% of lighting energy in Test 4, lesser than the 74% in Test 3. However, the integrated system is still able to maintain the DGP at below 0.35 and working plane horizontal illuminance at above 500 lux during daytime in Test 4. Visual comfort is not compromised in both orientations.

4. DISCUSSION

Current results suggest that more lighting energy savings can be achieved if more daylighting is available. This matches with the observations in some previous studies, e.g., Lee et al. (1998), Lee et al. (2009), Chaiwiwatworakul et al. (2009), etc. Taking weather conditions, building orientation and sky view condition into account in evaluating the performance of auto-dimming and automated blinds is important. This paper provides the first report on the performance of an integrated lighting and daylighting control system in a rotatable testbed in tropical region.

An outdoor rotatable test facility with plug-and-play capability provides a highly flexible test bed for various green building technologies. The BCA SkyLab allows the test bedding of individual technology or a number of technologies simultaneously as an integrated system, leading to new scientific insights on the performance and characteristics of green building technologies.

5. CONCLUSION

This study investigates the lighting energy performance and visual comfort of several lighting and daylighting technologies: LED, auto-dimming lighting and automated blinds in a rotatable test facility, BCA SkyLab, in Singapore. The interior of the facility simulates a typical office environment. Compared to non-dimmable lighting, auto-dimming lighting shows about 57% savings in lighting energy consumption. LED lamps provide about 42% of lighting energy savings compared to T5 fluorescent lamps. An integrated system consisting of LED lamps, auto-dimming lighting control and automated blinds achieves up to 74% of lighting energy savings compared to a base system consisting of T5 lamps, non-dimmable lighting control and manual blinds. The energy savings potential increases with daylight availability. In Singapore's tropical climate, the integrated system shows excellent capability to provide visual comfort while achieving significant lighting energy savings, demonstrating the value of an outdoor rotatable test facility in R&D.

Future work can include evaluating thermal performance of the integrated system, testing its performance in other building orientations with longer durations, as well as further integration with air-conditioning control to optimise the energy performance of the system.

ABSTRACT

As one type of decentralized renewable energy system, BIPV has been widely adopted to reduce carbon emissions. BIPV design incorporates original structural analysis, power matrix design, photovoltaic panel design, etc. Factors that influence BIPV design process also include total installed capacity, construction material costs, electricity price returns, investment payback period and enterprise income. The iterative design process is time consuming and very complicated. Nowadays, Building Information Modelling (BIM) is the most promising technology for enhancing the performance and quality of construction. Ever since its gestation, BIM has promised endless prospects for people, organizations, products and processes in the construction industry. Yet there is limited use of BIM on BIPV system. In this paper, the author proposes a BIM based integrated BIPV design system and presents how the system can be used to facilitate the design process in a real project. The author finds that the system is intelligent and efficient, which can help designer make better design decisions before construction and save valuable time.

Keywords: BIM, BIPV, renewable energy

1. INTRODUCTION

There is unprecedented interest and research in renewable energy technologies driven by the insecurity of supply, increasing cost, and environmental degradation issues associated with fossil energy resources, among which solar energy is the most abundant, inexhaustible and clean one. The building sector is the biggest single contributor to total energy consumption which consumed 40% or more of the total energy usage in many countries. One of the most promising renewable energy technologies is Building-integrated photovoltaic (BIPV)(Kim et al. 2015).

BIPV module is a semiconductor device that converts solar energy directly into useful electricity. Photovoltaics (PV) are seen to be generally of benign environmental impact, generating no noise or chemical pollutants during use. It is one of the most viable renewable energy technologies for use in an urban environment, replacing existing building cladding materials. (Tsoutsos et al. 2005)

Nowadays, Building Information Modeling (BIM) is the most promising technology for enhancing the performance and quality of construction. BIM is a technology that is used to integrate a three-dimensional building model with building information through the life cycle of the building. (Anon n.d.)

There are studies using BIM on BIPV research. For example, Xuan applied BIM technology for modeling and analyzing the tilt angle of a BIPV panel (Xuan 2010). Dixit et al. developed an API program in Autodesk Revit to calculate insolation which was compared with the measured insolation (Dixit & Yan 2012). Gupta et al. developed a conceptual framework for PV simulation using an open BIM standard format (Kuo et al. 2016).

Although the emerging BIM technology has provided a better design platform in a 3D digital space, there is still a lack of study on a BIM based integrated BIPV design system. To address this challenge, this study proposed a BIM based integrated BIPV design system which has the potential to facilitate BIPV design process and help designers make more informed decisions. This system is developed based on BIM software Revit and Dynamo. While the majority of BIPV systems are interfaced with the available utility grid, BIPV may also be used in stand-alone, off-grid systems. This study focuses on the available unity grid BIPV system design.

This paper is structured as follows: Section 2 describes the traditional 2D based BIPV design procedure. Section 3 presents the concept of BIM integrated BIPV system. Section 4 discussed BIM integrated BIPV design system through case studies. Section 5 presents the conclusions and highlights the future work.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2. 2D BASED BIPV DESIGN PROCEDURE

BIPV systems should be approached to where energy conscious design techniques have been employed, and equipment and systems have been carefully selected and specified. Design considerations for BIPV systems must include the building's use and electrical loads, its location and orientation, the appropriate building and safety codes, and the relevant utility issues and costs (Steven Strong n.d.). The 2D based unity grid system BIPV design procedure is as follows:

- Azimuth angle selection

Azimuth is the array's east-west orientation in degrees. In most of the solar PV energy calculator tools, azimuth value of zero is facing equator in both northern and southern hemispheres. The modules on an array are faced to south in order to get the most out of the sun's energy. In the southern hemisphere, it is the opposite.

- Inverter selection

An inverter is used in the system where AC power output is needed. For grid connected systems, the input rating of the inverter should be same as PV array rating to allow for safe and efficient operation.

- PV panel selection

The limiting factors sizing grid-connected PV panels are the available space (often a roof), the investment costs and the regulatory frameworks including subsidy and promotion programs.

- Solar PV panel mounting system selection

The shape and size of which will vary with the mounting system manufacturer. PV panel mounting system should endure wind loads that are required by local standards.

- Panel column calculation

Panel column is determined on the width of the roof and the panels on each group which has to meet the requirement of the distance

- Panel row calculation

Panel row is determined on the width of the roof and the panels on each roof which has to meet the requirement of the distance.

- PV panel calculation

The total number of PV panels is calculated by adding all PV panels.

- PV panel grouping

Grouping of PV panel is determined on the characteristics of PV panel and inverters.

- Installed capacity calculation

Installed capacity is determined on the PV panel numbers and characteristics.

- 2D architectural drawing generation

3. THE CONCEPT OF BIM INTEGRATED BIPV SYSTEM

BIM technology deals with the generation and management of the virtual representation of a building in a virtual environment. In a BIM -Based BIPV design process, designers can apply BIM technology to explore different design concepts in a short time and make more informed decisions. The following are BIM the concept of BIM integrated BIPV system.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.1 Data collection and BIM model creation

In the study, BIM software Autodesk Revit was used to create a BIM model of the BIPV factory house and intelligent BIM component models. After the building environment information and the 2D CAD drawings of the BIPV house were collected, the CAD files were imported into Revit as a reference to create a BIM model and building environment information was set into the BIM model.

Besides the general building components, the corresponding BIM models of the BIPV components were created , including PV panel models, inverters, mounting stackers.

3.2 Integrated BIPV BIM model generation

Autodesk Dynamo extends BIM with the data and logic environment of a graphical algorithm editor which allows users to generate algorithms to analyze data, read and edit data from Revit, create geometry in Dynamo or edit the geometry in Revit files (Anon n.d.).In the study, a large assortment nodes of Dynamo were built to create the integrated BIPV BIM model.

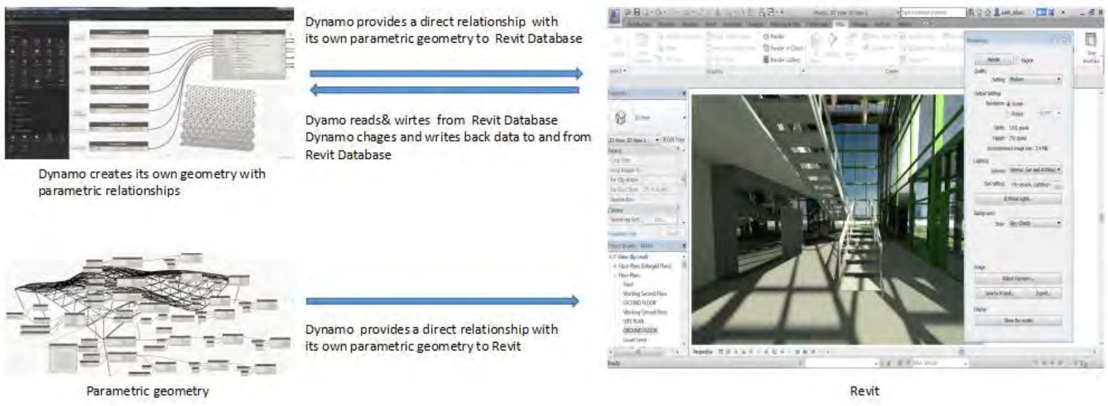

Figure 1: Revit and Dynamo

4.2 BIPV BIM model generation

The nodes of Dynamo built to create the integrated BIPV BIM model is shown on Figure 10 -Figure 12. In the nodes, the user can select tilt angle inverter, mounting bracket, PV panel, PV panel orientation and group panel number through pre-defined options and determine other parameters in nodes to generate integrated BIPV BIM models as shown on Figure 13 and Figure 14.The visualization feature of the BIM model allows the designer to better understand the design effect and make more informed decisions and compare different design schemes.

5. CONCLUSIONS AND FUTURE WORK

This study proposed a BIM based BIPV design system. In this paper, BIM models of a factory building and BIPV components were built using Revit. Information such as building location, building orientation, building area and real product parameters were contained in the BIM model. A series of dynamo nodes were built to analyze data, read and edit data from the Revit BIM model and generate integrated BIPV BIM models of the factory. Finally, the traditional plan, section, elevation, as well as other reports are generated using automation and customization features of BIM software. The model-based approach increases efficiency of BIPV design process and the designer could visualize a completed building along with all its components to make better design decisions before construction which helps to save overall time and the cost of the project.

In the future, more BIPV BIM component models will be added to the system to provide more options for designers and the cost of the components will be included in the BIM model for cost estimation of the BIPV system.

ABSTRACT

Hong Kong as an international finance centre is a fast-paced and high density community, where the development of sustainable built environments faces numerous challenges. In-situ reprovisioning of Sha Tin Water Treatment Works – South Works is an example demonstrating how the built environment of the water treatment works is enhanced despite the challenges.

Sha Tin Water Treatment Works, comprising the South Works and North Works, is the largest treatment works in Hong Kong meeting about 30% of the total fresh water demand in the territory. The South Works was commissioned in 1964 with a treatment capacity of 364,000 m3 per day while the North Works was commissioned in stages since 1973 increasing the treatment capacity to 1,227,000 m3 per day. Due to the aging of plant and equipment which are approaching the end of their service life, the South Works requires major renovation and replacement to meet the growing demand.

Achieving sustainable reprovisioning of the South Works, building solutions including but not limited to onsite green building planning and massing, hydro power generator, ice storage system and Thermal Vision Based Security Surveillance (TVBSS) system enhancing energy saving and minimizing light pollution to neighbourhoods, etc. which have been considered in the design, will be discussed in this paper.

Keywords: sustainable development, green building, energy efficient

1. INTRODUCTION

Sha Tin Water Treatment Works (STWTW) is the largest water treatment works in the Government of the Hong Kong Special Administrative Region (HKSAR). It was commissioned in 1964 with three subsequent expansions bringing the total nominal treatment capacity to 1,227,000 m^3/day. The 52 years old plant and equipment in the South Works are approaching the end of their service life and require major renovation and replacement.

The challenge is to complete the in-situ reprovisioning of the South Works together with major common facilities for both the South Works and North Works within the site, which is already fully utilised. It is also necessary to maintain continuous operation, maintenance and security of the North Works during the South Works upgrading.

In the last 50 years, economic development was the driving force globally to create a better world. 50 years on, the focus has shifted to sustainable development, ensuring that our descendants can enjoy a continuous growth in a healthy manner.

As the design of overall site layout is dictated by water treatment process train, modern treatment technologies were incorporated to enhance site utilisation and resolve the congested site condition. Apart from providing the state-of-the-art treatment technology, the project also aimed at developing an integrated building design which respects the existing surrounding landscape environment and its adjacent land users. The paper will be focused on the sustainable building development and energy efficient design.

2. BUILDING PLANNING AND MASSING

STWTW is located in a natural valley surrounded by two major country parks, namely, Lion Rock Country Park to the South and Kam Shan Country Park to the west. Although there are no direct pedestrian connections to these parks with STWTW, the design layout of buildings is to ensure a coherent green environment that responds to its surrounding open space.

Figure 1: Layout Plan of STWTW with Reprovisioned Administration Building and South Works Treatment Process Precinct

Buildings to be reprovisioned in the STWTW are strategically subdivided into two realm, i.e. Administration Building (See Figure 1 area highlighted in purple) and the water treatment process precinct of South Works (See Figure 1 area highlighted in orange). Each individual realm is characterized by its unique site features.

2.1. Administration building

The administration building encompasses new laboratory space, administration offices, control room for plant operations and training facilities. Sustainability and performance are primary motivators in the design of the building. The design is less about creating a building and more about the concept of tucking the laboratory and control facility into the adjoining hillside to take full advantage of the benefits of a green roof and energy conservation. The shape and form of the building is highly influenced by the unique site characteristics. Horizontal roof surfaces and the terraced building mass allow the building to have a low profile, minimizing the visual impact on the site. It will effectively blend into the hillside.

The building has a modern architectural expression, with glass, metal and stone used throughout the exterior. The design attempts to maximize the amount of day light entering into the building, thereby creating quality workspaces with views that provide the staff with a sense of connection to the outdoors. Sunshades and glass technologies allow this building to perform in a highly efficient manner. The exterior of the building is expressed with clean lines and patterns, with a minimal amount of features.

Figure 2: Design of administration building cum Mainland East Laboratory

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Key elements of the design are:

- The design of the new building will have a distinct identity.
- The laboratories are designed with standard modules to create consistency and provide flexibility for future reconfiguration.
- The Control Room is located on the third level for clear viewing of the treatment facility.
- Circulation patterns are organized throughout the building to allow visitors to appreciate the various functional components.
- Upper levels are connected by ramps terminating at the Roof Garden and Observation Platform Walkway.
- The roof of the ramps will provide a look-out oriented towards Amah and Lion Rock. The entrance is low and set back to preserve views to Lion Rock.
- Light-filled workspaces are provided for the laboratory and supporting staff.
- The building is integrated into the landscape.

2.2. Treatment process precinct

In line with the administration building, the treatment process precinct of South Works is situated in a large area surrounded by green mountains with a lot of vegetation.

Integrating – The development of buildings aims at creating a complex of different water treatment process units which are designed with simple massing and harmonized with the natural landform. Each building within the process precinct is designed to height fits for its function in order to reduce environmental impact caused by excessive building height. In addition, extensive greenery is provided to the ground, roof and the elevations of the buildings. It helps to blend the buildings with the nature.

Simple – It is aimed at adopting a simple and modern style. The facade of buildings is designed to be precast concrete cladding with fair-faced concrete finish. With the introduction of green features on the elevations and the roof, the monotonic appearance of a linear and long building is dissolved and giving interesting elevations. A different colour is assigned to each individual building. The strong contrast between the light grey wall colour and the colour wall gives a remarkable identity to each of the building.

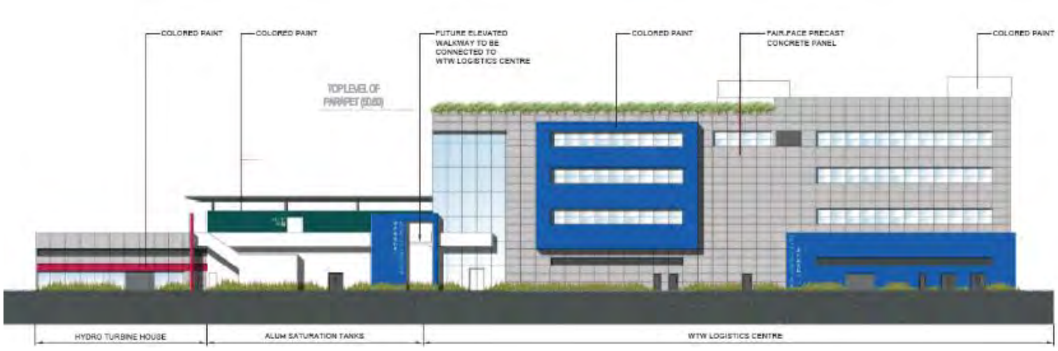

Figure 3: Design of treatment process precinct

Real Materials – Recycled materials such as structural steel, fair-faced concrete panel, stone, recycled plastic, recycled pavers, environmentally friendly paint etc. are extensively used throughout the treatment plant as far as practicable. The materials proposed are durable, environmentally friendly and less maintenance is required.

Quality of workplace – In the building design, different aspects such as view, capture of daylight, ventilation, spatial arrangement etc. are considered. It is aimed at providing a healthy and comfortable work place for the users of the development.

3. SUSTAINABILITY AND ENERGY

In terms of sustainability, the building design follows the Hong Kong Building Environmental Assessment Method (BEAM) managed by the Hong Kong Green Building Council and BEAM Society.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

In the sustainability design, one of the key factors is maximization of natural lighting. In this regard, the solar time throughout the year has been checked and used in the building design. The application of the concept of solar time for passive solar design, and the angular relationship between the sun, the building and any shading devices and obstructing bodies is considered. The degree difference in the altitude of the sun at solar noon between winter and summer combined with local climatic data was used to determine at what time of the year solar gain will be beneficial for thermal comfort in winter, and when it should be blocked with shading in summer.

Rainwater harvesting system is incorporated to form part of the sustainable design. It is simply the collection of rainwater for use that would otherwise go down the drain. An extensive green roof system is implemented on the Administration Building. A water management system with the extensive green roof system can collect rainwater and become a part of the landscape feature. Leaves and other debris would be filtered out before the collected rainwater to be conveyed to a storage tank. The collected rainwater is eventually pumped through distribution system for irrigation purpose.

In the design of the Administration Building, ice storage system is incorporated as an energy management tool that transfers energy use from peak-hours to non-peak hours. As a result, air conditioning can be provided more efficiently, by using lower electricity costs at non-peak time when the energy demand is low at night, to freeze water into ice. The ice is then melt during the day-time to reduce the consumption of electricity at higher costs to meet the air conditioning demands during peak time.

STWTW treats raw water from 5 different sources during the day and throughout the year. Under the existing pumping/transfer pattern, the draw-off from the High Island Reservoir can be at a head of over 25 m when reaching the STWTW. Currently, the excess energy is dissipated by using the Energy Dissipating Chamber. Recognizing the steady draw-off from the High Island Reservoir and the significant potential energy associated with this route, a Hydro Power Plant is proposed to recover the energy from the excessive static head which is now wasted in the energy dissipation chamber.

The design of water turbine generator system for electricity generation is based on the maximum and minimum water power available under different flow and available head. The Hydro Power Plant serves as a base load generating plant to supplement the 380V utility supply at STWTW and is operated for parallel connection with the grid of CLP Power Hong Kong Limited through a unit power converter for automatic synchronization.

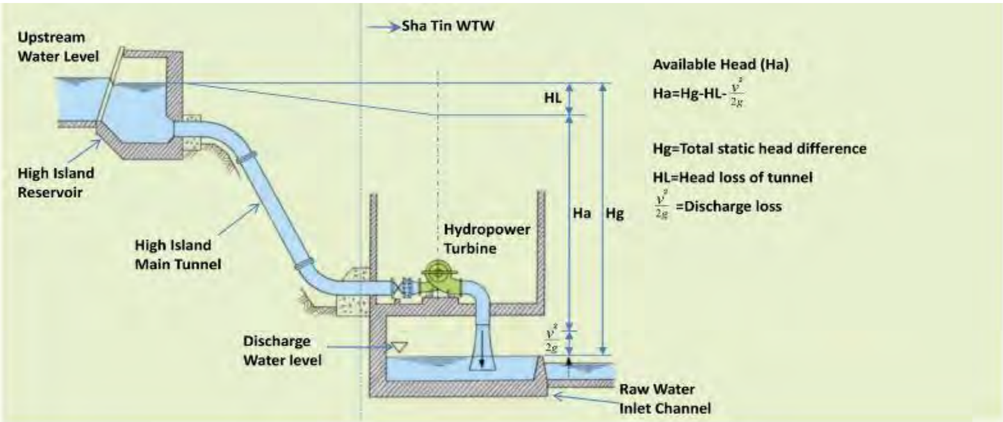

Figure 4: Available head for hydro power plant

4. OUTDOOR LIGHTING AND GREENING

STWTW requires enhanced security measures including outdoor area lighting and security lighting. Security precautions in STWTW is essential in order to prevent theft, unauthorised entry and safeguard premises against vandalism. In the installation, lighting is designed to fulfil two basic functions for (a) outdoor area lighting; and (b) security lighting.

Outdoor area lighting is designed to give a level of illumination appropriate to the use of the area. The lighting should normally be sufficient for normal conditions and if necessary, should be capable of providing an adequate level of illumination at the security fence line when used without the security lighting.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Traditionally, and for those being installed in the present STWTW, fixtures are of High Intensity Discharge (HID) type, either of High Pressure Sodium (HPS) or Metal Halide (MH) lamp. They are always known to have poor energy efficiency, shorter lamp life and poor light level uniformity. Furthermore, they are not considered as Green Power product.

For security lighting, it must be designed to meet the requirements laid down by the Security Bureau of HKSAR. The lights should be strategically located with the required minimum illumination level, using existing buildings whenever possible, but otherwise using poles. The lights should be focused to cover, as far as is practical, the entire security fence line.

However, the excessive light level emitted from the existing STWTW induces light pollution to the residential area in close proximity to the treatment works.

In visiting and reviewing the lighting scheme for open areas at STWTW, due considerations are given to the avoidance of light pollution, over-illumination, but with the minimum level of "lux" or illumination attained to meet safety and security needs on site, particularly at the boundary fence of the works. The approach or principle adopted in engineering the design basis for the lighting scheme in STWTW is "Green Power, Energy Saving, & No Light Pollution".

The context of Light Pollution is not limited to just over-illumination, but also means light intrusion or trespassing, glare disturbances. In other words, it means "suitability" or "appropriateness" of lighting arrangements to meet safety and security needs, but not to cause interferences or disturbances to others.

The application of LED to replace SON floodlight has most of the advantages to be adopted. It is noted that LED in today's lighting market has established its proven ground with good performance, reliability, energy efficiency and easier adaptation. Green and saving energy is achieved by means of using LED, each installation coupled with individual solar panel and wind turbine, and adopting dual mode operating regimes in outdoor area lighting under two open area zones, the essential and idling.

The use of state-of-art thermal network camera complemented with conventional cameras and an intelligent lighting network control system, coupled with Thermal Vision Based Security Surveillance (TVBSS) system as the basic security system is proposed, which is used to further control and dim down lightings in essential open areas and service roads for energy saving and to mitigate the effects of any light pollution caused by public lighting in the works.

Figure 5: Thermal Vision Based Security Surveillance (TVBSS) system

The cameras of TVBSS system do not capture objects under visible light as for conventional cameras. They detect invisible thermal radiation emitted from the objects, and movement of any objects in the field covered by the camera, regardless of darkness, brightness, smoke or fog in the environment. They provide an effective means to detect the movement of any objects under surveillance that would trigger further actions, and greatly enhance the effectiveness of the surveillance system. It will not only provide reliable security surveillance and tracking trespasser in a dark environment, but also further help dim down lightings in essential open areas and service roads etc. to only one-quarter of normal power in normal dark hours, at a minimum of 25 lux illumination. This is a strategic approach to enhance energy saving and to minimize light pollution in open areas in the new STWTW.

A triple-control illumination system is applied for open area lighting and security lighting, viz. a 3-step dimming to 1) none or minimum illumination overnight; 2) to a mid-lighting level which is regarded as a minimum environment for safe walking and patrolling in sensing movements by TVBSS system or by manually setting; and 3) the highest

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

intensity level for safe work and inspections. Different precincts within STWTW have different lighting requirements and hence different energy consumptions. Hence, zoning for lighting will help energy saving at the precincts that lighting in dark is not a prerequisite. The two different zones of open area lighting of STWTW are i) essential zone including all roads and major buildings; and ii) idling zones including plant area such as filters and water tanks. The criteria and operating regimes recommended for lighting designs over different open area zones and security lighting are summarized at below Table 1. Moreover, energy saving is achieved through the use of LED lighting.

Location / Zone		Base lighting in dark hours	Triggered by TVBSS / Manual Override	Full Intensity during Work/ Inspections on Manual Demand
Open Area Lighting	Essential Zones	25	75	150
	Idling Zones	0	75	150
Security Lighting	Boundary Walls & Fencing	25	75	150
	Security Gate House	75	150	N/A

Table 1: Triple-Control Illumination System Illumination Levels (LUX)

The total greenery areas for the reprovisioned STWTW is not less than 30% of its total site area. The greening strategy aims at creating and attractive environment which is coherent with the building layout for staff and visitors. The site landscape is organized on a linear framework which aligns with the grid form of the building roofs to provide logically connected outdoor space for staff, low-maintenance and robust greenery around the treatment process precinct. The design brings the landscape features into the site which provides woodland areas, green roofs and boundary evergreen planting with native species adding a natural quality to the space.

5. CONCLUSION

This paper summarizes the designs regarding to the sustainable building development of the reprovisioning of STWTW. Having the administrative building and treatment process precincts imbedded in creating a synergy and coherent relation with the topological character, the buildings and landscape features as a whole integrate with the surrounding environment and the adjacent land users.

The sustainable designs, including green roof system, natural lighting system, rainwater harvesting, ice storage system, hydro power generator, and the thermal network camera system, enhance energy saving and minimize the environmental impact to the neighbourhoods.

ABSTRACT

Pingtung County is located at the southern extremity of Taiwan. In order to cope with the impact of climate change, Pingtung County government is actively promoting the development of public transport systems, reducing of greenhouse gases caused by private transport emissions, and minimizing the impact on the environment.

Pingtung County government is not only actively seeking rail construction plan from the Center Government but also planning to expand the public transport coverage by building regional transit center, hierarchical bus network and bicycle sharing system.

The regional transit center is including one for main hub (Pingtung), two for secondary hubs (Chaozhou, Fangliao), and three for Sightseeing function hubs (Donggang, Shueimen, Hengchun). The hierarchical bus network is including main line bus, branch line bus, suburban bus, tourist bus, and Demand Responsive Transit System bus. The bicycle sharing system provides the last mile feeder service.

In order to increase public transport usage, Pingtung County Government also provides high quality, high technology, and intimately services by building bus shelters, bus information system, and executing bus service quality evaluation plan and overall marketing plan.

However, those policies will not be completed quickly. Therefore, we will determine the priority of policies by citizen demands and available resources, and promote those policies progressively to achieve the vision of transportation development of Pingtung County.

Keywords: climate change, public transport, development

1. INTRODUCTION

2016 marks a milestone in railway development in Pingtung County. The elevated railway has been constructed and TRA Rapid Transit Systematization is expected in the near future. However, the problems related to bus service in Pingtung County remain unsolved despite advances in railway infrastructure. Bus service quality has seen slow progress due to challenges incurred by "convenience of private vehicles" and "deficits in bus service operation", which has in turn caused a decrease in ridership. In light of the status quo, the prospect of TRA Rapid Transit Systematization does not seem as promising as expected. The increase of bus ridership by improving the operation of Pingtung's bus service has become an issue of concern, particularly when TRA Rapid Transit Systematization is being carried out.

There are a great number of measures to increase bus ridership. Generally, these measures can be categorized into the push-pull strategy, where the push strategy, based on the price mechanism and use management, is intended to curb the growing rate of private vehicle ownership and reduce the demand for the use of private vehicles, while the pull strategy, which works by improving the service quality of mass transportation, is adopted to lower the market share of private vehicles. In terms of improving bus service quality, several aspects should be taken into consideration, including the appropriateness of bus routes, frequency of bus runs, the comfort level of bus waiting areas, the provision of bus schedule information, etc. With a focus on the bus route network, this study aims to examine the current layout of the network. It is expected that the research results will serve as a reference to design a network that meets the demands of both the public and bus service operators, thereby raising the willingness of the public to take buses. Accordingly, the objectives of this research project are set as follows:

identifying the drawbacks of urban and county highway bus routes in order to bridge the rural-urban gap and to enhance the performance of mass transportation; raising the willingness of the public to use mass transportation systems and to cut down on the use of private vehicles; integrating the railway and bus systems to shorten travel time; and more effectively utilizing transportation resources, restricting the consumption of transportation resources, and enforcing the policies of energy saving and the reduction of carbon emissions.

2. CURRENT STATUS OF THE TRANSPORTATION NETWORK IN PINGTUNG

The mass transportation system of Pingtung County is mainly composed of the railway and highway transportation system. The "TRA Kaohsiung-Pingtung Chaojhou Rapid Transit Systematization Construction Project" for the railway system was completed in June 2016 when the rapid transit service along the section north to Chaojhou was put into operation. Currently, the railway system of Pingtung County consists of the Pingtung Line and the South Link Line, with the former connecting the Pingtung, Fengshan, and Kaohsiung areas, and the latter heading towards Taitung County. The Pingtung Line starts at Kaohsiung Port Station and ends at Fangliao Station with a total length of 68.2 kilometers; the Kaohsiung-Chaojhou section features an electrified double-track railway, while the Chaojhou-Fangliao section is non-electrified and single-tracked. The South Link Line, running from Fangliao to Taitung, covers a total length of 98.2 kilometers, and is still a non-electrified and single-track railway. The ridership of the Pingtung Line and the South Link Line is 11.542 million and 7,500 in 2013, respectively. In 2014, the ridership of the Pingtung Line was 11.539 million, and it was 9,000 for the South Link Line, indicating a slight growth for the latter and a drop (-0.02%) for the former.

The highway transportation system includes intercity freeway transportation as well as city-township buses and urban buses. There are four freeways in use, and bus routes, except for a small number of cross-county routes, are mostly city-township buses. There are a total of 56 bus routes, and there are 21 routes for urban buses that only run within a single administrative area.

The ridership of the 46 intra-county bus routes dropped from 2.917 million in 2010 to 2.63 million in 2012, and increased annually until it dropped to 3.405 million in 2015 from its high of 3.482 million in 2014. However, this was an increase of 0.775 million in comparison with 2012, with an annual growth rate of 5.14%. The ridership of urban buses increases from 0.302 million in 2011 to 0.502 million in 2015, with a noticeably high average annual growth rate of 13.45% for these five years as shown in Figure 1.

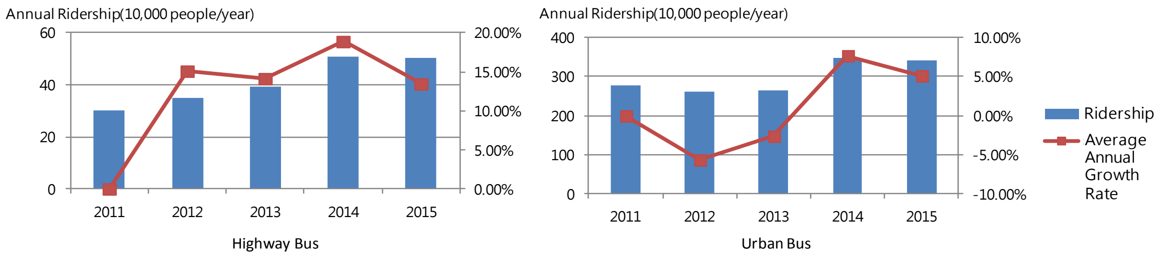

Figure 1: Annual ridership of highway bus and urban bus (unit: 10,000 people/year)

3. PROBLEMS IN BUS SERVICE

Although the overall ridership of the mass transportation in Pingtung County has seen growth since 2011, it can be noted from Figure 1 that there was a slight drop in 2015. Possible reasons are as follows:

- The bus routes are arranged based on the highway network, and mostly radiate out from more densely-populated areas to the less populated ones. Since the layout of bus routes was designed with the entire county in mind, one single bus is principally assigned for one route without adequate bus transfer facilities. This has caused over-length of the bus routes, the low frequency of bus runs, and inefficiency of transportation.
- There is no clear hierarchy for the bus routes. Except locals who are used to taking buses, tourists from outside the county, or locals who take buses less often, are incapable of differentiating the bus routes; they would rather use private vehicles instead.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Long distances and low traffic volumes in remote areas mean low profitability from bus operation; few bus service companies are willing to invest in the bus operation in such areas, which in turn causes inconvenience in seeking medical services and education, as well as in purchasing daily necessities for the locals.

4. PROPOSAL OF SOLUTIONS

In order to build a low-carbon transportation environment for Pingtung County, the promotion of public transportation use should be prioritized in order to reduce the use of private vehicles. To address the abovementioned problems in the public transportation of Pingtung County, the following solutions are proposed, which include: establishing regional transfer centers, designing a hierarchical bus network, and formulating a public transportation improvement project.

4.1 Establishing regional transfer centers

To enhance bus operation efficiency and to provide comfortable space for passengers, it is necessary that appropriate regional transfer facilities be established to better integrate the bus routes. First of all, highway bus transfer stations with comfortable waiting areas should be set up. As for the locations of the stations, an investigation should be conducted to understand the demand of the public for mass transportation, including their demand for the arrangement of bus routes that connect with railway stations, the frequency of bus runs within the administrative area where they live, and their bus transfer needs.

4.1.1 An analysis of the demand concerning bus run frequency and bus transfers

4.1.1.1 Prediction of the demand for the frequency of bus runs at railway stations

According to the prediction results regarding the demand for the frequency of bus runs at railway stations on weekdays in the "Series of the Fifth Taiwan Area Comprehensive Transportation Planning Research - Study to Review the Intercity Transportation System Demand Model, as well as Update the Parameters (1/3)", there are a total of 18 bus stations adjacent to railway stations in Pingtung County, among which the top three bus stations in terms of ridership are Pingtung Station, Chaojhou Station, and Fangliao Station. If we divide Pingtung County into northern, central, and southern Pingtung, these three stations can be identified as the railway transportation centers for these three regions, respectively.

4.1.1.2 An analysis of the characteristics concerning the frequency of highway bus runs

According to the Origin-Destination (O-D) data in regard to urban buses and county highway buses, suggestions based on the frequency of bus runs, origins and destinations, as well as the distribution of transfer locations and the quantity of transfers in each administrative area can be proposed as a reference for the location selection of bus transfer stations.

Based on the data of origins and destinations in rides that use IC-Cards or ticket machines, the frequency of bus runs in each administrative area was analyzed. The results show that Pingtung City ranks at the top in the average daily number of bus runs, followed by Neipu Township, Hengchun Township, Wandan Township, Chaojhou Township, and Ligang Township, with Pingtung City and Ligang Township categorized as the northern Pingtung area; Chaojhou Township, Neipu Township, and Wandan Township as the central Pingtung area; and Hengchun Township as the southern Pingtung area.

When it comes to the average number of transfers on a daily basis, there are 136 persons making a transfer in Pingtung City, 10 persons or more in Wandan, Chaojhou, and Neipu, and 9 persons in Hengchun and Ligang, indicating that, except for Pingtung City, where a large number of bus routes converge, there are a lot fewer transfer spots in the townships, which accounts for the low number of transfers.

4.1.2 Location selection of regional transfer centers

4.1.2.1Criteria for the selection

In the bus transfer system of Pingtung County, Pingtung Station still serves as the main bus transfer station. However, with the "TRA Kaohsiung-Pingtung Chaojhou Rapid Transit Systematization Construction Project" being implemented, it is necessary to re-examine the current status and design a suitable mass transportation network upon which to establish bus transfer centers. The criteria to select the locations for the transfer centers include:Being near railway transportation systems;Serving the purpose of bus transfer for tourism or leisure activities;Being on main arteries that connect with administrative areas.

4.1.2.2The selection result

After the initial selection process, the chosen sites include: seven locations with railway systems (Pingtung Station, Gueilai Station, Linluo Station, Sishih Station, Zhutian Station, Chaojhou Station, and Fangliao Station) and five sites that facilitate tourism activities, or are on the main arteries with easy access to administrative areas (Ligang Station, Gaoshu Station, Shueimen Station, Donggang Station, and Hengchun Station). However, not all these sites meet the criteria for a transfer center. On account of this, second selection phase was conducted with the criteria listed below:

- The importance of Pingtung's life circlehierarchy system
- The size of the hinterland around the site
- The width of the road in front of the site
- The degree of difficulty to acquire the land lot for the site
- The number of bus routes in use
- How many varieties of transportation means are available at the site?
- Whether or not the establishment of the transfer center can facilitate tourism activities

In accordance with the above seven criteria, six sites were chosen, including one main transfer center (Pingtung Station), two secondary transfer centers (Chaojhou Station and Fangliao Station), and three transfer stations for tourism purposes (Donggang Station, Hengchun Station, and Shueimen Station). See Figure 2.

Figure 2: Six transfer centers in Pingtung country

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4.2 Hierarchical bus network

In consideration of the fact that Pingtung is geographically a long and narrow county, the layout of the transportation system is in a north-south direction and the bus routes radiate out from densely-populated areas to the less populated ones. Based on the railway systems, the highway network, and the development characteristics of tourist spots in Pingtung County, the overall "radiating-patterned" bus transportation network can be hierarchically categorized into seven levels: bus stations near railway systems, cross-region expressway buses, main artery buses, sub-arterial road buses, regional buses, tourist shuttle buses, and Demand-Responsive Transit (DRT). Definitions of these seven levels of bus service are listed in Table 1.

Type	Definition
Bus stations near railway systems	Routes under the Rapid Transit Systematization project
Cross-region expressway bus	Running on cross-county/ city expressways
Main artery bus	Meant for transportation service on main arteries, including highways with high traffic volumes
Sub-arterial road bus	Subsidiary to main artery buses and principally running on sub-arterial roads that connect with peripheral areas or tourist spots, such as cross-township buses
Regional bus	Running within the same township or city; only part of the routes connect with adjoining townships. The routes with this type of bus service are under the jurisdiction of the local government, such as urban buses, shuttle buses, circuit buses, etc.
Tourist shuttle bus	Providing bus service between transfer centers and tourist spots, satisfying the needs for tourism
DRT	Providing bus service for remote areas without bus routes; DRT service offers access to mass transportation stations or major tourist spots near the remote areas.

Table 1: The hierarchical bus network in Pingtung county

With the planning of cross-county expressway bus routes, the adjustment of bus routes in keeping with the Rapid Transit Systematization project, the establishment of new bus routes to areas without bus service, the planning of a more complete network that connects tourist spots, and the provision of DRT service for remote or mountain areas, the result will be as follows: three new cross-region expressway bus routes; improving six main artery bus routes; 44 sub-arterial road bus routes, including the adjustment of one Rapid Transit Systematization bus route; 27 regional bus routes, including the adjustment of one route and the establishment of five new routes; five tourism bus routes (originally three plus two new routes); and 21 DRT routes (10 of which are new).

The overall number of routes will increase from the originally 88 (county highway: 56; urban bus: 19; tourism bus: 2; DRT: 11) to 108 (cross-region expressway: 5; main artery: 6; sub-arterial road: 44; regional bus: 27; tourism bus: 5; DRT: 21). The added 20 bus routes cover the areas from northern Pingtung to northern Kaohsiung and from central Pingtung to Fengshan, thereby providing a more convenient public transportation service.

4.3 Formulating a public transportation improvement project

Prioritized policies, based on the available resources and the needs of the public, will be formulated to establish regional transfer centers and the hierarchical bus network. To encourage the public to use mass transportation systems, bus waiting sheds, step entrance buses and electric buses, the real-time bus information system, the bus service quality evaluation program, and a comprehensive marketing plan are among the strategies to increase ridership with high-quality, technologically advanced, attentive, and publicly attractive services.

- Subsidies for bus operation deficits in remote areas: Safeguarding the rights of mass transportation for residents in remote areas, expanding passenger population via long-term operation;
- Shuttle bus service for large-scale events: Alleviating traffic congestion during events by encouraging event participants to take buses;

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Replacing old buses with new ones: Promoting the use of accessible buses, electric buses, and double-decker buses to enhance the quality of bus rides;
- Setting up bus waiting sheds: Improving the bus waiting environment, thereby raising the willingness to take buses;
- The real-time bus information system: Providing the information of bus arrival, thereby shortening waiting time without the sense of uncertainty in waiting for the buses;
- The bus service quality evaluation program: Supervising bus service operators to continue improving the bus service quality;
- Promoting the marketing plan to maximize ridership: Launching various price or non-price based marketing measures.

5. CONCLUSION AND SUGGESTIONS

5.1 Conclusion

- The reduction of motor vehicle use is the first step to building a low-carbon transportation environment. Vehicles of high passenger capacity, including railway systems such as MRT, LRT, and Monorail, and highway transportation systems such as BRT and BUS, are more preferable to transportation means of low capacity. Given the mass transportation environment and roadway conditions of Pingtung County, the promotion of low-carbon transportation should start with the establishment of an improved and better-integrated mass transportation network.
- Pingtung County is one of Taiwan's strongholds for agriculture and fishery industries. Its mass transportation systems greatly differ from those of urban commercial areas, and users of mass transportation in Pingtung are used to the current transportation systems and routes. To eliminate the impacts arising from the adjustment of routes and to enhance transportation efficiency, strategies including establishing transfer centers, categorizing the routes, adjusting part of the routes, establishing new routes for a more complete transportation network, and improving the bus waiting areas are proposed to achieve a low-carbon transportation environment.
- After route integration, there are 108 bus routes of six types, which replace the original 88 bus routes that only included county highway and urban bus routes, thereby more fully satisfying various transportation needs.

5.2 Suggestions

- Profitability is often a challenge in the early operation phase for new bus routes, and deficits are mostly inevitable. For the sustainable operation of bus service, competent government authorities should provide subsidies to cover the deficits. After a certain period of operation, reviews should be conducted to determine the adjustment of the routes, the frequency of bus runs, or the cancellation of the routes.
- To encourage the public to use mass transportation systems instead of private vehicles, it is imperative to provide safe and comfortable waiting areas and space in the bus. The priorities of the government's competent transportation authorities should be placed on the use of passenger-friendly buses, the establishment of transfer centers, and the provision of real-time bus information.

ABSTRACT

The paper presents potential for decreasing of organizational environmental impacts of public organizations on case study of Czech Ministry of Labour and Social Affairs. It analyses actual organisation's environmental impacts and sets several variants for their reduction by eight to twenty-three percent. The highest potential for improvement laid in renovation of windows and in increasing the efficiency of cooling of two big server rooms. On the other hand, the potential for reduction of organisation's environmental impacts related to optimization of office operation was found in most of the observed environmental indicators only small or medium.

Keywords: corporate social responsibility, energy saving, life cycle assessment

1. INTRODUCTION

1.1 Corporate social responsibility of public organizations

Corporate social responsibility (CSR) slowly but steadily becomes a standard element of operations of public organizations in Czechia and some ministries act as front runners and behave as a shining example for the other public bodies in the country. This paper presents one example of efforts on the case study of Czech Ministry of Labour and Social Affairs (hereafter referred to as MPSV, official abbreviation in the Czech language).

1.2 Motivation

The practical motivation to undergo the presented work was demand from the MPSV to improve its overall efficiency and reduce environmental impact of its operations. The research motivation was general lack of information on how significant is contribution of operation of historical building stock to the environmental impacts of such institution.

1.3 Objectives

The main objectives of the presented paper are i) to analyse overall environmental impacts of operation of the MPSV; ii) to present potential for reduction of the impacts by technical and managerial measures; and iii) to compare the improvement potential coming from possible energy savings in the ministerial buildings with various non-building-related measures.

2. METHODS

2.1 Analysis of overall environmental impacts of operation of the Czech Ministry of Labour and Social Affairs

The analysis of the environmental impacts of the operation of the MPSV was based on life cycle assessment (LCA) methodology with use of GaBi 6 software. It was divided into the two areas: i) impacts resulting from operation of the main building; ii) impacts resulting from operation of the offices and sourcing of office supplies.

The study analysed the six impact categories:

- Global warming and climate change;
- Acidification;
- Eutrophication;
- Photochemical ozone creation;
- Abiotic resource depletion;
- Primary energy consumption.

The following paragraphs describe the boundary conditions and inventory analysis of the two areas.

Operation of the main building

The MPSV resides in an old building in Prague historical conservation area (see Figure 1). The building of MPSV was built in 1920's and the building envelope has not changed since then. External walls of thickness of 60 cm are made of full bricks without any additional thermal insulation; hung sash windows are original; some parts of roofs are thermally insulated. The building has central heating system; source of heat is gas boiler house in adjacent complex of buildings. The heat is delivered by hot water piping with 90/ 70°C temperature gradient; the nominal input heat power is 901 kW. The building does not have a central cooling system; there are only several cooling units in selected offices and there are large cooling systems in two datacentres (running central registers of the Ministry).

Figure 1: Residence of MPSV in prague (Source: Mapy.cz)

The main source of the environmental impacts of buildings' operation is the energy consumption. The energy consumption has been further categorized and analysed based on data from invoices for the past 3 years delivered by MPSV and from own measurements in situ. The main consumption of electricity goes with cooling of server rooms (473 MWh/year), running of servers (429 MWh/year), electricity consumed from sockets in offices (213 MWh/year), lighting (71 MWh/year), water heating (46 MWh/year) and other consumption (32 MWh/year). Consumption of heat was 912 MWh/year.

Besides energy, in the building was yearly consumed in average 6,230 m3 of fresh water and 30 l of detergents.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Operation of the offices and sourcing of office supplies

As inputs to the LCA of offices operations were included consumption of printing and copy paper (1,327 kg/year), office consumables (modelled separately by included mass of paper, metal, plastics, PVC, polypropylene, inks and toners), office furniture (chairs and tables purchased in 2014 modelled as typical office set), and computers and laptops.

2.2 Potential for reduction of the impacts by technical and managerial measures

The potential was based on proposed energy saving measures and estimated energy savings potentials:

- M1: Complete renovation of all windows resulting in reduction of the U values of glazing from approx. 2.6 W/m²K to 1.0 W/m²K by replacement of the outer single glazing by double glazing and new window gaskets (yearly energy saving potential 250 MWh and additional 125 MWh respectively)
- M2: Replacement of lights and reduction of number of lamps in spaces where actual number is not necessary (potential of yearly savings 19 MWh)
- M3: Increase in efficiency of the data centres by installation of units using freecooling in winter season and improvement of cold distribution in the server rooms by division into cool and warm aisles (potential of yearly savings 76 MWh)
- M4: Utilization of exhaust heat for hot water pre-heating (13.3 MWh/year)
- M5: Removal of flow water heaters for hot water preparation in toilets (savings 25 MWh/year)
- M6: Adjustment of hot water circulation by switching of the circulation pump between 7 PM and 6 AM and reduction of water consumption by installation of faucet aerators (energy saving potential 2 MWh/year)
- M7: Installation of model-based predictive control of the heating system (potential to save 108 MWh of heat yearly)
- M8: Operational measures – i) reduction of operational temperatures in most of spaces as a result of complete renovation of windows (due to improved airtightness and warmer surfaces) and ii) replacement of old refrigerators by new ones; iii) replacement of old reading lamps by new with LEDs (approx. saving potential 32 MWh/year).

Measure		Heat	Electricity	Natural gas
		[MWh]	[MWh]	[MWh]
M1	Windows renovation	-375.0		
M2	Lighting		-19.0	
M3	Increasing efficiency of data centres cooling		-339.0	
M4	Utilization of exhaust heat for hot water pre-heating	+60.5	-46.2	-27.6
M5	Removal of flow water heaters		-25.0	
M6	Adjustment of hot water circulation			-2.0
M7	model-based predictive control	-107.5		
M8	Operational measures		-32.0	

Table 1: Energy saving potentials of proposed measures

Measures can be combined; however, some measures contraindicate others. The following possible combinations of measures were further analyzed:

- Var.1: M1, M2
- Var.2: M1, M2, M3
- Var.3: M1, M2, M3, M4
- Var.4: M1, M2, M7
- Var.5: M1, M2, M3, M7
- Var.6: M1, M2, M3, M4, M7, M8
- Var.7: M1, M2, M3, M5, M6, M7, M8

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.3 Comparison of the improvement potential coming from possible energy savings in the buildings with various non-building-related measures

The values of environmental indicators coming from the LCA in the first step (Section 2.1) set the reference level. Various scenarios of improvement were combined from the possible reduction of the impacts resulting from work described in Section 2.2. For these scenarios were calculated and analysed respective environmental impacts.

3. RESULTS

3.1. Results of analysis of overall environmental impacts of operation of the Czech Ministry of Labour and Social Affairs

The overall environmental impacts of operation of MPSV are presented bellow in Table 2 and Chart 1 shows contribution to environmental impacts by areas of investigation. As can be seen, in most environmental categories, impacts related to operation of the MPSV building dominates above office operation and sourcing of office supplies. Therefore, it also provides higher potential for impacts reduction.

Impact category	Unit	Value
Abiotic Depletion (elements)	[kg Sb-Equiv.]	6
Abiotic Depletion (fossil)	[GJ]	14 674
Acidification Potential	[kg SO_2-Equiv.]	7 284
Eutrophication Potential	[kg Phosphate-Equiv.]	616
Global Warming Potential	[kg CO_2-Equiv.]	1 383 924
Photochem. Ozone Creation	[kg Ethene-Equiv.]	471
Primary energy consumption	[GJ]	18 477

Table 2: The overall environmental impacts of operation of MPSV

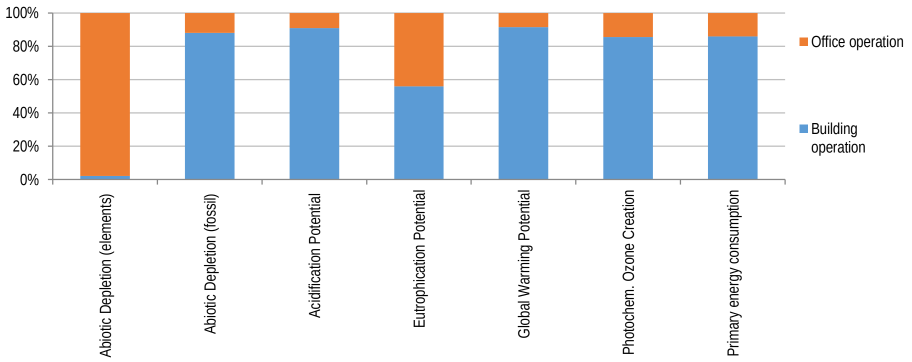

Chart 1: Ratio of the two areas (building operation; office operation and sourcing of office supplies) on the environmental impact categories

Impact category	Impact	Share of the main contributors of office operation and sourcing of office supplies on the environmental impacts [%]				
		Office supplies	Furniture	PC + Notebooks	Printing paper	Other
Abiotic Depletion (ADP elements) [kg Sb-Equiv.]	5.90	2	0	97	0	0.3
Abiotic Depletion (ADP fossil) [GJ]	1 759	18	60	13	4	3.6
Acidification Potential (AP) [kg SO_2-Equiv.]	660	15	47	27	5	4.8
Eutrophication Potential (EP) [kg Phosphate-Equiv.]	272	3	12	76	6	4.0
Global Warming Potential (GWP 100 years) [kg CO_2-Equiv.]	117 092	12.6	66	19	1	0.9

Photochem. Ozone Creation Potential (POCP) [kg Ethene-Equiv.]	68.4	12	54	27	5	2.8
Primary energy demand from ren. and non ren. resources (net cal. value) [GJ]	2 962	15	59	10	9	7.3

Table 3: The environmental impacts of office operation and sourcing of office supplies and share of the main contributors

3.2. Potential for reduction of the impacts by technical and managerial measures

Chart 2 summarizes the potential for reduction of the environmental impacts by combinations of building operation saving measures outlined in section 2.2. From the proposed combinations, the variants 2, 3, 5, 6 and 7 have high potential to decrease the environmental impacts.

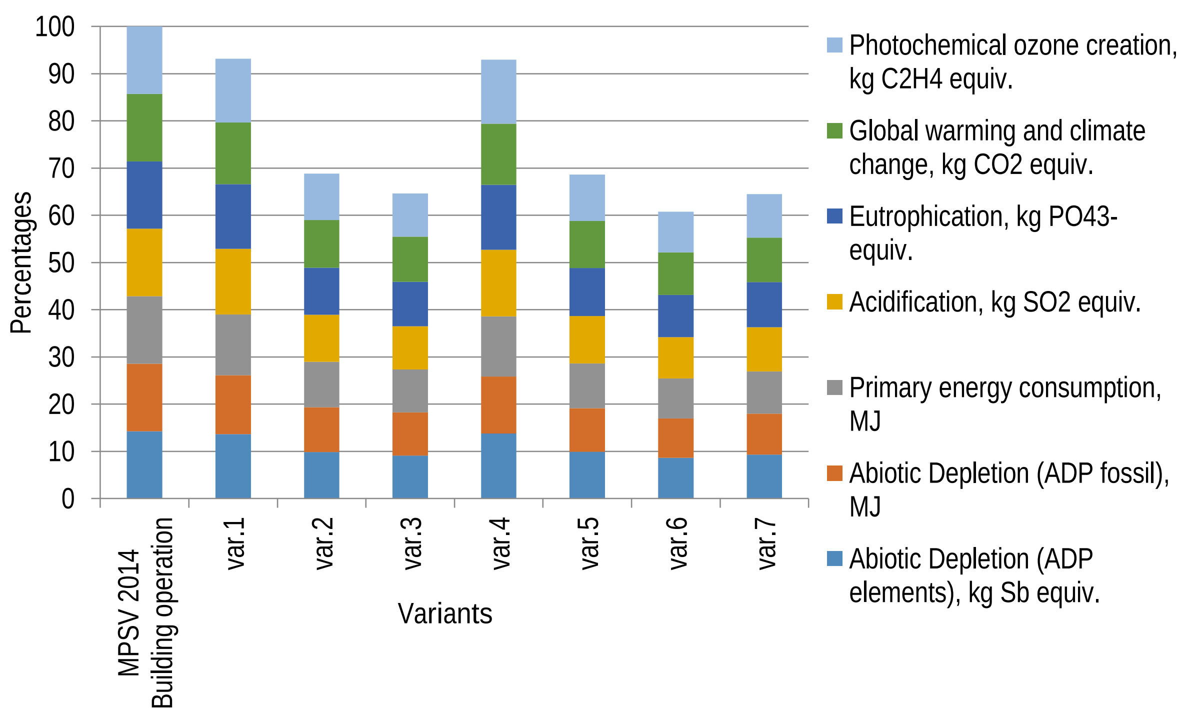

Chart 2: Environmental impacts saving potential of proposed measures compared to current state

4. CONCLUSIONS

The paper analyses actual organisation's environmental impacts and sets several variants for their reduction by eight to twenty-three percent. The highest potential for improvement laid in renovation of windows and in increasing the efficiency of cooling of two big server rooms. On the other hand, the potential for reduction of organisation's environmental impacts related to optimization of office operation was found in most of the observed environmental indicators only small or medium.

ACKNOWLEDGEMENTS

ABSTRACT

This study plans to review and evaluate the interior design strategies corresponding to indoor light, and heat by introducing Green BIM tool into the indoor space planning and design stage, and takes an office space in Tainan as the practical operation object of interior design. According to the user requirement, with the assistance of Green BIM tool, the optimum design proposal meeting the Eco-Efficiency concept is proposed. The evaluation and analytical items involved in the Green BIM proposed in this study will be determined according to actual requirement, including heat insolation, and illumination analysis. Autodesk Revit was used as the main software tool to discuss how the Green BIM tool assists green design strategy in the present practical application of interior design for finding out optimum design program.

Keywords: green BIM, interior design, optimum design

1. INTRODUCTION

1.1 Background and motivation

The information society is a common adjective of a modern society, mainly due to the rapid development and progress of “Information Communication Technology (ICT)”, as well as for people’s desire of receiving information. In terms of the construction industry, it can enhance productivity.

More specialization at each stage of the construction industry should be able to improve the quality and efficiency, but if the integration is neglected, the low productivity would be caused. This is one of the main reasons that the development and application of “Building Information Model (BIM)” in the construction of the industry has become one of the most popular issues in the global engineering and academia. In addition, BIM software has been also widely used in “Project Delivery Integrated (IPD)”, a popular architectural project delivery model in recent years.

Green BIM stresses that due to local climatic conditions to analyze “Building Performance Analysis (BPA)” from the beginning of the design with BIM as the basic tool, and through the “design” and “assessment” of the decision cycle to result in the “Optimum Design” program for environmental benefits. The selected program via BPA will affect building performance in the whole building life cycle, and the ultimate goal is lifting the overall “Eco-Efficiency (EE)”, lowering the environmental loads and costs, so that to improve environmental quality.

After the completion of a new building, roughly determine the environmental performance of the overall construction, but it still has a gap with which of the use stage. Therefore, whether the environmental performance can be remained or better after finish interior design and decoration needs to check.

1.2 Purpose

In this study, the indoor light environment and thermal environment were reviewed and evaluated by using the Green BIM tool at the beginning of the interior design. An office space in Tainan City was taken as the research object, and the analysis results of the light and thermal environment will be used as reference for interior design and decoration in the future. In addition, to ensure that the interior decoration to take into account the environmental quality and energy saving.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2. OBJECTIVES, METHODOLOGY AND PROGRESS

2.1 Objectives

The object of this study is a narrow type of office space, which the area is about 125 m3, in the 12th floor (top floor) of the mixed residential and commercial building on Dongmen road of Tainan City. The office space has a special sloping roof of about 7 meters high occupies a half of the space and near the south windows which are the closed-type of glass curtains (shown as in Figure 1). However, four roof openings have a chance to carry out thermal buoyancy ventilation. Because the office located in the top floor, the roof affected by the solar radiation is serious, how to isolate the radiation is need to be considered more when proceeding interior design and decoration. The plan and section of the office space are shown as in Figure 2.

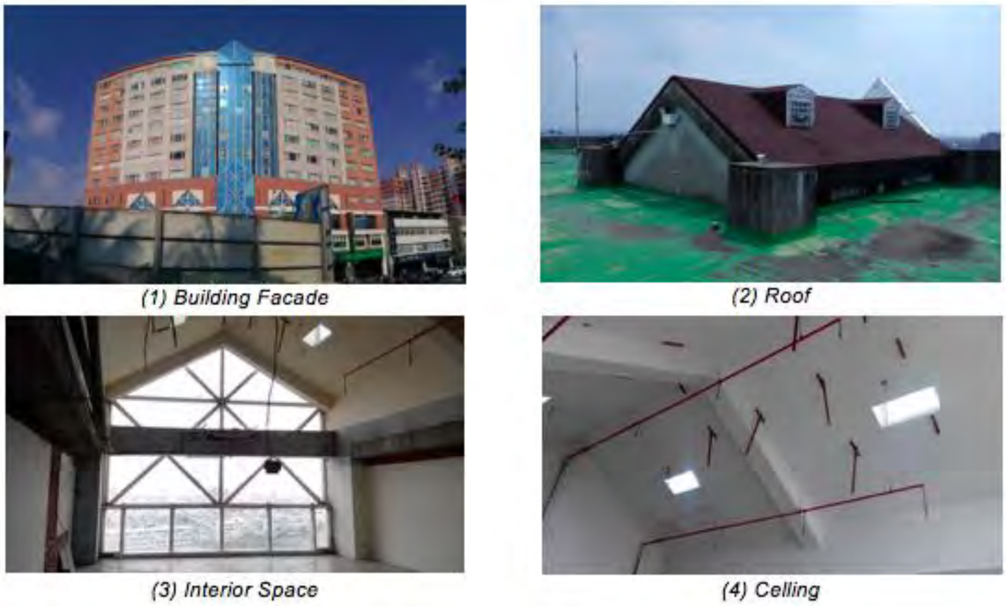

Figure 1: Photos of the research object

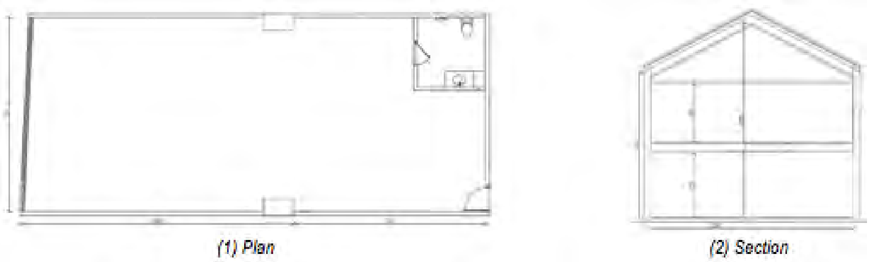

Figure 2: The plan and section of the research object

2.2 Methodology and progress

Most of the researches about Green BIM for design decisions of green building were utilized the analysis software of Autodesk Inc to carry out related issues. In terms of building types, there are residential space, school space, office space, transportation space, library space, etc. This research takes the case study method, which is to investigate and analyze a specific object in the research object group, and to clarify its characteristics and its formation process. The software used in the study is mainly for "Autodesk Revit (2016 Edition)". Via the settings of the current situation include meteorological information, drawing information, 3D model establishment and parameter setting, etc., the performance analysis of indoor light and thermal environment in the office space were conducted, and then in accordance with the results of the virtual performance analysis, the current environmental problems and performance of the office space also were clarified. The results of the study will be reference for the following decision of interior design and decoration.

In this study, the use of BPA in Autodesk Revit carried out, and it mainly includes solar load analysis (insolation) and lighting analysis (illumination). The date for analyzing first was set October 7 (fall), and its sunrise and sunset

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

times are 5:53 am and 5:41 pm, a total of about 9.8 hours. The analysis of illumination was only aimed at the lighting environment under natural lighting. In the study, the time of analyzing illumination is respectively set at 7:00 am, 12:00 noon and 5:00 pm to compare the differences.

3. RESULTS

3.1. Analysis of thermal environment

The distributions of insolation from the external and internal surfaces of the office space respectively are shown in Figure 3 and Figure 4. As shown in Figure 3, the cumulative amount of insolation is up to 6069 Wh/m^2, in particular on the roof. In Figure 4 (1) - (3), the cumulative value, average value and peak value of insolation are presented respectively. From the results, the higher insolation area (yellow and green areas) is mainly concentrated in the south side of the windows within the range of about 1/5 room depth (about 3.5m). As shown in Figure 4 (3), when the sun is the largest, the range of the higher insolation will be up to about room 1/4 depth (about 4.2m). Therefore, in the future, in addition to the design considerations of shading and heat insulation, the heat removal in this area should be strengthened.

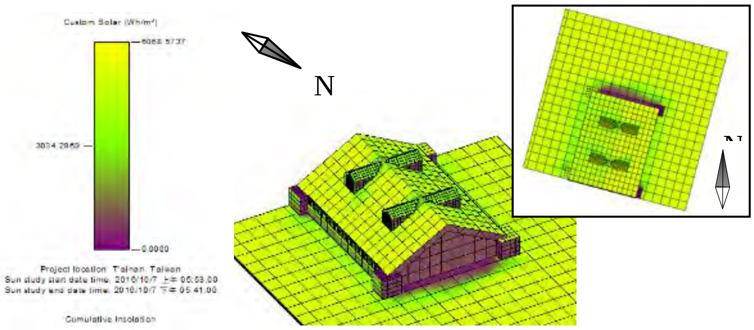

Figure 3: Distribution of cumulative insolation on the roof

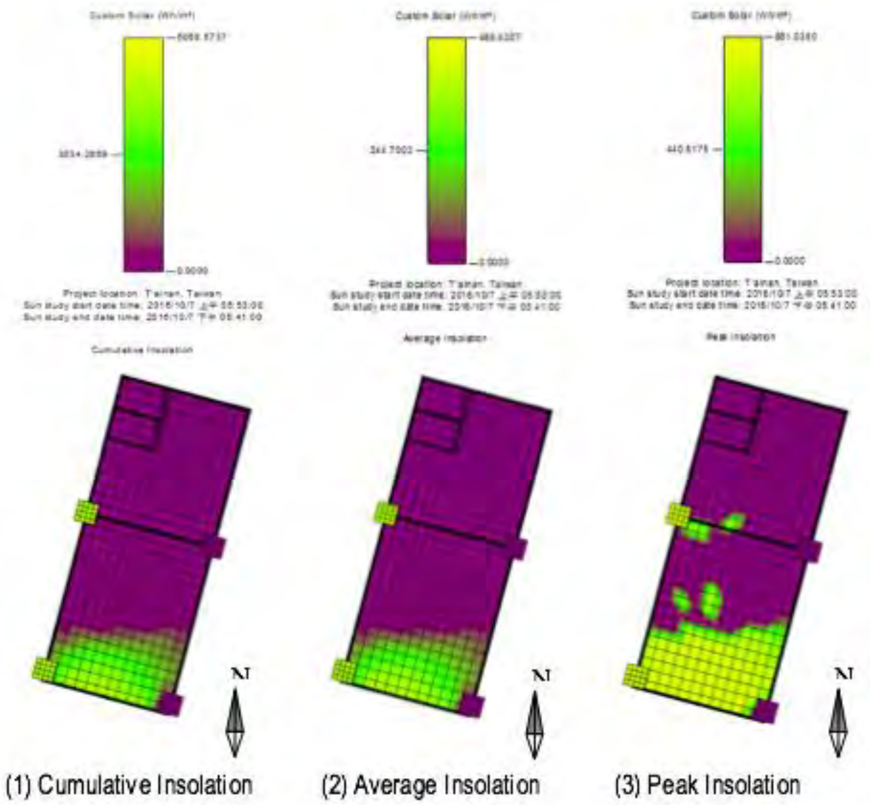

Figure 4: Distribution of Insolation on the plan

3.2. Analysis of light environment

Indoor illumination distribution of office space is as shown in Figure 5. If the 500Lux above the office lighting requirements for the standard, at 7:00 am, the south side of the windows extend inward about 1/4 room depth (about 4.2m) can rely on natural lighting, to noon can be more than half, at 5:00 pm, only the local area near the windows can reach this standard. More details about distributions of illumination in the office space are shown in Figure 6 - 8.

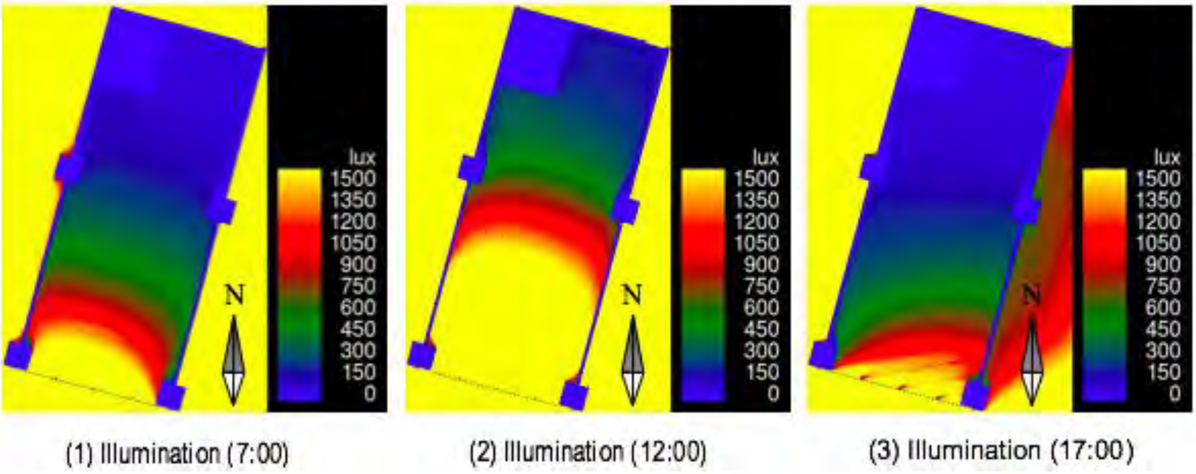

Figure 5: Distribution of illumination on the plan

Figure 8: Distribution of illumination in the office space near the door

4. CONCLUSION AND RECOMMENDATION

In this study, the Green BIM tool was conducted for BPA before interior design and decoration. BPA spent time limited, so that it did not affect the progress of the design. In addition, it can help design decisions and improve environmental performance. The results show that the area, within about 1/4 room depth, near the south side of the windows, should be paid attention to the heat removal. The buoyancy ventilation strategy can be considered, but also strengthening sunshade and heat insulation in the area near the south windows should be necessary. In terms of Light environment, artificial lighting is needed for areas outside the region near the windows to supplement the indoor illumination. Lamp circuit configuration with parallel window surface also can be utilized for saving energy by switch control.

This study also can be aimed at different seasons for BPA, or other factors, for example: acoustic environment, airflow environment, etc., so that interior design decisions can be based on BPA to obtain the most optimum program.

ABSTRACT

There were lots of local buildings in rural area in Taiwan, which were over 40 years but still can afford the daily livings. These cultural and typical types of buildings in some cultural small town represent for the unique building styles, and to arise the issue for the revival of the cultural building for more sustainable attitude. This study is based on the requirement of this topic and following the policy of Kaohsiung City Government to renovate a traditional Tobacco Barns into more sustainable Kaohsiung LOHAS House.

The Tobacco Barns is a traditional house which combines the local industry of tobacco drying and a house living space, and this type of building is very popular and unique in Meinong district in Kaohsiung. This study conducted the processes from local climate data analysis, which is based on the local elementary school. The energy issue is the main target to verify the new possibility of the decisions to deal with the material and openings from eight orientations. The AutoDesk-Ecotect analysis was adopted to make the integrated analysis processes which will be in the same model and analysis methodology. The factors including heat load of transfer, indoor predicted temperature and daylighting situation were considered to make the comparison of the energy efficiency by the local common renovated material and opening styles. The suggestions were conducted by the methodology and for the further comparison of different design proposal with results of maintenance evaluation and energy saving fee to let the house owner do the decision making.

In this study, through the collection of relevant literature, data integration and analysis, the results showed the cross analysis with four material of wood, rammed earth wall, concrete and bricks structure, with different opening rate is 20%, 50%, 80%, and with horizontal shading monolayer bilayer depth by 0, 0.4, 0.6, 1.0, 1.8 ratio. The simulations of thermal environment and light environment were both verified to make the calculation of the estimated efficiency. The results can be used and references in this area for who wants to make the renovation.

Keywords: opening rate, shading form, shade depth ratio, EUI energy dissipation value

1. INTRODUCTION

For urban and rural renewal, old buildings can be revitalized through renovation. But when re-planning and redesigning buildings, reinforcing appearance-related structures, improving indoor spatial functions and outdoor landscape arrangement, we need to pay attention to evaluations and analyses of rebuilding costs and energy efficiency when examining whether the rebuilding process meets the concept of sustainable construction. The purpose of this study, thus, is to investigate the energy consumption efficiency of rebuilding and regeneration and material use strategy; the research subject case study is a tobacco building in the Meinong area. By contrasting the formation of traditional settlement type of tobacco building, the research scope is expanded to the whole area and region. The regeneration movement of the tobacco building has been examined for the purpose of conducting an architecture design study.

2. RESEARCH METHOD

Architecture theory is developed herein from the design of manual modules via a computer simulation analysis based on the comparison of heat transfer of various materials in the thermal environment, as well as the consideration of the indoor window opening conditions and the exterior architecture structure. The relationship between these factors is quite complicated. Thus, due to the limitations of conditional factors, previous studies have been taken into consideration to classify simulation factors for later analyses of the key ones. This section first explains the simulation case, the structure of simulation process, limitations and conditions.

2.1 Establishment of simulation case

In principle, the site of architecture simulation was selected in Meinong, Kaohsiung City at latitude and longitude of λ= 190°54' and φ=22°90', respectively, and sea level of 543 meters (Figure 1) for this study. The architecture type is a four-ping tobacco leaf baking room located at the north orientation with an 85° angle of incidence; thus, the main chickened structure of the tobacco building is used as the basis for the main simulation test. Values in different orientations are then simulated for the purpose of comparison.

Figure 1: Site map/ aerial image

2.2 Analysis method

For the analysis of the experimental simulation, 132 sets of architecture types were set up; the simulation conditions were established by using the main structure of the tobacco building as the center. Different amounts of sunlight were acquired according to the different orientations of architecture. This study uses eight orientations: north (N), northeast (NE), east (E), southeast (SE), south (S), southwest (SW) and northwest (NW) for the simulation. The values acquired in the simulation include: the thermal environment of architecture materials, window opening ratio, shield format and shield depth. Through statistical analysis, the relationships among four different types of construction materials have been defined, as well as the changes in the thermal environment have been analyzed by using combinations of shield types (Figure 2).

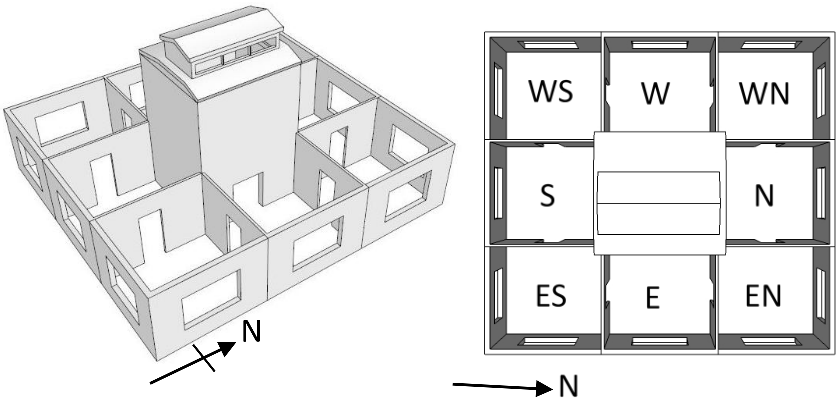

Figure. 2: Orientations of architecture in the simulation

2.3 Integrated evaluation and analysis method

This study focuses on the discussion of energy consumption in different spatial orientations; ECOTECT, a computer simulation, is adopted for the presentation. Unlike the single consideration of construction materials or window opening ratio, this study concerns the close relationships among architecture orientation, building envelope and energy consumption. For example, natural lighting, shield and depth are impacted by the changing conditions. Therefore, they all play an important role in energy-saving. We discuss the design application of architectural space via analysis of the amount of sunlight reflection, the thermal environment of various spatial orientations, window opening ratio, the use of responsive materials, and EUI (energy use intensity). Suggestions for improvement are also proposed according to the simulation results and analyses of the design of the architecture rebuilding.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. INTEGRATED COMPARISON AND ENERGY CONSUMPTION SIMULATION ANALYSIS

Via computer simulation, this study analyzes influential factors of architectural space, including the relationships among suitable construction materials, window opening ratio, shield format, depth ratio, amount of sunlight and thermal environment. The simulation of eight orientations helps us to ascertain the relationship between orientations and thermal environment, and to analyze the impact on the annual EUI of an indoor air conditioning system.

3.1 Total EUI comparison with an opening ratio of 20%

The results below are found after comparing and analyzing EUI in different orientations. (Table 1)

This study uses a fixed width and length ratio of window opening to discuss EUI in different orientations, and finds that EUI is reduced with the increased depth and that the decrease ratio is also reduced along with the increase of depth ratio. Wooden and rammed earth structures as construction materials are proven to provide the best energy saving effectiveness since these two have window opening ratios falling within the range of low energy consumption; concrete structures, due to higher heat capacity and difficulty of heat dissipation, have EUI of air conditioning systems within the middle range of energy consumption; and some spaces of bricked structure also reach the middle energy consumption range due to spatial orientations. (Figure 3)

Construction Materials/Shield Format		EUI %		
		Low	Middle	High
Wooden	Single Layer	100	--	--
	Double Layers	100	--	--
Rammed Earth	Single Layer	100	--	--
	Double Layers	100	--	--
Concrete	Single Layer	25.5	75.5	--
	Double Layers	25.5	75.5	--
Bricked	Single Layer	66.7	33.3	--
	Double Layers	62.5	37.5	--

Table 1: EUI comparison of an opening ratio of 20%

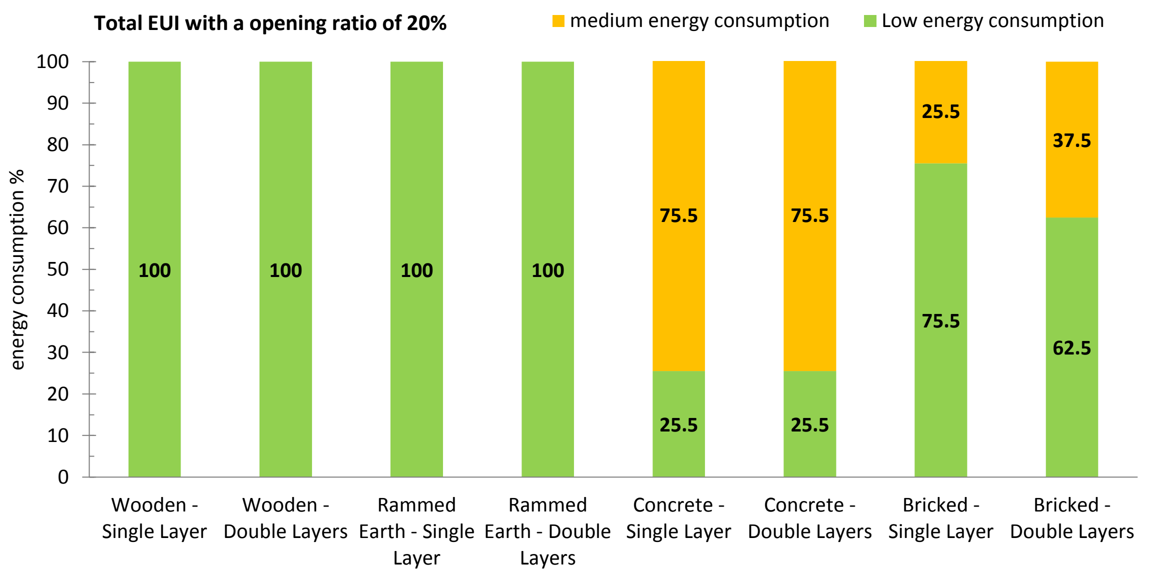

Figure 3: Total EUI comparison with an opening ratio of 20%

3.2 Comparison of total EUI with an opening ratio of 50%

The results below were garnered after comparing and analyzing EUI in different orientations. (Table 2)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

From Table 2, the EUI diagram at a window opening ratio of 50%, the structure with 50% more concrete belongs to the range of high energy consumption. Both single and double layered vertical shield structures have no impact on energy consumption. Wooden structures have the optimal EUI with significant impact of reduced EUI after the installation of double layered horizontal shield structure; rammed earth structures fall within the range of middle energy consumption with the same effectiveness after the installation of double layered horizontal shield structure; and bricked structural space falls within all ranges of energy consumption, from low to high. Therefore, other combined bamboo structures shall be considered for orientation selection to achieve the balance of spatial use and dynamic energy of an air conditioning system, as well as to form composite-structured architecture. (Figure 4)

Construction Materials/Shield Format		EUI %		
		Low	Middle	High
Wooden	Single Layer	62.5	37.5	--
	Double Layers	50	50	--
Rammed Earth	Single Layer	20.8	79.2	--
	Double Layers	22.9	77.1	--
Concrete	Single Layer	--	39.6	60.4
	Double Layers	--	41.7	58.3
Bricked	Single Layer	12.5	81.25	6.25
	Double Layers	12.5	83.4	4.1

Table 2: EUI comparison of an opening ratio of 20%

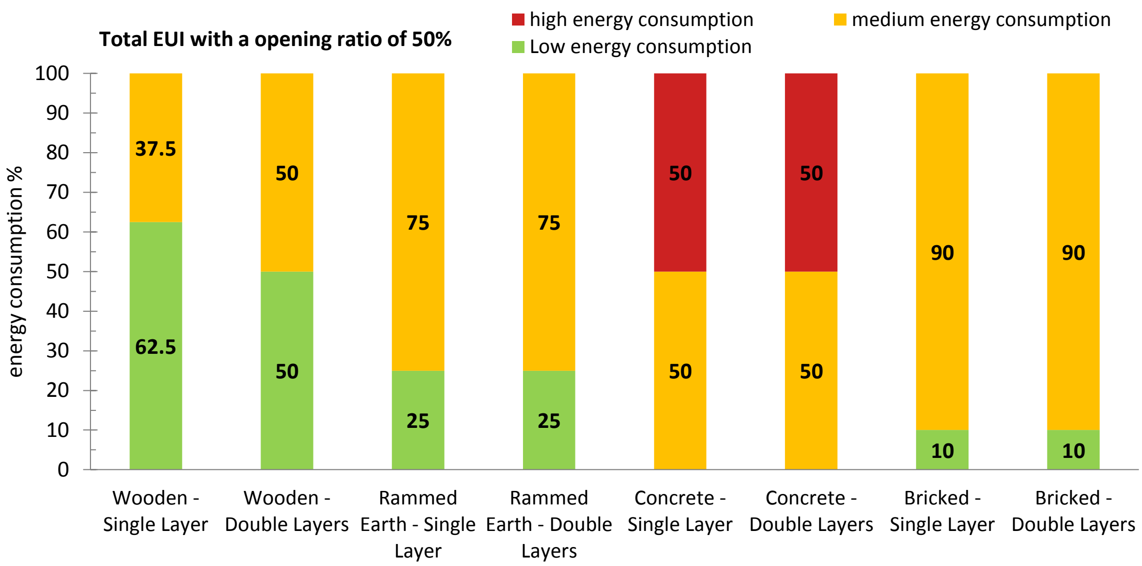

Figure 4: Total EUI comparison with an opening ratio of 50%

3.3 Total EUI comparison with an opening ratio of 80%

The results below were found after comparing and analyzing EUI in different orientations. (Table 3)

As shown in Table 3, with the EUI diagram at a window opening ratio of 80%, due to large window openings, structures with various construction materials exhibit high EUI to reach a high energy consumption range. Wooden structures, due to small heat capacity, maintain low energy consumption in some spaces, while rammed earth and wooden structures have the same coefficient of energy consumption ratio. Because of the slow speed of heat dissipation, concrete structures normally have higher EUI, with 75% falling within the range of high energy consumption. Although bricked structures have higher heat capability, they easily dissipate heat. Hence, EUI coefficient is relatively constant with the only impact of single window opening and double window openings being at the energy consumption ratio of 1:1. The design of large window opening with a ratio of 80% is shown in a bar diagram; even when a double-layered shield panel is installed on the exterior window opening, the energy consumption coefficient still remains constant. That proves that even with the use of large window aperture in architectural space, there is no need to use the design of double layered shield panels (Figure 5).

Construction Materials/Shield Format		EUI %		
		Low	Middle	High
Wooden	Single Layer	10.4	37.5	52.1
	Double Layers	10.4	37.5	52.1
Rammed Earth	Single Layer	10.4	37.5	52.1
	Double Layers	10.4	37.5	52.1
Concrete	Single Layer	--	25	75
	Double Layers	--	25	75
Bricked	Single Layer	--	50	50
	Double Layers	--	50	50

Table 3: EUI comparison of a window opening ratio of 80%

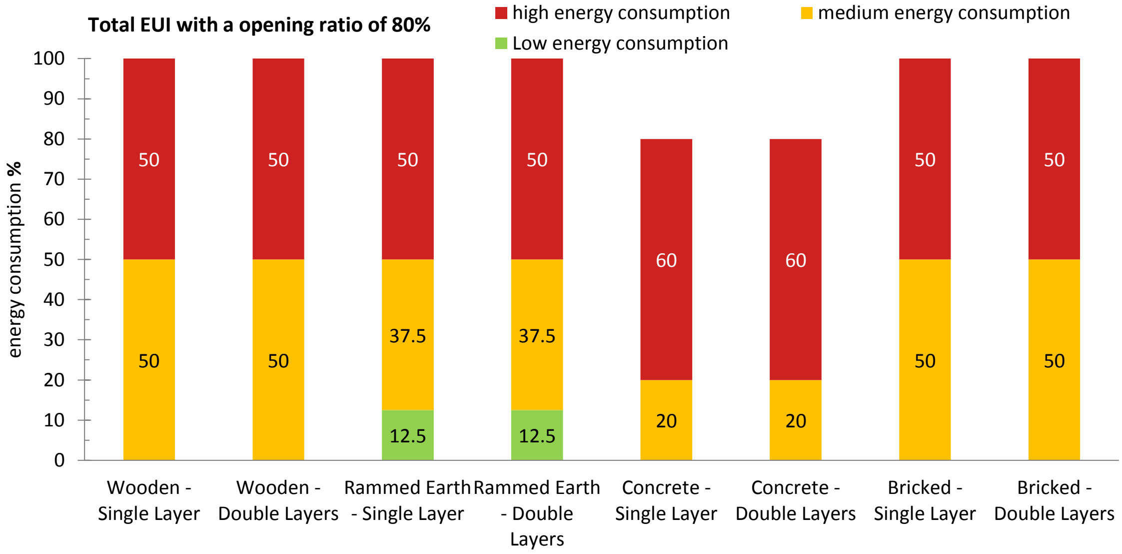

Figure 5: Total EUI comparison with an opening ratio of 80%

4. CONCLUSION

This study, after experimental simulation and analysis, examines the relationship of annual EUI of indoor spaces in different orientations corresponding to the motives and purposes of this study. Concrete conclusions and suggestions below are acquired for the reference of future studies on energy conservation of buildings.

The wooden spatial structure with a window opening ratio of 20% consumes less energy than the basis value of 30 kWh/m2.yr while at an opening ratio of 50%, energy consumption variance is determined by single or double openings. At a ratio of 80%, the increase of EUI also falls within the range of basis value and only Space N maintains lower energy consumption than the basis value.

The wooden and rammed earth structures at an opening rate of 20% consume lower than 30 kWh/m2.yr, and at a ratio of 50%, the EUI still falls within the basis range, while space in the N orientation has EUI lower than the basis value, indicating the significant variance of EUI due to the angle relationship in different orientations. At a ratio of 80%, EUI values in the ES and WS orientations both exceed the basis range. As a result, for spaces with double window openings, sunlight and west orientation should be considered in terms of design.

The concrete spatial structure at an opening ratio of 20% has EUI within the basis range, but at a ratio of 50%, the ES and WS orientations have EUI exceeding the basis range due to sunlight exposure and west orientation. At a ratio of 80%, a double-opening design significantly exceeds the basis value of 30 kWh/m2.yr. This indicates the impact of opening design of space on the EUI of an air conditioning system.

The bricked structure is found to exhibit a significant level of change for the EUI of an air conditioning system. At an opening ratio of 20%, single and double designs of opening have relative impacts on EUI; at a ratio of 50%, the

EUI is found to fall within the basis range, and only the N orientation falls below the range of 30 kWh/m2.yr. At a ratio of 80%, due to large window opening, single or double openings become an important factor related to EUI.

Sustainable Midfield Concourse Development at Hong Kong International Airport

Kevin POOLE[a]

[a] *Airport Authority Hong Kong, Hong Kong SAR, kevin.poole@hkairport.com*

ABSTRACT

Buildings in Hong Kong account for about 90% of our electricity consumption and 60% of Hong Kong's greenhouse gas emissions. Using energy more efficiently would help reduce greenhouse gas emissions. Through incorporating sustainable design features, new green buildings have an opportunity to significantly reduce energy demand, while delivering comfortable, healthy internal environments. Situated to the west of Terminal 1 and between the two runways, the newly commissioned Midfield Concourse (MFC) is a major project recently delivered at Hong Kong International Airport (HKIA). The five-level concourse has a total floor area of 105,000m^2 and is connected to Terminal 1 by an extension of the automated people mover (APM) system. There are 20 new aircraft parking positions that help increase the passenger handling capacity by over 10 million passengers per year. Focusing on the MFC project as a case study, this paper describes how the early consideration of sustainable design principles and a systematic evaluation and prioritisation of the possible combination of passive design strategies and low-energy active design techniques can help take forward innovative ideas and sustainable design initiatives through the different stages of a project in delivering an energy efficient high-performance building. The MFC serves as testament confirming HKIA's commitment to being a green airport. Adopting a similar green design strategy for the planned Expansion of HKIA into a Three-Runway System will bring similar sustainability benefits for HKIA and Hong Kong.

Keywords: energy use, sustainable design, innovative ideas

1. INTRODUCTION

1.1 Background

Buildings account for about 40% of energy use worldwide (Zuo and Zhao, 2014; WBCSD, 2009). In Hong Kong, the main energy used in buildings is electricity and these buildings are responsible for about 90% of our electricity consumption and 60% of Hong Kong's greenhouse gas (GHG) emissions (Environment Bureau, 2016). Energy saving and green building transformation has a great potential in contributing to Hong Kong's GHG emissions reduction target.

While significant energy savings can be achieved in existing buildings by behaviour changes of occupants, new green buildings can contribute by significantly reducing energy demand in the first place by incorporating sustainable design features, while delivering comfortable, healthy internal environments. However, sustainable building design is a complicated process that involves a large number of design variables, each with a range of feasible values (Wu et al., 2016). Besides, planning and construction of new buildings are often carried out under tight programmes, requiring rapid information turnaround amongst the relevant design team members and quick decision-making. A good decision-making framework and relevant design tools are required by building designers for a systematic evaluation and prioritisation of the possible sustainable design initiatives, including options for incorporation into the design, while taking into account the fundamental factors of investment cost, maintenance and operational requirements in building construction.

1.2 Objectives

Sustainable design initiatives may be categorised into different aspects such as energy use, water use, indoor environmental quality, material and site aspects. The energy use of buildings would be most relevant with respect to achieving GHG emissions reduction. Focusing on the newly commissioned Midfield Concourse (MFC) at Hong Kong International Airport (HKIA) as a case study, this paper discusses the energy use aspect and describes how the early consideration of sustainable design principles and a systematic evaluation and prioritisation of the possible combination of passive design strategies and low-energy active design techniques can help take forward innovative ideas and sustainable design initiatives through the different stages of a project in delivering an energy efficient high-performance building.

It is hoped that the experience gained from the MFC project as illustrated in this paper may help promote a better understanding of the green building design process and encourage more widespread implementation and development of high-performance buildings.

2. MIDFIELD CONCOURSE AS CASE STUDY

Situated to the west of Terminal 1 and between the two runways, the MFC is a major project delivered at HKIA. The 105,000m^2, five-storey MFC commenced construction in December 2011 and began operation since December 2015. The construction period included extension of the automated people mover (APM) system from the existing Terminal 1. To enhance the airport operations, there are 20 new aircraft parking positions provided at MFC, increasing the passenger handling capacity by over 10 million passengers per year.

2.1 Green airport design strategy

The MFC has been designed as an exemplar sustainable building that contributes to HKIA's pledge to be one of the world's greenest airports. The MFC project team understands that the early building design phases play a crucial role in determining life cycle performance in terms of resources and energy consumption. At the project design stage, the optimisation potential is still large at relatively low cost. In the latter planning and construction phases, the change possibility rapidly decreases, with simultaneously increasing costs (Kovacic and Zoller, 2015).

Various sustainable design initiatives including innovative ideas and green design options were therefore evaluated early in the initial scheme design stage through the development of a project-specific "Green Airport Design Strategy". The Strategy was prepared in order to identify opportunities for incorporating elements in the design that would enhance environmental efficiency and minimise the project's impact on the environment over its whole life cycle. The Strategy put emphasis on three key pillars of green building design, namely the inclusion of reduced resource use, the maximisation of operational efficiency, and the enhancement of health and wellbeing for the building occupants as illustrated in Figure 1.

2.2 MFC green design process

Figure 2 illustrates the systematic approach adopted in deriving the consideration of green design initiatives in the MFC project.

Researchers have emphasised the importance of setting sustainable target values early in order to drive the green design process forward (Russell-Smith et al., 2015). However, a challenge that often arose was how best to set the sustainable design targets. In the MFC project, this was achieved via undertaking relevant benchmarking studies early, reviewing existing green design practices at HKIA and overseas airports to provide a comparison between relevant data sets. Through the use of passive and active design measures, the design team targeted to reduce CO_2 emissions or annual energy consumption by at least 20% over the baseline situation that was established based on the Performance-based Building Energy Code (EMSD, 2007).

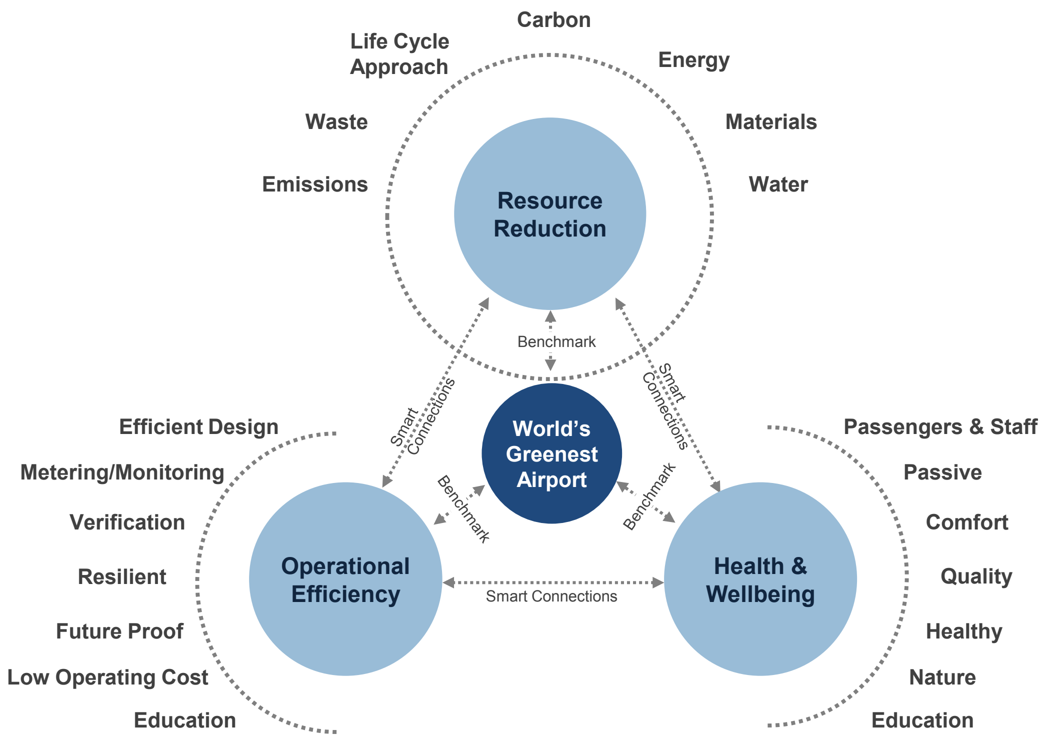

Figure 1: Pillars of green buildings emphasised in MFC design

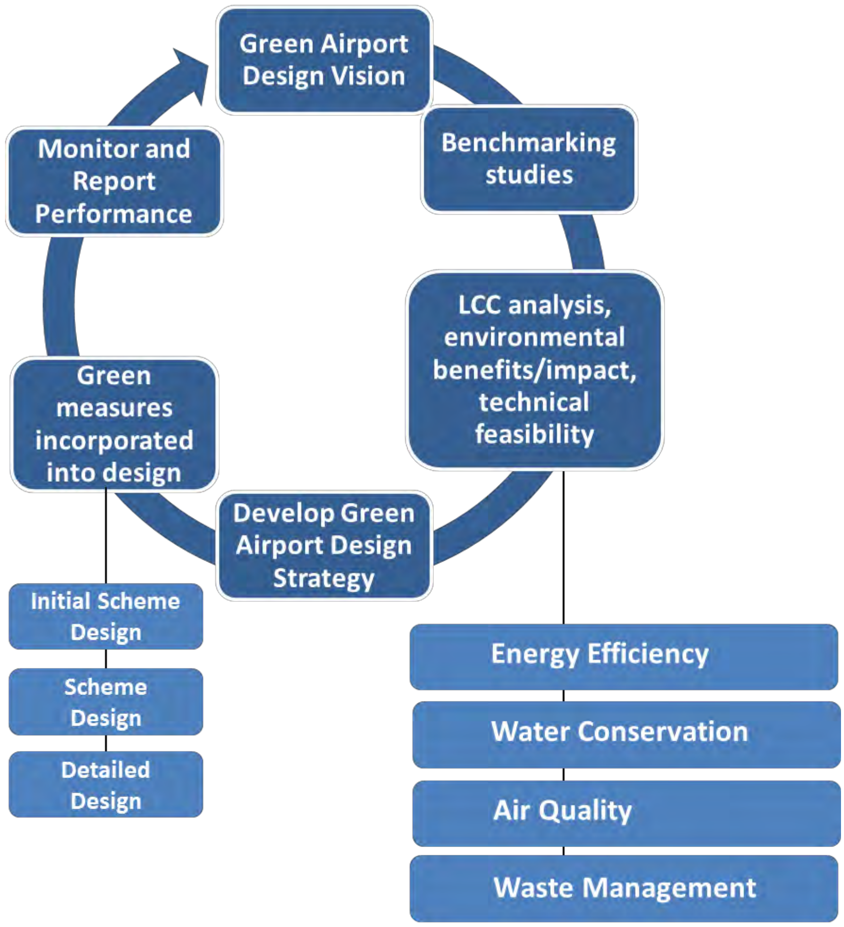

Figure 2: MFC green design process

2.3 Life cycle cost analysis

Researchers have pointed out that an integrated planning process that considers life cycle costs (LCC) and optimisation can significantly reduce the follow-on costs in the design and construction process (Kovacic and Zoller, 2015). The LCC and benefit methodologies currently used in the building and construction industry are mostly implemented for economic evaluation of specific, mostly technological aspects. Although the LCC methodology is well developed and standardized, it is still facing numerous difficulties in practice. Lack of reliable data and data accessibility are some of the most common problems. To overcome these obstacles, the combined approach of considering both LCC and life cycle assessment is advocated by some researchers (Kovacic and Zoller, 2015).

In the MFC project, the team considered, where possible, the 25 year LCC and also considered the environmental benefits and impact of the green design initiatives as advocated by researchers. The LCC analysis was found particularly useful in facilitating a systematic evaluation of the options for passive and active energy design in the MFC project. For example, the 25 year LCC for alternative roof light design options, including (i) conventional skylights (Baseline option); (ii) conventional skylights with light diffusing system; (iii) conventional skylights with light shelf; (iv) conventional skylights with automated solar shading; and (v) north-facing skylights were compared and the results revealed north-facing skylights to be the preferred primary option having the lowest 25 years LCC, while not requiring maintenance beyond that of normal skylights. There are also additional benefits in that the design of the north-facing skylights could be integrated with the requirement for smoke ventilators, and also photovoltaic cells inclined to capture the optimum sunlight for power generation. Figure 3 illustrates the design of the north-facing skylights.

Figure 3: Design of north-facing skylights located on roof along the true east west axis of MFC

3. PASSIVE AND ACTIVE DESIGN STRATEGIES

There are two basic design paradigms of strategies and technologies applied to buildings - passive design and active design (Balaban and Oliveira, 2016). In passive design, natural elements such as air flow and sunlight are used to provide a comfortable indoor environment while reducing energy demand for mechanical and electrical systems such as air conditioning and artificial lighting. On the other hand, active design is the use of state-of-the-art systems and newer technology to improve energy efficiency.

This section presents further details regarding the design process undertaken in evaluating and prioritising the possible combination of passive design strategies and low-energy active design techniques.

3.1. Passive design methodology

Passive design techniques were adopted and have embedded energy use reductions into the MFC design from the outset. The MFC focussed primarily on the use of natural daylight, both to reduce energy consumption associated with artificial lighting and to improve the internal environment, allowing passengers and staff views and connections to the outside environment.

3.1.1 Reducing artificial lighting demands

Energy modelling undertaken at the initial scheme design stage indicated that lighting energy could account for almost 30% of energy consumption in the baseline situation. The design of a good natural daylight system will optimise the amount of daylight entering the space, decreasing energy bills and increasing occupant connectivity with the outdoors.

The MFC was designed to be oriented along the north-south axis, providing two long facades through which daylight is introduced through vertical glazing. Due to lower annual solar heat gains on east facades in Hong Kong, it was found possible to increase the glazed area on the east elevation in order to admit more daylight, at a relatively low solar heat gain penalty. Hence, the east facade features taller glazing to maximise daylight and views whereas the west façade glazing has been reduced in height and provided with external shading devices (see Figure 4). Performance is further enhanced by incorporating the afore-mentioned skylights on the roof by orientating them to face true north. The skylights block the majority of direct sunlight from the south but allow diffused light to enter from the north. These strategies work in parallel with intelligent daylight and occupancy controls to optimize performance.

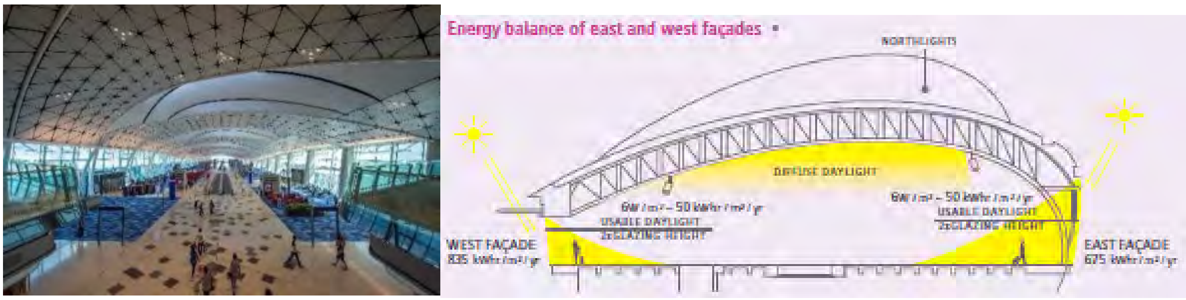

Figure 4: Energy balances of east and west facades at MFC

3.1.2 Reducing solar heat gain

In addition to adopting an optimised façade design, a shading hierarchy was followed to reduce solar heat gain and these involved the following steps:

- Step 1 - Reducing window to wall ratio: ASHRAE Standard 90.1 recommends a maximum window to wall ratio of 40% as a starting point. This target was used in the lower floors. At the departure concourse level, a more conventional window to wall ratio of approximately 60-80% was adopted; however, due to reduced floor to ceiling heights, the overall area of glazing is significantly less compared to Terminal 1 and many international airports.
- Step 2 - Adopting high performance glazing: High performance glazing is a highly effective method to reduce solar gain and it is a permanent solution which requires no additional maintenance compared to traditional facades. The use of glass with low solar heat transmission but high visual light transmission also maximises natural daylight benefits while minimizing heat gain.
- Step 3 - Incorporating external shading systems: the use of external shading devices and overhangs to block direct solar heat gain from specific orientation and solar angles.
- Step 4 - Using opaque façade elements: the MFC has a relatively large roof area compared to the volume of the building. To mitigate solar heat gain, thermal insulation is used in the roof to reduce the U-value to below 0.3W/m^{2}K, while a relatively light roof covering reduces internal gains further.

3.2. Active design methodology

In addition to the passive design strategies, low energy active design techniques are required for delivering energy in the most efficient way. The energy modelling process revealed that the artificial lighting and also air conditioning systems consume a large portion of the total energy demand. Therefore, a number of innovative and effective energy saving methods have been adopted in the MVAC and lighting systems.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.2.1 Best practice cooling solutions

Several best practice air conditioning solutions have been incorporated into the MFC, with the following elements exceeding the requirements of Hong Kong's Building Energy Codes:

- Variable air volume (VAV) system: VAV systems are used for conditioned air delivery. Air handling units (AHUs) are provided to allow quick response to the dynamic cooling loads in predetermined zones. Each VAV system is controlled by its own CO_2 sensor and room temperature sensor to modulate the fresh air and recirculated air supply appropriately to maintain the indoor environmental requirements.
- Binnacle air delivery system: Binnacle air delivery systems are used in the departures level which has large floor to ceiling heights and ties in with the AHU systems. The binnacle system allows only the lower occupied zones to be conditioned.
- Free cooling: The flow of external fresh air delivered into the building is increased when the external air temperature and RH are lower than the pre-determined values to provide free cooling to the indoor spaces, reducing the work load of the chillers and achieving energy savings.
- Variable chilled water flow: As the MFC is a long and narrow building, chilled water needs to be pumped for large distances. Variable water pumping systems are adopted and these save energy by reducing the flow of chilled water when demand is low.
- Water cooled chiller system: Water cooled chillers offer significant energy savings compared to air cooled equivalent. Five variable speed water cooling towers are provided at MFC for chiller cooling to serve the building loads.
- Water recycling system: The MFC employs two water recycling systems. Grey water is recovered from washing basins, cleaner' s sinks, showers and kitchen drainage and treated by the on-site grey water treatment plant; and condensate water is recovered from air conditioning system. Water recycled from both systems is used to offset the use of potable water for cooling tower make-up.

3.2.2 Active design of renewable technologies and transportation systems

Approximately 1,200m^2 of photovoltaic (PV) panels are installed at MFC, providing around 120kWp of clean power to offset the use of grid electricity. The PV panels are mounted on sloped south-facing areas of the roof skylights. This gives the panels an improved performance when compared to horizontal mounting.

While maintaining timely, efficient and comfortable transportation, several green initiatives have been included to minimise energy consumption from MFC transportation:

- Regenerative power: The APM train system incorporates regenerative power from the braking function. Lifts are also equipped with a regenerative unit that distributes the captured power to the building power supply;
- On-demand escalators: Horizontal transportation systems such as moving walkways and escalators are controlled to only operate when in use, as detected by motion sensors.

3.3. Energy modelling

Detailed building energy consumption modelling was performed to allow comparative analysis of building designs and technologies. With consideration of the various passive and active design technologies incorporated, the energy performance of the established MFC design was compared with the baseline situation established following the EMSD's Performance-based Building Energy Code. As illustrated in Figure 5 below, the simulation results indicate that the MFC can achieve beyond the targeted annual energy consumption reduction of 20%.

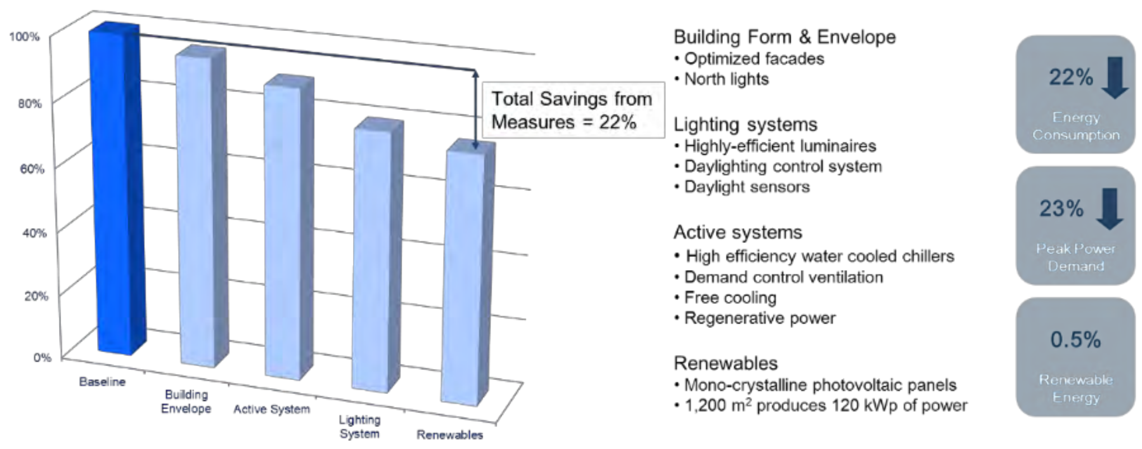

Figure 5: Energy saving from MFC green design initiatives

3.4. Commissioning, operation and maintenance

It is essential that the MFC building systems function efficiently to allow optimal performance. To support this objective, an extensive commissioning process was adopted on the project. Further to this, operations and maintenance staff were trained to use the systems effectively so as to realize all benefits. The benefits of extensive commissioning and staff training include reduced energy use, lower operating costs, fewer contractor call-backs, better building documentation, improved occupant well-being and productivity, and verification that the systems are able to perform in accordance with project requirements and expectations

4. CONCLUSION

Focusing on the MFC project as a case study, this paper describes how the early consideration of sustainable design principles and a systematic evaluation and prioritisation of the possible combination of passive design strategies and low-energy active design techniques can help take forward innovative ideas and sustainable design initiatives through the different stages of a project in delivering an energy efficient high-performance building. The MFC serves as testament confirming HKIA's commitment to being a green airport. Adopting a similar green design strategy for the planned Expansion of HKIA into a Three-Runway System will bring similar sustainability benefits for HKIA and Hong Kong.

The Use of Recycled Aggregates for Full Depth of Sub-base in Pavement Construction in Hong Kong

HUI Hok-tung[a]

[a] *Highways Department, Government of the HKSAR, Hong Kong SAR, sernd2.rnd@hyd.gov.hk*

ABSTRACT

Thousands of tons of inert construction & demolition (C&D) wastes are being generated from construction activities in Hong Kong daily. The inert portion of the C&D wastes, including broken rocks, concrete and soil, are delivered to the two fill banks in Hong Kong, which only have limited stockpiling spaces. In addition to the efforts made by the construction industry in minimizing the generation of C&D surplus, recycling of these inert C&D materials can surely alleviate the burden on the fill disposal facilities. Recycled aggregates can be derived from these inert C&D wastes for use in many areas of construction. One of the common applications of recycled aggregates is to be used in the sub-base layer for pavement construction. In the past, recycled sub-base was used with the presence of a capping layer of virgin aggregates to avoid the phenomenon of cementation, which may affect the performance of the sub-base layer. By addressing the cementation problem in recycled aggregates together with other measures to do away with the capping layer of virgin aggregates, the construction industry is encouraged to use recycled aggregates more extensively, which not only helps alleviating the capacity pressure at the fill banks, but also minimizes the use of natural resources by reducing the use of virgin aggregates. This paper discusses the latest research studies by Highways Department in collaboration with The Hong Kong Polytechnic University on the use of recycled aggregates for full depth of sub-base material in pavement construction, the quality control of recycled aggregates, and the implementation as an alternative for sub-base construction in local distributors and feeder in the Hong Kong road network.

Keywords: waste management, sub-base, road, recycled aggregates

1. INTRODUCTION

The construction industry in Hong Kong generated over 55,000 tonnes of C&D wastes daily (Environmental Protection Department, 2015). Currently, major portion of inert C&D wastes are going to the two public fill banks in Hong Kong (Environmental Protection Department, 2015), namely Tuen Mun Area 38 and Tseung Kwan O Area 137, for temporarily stockpiling for later reuse for reclamation or earth-filling projects. Potential ways of reusing the C&D waste were also explored by Highways Department for consuming the C&D waste generated by the local construction industry. One of the options is to reuse the C&D materials as recycled aggregates in sub-base in pavement construction. The use of recycled aggregates in sub-base could also reduce the use of virgin material which helps conserving natural aggregates in our environment.

2. THE USE OF RECYCLED AGGREGATES AS SUB-BASE

2.1 Recycled aggregates and sub-base

Aggregates are granular materials used in construction, commonly used in mixing of concrete and as sub-base materials for pavement construction. Aggregates could come from natural sources or be derived from C&D wastes including crushed concrete rubbles, ceramic tiles and crushed bricks (Poon & Chan, 2007). In Hong Kong, recycled aggregates can be used in both concrete and sub-base materials for pavement construction (Civil Engineering and Development Department, 2006). The sub-base layer forms the upper layer of the pavement foundation. Within a flexible pavement structure, the sub-base is also treated as a structural layer to spread the loading from the surface down to the subgrade (Highways Department, 2013) Typical cross-sections of concrete and bituminous pavement with sub-base layers extracted from Highways Department Standard Drawings H1101 and H1102 are shown in the Figure 1 and Figure 2 below respectively:

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

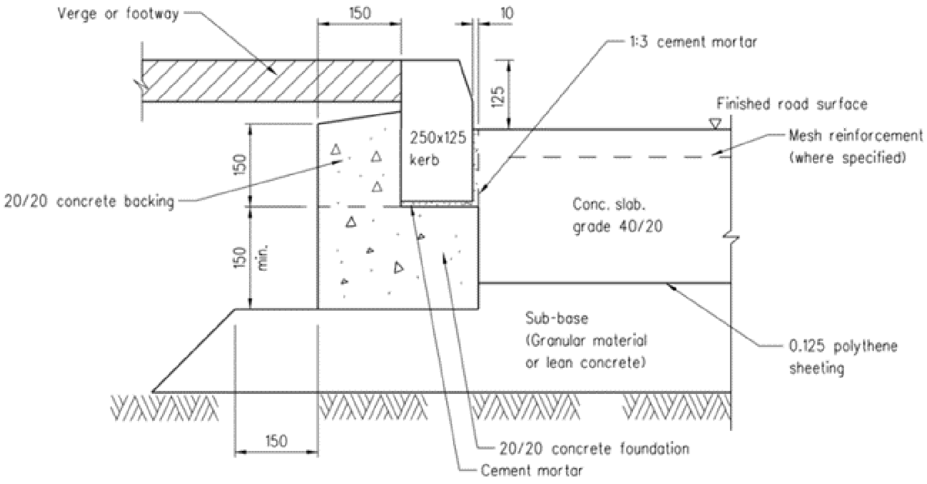

Figure 1: Typical cross section of concrete carriageway (Highways Department standard dDrawing)

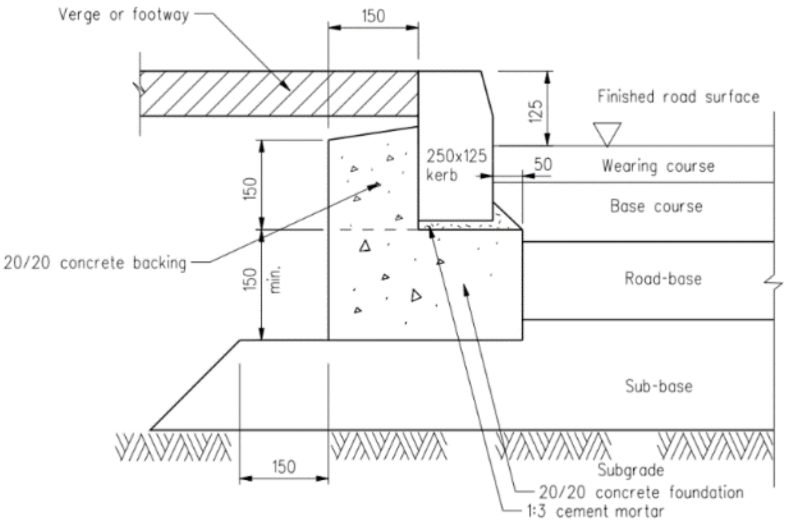

Figure 2: Typical cross section of bituminous carriageway (Highways Department standard drawing)

2.2 Previous study and practice in Hong Kong

Early laboratory tests and site trials revealed that the phenomenon of cementation may occur in recycled aggregates in sub-base layer in the presence of water. Cementation process happens when the unhydrated cement fines in recycled aggregates react with water under humid condition (Hiller et al., 2011). In the process of cementation, part of the sub-base layer would be hardened. It may increase the stiffness and bearing capacity of sub-base, but it may also affect the performance of the sub-base layer, particularly the drainage problem and the cracking problem in asphalt. As cementation happens in the recycled subbase over time, cracks on the recycled subbase may develop afterwards when the layer is subject to thermal expansion and contraction. The cracks in the sub-base layer may propagate upwards to the roadbase and eventually to the pavement surface as reflective cracking. In order to avoid cementation of recycled aggregates, a layer of virgin aggregates were used as a capping layer on the recycled aggregates layer at an approximate 4:6 thickness ratio. By adding this layer of virgin aggregates, the performance of the sub-base with recycled aggregates was satisfactory. This specification was then incorporated into the General Specifications for Civil Engineering Works (2006 Edition) as an option to allows the use of recycled aggregates as sub-base. Under this specification, the sub-base consists of two types of materials, a layer of recycled aggregates and a layer of virgin aggregates as capping layer (Civil Engineering and Development Department, 2006). However, this involves more working sequences in the laying and testing works. Moreover, the properties of the recycled aggregates vary a lot and make the quality control more difficult. These factors could be the reasons to explain the uncommon usage of this specification.

3. LATEST DEVELOPMENT

3.1 Recycled aggregates for full depth of sub-base

To promote the use of recycled aggregates in sub-base, Highways Department simplified the laying and testing working by avoid using two layers in sub-base when using recycled aggregates, i.e. to use full depth of recycled aggregate without the virgin aggregates capping layer. We also minimized the uncertainties in recycled material quality to reduce the risk of non-compliance. Collaboration studies were carried out with Hong Kong Polytechnic University and Highways Department in 2012 and 2014 to investigate the use of full depth recycled sub-base in Hong Kong road networks.

3.2 Minimize cementation in sub-base

Two layers of sub-base were specified in the General Specifications aimed to eliminate the cementation of recycled aggregates. Researches in the past found that cementation is caused by dicalcium silicate (C_2S) in cement (Hiller et al., 2011). C_2S in concrete hydrates and provides strength to concrete gradually for a long time. Therefore, if concrete is crushed as C&D waste into recycled aggregates and is used as sub-base, cementation will occur in the sub-base layer. Laboratory tests found that finely crushed concrete with size less than 0.15mm contains the most C_2S which contributes mostly to cementation in sub-base with recycled aggregates. It was found that by controlling the fine content in the gradation of recycled aggregates, cementation in sub-base could largely be minimized. Moreover, by controlling the fine content, it will compensate the possible extra fines generated during transportation and compaction of the recycled aggregates. Therefore, recycled aggregates can then be used in full depth of sub-base layer without the virgin aggregate capping layer.

Figure 3: Core taken from early site trial indicating significant cementation occurred in recycled sub-base layer

3.3 Minimize uncertainties in material quality

C&D Wastes typically contains crushed concrete, crushed rock, steel, wood, plastics, paper, foam, brick, ceramics, glass, etc. Among these constituents of C&D wastes, only crushed concrete and crushed rock are most suitable to be used as recycled aggregates. We can ensure the quality of recycled aggregates by removing other unwanted constituents from the C&D waste. However, it is impractical and expensive to totally remove these unwanted constituents. Therefore, we have to determine the acceptable percentage of these unwanted constituents to be used in sub-base.

Figure 4: Typical C&D waste

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

One of the common unwanted constituents in C&D waste is steel. Steel can be removed by magnet effectively unless it is embedded inside crushed concrete. As steel has high resale value, the industry usually has good incentive to remove steel from C&D waste before it becomes recycled material. The amount of steel in recycled aggregates is limited to 1% by weight.

Other light weight materials in C&D waste, such as plastic, foam, wood, papers, etc, must also be removed as far as practicable. These elements occupy space but cannot sustain loading, they may introduce weak points in pavement when they become part of the sub-base layer. There are numerous ways to remove these light weight unwanted constituents that had been using in the recycled industry, namely sieving, washing, wind blowing and manual pick. Sieving can effectively sort out those larger size unwanted constituents; Washing can separate the unwanted constituents by their density (i.e. less dense constituents will float on surface of water while dense constituents will sink to the bottom of the tank); Wind-blowing can remove light weight unwanted constituents; Lastly, manual picking, which is a rather low cost but effective technique. Manual picking had also been implemented at the Construction Waste Sorting Facilities operated by CEDD. The amount of light weight unwanted constituents can be practically limited to 0.3% by weight.

Figure 5: Wind-blower for sorting light weighted unwanted constituents in C&D Waste at the sorting facility in Tseung Kwan O Area 137

Figure 6: Manual picking unwanted constituents in C&D Waste at sorting facility in Tseung Kwan O Area 137

Another unwanted constituents are bricks. Bricks are weaker than crushed concrete and rock. They are susceptible to further breaking. If they become part of the sub-base layer, they may affect the stiffness and gradation of the sub-base and affect the performance of the pavement. However, bricks in C&D waste usually have similar size and density with crushed concrete or crushed rocks, which makes them difficult to be separated by the abovementioned methods. The only practical way to remove bricks is by handpicking from large size sieves. Therefore, it is necessary to set a practical limit to the amount of bricks without affecting sub-base performance. To determine this limit, we tested the engineering properties of recycled aggregates in laboratory and verify their performance by site trials and computer simulation. Results show that the limit of the amount of bricks in recycled materials can be proposed to 20% by weight (Wang, 2015). Similar limits are adopted in other overseas standards.

Glass, tiles and ceramics in C&D waste also have similar size and density to crushed concrete and rock. They can also be removed manually if they are in large pieces. However, they may be difficult to be identified for smaller size as they have similar colour with crushed concrete and rock. Nevertheless, according to the past statistics, glass, tiles and ceramics only contribute to a small portion in local C&D waste and their effect to the sub-base should not be a concern. These kind of miscellaneous inorganic materials are limited to 1% by weight in the recycled aggregates.

3.4 Addition of recycled glass cullet in sub-base

To promote the use of recycled glass, our collaboration research with the Hong Kong Polytechnic University also investigated the feasibility and performance of sub-base materials with recycled glass cullet. Laboratory tests and site trials indicated that it is feasible to use crushed recycled glass cullet as replacement of the fines in the sub-base materials. It was reported in study that the use of glass cullet increases the stability of the sub-base due to the angularity of the glass cullet (Poon, 2013). A study performed by the Texas Tech University College of Engineering also concluded that the use of glass cullet in sub-base do not affect the engineering properties of the sub-base layer by limiting the glass cullet content up to 20% of the total mass of sub-base (Nash et al. 1995). Most specifications in the US indicate that the replacement percentage of glass cullet in sub-base is between 5% and 20% of the total mass, and the replacement percentage is limited to 10% of the total mass in Australia (Poon, 2013). Limit of 10% by total mass is finally adopted for recycled glass cullet used in sub-base.

4. CONCLUSION

With the findings from laboratory tests, sites trials, computer simulations and exchanging views with trades addressing the factors that hinder the use of recycled aggregates as sub-base, Highways Department published the Particular Specifications for the laying sub-base with full depth of recycled aggregates in 2015, which also allows the option of using of recycled glass cullet as fines replacement. Project proponents can incorporate the Particular Specification into their works contracts. Currently, the particular specifications of full depth recycled sub-base are already included in the recently awarded term contract of Highways Department (Contract No. 02/HY/2015). We are confident that the use of recycled aggregates in sub-base will become more popular in future.

ABSTRACT

The concept of sustainability has been spreading in the construction industry, introducing tools and methods that may assist in the process of decision making and allowing improvements in management techniques as much as in production processes. Thus, this research aims the selection of materials by means of the proposition of a decision making method – the Choosing by Advantage (CBA) assisted by the Life Cycle Assessment (LCA). It was adopted a commonly employed component in temporary facilities of construction sites in the construction industry, the tiles. The adopted tiles were composed by recycled material (polyethylene – aluminum) and by non – recycled materials (galvanized steel). It was applied a multi-criteria methodology, in which the CBA method proposes the analysis of the best type of tile according to sustainability parameters – ecological, economic and social. In this study, LCA complements the CBA by means of the evaluation of environmental impacts, where the factor "Carbon Dioxide Equivalent (Emission CO_{2eq})" was examined as a factor generated by the transportation of the tiles from the factory to the authorized reseller. By means of the implementation of the decision making method, it was verified the feasibility regarding the application of the LCA as a support tool to the CBA method for the selection of materials that cause less impact as a positively complementary methodology. It is concluded that the adopted methodology assists in the dissemination of sustainability in the stage of execution, according to a systemic approach based on sound information.

Keywords: decision making method, life cycle assessment, carbon dioxide equivalent emission

1. INTRODUCTION

Abraham et al. (2013) considered that the construction industry sector frequently experiences issues regarding decision making processes. The complexity of the decisions to be taken by designers and others involved consists in the selection process of the building system as much as in the process of material selection. According to the authors, these issues demand a group of approaches called Multi-criteria Decision-Analysis (MCDA).

Models of multi-criteria decision may present the capacity of systematically formulate and compare different options against other vast sets of projects criteria, providing a versatile tool to deal with complex tasks regarding the decision making process (MILANI et al. 2011).

Even considering the building frequency of temporary facilities and their cycle (mounting process, usage, disassembly process and reutilization), studies regarding the sustainable development of the project process of this system in the construction site are not abundant. Arslan and Cosgun (2008) verified that, in order to improve the performance of emergency or temporary facilities, industry may need to explore the environmental aspects of these buildings throughout their existence phases.

This research aimed to verify the combined applicability of two methods in order to assist the decision making process in the selection of tiles for construction site facilities, considering the environmental impact category of global warming and the "Carbon Dioxide Equivalent Emission (CO_{2eq})" factor generated by the transportation of the tiles from the factory to the authorized reseller. In order to accomplish this analysis, the decision making systemChoosing by Advantage (CBA) assisted by the Life Cycle Assessment (LCA) was employed.

2. MULTI-CRITERIA METHODS

The multi-criteria methods, as the decision making studies are designated, have been highly utilized in the solution of problems, since they may clarify to the decision maker the possibilities of choices. When a project staff chooses

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

an alternative, the approach may not be always overt, and rarely a formal method of decision making is employed (ARROYO, TOMMELEIN, BALLARD, 2015).

Milani et al. (2011) utilized the MCDA assisted by the life cycle assessment to the selection of composite materials and the considered criteria were cost, mechanical and thermal properties and environmental impact. In the research, it was compared a pure plastic gear with a polyethylene terephthalate (PET)/ alternative aluminum powder composite, one of the results highlighted that the performance of the composite material and the attributes of cost are modified during the project process.

In addition to economic and structural factors, due to global changes, other factors may also be part of corporate responsibility, as issues oriented to natural environment and society. Regarding sustainability, one alternative is to perform modifications in the production processes of companies in order to reach ecologically sustainable options.

2.3 Choosing by advantage (CBA)

The CBA system, according to Suhr (1999) is based on four principles: 1) the decision makers must learn and skillfully utilize tangible methods, 2) the decisions must be based on the importance of the advantage, 3) the decisions must be anchored on relevant facts and 4) different types of decisions demand different methods of decision making.

The difference of CBA, when compared to other methods, is the systemic analysis reconsidering the decision. Suhr (1999) indicates that the difference between sound methods and unsound methods are the weighting rating given to wrong items, for example: advantages and disadvantages, pros and cons, criteria and objectives. In advance, CBA is a system that compares the advantages of the alternatives.

The CBA method for moderately complex decisions divides the process of Decision Making in five phases: 1) stage-setting, 2) innovation phase, 3) decision making phase, 4) reconsideration phase and 5) implementation phase (SUHR, 1999). This article emphasis Phase 3, the decision making phase.

3. LIFE CYCLE ASSESEMENT (LCA)

LCA is a tool utilized to assess the potential environmental impacts of a product system throughout its life cycle. This tool may be divided into four phases: definition of objective and scope; analysis of Life Cycle Inventory (LCI); Life Cycle Impact Assessment (LCIA) and interpretation of results (ABNT, 2009).

Onwards the results obtained by LCA it is possible to recognize the aspects that may cause more impact throughout the life cycle and, according to NBR ISO 14.040 (ABNT, 2009), by means of the interactivity among the phases of the LCA, it may be possible to achieve the completeness and consistency of the research and of the results.

According to Passuelo et al. (2014) there is a lack of studies about the LCA of construction materials in Brazil, what determines the necessity of studies that relate the practice of LCA in the local scenario in order to transform this object into a management tool applicable to the Brazilian reality.

4. RESEARCH METHOD

The employed research procedure was based on three available methods:

- Five stages of Phase 3 – Decision Making of the CBA (SUHR, 1999) ;
- Proposal of the authors Arroyo, Tommelein, Ballard (2015), suggesting the complementation of Phase 3 – Decision Making process with two more stages considered in Phase 2 – Innovation of CBA (SUHR, 1999), making the decision making procedure more comprehensive, embodying seven stages; and
- LCA as a tool disclosed by technical standards, allowing the evaluation of environmental impacts caused by materials and systems of products– NBR ISO 14.040 (ABNT, 2009), in order to assist the decision making process regarding environmental aspects.

Figure 1 exemplifies how the method was composed in order to be applied in this research.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

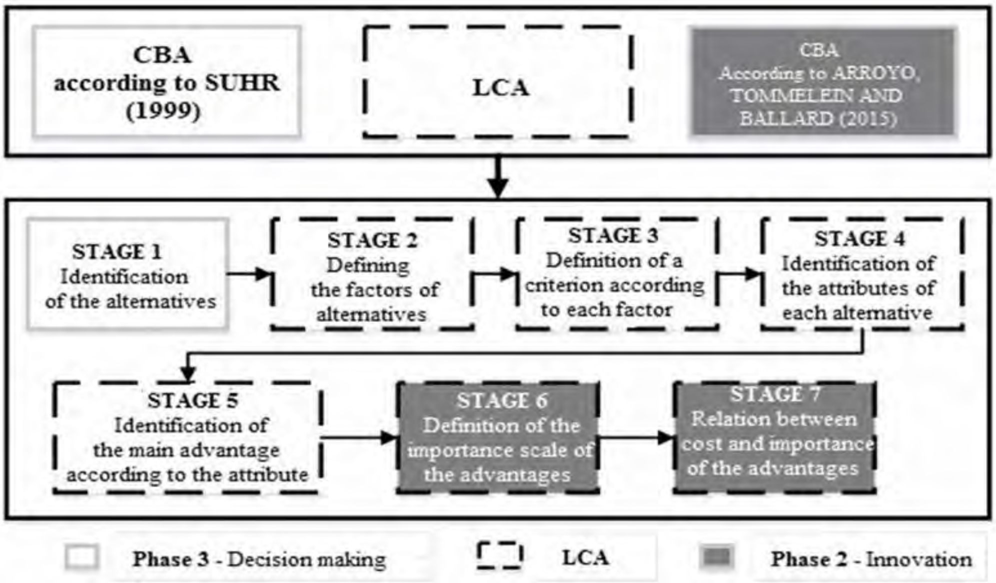

Figure 1: Participation of cba and lca in the method: Authors, 2016

This research was focused on the "Carbon Dioxide Equivalent Emission (CO_{2eq})" of the analyzed tiles, which was the factor chosen to be studied on Stage 2 of Phase 3, regarding the Decision Making method CBA aggregated to the LCA which assisted the decision making process until the last stage.

For the effective application of the LCA, it was utilized a software in order to manipulate the data, as well as a database of life cycle inventories. The employed software was the Open LCA® and the ELCD 2.0 (ELCD, 2016) database; both were chosen because of the free availability.

In this research, it was analyzed the transportation stage of the tiles from the factory to the authorized reseller. Therefore, the data collection considered the calculation of the average distance between the factory and the cities in which the tiles were resold; the distances found are analyzed in Table 1. This analysis was made by means of a direct contact with the manufacturer of the tiles.

The analyzed tiles were constituted by: recycled material of long life package (polyethylene – aluminum); metallic corrugated in galvanized steel and; metallic trapezoidal in thermo-acoustic galvanized steel. Thus, by means of the software, the data provided by the manufacturers were compiled in order to obtain the CO_{2eq} emission regarding the category of global warming. In order to achieve the CO_{2eq} emission data caused by the transportation of the tiles, it was utilized the method consolidated by the Intergovernmental Panel on Climate Change (IPCC) (IPCC, 2013).

5. CASE REPORT

The selection of the tiles for the application of the method concerns the fact that the tile is one of the required components in temporary facilities of construction sites, and during the transportation process, the emission of greenhouse gases occurs.

The typology of the three analyzed tiles were: 1) tile containing recycled substances of long life package (polyethylene – aluminum); 2) corrugated galvanized steel tiles ; 3) thermo-acoustic trapezoidal galvanized steel tiles, aiming to compare the different variety of tiles available on the market, which are employed in temporary facilities of construction sites.

5.1 Characterization of the tiles

The tiles presenting recycled material of long life package are composed by plastic (low density polyethylene LDPE) and aluminum of the packages, with an external layer of virgin aluminum, which is not part of the residues of the long life packages, adhered to the tiles in order to improve the thermal performance. The measures of these tiles were 2, 20 of length, 0, 92 of width, 6mm of thickness and 14 kg per unit.

The corrugated tiles constituted of galvanized steel are not painted metallic tiles, manufactured from a steel sheet covered by a thin layer of protection composed by pure zinc (galvanized sheet). The function of the zinc is to avoid the corrosion process. The tiles used in this research were corrugated and natural (no painting), they presented width of 1,10m, length of 2,20m, thickness of 0,50mm and weight of 9, 9 kg per unit.

Trapezoidal tiles manufactured in galvanized steel are not painted metallic tiles produced by two steel sheets (sandwich tiles), coated by pure zinc (galvanized sheet). In order to be designated as thermoacoustic, it must be filled with an insulating material as Expanded Polystyrene (EPS) or Polyurethane (PU), for example, thus characteristics that may improve the thermal and acoustic performance will be developed. The tiles applied in this study presented the shape of a trapezium, width of 1,10m, length of 2,20m, thickness of 0,50mm and a layer of EPS with 50mm of thickness, each piece weighted 21kg.

5.2 Application of the method

The research was developed considering the stages described in frame 1.

Stage 1	Identification of the alternatives – The alternatives chosen to the application of the CBA method were the three types of tiles specified in item 5.1, utilized in temporary facilities of building sites.
Stage 2	Definition of factors - The "Carbon Dioxide Equivalent Emission (CO_{2eq})" factor was analyzed. Therefore, in Stage 2 the LCA was integrated in order to assist the CBA decision making method, in which the potential category of global warming was analyzed with regard to the transportation process. This factor was investigated regarding the transported distance and the weight of the tiles from the factory to the authorized reseller.
Stage 3	Definition of a criterion regarding the factor – The criterion adopted to analyze the potential factor of global warming was: lower emission of CO_{2eq}.According to the principle of sustainability, lower emissions of CO_{2eq} are related to a lower contribution to the global warming effect.
Stage 4	Report of the attributes of the alternatives –In Table 1 the attributes of the alternatives were expressed, in other words, the quantity of $CO_{2\ eq}$ emitted by the transportation of the tiles to the reseller.
Stage 5	Decision of the main advantage – The main advantage indicated by the decision maker regards the tile presenting a lower $CO_{2\ eq}$. emission.
Stage 6	Definition of the importance scale of the advantages – In this research, as a single factor was analyzed ("$CO_{2\ eq}$ emission"), consequently it was evaluated by a maximum punctuation of 100 points.
Stage 7	Relation between cost and importance of the advantages – After the attribution of the scores to the advantages, a calculation was made and the total of the importance of the advantages was obtained. The value of each alternative was also obtained, in other words, the price of each tile (unit) per square meter was achieved, a graphic IofA x R$ was schematized,

Table 1 exhibits important data as the average distance traveled by the truck in order to transport the tiles from the factory to the sales area, considering that this resale may be direct as it is the situation of the metallic tiles in galvanized steel or may be performed indirectly, as the recycled tiles, which the manufacturer transports the product to another specific sales area.

Types of Tiles / Distance and Lorries	Recycled material Polyethylene-aluminum	Corrugated Galvanized Steel	Thermo-acoustic Trapezoidal Galvanized Steel
Average transportation distance from factory to resale	1.225 km	535 km	535 km
Lorry utilized in the transportation	Truck 22 tonnes or Truck 14 tonnes	Truck 25 tonnes or Truck 12 tonnes	Truck 25 tonnes or Truck 12 tonnes

AUTHORS, 2016

Table 1: Distance data

According to the metadata of ELCD 2.0 (ELCD, 2016) the utilized methods were prepared according to the weighted average of the trucks in accordance to the emission standards EURO, in other words, EURO 0 to EURO 4. The valid cargo considered to the transport was 17,3tonnes and 27t, due to the types of trucks utilized and detailed on Table 1, and, mainly, for being modules that represent "process systems" and for considering the early life of the diesel.

6. RESULTS

Due to the fact that tiles present the function of covering the facilities, a reference unit of coverage of 50m² was adopted in order to perform the calculation. In addition, an analysis was made regarding the sensibility of the disclosed data. Thus, the calculation was performed considering the average distance and a distance of 100km (standard), in order to make it possible to analyze the interference of the characteristics of the tiles, as the transported weight and volume.

In order to quantify the CO_{2eq} emission level, it was employed the Life Cycle Impact Assessment (LCIA) method developed by IPCC, which utilizes the Global Warming Potential (GWP) in order to transform the emissions of greenhouse gases into emissions of CO_{2eq}, considering a time line of 100 years (IPCC, 2013).

The modules adopted as reference to the calculation of CO_{2eq} emission were "Lorry transport, Euro 0, 1, 2, 3, 4 mix, 22 t total weight, 17,3t maxpayload - RER", a more decisive module when compared to the "Articulated lorry transport, Euro 0, 1, 2, 3, 4 mix, 40 t total weight, 27 t maxpayload – RER", according to Table 2.

TILES	IPCC 2013 - GWP 100a (CO2eq)					
	Distance of 100km			Real Distances		
	Tonnes x km	Max. 27 tonnes	Max. 17,3 tonnes	Ton x km	Max. 27 tonnes	Max. 17,3 Tonnes
Polyethylene – aluminum Recycled material	42,0	0,00492	0,00819	514,5	0,06023	0,10018
Metallic Corrugated	24,8	0,00281	0,00468	132,6	0,01547	0,02573
Metallic thermoacoustic	52,6	0,00609	0,01014	281,4	0,03293	0,05477

AUTHORS, 2016

Table 2: Global warming according to real and standard distances with the maximum cargo weight of the truck

According the real distances, the module which contributed the most for the category of to this analysis, the average distance directly affected the results, as the longer distance refers to the recycled tile (1225 km), followed by the metallic tiles presenting the same distance (535 km). In this case, as the distance for the metallic tiles was equivalent, the predominant factor for the result of the emission level was the weight, as in order to cover 50m² it is necessary 0,526 tonnes of thermoacoustic tiles and 0,248 tonnes of corrugated metallic tiles.

However, when the standard distance of 100 km was adopted, the transportation of the thermoacoustic tile was the most critical. In order to perform this analysis, it was observed that the weight of the tiles was decisive for the results, as to cover 50m², the thermoacoustic tiles own a higher weight of 0,526 ton/ m², followed by the recycled tiles, 0,420 ton/ m² and the corrugated metallic tiles, 0,248 ton/ m². Henceforth, Table 3 exhibits the results of the joint application of the CBA method assisted by the LCA, where it may be seen six of the seven stages briefly explained on the research method.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

ANALYZED FACTOR	ALTERNATIVES

Carbon Dioxide Equivalent Emission – according to the average distance Criterion: Lower CO_{2eq} emission	Attributes: 1,00 Advantage:	0	Attributes: 0,26 Advantage: lower CO_{2eq} emission	50	Attributes: 0,55 Advantage:	0
Carbon Dioxide Equivalent Emission – according to the distance of 100km Criterion: Lower CO_{2eq} emission	Attributes: 0,82 Advantage:	0	Attributes: 0,47 Advantage: lower CO_{2eq} emission	50	Attributes: 1,01 Advantage:	0
TOTAL IofA		0		100		0

AUTHORS, 2016

Table 3: Results of the application of cba assisted by lca.

In order to conclude the selection of the tile, the economic aspect was considered. Stage 7 of the research method presents a graphic containing the cost of the tiles according to the Importance of Advantage (IofA).

The values of the tiles were calculated referring to 1m². The polyethylene – aluminum recycled tile costs R$ 16,58/m², the corrugated metallic tile in galvanized steel costs R$ 16,54/m² and the thermoacoustic metallic tile in galvanized steel with EPS costs R$ 44,64/ m². Thus, the graphic presented by Figure 2 illustrates the relation between Importance of Advantage and costs/ m² of the tiles.

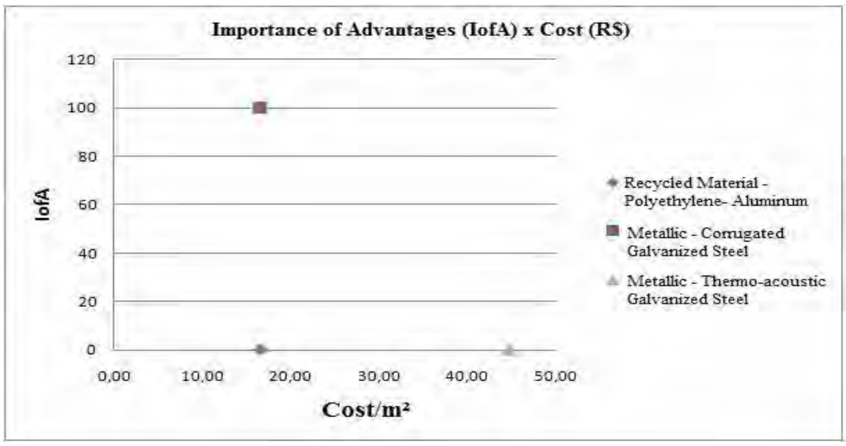

Figure 2: Graphic of the relation between the importance of advantage x cost of the tiles: Authors, 2016.

Therefore, after the implementation of the method, it was possible to identify that the most convenient tile regarding the factor of greenhouse gas emission was the corrugated metallic in galvanized steel, which emitted less CO_{2eq}, and presented a reasonable market price. However, it is emphasized that other factors must be assessed in order to complete the process of material selection.

7. CONCLUSION

According to the performed evaluations, the possibility of achieving several results was verified, what presents a direct dependency with the unit of reference. In this work, the application of LCA allowed to determine the quantity of emitted $CO_{2eq,}$ by means of the categoryassociated to global warming. However, the necessity of analyzing other categories of environmental impact that may relate other ways of emission not contemplated by the category of global warming is existent.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Brazil does not own an implemented database that represents the reality in all levels of the country, thus, it justifies the use of an international database. The ideal is the performance of an adaptation of the information presented by the database as reference. However, the objective of this research was to demonstrate the contribution that LCA may provide to the decision making methods, because LCA effectively contributes by facilitating the choice made by the decision-maker.

Characteristics as volume and weight, in addition to the average distance traveled by the vehicle and the utilized vehicle must be considered in order to analyze the transportation process of the tiles. These factors must be simultaneously studied as they directly affect the emission levels, enabling a critical examination by the decision maker at the moment of the analysis according to the unit of reference.

Thus, the accuracy of the method adopted in this research was validated. The LCA verified the CO_{2eq} emission and the method of decision making verified the advantages of the tiles by means of the principle that when the CO_{2eq} emission level is lower, consequently the transport causes less social and environmental impacts.

It is important to emphasize that the result obtained with regard to the CO_{2eq} factor, does not characterize the ideal tile for the selection of the material to be utilized in temporary facilities in construction sites, since this analysis must be made by considering other factors that may characterize the environmental, social and economic impacts. Thus, the decision making process in the sector of construction industry requires attention aiming the improvement of this area.

ABSTRACT

A building life cycle assessment tool was developed and linked with an energy simulation tool, allowing to take into account the strong interactions between the energy and the environmental performance of buildings. This life cycle assessment tool was then extended at the urban level to evaluate the environmental impacts of a district including many buildings, streets, public spaces and technical network. Building and neighbourhood design alternatives can thus be compared, providing assistance in the decision process. However, the reliability of LCA tool is essential to guide the decision maker towards sustainability. A methodology is presented here to investigate the most uncertain inputs. Factors affecting the building energy performance, the building lifetime and the choice of the electricity mix were identified as the most influential factors which could alter the results' robustness.

Keywords: life-cycle assessment, building energy simulation, sensitivity analysis

1. INTRODUCTION

Because of its high environmental impact, the built environment has been identified as a key sector to face today's energy and environmental challenges. The quantitative and multicriterial life cycle assessment (LCA) methodology, according to ISO 14040, is particularly adapted to study and helping to reduce these impacts. By comparing their environmental impacts, several projects corresponding to the same functional unit can then be ranked according to their performances.

In order to guide the decision towards the most sustainable alternative of a building or district project, robust LCA tools are necessary. Such tools should take into account the specificities of the building sector. Therefore, it was decided to link a building and district LCA simulation tool with a dynamic building energy simulation (DBES) tool.

During a project, the LCA practitioner has to make a lot of choices which can affect the results' robustness, i.e. the ranking of different project alternatives. Quantification methods like sensitivity analysis (SA) can be used to investigate the influence of uncertainties. The objective of the study presented hereunder is to identify the most influential factors met in building LCA. Uncertain factors are therefore described and a SA method is applied in the case of a family house.

2. LCA OF BUILDINGS AND DISTRICTS

LCA has been applied to the building sector since the 1990s. It was first used for buildings only and was then extended to the district level during the 2000s However, when assessing the environmental performances, the buildings and districts specificities should be considered.

2.3 Specificity of the built environment

Contrarily to most industrial products, a building is generally constructed only once: it is unique. LCA practitioners have therefore little resources and time for a study. Dedicated LCA tools make such studies simpler if they are linked to a graphic modeller and an energy simulation tool.

When conducting a building LCA, all life cycle stages must be considered: e.g. construction, use phase, renovation, and end-of-life. Due to the long building lifetime, the use phase is predominant and contribute to 80 % of the energy consumption in conventional buildings. This part is reduced to 50 % in low energy buildings.

Some choices made during the energy assessment of a building (e.g. the insulation type or thickness) influence not only its energy performance but also its environmental one: some insulation material having better thermal properties may have higher environmental impacts. Both energy and environmental assessment should be conducted together in order to estimate the global benefit of a choice.

Dynamic phenomena must also be considered. Meteorological phenomena and occupants' behaviour cause dynamic variations of the building energy load. The electricity production mix is also not static during the year. [5] showed that choosing an annual or a dynamic LCA could have a large influence on impacts evaluation.

At the neighbourhood level, interactions between buildings and with networks occur. For example buildings can shade each other. The entire district is affected by urban heat island phenomena.

Dedicated tools have been developed to assess the environmental performances of the built environment and take into account the sector specificities.

2.4 Description of the building and district LCA tool used in this study

Due to the importance of the energy consumption in the use stage as well as the links between the energy and the environmental performances, a building and district LCA simulation tool (novaEQUER) was linked to a DBES tool (COMFIE).

In COMFIE buildings are divided into thermal zones. For each of them, the temperature, and the heating and cooling loads are calculated by solving thermal equations. LCA can then be performed using novaEQUER. Building materials, thermal results, energy type, but also water consumption, transportation and waste produced during the use stage are taken into account. The LCA can be either annual (e.g. static) or dynamic (hourly load and hourly electricity production mix allocated to different uses). Twelve environmental indicators are calculated (Table 1).

Environmental indicator	Legend	Unit
Cumulative energy demand	(CED)	GJ
Water consumption	(W)	m^3
Abiotic depletion potential	(APD)	kg Sb equiv.
Non radioactive waste creation	(NRW)	t equiv.
Radioactive waste creation	(RW)	dm^3
Global warming potential	(GWP 100)	t CO_2 equiv.
Acidification potential	(AP)	kg SO_2 equiv.
Eutrophication potential	(EP)	kg PO_4^{3-} equiv.
Damage caused to ecosystems	(BD)	PDF.m^2.yr
Damage caused to human health	(HD)	DALY
Photochemical oxidant formation	(POP)	kg C_2H_4 equiv
Odour	(O)	Mm^3

Table 1: Environmental indicators used in novaEQUER

In order to simplify the use of the tool, a dedicated graphic modelling tool (Alcyone) allows describing the geometry of all buildings in a district. When assessing the performance of a building, the others are considered as shading objects for a higher precision of the simulation results. Another module in novaEQUER concerns the district LCA. All buildings LCA results are included and the public space, technical networks and streets are described.

NovaEQUER is a commercially available software. It is used by consultants or architects in the eco-design process at building or district scale.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. RELIABILITY OF LCA AT THE BUILDING LEVEL

If buildings and districts LCA tools are used in decision-making processes, they have to provide reliable results. Otherwise, they may lead to decisions that are not the most sustainable. However during an LCA study, practitioners are facing many choices, and uncertainties in the input can affect the results robustness.

Results of different LCA tools were compared in research projects in order to investigate their robustness. Eight European tools were compared within the network PRESCO. The results were similar and the scattering was +/- 10% of the mean value between the tools when evaluating the GWP during the entire life cycle of a wooden construction. In another project, two French building LCA tools were compared. It highlighted methodological differences in the tools as well as differences due to life cycle inventory databases.

Uncertainty quantification methods can be set up in order to analyse the results' robustness of a building LCA tool when comparing project alternatives. With uncertainty analysis (UA), uncertainties are propagated through the model, enabling to understand the uncertainty level in the outputs due to the input uncertainty level. The Monte Carlo method is often used to do this. As a result, probability distributions are obtained for each output. Another method, the SA, aims at better understanding influence of uncertain factors in ranking them, according to their contribution to the output uncertainty. SA is also called key issue analysis or uncertainty importance analysis in LCA. A simple and quick SA method is presented hereunder after having introduced uncertainty sources met in building LCA.

3.1 Uncertainty in building LCA

Five uncertainty sources that were identified in building LCA are described below.

- Hypotheses about the building: During the DBES and LCA simulation a lot of hypotheses must be done. They concern the building envelope and systems, the occupant's behaviour or the building and its components lifetime. These hypotheses are uncertain and a range of values around a reference value is considered.
- Long term evolution: Buildings have a long lifetime and the long term evolution of the context is largely unknown (e.g. change in the electricity production or materials end of life processes). Prospective scenarios, describing a large range of possible futures, can be used to model this type of uncertainty.
- Modelling methodology: Some aspect may be modelled in different ways in LCA. For instance regarding recycling, two allocation methods can be used: the cut-off or the avoided burden method In the avoided burden approach an environmental benefit is considered because recycling avoids a standard production. This benefit is split between the construction stage and the end of life. In the cut-off approach, the benefit is only accounted for in the construction phase whereas no avoided impact is allocated to end of life, supposed to be in a far future so that the benefit is uncertain.
- Life cycle inventory (LCI): The way to inventory all emitted and extracted substances to the environment for building materials or processes also leads to uncertainty. Data availability and quality are drivers of this LCA phase. The choice of marginal or average data for the inventory does not give the same image of a product or process. Additionally, simplifications of the inventory are sometimes conducted, e.g. gathering many substances in a single VOC (volatile organic compounds) group, which leads to the reduction of some substance effects (e.g. dioxins are more toxic than the average of VOCs).
- Life cycle impact assessment (LCIA): The aggregation of substances into environmental impact categories is uncertain. Indeed, effects of substances alone or of interactions between substances are not always well known. And the effect of substances may vary with the time and the emission location.

3.2 Sensitivity analysis: The Morris screening method

Uncertainty and sensitivity assessment requires a large number of simulations to ensure convergence of the results. At least one thousand simulations in UA or thousands of simulations in global SA are required. The Morris method, which belongs to the screening techniques, has the advantage to be quick and simple. The aim is to rank the input factors according to their influence. It gives also information about the linearity and the presence of interactions.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Screening techniques allow a fast exploration of the model behaviour. Instead of considering all possible values of all input factors, only a few sets of values are kept thanks to a discretisation into a finite number of levels. So, it is not necessary to specify the probability distribution for each factor; only an upper and a lower limit are required. Then an OAT (One-step-At-a-Time) method is repeated r times. Each OAT can be considered as a trajectory in the space of input factors, for which each input is varied while keeping the others constant. Elementary effect (EE) can be estimated for each input like in Equation 1, where j is the factor index, i the repetition index, f the considered model and Δ the jump between two discretized values.

$$EE_j^i = \frac{f\left(x_1^i, \dots, x_j^i + \Delta x_j^i, \dots, x_d^i\right) - f\left(x_1^i, \dots, x_j^i, \dots, x_d^i\right)}{\Delta}$$

Equation 1

The average EE is calculated as in Equation 2: the higher this average, the higher is the influence of the factor j. By calculating the absolute value, the compensation of two opposite EE is avoided.

$$\mu_j^* = \frac{1}{r}\sum_{i=1}^{r} |EE_j^i|$$

Equation 2

The standard deviation is calculated as in Equation 3. A large standard deviation indicates the presence of non-linearities or interactions between the input factors.

$$\sigma_j = \sqrt{\frac{1}{r-1}\sum_{i=1}^{r}(EE_j^i - \mu_j)^2}$$

Equation 3

To have an overview of the influence of each factor, σ_j is drawn as a function of μ_j^* in a Morris graph. So three input types can be identified: inputs having negligible effect (small σ_j and μ_j^*), inputs having large effect without interactions (small σ_j and large μ_j^*) and inputs having non linear effect or interaction effects (large σ_j).

4. CASE STUDY AND RESULTS

4.1 Description of the case study

The Morris method was applied on a case study to investigate the influence of uncertain input factors. A single family house from the INCAS platform in Chambéry (France) was chosen. It is a concrete house of 90 m² (living area) corresponding to the performance of the passive house standard and using electric air heating. COMFIE and novaEQUER were used respectively to perform DBES and LCA. The statistical software R was used to conduct the SA.

In this first study, a set of 22 uncertain factors were investigated (see Table 2). The uncertainty due to some factors, like the waste production or the occupants' transportation during the use phase, was not taken into account in this first step. The variation intervals were chosen to describe the uncertainty on these factors are given in Table 2. In some cases, the variation occurs around a reference value (+/-), e.g. for factors influencing the energy performance. Because the house is already built and its characteristics well known, a quite low uncertain range was chosen for most of these factors. The reference scenarios correspond to hourly mean values for a housing with four main rooms.

Most of the ranges were found in the literature, others were assumed. Regarding thermal bridges a high uncertainty range was considered because the literature gives a wide range of values for each thermal bridge type. Two French electricity production mixes, implemented in novaEQUER were investigated: a static one considering an annual average and a dynamic one which varies hourly and for each type of use. In order to take into account uncertainty due to LCI and LCIA, different types of concrete were considered (a normal concrete and a prestressed) and different time horizons were investigated for the GWP.

Uncertain factor		**Variation range**
Climate and site	Outdoor temperature	+/- 0,5 °C
	Global horizontal radiation	+/- 10 %
	Albedo (ground reflection)	+/- 15 %
Scenario	Indoor temperature setpoint	+/- 0,5 °C
	Occupancy	+/- 10 %
	Internal gain	+/- 10 %
	Ventilation	+/- 10 %
Envelope	Windows thermal resistance	+/- 5 %
	Windows solar factor	+/- 5 %
	Insulation material thickness	+/- 0,5 cm
	Concrete thickness	+/- 0,5 cm
	Thermal bridges	+/- 50 %
	Material loss rate (during construction)	0 to 10 %
Lifetime	Building lifetime	40 to 120 yr.
	Windows lifetime	11 to 59 yr.
	Painting lifetime	8 to 36 yr.
Climate and site	Factory to site materials transportation	15 to 135 km
	Site to landfill materials transportation	5 to 45 km
Context	Water network efficiency	50 to 100 %
	Electricity production mix	Static or dynamic
LCI data	Concrete type	Normal or prestressed
LCA method	IPCC time horizon	20 yr. or 500 yr

Table 18: Investigated uncertain factors and variation range

4.2 Results

2300 simulations of the model were necessary to identify the most influential input factors using the Morris screening. It took about 2h40 minutes with a six cores computer. A Morris graph plotting the standard deviation of the effect, σ_j versus the average absolute effect, μ_j^* (Equation 2) and (Equation 3) was obtained for the twelve environmental indicators calculated in novaEQUER, (Figure 1 for CED and GWP).

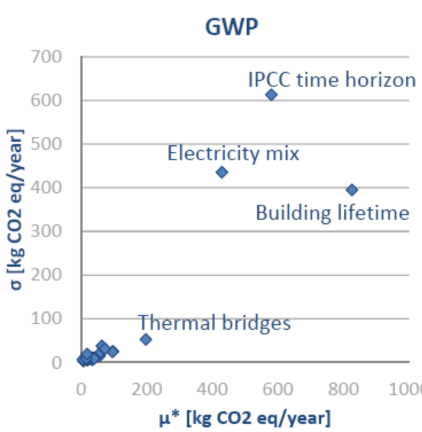

Figure 1a: Morris graphs for the CED

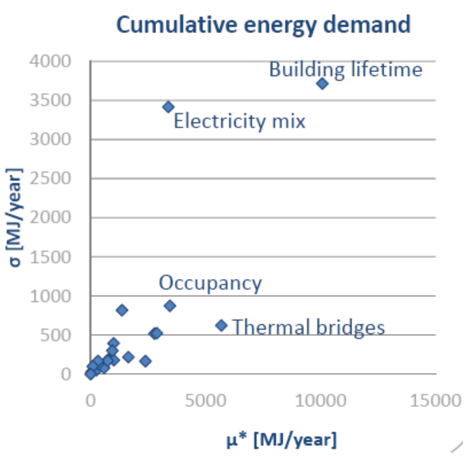

Figure 1b: The GWP

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

For the GWP (Figure 1a), the drivers identified by their large μ^* are the IPCC time horizon, the type of electricity mix. Although the results are given per year, the building lifetime influences largely the results. It is due to interactions between this factor and others like the windows or the painting lifetimes. A hypothesis in novaEQUER stipulates that the building components are not replaced if the replacement occurs in the last 10 % of the building lifetime.

For the CED (Figure 1b), the building lifetime and the electricity mix are input factors having a strong influence. The most influential factors for the energy performance are also prominent on heating load (e.g. thermal bridges). This confirms the influence of the building energy performance. The occupancy has also a high influence. Indeed, if there are more inhabitants, more hot water will be consumed, resulting in a variation of the energy demand to heat the water.

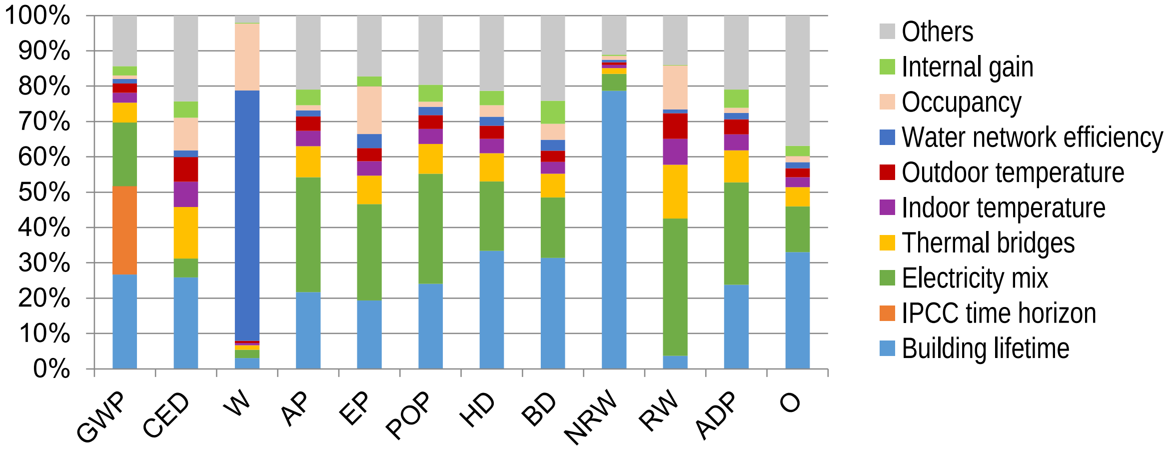

Figure 2: Contribution of uncertain factors to the global uncertainty

Figure 2 summarises the influence of the investigated factors on the twelve environmental indicators. For each factor j, the relative influence on the output uncertainty I_j^* is calculated considering the Euclidian distance to Morris graphs origins, as in Equation 4. The most influential factors for GWP and CED also have a large influence on the other environmental indicators.

$$I_j^* = \frac{d_j^*}{\sum d_j^*} \qquad \text{with} \quad d_j^* = \sqrt{\mu_j^{*2} + \sigma_j^2}$$

Equation 4

5. DISCUSSION

Some factors influencing the energy performance (temperatures, thermal bridges, occupancy) are also drivers of the environmental performance. These results confirm the strong influence of energy issues in building LCA. The chosen electricity production mix type has also a strong influence for most of the twelve indicators calculated in novaEQUER because static and dynamic mixes do not have the same carbon contents. For water consumption, the water network efficiency is identified.

In this first study, a limited set of uncertain factors was considered. For instance the influence of factors like transportation of occupants or waste creation during the use phase, as well as the uncertainty due to methodological choices, was not taken into account. Uncertainties in the LCI and LCIA steps were also poorly represented. In a next step, these sources of uncertainty have to be investigated in order to have a better idea of the LCA drivers. Improving the knowledge on the most influential factors could lead to reduced output uncertainty.

Only one alternative of the project was considered but the final aim is to investigate the results robustness, i.e. to look at the possible change in the alternatives ranking. Furthermore, the case study concerns a single house but the method, can be used for a district. Finally, no temporal evolution of the building or its context was considered. In the simulation, the same electricity production mix was used during the entire lifetime. No degradation of the performance due to material wear was taken into account. However, this type of change can influence the environmental performance.

In order to evaluate more precisely the contribution of each uncertain factor, sensitivity indices, like Sobol indices, should be calculated but their computation time can be high when considering many factors. Therefore, it is preferable to conduct first a Morris screening to determine the most influential factors. Then, sensitivity indices can be calculated after having excluded less influential inputs of the model.

6. CONCLUSION

The simulation tool presented in this paper enables to assess the environmental performance of complex systems like buildings and districts. Because different alternatives can be easily compared, it provides a design aid to progress towards sustainability in the building sector.

In order to orient the decision towards more sustainable alternatives, it is necessary to investigate the robustness of building LCA tools. A Morris screening was performed to rank uncertain factors based on their relative influence on the output uncertainty. In this first study, a few uncertain factors were investigated. In this case study, the most influential ones are the electricity production mix, the building lifetime as well as some contributors to the energy efficiency. The results confirm the influence of the energy performance in the environmental performance. In a next step, the influence of more factors will be determined. Then UA analyses will be carried out on comparative LCA to investigate the results' robustness: the ranking of different uncertain alternatives of a project will be studied. Lastly this work will be extended to districts.

ACKNOWLEDGEMENTS

This work was performed in the frame of the research Chair ParisTech VINCI "Eco-design of buildings and infrastructure". A collaboration is organized with ICARE at HUST in Wuhan.

Track 9: Transforming SBE Policies for People

Session 1.12: Regenerating Urban Space in Neighbourhoods

Cultivating a Village Impulse in the Midst of Warsaw, the Jazdów Settlement of Finnish Houses

Dariusz ŚMIECHOWSKI[a]

[a] *Academy of Fine Arts in Warsaw, Poland, dariusz.smiechowski@gmail.com*

ABSTRACT

A unique low-footprint settlement with small wooden houses in the Warsaw's centre has escaped vanishing and enters its new phase.

It has been perceived in contrasting ways – either as a living structure, a peaceful green enclave challenging the mainstream life, or as an un-modern, shameful village-like insert, occupying expensive land that would be attractive for potential prestigious investment.

The Jazdów's history dates back to the beginnings of Warsaw. Through ages, its prevailing functions related to residential, gardening and curative purposes.

Today's Jazdów Settlement, situated on the former garden and hospital grounds, is a remnant of the larger estate started in 1945 when housing was scarce for those engaged in Warsaw's reconstruction. The Finnish-made pre-fabricated houses were part of war restitution to the Soviet Union, and brought to Poland to help emergency needs.

In 2013, the settlement avoided destruction initiated by the previous district authority (tenants pushed-out, homes demolished, eco-niche endangered). Now it has a chance for preservation and balanced development, taking a role of the socio-cultural hub, with limited residential function retained. Some houses are being adapted. Land-cultivation and eco-development impulses are expressed.

There is a chance here to build a transferable model for civic-management. The process of forming a partnership of organizations and individuals (most remaining tenants included) as well as a broader neigbourhood within the institutions in a larger area is led by such values as cooperation and openness.

The research of civic-managed areas across Europe is pursued, with the involvement of sociologists, architects, landscape architects, activists.

Keywords: sustainable neigborhood, generated structures, civic-management

1. UNIQUENESS OF JAZDÓW SETTLEMENT

The Jazdów Settlement in Warsaw is hard to be defined in clear urbanistic categories. It's few hectares' territory is part of a long green stretch of the Vistula Escarpment. The enclave is situated within the complex of city's remarkable parks and is considered as something between an urban village and an inhabited park.

From the point of view of sustainability, its wooden houses, other historic buildings and rich vegetation have formed a niche, where substantial urban interventions should be strictly limited. On the other hand, as being part of the central district of Warsaw, close to the Parliament, government buildings and embassies, it bears the risk of becoming an attractive plot for investment of stereotypically prestigious character. Those who would like this area to be developed in a more intensive way, have their arguments against its village-like features, describing the Finnish houses settlement as being shameful, un-modern, while occupying expensive municipal land. Clear ownership rights, like in a case of Jazdów, are quite rare in Warsaw where much of property, nationalized after the World War II, tends to be claimed back by previous owners or speculators. On the other hand, those who would like to protect the Jazdów's nature and buildings, describe its values as "priceless", non-material. Many even

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

propose that the existing landscape should be saved “just as it is”, without major changes in its structure and specific atmosphere.

1.1 The place’s history, character, atmosphere

The character of the Jazdów Settlement’s landscape has been shaped by the morphology of the Vistula Escarpment, the land-cultivation and curative impulses. The identity of Jazdów has always been bound with the core of the history of Poland.

Jazdów dates back to the times of the Dukes of Mazovia’s presence (12th-15th Centuries), their castle situated on the cliff, securing a strategic river-crossing nearby to the east. Bona Sforza, the queen of Poland (in the years 1518-1557) had her manor in Jazdów, with an Italian garden. She is famous for introducing a number of vegetable species that are basic atributes of Polish kitchen. In the 18th Century, Jazdów became part of one of the largest urban east-west axial layouts of Warsaw (Stanislas Axis), with sophisticated geometrical compositions, parks, g**ardens, residencies. On the today’s site of the Jazdów** Settlement, there existed a village (relocated to the main line of the Stanislas Axis around 1780). To this day, the Polish Parliament has the address at Wiejska (Village street).

From 1794, army barracks and hospital brick buildings were developing in the area. In the end of the 19th Century the romantic Ujazdowski Park was laid out on the site of the former military drill square between the main avenue (part of the Royal Route and Calvary Road - Aleje Ujazdowskie) and the hospital grounds. The dominant hospital function remained here till 1944, in its last years serving the war victims. Some of the hospital buildings are still on their positions (three of them among the Finnish houses; one still used as day-care department of the Nowowiejski mental hospital). In the history of the area’s military and curative usage, local gardens served self-sufficiency, but during the war and until 1951 they were partly used as a provisional burial ground. From the summer 1945, first inhabitants were moving to Finnish prefab houses assembled fast in free spaces of the former hospital site. Their tenants were mostly architects and builders employed in Warsaw’s reconstruction. The new settlement, being a council estate, planned as temporary (for some 5 years), but much of it has survived to this day. What is remarkable is that the single-family houses from the war period, having the size of huts (about 50-60m^2 area each) served tenant families well enough to spend most of their lives here. Compared to all other council flats in Warsaw, they were so different; not easy to maintain but very much appreciated and often arising jealousy among those who looked at them as an example of luxurious location in the most attractive city district.

The houses were ready-made, but many of them have undergone transformations. Some were extended according to family needs, in spontaneous but modest variations. Features of this green enclave may be associated with generated structures of which Christopher Alexander writes in the context of living processes. “ALL the well-ordered complex systems we know in the world, all those anyway that we view as highly successful, are GENERATED structures, not fabricated structures”.

The houses themselves were, literary speaking, “fabricated structures” in respect to their primary design, but after decades and transformations, they play a subtle role in a generated landscape, where nature has got a dominant role. The houses’ special feature is that they could have been called “sustainable”, if this term were used in the time of their construction. This is for many reasons, not only because organic materials were used, but also for their modesty and flexibility to adjust to needs of their users. To continue the Alexander’s language, the Jazdów Settlement, as a whole, would most probably arise “more from the process than from an imagined design”. There was never any carefully detailed lay-out plan for the Settlement. Some houses were situated in line but mostly in clusters. Modest hedges, low fences and more organised paths came later, when inhabitants felt it necessary to achieve some privacy and protection from intruders. They also wanted to care for their gardens much better than the municipal services could.

One can feel all grades of spaces here – from public to private. Similarities can be found between the Jazdów Settlement and habitats of a similar history in Poland. Comparison can also be made of the atmosphere of Jazdów to the Finnish examples – like Puu Käpylä, the first larger area of wooden prefabricated houses (1926), based on the garden-city models. The other Finnish reference are the same types of prefabricated houses as in Jazdów that are still in a good condition in locations in Finland.

Figures 1 and 2: The landscape characters of Puu Käpylä in Helsinki and Jazdów Settlement in Warsaw.

1.2 Contemporary planning and ideas versus the identity of the Jazdów Settlement

When Poland was recovering from many years of annexation and from 20th Century wars, this part of Warsaw was to play its role in renewal efforts.

Two years before the time Poland gained its independence in 1918, there was a concept drawn for the general plan of Warsaw, in which a large complex of major Polish state administration buildings was proposed on the Warsaw Escarpment in the area of Jazdów. The competition for the Ministry of Foreign Affairs headquarters followed (1926). The entries presented gravely visions exchanging the hospital buildings with monumental edifices.The competition results were met already then with strong criticism in professional circles, as showing the proposed solutions as inadequate for the area. Anyway, the Parliament complex, developing next door, seemed to be a kind of neighbourhood good enough to give way to situate similar functions here. Although there have been a few major urban ideas or interventions (including decisions now and then to remove the Finnish houses), a “real” urban plan for the area has never been elaborated. The French and German embassies (1967-71; 2005-2007) were supposed to be first to start the “cleaning” of the site (to build the embassies, tens of houses were removed). The years 1971-74 marked a major change on the map as the motorway crossing the escarpment and cutting through Jazdów was built, dividing the area and causing removal of another number of Finnish houses.

From the beginning of the Polish transformation in 1989, the area started to draw attention again – as a valuable potential ground for investment. With the end of the communist era, there came the time for independent architectural and planning practice. Andrzej Kiciński – architect and urban planner, proposed the formation of the National Park of Art and Culture in the area of Jazdów, as an expression of the idea of the “Agora of Polish Democracy”. The concept was to preserve some of the characteristic features of the area (small scale, new buildings scattered among greenery). Any residential function was excluded though in the concept (the houses meant to be removed). In the year 2012 the municipality decided to take down all the houses and four of them were taken away from their sites for a start (they were later found in pieces in other places in Poland, advertised for sale). The demolition caused protests of inhabitants supported by active citizens. In result, workshops were organised within the framework of public consultations on the future of Jazdów.

The recommendations of the consultations were promising both for the development of citizen-democracy in Poland and the future of the Settlement playing an important socio-cultural role in Warsaw. In 2015, the newly elected district authorities decided, that no more Finnish houses would be demolished, no more tenants removed and that there would be a possibility to enliven empty houses with various activities. First agreements with non-governmental organisations having socio-cultural and ecological profiles, were signed for the period of one year (the time contested by new tenants as too short). In spite of the new decision, promising a new perspective, no clear future for Jazdów, from the point of view of planning, has been inscribed. Nothing is stabilized from the formal longer-term point of view. Aside of actual policies of the district authority, there is an undercurrent of contradictory opinions among urban planners and architects concerning the Settlement’s future. The non-governmental organisations are often felt as associated with city-activists who often protect vulnerable areas from over-investment.

The local plan has been in its design phase for years now. Its latest concept has been very simplistic, technocratic, taking neither the genius loci, nor any wider civic-society's needs into consideration. It just followed the general Study, in which Jazdów's destiny is administrative functions, eventually joined by services. In order to be able to get a realistic input into the local spatial development plan, the architectural and urban design competition has been prepared but not launched. The competition would not solve the problems which are being successfully dealt with on the grass-root level and according to the public consultations' results, with the perspective that a bottom-up plan could be prepared.

1.3 The potential gathered in Jazdów over last years

In 2012, as the process of displacement of tenants was pursued and houses started to be taken down, an important role was played by the Finnish ambassador, who even called upon sentimental bondage with his father supposedly working in the factory in which the houses were prefabricated. The working group was co-organised and hosted by the embassy and the Jazdów's tenants association, to discuss the future of the Settlement, or at least just save a few houses, where cultural activities would take place. Wider interest arised later on as many houses and gardens opened for activities (exhibitions, talks, meetings, concerts). The openness and inventiveness widened when the Open Jazdów (Otwarty Jazdów) initiative was non-formally established, with many of the houses and gardens coming back to life for a few months of summer. During the following season, the Social Dialogue Square was created in the centre to host music shows, film screenings, etc. Garage sales were organized. An apiary was situated around one of the houses and the Queen Bona's gardens were in a way re-started. Some houses and their gardens started to partially re-used. That year was marked by much pressure from the side of organizations and enthusiasts but there was little activity on the municipality's side.

Social process once triggered, is encroaching larger and larger areas in and around the Jazdów Settlement. There has been a large potential gathered of activities like workshops, study visits, architecture education activities for youth. Diploma works were made on the re-usage of Finnish houses by students of the situated nearby Interior Design Department of the Academy of Fine Arts. There were landscape architecture workshops of the Warsaw University of Life Sciences. The Faculty of Architecture of the Warsaw Technical University students had their surveying practices and workshops. The results of Polish – Finnish interdisciplinary design workshops on the themes connected with the visions of the future for Jazdów were shown during the exhibition "Warsaw under Construction". These are just some initiatives, but there have been many more – adding to the potential gathered for civic-management and bottom-up planning.

Figures 3 and 4: The multilateral communities – the Polish- Finnish working group in 2013 gathered to protect the Jazdów Settlement; the 2015 development of city-gardening (photo: Motyka i Słońce).

The public interest and debate has influenced at least the moods on the side of the official administration body (ZGN; Real-Estate Management Administration) and better relationship with the district authorities developed. The change of approach and increased visibility, meant more tolerance and the change of policy. Cultural and socially-oriented activities are being more and more imprinted in the physical space.

The generated structure, as described by Christopher Alexander, is continuing to develop as a process. Although during last few years not much has changed in Jazdów in respect of its basic structure, there are many examples of spontaneously planned and realised interventions. Some houses got new users, their surroundings got new

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

community gardens, some garden spaces that were "semi-privatized" are becoming still more open. There are projects realized, but until there is a more clear urban development plan, it is not possible for the new tenants (non-government organisations) to invest much in the renovations.

2. THE PERFORMANCE OF JAZDÓW SETTLEMENT

The Jazdów Settlement's everyday users can be recognized as groups having differentiated interests and rhythms of activity (residential, educational and socio-cultural, curative, gardening, recreational, administrative). There are 27 Finnish wooden houses, 7 of them still inhabited by the tenant population of about 20 persons. Inhabitants of the council flats (Finnish houses) are more or less integrated into the local community as a whole. There has never been any solid survey done, nor any research on the technical performance of the Settlement. Basic city services are in place, with the exception for heating and hot water. These were left to be solved by inventive users, usually adopting traditional wood or even coal burning stoves and electric devices. Some houses have been additionally insulated, although a larger number of them are just left as they used to be from the time they were erected – with a thin layer of fibreboards in the walls. The present purpose of efforts to overcome the Jazdów Settlement's crisis of becoming dysfunctional, is to fill all the existing structures and gardens with activities and not to lose the all-time inhabitants.

2.1 Striving for sustainability versus temporary status

The brick buildings in the Jazdów Settlement's area are listed (remnants of the former hospital). It does not mean they are under a real protection, being maintained in a proper way, but at least they cannot be demolished in the face of law. The Finnish houses are devoid of any conservator's protection. Some of them have been cared for by their tenants, some neglected. They are "poor by their nature" and it has always been like this with wooden structures in the Polish history. There is scarcity of timber structures, especially in Warsaw. On the other hand, the Finnish houses have their own extraordinary chance as they can be understood more as belonging to the organic and non-urban world and thus being a rarity. The other advantage is that they are characterized by natural dynamism of changes, mobility, diversity – the features looked for, when sustainability is striven for.

2.2 Election of study case

The danger of neglect and destruction on one hand and the grass-root efforts to protect the Jazdów Settlement on the other, brought many like-minded individuals and organizations together. Most of inhabitants feel connected with new initiatives but there are also some that protect their privacy still more. Both strategies are set for survival. Now, there are tens of organizations either using the houses and gardens or preparing to use them for their statutory aims. The topics tackled are such as: sustainability and ecological lifestyle (low footprint; assessment methods and optimization in planning), heritage protection, city-activism, continuation and development of therapeutic character and functions of the area (development of city-gardening), cultural and educational initiatives (with a possibility to cooperate with local schools and kindergartens, with the hospital, neighbouring embassies and public institutions), sports, scouting, cooking with refugees or folk music. There are possible exchanges and coalitions with similar territories (areas or enclaves protected and developed by local communities). There is also a collaboration developing among the institutions within the city district of Ujazdów, in which the Open Jazdów (Otwarty Jazdów) as the Partnership for the Jazdów Settlement is an active member.

3. THE PARTNERSHIP FOR THE JAZDÓW SETTLEMENT

In the last years, the activities of the community that gathered in and around Jazdów had a character of a coalition. In 2015, the Partnership for the Jazdów Settlement was formed as an informal group of interest, gathering the interested individuals, institutions and organizations, with the hope to work with many issues concerning the everyday management in a grass-root way and hopefully in cooperation with the municipality. There are a few working groups: Environment and Building, Social Economy, Civic-management, Culture and Education. The Partnership has a chance to work out a model of such management and advocacy for the Settlement that would fit most its character and enhance the community spirit. The initiatives wpuld not have achance to develop this way without one person – a dedicated young inhabitant (Andrzej Górz).

3.1 Research into urban autonomies, to work out the governance model

The Jazdów Settlement has a chance for experimenting a certain autonomy, not having to depend on questions of land ownership. Uncertainty concerning the future plans of the land-owner ("the city") is an understandable problem though. The fact that the land belongs to the municipality (meaning everybody) may be treated as disadvantage on one hand, but an advantage on the other (as far as there is dialogue, understanding and will to work out a common set of values). For the city administration and services, such a kind of settlement has always been an uneasy case to deal with. The routines are often not in tune with the area's specific character and this is not only the problem of Jazdów. It has been suggested by the Partnership for the Jazdów Settlement that all projects concerning public space improvements or just changes within the public spaces in this area were postponed until a general concept or the awaited local plan are worked out. To find the best civic-management model, the study supported by the European Culture Foundation has been launched. Its goal is to research the similar cases in Europe in order to develop a practical formula for cooperative, cross-sectoral, community-based management for the Jazdów Settlement. The research phase is to choose and analyse the best practices of creating and functioning of community managed entities (the best if having a special legal status compared with such as those of cooperative housing, trade cooperatives, allotments, etc.). The development phase is to bring together partners from the municipality of Warsaw and other foreign as well as Polish partners, to tailor two solutions: the model of management for the Jazdów Settlement and the regulations for the City of Warsaw that would allow for collaboration between the municipality and the Jazdów Settlement, to sustain Jazdów in the long term.

The study is to find out what experiences are possible to share between similar places-initiatives (specially of a certain level of an urban autonomy). The criteria were set to compare the Jazdów Settlement with other places of similar character:

- inhabited (a least to some extent); - physical space larger than one building; - diversity and accessibility; - growing out of civil society initiatives; - the property status regulated; - the managing organization diversified, multi-sectoral; - the activity agenda accessible to all, with a character of public mission; - transparent (everybody may participate or follow the processes); - sharing-economy elements included;
- an ecological agenda (self-sustenance, renewable energy, ecological education).

3.2 Jazdów as a possible expression of citizen democracy

A few inhabitants of the Jazdów Settlement were not representative enough to be recognized as a citizen group to have a strong, valid voice. They seemed easy to be dealt with, when the "clean-up" policy was implemented. Scared and unable to react, while the steps of the municipal authorities were offensive and consequent. There were losses as some houses were taken down and a number of inhabitants have left the place. Fortunately, some of them proved to be able to stay. It seemed natural that a larger community would soon gather around those endangered as the place itself having this particular character proved to be needed by a larger population. In result a shared feeling of ownership, as well as strength of togetherness have developed.

3.3 Conclusion: would the model of Jazdów be transferrable?

The partnership model for a unique generative structure like the Jazdów Settlement is aimed at sustainability in everyday practice. Active communities characterized by openness and diversity have a chance to perform as hubs of urban knowledge and experience. If only they are allowed to survive and – still more – supported to develop, their feedback, or rather their mission, may be to influence the basic city policies and help with their implementation, as well as transfer the achieved results further on. Multilevel urban governance, and especially the community governance methods may be enhanced if civic-managed areas are allowed to flourish. The research in civic-management and experiences of the Jazdów Settlement shows that citizen empowerment may still become stronger through the art of working together in a challenging situation of a village-like settlement in the middle of the city. It is possible that small communities (autonomous to a certain extent) and municipalities may come to agreements in order not to govern in a schematic way but to cooperate, allow for a free flow of exchanging ideas, knowledge, experiences.

ABSTRACT

The development of productive transforming of urban transport land has got more and more attention. And We divide it into three categories, the first one is three-dimensional and efficient use of transport land to conserve land resources; The second is the fuse of traffic space and its other neighbouring urban functions to achieve efficiency multi-functional mixed land use; And finally, it is the integration of traffic space with urban productive space directly that not only can achieve efficient use of mixed land, but also provide a more direct way for the sustainable city. Currently, the research and practice for the first two phases have been fruitful, but the research of the last one is still in its initial stage or under exploration.

The paper attempts to analyze the technologies of transport production. If divided from transport space's type, these technologies can be divided into three types. The spaces on two sides of the road and especially the large-area road buffered region or idle land can carry out more types of energy production technologies, including renewable energy utilization and agricultural cultivation. Finally, we analyzed New York landscape architects Starr Whitehouse's three concepts of the Brooklyn-Queens Expressway to show three categories of transport production.

Keywords: traffic space, productive, energy, agriculture

1. INTRODUCTION

Transport is an important link that connects the multiple functions of land use. However, the environment created by urban transport, as the process space that connects the beginning and ending of people's daily life, is often neglected by people in planning and constructions. Everyone will contact and feel the "third space" of a city —the influences of the urban transport environment on citizens are non-neglected. In The Death and Life of Great American Cities, there is one paragraph that perfectly expounds on this opinion. A city sidewalk by itself is nothing. It is an abstraction. Streets and their sidewalks, the main public places of a city, are its most vital organs. The massive energy consumption and land waste have a serious effect on the environment of urban traffic. The urbanization of China has consumed as many as 40 percent of cement and over 50 percent of steels in the world. As the basic infrastructure of urbanization, urban traffic has emerged as one of those sectors consuming the most energy in China. The automobile powered by the gas and diesel have contributed about half of the emission of carbon monoxide and nitrogen dioxide in the atmosphere. The development of electric vehicles in recent years can relieve the pollution caused by urban traffic to a certain extent. However, it should be noted that the electricity is still used as the source of secondary energy in China. China is heavily reliant on the burning of coal, which will result in more pollution. Hence, the key to easing the pollution in the urban environment should lie in the development of renewable energy. Due to the mind-set that building more roads can help to deal with traffic congestion, the area of the land used for urban traffic has been on the increase. It turns out that traffic congestion has become an increasingly more serious issue. Many experts on urban transport in the USA and Europe believe that most of the space for urban road in China has not been fully utilized. If some appropriate actions can be taken, the traffic capacity will be increased by 30 to 50 percent.

In a word, the environment of urban traffic is faced with many problems, including the urban structure lacking the connectivity, the constraint on urban vitality, the huge energy consumption and the low efficiency of land use. With the purpose of solving those problems, further efforts can be made to combine urban traffic with production city. It can fully realize the urban potential for production, which will also provide a new solution to the urban sustainable development.

2. ANALYSIS OF PRODUCTIVE

The developmental process of the human society has undergone the separation from traditional production functions from the city. To change the problems by the current city's emphasis consumption and enable the city to achieve more sustainable development, the concept of productive is being emphasized once again and returns to city. Such a production is not limited to agricultural production, yet it includes richer connotations.

By absorbing experience from foreign theories and combining the author's conclusions and thoughts, Professor Zhang Yukun of Tianjin University of China attempts to set up a theoretical system of "production city" that has richer connotations. "Production city" is a multiple-layer urban-town system that takes green production as the main characteristic and integration; by using the basic means of reservation, replacement, superposition, integration and reconstruction, attempts to establish a perfect industrial structure within the most appropriate region, which provides new thinking for a city's sustainable development. Such urban planning concept emphasizes the active "production" functions of a city, and incorporates the "saving" function that is traditionally considered as passive into the "production city" theoretical system. It is thought that "saving" is also a type of "production" from a certain perspective.

The intensive utilization of land and space can be referred to as a production function of the space. To a certain extent, the integration of urban transport and architecture can realize the spatial production of urban traffic system. But in most cases, the compensation has been confined to the urban traffic or the area surrounding the transportation junction featured by the frequent change of means of traffic. The majority of the linear urban road can not directly combine with architecture space, but there is still some potential for production function. If the urban roads which have been neglected can be fully utilized for the production of space, it will create huge benefits for the sustainable development of the city.

3. CLASSIFICATION OF PRODUCTION OF TRANSPORT SPACE

The productive urban transport can be divided into three types: From the perspective that saving is a type of production, the efficient land use of transport is productive; secondly, the complex land use of urban transport space improves the efficiency of land use; the third type is directly integrating the space of productive functions and transport spaces, which has become a completely new means of reforming the transport space.

3.1 Efficient land use of transport itself

As early as the Renaissance, Leonardo da Vinci proposed the thinking of "the system of pedestrian and roadway 3-dimensional dividing". German planner, Ludwig Hilberseimer, proposed the 3-dimensional transport plan that different planes divide the human traffic and vehicle traffic. In the current day that emphasizes green traveling, people are trying to use the complex transport space to improve the utilizing efficiency. Comprehensively utilizing the urban road space and especially the urban road underground space is one of the important means of efficiently utilizing urban road space.

The TransGlide 2000™ Bicycle Transit System is a new strategy in bicycle transport. This technology increases the efficiency of the bicycle by providing an environment within which bicyclist can ride comfortable, making the bicycle a faster, safer, less expensive, and more convenient mode of transport in urban areas. STS's Transglide 2000™ bicycle transit system has many advantages. (Figure 1)

Figure 1: The TransGlide 2000™ bicycle transit system (http://www.biketrans.com/gallery.html)

3.2 The mixed-function land use of transport

One of the urban transport's roles lie in connecting various functional spaces within the city, so that people can come and go more conveniently and effectively. The current cities attach unprecedented attention to transport, yet the wide and dense roads bring more trouble to the crowds that go through the city. This is because these traffic facilities cut the city's continuity, forcing various functional relations in the city to be more distant instead of being denser. An increasing number of architects, planners and landscape designers have already noticed the problems existing in the urban transport and thought about the new urban transport space. They attempt to establish closer relations between the urban transport and the architectures & landscape with various urban functions. They even integrate these two into one. The urban transport space can be carried out smoothly and safely. It can also be abundant, interesting, comfortable and enjoyable. In the 3-dimensional urban spatial coordinates, the transport space can be inserted with the architectural space through various dimensions and stacked up.

The student of British Bartlett School of Architecture, Alex Sutton, proposed a new concept in his graduation work—In the future, airports do not need to be constructed in the suburbs and airplanes can take off over the street. The future airport should be one part of the city. (Figure 2) Such a designing that transport fundamental facilities will be dissolved into cities attracts full attention and affirmation from people. It can be seen that the integration of urban transport and a city's other functions is very necessary.

Figure 2: Concept of future airport (Alex Sutton, 2016)

3.3 The combination of transport and production

If the concept of productive space is introduced into the transport space, it will achieve the sustainable development of urban transport to a larger extent and bring unexpected social, economic and ecological benefits.

Solar Serpent is a case involving the land use of transport for energy production. Developed by the Mans Tham who is a Swedish architect and urban planner, it is a device which can provide energy for the expressway by making use of solar power. In 2010, the design was unveiled at the Summit Conference of Major Cities of the World held in the University of California, Berkeley. Because the traditional solar power generation occupies a large area of land, the limitation of land resource has become a major constraint on the utilization of solar power. If the upper space of the expressway stretching for about 800 kilometers can be utilized for solar power generation on a large scale, it will save the land greatly. Moreover, Solar Serpent also has many advantages. Firstly, the most direct advantage of utilizing renewable energy is to reduce the emissions of harmful gases. Besides, when the transport system carries out energy production, using the spaces over and onee both sides of the road may have some indirect advantages of this transport system's energy conservation. For example, setting up the solar PV panel up the road can effectively block the radiation of sunshine on the road, lengthen the life of the road and lower the costs of maintaining the road. It also plays a certain role of promoting the transport tool's energy conservation on the road. The solar panels on the road can block solar radiation for driving automobiles and prevent the AC's energy consumption caused by rising temperature within the vehicle in summer.

If a city can carry out agricultural production, it can not only solve the pressure on agricultural production brought by the rural population's migration, but also make the urban life more comfortable and ecological, which alleviates the urban problems brought by urban expansion and prevent reverse-urbanization phenomenon to some extent. The urban transport land use is a type of land that accounts for a high proportion in urban land. It needs to take the transport greening and buffered land as affiliated land. If we can fully utilize the scattered land for agricultural production in these cities, it not only can solve the grain problem to some extent, but also plays a certain ecological role in the urban transport. It also brings more attractive landscape outcomes for urban residents' traveling.

4. TECHNOLOGIES OF TRANSPORT PRODUCTION

Energy harvesting technologies from road infrastructure is a new research territory that encompasses technologies that capture the wasted energy occurred at pavements, accumulate and store it for later use. Eventually, the paths of gathering energy still depends on various scientific technology, such as nano-science, electrical science, machinery and environmental engineering. These technologies can be applied into transport panning and transport infrastructure facility construction. New technology will bring new thoughts for transport planning. It is also necessary for urban planning designers to get to know and master these technologies.

We can find out that these technologies can be divided into asphalt solar collectors combined with pipes; photovoltaic applications (PV); piezoelectrical and thermoelectrical generators; induction heating and; phase change materials and nano-materials. If divided from transport space's type, these technologies can be divided into three types: on two sides of the road, on the road's surface and over the road. If fact, the spaces on two sides of the road and especially the large-area road buffered region or idle land can carry out more types of energy production technologies. (Table 1) These technologies are not restricted by the transport space and only utilizes transport land efficiently. Therefore, they are not enlisted in the statement, including renewable energy (solar energy utilization, wind energy utilization, biological energy and other renewable energy) and agricultural cultivation.

Traffic Space	Energy Harvesting Technologies
Side Space	PV-Noise Barriers
Surface Space	Piezoelectric Sesnsors PV-V2G Induction Charging Nanomaterials Phase Change Materials TNO
Upper Space	PV Canopies Asphalt Solar Collector/Hydronic PV Bridge Roofs

Table 1: Comparing the energy harvesting technologies applied to different traffic space

5. CASE ANALYSIS

Brooklyn-Queens Expressway(BQE) was completed in the 1950s. A lower groove was used to change the twisting lines at the upper layer, which could ease the traffic congestion at that time. The BQE which was built had divided the physical surrounding into two parts. It also formed an unnatural boundary between them by splitting and even damaging the surrounding environment. The existing roads which connected sidewalk and pedestrian overpass were not wide enough to satisfy the needs. In addition, the overly high speed of those vehicles on the road would

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

pose a hazard to human safety. With the automobile exhaust and noise pollution of BQE spreading to those communities around, it had affected the life of local residents.

New York landscape architects Starr Whitehouse came up with three concepts to improve the Brooklyn-Queens Expressway, the first concept called Maximum Green, the second one Connections, and the last one Green Canopy. These three concepts explain the transport space's production from three aspects. (Table 2) In Concept 1, maximum green is one designing of utilizing transport and mixed-function land use, fully utilize the road's buffered space and carry out greening or grow agricultural plants. In Concept 2, connotation is a highly-efficient utilization of the transport space and a transport designing of carrying out 3-dimensions on limited land area. It adds more relations on the original roads to alleviate the division of transport on the city's original fabric. In Concept 3, green canopy is the designing of integrating transport and production, which achieves the integration by combining the PV panel and green integration. As shown in the survey, the transformation elements in the first two concepts have been recognized. The Concept 3 has won the most support from the community. In other words, the community can well accept the combination of urban traffic environment and production city. Instead of broadening the road to improve the environment on the two sides of the road, BQE Enhancement Project has resorted to increasing the area of green land and creating more connections. A variety of methods have been employed to make the urban transport more public and human-centered. It has combined the urban transport with the community more effectively. What is worth mentioning is that Green Canopy has successfully introduced production function into the transformation of urban traffic environment. Hence, it has solved those problems faced by the base quite well.

Concept	Benefits	Drawbacks
Concept1 Maximum Green 	● Slow traffic ● Shortens crossing distances by 11 feet ● Adds 6500 square feet of pedestrian space ● Adds nearly 1 acre of plantings and 412 new trees ● Employs innovative storm water capture and reuse system ● Optional to reduce noise at street level.	● Limited noise reduction ● Does not increase accessibility ● Parking would be substantially limited and would require heavy enforcement
Concept2 Connections 	● Reconnects severed cross streets ● Increases connectivity for neiborhood ● Slows traffic ● Adds plantings,trees,and storm water management system ● Optional to add up vines ● Potential for solar cells income	● Limited noise reduction on Hicks Street ● Expense of each bridge
Concept3 Green Canopy 	● Visually screens the highway ● Adds 100000square feet of vines ● Reduces noise by 9 decibels at street level ● Potential for income from photovoltaic panels ● Reconnects severed cross streets ● Slows traffic and manages storm water	● High cost ● Major construction on Hicks Street

Table 2: Comparative analysis of three concepts

6. CONCLUSION

The research on the transport space's production can determine the transport system's green production from the quantitative perspective, which plays a certain role in promoting the society, economy and environment. Besides, it also has many research values and meanings.

The power generation for urban traffic system is of significant meaning to easing the shortage of power supply. With the drain of conventional fossil energy, new energy should be found to satisfy the growing demand for urban energy. As a type of new energy which is not exhaustible, the renewable energy has the advantages of huge

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

reserve and clean production. Hence, the renewable energy can be utilized in the traffic system so as to reduce the use of fossil energy and air pollution. The electricity produced can integrate with the urban power grid, thus satisfying those urban residents' need for electricity. The agricultural production of traffic system can infuse new vitality to the dense urban space with the simple function. To a certain extent, it can also ease the over-concentrated function of urban space, tackle the traffic congestion and reduce the urban pollution. The plants can also improve the urban micro-climate and ecological environment by absorbing the carbon dioxide through the photosynthesis. All of those functions must be realized based on the urban traffic system. The greatest advantage is that it can achieve the intensive utilization and production without occupying a large area of urban land.For the urban planning, it is necessary to consider various production measures and functions at the beginning of the planning, carry out overall planning and coordination of various urban spaces, including production, transport, living and entertainment. It is also necessary to analyze the space that sunshine can radiate and the land space with fertile soils, so as to reach the aim of achieving resource, energy and production to the largest extent. The aim and procedures of the transport system's green production have reforming changes and meanings, which make people consider more influence factors and involved aspects in the urban planning.

Nature-based Urban Space Transformation

Kristin BARBEY[a]

[a] *Karlsruhe Institute of Technology, Germany, kristin.barbey@berlin.de*

ABSTRACT

Climate change and climate impacts require in consequence of their anthropogenic causes a changed handling of space and nature. The objective of this research project is to develop a consistent Integrative Spatial Concept towards a Nature-orientated, Climate-friendly Metropolises 2050, looking for the best place to implement most efficiently the different measures of Climate Protection and Adaptation in the urban and regional context. The Concept of Interacting Strategies: Nature Development and Urban Restructuring and Energy Transfor-mation and The Principles of Connecting and Interacting within a participative process present a path of spatial sustainability in an ecological, aesthetical and sociopolitical regard. The Project Nature is the content base of the Integrated Spatial Conception Climate Protection and Adaptation and the objective of all spatial decisions.

The special challenge in the realization of spatial strategies for Climate Protection and Adaptation and in the success of the transformation is about The Principles of Connecting, Cooperating and Interacting. The upcoming tasks will only be accomplished through a common Societal Act of Solidarity.

Finally the paper questions the transfer of the presented local and regional strategies to the mega-urban level and demands a new Transdisciplinary Thinking considering the entire body of a Megacity.

Keywords: *Integrative Spatial Concept Climate Protection and Adaptation, Project Nature*

1. INTEGRATIVE SPATIAL CONCEPT CLIMATE PROTECTION and ADAPTATION

Out of the overview of already established concepts in European metropolitan regions and due to the analysis of recent research results in climate change and spatial development, forestry and energy science, space and water management, planning theory and nature philosophy, The Concept of Interacting Strategies:

Nature Development and Urban Restructuring and Energy Transformation on every spatial level and scale: Region and City and District and Quarter and House is developed, including the essential theoretical basis for the spatial conception. (Barbey 2014, 50) Within the conception of The Integrative Spatial Concept, the question of the theoretical basis for spatial design and decision-making processes is fundamentally important as well as the definition of priorities and the consideration of spatial effects within the integrative setting of different strategies with the aim to achieve spatial sustainability even in an aesthetical sense. (Barbey 2012, 7-9)

1.1 The project nature

The content basis of the spatial concept, developed in this research project, is the Project Nature. The recognition of the anthropogenic responsibility for global warming and the related climate impact as observed by the IPCC 2007 and 2014 demand the change of the previous form of anthropogenic spatial use (e.g. CO_2 emissions → atmosphere) in expression (e.g. CO_2 emissions) and development (e.g. land use). Climate change and climate impacts require in consequence of their anthropogenic causes a changed handling of space and nature. (Barbey 2014, 50) The content basis of the spatial concept: the Project Nature, starts with the basis of the climate change problem: the way of handling nature. The anthropogenic (man-made) causes of climate change besides natural effects of loss of genetic diversity, species and ecosystems results in a major part on the ignorant way to treat nature: nature has to take up a central position within the discourse and the conception of future spatial development perspectives. (Barbey 2012, 8)

The Project Nature signifies the theoretical background and conceptual basis of the spatial concept and represents within the setting of the Spatial Strategies Climate Protection and Adaptation, the strategic objective for the spatial decision. All represented spatial strategies (Nature Development and Urban Restructuring and Energy Transformation) are orientated according to the Project Nature. In the process of the Integrated Spatial Conception, the orientation on the strategic aims of the Project Nature is of primary importance for the development of future

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

decisions in dealing with space. The Project Nature includes the qualification of ecological potentials, the stabilization of ecosystems and the renewal of existential space substance. The principle of the ruthless use of natural resources (e.g. CO_2 emissions → atmosphere), as the actual cause of the expected damaging effects of anthropogenic climate change, must be turned into the principle of saving, protecting and developing nature. It is the fundamental project to secure the human existence and maintain decent living conditions as well as to sustain actively Climate Protection and Adaptation. Climate protection, climate adaptation and energy transformation have to be placed on every spatial level and scale. To develop a Nature-orientated, Climate-friendly Metropolitan Region the following strategies are essential: Nature Development and Urban Restructuring and Energy Transformation. The Concept of Interacting Strategies: Nature Development and Urban Restructuring and Energy Transformation has to be developed in the local and regional context on all spatial levels: Region and City and District and Quarter and House. (compare Barbey 2014, 50)

The Project Nature is inspired by the german philosopher Gernot Böhme, who explains in “Die Natur vor uns” (“Nature ahead of us”): The challenge to mitigate climate change and to adapt to its impacts lies ahead of us, as well as “to recognize the state of nature as a common task”. “This signifies not only the conservation of nature as something given, but rather the establishing [or development] of nature, even a state of nature, […] that provides a humane existence in foreseeable future. […] Nature lies ahead of us: as a challenge”, “Nature has become finally […] a project.” (Böhme 2002, 10-26-28)

The process of urban development, which usually begins by the setting of building - and Infrastructure into the open space, should now start from the consideration of the natural conditions (invers). Urban development should be orientated, adapted and integrated to the natural, climatic, and geographical conditions of the site in the local and regional context. The globally accepted philosophy of sustainable development does not provide a profound response to the quintessence of the essential question of our century: the human relation to nature. The fundamental philosophical and ethical basis for a changed handling in respect of nature is needed to give a contemporary societal orientation by a forward-looking explication of the human relation towards nature. Essential aspects of “the respecting appreciation in contrast to the annexation or exploitation of nature” are mentioned e.g. by the German philosophers Martin Seel and Jürgen Habermas, who describes “the immediate aesthetical perception of nature as the essential premise of the potential appreciation of nature”. (Habermas 1997,99)

1.2 Aesthetical principles

With the intention of combining ecological and aesthetical aspects in the spatial qualification of the metropolitan area, aesthetical principles are defined in addition to the mentioned ecological principles of the Project Nature, which are in the consideration of the integrative spatial concept of adequate relevant importance. These aesthetical principles orientate the design and the decision making process of the spatial setting to a substantial aesthetic level and represent basically the spatial principles of Concentration and Protection as well as the paradigm of the 21st century towards a sustainable development related to a changed handling of space and nature: Ressource Saving and Energy Efficiency. (Barbey 2014, 50)

2. NATURE-ORIENTATED, CLIMATE-FRIENDLY METROPOLITAN REGION

Applying this content basis and reflecting the particular site-specific consideration such as natural geographical and urban spatial, climatic and energetic parameters, the Integrative Spatial Concept is developed for the metropolitan region Rhine-Neckar with a view to achieving a Nature-orientated, Climate-friendly Metropolitan Region Rhine-Neckar 2050 (Figure 1). This research project is an exemplary attempt to develop a consistent spatial concept relating to the Metropolitan Region Rhine-Neckar (5.640 km^2, 2,4 Mio. inhabitants, the warmest region in the south-west of Germany with projections of increasing heat, rain and flood events, dense polycentric urban structure of cities as Heidelberg, Mannheim and Ludwigshafen and villages in a diverse open space and landscape structure, important universities and highly industrialized urban poles situated in a beautiful Rhine-valley landscape framed by hilly Palatinate and Odenwald forests, confluence of Rhine and Neckar) and the City of Mannheim (145 km^2, 300.000 inhabitants) looking for the best place to implement most efficiently the different measures. As an informal planning instrument, the Integrative Spatial Concept could be the basis for discussions and civic participation with the intention to support the spatial realization of the climate protective and adaptive transformation. (compare Barbey 2014, 50-51)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The design and the decision making process of the spatial concept is furthermore based on the results of different regional studies and some interesting aspects in existing urban and regional concepts. Combining the knowledge and database of transdisciplinary regional research (climatic, demographic and spatial development, forestry and energy science, space and water management, planning theory and

nature philosophy) as well as discussing and verifying the most efficient position (even in an aesthetical sense) for every measure in the local and regional context (compare Barbey 2012, 7-8-9), the spatial concept shows, which appropriate strategies for climate protection and adaptation should be placed where and at which place such measures could be concentrated to advance Climate Protection and Adaptation and to realize the processes Nature Development and Urban Restructuring and Energy Transformation actually on a grand scale. The catalogue of strategies, which could be considered as a kind of Roadmap 2050 Climate Protection and Adaptation for the Metropolitan Region Rhine-Neckar, is considered to be forward-looking. (compare Barbey 2014, 51)

2.1 Recommendation for actions in metropolitan regions

In the sum of the interactive strategies Nature Development and Urban Restructuring and Energy Transformation, for which the effects can be approximately valued on the results of recent scientific reports, 50% energy can be saved, 70% CO_2 emissions can be reduced and 100% of the electricity demand can be covered by renewable energies in 2050. The Integrative Spatial Concept shows the potentials of Climate Protection and Adaptation, the focus of strategies and the combination of measures and their interacting effects and synergies. It represents concentrated activity of priority action areas as well as challenges of local and regional interaction. It locates the objectives Climate Protection and Adaptation and formulates the idea Nature-orientated, Climate-friendly Metropolitan Region 2050 as a common task for local stakeholders and the metropolitan society with a concrete time frame. In the general view of the integrative spatial concept a self-evident picture is developed within the implementation of the different measures. The conception of the spatial setting of the strategies in the plan seems partly self-evident, which is caused by the exact consideration of the site-specific geographical reference and about the Where and How of the integration of measures in the spatial context. The spatial effects of the strategies serve besides Climate Protection and Adaptation to substantial improvement of ecologic and spatial aesthetic qualities. (compare Barbey 2014, 51)

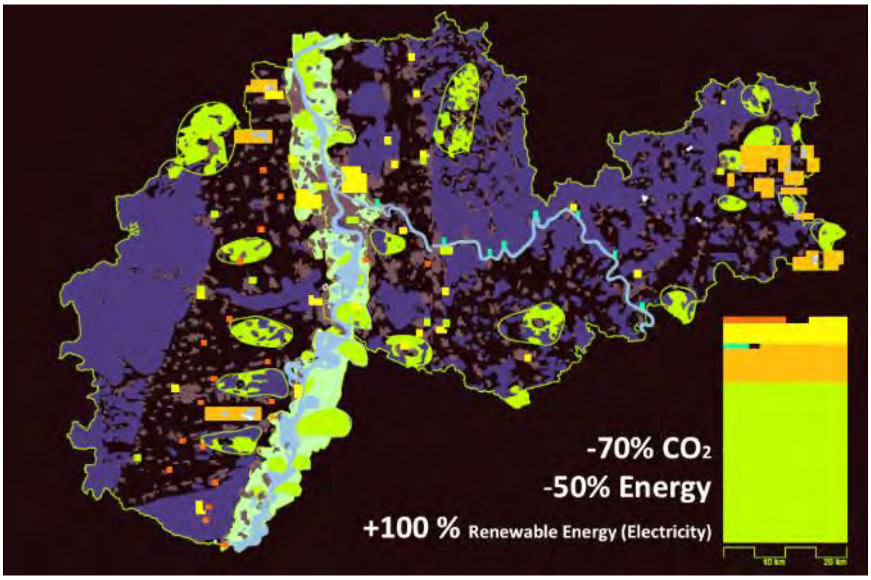

Figure 1: Nature-orientated, climate-friendly metropolitan region 2050
legend: green: new forests, orange: wind energy, yellow: photovoltaics, turquois: hydroenergy red: geothermal energy

The strategies are located within the conceptual designing and decision-making process in Figures 1 and 2 according to the analyzed specific characteristics and abilities of the particular spaces and describe the spatial potentials for Climate Protection and Adaptation in metropolises and metropolitan regions. The overall view of the integrative concept shows the synergetic principle of the interaction of Nature Development and Urban Restructuring and Energy Transformation for Climate Protection and Adaptation. This approach is explicitly oriented to the spatial possibilities and geographical as well as natural conditions of the sites and the existing urban building stock. In the setting of the measures the spatial aesthetic principles mentioned above, have been applied under the title: Concentration and Protection or rather keeping free, which will be explained here with a few examples:

***The principle of emphasizing the natural characteristics**:* The Rhine valley is emphasized as landscape-park with new forests and retention areas. The Palatine and the Odenwald forests are kept free of energy-related interventions. They are protected and presented as specific natural treasure of the metropolitan region. ***The principle of integration in the environmental context**:* New forests are integrated in the sparsely wooded Rhine valley, in the Kraichgau, in the landscape along the Rhine and as urban forest in the cities and additional forest in the Odenwald forest. ***The principle of spatial concentration of structural, natural and energy-technical interventions as well as the continuance of existing potentials**:* Five wind parks are concentrated and connected to existing wind parks and existing networks. According to the priority positioning of the strategy *Nature Development*, the construction of wind energy plants in the Palatine forest and Odenwald forest is a taboo – environmental and landscape protection play the major role in decision-making. ***The spatial characterized choice of location (choice of the adequate location, by weighing up climate protection, climate adaptation and spatial aesthetics)**:* Industrial and commercial areas have the greatest potentials for generating solar power compared to other urban space typologies, because of their large roof structures, as well as façade surfaces. In these areas the energy yield is the highest. For this as well as for aesthetic and practicable reasons (simplified realization of civic power plants), an urban concentrated use of photovoltaics is recommended.

Table 2: Examples of spatial aesthetic principles and their application (Barbey 2014, 51-52)

3. NATURE-ORIENTATED, CLIMATE-FRIENDLY METROPOLIS

The regional strategies: Nature Development and Urban Restructuring and Energy Transformation are transferred to the local level: Green Metropolis and Inner City Development and Energy Efficiency and Energy Generation and the concept Nature-orientated, Climate-friendly Metropolis Mannheim 2050 (Figure 2) is developed to show in addition to the regional (Figure 1), the urban spatial potentials of Climate Protection and Adaptation. Only in the interaction of integrated regional and local urban strategies the spatial ambition: Nature-orientated, Climate-friendly Metropolitan Region 2050 could be realized. (Barbey 2014, 52)

3.1 Recommendation for actions in metropolises

The following recommendations for actions in Metropolises are derived from the conception Nature-orientated, Climate-friendly Metropolis Mannheim 2050 (Figure 2):

1. Consideration of the natural green space as starting point in urban planning processes and as basis of future urban development:

Establishment of a continuous green space system to develop a resilient spatial structure, which connects the different quarters of the city

Development of the individual urban districts as nature based objects on the ground of the natural green space

2. Development of the individual urban districts as functional clusters of Climate Protection and Climate Adaptation:

Interaction of the concepts Green Metropolis and Inner City Development and Energy Efficiency and Energy Generation, which in total creates a Nature-orientated, Climate-friendly and Water-sensitive Metropolis 2050

3. Nature-orientated, Climate-friendly and Water-sensitive urban development including in every quarter: Concept of Green Metropolis and Concept of Inner Urban Development and Concept of Energy Efficiency and Energy Generation with the aim to develop Spatial Qualities and Spatial Sustainability in the City. (Barbey 2014, 52-53)

4. PRECONDITIONS FOR CLIMATE PROTECTION AND ADAPTATION

The Concept of Interacting Strategies

The Concept of Interacting Strategies Climate Protection and Adaptation:

Nature Development and Urban Restructuring and Energy Transformation and The Principles of Connecting, Cooperating and Interacting must be developed on the essential level of preparation: Climate Policy – Spatial Concept – Climate Economics, on the level of realization: City – Energy Providers – Entrepreneurs – Citizens – Planners – Universities and on the spatial level: Quarter and City, Metropolis and Metropolitan Region, Metropolitan Regions and Nations, Metropolitan Regions Global

Metropolises and Metropolitan regions are important global players towards Climate Protection and Adaptation. Only in the global network of metropolises and metropolitan regions and their interacting spatial strategies, the essential effects of climate protection and climate adaptation can be developed on a global level and the aims of Climate Protection and Adaptation can be reached. (compare Barbey 2012, 340-341)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

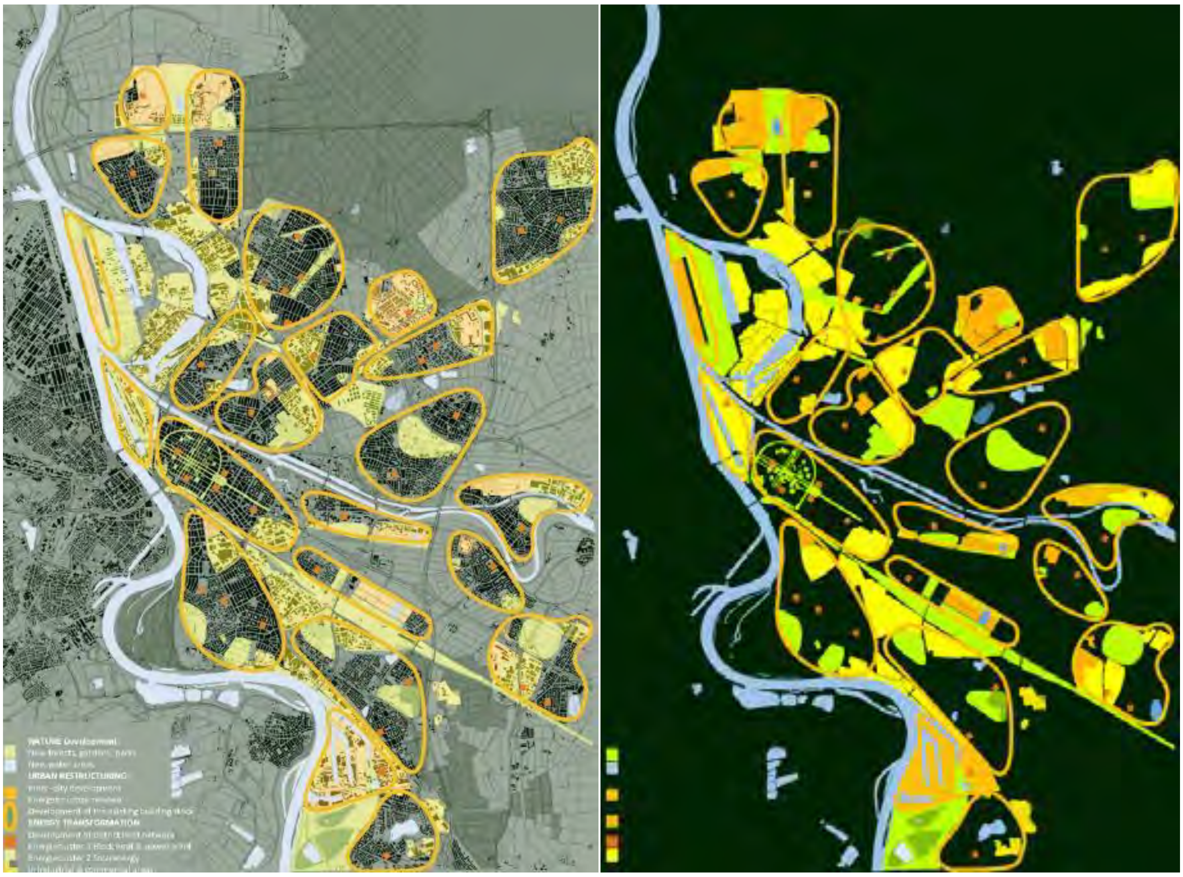

Figure 2: Nature-orientated, climate-friendly and water-sensitive metropolis 2050
Legend: nature development / green metropolis: green: new forests, gardens, parks, blue: new water areas urban restructuring / inner city development: orange: inner–city development, energetic urban renewal, orange line: development of the existing building stock energy transformation / energy efficiency and energy generation: development of district heat network, red: energy cluster 1 block heat and power plant, yellow: energy cluster 2 solar energy in industrial and commercial areas

Political commitment Climate Protection and Adaptation

First experiences in the implementation of the mentioned international examples point to the essential role of political commitments for the spatial implementation of the formulated political aims. Political commitments have to be represented in spatial concepts with a concrete time horizon of realization. They have to correspond to the space and its specific conditions. (Barbey 2014, 53)

The Principles of Connecting, Cooperating and Interacting

The special challenge in the realization of spatial strategies for Climate Protection and Adaptation and in the success of the transformation is about The Principles of Connecting, Cooperating and Interacting. The upcoming tasks will only be accomplished through a common Societal Act of Solidarity. The Concept of Interacting Strategies Climate Protection and Adaptation on the societal level points to the potential to realize appropriate strategies as well as to achieve an appropriate impact of Climate Protection and Adaptation by the societal network of a cooperating citizens and stakeholders. (Barbey 2014, 53) The Interaction of political commitment and civic participation is a key condition to realize Climate Protection and Adaptation. Politicians, citizens, entrepreneurs, planners, architects, engineers, economists, sociologists and artists have to work together to create intelligent solutions for a sustainable urban development. The consistent Integrative Spatial Concept Climate Protection and Adaptation could be the basis for discussions and civic participation with the intension to support the spatial realization of the climate protective and adaptive transformation.

4. CHANCES

Nature Development – Urban Restructuring – Energy Transformation

are qualification processes, which can lead to an improvement of existing qualities.

Nature Development → Chance of ecological (+ aesthetical) Qualification

Urban Restructuring → Chance of aesthetical (+ ecological) Qualification

Energy Transformation → Chance of sociopolitical (+ ecological) Renewal

In connection and interaction of these strategies a development path of sustainable spatial development will be developed in an ecological, aesthetical and sociopolitical regard. (Barbey 2014, 53)

5. NATURE-ORIENTED, CLIMATE-FRIENDLY MEGACITY 2050?

The presented Integrative Spatial Concept sets an example of a possible path towards a Nature-based, Climate-friendly Metropolitan Region 2050. Every mentioned Spatial Strategy and Principle for Climate Protection and Adaptation is generally applicable in every City and Metropolitan Region in Europe and beyond. In addition the described Process of Conception is generally transferrable to every City and Metropolitan Region in the world, always supposing that the selection, the dimension and the combination of strategies are well adapted to the site-specific spatial, energetical, climatical and cultural conditions. After focusing Spatial Strategies Climate Protection and Adaptation on the level of the Metropolitan Region and the Metropolis, the open question is now: will it be possible to transfer the presented strategies even to the level of Megacities? The overview of existing social and ecological problems in Megacities demands the creation of new ideas and new planning strategies - the responsible view towards a Nature-orientated, Climate-friendly Megacity challenges certainly an Integrative, Transdisciplinary Thinking to figure out possible solutions at the local mega-urban level, considering imperatively the entire body of a Megacity. The fundamental question of all mega-urban development is the Project Nature, i. e. the consideration of the natural conditions. The urban development and restructuring of Megacities must be orientated, adapted and integrated to the natural, climatic and geographical conditions of the local and regional context. The essential question of our century: The Human Relation to Nature is drastically present facing existing and future societal and environmental phenomena of mega-urban development worldwide. A changed handling in respect of Nature and Humanity is needed to give liveable perspectives on a global level.

ABSTRACT

Accessibility to water sources has played a decisive role in the location and growth of human settlements, fulfilling a key role in the historical development of cities, as in the case of Cuenca, where the Tomebamba River defined its foundation place. Recent urban development has weakened the relation between cities and their rivers, and it is urgent to rediscover the potential of rivers and their banks in the urban fabric, not only as generators of urban biodiversity, but as a public space that contributes to social resilience and builds urban identities. This paper studies the historic relationship between urban dwellers and the river, in 1.5km of the Tomebamba River that runs in front of the Historical Centre of Cuenca, through uses and perceptions of its users. A series of semi-structured interviews were explored using discourse analysis, word frequency, and spatial visualization, to reveal perceptions associated with places and space morphologies, and how they have changed through time. The results shows that historical use of this city place was related to production and leisure, having a strong relation to the river as a water source, whereas now production is no longer related to the river; instead, newcomers have occupied the space, promoting new uses in the river margins, having little to no relation with the water, modifying landscape perceptions and building new urban identities.

Keywords: urban regeneration, riverbanks, landscape perceptions.

1. INTRODUCTION

1.1 Background of the research

The construction of identity related to resilience can be understood through human-environment relationships. By studying and exploring human behaviors, perceptions and spatial configurations, one can suggest socio-environmental improvements and better urban regeneration strategies (Cheshmehzangi & Heat, 2012). In this context, the study of the relationship of the city with its rivers is important because accessibility to water resources has played a key role in the location and growth of human settlements, being significant to the historical development of cities and the definition of the urban landscape.

Despite its importance, in many cities around the world the relationship between rivers and their cities has weakened (Novotny, 2009) so it is urgent to rediscover the potential of rivers and streams in the urban fabric (Beja da Costa, 2009) and its role as a public space capable of strengthening social resilience, understood as the ability of a group or community to recover or respond positively to a crisis (Maguire & Hagan, 2007).

1.2 Purpose of the research

In the case of Cuenca, rivers have played a key role in its development. This paper studies the historic relationship between urban dwellers and the river, in 1.5km of the Tomebamba River that runs in front of the Historical Centre of Cuenca, through uses and perceptions of its users. The end goal of this work is to define the interrelation between morphology and perception, and the way it generates urban identities.

1.3 Location of the study area

Cuenca is located at the south of Ecuador, in the Andes Mountains, 470km, at 2.530 meters above sea level. Four rivers run through the city: Tomebamba, Yanuncay, Tarqui and Machángara. The Tomebamba River has its headwaters in the Cajas National Park, a moorland and wetland ecosystem that contributes to the water recharge, providing high quality water for cities in the Andean Highlands and parts of the coastal plain (Buytaert et al., 2006; Serra & Hermida, 2017).

Cuenca and its predecessor settlements, Guapondelig and Tomebamba, have always maintained a close relationship with water. The Spanish foundation took place in the Inca and Cañari city, north of the Tomebamba River. In 1947 the city expanded south, with the implementation of architect Gilberto Gatto Sobral Urban Plan. Since then, Cuenca has experienced expansive growth, passing from 288,29ha in 1950 to 7.248,23ha in 2010 (Hermida et al, 2015). Geographical corridors marked by rivers and streams determined this growth.

In 1982, through the Urban Development Plan of the city, local government showed interest in riverbanks (Jaramillo, 1982) situation that resulted, years later, in the generation and improvement of linear parks adjacent to the rivers. However, these spaces have not been resolved as part of a comprehensive network of urban green.

2. THEORETICAL REVIEW

The importance of urban spaces for identity has been acknowledged since the 60's (Bernardo & Palma-Oliveira, 2016). Identity refers to the distinction between certain elements from the whole, its recognition as a separate entity (Lynch, 1960). However identity can also refer to the relationship between elements with another. Urban identity is made up of different components; socio-economic structure, socio-cultural structure, built environment and urban image (Murzyn-Kupisz & Gwosdz, 2011; Yaldiz et al. 2014). The first two can be analysed through perceptions and uses of space, while the last two can be summarized as spatial morphology. Accordingly, the identity in an urban environment is defined by space and the activities and events that take place.

Morphology refers to the relationships between different elements; it is based on the idea that "the way things are assembled matter" (Hillier, 1996). The morphology of a city is reflected in a hierarchy of different sub-centres or groups along various scales, from the city to the suburbs, organized around different economic functions (Batty, 2008). Urban morphology provides us with valuable information about the structural characteristics of a city; it gives insight into the structural origins and impacts of historical change on the chronological processes concerning the construction and reconstruction of a city (Ariza-Villaverde et al. 2013). Morphology can be studied through road network connectivity, buildings, and diversity of land uses, which provide information on urban patterns influenced by the growth of the city under various urban plans and regulations and different socio-economic contexts.

The urban environment is characterized by the embodiment of certain kinds of identities in space, while space is dematerialized into non-discursivity and therefore into identity and culture (Hillier, 1996). Consequently the relationship between human behaviour and perception with the urban environment can be studied; this relationship is linked to memory, culture, knowledge and emotions and generates urban identity.

3. METHODOLOGY

Historical maps, which identify changes in patterns of use and connectivity, were consulted to analyse the spatial morphology in relation to the Tomebamba River over time. References and historical texts, poems, and songs about the Tomebamba River, that provided important information regarding uses through history, were also reviewed. Semi-structured interviews were explored using discourse analysis, word frequency, and spatial visualization, to reveal perceptions associated with places and space morphologies, and how they have changed through time. The historical perception had two types of informants: town historians and elders (70-85 years old) who lived their childhood, adolescence and youth by the Tomebamba River. The current perception was also obtained with two types of informants: residents and users of the Tomebamba River, which are not necessarily the same people. The interviews were digitized, enabling their explorations through discourse analysis, word frequency and spatial visualization with Atlas.ti by QGis. The information obtained from interviews and its relation to the analysis of changes in the spatial morphology of the city over time, allowed looking at the historical and spatial context of the city in connection with activities linked to the River, providing knowledge to understand the relationship between uses and the configuration of the city over time.

4. RESULTS AND DISCUSSION

4.1 Cuenca in the twentieth century

During 1900-1910, the axis of the Tomebamba River was the division between the consolidated and the expansion area of the city, called El Ejido. Two bridges served as entrances from the south and east of the city, basically intended for the use of pedestrians and carriages. In 1912, with the arrival of the first car, the planning and

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

inhabiting of the city changed (Carpio, 1976). In this period, the river was perceived by people as a means of sanitation of the city, sewage was transported by canals passing through the streets and flowed into the Tomebamba river (Vega, 1997), In addition, the height and abundant river flow were used by the population for productive purposes (Morales, 2011). From colonial times until the first decades of the twentieth century, the mills on the banks of the Tomebamba River started emerging and gaining importance in grinding wheat for flour production. The banks were not considered as public spaces for leisure and recreation, yet close to them, on the south bank of the river, facilities such as the hospital, the morgue and the nursing home, all of them public, had been installed (Albornoz, 2008). In this same bank the slaughterhouse had been built and used the river for the evacuation of its waste (Jamieson, 2003).

Figure 3. Map of Cuenca, 1930. Source: Albornoz. B. 2008.

Between 1910 and 1930 (Figure 1), the connectivity between the northern and southern riverbanks increased, with the construction of two new bridges: Mariano Moreno and Centenario (García & González, 2016). The buildings near the river began to have greater value so many of them were renovated and changed their traditional colonial style, to make way for the Republican style; this happened in parallel with economic growth in the region, given by the export of *toquilla* straw hats, also known as Panama Hats (García & González, 2016). Each of these houses had secondary accesses that directly linked to the Tomebamba River. By 1930 the canals that moved sewage into the river were concealed and at the same time, the number of hydraulic mills that were used for grinding wheat increased, transforming the area into the seed of the industrial region of Cuenca (Vega, 1997).

Since 1950, the southern area of the Tomebamba River began to urbanize consolidating and increasing the connecting of the middle terrace to the lower one. Along the northern bank, streets emerge to join the east-west ends of the city (Carpio, 1976). A great river flooding, precisely on 1950, caused the destruction of three of the five bridges that crossed the Tomebamba. According to Carpio the local traffic was affected for several years. Together with bridges, the slaughterhouse was destroyed and later relocated downstream. Despite this event, the educational facilities, parks, public squares and hospital were maintained and augmented in the southern area of Tomebamba River (Albornoz, 2008). By 1970 the green areas along the riverbanks became public spaces (Albornoz, 2008). Traditional building systems were replaced and consequently the materiality of the buildings in the area changed, allowing taller buildings of three or more levels (Carpio, 1976).

4.2 Cuenca in the twentieth-first century

In this century, the largest investments were aimed at roads and automobile connectivity; underpasses were built on the southern riverbank. For non-motorized mobility three new footbridges were constructed and, on the northern bank, infrastructure for pedestrians and cyclists was built. The use of the Tomebamba River as a production site was significantly reduced due to the disappearance of the mills. Traditional uses, such as "bathing" in the river and "trout fishing" were almost none and the presence of the washerwomen was maintained, although in a lesser degree (García & González, 2016. Novillo, 2010); meanwhile, in view of the magnitude of the problem of contamination of the riverbeds by the discharge of wastewater, the public company in charge of water treatment of the city designed plans for its management. The slope formed between the intermediate terrace (Historic Center) and the lower terrace, traditionally known as "El Barranco" does not lose its iconic character, it remains a quaint place suitable for cultural, artistic and sporting activities, also extending its use for night activities; with the presence of commercial premises, hotels, bars, restaurants, nightclubs, among others. Due to the expansion of the city, the Tomebamba River is no longer a limit and has become part of the central urban area, where walking, wandering and sightseeing are daily activities for both locals and tourists that visit the city.

4.3 Perceptions

In-depth interviews offer another look at the changes in the uses and perceptions that have occurred in the Tomebamba River over time. Keyword counts were made on the transcriptions of the interviews using Atlas.ti that revealed diachronic differences in the relationships of citizens with the river. One hundred keywords that relate to four dimensions of the study were selected: uses of the Tomebamba river (26 words), perceptions (42 words), natural environment (11 words), and built environment (21 words). Different variations of these words between interviews that referred to the mid-twentieth century and the twenty-first century were recorded based on their relative frequency. As seen in Figure 2, there are differences in the presence of words in the two analysed historical moments.

Figure 2: Comparison between mid-twentieth century and early twenty-first century.

There are words that show important differences between the two sets of interviews (Figure 3). In the mid-twentieth century: swimming, fishing, eating and washerwomen, while in the twenty-first century: walking and sports. The frequency of words indicates that uses of the Tomebamba River during the twentieth century were related to the water, with the exception of the word eating, while uses in the twenty-first century relate to the riverbanks. The word eating refers to picnics that were done frequently in the riverbanks in the twentieth century and is returning slowly today.

The words associated with pleasure, dislike, safety and environmental sensations also show important differences. In the previous century words that refer to positive perceptions, such as beautiful and like, and others that refer to negative perceptions like rubbish, horrible and danger, standout. The latter refers to the dangers related to natural phenomena such as flooding, not criminal activity. The words that predominate today are safety and noise. The first refers to the concern of criminal activities along the river that have been reported by respondents, and the second to motorized traffic taking place in the adjacent streets.

Four words contain the main contrasts in relation to the natural environment of the river. In the previous century words like flooding, stones and deep-water predominate, clearly linked to water and, particularly, with the riverbed. In contrast, today the word riverbank predominates. This opposition expresses a difference in the use of the river,

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

before more related to water, and now more closely linked to the banks. In fact deep-water and stone refers to the practice of 'getting into the river', jumping from a high stone to deeper water areas.

The words that show more contrast in relation to the built environment are mills, vado, parks, commerce and pedestrian paths. In the twentieth century words like mills and vado were more present. The word mill refers to the use of the river as a means of production, providing energy by spinning stone mills that were used to grind wheat, barley and corn. The word vado is related to a representative place that connected the two riverbanks and was part of the road that transported people to the south of the country. Currently the words parks, commerce and pedestrian paths are present, all referring to activities that take place on the riverbanks or on the immediate environment, and even though parks and pedestrian paths existed in the previous century, its presence in the imagination of people is intensified today.

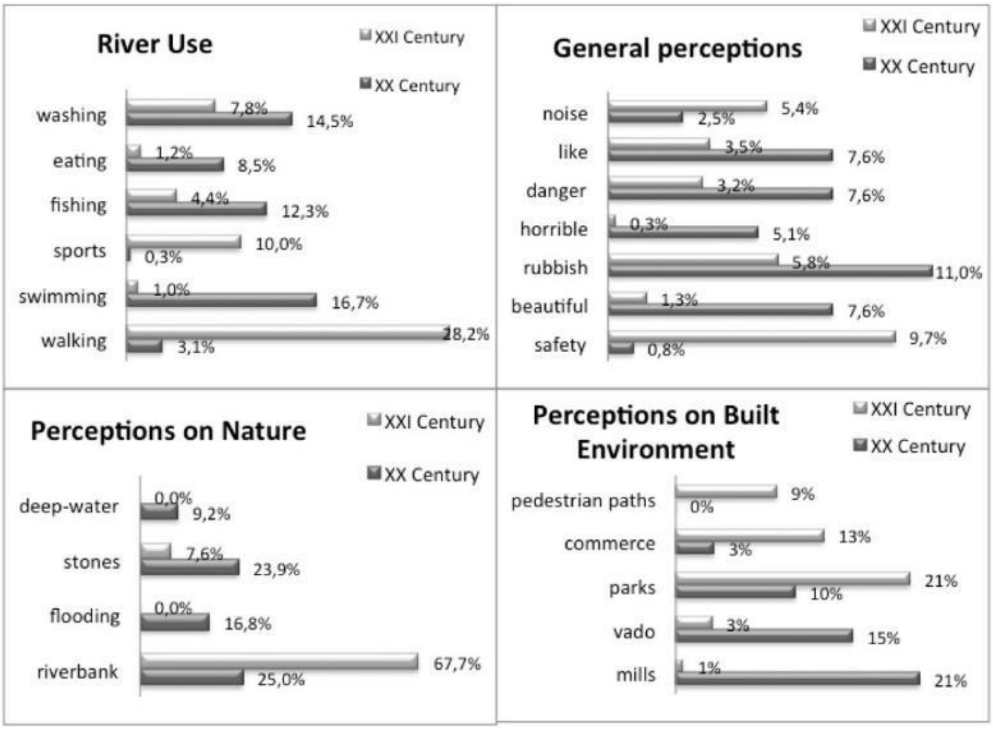

Figure 3: Relative word frequency comparison: mid-twentieth and early twenty-first century.

5. CONCLUSIONS

The identity relationship of a city with its main river is close-knit, and the city of Cuenca is no exception. In both periods the river frames the city and becomes a highly valued element by its inhabitants. Access, parallel roads, bridges and green spaces that have been built around and on the river have contributed to greater relationship and sense of belonging of the city inhabitants. Therefore, we can say that the way in which the space around the river is 'built' is crucial to the way we relate to it and contributes in the construction of identity of the place. The main changes in perception regarding the river arise precisely through the uses it allows, and the uses that we allow ourselves in relation to it. In the mid-twentieth century the identity of the river was determined mainly by water because of three consideration: first, water was a means of production that provided hydraulic power to move mills and generate electricity, and as a means of getting rid of solid and liquid of city; secondly, the river was a fun space for bathing and collective games; and lastly, there is the consideration of the river as a barrier, as a boundary separating the productive zone from the inhabited area, the rural from the urban. In contrast, at the beginning of the twenty-first century the identity of the river is determined mainly in the use given to its banks as a social meeting place between different people and for economic exchange. The changes that public spaces, like the Tomebamba River, undergo cannot be understood isolated from its context. The production system of the city has changed from a subsistence agricultural model to one based on services and high value-added production. Public spaces are places of encounter and exchange of ideas and have a potential to increase the social capital and productivity of a city, a subject worth exploring in future research.

ABSTRACT

River channelisation is a conventional approach of resolving flooding problem in view of its outstanding hydraulic performance. Such design, however, has a negative impact on the city landscape and also leads to degradation in the ecology and subsequent decline in ecological habitats and overall biodiversity. With a vision of providing sustainable drainage services and pursuing a higher standard in environmental and ecological preservation, the Drainage Services Department (DSD) of the Government of the Hong Kong Special Administrative Region has incorporated environmentally friendly design in its drainage improvement projects in Ho Chung River, Upper Lam Tsuen River and Kai Tak River. Indeed, incorporation of environmentally friendly drainage design in a densely developed area like Hong Kong is a great challenge. In this paper, the improvement of ecology, enhancement of biodiversity and the characterised features of the abovementioned rivers achieved in the drainage improvement projects will be discussed. Looking ahead, by adopting the concept of manifesting and revitalising water bodies into drainage improvement works and development of new development areas, the community will be further benefited from the improved environment. In the revitalisation of Tsui Ping River at Kwun Tong as well as the drainage planning of new development areas, DSD will adopt new standards in the planning and construction of drainage facilities with a view to providing a better environment for the public.

Keywords: channelization, blue infrastructure, community empowerment, ecological enhancement, flood protection, green infrastructure, revitalisation, water friendliness

1. INTRODUCTION

From 1970s to 1980s, there was a need for new towns development through urbanisation of rural areas to cope with the increase in population and to improve the living environment by decentralising the population from the over-crowded urban districts. Once served the purpose for natural land drainage, natural rivers and waterways flowing through these development areas have to be modified in a form of new man-made (engineered) channels.

As a result of modification of land use, change of drainage characteristics and pattern, and increase in impervious areas, the quantity and peak stormwater runoff within these urbanised areas would be increased. As the surface runoff was no longer able to infiltrate into the ground, substantial rapid surface flows would occur which would not only cause imminent inundation to local areas, but also create secondary flooding due to overflow from those under-capacity rivers and waterways.

To improve the situation, the Hong Kong Government decided to develop flood control strategy to increase the drainage capacity of the concerned waterways. Channelising natural rivers and waterways such as concretising, straightening, deepening and widening were typical solutions to enhance the drainage capacity.

Although the flooding situations were improved through extensive drainage improvement works, this type of channelisation works has led to degradation in the existing ecology and subsequent decline in ecological habitats and overall biodiversity. In addition, the robust and flood-proofing-tight engineering facilities also discouraged the public from accessing and enjoying these valuable natural resources.

In late 1990s, the Hong Kong Government took a first step forward to restore the ecology within the channels by applying green elements into the drainage improvement works. This was a significant step shifting from sole flood control focus onto two-dimensional consideration of flood management and riparian ecology.

Since then, the Hong Kong Government has been continuing to improve the drainage networks by adopting the concept of river revitalisation with holistic consideration on functional, environmental, ecological and aesthetic

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

aspects, with an aim to creating the world's built, natural and social environments. This is also a "transformation" from two- to multi-dimensional management strategy to achieve the goal of sustainable drainage services provision.

2. RIVER CHANNELISATION

Hong Kong was experiencing continuously flooding in various areas from 1970s to 1980s, the Government understood that the early constructed drainage systems were insufficient to drain the substantial surge of runoff due to rapid urbanisation. Therefore, the government conducted the Territorial Land Drainage and Flood Control Strategy Study – Phase 1 (TEL I) in 1988. The study identified the levels of protection against flood on drainage requirements. This study also developed a drainage masterplan for New Territories to cater for the future new town developments.

In 1991, Territorial Land Drainage and Flood Control Strategy Study – Phase 2 (TEL II) was conducted to identify and manage flooding black spots. It also developed a strategy to manage drainage system along private areas to improve the overall drainage operation and management to enhance the drainage functionality and reduce the consequents of flooding. In 1995, Territorial Land Drainage and Flood Control Strategy Study was moved into Phase 3. In this phase, the cost effectiveness and impacts on environment for drainage projects were reviewed. These studies were not just forming the backbone for the stormwater design standards, but also leading the way on identification of flood protection levels and determination on the extent and degree of associated drainage improvement works.

To alleviate the potential flood risk, one of the solutions was to straighten, widen and deepen the existing natural meandering rivers, and channelised to rectangular or trapezoidal concrete-lined canals in order to increase the hydraulic conveyance. However, these treatments would degrade the riparian ecology and waterway's health without environmental benefits being taken into consideration.

In addition, some of the long-existing rock channels or open nullahs in urban areas were decked to create additional lands for development as well as to mitigate odour issue due to cross connection to sewer. These additional lands were generally for constructing open spaces, such as parks and roads. While the properties of these drainage facilities were changed entirely as they were transformed to underground culverts, the entire ecosystem was destroyed.

2.1 Case Study: Sheung Yue River

Sheung Yue River is also known as River Beas which is located in northern side of New Territories. In the 1990s, the areas alongside Sheung Yue River were frequently experiencing severe flooding during wet season. In late 1990s, DSD decided to conduct improvement works to enlarge its hydraulic capacity and hence reducing the flooding risk.

The original alignment of the river was being straightened to improve the flow path along the river as well as to increase the width of the river to enlarge the cross section. Additional to these works, it also concretised the banks to increase the conveyancy of the channel to provide additional capacity of the river.

As the river was trained and straightened to improve the hydraulic capacity, these works destroyed some of the habitats and increase the flow velocity within the river which some of the fauna and flora were disappeared from the river.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. ECOLOGICAL IMPROVEMENT FOR CHANNELS

In late 1990s, flooding situations alongside the rivers have been greatly improved after completion of a series of drainage improvement works. With a vision of providing sustainable stormwater drainage services and pursuing a higher standard in environmental and ecological preservation, the Hong Kong Government adopted the sustainable development approach and started to implement greening elements into drainage improvement works to enhance the ecology in the channelised waterways. Most of these works were mainly adopted for ecology enhancement which provided some environmentally friendly elements to allow aquatic fauna to breed and live healthy within the channel. During this stage, some early revitalisation initiatives were taken on board including:

- Using gabion and geo-fabric reinforced grass lining to stabilise river banks;
- Leaving channel beds unlined to provide natural substrate that supports aquatic flora and fauna;
- Leaving embankment unlined to promote vegetation growth;
- Retaining meanders as wetland habitats, and creating by-pass channels to preserve natural river and stream channels;
- Creating shallow ponds for aquatic planting along drainage channels to provide habitat for wetland fauna;
- Creating wetland habitats and reed beds adjacent to drainage channels; and
- Providing habitat enhancement measures to enhance the habitat complexity.

In 2005, DSD published the Practice Note No. 1/2005 – Guidelines on Environmental Considerations for River Channel Design. This Practice Note recommended a design framework, with an objective to produce a river channel design as environmentally friendly as possible, for use in the project planning and design stages. It covered the essential environmental aspects to be considered in conjunction with requirements/standards with respect to other design aspects.

3.1 Case Study: Ho Chung River

In order to provide a better balance between the needs of reducing flood risks and conserving the river ecology, a number of ecological features has been adopting in the drainage improvement works at Ho Chung River. For example, the flow deflectors formed with big boulders not only provide potential refuges for fish during spates, they also enhance the habitat complexity to create more diverse micro-habitats. In the sections where concrete retaining walls have to be adopted due to land constraints, the fish shelters can provide hiding spaces so that aquatic animals may protect themselves by moving inside.

To address the needs for re-provisioning of an original Fung Shui Weir while reducing the potential effects of obstructing the upstream movement of fish and other aquatic animals, the construction of fish ladder not just provides easier pathways for upstream migration, its appearance also follows the general pool and riffle pattern at the immediate upstream natural section. Such integration of ecological enhancement features and engineering techniques has demonstrated that engineers and conservation groups can work together to find out more sustainable solutions to address our social needs on flood control, where drainage improvement works in natural streams are inevitable.

3.2 Subtitle Case Study: Upper Lam Tsuen Rive

Lam Tsuen River valleys area, including upper Lam Tsuen River had suffered from flooding threat and these valleys had been listed as flooding black spots. Therefore, drainage improvement works was conducted in Upper Lam Tsuen River with primary aim to reduce the flood risk of the river course. During construction, various measures have been adopted in order to minimise the negative impacts brought out by the works done to the surroundings, including translocation of Paramesotriton hongkongensis (Hong Kong Newts) and conducting ecological monitoring.

After the completion of the project, some beautification works were conducted to preserve the natural environment. As a result, the concept of sustainable development can be implemented.

4. RIVER REVITALISATION

The 2015 Policy Address stated "We will adopt the concept of revitalising water bodies in large-scale drainage improvement works and planning drainage networks for new development areas so as to build a better environment for the public." and "… this is aimed at promoting greening, biodiversity, beautification and water friendliness in addition to achieving efficient drainage, with a view to building sustainable drainage facilities and providing a better living environment.". From this onward, the concept of river revitalisation has further been formally materialised with an aim to changing the culture of the community with water friendliness.

In the same year, DSD promulgated the Practice Note No. 1/2015 – Guidelines on Environmental and Ecological Considerations for River Channel Design. This version is an update based on DSD's Practice Note No. 1/2005 and all items summarised in previous section are relevant. In addition, blue-green infrastructure concept is particularly introduced. This concept aims at improving the sustainability and resilience of Hong Kong's drainage systems to meet the contemporary public aspirations for natural environment, to protect local culture and rural lifestyle.

With the prime objective of flood protection in mind, to revitalise a river, it will not only restore ecological value or enhance the environment, but also provide additional social and economic benefits to the surrounding community. The potential benefits arising from river revitalisation are summarised in above figure.

Looking ahead, by adopting the concept of manifesting and revitalising water bodies into drainage improvement works and development of new development areas, the community will be further benefited from the improved environment. In the end of 2015, DSD commissioned a consultancy study on revitalisation of water bodies to assess the feasibilities and benefits could be provided by revitalisation of water bodies. All these works were aimed to moving Hong Kong from a flood resistance city to a flood resilience city and enhancing the sustainability of the overall development in Hong Kong.

In the revitalisation of Tsui Ping River at Kwun Tong as well as the drainage planning of new development areas, DSD will adopt new standards in the planning and construction of drainage facilities with a view to providing a better environment for the public.

4.1 Case Study: Tsui Ping River

King Yip Street nullah was constructed more than 50 years ago. Riding on the opportunity of the transformation of Kowloon East into an attractive alternative Core Business District (CBD2) to sustain the economic growth of Hong Kong, DSD will adopt an integrated approach to transform King Yip Street nullah into a blue-green infrastructure "Tsui Ping River" with environmental, ecological and landscape upgrading, including enhancement of drainage capacity, provision of riverside walkways and landscaped decks, and improvement of pedestrian facilities in the adjacent area. The scope of the revitalisation of Tsui Ping River comprises but not limited to the following main items:

- Beautification of existing nullah by provision of attractive waterscape design, water retention features to retain water during low tide;
- Provision of landscaped walkways along Tsui Ping River to enhance walkability;
- Provision of landscaped decks over Tsui Ping River;
- Modification and face-lifting of Kwun Tong Road Footbridge; and
- Pedestrian path enhancement in the vicinity of Tsui Ping River.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4.2 Case Study: Kai Tak River

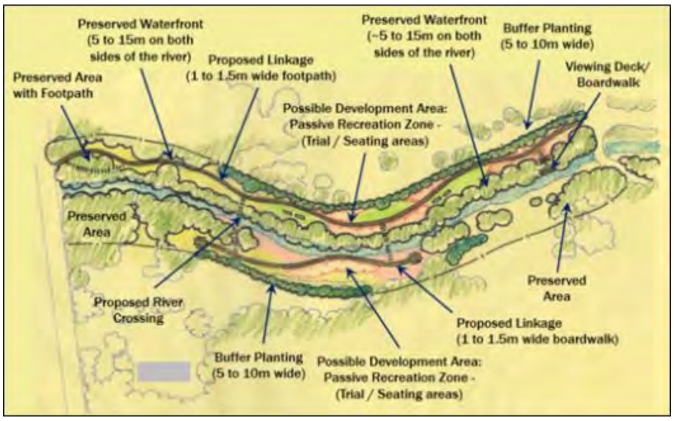
Kai Tak River has been continually modified since 1920s to suit the development needs in the vicinity. Experiencing about a century of transition, it is geographically and historically bonded with the surrounding districts, witnessed the development of Hong Kong. In order to improve the drainage capacity of Kai Tak River and to mitigate the flooding risk to surrounding areas, DSD is carrying out improvement works since 2011 at upstream and midstream sections of the river. With this opportunity, landscaping measures and ecological features have been incorporated into the river channel design to revitalise it as a "green channel corridor" via the following solutions:

- Placing boulders at the river bed to slow down the river flow at local spots for fish gathering and enhance the appearance to be more natural;
- Inclusion of fish shelters alongside river bank for providing a refuge to prevent fish and other aquatic organisms from being swept away during periods of high water flow, in order to enable a sustainable ecological environment;
- Beautification works at river wall; and
- Planting shrubs and plant alongside the river banks.

4.3 Case Study: Tung Chung River Park

Tung Chung River is identified as an ecologically important stream with important ecological functions. With the extension of Tung Chung New Town, the Government is planning to restore the existing man-made river channel at the downstream, and develop a 3.3-hectare of land adjacent to the river as Hong Kong's first river park where the public can get close to the river for enjoyment.

In order to balance the impact to the habitat and enjoyment of the public, passive designs, such as boardwalks, viewing decks and footpaths are envisaged. Native vegetation will be preserved as far as possible to maintain the existing habitat. The river park will set as an example for the public to treasure rivers as a crucial social and ecological resource to nurture water friendly culture.



5. CONCLUSION

For Hong Kong, it comes a long way from river channelisation to river revitalisation, from flood protection to ecological enhancement, from isolation to water friendliness and public enjoyment. The ultimate goal is to create, enhance and sustain the world's built, natural and social environments. The transformation of channelisation to revitalisation demonstrated the agility to embrace change and adaptation of the Government and the society in response to the request of building a sustainable environment.

Looking forward, river revitalisation is an overwhelming and irresistible trend, not just in the Hong Kong context, but worldwide, and as one of the core subjects in water management for sustainable development. The below table shows the concept for developing a strategy for revitalisation from different aspects.

	Urban Waterfront	Ecosys Restoration	River Restoration
Strategy	- Analysis of the Overall Economic Benefits - Analysis of Direction for Waterfront Development - Investment and Financing Strategy - Mechanisms of Implementation and Operation Mode - Sustainable Development Strategy	- Feasibility Study/ Benefit Analysis - Mechanisms of Implementation and Operation Mode - Policy Assessment	- Feasibility Study/ Benefit Analysis - Integrated Water Resources Management Program - Policy Assessment
Planning	- Urban Spatial Structure/ Development Strategy - Waterfront City Planning - Waterfront Landscape Planning - Ecotourism Planning	- Ecological Environment System Planning/ Design - Development of Water Ecology Strategy - Operation and Maintenance Program	- Overall Design of River - Watershed Pollution Survey/ EIA - Drainage Planning - Flood control and Drainage Scheme - Water Recycling Scheme
Design	- Architecture and Urban Design Strategy - Green Space and Waterfront Open Space Design - Waterfront Landscape Design - Waterfront Transportation Design	- Environmental Remediation Technology Program - Design of Natural River - Water Sensitive Urban Design	- Physical Design Parameters - Water Purification Process Design - Hydraulic Structures/ Slope Revetment Design
Engineering	- Cost and Contract Management - Construction Management/ Value Engineering - Later Stage Management/ Optimization	- Project Feasibility Analysis - Cost and Contract Management - Construction Management/ Value Engineering - Later Stage Management/ Optimization	- Project Feasibility Analysis - Cost and Contract Management - Construction Management/ Value Engineering - Later Stage Management/ Optimization

By adopting the concept of manifesting and revitalising water bodies into drainage improvement works and development of New Development Areas, the community will be further benefited from the improved environment. In revitalisation of river as well as the drainage planning of new development areas in the future, the Government could consider adopting new standards in the planning and construction of drainage facilities with a view to providing a better environment for the public.

ABSTRACT

World energy consumption has increased rapidly in recent years and shows no indication of slowing. In Hong Kong, this situation is more critical due to its high demand in urban energy consumption and scarcity of natural resources within its jurisdiction. To push Hong Kong to the very forefront of the fight against climate change and form a low-carbon urban transformation, energy benchmarking is one of the most effective ways to set up industry's best practice and achieve sustainable development.

While there exist a few benchmarking programmes worldwide, such as ENERGY STAR Portfolio Manager in the US, NABERS in the Australia, they are limited to benchmarking the existing buildings without customised improvement advice to enhance energy efficiency. Hong Kong, with its extremely high-density urban form, starts to develop its own benchmarking tools in recent years for the unique built environment, some early attempts include HK BESTOO developed by Hong Kong Green Building Council (HKGBC) and Energy Utilisation Indexes and Benchmarks developed by Electrical and Mechanical Services Department (EMSD).

In order to accelerate the low-carbon urban transformation, a more comprehensive benchmarking system is needed to evaluate and improve the whole building energy performance. It will surpass the existing benchmarking programmes around the world by assessing the building to the system-level details and provide ratings based on different building system types. Additionally, the world's first "What-If" Function will provide the building owner with tailor-made suggestions to improve the building energy performance. This paper reviews the state-of-the-art methods in building energy benchmarking and proposes a new benchmarking system specifically catering to Hong Kong's unique built environment to promote the low-carbon urban transformation in Hong Kong. This project was initiated by the HKGBC with the aim to improve building energy performance in Hong Kong. Arup was appointed as the consultant to undertake studies.

Keywords: low-carbon, urban transformation, energy benchmarking

1. INTRODUCTION

In Hong Kong, buildings account for 60% of carbon emission and 90% of electricity use (HKPC, 2016). Focusing on making buildings more energy efficient with the initiative of the HKGBC is the key to grasping the opportunity of meeting Hong Kong's carbon reduction target without going into the current fuel mix debate. As shown in Figure 1, in order to fit in the roadmap of the overall carbon reduction target, 52% of the reduction in electricity in the building sector needs to be achieved by 2030, as compared to the level of 2005 (HKGBC, 2014). According to the Buildings Department, there are around 2,459 existing office/commercial buildings in Hong Kong. With proper strategies, retrofitting and optimising these existing buildings can bring large reduction to the entire building sector, almost half of the target. Along with Hong Kong's high-density building context, comes the large variation in building functions and base building provision. Simply comparing the Energy Utilisation Index (EUI) may miss the underlying factors and opportunities for improvement in energy efficiency. Among current available policies and strategies, benchmarking is likely the best tool to push the baseline of existing buildings and drive the market to meet this long-term target for Hong Kong. In the latest Energy Saving Plan from the Hong Kong Government also emphasises the importance of energy benchmarking as the first stage of the energy saving and green building

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

transformation (Environment Bureau, 2015). This paper focuses on the benchmarking of Central Building Services Installation (CBSI) of Commercial Buildings (Office/ Retail) (HK BESTCOM).

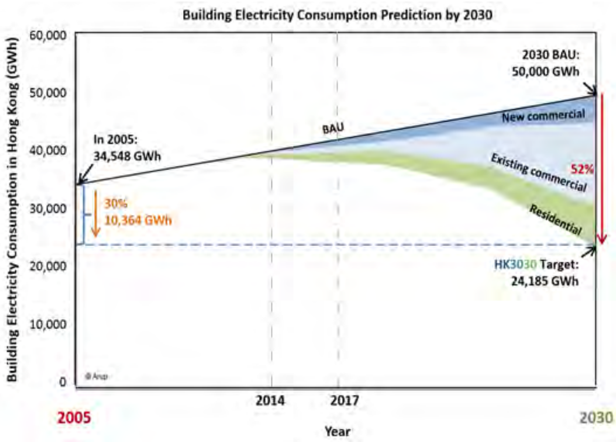

Figure 1: Impact of carbon reduction in Hong Kong's building sector

1.1 State-of-the-art methods and existing rating programmes worldwide

Originally, the word "benchmark" was used exclusively in topography to precisely define a reference point in terrain or geological analysis. When the term was first used in building industry, it referred to energy benchmarking, specifically assessing the energy performance of buildings of similar type. Many research projects have been conducted since the emergence of energy benchmarking in building industry. Broadly, the existing energy benchmarking methods can be put into four categories (Sartor et al., 2000):

Points-based Rating System: A system provides standards and guidelines to measure how efficient and environmentally friendly a facility is. A good example is the USGBC's Leadership in Energy and Environmental Design (LEED) rating system. However, the scoring system for building energy efficiency can be misleading, which requires a careful review of the points-based rating mechanism (Turner and Frankel, 2008).

Hierarchal and End-use Metrics: It is a process of categorising the whole building level energy use and gradually looks into the underlying systems and components level to capture the performance data. This approach requires segmented data that are usually not readily available, which requires the sub-metering of the system and component loads, following the hierarchical process (Sartor et al., 2000).

Statistical Approach (Regression): Statistics for a population of similar buildings are used to generate a benchmark against which the building Energy Utilisation Index (EUI) is compared. This data-driven methods provide an efficient method to compare building energy performance (Chung, 2011) (Hong et al., 2015). This method can effectively normalise the EUIs by removing the effect of building characteristics (Chung, et al., 2006). US Environmental Protection Agency's ENERGY STAR Portfolio Manager Programme, for example, accounts for the differences between buildings through the use of regression models and normalisation methods that are used to generate a ranking score based on energy efficiency ratios (ENERGY STAR, 2011).

Simulation Model-based Approach: It calculates energy benchmarks based on an idealised model of building performance. Modelling approach in benchmarking has the advantage of flexibility, able to be tweaked to account for a wide range of factors that contribute to variation in energy use. A disadvantage is the gap between the calibration of simulation modelling and actual building operation (Sartor et al., 2000).

Globally, several building benchmarking programmes have been developed based on some the above methods. The US EPA's ENERGY STAR Portfolio Manager Programme and National Australian Built Environment Rating System (NABERS) are based on historical energy consumption data and adopts statistical approach (Hicks and Neida, 2000) (Hicks and Clough. 1998). ASHRAE's Building Energy Quotient (bEQ) rating system adopted the simulation model-based approach for its "As Designed" evaluation method. For Singapore, the benchmarking reporting is conducted annually. However, there is some preliminary analysis and normalisation for chiller ages, data centre area, etc. (BCA, 2016).

1.2 Challenges in benchmarking programmes in Hong Kong

Though many building benchmarking programmes are available, they may hold certain limitations in the case of the benchmarking programme in Hong Kong. Existing programmes such as ENERGY STAR Portfolio Manager Programme and NABERS are based on local building context and are not globally compatible, especially in Hong Kong, where buildings are unique in their complex mixed-use nature. More studies were conducted identifying other energy performance factors beyond the current limitation of existing benchmarking programmes (Olofsson et al., 2004) (Signor et al., 2001).

Based on the literature review, it can be concluded that the statistical approach is adopted by a majority of the benchmarking programmes. However, a tailor-made methodology for building energy benchmarking in Hong Kong should be developed based on Hong Kong's building context and associated factors. On top of that, more innovative functions shall be created to accelerate the retrofit of existing buildings and drive the low-carbon transformation in Hong Kong.

2. METHODOLOGY

2.1 General considerations

In order to develop a new benchmarking programme for Hong Kong based on the statistical approach, it is essential to understand the benchmarking process. Through extensive research on various studies to conduct building benchmarking (Matson and Piette, 2005) (Pérez-Lombard et al., 2009), it can be concluded that a qualifying building energy benchmarking process should contain at least four steps illustrated in Figure 2. This process should not be treated as a purely statistical process, but rather an integrated process supported by both solid engineering reasoning and statistical analysis.

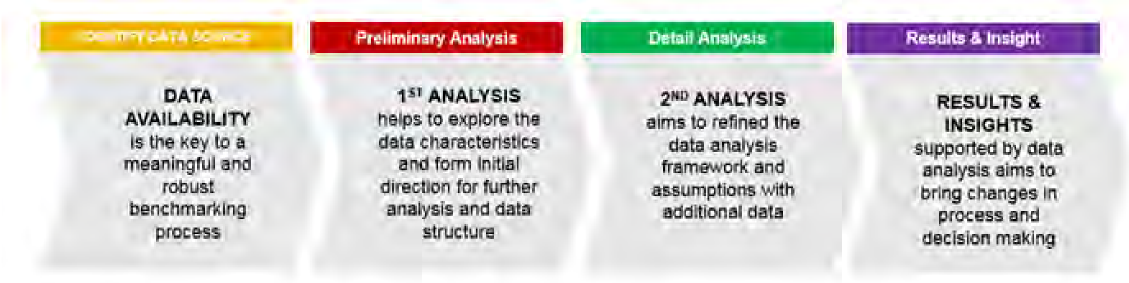

Figure 2: Basic steps of building energy benchmarking process

The process of benchmarking is to normalise, or in other words, to eliminate variation in buildings' inherent characteristics before evaluating their energy use. There are some fundamental rules that should be clarified before this method could be applied to the real database. The building energy consumption depends on many parameters. These parameters include physical constraints (system type, area, operation pattern, etc.) and performance factors (lighting power density, system efficiency, etc.). These physical constraints explain the basic characteristics of a building, while the performance factors are performance related, which describe how efficiently a building performs given its physical constraints. Though the performance factors are directly related to the energy consumption, they are not parameters that explain buildings' physical variations and therefore should not be used for normalisation. Instead, the performance factors could be used for energy use prediction and optimisation.

Before going into the details of methodology, it is necessary to visualise the process of the benchmarking tool from the users' (building owners and management company) perspective in order to optimise its attributes. Based on the characteristics of the two types of parameters, a new benchmarking tool can be developed containing two major functions: i) A Basic Tool for building normalisation supported by statistical analysis; ii) An Advanced Tool based on performance factors with "What-If" Function, which serves the purpose of the retrofit optimisation process. Two functions can be integrated as shown in Figure 3 to form a feedback system and help make decisions for energy efficient retrofitting.

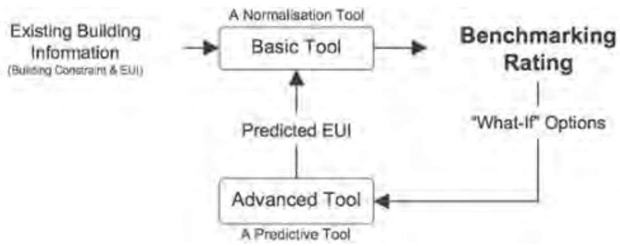

Figure 3: The integrated benchmarking system

2.2 Data processing

Data Collection and Filters

The database for the energy benchmarking was established with the support from Electrical and Mechanical Services Department (EMSD). Data sets were initially collected and analysed for the purpose of the development. Due to the variation of data quality, a filtering process was designed to remove outliers inappropriate for the benchmarking tool. Certain data sets were filtered out to ensure that the remaining can represent the energy use pattern of typical buildings in Hong Kong.

Categorisation

Through the preliminary analysis, the distinctive difference in EUI is found for buildings with centralised system of air handling unit (AHU) or fan coil unit (FCU) and decentralised systems (Figure 4). This is mainly due to the difference in energy use by air-side systems. For AHU and FCU system, the fan energy for distributing the conditioned air is on account of the building owner and tenant respectively. For the decentralised system, all the energy associated with air-conditioning is consumed by the tenant. So it is necessary to divide the buildings into three categories based on these system types.

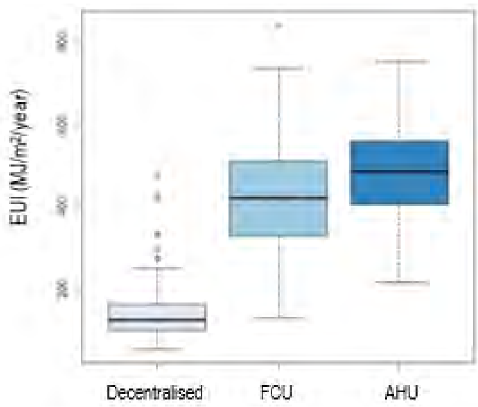

Figure 4: EUI for commercial buildings with different air-conditioning systems

2.3 Basic tool development

Regression Analysis

For the Basic Tool, the main focus was to develop a multivariate regression model for each of the category, namely FCU, AHU and Decentralised buildings. In order to make sure the regression equations represent the effect of the most significant features affecting the building energy performance, the development process includes: i) Reviewing available variables as building constraints; ii) Perform regression iterations by including different variables and transformations; iii) Review statistical indicators and determine the best regression model.

The statistical indicators adjusted R-Squared and t-scores are both investigated during the process. Since the regression model is not a prediction tool, adjusted R-Squared alone can be misleading because it is affected by the characteristics of the database and chosen variables. So the t-scores were also investigated to make sure the level of uncertainty associated with regression parameter estimates are minimised for the statistical analysis.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Rating System

After the regression model is developed, a rating scale for the building energy performance can be established based on the Energy Efficiency Ratio (EER):

$$EER = \frac{EUI_{measured}}{EUI_{normalised}}$$

Equation 1

With the above ratio, a building can find out its relative performance against other buildings from the percentile ranking shown in Figure 5. If a building's $EUI_{measured}$ is lower than $EUI_{normalised}$, the EER value and percentile value will be lower, indicating the building is more energy efficient when compared to the market norm. For example, if the corresponding percentile is 20th, its energy performance is better than 80% of the similar buildings.

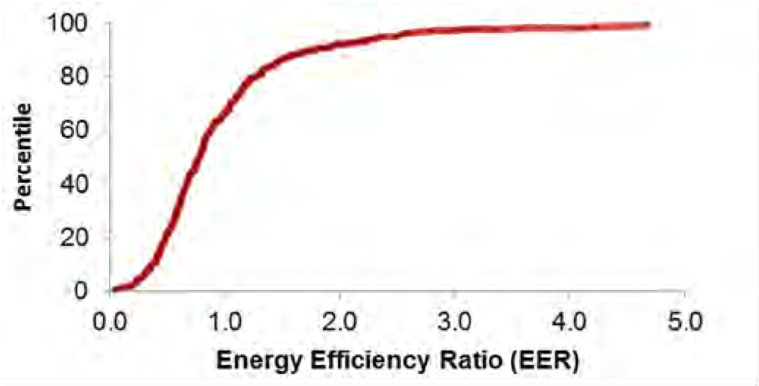

Figure 5: Distribution density and cumulative distribution function for the rating system

2.4 Advanced tool development

The Advanced Tool provides opportunities for strategic planning and future improvement before actual implementation, which overcomes the limitation that the existing benchmarking tools only provide the rating based on the normalised building EUI. The "What-If" Function focuses on three major systems: air-conditioning, lighting and lifts. To achieve that, the correlation between the change of performance factors and the relative energy saving for that particular system should be understood, and then the energy saving for the whole building can be predicted. Among the three systems, the air-conditioning system is the most sophisticated with many possible configurations. Series of energy models were simulated to allow user to choose from as many as 12 systems with different heat rejection types, chiller types (constant speed vs variable speed), chilled water supply loops and oil-free chillers. For each case, a range of average rated coefficient of performance (COP) values was simulated. All the simulation results form a large matrix of energy consumption for a typical building. Once the "What-If" Function knows which case the existing system belongs to, the relatively more efficient systems will show up in the "What-If" Function as improvement options. The "What-If" Function for lighting is based on the calculation of the change in lighting power density, operation hours and occupancy sensors. For lifts, the "What-If" Function focuses on lift system type with different efficiencies.

3. DEVELOPMENT OF THE ONLINE PLATFORM

The outcome of the study is a comprehensive online platform for commercial buildings (office/ retails) in Hong Kong (http://hkbest.hkgbc.org.hk) as part of HKGBC Benchmarking and Energy Saving Tool Series to target the key energy consuming sectors. The Free Benchmarking Tool gives a general rating for the user and the Recognition Scheme is a paid service that offers detailed rating output and Advanced Tool with "What-If" Function. It is also a certified rating process with the engagement of an authorised assessor to provide professional advice.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4. CONCLUSION

Traditionally, a one-dimensional index was used to describe energy efficiency, comparing a building's energy use over time against itself. This provides little insight into improvement actions for individual buildings. In response, this paper introduced a new approach to transform Hong Kong into a low-carbon urban development. The outcome of the study is an integrated benchmarking system developed for Hong Kong's unique building context to evaluate the building energy performance and provide optimal retrofit measures with a "What-If" Function. This benchmarking programme has been developed to support decision making by revealing high-level information such as each building's market position in terms of energy use, energy-saving potential for the key energy consuming building sectors and the local market's performance compared to the rest of the world. This allows building owners to understand the real energy performance against similar buildings through a verified assessment process. The successful launch of the tool is a milestone for Hong Kong to achieve its long-term energy-saving target.

ACKNOWLEDGEMENT

This is a consultancy study commissioned by the HKGBC and the project with funding support by the Construction Industry Council. The project team is indebted to the Construction Industry Council, the HKGBC, EMSD and other organisations that have contributed to the collection of building data together with excellent advice and insights in the process of the development.

ABSTRACT

The discussion about sustainability in the construction and real estate sector was so far mainly focused on the contribution of individual buildings, quarters or cities to sustainable development. Several sustainability assessment systems have been developed and applied, which include technical, environmental, economic and social aspects.

Energy production and consumption has a major impact on sustainable development. Hence, the amount and impact of resource usage and environmental degradation associated with the construction sector and occurring within the life cycle of buildings are depending on the characteristics of the existing energy system. Private households shift to being consumers and producers of energy, thus becoming a more important part of the complex energy system. Furthermore, nature and amount of energy usage influence life cycle costs of buildings, affordability of housing, or external costs caused by the energy systems.

Due to the high relevance of sources and the efficiency of energy use for realising sustainable development, as well as increasing interdependencies between buildings and energy generation and usage, energy systems become accordingly relevant as a distinct object of sustainability assessment.

This article will concentrate on the question which criteria and indicators are appropriate to describe and assess the sustainability of energy systems. Two basic approaches will be outlined: firstly, the development and use of checklists or indicator sets, providing orientation for the collection and interpretation of data raised, and a basis for context-specific selections of indicators, by investigating each indicator separately. Secondly, the development and use of indicator systems, which provide a fundament for a finally aggregated assessment result. Methodological and conceptual questions associated with these two approaches that are discussed in this article can also be transferred to other subjects of assessment.

The article is based on preliminary results of an ongoing research project in Germany, financed by the German Helmholtz Association.

Keywords: energy measurement and verification, sustainability assessment, indicator sets and systems

1. INTRODUCTION

The focus of sustainability-related debates in the construction sector is presently shifting from individual buildings to much more complex subjects of investigation, in particular urban residential districts and entire cities. The latter should no longer be considered being the mere sum of all buildings. Due to their close interconnections, they also have to be an assessment objective of a scientifically-based system analysis as spatial units. Sustainability assessment systems such as DGNB, LEED and BREEAM provide criteria especially for cities and urban quarters, which focus on an evaluation of the ecological, economic, socio-cultural, technical performance as well as the quality of the planning. They examine all relevant topics and issues of sustainability, including the supply of energy. Beyond the rather crude way of addressing energy issues in these existing tools, energy systems, as increasingly relevant subjects of sustainability assessment particularly in urban contexts, have to be analysed in a more comprehensive and integrated way. Main reasons for this are:

- The energy system, similarly to other basic supply systems, has to be understood as a socio-technical system, in which technical and social elements and realities interact in various ways.
- Options, opportunities and challenges of integrated solutions for the generation of renewable electricity and heat are becoming more diverse and complex, e. g. due to new actors. For instance, buildings are no longer only consumers in the energy market, but also producers ("prosumer"). Developing integrated solutions gains more and more importance for local energy supply and grid operation. The current trend in implementing such approaches promotes decentralization of the energy system towards a "smart" network based on many small regional and local units that provides innovative network and system implemented out in compliance with the principles of sustainable development.
- In order to protect ecosystems, a more environmentally sound energy generation and usage is required, in addition to a more efficient usage of materials based on the idea of a circular economy. Resource use and environmental degradation are strongly influenced by the direct use (e.g. heating and lighting in buildings) and indirect use of energy (e.g. included in building materials to newly construct, restore and maintain buildings). In principle, the energy supply sector can be regarded as an up streamed branch of the construction industry; therefore, it should be carefully analysed how a transformation of the energy supply towards more sustainability affects the sustainability of the construction industry.
- Official international and national objectives and target values, and according political decisions, such as the Agenda 2030 and the Sustainable Development Goals at the global scale or National Sustainability Strategies, clarify and reinforce the key role of energy for social and economic development in line with the objectives of environmental protection.

In Germany, this led to a discussion about the sustainability of energy supply and the sustainability assessment of future options to design the national energy system. The national federal German energy concept from 2011 is based on the three classical energy policy goals energy supply security, affordability and environmental compatibility. One key statement of this article is that ensuring energy system sustainability requires considering additional assessment criteria beyond the three classical ones mentioned above, such as health compatibility, equitable distribution, low risk, or societal participation To check the degree to which these requirements and goals are met, suitable tools are needed to describe, assess, and steer the energy system. In addition to technical functionality, these tools have to focus on interrelationships between energy technologies and the natural environment, the economy and the society. Suitable assessment criteria and indicators and their flexible use in terms of a checklist will be discussed in the following.

2. ENERGY SYSTEMS AS OBJECTS OF ASSESSMENT

A system can be defined as a “set of elements with certain properties, of their interdependencies, and of their interactions with the environment”. Energy systems are commonly understood to be technical systems for the supply of energy. Active elements of these systems are technical facilities to produce primary energy carriers as well as systems to convert, store, transport, and use energy. Passive elements of the system are the energy carriers used. The attributes of these elements are of technical (e.g. capacities, efficiencies, availabilities, calorific values), economic (e.g. energy costs, plant and operation costs), and ecological character (e.g. emissions, consumption of resources). Implementation of the necessary transformation processes to meet goals, such as the German ‘Energiewende’, however, requires the energy system to be understood as a socio-technical system, in which technical and social elements and realities interact in various ways. The energy system is an open system interacting with overall economy, the environment, and the society, which represent corresponding systems. The state of this socio-technical system is characterized by certain attribute values at a certain time. System boundaries have to be chosen as a function of the object and perspective of assessment. When defining the system to be assessed, geographical conditions have to be specified. The existing technical system and the corresponding systems are determined by the geographic area in which they act and interact. Moreover, the time horizon has to be specified (hourly, annual or perennial assessment).

When deciding on detailed goals or action strategies, it is therefore important to not only consider the supply side, technologies, and infrastructures, but also the demand side and in particular the consumer and user behaviour of private and public actors involved as well as their interests, needs, and their rights of disposal. Moreover, the society’s acceptance of existing or new system elements, its participation in decision processes, and the handling of existing or expected conflicts have to be assessed.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. ASSESSMENT CRITERIA AND INDICATORS – SET OR SYSTEM?

Assessment of sustainability is based on criteria and indicators. Indicators essentially serve to facilitate the representation of complex situations. They can be used as orientation aids in decision, control, and communication processes. Indicators initiate and support discussion, learning, and awareness building processes.

Indicators may be grouped in sets and systems. A set of indicators is a compilation of indicators used in a certain assessment context. This list can be complemented any time. A system of indicators essentially consists of a defined set of indicators and other components adapted to the assessment object. Local and spatially superordinate (national or international) indicator systems mainly differ in their basic understandings of contents, measurement variables used, reference values, and in the goals and addressees of indicator use. Use of internationally established indicator systems allows for a regular comparison of developments in different countries. Frequently, indicator systems serve to determine a fully aggregated index. This approach is associated with both advantages and drawbacks (easy communication of information versus information loss and problem of determining weighing factors). While the number of indicators in indicator systems is adapted at longer intervals only, a set of indicators can be adapted continuously.

Indicator systems are used in scientific and politico-institutional contexts on various spatial and political levels, e.g. on the supranational level of the European Union. Here, key indicators have been selected for ten areas. These key indicators are further detailed by so-called operative and describing indicators. As an example, the area of climate change and energy is outlined in Table 1. Every two years, the indicator system is used to assess changes as a function of time.

Area	Key Indicator	Operative Indicators	Describing Indicators
Climate change and energy	• Primary energy consumption	• Energy dependence; share of renewable energies in gross end energy consumption	• Domestic gross energy consumption of fuels • Electricity production from renewable energy sources • Share of renewable energy sources in fuel consumption of traffic • Co-generation systems

Table 1: Energy-related indicators of the EU Sustainable Development Strategy (EU SDS).

4. ADDITIONAL CRITERIA AND INDICATORS NEEDED FOR THE ASSESSMENT OF ENERGY SYSTEMS

Chapter 40 of Agenda 21 adopted by the United Nations Conference on Environment and Development (Rio de Janeiro, Brazil, 1992) already requested development and use of measurement parameters or criteria to assess national and international development processes. As in other sectors, the information obtained with the help of indicators in the energy sector mainly serves to analyze and evaluate the success or failure of measures taken (e.g. in the context of the 'Energiewende') and to determine trends. This information is the basis of consulting services and decision-making. Development and use of suitable indicators depend on normative or methodological goals as well as on the target group addressed (experts, politicians, public, energy consumers and so on).

Requirements to be met by indicators for the analysis of the energy system are listed in Table 2. They have to be considered when determining additional indicators.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Scientific Requirements	Representativeness and adequacy as regards ecological, economic, and social contexts; reproducibility of results; reproducibility of aggregation and of selection criteria; data quality; transparency of methods, assumptions made, or uncertainties of data
Functional Requirements	Sensitivity to changes in the course of time, suitability for determining trends, early warning, international compatibility, sensitivity to economic, ecological, and social interactions
Requirements from **the User's** Perspective	Goal orientation, addressee-adequate concentration of information, political controllability, understandability by politics and the public, consensus in society on the suitability of an indicator for presenting relationships and on the interpretation context
Practical Requirements	Data availability, possibility of regular updates, acceptable data supply expenditure

Table 2: Requirements to be met by energy-related indicators.

From the goals, such as the preservation of the ecosystem, saving of resources, maintenance of capital, securing health, comfort, and social solidarity, assessment criteria can be derived to support the development and specification of suitable indicators. Such criteria are listed in the left column of Table 3.

5. APPLICATION EXAMPLE: "ENERGY-TRANS" PROJECT

Within the framework of the ENERGY-TRANS Helmholtz Alliance, sustainability indicators were developed to assess the energy system in Germany with the participation of the authors of this article. The project was aimed at defining indicators to better study the energy system from the society's demand and user side and to better analyze the interfaces between technical and social factors that decisively affect the required system transformation process. The set of indicators proposed by the Alliance included generally accepted techno-economic and ecological indicators, such as energy consumption, energy efficiency, emission rates, or the share of renewable energy sources in energy production. Such indicators are also used in the monitoring report of the federal government. In addition, the Alliance proposed other indicators, such as areas needed for energy plants or the extent of internalizing external costs in the energy system, and indicators to better represent the socio-technical characteristics of the system. The latter describe the interaction and active participation of citizens in the transformation of the energy system or possibilities of participation in decision processes when planning infrastructure projects in the energy sector.

The left column of Table 3 lists criteria for a systematic assessment of the energy system on the national level as well as topics and indicators discussed in literature. This list does not claim to be complete and may be extended. It is to serve as a checklist or selection menu for a first assessment. The right column lists the indicators developed in the ENERGY-TRANS project, thus illustrating how the catalogue can be complemented.

criteria	indicators ENERGY-TRANS
overall economy („macro level")	• Use of Primary Energy, Final Energy Productivity of the German Economy, Final Energy Productivity of the German Industry, Final energy consumption of private households per capita, Final Energy Productivity of Trade, Commerce and Services; Specific Energy Consumption of Households for Heating (Temperature Adjusted), Final Energy Consumption in the Transport Sector, Modal Split in the Transport Sector
energy transformation sector	• Share of Renewable Energy on Gross Final Consumption of Energy, Installed Capacity of Renewable Energy Power Plants
emissions	• Energy-related Greenhouse Gas Emissions, Energy-related Emissions of Acid-forming Gases
health risks	• Energy-related Emissions of Particulate Matter, Energy-related Emissions of Cadmium, Energy-related Emissions of Mercury,
environmental risks	• Amount of High-Level Radioactive Waste which has not been transferred to a safe final disposal place, Energy-related Hazardous Solid Wastes,

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

causally determined economic factors	• Energy Import Dependency, Volume of publicly financed loans for energy-related investments, Market Share of the Four Biggest Electricity Companies in Total Electricity Production • Share of Employees in the Renewable Energy Sector on Total Employees, Gender Pay Gap in the Highest Salary Group in the Energy Sector, Relation of technician salary to manager salary in the big energy suppliers, Not used renewable electricity due to management measures
affordability	• Monthly energy expenditures of households with a monthly net income less than 1,300 Euros
support to developing countries	• Share of Development Aid Expenses for Energy-related Projects on Total GDP
stock of energy resources (deposits, potential of renewable energies)	Not covered
avoided environmental damages	• Added Value Creation from Energy Efficiency Measures in Households,
external benefits	• Added Value Creation from the Renewable Energy Sector
external costs (damage costs)	Not covered
internalization of external costs	• Degree of Internalization of energy-related external costs
research and development	• Number of University Graduates in the Field of Energy Sciences, Federal Expenditures for Energy Research, Number of German Patents in the Field of Renewable Energy and Energy Efficiency, Number of Start-ups in the Renewable Energy and Energy Efficiency Sector, Relation between Costs saved for Imported Conventional Fuels and Investments in RE Technologies
competition for land	• Area under Cultivation of Energy Crops
acceptance by the general public/ society	• Acceptance of Grid Extension for Achieving 100% Renewable Energy Supply, Acceptance of Renewable Energies in the Neighborhood, Share of Population Satisfied with Opportunities to Participate in Decision Making for power transmission grids, Share of Tourists Who Perceive Energy Power Technologies as Being Disruptive in the Vacation Region Share of Population living in Regions with the Objective to shift to 100% Renewable Energy
tourism	Not covered
demographic factors	• Share of Households Buying Renewable Electricity
transport structure	• Number of Electric Vehicles
efficiency of energy use	• Share of Installed Smart Meters Mandatory for Large Electricity Consumers
grid infrastructure (e.g. investments in the energy transport infrastructure)	Not covered
spatial distribution of power plants (e.g. degree of centrality vs. de-centrality of energy generation plants)	Not covered
ownership situation	• Number of Energy Cooperatives Engaged in Renewable Energy Plants, Share of Households Producing Renewable Electricity
supply reliability and quality of voltage	• SAIDI (System Average Interruption Duration Index) of Electricity

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

power generation technologies (e.g. installed generation capacity, efficiency, conversion and distribution losses, level and pace of innovation, type of conversion technology)	Not covered
compliance	• Share of regulatory tools in the planning of power transmission grids which fulfil participation requirements

Table 3: „Checklist“ for a systematization of the valuation object „energy system”

Based on this comprehensive list of indicators, indicator systems can be compiled for specific assessment tasks. This compilation may also include further information, methods, and algorithms for analysis and assessment of the indicators. In this way, the assessment method can be adapted flexibly to the respective contexts. Practical implementation is being discussed at the moment.

6. OUTLOOK

Apart from the selection of suitable indicators and their analysis and evaluation with appropriate methods, interactions among these indicators and the goals defined are important, but have hardly been considered systematically so far. Interaction analyses are required to identify and study existing or potential target conflicts and to determine indicators of higher or lower relevance (due to the number and intensity of interactions with other indicators). This will help more adequately develop problem solution strategies. The highly suited cross-impact analysis method has not yet been applied systematically in most of the indicator-based studies in the energy and other sectors. Here, there is a considerable need for analysis and research in the future.

ABSTRACT

Cities constitute essential parts of the built environment. Although being crucial “engines” of socio-economic growth, they cause significant environmental loads. Therefore, they have a major role to play in sustainable development. Their design and adaptation to future requirements should always follow the sustainable development principles. This is an ongoing process that must be actively managed. However, which methods and procedures can support such a process? Since cities are complex entities, in urban transformation processes, the district/neighbourhood level has been proved as appropriate for implementing sustainability principles. Thus, the paper focuses on the district-scale sustainable development and deals with issues related to the management of the process, including: a) the identification of local actors having a direct influence on the district’s development, the selection of the object of assessment and the determination of the district’s current state, followed by b) the formulation of goals and the investigation of possibilities on how to act towards these goals. This also presupposes the analysis of relevant actors regarding their motives, property rights and possibilities for action. Through this analysis, the importance of a flexible indicator system adjustable to the district’s local conditions for the definition of goals, indicators and target values and the monitoring of progress based on this system are highlighted. The main result is a detailed analysis of the relevant actors and actor constellations as well as the development and application of indicator systems. The difference between sustainability assessment systems, as a basis for certification, and indicator sets/systems, as “tools” supporting sustainable district development, is also discussed. Specific experiences from Germany are considered in connection with the subject of “living laboratories” and the research project “Urban Transition Lab 131” focusing on a specific city district in Germany.

Keywords: sustainable neighbourhood, urban transformation, indicator set

1. INTRODUCTION

The UN predicts that by 2030, almost 60 per cent of the world’s population will live in urban areas (UN, 2014a). Given the current urbanisation trends, sustainable development challenges – and therefore, opportunities to be grasped – will be increasingly concentrated in cities. According to the latest progress report of the UN-HABITAT II (UN, 2014b) the current urbanization model is unsustainable in many respects and new conditions need to be defined to achieve inclusive, people-centred and sustainable global development. Cities, although being crucial “engines” of social and economic growth, have not succeeded in suitably addressing emerging and existing challenges, such as urban sprawl, congestion, air pollution, greenhouse gas emissions, social inequalities and poverty. In this sense, sustainability-related efforts in both science and policy arenas are broadening from building level (micro-scale) to neighbourhood and city level (meso- and macro-scale). A number of recent initiatives already attempt to address the common challenges in cities by providing recommendations and global targets for sustainable urban development. For example, “sustainable cities and human settlements” (Goal 11) is one of 17 Global Sustainable Development Goals (SDG) that make up the UN 2030 Agenda for Sustainable Development and it paves the way for fully transformative urban commitments and principles. At the same time, the outcome document of Habitat III (Parnell, 2016) will be the New Urban Agenda (NUA) providing guidelines and policy recommendations for sustainable urban development for the next two decades.

However, accomplishing sustainable urban development is a highly challenging task due to its complex and continuously-evolving nature. Many cities struggle to meet their sustainability commitments and determine detailed targets. Breaking down the “city” into smaller, more manageable urban units (i.e. neighbourhoods), and systematically involving local people and institutions (e.g. homeowner associations, business communities, residents’ groups, etc.) in their transformation and improvement process as “co-creators” and “change agents” is expected to facilitate a transition to urban sustainability. The neighbourhood level, as an intermediate level of analysis and action between the city level and that of individual buildings, has increasingly been proved as a promising level for developing and implementing sustainable urban interventions (Berardi, 2013). Within a neighbourhood, different types of community groups and social networks are formed and maintained providing in principle more opportunities for interaction and active participation in collective decisions and actions. Additionally, compared to the city scale, people residing in the same neighbourhood are more likely to share similar daily living experiences and exhibit a higher level of motivation to influence their immediate living environment.

However, the neighbourhood-scale sustainable development is an ongoing process that requires continual engagement, monitoring, assessment and revision. The paper focuses on issues related to the understanding and management of the process, including: a) the analysis of the current state and problems of neighbourhoods, including the identification of local actors having a direct influence on the their development, b) the creation of an appropriate set of indicators to monitor and assess performances, and finally c) the planning of a future strategy including the formulation of targets and the investigation of possibilities to act towards these targets.

2. SWIFTING TOWARDS A PROCESS-BASED APPROACH

Over the last decades, several sustainability assessment systems and tools have been developed for urban districts and neighbourhoods, mostly as a result of an attempt to expand and adapt already established sustainability assessment and certification systems of buildings, in order to better address the complexities of the urban scale (Sharifi and Murayama, 2013). This involves moving beyond dealing solely with issues related to the performance of single buildings and incorporating issues related to e.g. the quality of urban design and environment (e.g. design of public spaces, etc.) as well as to the way how people move, work and live within a place. However, these systems and tools are usually suited for assessing districts that are newly designed or in a planning phase, and thus mainly support planners and developers to consider the sustainability model at the master planning stage. Most of them are based on a performance- or outcome-oriented approach (absolute assessment of the performance), providing rating and/or certification based on the assessment result (level of sustainability at a particular point in time), but failing to reflect the dynamic and constantly changing nature of an existing neighbourhood. Therefore, they are still too inflexible to fully support the sustainability transformation and improvement processes of existing districts (Lützkendorf and Balouktsi, 2016a). In this case, it makes more sense to shift towards a more process-oriented approach and conduct “distance to target” assessments, namely measure the distance(s) between the current and the desired status (both short-term and long-term target).

Often, local authorities are not willing to support/allow for an absolute sustainability assessment for the area they represent to avoid the risk of stigmatisation and other substantial disadvantages a poor performance/score may cause. A neighbourhood of bad reputation may discourage potential investors and developers from engaging in its improvement processes and from covering (part of) the occurring development costs. However, there are cases where the developers or investors are the ones initiating the development process of an existing neighbourhood seeking to make profits through e.g. higher property values and higher market demand. In this context, receiving a sustainability certificate can be a long-term sub-target for an improvement process to attract more renters and homeowners. Hence, as a compromise, the two approaches can be combined to maximize the benefits. Another reason why most of today’s sustainability assessment systems can be considered as inflexible is that they usually use a “fixed” set of indicators. However, the sustainable development of an existing neighbourhood is a process driven by various types of stakeholders with different ambitions and interests, as well as different possibilities and capacities to act, compared to the planning of a new neighbourhood, where the main decision-maker is the developer. Having a “flexible” indicator set, capable of reflecting and adapting to the varying and time-evolving local interests/needs within the area and responding to emerging issues, would be an advantage – mainly because different perspectives can be considered within one system. In this case, different indicators can be used for assessing the same issue as a way to map the perspectives of different actors and to identify causes and/or effects of this (Lützkendorf and Balouktsi, 2016b). In process-oriented approaches, contrary to certification systems providing a fully aggregated version of the assessment result, the risk of double-counting is not present.

3. BASIC STEPS FOR SUPPORTING SUSTAINABLE NEIGHBOURHOOD DEVELOPMENT

3.1 Initiation phase

Initiation of a development process can occur in one of two ways (or their combination): top-down or bottom-up. Top-down initiation results from decisions made at the highest level, e.g. by local authorities as a response to specific problems or a hotspot of problems, or by researchers in collaboration with local authorities as a way of testing new approaches (e.g. urban living laboratories – see 4.2). On the other hand, bottom-up initiation usually begins as an attempt of a local interest group (e.g. property owners association) to harness a specific opportunity serving their interests (e.g. urban improvement districts – see 4.1). This is identified as Step 0 in Figure 1. To adequately manage the process, the composition of a committed "core team" (CT) is required, mainly consisting of a coordinator and key prime consultants/experts. The CT has usually a facilitating and steering role. As the responsibilities increase along the process, the CT evolves to engage a broader variety of local skills and experience (local stakeholders/representatives) and build the "overall team" (OT). Involving local actors as active consultants in the process empowers them to enjoy greater influence over what happens in the neighbourhood and generates a sense of ownership of the goals and long-term commitment to their implementation. A number of action steps are suggested in the following to help understanding and improving the organisation and planning of the development process itself.

3.2 Moving along the process

The spatial boundaries of a neighbourhood cannot always be defined in a consistent way; they must be adapted to the issues investigated and the indicators applied. It may be a territorially defined administrative unit of a city, an area of study/application whose demarcation is made from a contextual perspective, or an area the residents identify themselves with, and thus develop a higher sense of responsibility. A different boundary line can be drawn for each specific topic. Therefore, the initial selection of the boundaries of the area of intervention should be rough (not specified in an exact/fixed way based only on the administrative geography) to permit layering and overlapping, so as to adapt to the different goals and issues under examination (Step 1 – Figure 1). Having selected the location and an approximate area of intervention, it is important to describe and analyse its profile including basic statistics and background information about the residents, places, services, infrastructures and activities which make up the area (Step 2 – Figure 1). At this point, appropriate profile indicators (a term also used in ISO 37120:2014) should be selected for describing essential characteristics of the area investigated. No targets can be defined as reference lines for these indicators on the district level, as they "cannot be influenced" (at least not directly) by interventions of local actors and serve only information purposes (e.g. total number of households, percentage of unemployed people, etc.). However, some of them may give "early warnings" of problems to occur in future. In this case, strategies can be developed for fighting the consequences of these developments observed with the help of profile indicators. As part of the neighbourhood profile, it is also important to identify the main local actors operating or living in the area (i.e. homeowners, business owners, lobbies, associations and unions, local institutions), as well as their interrelationships.

The next step would be to develop a flexible indicator set to reflect the goals and aspirations for the neighbourhood improvement project and support the assessment of the progress towards sustainable development. The third step in the system's development is an extensive review of other relevant indicator sets and systems to obtain an insight into what has already been put into practice and will best suit the special characteristics of the neighbourhood under investigation. This is the so-called "top-down" or "expert-led" approach that is mainly driven by expert knowledge (Step 3 – Figure 1). Achieving compliance with national or international standards is also critical (e.g. with ISO 37120:2014). Furthermore, it is essential that existing national or regional sustainability strategies are taken into account if available.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

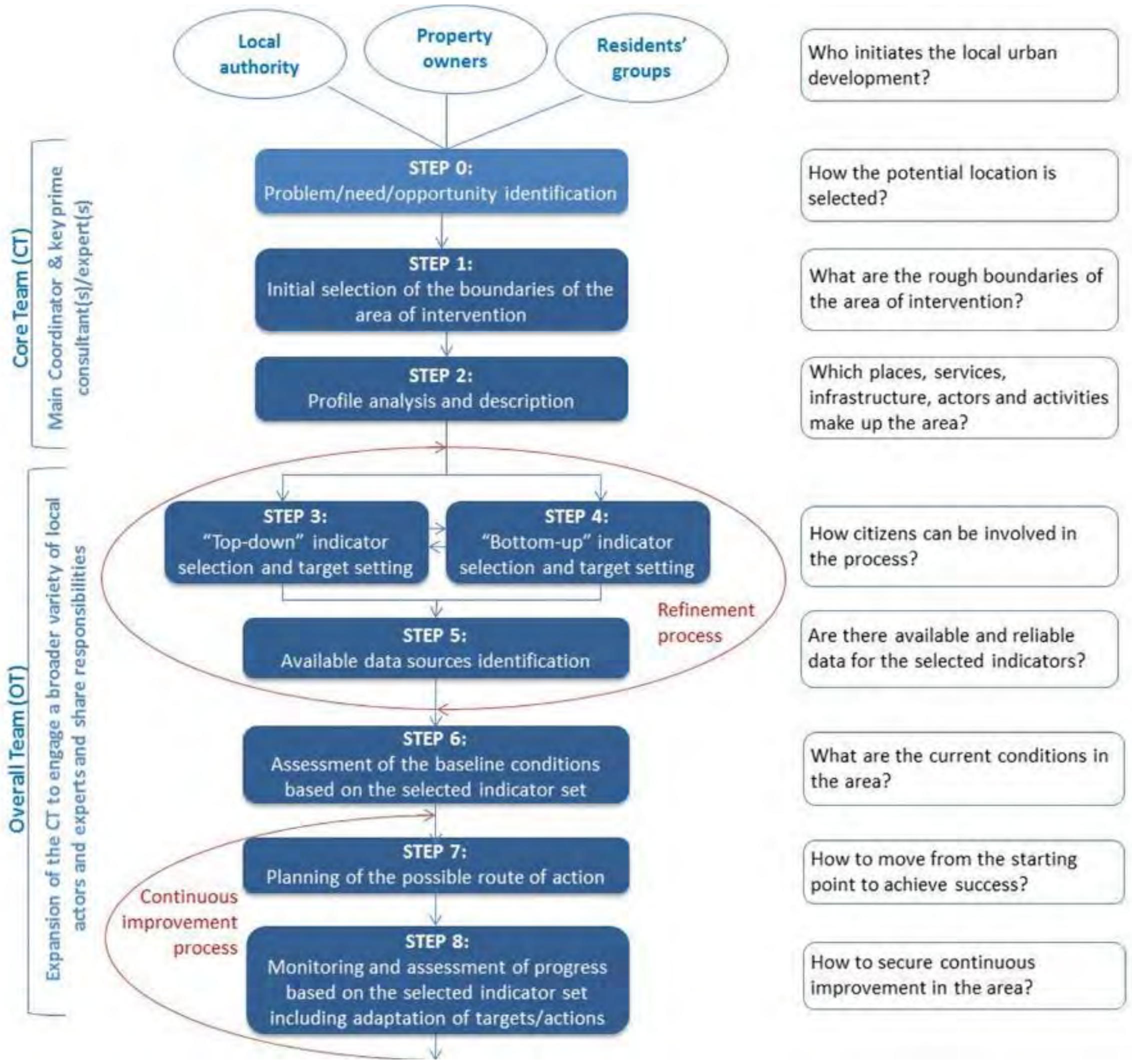

Figure 1: Basic steps for supporting sustainable neighbourhood development process

After utilising a top-down approach to select core problem areas and an initial set of core indicators, the needs and desires of stakeholders should be identified and accommodated through a bottom-up approach (Step 4 – Figure 1). To trigger and extract these, multiple interactive work sessions with local actors and residents should be organized, with experienced facilitators (e.g. researchers who have a good knowledge of both environmental and social sciences) guiding them through a "vision" process. Some of the specific issues and concerns of the people may already be reflected in the list of the selected core indicators. The rest should then be translated into context-specific indicators and targets. The iterative nature of the community-science interaction in the form of different participatory processes allows for a more diversified understanding that combines scientific and local knowledge. Finally, available data sources should be identified for the assessment of the selected indicators (Step 5 – Figure 1). In cases where data are not available in sufficient quality, the indicator set should be refined and supplemented with consequential indicators (alternative indicators to be used instead of a core or context-specific indicator) or new mechanisms for data generation should be suggested. This is possible only in cases where several indicators exist that can be used to assess the same criterion/thematic area. For example, the energetic quality of residential buildings (criterion) can be described and assessed in several ways; e.g. in terms of the energy demand, energy consumption, specifications for envelope and building services, etc. Therefore, it is possible to adapt the selection of the indicators to the available data and information.

Before starting the planning of a future improvement strategy, the baseline performance of each of the selected indicators should be identified through a first assessment (Step 6 – Figure 1). This will form the basis for setting specific short-term and long-term targets (intended result) per indicator taking into account, among others, current political and scientific debates, regional and national action plans and existing targets in other comparable areas/regions. Once the targets have been set, the next step is to identify the measures of intervention needed to

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

meet them and the stakeholders able to act related to each specific problem, thus to plan the possible route of action by assigning specific responsibilities and tasks to specific stakeholders (Step 7 – Figure 1) This should result in a clear road map. It is also important to convince "passive" actors to accept the planned changes, as well as to consider any risks that might jeopardize the plans (e.g. target conflicts, unwillingness to cooperate, etc.). For example, a tenant can be considered as a passive actor in the case of an energy modernization of a residential building. In any case, the possible measures of intervention should be made transparent, as far as possible, regarding their specific advantages and disadvantages for each affected party. Last but not least, establishing suitable mechanisms for monitoring and assessing the progress regarding the extent to which the various targets (short-, medium or long-term) are achieved is essential for securing continuous improvement in the area (Step 8 – Figure 1). In this way, an understanding can be gained on how effective the plans are and what adaptations of targets and actions are required for progress towards sustainable development.

4. INSTRUMENTS

A broad range of instruments is imaginable, currently under discussion or even tested, that may help to implement the process described above or particular steps of it. In the following, two examples are outlined addressing different facets of urban district development.

4.1 **"Urban improvement districts" as a new financial framework**

The process of sustainable neighbourhood development is usually associated with substantial financial expenditure and cannot be supported by a top-down strategy alone. Therefore, it is essential to ensure the necessary financial resources for the implementation of the concept by creating incentives for local actors and mobilizing private capital to complement public funds. State and private actors have the common goal to stabilize or revitalize neighbourhoods. One stimulus for the land and property owners can be that an improvement in the quality of the site/location can have a direct and positive effect on the real estate value of their properties through improved performance. Therefore, the traditional methods of urban development (government-driven action) and private-driven initiatives in this field can be seen as two sides of the same coin – there is a place for public–private partnerships, like "Urban Improvement Districts" (UID), in neighbourhood transformation processes. UIDs, e.g. in form of business, housing and neighbourhood improvement districts (BID, HID, NID) (Kreutz, 2009), offer a framework for pooling initiatives to support sustainable neighbourhood development and mark an "in-between position" between the private and public domains. UID's are legally defined areas in which the improvement processes are realised on the basis of private initiative, including the participation and self-organisation of local stakeholders to implement the necessary measures, and the use of financial resources of private stakeholders, e.g. landowners in the case of HID's. To this end, in many of these models a task manager is assigned, who cooperates with both the (local) private stakeholders and the municipal authority. UID's are financed by a tax which is levied by the municipality and collected from all land owners in the area. The authors believe that a process-based sustainability assessment can be effectively combined with the UID's framework. UID can provide the organizational and financial framework for the implementation of sustainability measures identified as a result of an analysis of the present situation.

4.2 **"Living labs" as a new form of collaboration and co**-creation

There is a basket of living labs around the world focusing on sustainable urban development and including actors from all sectors of society, academia, government and industry, in combination with the community (Salter and White, 2014). Many of them have universities as the driving force for their development and implementation. Living labs distinguish themselves from other innovation approaches in development processes by supporting the participation of multiple stakeholders beyond consultation and towards joint decision-making, focusing on the idea of empowerment and co-creation. Such a process is now being supported and moderated in the research project "Urban Transition Lab 131" by a scientific team appointed by "KIT Centre Humans and Technology" of the Karlsruhe Institute of Technology (KIT), in collaboration with the city of Karlsruhe and many other parties at urban district level. The development of a methodological, transdisciplinary basis and the selection of indicators by the KIT project team are still on-going. Bottom-up indicators will be further developed and agreed on, together with the actors involved in the urban transition lab. This will be achieved by carrying out specific surveys of certain groups of actors in the district. In this context, the residents' general understanding of sustainability has to be investigated. In addition, "fact sheets" will be created for the description and communication of appropriate bottom-up and top-down indicators, while, in consultation with the municipal administration and other influential stakeholders, the data collection for each individual indicator will be pushed forward. An initial presentation of such “fact sheets” has already been provided (Lützkendorf et al., 2016). Here, the problem of data protection has been proved to be a challenge. One approach is the active provision and release of data through the residents and businesses in the neighbourhood on a voluntary basis - as a form of participation.

5 CONCLUSIONS AND OUTLOOK

Sustainable development of a neighbourhood is a long-term, ongoing process. It is possible and advisable to carry out this process in close interaction with local actors. It is necessary to develop mechanisms that bring together experts and community members to develop indicators that stimulate and measure the progress towards sustainability. In this case, the instrument of “living labs” supports the process by fostering collaboration and co-creation (co-design). Such collaborative actions can provide a flexible indicator set that reflects local values, necessary actions and possibilities to act. The current discussions about the further development of ISO 37120 also point in this direction. Once the final list of indicators best suiting the characteristics of the neighbourhood is acknowledged and widely accepted, the indicators need to be clearly and precisely described and documented. The development of a “factsheet” for each indicator that contains all necessary information is necessary. Within the context of the further development of such factsheets, their purpose should not only be to identify and list all possible data sources and alternative calculation procedures for each indicator, but also to identify the acting stakeholders and their options/opportunities for action to implement specific measures to achieve progress. Besides the growing political commitment worldwide towards the inclusion of local actors in the sustainable neighbourhood development process, it is also important to find solutions to better mobilise capital required for investments in the process. One approach, among others, for this, is the model of Housing Improvement Districts (HID). In the near future, more new models of public-private partnerships should be tested in the context of neighborhood sustainability transformation processes, as a precondition to become more familiar with the new roles and tasks that are associated with it.

How Can We Assess the Achievement of The Sustainable Development Goals? – A Review of Indicators and Their Application at the City Level

Roland ZINKERNAGEL[a]

[a] *Lund University, Sweden, roland.zinkernagel@iiiee.lu.se*

ABSTRACT

This paper focuses on the assessment of the UN Sustainable Development Goals (SDG) and the use of indicators to assess performance at the city level. Although indicators need to reflect the particular local conditions and requirements, the SDGs can provide guidance to local governments on how to assess progress towards sustainable development, both at global and local level. A challenge is that there is no common definition of sustainable cities and often indicators are failing to include the entire spectrum of sustainability, in effect they tend to be dominated by assessing the environmental/ ecological performance.

In this paper the use of indicators to evaluate the progress of sustainability in cities will be reviewed. The results of the review will be used to compare existing indicators used to assess sustainable development in cities to the indicators suggested by the UN SDGs.

Keywords: sustainable neighbourhood, indicators, sustainable development goals

1. INTRODUCTION

In the autumn of 2015 the UN introduced the Sustainable Development Goals (SDGs) in order to be able to provide guidance at global, national, regional and local level towards a more sustainable world (UN, 2015). The 17 goals cover all three different aspects of sustainable development as defined by the Brundtland commission. They comprise of 168 targets and 239 different indicators in order to be able to follow up progress towards reaching the Sustainable Development Goals (UN-1, 2016). The indicators are currently still under development, at the moment several of the indicators are still being discussed (UN-2, 2016). The need for indicators has been identified by the United Nations in order to make it possible to measure progress and to make sure that no actor is left behind (UN, 2015).

This paper focuses on the assessment of the SDGs and the use of indicators to assess performance at the city level. Although indicators need to reflect the particular local conditions and requirements, the SDGs can provide guidance to local governments on how to assess progress towards sustainable development, both at global and local level. So far, there has been done very limited research on the application of the Sustainable Development Goals on local level.

In this paper the use of indicators to evaluate the progress of sustainability in cities will be reviewed. The results of the review will be used to compare existing indicators used to assess sustainable development in cities to the indicators suggested by the UN SDGs.

2. INDICATORS FOR THE EVALUATION OF SUSTAINABILITY PERFORMANCE OF CITIES

Indicators are a useful and efficient tool to collect information on performance and can be used as one foundation for local policy making (Miller, 2005). The Programme of Action for sustainable development, which was adopted at the United Nations conference on Environment and Development in Rio de Janeiro in 1992, asked for the development of indicators for sustainable development in order to be able to take grounded decisions that foster a self-regulating, integrated and holistic sustainable development (UN, 2007; UNSD, 1992). Ever since, many sets of indicators have been developed to assess the development of sustainability, including sustainability in cities. The ISO 37 120 standard on global city indicators (International Organisation for Standardization, 2014) and the indicators suggested to assess progress towards the SDG being two recent examples on global level. Both build on experiences made from earlier indicator systems, such as the UN Habitat Urban Indicators (UN Habitat, 2004) and the Millennium Development Goals and their associated indicators (UN, 2008). Many cities and regions have

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

also been developing own indicators to measure progress towards global as well as local goals and targets (Astleithner et al., 2004; Tanguay et al., 2010; Neumann et al., 2015; Vázquez et al., 2015).

2.1 What are sustainability indicators?

Indicators are a useful tool to assess the current status (Wilson et al., 2007; Kitchin et al., 2015; King, 2016). Giving feedback and performance assessment is the most important role that indicator systems have, the emphasis is on locating the problem (Fitz-Gibbon, 2002; Science for Environment Policy, 2015). An indicator shows that a certain condition exists or certain results have or have not been achieved (OECD, 2008; Astleithner et al., 2004; Horsch, 1997), using the same indicator several times makes it possible to see trends and development directions. This needs to be connected to a realistic target that should be achieved within a defined time (OECD, 2008). Indicators are non-subjective tools and measure variables over time and/ or space and are seen as decision support instruments. They do not need to be quantified, measurement can be on the basis of qualitative scales (Astleithner et al., 2004).

9 Frameworks and criteria for selecting indicators

Research has developed frameworks in order to be able to group indicators and find causal relationships between the indicators or alternatively frameworks that make it possible to structure reality and facilitate the identification of crucial intersections where indicators would be most meaningful. The development and use of a conceptual framework based on causal networks will aid the selection process as it “facilitates the identification of the most relevant indicators for a specific domain, problem and location” (Niemeijer and de Groot, 2008). Similarly Hak (Hák et al., 2016) and Singh (Singh et al., 2009) consider the use of conceptual frameworks advantageous for indicator selection. Alternatively, system dynamics modelling can be used as a framework to reflect the complex nature of sustainable development (Dahl, 2012). Most commonly used examples of frameworks are the Pressure-State-Response model and its derivatives (Niemeijer and de Groot, 2008) or conceptual frameworks such as policy-based or conceptual approaches (Hák et al., 2016).

Furthermore, indicators can be grouped according to the type of development they measure. Costa (Costa, 2015) groups them into reflective (a manifestation of what is being observed), causal (where an action influences the outcome of the indicator) or composite (where the outcome of the indicator is a result of several correlating factors) indicators. Based on an approach focusing on an evaluative scheme, indicators can be grouped according to what they are measuring, i.e. inputs, processes, outputs or outcomes (Luederitz, in press).

There are quite a number of selection criteria that have been identified and certainly there are a lot more that are being used in the field. The criteria that are most commonly found in research are that they should be policy relevant, that they should be reliable and measurable, that indicators should be wide in scope and that they should be simple (Böhringer and Jochem, 2007; Ness et al., 2007; Wilson et al., 2007; Science for Environment Policy, 2015; Niemeijer and de Groot, 2008). There is however a plethora of selection criteria that spans from analytical soundness to process orientation to the ideal number of indicators used.

As Niemeijer points out “there is considerable room for improvement in the indicator selection process” (Niemeijer and de Groot, 2008).Click here to insert your content.

3. RESULTS

3.1 How have cities used sustainability indicators?

A literature search was conducted using search terms such as city development, indicators, sustainability assessment and related words in different combinations in order to get an overview how city development has been assessed and what schools of thought exist to structure indicator development. The literature search revealed that research has focused mostly on selection criteria, i.e. which characteristics the indicators should fulfil in order to provide useful information to the policy maker or whoever might be using the data derived from the indicators (Böhringer and Jochem, 2007; Ness et al., 2007; Wilson et al., 2007). The research that did investigate in cities' selection criteria for choosing indicators did however show that usually indicators are selected by political prioritisation, perceived importance and/ or data availability (Keirstead and Leach, 2008; Shen et al., 2011;

Lehtonen et al., 2016). There is an implementation gap between the scientific discussion on indicator selection criteria and the application of these criteria on practical level in cities.

However, cities have been and are using indicators to a larger or lesser degree. Indicator use for the assessment of economic efficiency, of living standards or pollution are but a few examples. Environmental indicators have been used in cities increasingly in parallel to the increasing environmental degradation that went along with an increasing industrialisation (Munn et al., 1988). Social indicators have been used since the first half of the 18th century although they have been continuously refined and contextualised since then (Cobb and Rixford, 1998). It is worth noting that the use of indicators has been changing over time, in line with an increasing trend to incorporate 'New Public Management' ideals into public administration, i.e. the ideals of cost-efficiency, decentralisation, customer-orientation and empowerment. The desire towards economic efficiency is reflected in the choice and use indicators in the public sector (Astleithner et al., 2004).

With the introduction of the sustainability concept and its application to city development comes the urge to develop sustainability indicators as described above. A challenge is that there is no common definition of sustainability or sustainable cities (Huang et al., 2015). Despite the three decades that have passed after the Brundtland commission's report are indicators failing to include the entire spectrum of sustainability, even though they are meant to assess the sustainability of a city; in effect they tend to be dominated by assessing the environmental/ ecological performance (Tanguay et al., 2010; Böhringer and Jochem, 2007). Luederitz carried out a cluster analysis of scientific literature on the sustainability performance of urban neighbourhood development and came to the conclusion that none of the 21 papers covered all of the three sustainability aspects or at least not to a significant degree (Luederitz et al., 2013).

The literature review has shown that a lot of research in the field of assessing urban sustainable development has been done comparing different indicator systems, i.e. groups of indicators that collectively describe a state or condition. Examples of indicator systems are the Ecological Footprint, Environmental Sustainability Index, Dashboard of Sustainability, Welfare Index, Genuine Progress Indicator, Index of Sustainable Economic Welfare, City Development Index, Emergy/ Exergy, Human Development Index, Environmental Vulnerability Index, Environmental Policy Index, Living Planet Index, Environmentally-adjusted Domestic Product, and Genuine Saving. This list is however not exhaustive and could be extended. Similarly to the use of individual indicators, research has assessed the varying usefulness of indicator systems but not the extent that cities actually have used the different indicator systems.

Shen (Shen et al., 2011) uses the International Urban Sustainability Indicators List (IUSIL), which consists of 115 indicators formed into 37 categories, in order to analyse and compare different sets of sustainability indicators chosen in various cities around the world. Comparability across cities is argued to be important to create a common baseline and be able to apply successful tools and measures. At the same time Shen also realises that "there is no single set of indicators that suits equally to all cities" (Shen et al., 2011). Similarly, a varying understanding of what sustainability is will lead to different indicators being selected, and in turn that means that the selection of indicators will influence the sustainability statues that the indicators give (Wilson et al., 2007).

Mori analyses 14 indicators systems and some applications of composite indices regarding their coverage of the triple bottom line, if they cover a global or local perspective and whether they follow the perspective of weak or strong sustainability and concludes that none of the systems satisfies the requirements necessary to reach sustainability (Mori and Christodoulou, 2012).

For the purpose of this paper global or international indicator systems were analysed and compared to the structure of the UN Sustainable Development Goals. This made it possible to see to what extent indicator systems cover the same or similar aspects as the SDG. The indicator systems that were chosen in this research were selected on the grounds of their coverage, i.e. they need to cover at least the three most common aspects of sustainability (environmental, economic and social aspects), need to be developed for a larger geographical area and have been widely used. The following indicator systems were chosen: SDG indicators, ISO 37 120, UN habitat urban indicator guidelines, European Common Indicators, Better Life index, Sustainable city index UN Commission for Sustainable development's Indicators for sustainable development, Urban Sustainability indicators.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Name of indicator system	SDG indicators	ISO 37 120	Better Life index	CSD indicators of SD	UN Habitat Urban indicator guidelines	European Common Indicators (ECI)	Urban sustain-ability indicators
Year of intro-duction/ most recent version	2015	2014	2011	2007	2004	2004	1998
Number of indicators	239	94	24	49	38	10	15
Actual use in cities	No numbers available yet	30 cities have reported at least some indicators	Reporting mostly on country level	No information on use in cities	Different versions are used by 200+ cities	Tested by 42 cities	No information on use in cities

Table 1: Overview over analysed indicator systems

In lacking input on the factual use of sustainability indicators by cities it was decided to use the application of the above indicator systems as an approximation. Table 1 shows how many cities have been using the indicator systems. The UN Habitat indicator guidelines have been most frequently used. They have been introduced more than ten years ago and while this might be used as an argument for their extensive use it is worth noting that other, older indicators have been less popular up to the degree that there is no information to be found. Many indicators, especially European ones have been developed through different EU financed projects. Even though the intention is to ensure the use of them after the end of these projects it seems that this is not happening. Either new indicators are being developed (building on the experience of the previous ones) or they are being replace by other indicator systems. In the case of the UN Habitat Urban indicator guidelines, they have been incorporated in the Millennium Goal Indicators, which in turn have been incorporated in the Sustainable Development Goal indicators. What becomes obvious is that indicators in the field of sustainable city development (Goal 11 of the SDGs) and water and sanitation (Goal 6 of the SDG) have been equally important already in the UN Habitat indicators.

When analysing the most commonly used indicator sets (UN Habitat urban indicator guidelines, ISO 37120 Smart City Data, European Common Indicators) and the topics that they cover it becomes possible to get an indication which indicators are most commonly used by cities. This analysis reveals that indicators within Goal 11 are most popular (49 indicators). The indicator that can be found in all three indicator sets is the one on air quality, i.e. levels of PM10 and PM2.5. Also aspects of waste management are frequent as are indicators on settlements on hazardous locations. The second most used indicator group is the one represented by Goal 6 (18 indicators) where indicators on access to safe drinking water, wastewater management and availability of sanitary facilities can be found in all three indicator sets. Indicators under Goal 16 (15 indicators) are the third most popular. The indicator on victims of homicide can be found across the indicator sets as well as indicators on the percentage of women in public institutions/ city government and participation rate in municipal elections. Areas that are not at all covered are the ones associated with Goals 2 (zero hunger), 10 (reduced inequalities) and 14 (life below water). The results of this analysis go in line with the findings of the literature review that sustainability indicator sets tend to be dominated by indicators on the environmental performance (Tanguay et al., 2010, Böhringer and Jochem, 2007).

Figure 1 visualises the diversity and to which extent different indicator systems include all aspects of sustainability, following the structure of the SDGs. The extent to which indicator systems has been increasingly covering all aspects of sustainability becomes obvious when considering the time of introduction of the respective indicator set. At the same time it also becomes obvious that some indicator sets, in this case the ISO 31 120 standard on Smart City Data, are specialising on certain aspects in order to attempt to fully cover this topic. Even when disregarding the fact that the SDGs have by far the most number of indicators it becomes obvious that they are the ones that most holistically cover all aspects of sustainable development.

Figure 1: Comparison of indicator sets regarding their coverage of sustainability aspects

3.2 Usefulness of SDGs at local level

One of the SGDs, goal 11, is specifically addressing cities and human settlements, setting the target to make them inclusive, safe, resilient and sustainable. This is the result of experiences with the implementation of the millennium goals as well as the lobbying to recognise cities as an important driver for transformation as well as the importance of a bottom-up approach for global change (UCLG, 2015) ("SDGs: Sustainable Development Knowledge Platform," n.d.). Despite a specific goal focusing on the urban perspective, all goals are relevant for cities, and so are their respective indicators. Of the 239 indicators 215 are considered to be relevant on local level, see Figure 2 below.

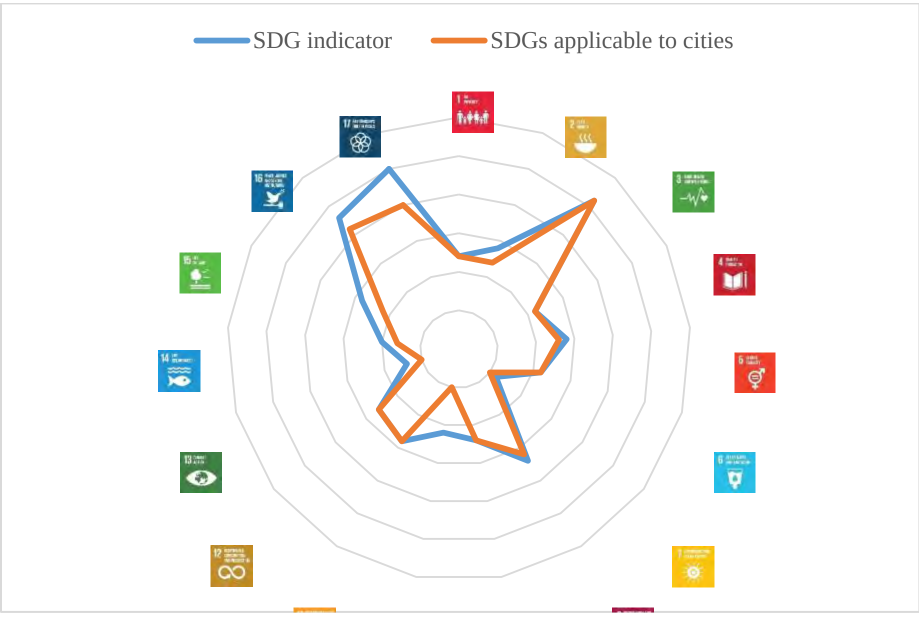

Figure 2: Comparison of SDG indicators and their relevance in a local context

Research regarding the implementation of the SDGs on local level is still limited. One example is the study by Simon (Simon et al., 2016) who tested collecting data on the SDGs for five cities. The focus of that study is on Goal 11, and makes suggestions on how the usefulness of the SDGs can be maximised on the local level. United Cities and Local Governments produced a non-scientific guide for local governments on important aspects to consider when implementing the goals locally (UCLG, 2015).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

A comparison between the commonly used indicators and the ones suggested within the SDG framework identifies which topics are most common across the indicator systems. These indicators cover air pollution, waste management, sanitation and drinking water, education and safety and security. This goes in line with findings from the literature review i.e. that environmental aspects de facto dominate 'sustainability assessments'. The types of indicators that are not included in systematic sustainability assessments are opinion-based indicators, alternatives to GDP as a measure of wealth or indicators based on an ecosystem approach, as suggested by Vazques (Vázquez et al., 2015).

4. DISCUSSION

Cities are using indicators to be able to identify changes over time, to assess performance and for decision makers to be able to make the appropriate policy decisions, yet it is not sure if the use of indicators actually benefited the city's development. The literature review revealed that there is a gap between the academic view on which criteria to use when selecting indicators and the practical approach of cities. This is furthermore illustrated by the lack of scientific evaluation of the use of indicators in cities and the impact they might have had on cities developing towards sustainability.

The UN Sustainable Development Goals are an attempt to define a holistic target situation. As the comparison of the SDG indicators with other indicator systems showed, the SDG indicators indeed cover sustainability aspects to the largest extent of all indicator systems. It is clear that this is not least due to the fact that the SDG indicators are by far the largest in number of all the analysed indicator sets, at the same time it becomes also clear that the purpose of the sustainable development goals is to be applicable in a large variety of global contexts.

SGD indicators are to a large extent relevant also on the local level. The apparent exception here are most of the indicators under goal 10, reduced inequalities. These indicators are aimed at the national or international level, such a migration policies or international trade. Locally adapted indicators would need to be developed to sufficiently reflect this goal.

Using the SDG structure for sustainability assessment at local level would make it possible to receive a broad and combined picture of sustainability performance. Cities need to be able to choose and prioritise amongst the indicators according to the local conditions. This is a consequence of the approach that the UN has chosen by developing goals that need to be usable in a global context. Although it is interesting to be able to see how peer cities perform it will however in practice be very difficult to do direct comparisons as different aspects will be more or less important, both from a sustainability perspective but also on a political and managerial position. Tracking changes over time in one city is considered more valuable for cities to progress towards sustainable development.

Session 4.12: Healthy Building, Human Comfort & Wellbeing

Healthy Buildings and Energy Performance – A Balancing Act

Eriko TAMURA[a], Mark RICHARDSON[b]

[a] *Arup, Hong Kong SAR, eriko.tamura@arup.com*
[b] *Arup, Hong Kong SAR, mark-a.richardson@arup.com*

ABSTRACT

The world is seeing a rapid move towards Healthy Buildings. This is in part based on recent research and insights relating productivity to building design and in part due to a changing society which is becoming more health conscious. As such designers, property developers, building operators and building users are concerned about implications to building design, initial and operational costs, operation and maintenance, etc. A key consideration is the impact on energy performance, where in recent years building design has generally pushed towards energy reduction; healthy building design may challenge this. In this paper, experience from designing high grade offices and other high performance buildings is used to frame the discussion and highlight the challenges and opportunities that high quality built environment design and implementation can offer.

This paper offers key insights to practitioners when applying these principles in a range of development contexts. Consideration is given to a building environment which is challenged by poor external air quality, a working culture that favours longer hours in smaller spaces and low energy prices. It concludes by highlighting a number of initiatives which where feasible are quantified based on effect, difficulty of implementation and long term practicality.

Keywords: energy saving, high-performance building, healthy building

1. INTRODUCTION

The building industry has been under a great pressure to reduce energy consumption and greenhouse gas emission to slow global warming. In 2015, the government of Hong Kong SAR issued Energy Saving Plan for Hong Kong's Built Environment 2015-2025+, which set out a target for energy intensity reduction of 40% by 2025 using 2005 as the baseline. Buildings account for 90% of total electricity consumption in Hong Kong and the statutory requirements and regulations for both new and existing buildings have been reinforced regularly. In the course of pursuing high-energy performance building envelope performance improved. Curtain wall systems with high window-to-wall ratios (WWR), require high energy performance glazing with darker colour is typically required to comply with a statutory requirement in Hong Kong.

Globally there is a growing awareness of the impact a built environment can make on physical and psychological health, indicated by sick building syndrome, absenteeism, etc. Following this trend, a building certification system, the WELL Building Standard® was launched to quantify health and well-being of the built environment. This is additional to sustainability focused green building certification systems such as Leadership in Energy and Environmental Design (LEED®) or the Building Environmental Assessment Method (BEAM) Plus in Hong Kong.

Through technical studies for a notional commercial office building incorporating healthy building concepts while maintaining a high energy performance, challenges and opportunities to design have been identified. This paper summarises the findings.

2. DEFINITION OF HEALTHY BUILDING

In the context of building design, this paper focuses on air and light as the factors which have a direct impact to the physical and psychological health of building occupants. The term of healthy, health or well-being in this paper means a performance which minimises harm to physiological and psychological health.

2.2 Air quality

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Air pollution increases the risk of strokes, heart disease, lung cancer, and both chronic and acute respiratory diseases – it is estimated that outdoor air pollution caused 3.7 million premature deaths worldwide in 2012. Particularly in Hong Kong, industrial air pollution and road site pollution from busy traffic threaten people's health. To enhance the energy performance of buildings, envelope air tightness is required to be higher with less infiltration, therefore ventilation of interior spaces requires mechanical ventilation. A healthy building may mean that indoor air has better air quality than outdoor air in some polluted cities.

10 Light environment

It is an established science that sunlight at different times of day effects human circadian rhythms, although the exact mechanism is not fully understood. However, in a highly controlled built environment, such as office buildings, where occupants may spend nearly half of the day under artificial light, this connection to the natural condition is lost and occupant health can suffer.

3. AIR

3.1 Air pollutants and impact on health

The first step to achieving a better indoor air quality (IAQ) is to identify the pollutants, source of the pollutants and limit of contamination of specific pollutants. Air pollutants are known to cause various health issues, for instance, particulate matters are recognised to cause respiratory and cardiovascular disease.

3.1.1 Criteria

Various organisations advise the maximum allowable concentration of air pollutants including: Environmental Protection Department, HKSAR (EPD); World Health Organization (WHO); U.S. Environmental Protection Agency (EPA); and the WELL Building Standard. The recommended or required values for critical air pollutants for a commercial office building in an urban area by various organisations are summarised in Table 1. In Hong Kong, The EPD has established a voluntary scheme, IAQ Certification Scheme, in which two classes of certification level are quantified: Good Class and Excellent Class. The Good Class is classified as 'IAQ that provides protection to the public including the young and the aged', being entitled to obtain one credit is the local green building certification system, BEAM Plus.

Pollutant	Source	Unit	Maximum Concentration				
			EPD [4]		WHO [5] [6]	EPA [7]	WELL* [2]
			Excellent	Good			
CO	**Outdoor** Tobacco smoke, vehicular exhaust, Industrial activities, construction activities / heating equipment	ppm	1.7 (8hr)	8.7 (8hr)	90 (15min) 50 (30min) 25 (1hr) 10 (8hr)	35 (1hr) 9 (8hr)	9 (8hr)
$PM_{2.5}$		μg/m³	N/A	N/A	10 (1yr) 25 (24hr)	12 (1yr) 35 (24hr)	15 (1yr)

3.2 Energy vs air quality

For the pollutants from outside of the building identified in Table 1, air purification or filtration will be effective and for the pollutants produced indoors, adequate outdoor fresh air supply is fundamental, provided that the outdoor air quality is of sufficient quality. For a grade A office building in Hong Kong, with centralised air conditioning, filtration of outdoor air is applied. Different types of filtration are investigated in terms of pollutant removal, implications to energy consumption and maintenance, etc. as shown in Table 2. The figures are based on typical systems installed in Hong Kong.

Minimum efficiency reporting value (MERV) rated filters are categorised based on their filtration levels of dust or particulate matters. MERV 13-16 filters are typically applied for superior commercial buildings. The higher the rating is, the higher the pollutant removal efficiency as well as pressure drop are. When every AHU in a commercial office building (with recirculation) has a MERV 14 filter, energy consumption by AHUs is estimated to increase by approximately 7% when compared to a MERV 13 filter. A desktop study to estimate the PM2.5 concentration in the same office building suggests that when MERV 13 filters are installed, the PM2.5 and PM10 values of indoor air will not exceed the values recommended by WHO. This study used actual outdoor PM2.5 recorded in a business district of Hong Kong Island where 1-year mean level of PM10 is around 23 $\mu g/m^3$, which is higher than the recommended value by WHO (20 $\mu g/m^3$). For this case, considering the energy penalty and the effectiveness at achieving a good level of PM, MERV 13 filters can be considered.

On the other hand for other pollutants mainly generated indoors such as HCHO and VOC, activated carbon filters and catalytic ionizers were investigated. As the filtration or purification mechanism of those filters is a chemical reaction, the pressure drop associated with the filtration is smaller than MERV filters. However, electricity input is required for operation and activation of the filter.

Mechanism	Fibre (MERV filters)		Activated Carbon	Catalytic Activated Carbon	Catalytic Ionizer
Major target pollutants	MERV13 PM	MERV14 PM	HCHO TVOC	NO_2 HCHO TVOC	HCHO TVOC Germs
Filtration efficiency	90% PM_{10} 85% $PM_{2.5}$ 50% ultra-fine PM	95% PM_{10} 90% $PM_{2.5}$ 85% ultra-fine PM	~80% NO_2	~95% NO_2	99% TVOC 95% HCHO
Implications to energy	Pressure drop ~120Pa	Pressure drop ~150Pa	Pressure drop ~100Pa	Pressure drop ~50Pa	<45W
Maintenance frequency	Yearly replacement	Yearly replacement	Washing 2/half year	Weekly washing	2 years
By-products	Nil	Nil	Nil	Nil	O_3

Table 2: Types of air filters for primary air handling units and air handling units

3.3 Design options and strategy

When health is given a higher priority in building design, it starts to become apparent that traditional variable air volume (VAV) systems, which combine fresh air delivery with maintaining temperature and humidity set points have limitations. The limitations primarily arise locally within offices at high pollutions zones (e.g. printing rooms) or in high and variable occupied rooms (e.g. meeting or seminar rooms). As such the use of dedicated outdoor air system (DOAS) responding to multiple local sensors show significant advantages for air quality.

Feedback from building management teams often includes multiple complaints regarding meeting room air quality when served by VAV systems. This generally occurs as CO2 levels are measured once per floor in a return air plenum, accounting for only the number of people per floor. Fresh air then makes up a set percentage of the delivered air per floor. Total delivered air volume to each space is a function of room temperature and as such when meeting rooms become heavily occupied, CO2 levels increase faster proportionally than heat gains and fresh air is underserved. Computational simulation of a typical office, based on ASHRAE fresh air volumes plus

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

30%, highlight that meetings rooms served by VAV systems will have CO2 levels higher than 1,000ppm, i.e. higher than ‘Good Class’ by EPD (Table 1). Figure 1 below shows VAV performance compared to DOAS. The adoption of DOAS overcomes this and requires pollution sensors in each zone of concern.

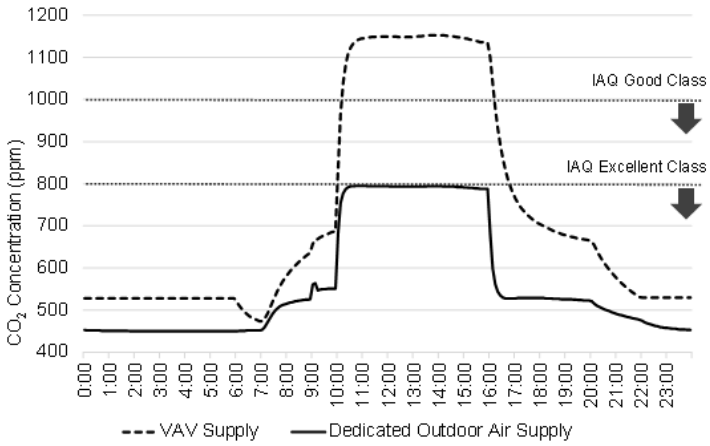

Figure 1: Comparison of fresh air supply systems regarding CO_2 concentration

4. LIGHT

Research has shown that light has a strong relationship with human circadian rhythm, regulating human body clocks and human health. Although the science still leaves uncertainties including the combined effect of different colours, intensities, spectra and experience of light, it is well established that daylight is the best light for human health.

4.1 Natural light and artificial light

The British Standard Code of Practice for Daylighting summarises the benefit of daylight as follows: 1. Regulation of the circadian system; 2. Mood; 3. Seasonal Affective Disorder (SAD); and 4. Ultraviolet radiation. WHO suggest that disruption of circadian rhythm can increase the risk of heart disease. Daylight has variations in light intensity, spectral wavelength distribution and direction throughout the day, all of which are believed to have effects on the circadian rhythm. However, the eyes’ biological reaction to light is also affected by the surrounding environment such as a phenomenon known as The Purkinje Effect: when illuminance level is low, human eyes are more sensitive to blue lights.

Due to higher energy efficiency, LED are getting more popular. For a typical office building, lighting power can be reduced by 2-7% compared to T5 fluorescent tubes. By understanding the benefits of natural light or daylight to human health, there is a trend for artificial lighting to mimic daylight in terms of colour temperature variation, directional variation over time and spectral distribution. Improved LED technology in the past few years is reducing issues associated with the technology such as flickering and inconsistent colour, etc. LED has flexibility in control including colour, intensity and daylight spectrum matching. These characteristics of LED enable an artificially lit environment for human health.

4.2 Quality and quantity of light in a space

Major building elements which affect the quality and quantity of light through building façade are identified in Table 3. Glazed curtain wall buildings with high WWR are still favoured for commercial office buildings, maximising the view out from the rental space. When occupants are angled towards a glazed façade, occupants are given access not only to the views but also to daylight. Daylight is commonly measured by the average daylight factor (ADF). In general, higher VLT and WWR directly contribute to higher ADF.

Building Element	Glazing	Shading Device	External/ Internal Blinds
Parameters	• Visual Light Transmittance (VLT)	• Depth	• Configuration

	• Shading Coefficient, in relation with VLT (SC) • Colour Rendering Index (CRI) • Window-to-Wall Ratio (WWR)	• Orientation (horizontal/ vertical) • Material	• Control (automatic/ manual) • Colour • Material

Table 3: Building elements and parameters to affect quality and quantity of light

Fabric heat gain through building envelope is affected by building orientation, WWR, SC of glazing, U-values of opaque area and density of opaque area, etc. These parameters must be optimised to control heat transfer through the building envelope while achieving targeted VLT and CRI of glazing to ensure the quality of daylight.

4.2.1 Criteria

Lighting criteria under various green building certification systems and standards are compared and highlighted in Table 4. Green building certification systems such as BEAM Plus and BREEAM tend to set the daylighting requirement relative to surrounding environment. This allows flexibility to achieve design criteria. On the other hand, the SLL Code for Lighting and WELL suggest lighting performance of a lit space to suit activities and the visual comfort of occupants.

Source	BEAM Plus	SLL	BREEAM	WELL
VLT	N/A	N/A	N/A	60% (>2.1m from floor) 50% (≤2.1m from floor)
WWR	N/A	N/A	N/A	20-60%
CRI	Ref: SLL	80 for office space	N/A	Ra ≥ 80 R9 ≥ 50
Illuminance (basis for assessment)	Ref: SLL	500 lux for writing, typing, etc.	300 lux	300 lux
ADF	≥ 1.0%	N/A	≥ 1.5%	N/A

Table 4: Requirements and suggested criteria for façade and lighting design of office by different organisations

4.3 Air-conditioning energy vs lighting energy

Glazing with a higher VLT allows higher quantity and quality of daylight to the indoor space which reduces energy consumption and cooling load by artificial lights. At the same time, a higher SC associated with a higher VLT increases solar heat gain, resulting in higher air-conditioning energy. By balancing VLT and SC, the maximum energy saving can be obtained. Various sets of glazing properties are tested using computational simulation to understand the combined energy saving of lighting energy and air-conditioning energy.

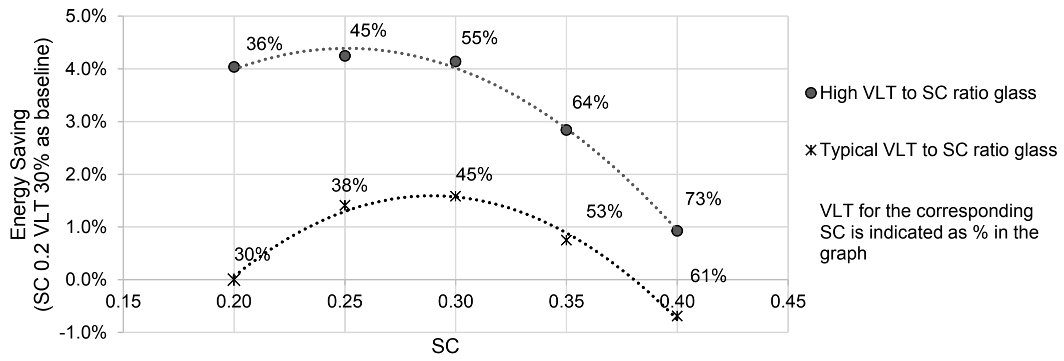

Figure 2: Combined energy benefit comparison for different glass properties: Lighting energy and air-conditioning energy

In Figure 2, the energy saving is obtained as summation of lighting energy saving and air-conditioning saving against the baseline glazing. Lighting energy saving here indicates higher daylight availability, thus better lit environment for human health. Under the climate of Hong Kong, for a typical open plan office building, VLT and SC can be balanced around 45% and 0.25 to 0.30, respectively to achieve the maximum energy saving.

4.4 Design Options and Strategy

The analysis presented in the previous section showed that the balanced point of VLT and SC of glazing can be identified by modelling lighting energy and air-conditioning energy consumption. With the presence of shading devices, daylight enhancing features such as light shelves and the surrounding built environment, the balanced point will vary even under the same climatic condition. These parameters are necessary for the assessment to choose the optimised glazing for a given architectural design.

5. CONCLUSION

Among various parameters which are known to affect human health, this paper highlighted backgrounds and design considerations to achieve a good indoor air environment and light environment. Through literature reviews, desktop studies and computational simulations, challenges and opportunities were identified. For a building, target performance can be set for energy and health based on the function of the space, referring to the global benchmarks. To meet the target, design should be assessed regarding the two performance indicators at the same time because design parameters can affect the two indicators with different magnitude. Globally, there is on-going research regarding building design and human health in science, medical and building industries. It is important for a building design practitioner to understand the science behind a healthy building concept and to establish a clear objective and target for a design to meet building owners' and users' expectations.

Significance of Sky Gardens for Healthy High-Rise Living of Urban Children and Old Adults

Tony IP[a]

[a] *Ronald Lu & Partners (Hong Kong) Ltd., Hong Kong SAR, tonyip@rlphk.com*

ABSTRACT

A new typology of sky gardens has been driving design of residential high-rises, which aims at offering communal green spaces at high levels for enhancement of social interactions and neighbourhood place-making while improving environmental conditions simultaneously. However, criticisms have been found that these communal green spaces are merely as gimmicky features and of a low occupancy rate. Indeed, children and old adults spend most of their time in residence. Are these gardens designed for their daily living?

This paper is an attempt to evaluate the effectiveness of these sky gardens contributing to social integration and health development of children and old adults in high-density high-rise contexts. Having reviewed policies, regulations and guidelines in Hong Kong and Singapore, the study investigates the desirable provisions of communal green spaces and amenities in support of a healthy living environment; and co-relates their applicability to the contexts of high-rise residential developments. Case studies of forty residential high-rises in Hong Kong and Singapore map out diverse spatial, functional and landscaping design of sky gardens. Qualitative comparative analysis identifies key design attributes to children and old adults' enjoyment and their everyday life.

The findings inform that the current designs of sky gardens follow nominal prescriptive requirements of the government's green incentives which emphasize environmental performances, but are less likely deliberated from users' perspectives with respect to social and psychological benefits. Seldom of them pay attention to creating children and elderly friendly communal spaces at high levels. Sense of safety and lack of active facilities at existing sky gardens are observed. Recommendations are made to the criteria of the green incentives not only appealing for residential high-rises with nominal amount of green but also qualifying the green to be liveable and enjoyable by daily frequent users comprising children and old adults.

Keywords: policy and regulation, inclusive eco-design, sustainable neighbourhood

1. BACKGROUND

The higher we live from the ground level, the more disconnected we feel from the natural world and even from each other within a community. The population of Hong Kong is expected to remain on an ageing trend, which urges for more health and recreational facilities. On the other hand, urban children are growing up detached from the natural environment and lacking face-face social interaction. How can we improve this situation in high-density high-rise contexts?

Meanwhile, a new typology of sky gardens has been driving design of residential high-rises and offering communal green spaces at high levels for enhancement of social interactions and neighbourhood place-making while simultaneously improving environmental conditions. Children and old adults spend most of their time in residence and are the most frequent users of sky gardens during the daytime.

This study is an attempt to evaluate the effectiveness of these sky gardens contributing to social integration and health development of children and old adults in high-density high-rise contexts. Having reviewed regulations and advisory guidelines in Hong Kong and Singapore, this study investigates the desirable provisions of communal green spaces and amenities in support of a healthy living environment; and co-relates their applicability to the contexts of high-rise residential developments. Case studies of residential high-rises in Hong Kong and Singapore map out diverse spatial, functional and landscaping design of sky gardens. Qualitative comparative analysis identifies key design attributes to children and old adults' health and wellbeing.

2. DEFICIENCIES IN HIGH-RISE URBAN LIVING

A study on residents' behaviour in a high-rise apartment concluded that there was a high degree of anonymity and social isolation, including pervasive ignorance about neighbours and little inclination to establish friendly relations with neighbours over forty years ago (Zito, 1974). These phenomena are not uncommonly found in residential high-rises nowadays. Six types of fears are found in high-rise residence, including a fear of neighbours' suicides, a fear of fire, a fear of collapse of the building due to earthquake, a fear of the building to be attached in the post-911 era, a fear of crime due to fear of strangers, and a fear of becoming ill due to spread of communicable diseases (Robert, 2007). Furthermore, children in high-rises have fewer chances to go outside to play. They are either to be kept indoors under over-protection or left relatively unsupervised outdoors far away from residences. Children have difficulty developing friendships in their living environment and result in behavioural problems or poorer social skills (Fowler, 2008).

3. COMMUNAL GREEN SPACES IN URBAN LIVING

Pleasant communal green spaces could encourage social interaction among neighbours are important to urban dwellers in high-rise living. Recent research findings have given an important message that we need adequate levels of nearby green spaces in urban living.

Psychological performance

Urban dwellers have a strong request for pleasant communal activity spaces and greenery (Chien & Wang, 1999; Huang, 2006). Urban green spaces with the natural setting can provide some peace and quiet away from the hustle and bustle of the city, and contribute to health and wellbeing (Baur & Tynon, 2010). Natural elements such as trees facilitate social interactions amongst neighbours (Kuo et al., 2002). The mental and physical health benefits are associated with time spent exposed to green spaces (McCurdy et al., 2010).

Social performance

Community treasures the value of communal green spaces. Pleasure-derived leisure experiences are found in a garden. The garden serves as a social arena for group gathering or a quiet, contemplative space to enjoy its peace and beauty (Connell, 2004). Community garden as a potential useful strategy to improve individual health and strengthen neighbourhoods, where each community member has a duty to maintain and foster vegetation of the garden, can enhance social connections, reciprocity, mutual trust, collective decision-making, civil engagement and community building through people's interactions among their neighbours and planning vegetation (Amulya, 2009).

Environmental performance

Cooling of the urban environment is of a priority in urban and building design for a subtropical region. Urban microclimate can be improved through urban greening and permeable building fabrics (Levermore & Smith, 2008). Effective landscape design creates thermal comfort and energy efficiency. Vegetation is a real tool for control of microclimatic conditions in external areas (Picot, 2004). Consideration in selection of trees commonly used in the landscape comprises solar transmissivity range in summer and winter, periods of foliation and defoliation, and maximum expected height (Brown & Gillespie, 1995).

Ecological performance

People living in cities are increasingly disconnected from the nature world, witnessing an extinction of experience (Goddard et al., 2009). Urban green spaces have considerably benefits that maximize the biodiversity of urban ecosystems and minimize the extinction of species and the extinction of the human experience of wildlife. The importance of urban green spaces with natural structures is to maintain high ecological diversity (Sandstrom et al., 2006).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Children-friendly urban environment

Biophobia may be developed due to people's fear of living things and unexpectedness from nature. It is not uncommonly observed at urban children especially for those living in metropolitan areas. Contact with nature can evoke negative feelings such as fear, scary, disgusting and uncomfortable; for instance, children raised in urban areas are afraid of being in the woods and were disgusted by the dirtiness of the outdoors (Collado et al., 2015).

Neighbourhood shared spaces and greenery are essential for children's healthy development. Findings of various studies revealed that children in the city become nature-deficit disorder with physical inactivity, social and psychological ramifications and increased chronic disease trend. In Lee and Min's research (2006), children's neighbourhood environment plays a key role in shaping their personality.

Children having more daily contact with nature are able to cope better with adversity. Urban children spending more time in nature enhance environmental attitudes and ecological behaviours. Activities with nature such as picking fruits, planting seeds or taking care of vegetables improve children's pro-environmental attitudes. (Collado et al., 2015) Garden activities should also be organized in a way that children have an opportunity to freely use and shape the environment's affordances, and a well-designed children's garden is recommended (Laaksoharju, 2012).

The elderly-integrated neighbourhood

Aging population poses strong demands on recreational facilities. They are the major daytime users of green spaces and amenities in or adjacent to their living premises. Gardens facilitate their daily activities including doing exercises, playing chess, reading newspapers, chatting with their friends and neighbours and playing with their grand children. Delvin and Zaff (1998) researched that elderly people prefer garden apartments than high-rises and have a greater sense of community there. Kweon et al. (1998) revealed that green common spaces benefit the social integration of inner-city older adults. Such strong social integration among older adults could also indirectly lessen public expenditure on individual elderly services.

4. SKY GARDENS DEVELOPMENT IN HONG KONG AND SINGAPORE

Sky garden is a micro-environmental design for improvement of wind environment in urban districts. It is also a recreational garden space for communal use. Vertical landscaping and open spaces at the intermediate or high levels of the high-rise are not only for benefits of microclimate but also fostering neighbourhood (Yeang, 2002).

The Hong Kong government issued 'green incentives' for sky gardens in domestic buildings in 2001, including Gross Floor Area (GFA) exemptions and relaxation of the allowable overall building height in regard to provision of sky gardens. Figure 1 illustrates a typical high-rise residential development where podium and sky gardens are for communal use and roof gardens are within the private premises of duplex units at the uppermost storeys.

Figure 1: Podium garden, sky garden and roof garden at a residential development in Hong Kong.

Policies on promoting sky-rise greenery are also found in Singapore. In 2009, the Singapore government announced a target of adding 50 hectares of sky-rise greenery by 2050 and its intermediate target of 30 hectares by 2030. These targets were written in the sustainable development blueprint which was developed by the Inter-ministerial Committee on Sustainable Development.

Two governments' emphases of purposes of sky gardens are fundamentally different from each another in accordance with their incentives and guidelines. These differences also drive the as-built sky gardens in diverse typologies. Hong Kong's sky garden is relatively environmental driven while Singapore's is socially-oriented. Hong Kong's requirements restrict locations and numbers of sky gardens, and more prescriptive details there. For instance, sky gardens are at least at ten storeys apart from each other or podium garden unless under exceptional circumstances where strong environmental justifications are requested. Doorstep green communal spaces scattered at various storeys or seamlessly integrated with common circulations to facilitate incidental neighbours' interactions are observed in Singapore but not Hong Kong. Table 1 summarizes detailed comparison of governments' incentives of two cities.

	Hong Kong	Singapore
Government Policy	Joint Practice Note (JPN) issued by Buildings Department, Planning Department and Lands Department.	Circular to Professional Institutes issued by Urban Redevelopment Authority. (Circular No. URA/PB/2009/12-DCG)
Year	First issued in 2001; revised in 2011	First introduced in 1997; revised in 2009
Sky Garden Objectives	Sky gardens provide natural ventilation, greenery and recreational garden space for communal use.	Sky gardens serve as quality communal spaces; and contribute towards the overall greenery and environmental quality.
Configuration	The minimum headroom is 4.5m and it is open-sided on at least two opposite sides for cross ventilation.	The proposed depth should be at least 5m.
Quantities	The maximum number of sky gardens provided is equal to or less than the number of residential storeys divided by 15. Such garden can be split into multi-levels but it occupies not less than one-third of the area of the floor plate.	Flexibility of quantities and configurations. Areas of a 45 degree projection line and a meaningful size of 5m in depth. No maximum number of sky gardens is specified
Locations	Locations of sky garden are recommended to be determined by wind tunnel test or computation fluid dynamic modelling but it is not compulsory. The first sky garden is located at not more than 10 storeys where more than one sky garden is provided and where there is podium garden.	No specific requirement.
Openness	Open-sided above safe parapet height on at least two opposite sides to provide cross ventilation	At least 40% of the perimeter should be open and 60% for additional GFA exemption.
Height	A clear height should not be less than 4.5m. There is no concern from Planning Department on the overall building height.	The guideline, which states areas of a 45 degree projection line for GFA exemption and a meaningful size of 5m in depth, implicitly defines the min. headroom is 5m.
Connectivity	It is accessible from the common area only.	One set of communal access via a lift or staircase serves the sky garden. If the sky garden is less than 60% of the floor plates, it should serve a minimum of 2 strata units to ensure its communal use in nature.
Greenery	Not less than 15% of the garden area is to be planted with greenery.	Lushly landscaped with a suitable variety of plants is required. The greenery should be enjoyed by the building users and be visible from the surrounding environment.
Incentives	GFA exemption for sky gardens if the above requirements are complied. However, floor height of sky gardens may not be exempted if the overall building height is capped under the OZP or the land lease.	GFA exemption: Flexibility of quantities and configurations. Areas of 45 degree projection line and a meaningful size of 5m in depth. No maximum number of sky gardens is stated. Additional floor height allowance for predominant sky gardens.

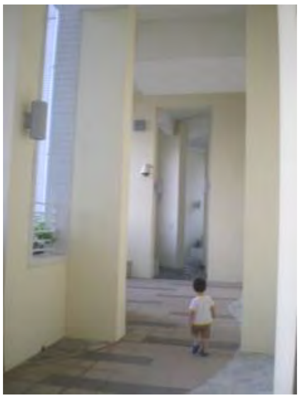
Table 1: Governments' incentives and guidelines on sky gardens in Hong Kong and Singapore

5. DISCUSSION ON EFFECTIVENESS OF SKY GARDENS IN HIGH-DENSITY HIGH-RISE RESIDENTIAL DEVELOPMENT FOR URBAN CHILDREN AND OLD ADULTS

To exemplify the benefits to promote health and well-being in urban living, case studies of forty residential high-rises in Hong Kong and Singapore map out diverse functions, configurations, connectivity and amenities of sky gardens.

Design intents of sky gardens commonly found in Hong Kong are to increase of the overall building height; demarcate zones of residential units in different sizes and property values; add value to refuge floors; offer extended areas of and/ or circulation to clubhouse areas; increase of greenery; and enhance building permeability. Most of study cases of sky gardens in Singapore that offer unique, pleasant, well-equipped communal green spaces that may outstand from other garden spaces at podium or street level; moreover, they are promoted as key marketing selling points for adding property values.

The most popular amenities in sky gardens are tea leisure area, sitting area, viewing platform, Taichi square, foot massage trail and strolling path. However, apart from good accessibility in connection with clubhouse, the developers may be lack of confidence on the performance of sky gardens and are unwilling to allocate management-intensive recreational facilities in sky gardens, in which discrete locations at high levels incur safety and security concerns. Structures and fire services provisions restrain spatial configuration of sky gardens, in particular sky gardens as refuge floors. It results in narrow spaces as illustrated in Figure 2 and Figure 3.



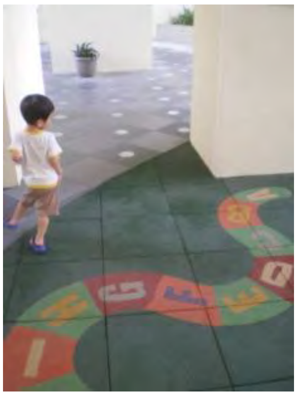


Figure 2 and 3: Spatial quality with 4.5m headroom but narrow spaces in a sky garden in Hong Kong.

Design of children and old adults friendly sky garden

Healthier and more active lifestyles, day-to-day interactions between human and the built environment are encouraged. Daily activities in green spaces, including 5-min green exercises, gardening, walking and even viewing of nature, can offer psychological and physiological benefits to urban dwellers. The respective contributing factors to promote health and wellbeing are summarized in Figure 4.

Indeed, children and old adults are the frequent users of sky gardens or communal green spaces during the daytime; meanwhile, childhood experiences with nature affect environmental attitudes and ecological behaviours. Key design considerations of advocating friendliness for children and old adults are as follows:

- Vegetation volume and multi-dimensional vegetation of rich in species enhance the level of naturalness.
- Communal green spaces indirectly help supervising children and old adults in impoverished urban neighbourhoods, and enhance their time exposed to nature and outdoor activities.
- Activities with nature, such as picking fruits, planting seeds or taking care of vegetables, nurture positive, ecologically responsible attitudes. Meanwhile, garden-based activities help to develop children’s ability to cope with adversity and zone of proximal development; and to foster their environmental attitude and ecological behaviours.
- A safe, secure and spacious environment but offering a feeling of adventure and semi-wildness simultaneously is an ideal. Children are able to freely use and easily modify materials in building their own world. Special features like water features and recreation amenities catch their attention.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Children are encouraged to see, touch and live with flora and fauna rich in diversity and learn to appreciate native species and eco-systems. As one step further than sustainable design that minimizes adverse environmental impacts, biophilic design advocates positive effects on the natural environment and enhances quality of habitats for human and wildlife.
- Design of soft landscapes shall consider native or non-invasive species of plants, vivid vegetation structures, appropriate soil depths and substrate compositions, and features that attract or facilitate bio-habitats.
- Sky gardens are scattered at multi-levels and close to living areas of residences to stimulate intimate touch with greenery in daily life. Doorstep gardens are recommended and residents are encouraged to maintain the vegetation and even plant their own vegetation there to enhance the ownership of communal green spaces and develop a deep affinity with nature. More importantly, children are allowed to play outdoors with neighbouring children under better supervisions with their parents. Old adults have more chances to stay outdoors.

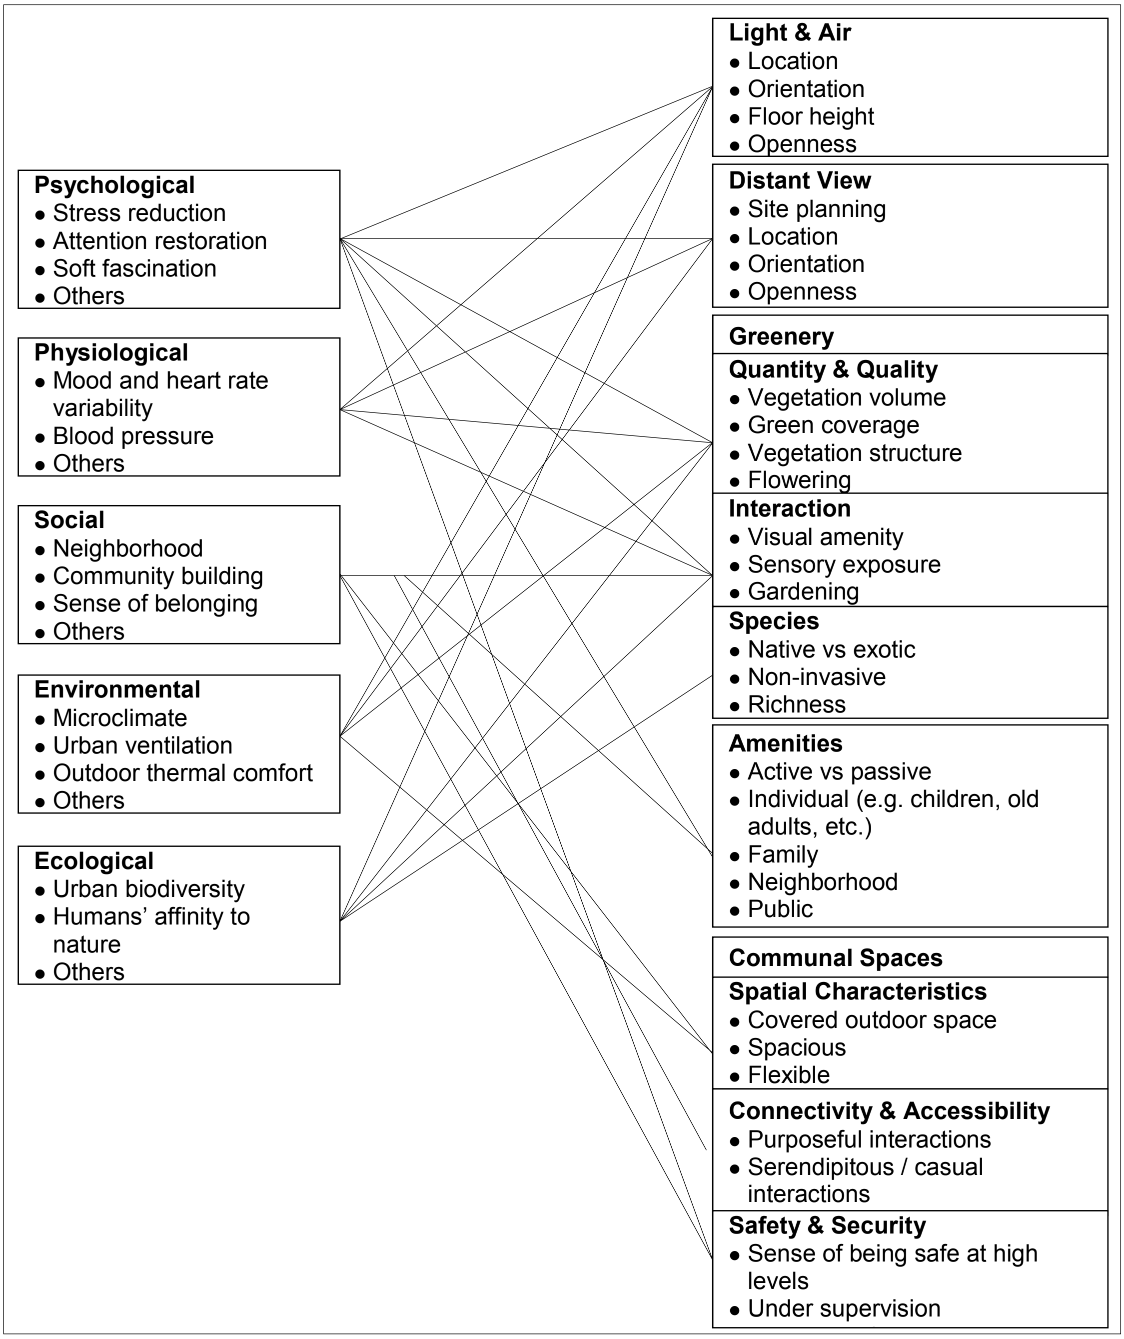

Figure 4: Contributing factors to promote health and well-being of urban living with sky garden

6. CONCLUSION

The higher we live from the ground level, the more disconnected we feel from the natural world and even from each other within a community. Quality urban living environment not only furnishes residents with convenient accessibility and adaptable conditions but also embodies welcoming communal amenities, enjoyable greenery and intimate human-nature interactions. Sky gardens improve environmental, social and ecological performances in urban living, and supplement deficiencies and needs in high density, high-rise residential developments, especially in Asian cities like Hong Kong and Singapore. With better understanding of typology of sky gardens, their benefits to the environment include improved human thermal comfort and urban microclimate; social cohesion by providing a community green space, provision of a place for individuals to escape from the busy city life, improved community integration for all age groups and improved health and well-being; and an awareness of and intimate contact with nature. Furthermore, the criteria of the green incentives shall not only appeal for residential high-rises with nominal amount of green but also advocate the green communal spaces to be liveable and enjoyable by daily frequent users comprising children and old adults.

Radon Infiltration in Rented Accommodation

Torben Valdbjørn RASMUSSEN[a]

[a] *Danish Building Research Institute, Aalborg University, Denmark, tvr@sbi.aau.dk*

ABSTRACT

Indoor radon levels were measured in 221 homes located in 53 buildings, including 28 multi-occupant houses and 25 single-family terraced houses. The homes consisted of rented accommodation located in buildings recorded as being constructed before 2010 and after the year 1850. The radon level in homes was measured and the buildings were registered for a series of variables describing upgrades, facilities, building components, construction characteristics and used materials. In addition, the radon level was measured in the basement in 9 of the buildings. The mean year value of the indoor radon level was 30.7 (1–250) Bq/m^3. The indoor radon level exceeded 100 Bq/m^3 in 5.9% of the homes, all located in single-family terraced houses. The investigated variables explained 5.9% of the variation in indoor radon levels, and although associations were positive, none of these, besides homes in single-family terraced houses, were statistically significant. However, a number of the variables seem to characterise homes with a low radon level. Approx. 75% of homes exceeding 100 Bq/m^3 indoor radon level had levels between 100 and 200 Bq/m^3 and 25% had indoor radon levels exceeding 200 Bq/m^3. The risk of indoor radon levels exceeding 100 Bq/m^3 in homes in multi-occupant houses was found to be very low, but the risk was highest on the ground floor in a building constructed with slab on ground.

Keywords: indoor environmental quality, radon, variables

1. INTRODUCTION

Radon-222 develops from the radioactive decay of radium-226 and has a half-life of 3.8 days. This gas seeps through soil into buildings, and if it is not evacuated, there can be much higher exposure levels indoors than outdoors, which is where human exposure occurs. In this way, radon affects occupants through the indoor climate.

The World Health Organization recommends states to introduce requirements for the maximum concentration of radiation from natural sources in the indoor air. These recommendations are the result of the World Health Organization's evaluation of radon as being responsible for 3-14% of lung cancer incidents, depending on the average radon exposure in different countries. Results show radon to be the second-largest cause of lung cancer (tobacco smoking is still the primary cause). Radon exposure must be taken seriously in the struggle against radon-induced lung cancer due to the large number of people who are exposed daily in buildings and especially in residential buildings. If people spend their whole life in a house with an average radon concentration in the indoor air that exceeds 200 Bq/m^3, their risk of getting lung cancer is higher than 1%. This is far too high and higher than what in other contexts is acceptable for a single-factor risk. Therefore, it is crucial to ensure a low radon level in the indoor air and to prevent radon from infiltrating into buildings. It is recommended that indoor radon levels in homes should be below 100 Bq/m^3.

In a national survey of radon in over 3000 Danish dwellings, the population-weighted average annual radon concentration was 59 Bq/m^3, which is more than twice the mean concentrations measured in the Netherlands and the UK, somewhat higher than the mean concentrations measured in Canada and the USA and about half the mean concentrations in Finland and Sweden.

In this study, radon levels in rented accommodation were measured in the winter of 2013/14 and again in the winter of 2014/15. The paper shows how well 221 homes for rented accommodation perform with respect to the recommendations for indoor radon levels, and to identify the association between indoor radon in these homes and floor level, multi-occupant houses, single-family terraced houses, and basements. The number of homes with radon levels exceeding 100 and 200 Bq/m^3 was determined.

2. MEASUREMENTS

Measurements were carried out in 221 homes for rented accommodation and in 9 basements. Families and building owners were invited to participate in a radon monitoring programme. The programme took place in the heating periods of 2013/2014 and 2014/2015 between November and May. 196 homes were located in 28 multi-occupant houses and 25 homes were located in single-family terraced houses. 221 families agreed to participate, and radon levels were monitored in their homes. The selected municipalities are located in regions where other studies have shown a 1-30% chance of finding detached single-family houses with radon levels exceeding 200 Bq/m^3. Three detectors (Gammadata Matteknik AB, Uppsala, Sweden) were distributed to each participant by mail in sealed aluminum-coated envelopes and returned after the integration period in a prestamped envelope. Each participant was asked to fill in a questionnaire regarding the date when exposure started and ended, as well as type of room in which the detector was placed. Participants were instructed regarding placement of the detectors (>25 cm from a wall and away from strong draughts and heat) and also instructed to clean and ventilate their homes as they usually would, so that representative levels were obtained. Information regarding year of construction, basement, crawl space, building and roof materials was gathered from the Danish Building and Housing Register. Information gathered from the Danish Building and Housing Register was used to make sure that homes represented typical rented accommodation in Denmark. In addition homes were registered for a series of variables describing the characteristics of the building where the accommodation was located. Registrations were carried out on site.

3. DWELLINGS

Homes were either rented accommodation located in buildings privately owned by land-lords or social housing owned by the Danish association of non-profit rented accommodation. Buildings were multi-occupant houses and single-family terraced houses. The buildings represented the building technique and commonly used building materials used in Denmark from 1850 until today.

Buildings were grouped into three types, Type A, Type B and Type C. Type C included both multi-occupant houses and single-family terraced houses.

3.1 Type A

Multi-occupant house built between 1850 and 1920. Buildings were constructed with a solid brick wall founded on masonry foundations. Sometimes single natural stones might be included in the foundations and outer walls. Suspended floors were timber floor constructions.

3.2 Type B

Multi-occupant house built between 1920 and 1960. Buildings were constructed with solid brick walls or cavity walls founded on cast-on-site concrete foundations. Suspended floors were timber floor constructions or reinforced concrete suspended floors cast on site. Solid floors against the ground were made of concrete.

3.3 Type C

Multi-occupant house or single-family terraced house built in the period from 1960. Buildings were constructed with load-bearing concrete constructions as prefabricated elements above the ground. Foundations and load-bearing basement walls were made of concrete cast on site. Suspended floors were made of reinforced concrete usually as prefabricated concrete elements. Solid floor against the ground were made of concrete cast on site.

4. EQUIPMENT

The detectors were closed passive etched track detectors, made from CR39 plastic film placed inside an antistatic holder (Gammadata Måtteknik AB, Uppsala, Sweden). During the integration period, alpha and its decay products cause damage to the film. Gammadata Måtteknik is ISO 17025 and ISO 14001 certified as well as EMAS (European Eco-Management and Audit Scheme) registered. Measurement methods are accredited according to standards of SWEDAC (Swedish board of Accreditation and Conformity Assessment) and accepted in 18 European countries by the European Cooperation for Accreditation of Laboratories (EAL).

5. RESULTS

Radon was measured for a median duration of 90 days (min–max: 60 – 194 days). A single representative indoor radon concentration for each home was calculated as the arithmetic average of the three measurements and used in all statistical analyses.

Table 1 shows the distribution of the determined mean year values of the radon concentration grouped according to floor level in intervals of 50 Bq/m^3. The minimum value was 1 Bq/m^3, the maximum value was 250 Bq/m3. The standard variation was 38.3 Bq/m^3, the median value was 18 Bq/m^3 and the mean value was 30.7 Bq/m^3. The ratio of homes with a mean year value of the radon concentration ranging between 100 Bq/m^3 and 200 Bq/m^3 was 4.5%. The ratio of homes with a mean year value of the radon concentration exceeding 200 Bq/m^3 was 1.4%. The ratio of homes with a mean year value of the radon concentration exceeding 100 Bq/m^3 was 5.9%.

Floor	0-50	51-100	101-150	151-200	>200	Number of homes
Ground floor	58	18	7	3	3	88
1st	50	0	0	0	0	51
2nd	38	0	0	0	0	38
3rd	30	0	0	0	0	30
4th	6	0	0	0	0	6
5th	8	0	0	0	0	8
Number of homes	190	18	7	3	3	221
Ratio in %	86.0	8.1	3.1	1.4	1.4	100

Table 1: The number of homes grouped according to the determined mean year values of the radon concentration is shown by their location, as the floor number, and in intervals of 50 Bq/m^3.

Table 2 shows the distribution of the determined mean year value of the radon concentration in homes grouped in intervals of 50 Bq/m^3 for homes located on the ground floor in multi-occupant houses.

	0-50	51-100	101-150	151-200	>200	Number of homes
Home over basement/crawlspace	42	5	0	0	0	47
Ratio i %	89.4	10.6	0	0	0	100
Home with floor on ground	9	7	0	0	0	16
Ratio in %	56.3	43.7	0	0	0	100

Table 2: The number of homes grouped by the determined mean year value of the radon concentration in intervals of 50 Bq/m^3. Homes were located on the ground floor in multi-occupant houses.

Table 3 shows the investigated variables that homes were registered for describing the characteristics of the building where the accommodation was located.

Figure 1 shows the mean year value of the radon concentration for homes in a building with a basement that had not been fire protected. The mean year value of the radon concentration of the indoor air of the homes was 30.2 Bq/m^3 determined with a standard variation of 37.4 Bq/m^3 and a variation coefficient of 124%. Homes located in a building without a fire protected basement numbered 120.

Figure 2 shows the mean year value of the radon concentration for homes in a building with a basement that had been fire protected. The mean year value of the radon concentration of the indoor air of the homes was 17.4 Bq/m^3 determined with a standard variation of 8.6 Bq/m^3 and a variation coefficient of 50%. Homes located in a building with a fire protected basement numbered 62.

Variables	Radon [Bq/m^3]	Std.var. [Bq/m^3]	Var. [%]	Number of homes
Suspended floors of concrete	15.7	8.8	56	63
Suspended floors partly of concrete and partly of timber floor constructions	29.6	8.5	29	8
Suspended floors of steel and brick materials	26.3	40.7	155	26

Original exterior walls (No retrofitting)	31.0	36.8	119	91
Windows with frames of plastic	26.0	40.9	157	97
Windows with frames of wood	26.6	18.2	69	97

Table 3: Mean year value of the radon concentration in Bq/m^3, together with the standard variation in Bq/m^3, the variation coefficient in per cent and the number of homes located in a building with the specific characteristic.

Other variables describing buildings with accommodation with a low radon level was: (radon concentration of the indoor air/standard variation/variation coefficient/number of homes)

- a building with an upgraded basement floor (16 Bq/m^3/7.4 Bq/m^3/46%/8)
- a building with homes with gaps around pipes going through the horizontal partition that was sealed and therefore the suspended floors were expected to be sufficiently airtight (22.1 Bq/m^3/30.9 Bq/m^3 /140%/45)

- a building with homes with suspended floors of concrete (15.7 Bq/m³/ 8.8 Bq/m³/56%/ 63)
- a building with homes with suspended floors partly of concrete and partly of timber floor constructions (29.6 Bq/m³/8.5 Bq/m³/29%/8)
- a building with an elevator (11.3 Bq/m³/6.4 Bq/m³/56%/29)
- a building with homes with a forced mechanical ventilation system connected to a heat recovery unit (7.5 Bq/m³/2.6 Bq/m³/34%/8).

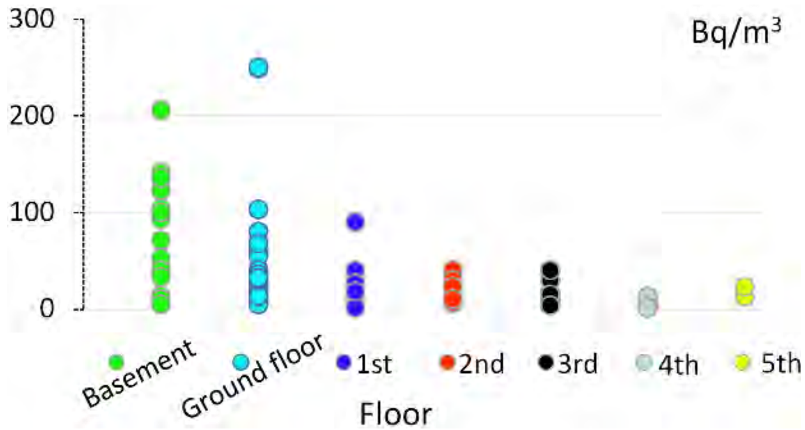

Figure 1: Mean year value of the radon concentration for homes in a building with a basement that has not been fire protected. Homes are located on the ground floor, 1st, 2nd, 3rd, 4th and 5th floors.

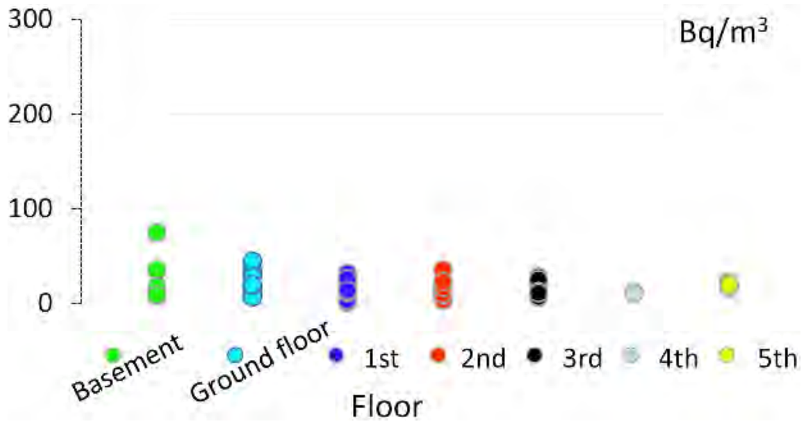

Figure 2: Mean year value of the radon concentration for homes in a building with a basement that has been fire protected. Homes are located on the ground floor, 1st, 2nd, 3rd, 4th and 5th floors.

6. DISCUSSION

This study found a mean year value of the indoor radon level of 30.7 Bq/m³ ranging between 1 and 250 Bq/m³. In total, 5.9% (13 of the 221) homes had indoor radon levels exceeding 100 Bq/m³, all located in single-family terraced houses. The investigated variables explained 5.9% of the variation in indoor radon levels, and although associations were positive, none of these besides homes in single-family terraced house were statistically significant. However, the fact that the basement floor had been upgraded, that the basement was fire protected, that gaps around pipes going through suspended floors was sealed, that suspended floors was of concrete, that suspended floors were partly of concrete and partly of timber floor constructions, the presence of an elevator and forced mechanical ventilation connected to a heat recovery unit was observed to be variables of interest determining low radon levels in homes. Unfortunately the number of homes located in a building with these specific characteristics was limited and therefore not concluded to characterise homes with a low radon concentration in rented accommodation.

The mean year value of the radon level of 30.7 Bq/m³ is somewhat lower than the population-weighted average annual radon concentration of 59 Bq/m³ for all Danish homes. The population-weighted average annual radon concentration of 59 Bq/m³ was based on 1-year measurements in 3012 single-family homes and 101 multifamily (apartment buildings) in Denmark, and measurements form the basis of a radon map covering Denmark.

The present study found the indoor radon level exceeded 100 and 200 Bq/m^3 in 10 (4.5%) and 3 (1.4%) homes, respectively. Approx. 75% of homes with indoor radon levels exceeding 100 Bq/m^3 had levels between 100 and 200 Bq/m^3 and 25% had indoor radon levels exceeding 200 Bq/m^3. Significant differences in indoor radon levels were found in homes located in multi-occupant houses. The risk of indoor radon levels exceeding 100 Bq/m^3 in homes in multi-occupant houses is very low, but if there is a risk, it is most likely to be found in the lowest accommodation in a building with a slab on ground. A risk of indoor radon levels exceeding 100 Bq/m^3 was found in homes in single-family terraced houses.

The high levels in homes in single-family terraced houses may be explained by the possible deterioration of their radon protection due to the development of micro-cracks in individual materials, cracks in joints between building components, fissures associated with aging of the homes, alterations in air change rates, or some form of construction alterations made by home owners, which may penetrate the radon barrier.

The municipalities selected in the present study were previously characterised as having the highest levels of residential radon concentration indoors in Denmark (1–30% of homes with levels over 200 Bq/m^3). Measurements showed that the soil type was the main determinant of indoor radon levels. The present study did not include measuring radon levels in soil. The homes in this study were located on clayey/sandy to clayey soil, with 2–18% sand and gravel content, and although radon variation in these soils can be expected, this is not described at each specific home location.

The present study has several limitations including power constraints, which may affect the ability to detect associations. Furthermore, information on many other variables such as the specific radon protection measure used, interior wall and ceiling materials, radon ground concentrations, radon diffusion resistance, air permeability of the soil, air pressure differences, and air change rates in all homes were not acquired in the data acquisition process. These variables are all important in relation to the variation in radon levels indoors. More work is justified, and a more comprehensive study utilising an extended model including these variables should be considered in relation to the variation in indoor radon concentration in Danish homes.

7. CONCLUSION

This study found a mean year value of the indoor radon level of 30.7 Bq/m^3 ranging between 1 and 250 Bq/m^3. In total, 5.9% (13 of the 221) homes had indoor radon levels exceeding 100 Bq/m^3, all located in single-family terraced houses. Approx. 75% of homes exceeding 100 Bq/m^3 indoor radon level had levels between 100 and 200 Bq/m^3 and 25% had indoor radon levels exceeding 200 Bq/m^3. Significant differences in indoor radon levels were found in homes located in multi-occupant houses. The risk of indoor radon levels exceeding 100 Bq/m^3 in homes in multi-occupant houses is very low, but if there is a risk, it is most likely to be found in the lowest accommodation in a building with a slab on ground. A risk of indoor radon levels exceeding 100 Bq/m^3 was found in homes in single-family terraced houses. None of the other investigated variables explained the variation in indoor radon levels in homes. However, the fact that the basement floor had been upgraded, that the basement was fire protected, that gaps around pipes going through suspended floors were sealed, that suspended floors were of concrete, that suspended floors were partly of concrete and partly of timber floor constructions, the presence of an elevator and forced mechanical ventilation connected to a heat recovery unit were not significant variables characterising homes with a low radon concentration in rented accommodation, but seen to be variables that need to be further studied.

ACKNOWLEDGMENTS

This study was supported by the Danish association of private land-lords of multi-occupant houses and the Danish association of non-profit rented accommodation.

ABSTRACT

This is a case study on IEQ control in a green industrial plant, which obtained both China Green Building Label—3 Star level and US LEED Gold Certificate. This paper focuses on three parts of IEQ control in industrial buildings, which are indoor temperature, air quality and noise. All green building products in this plant are discussed in the paper, such as, high reflection roof panels, enhanced building insulation, natural ventilation, fume& particulates collectors, acoustical inner panels and practical effects.

After years of operation, all the collected data indicates the significant of building a green industrial plant on reducing outdoor environmental pollution, improve IEQ and protect people's health. Also it could provide more economic benefits.

Keywords: green industrial building, building thermal insulation, IEQ control

1. PROJECT BACKGROUND

The development of green building mainly focuses on residential buildings and commercial buildings in china. Industrial buildings, which consume the largest part of total building energy consumption, have received little concerns. Building a high-performance green building in industry should consider not only the building itself, but also the manufacturing process and people health in the building.

This project is built strictly by owner, consulting company, design institute, GC and subcontractor under the direction of US LEED rating system. Based on US LEED Life-cycle concept, it begin with the feasibility research, pre-design decisions, continued through location selection, design, construction, operations and maintenance, refurbishment, and renovation. This project obtains LEED Platinum for office building and LEED Gold for workshop, which provides a typical study case for green building research in industrial area.

2. PROJECT INTRODUCTION

The project is located in Xi`an Hi-Tech industrial zone with a office building, 2 workshops and auxiliary buildings. Total structure area is 52000m^2, which separated by office building of 9,000 m^2 and workshop of 43,000 m^2. This paper focuses on the performance of workshops.

Workshops in the project are light-steel structure systems, one floor with large indoor space. Products in the plant are metal building components. Manufacturing process includes metal cutting, welding, metal forming, punching, coating, etc. (Figure 1).

Figure 1: Project aerial view

The project is located in temperate continental monsoon climate area. The annual average temperature is 13.1~13.4°C, 35~41°C in summer, and -1~8°C in winter.

3. PROJECT TARGET

The aims of building the project are to achieve both US LEED Gold Certification and China Green Building 3-star Label. Green building strategy is realized throughout the entire process from feasibility research, pre-design stage, design, construction, to operations and maintenance.

Considering the particularity of industrial buildings, indoor environmental quality (IEQ) is the main issue. To address a well-performing IEQ, suitable and practical design decisions are necessary in the early phase to ensure successful implementation. Based on the building aims, every single element that affect to IEQ control is considered in project design to provide a comfortable and energy-saving indoor environment, such as temperature, particulate matter and noise indoor.

4. IEQ CONTROL EFFORTS AND ITS EFFECTS

4.1. Indoor temperature

4.1.1 Indoor temperature control in winter

Gas radiation heating system is installed in workshops for winter heating due to the characteristics of manufacturing process, which is little human is needed for manufacture. The system can be programmed and activated individually by occupants with different comfortable sensation.

Area of heating load in workshop No.1 is 16788m^2.40 sets of heating equipment (thermal power: 51kw, 230V/ 50Hz) are equipped. Total thermal power in No.1 workshop is 2040kw.

Area of heating load in workshop No.2 is 18345m^2.44 sets of heating equipment (thermal power: 51kw, 230V/ 50Hz) are equipped. Total thermal power in No.2 workshop is 2244kw.

4.1.2 Indoor temperature control in summer

Production equipments in workshops have little thermal radiation during metal forming, punching, and cutting. Therefore, indoor heat load in summer mainly comes from outdoor. With no AC system in workshops, following green strategy presents how a passive green building works to provide a comfortable working environment:

- Close most of the louvers in the lower part surrounding the workshop buildings to block hot air.
- Install fans for particular workstations to enhance ventilate.
- High-performance roof panel is installed on the top of workshops. With extremely good performance on sunlight reflection and emission, the roof panel can reflect over 94% (SRI=94) of sunlight and heat to avoid the island heat effect in hot weather, and keep indoor temperature comfortable.
- Enhanced thermal insulation performance of building envelope via using high thermal resistance material. The heat transfer coefficient is 0.262 for roof and 0.270 & 0.386 for walls.

Table 3: Heat transfer coefficient (metal walls)

4.1.3 Natural ventilation

Harmful factors in workshops include particulate matter, heat, waste gas, etc. 3 kinds of natural ventilation systems are performed in workshops, which work together as a circle to improve indoor environmental quality.

Indoor carbon dioxide, industrial emissions and other harmful gases exchange with fresh air through unpowered roof ventilators.

The ventilation tower has better ventilation capacity than natural unpowered roof ventilator. Two roof ventilation towers with 201m and 75m long are installed for each workshop. As for heavy pollution area, painting room and the steel plate flame cutting area for instance, down slope ventilation towers are added to enhance ventilation.

The rain louvers with manual rotary switch are located in the lower part surrounding the plant building, which can be closed in winter.

4.1.4 Results of indoor temperature control

To confirm the actual effect on indoor temperature control by using high-performance building envelope, efficient operation management policy and green building design, 5 thermometers distributed in 2 workshops and outdoor (Figure 2).

Data from 5 thermometers (Testo 608, ±0.5°C) are collected 3 times a day at 11:00, 14:00 and 16:00. As Figure 3 and Figure 4 show, both in winter and summer, indoor temperature are lower than design values. The temperature difference between indoor and outdoor increases with the rise of outdoor temperature, which further

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

indicates the effect of indoor temperature control in large space workshops by using high-performance building envelop, effective heating system in winter and efficient operation management policy.

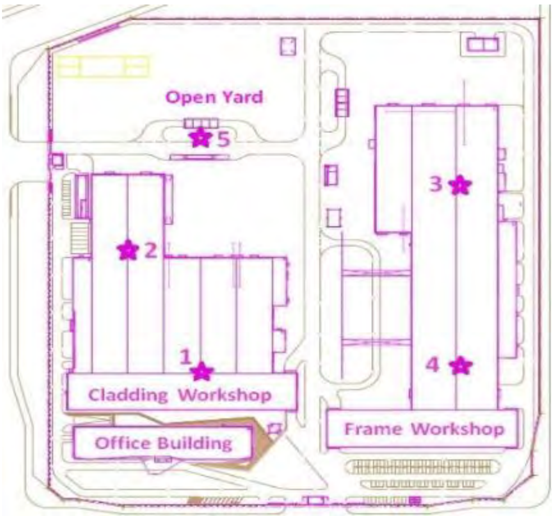

Figure 2: Thermometers distribution map

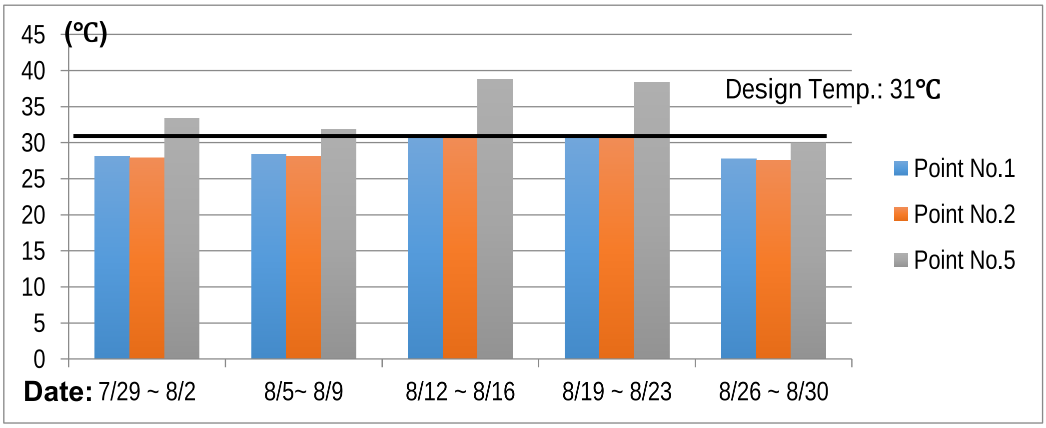

Figure 3: Temperature statistics in summer

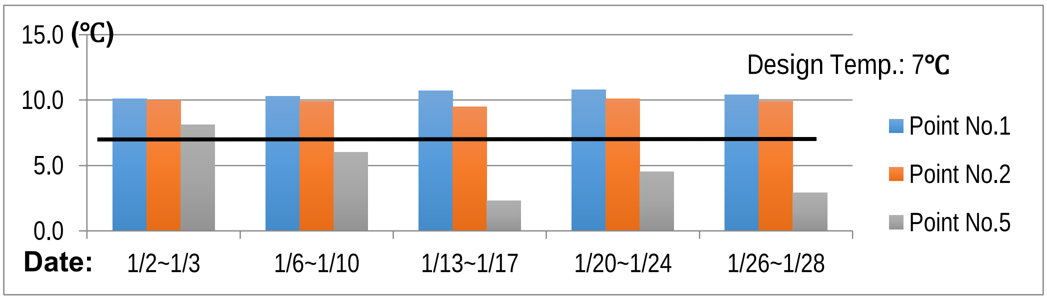

Figure 4: Temperature statistics in winter

4.2 Indoor emission

The concentration of harmful substances which generated by blasting dust, welding fumes, painting organic wastes is emitted up to standard after treatment. Workers entering the area must wear personal protective equipments.

4.2.1 Welding fumes control

Welding fumes collectors are installed to match welding stations. Collectors start automatically with welding guns. Collectors can move flexibly with theirs mechanical arms during welding. Meanwhile, training welder for efficient work to reduce the usage amount of welding rod.

Figure 5: Welding fume collector

4.2.2 Shot-blasting dust control

The dust-handling system in shot-blasting cleaning unit is applied with "whirlwind + pulse opposite-blowing flat bag" level-2 dust removal method. The filtration efficiency of filtration reaches to 99%. The treated effect complies with particulate level 2 emission of China National Standard.

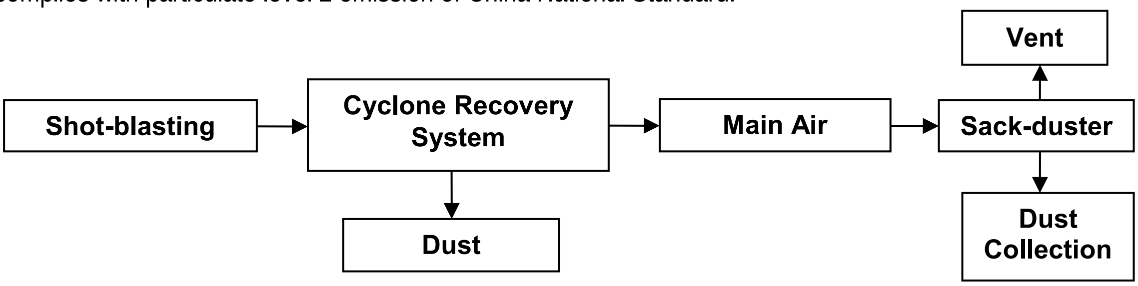

Figure 6: Shot-blasting dust control flow chart

4.2.3 Painting organic wastes control

The mist spray and organic wastes that generated from the painting room is collected with vacuum suction, and go through three layers of filtration which are labyrinth filter, glass fiber filter and double activated carbon fiber filter. The efficiency of paint mist filtration is 99%, and the rate of organic waste adsorption is 95%.

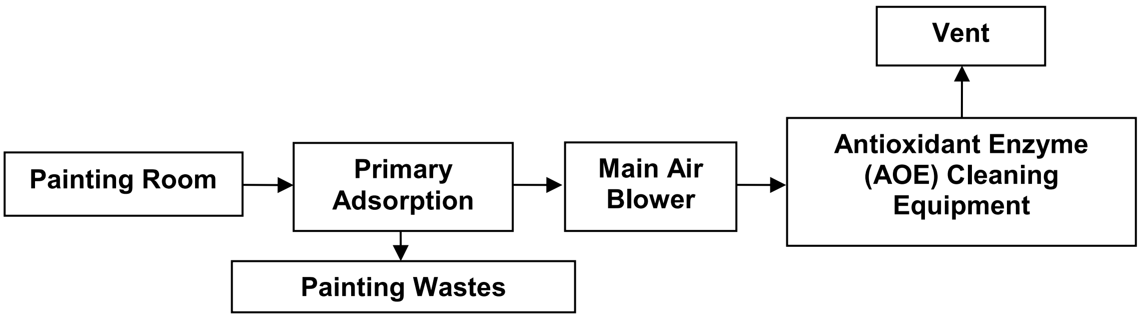

Figure 7: Painting wastes collection flow chart

Indoor emissions are reduced effectively. Testing report on manganese and its inorganic compound, indoor particulate matter, benzene and its inorganic compound shows that indoor emissions in workshops are much lower than national standards requirement.

4.3 Indoor noise

Indoor noise in the project comes from production equipments, welding and ventilation equipments. Required noise level is 85dB according to national standards.

Separating high-noise equipments and building shockproof ditch on equipment foundations are effective to lower noise from production equipments; Non-electric ventilations are placed on workshops instead of electric fans to lower noise from engine; Setting manual welding reverse machines to lower noise from welding process.

Furthermore, perforated acoustic panels are installed on the ceiling of workshops to reduce noise diffusion and indoor noise. Wearing earplug is necessary for people inside workshops.

No.	Test Point		Indoor Noise Record[dB(A)]					AVG.[dB(A)]
1	Outdoor	South Gate	45.18	46.68	41.2	42.66	41.62	43.468
2		West Gate	47.26	45	53.6	74.4	70.2	58.092
3	Cladding Workshop	Rack and Pallet Area Gate	68.36	65.62	69.9	82.68	81.56	73.624

8		Drilling and Cutting	83.46	78.94	71.66	71.96	75.3	76.264
9		Press-brake Shear	84.1	70.16	67.74	66.04	67.78	71.164

Table 4: Indoor noise record

5. ECONOMIC ANALYSIS

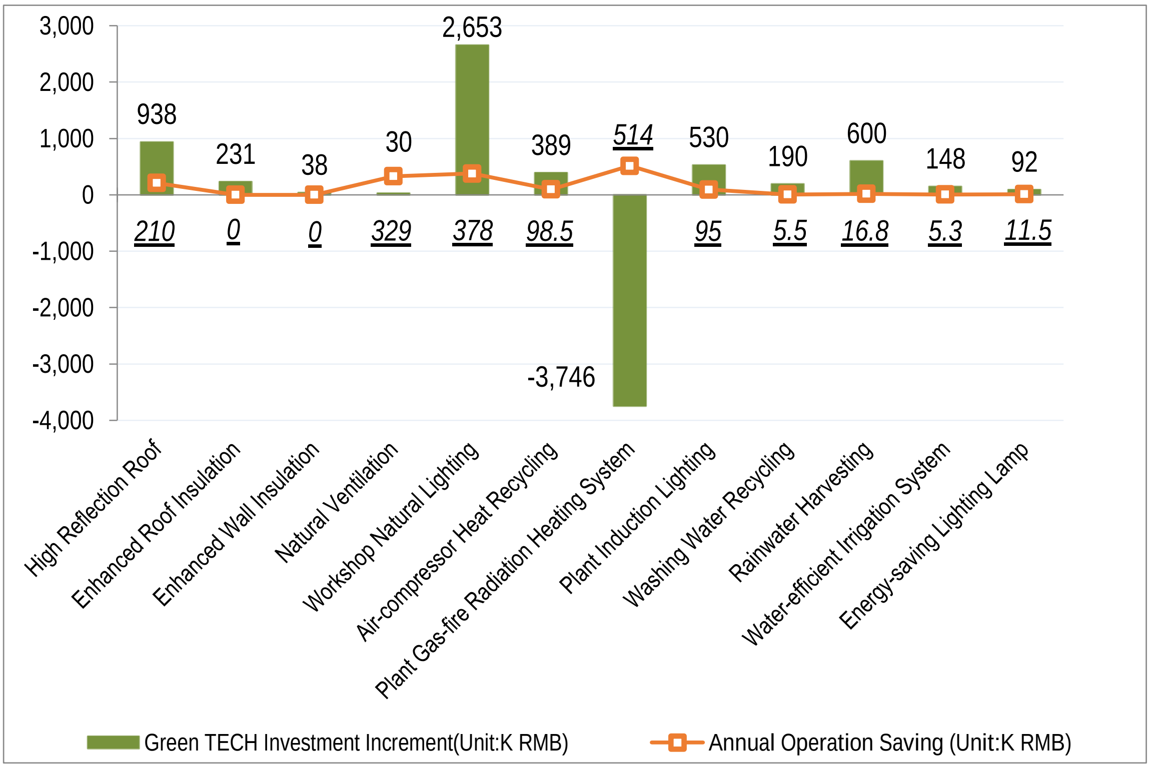

Figure 8: Investment increment and recovery period

Over twenty kinds of green technologies are presented in the project with a RMB 11,874 K increment of green investment. Figure 8 shows green investment increment of main green tech. and theirs annual saving ability during operation phase. Skylight panels on the top of workshops for natural lighting cost RMB 2,653 K. Compare with electric lighting, annual saving on indoor lighting is RMB 329 K. Gas-fire radiation heating system saves RMB 3,746 K due to the saving on municipal heating system investment. Compare with municipal heating fee, annual saving during operation is RMB 514 K.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Annual saving on operation phase is RMB 3,531 K in this project. The payback period is 3.4 a. Annual water saving amount is 7,360 T; electricity saving is 1,562,815 KW.H; natural gas saving is 76,072 m^3; ground saving is 0.3 hm^2.

6. DISCUSSION AND CONCLUSION

Indoor environment requirements of the industrial project are discussed in this paper with indoor temperature, indoor particulate matter and indoor noise. After years of operation, the collected data indicates that the gas radiation heating system, high-performance heat insulation envelope structure of workshop buildings and reasonable ventilation system ensure the comfortable temperature in winter and summer. The dust collectors and exhaust recovery equipments ensure the efficient control effect of indoor pollution. Noise-reducing by manufacture process, acoustic panels and personal protective equipments ensure people's health from noise harm.

From the above economic analysis on investment increment and payback period of green technologies, it can be observed that the investment on green technologies can be recovered shortly by appropriate green building strategy.

ABSTRACT

At present, environmental pollution, resources and energy depletion, fast urban development and blind sprawl in China have forced the transformation of urban construction from physical expansion to built-up area improvement. Thus, it is imperative to renovate the existing urban communities with green strategies. This paper firstly presents a review of the current green renovation of existing communities and points out the existing problems of these strategies: emphasizing on the application of single technique and lacking adequate consideration of the community integrity, focusing on material conditions improvement and lacking research and concern about social humanity, etc. To address these problems, the concept of productive city, with the purpose of promoting agriculture production, energy production, and social & cultural capital preservation and redevelopment in a proactive way, is pointed out in the paper. Then, the paper presents the integration strategies of productive green function which can be employed in different community spaces, including reserving the existing productive space, replacing the ornamental landscaping, fulfilling the unused space, overlaying the single function space, and restructuring the community space system (physical, social and cultural space system). According to different productive functions, we carries out case studies for different types of community productive green renovation. Finally, through the comparison with the current green renovation, the advantages of productive green renovation of existing community on economy, society, culture and ecology are discussed, aiming at providing reference for the inventory planning and community renovation in China.

Keywords: sustainable neighbourhood, green renovation, productive city

1. INTRODUCTION

According to the International Energy Agency, the proportion of building energy account for 32% of the world's energy consumption. Community, a basic unit of city, plays an important part in reducing the total building operational energy consumption. Therefore, it is imperative to renovate the existing communities with green strategies.

Generally, green renovation of existing communities mainly focuses on how to reduce energy consumption and carbon emissions in different aspects of existing communities. However, this paper aims to explore a community renovation paradigm, whereby work is carried out with the goal of not only reducing energy consumption but also promoting agriculture production, energy production, and social & cultural capital preservation and redevelopment in a proactive way. This paper will, firstly, review the current existing communities renovation research and practice (Section 2). Then it will indicate why the productive green renovation mode is the best choice for the context of existing communities renovation (Section 3). Afterwards the integration strategies of different productive green functions are presented (Section 4), followed by an elaboration of various kinds of renovation types by case studies (Section 5). Finally, the advantages of productive green renovation are discussed (Section 6).

2. LITERATURE REVIEW OF GREEN RENOVATION RESAERCH OF EXISTING COMMUNITIES

The research on green renovation of communities mainly focuses on three topics: appropriate technologies options; case studies; policy and participation mechanism analysis. There are relatively more research on the technologies options. Qiu Baoxing pointed out the necessary and extended green renovation items (Qiu B., 2016). Wang X et al. studied the technologies and indicator systems for the construction of green-community (Wang X et al., 2016). While Hoicka C E et al. analyzed the amount of energy and greenhouse gas emissions saved of different renovation strategies (Hoicka C E et al., 2011). We summarize current community green renovation strategies into five aspects via literature and practices: basic functions improvement, environment improvement, renewable energy utilization, resources recycling utilization, and intelligent service system application. However, as Table 1 indicates, different

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

strategies have different emphases but few researchers, architects or planners have considered the relations of different strategies or integrated them together.

Category	Technology	Advantage
Basic functions improvement	Energy efficient retrofit for buildings (e.g., Increasing insulation in the ceiling and walls) Installing barrier-free facilities Building stereoscopic garage Installing energy saving devices	• Meeting the basic living demand • Reducing energy consumption • Reasonable layout of buildings, transportation and facilities
Environment improvement	Land and lakes management Plants selection and planting Ecological infrastructure planning	• Minimizing the use of chemicals and irrigation systems • Increasing the green proportion • Improving micro-climate
Renewable energy utilization	Solar power Wind turbines Geothermal heating and cooling Bio-energy	• Making the full use of renewable energy • Minimizing the external supplies
Resources recycling utilization	Rainwater collection Grey water recycle and reuse Materials reuse Waste sorting and disposal	• Minimizing the environmental impact • Promoting the circular economy • Raising the reuse rate of materials
Intelligent service system application	Green transportation Dynamic supervision database Intelligent medical services or logistics systems	• Creating comfortable life • Improving the transportation efficiency

Table 1: Technology and advantage of different green renovation strategies

For the case studies, much of the research falls on the distinct renovation examples in specific context. For example, Han Qingmiao takes GWL-Terrein community in the Netherlands as example and analyzes the transformation background, implementation process and transformation effect in the original industrial land (Han Q., 2014).

As for the policy and participation mechanism analysis, the important role of civic engagement plays on the green renovation of communities has been highlighted (e.g., Vivek Shandas et al., 2008, Boland A and Zhu J., 2012). In recent literature the cooperatives and cooperative networks regarded as an efficient organizational form is proposed for involving citizens in the process of community green renovation (Purtik H et al., 2016). However, there is a lack of research and concern on social side of community renovation. Very little is known about how to undertake renovation (Fawcett T and Mayne R., 2012), how to manage the post-renovation community, and how to establish a social relationship in the process of renovation.

3. CONCEPT OF PRODUCTIVE CITY

Our productive city research team explored the concept of productive city based on the research of urban agriculture. Productive city is defined as a multi-level urban system with the green production as its main character, which also integrated with the functions of agriculture production, energy production and social & cultural capital preservation and redevelopment. With the purpose of promoting green production in a proactive way, the strategies of productive city includes not only reducing energy consumption but also increasing energy production within the minimum scope of each level. It aims at achieving the goal of self-sufficiency and sustainable development of each city as much as possible. Therefore, productive city is a system with many properties like production, ecology, hierarchy and integrity.

Productive green renovation of existing communities aims at reducing energy consumption, improving the community environment and achieving the goal of self-sufficient. Based on the existing community buildings, roads and landscapes, the community spaces which used for agriculture production, solar and wind energy production

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

are reconstructed or constructed. This kind of renovation mode changes the original community renovation paradigm that only focuses on the application of green technology. It integrates the living, production and ecology together, thus enabling a more productive, ecological and vibrant community to be built.

4. PRODUCTIVE GREEN RENOVATION STRATEGIES OF EXISTING COMMUNITIES

4.1 Reserving the existing productive space

Although the production function is not considered before community construction, there are still some productive planting activities in existing communities, such as community gardens, balcony agriculture and back gardens (Figure 1). During the renovation, the existing productive spaces are reserved and some of the public agriculture spaces are open to residents. Besides, residents from different clusters are encouraged to participate in repairation activities of agriculture facilities and adopt vegetables program. The public void spaces are transformed into important markets for community to exchange their vegetables. This reservation strategy respects residents' original life-styles and protects the economic interests of private garden owners. Meanwhile, the relationship between neighbors could be promoted. In general, the social humanistic value brought by this strategy may be much higher than production value.

4.2 Replacing the ornamental landscaping

Artificial lawn and ornamental garden-based community landscape is easy to produce pesticide pollution, burdening the community with a high maintenance cost. Productive community renovation changes this paradigm and replaces the original landscape with productive plantings. By this way, the community gains both the ecological and productive benefits. Some public space transformation adopts this strategy. For example, in order to change the mega-block into farmland, the spaces between buildings are expanded firstly. And then water systems and agriculture facilities are built. At last, different farming plantings are introduced in this area (Figure 2). The new view "productive landscape" replaces original decorate landscape and brings safe and abundant food for residents, which also increases species diversity.

4.3 Fulfilling the unused space

Plenty of unused spaces of existing communities are reasonably fulfilled by production function. For example, building roofs, which have little influence on residents, are reconstructed in parallel to community infrastructure transformation (such as elevator installation or rainwater pipe transformation), thus providing a convenient way for residents to reach the roof garden (Figure 3). The newly built roof garden also reduces the demand of food supply. According to the data of Wuhan Shilipu roof garden, the output from more than 37 kinds of vegetable species planted here satisfies the community dwellers' daily vegetable need and extra vegetables are sold (Dai X.G., 2011). There are various kinds of roof planting modes. Compared with planting boxes, the PV-based agricultural greenhouses which emerged in recent time has higher agriculture production, which brings additional energy benefit.

4.4 Overlaying the single function space

The community roads and outdoor parking lots have low space utilization because they are generally directly exposed to the sun. To compensate the occupation of land, community transport spaces are overlaid by agricultural production function, energy production function or a mixture of both. Agricultural production function-based traffic space transformation provides a way for people to use the upper space of roads and parking lots for installing devices to grow calabash, pumpkin or grapes. The newly created agriculture productive space serves as a communication space for residents where they can relax in the shade or pick fruits (Figure 4). While energy production function-based traffic space transformation means the upper space of roads and parking lots are used for installing devices to capture solar or wind energy. On one hand, it produces electricity. On the other, it reduces the automobile air conditioning energy consumption (Figure 5). As a distributed power system, the upper solar energy collection system of traffic space is connected with community charging piles or lighting system, which provides a more convenient living experiences for residents.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4.5 Restructuring the community space system (physical, social & cultural space system)

Community productive spacial system reconstruction includes two aspects, one is physical space reconstruction, the other is social & cultural space reconstruction. The former means that more space can be reused for raising the production rate (Figure 6). For example, the space between gables can be designed as a living and productive complex. The north side of this space can be used for living, while the south side can serve as greenhouse. Greenhouse provides vegetables for residents. In turn, the gray water and organic waste are recycled as fuel source for greenhouse, which creates a micro circulation system.

The goal of community productive renovation is not only to make the community self-sufficient on physical aspect, but to enhance community cohesion by the reconstruction of social humanistic space system. For example, the productive spaces mentioned above should be used for organizing community agriculture. Residents from different social groups are encouraged to communicate and cooperate with each other in these activities, so that the void spaces can be changed to social communication space and the stability of the community can be maintained.

Figure 1: Reserving the existing productive space

Figure 2: Replacing the ornamental landscaping

Figure 3: Fulfilling the unused roof space

Figure 4: Agricultural production-based traffic space transformation

Figure 5: Energy production-based traffic space transformation

Figure 6: Restructuring the community productive space system

5. CASE STUDY - DIFFERENT PRODUCTIVE GREEN RENOVATION TYPES OF EXISTING COMMUNITIES

According to different productive functions, the productive green renovation types of communities are classified into agriculture-based productive green renovation, energy-based productive green renovation and multi-productive functions-based green renovation.

5.1 Case study of agriculture-based productive green renovation

Agriculture-based productive green renovation seeks to explore an integration mode between agriculture function and living function. It fundamentally changes the way residents live, which allows people to grow, raise and produce their own food as close to their home as possible. The common agriculture pattern includes permanent farming, roof farming, greenhouse farming, and vertical farming. To add more agriculture output, the LED farming, helping grow more food in controlled environment, is introduced. Related agriculture programs, such as commul kitchen, agriculture skills classrooms and local food shops, are located within community.

In 2008, Atelier d'architecture autogérée (aaa) initiated a program called R-urban, which is a bottom-up framework aiming to help the city residents to transform their neighborhoods to face the challenges of the future. Agrocité, based in the city of Colombes, France, is one of the first pilot production units of this program. The area of this unit is 3,000 square meters. It consists of an experimental micro-farm, community gardens, educational and a range of experimental devices, such as, compost-powered heating, rainwater collection, solar energy generation, aquaponic gardening and phyto-remediation. A mix of public recreation spaces (e.g. the cooperative store and

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

cafe) and other cultural and educational spaces underpin a holistic community. By participating in these activities, residents acquired professional skills and the cooperation abilities as well as the ecological awareness are improved (Figure 7).

Figure 7: Renovation comparison of Agrocité

5.2 Case study of energy-based productive green renovation

Energy-based productive green renovation aims to make the most of community energy potential, which refers to the ability of a community to develop solar, wind and bioenergy for electricity, heat and fuel without causing damage to ecosystems. The energy system involves energy production, energy storage and energy management. Taking solar energy as an example, by applying photovoltaic solar panels, transparent solar panels and thermal solar panels on the buildings, roads and parking spaces, the community can change the solar energy into electricity and heat. The electricity is stored in Li-ion battery or Thermal Bank. Moreover, residents can share electricity through the use of energy internet.

The good case for the energy-based productive green renovation type is the renovation of Tassafaronga Village. In 2005, the Oakland Housing Authority made a new plan for this decrepit brownfield site, aiming at providing high-density, accessible, energy-efficient units for low residents. To make up for the electricity consumption, this village applied a 180kw photovoltaic system. Each building is equipped with a central, condensing gas water heater connected with rooftop solar collectors, which covers 60% of demand. The solar water heating devices are applied on the townhouse buildings and individually-controlled radiators are installed in each room (Figure 8).

Figure 8: Renovation comparison of Tassafaronga Village

5.3 Case study of multi-productive functions green renovation

Multi-productive functions-based green renovation represents a new paradigm of self-sufficient community, which reconfigures the relationship between living and multi-resources production. The objectives to be achieved covers local food, 100% renewable energy, zero waste, intelligent transportation, sharing economy & culture etc. All the productive systems are tied with each other. For example, The rainwater collected by water system are used for vegetables irrigation of food system, while the organic waste of food system are used for producing electricity of energy system.

The good case showing the way the multi-productive functions-based green renovation is the second nature: Country Garden Eco-reconstruction of Terrace Forest City, which achieved the first prize of student group for the Country Garden Forest City Landmark Architecture International Design Competition. The aim of this design is to create a completely self-sufficient living space without polluting and depending on outside environment. Inspired by the traditional courtyard houses, cave dwellings and terraced fields of China, it features the continuous terraced appearance with various communal and individual gardens. The different scales of farms distributing in the neighborhood are suitable for growing vegetables and fruits, such as, the backyard farms, the front yard farms and the communal farms located in the center, which also serve as public space for residents to communicate. Meanwhile, a range of solar panels arraying in the edge of the terraces are used for energy production. The cultivation and management of the production programs provides more employment opportunities for residents. The community kitchen, market and classrooms are situated inside the terraces, where residents can share skills and food (Figure 9).

Figure 9: The second nature: Country Garden Eco-reconstruction of Terrace Forest City

6. CONCLUSIONS

Compared with current community green renovation, there are lots of advantages of community productive green renovation: Firstly, this kind of renovation fundamentally changes the one-way energy flow pattern, giving community the capacities of self-renewal, self-regulation and self-recycle. Secondly, the line of food producing, food gathering and food trading is closely combined with residents' life, which reduces the cost of food transportation and provides more job opportunities for residents. In addition, the relationship of residents are enhanced by these productive activities, which is of great significance to the future development of community.

Although the practice of productive green renovation is still at the exploratory stage, the research of it has a significant advantage in response to problems like food or energy shortage. Hence, the strategy that agriculture, renewable energy and other production factors are actively integrated into residents' living will be widely applied in the urban future development.

ABSTRACT

55 commercial and institutional buildings have been surveyed by the authors and their collaborators using the Building Use Studies Methodology. Around 4,000 occupants scored over 45 factors related to their perceptions of the performance of these buildings and were invited to comment on ten of these – considered to be key factors. The aim of this paper is to explore the nature of the occupants' comments on these ten key factors: design; needs; meeting rooms; desk space: storage; comfort; noise; lighting; health; and productivity. Each comment was categorised as positive, balanced, or negative for analysis. Overall and as might have been anticipated, the higher the proportion of positive comments about any particular factor, the better it scored. Comparisons were undertaken of the nature of the comments between sustainable and conventional buildings, between New Zealand and overseas buildings, between commercial and institutional buildings, and between sustainable and conventional commercial buildings, all of which exhibited notable differences.

Keywords: commercial buildings, academic buildings, occupants comments, occupants perceptions

1. INTRODUCTION

Despite well-documented estimates of the large costs of employees compared to the rent and the energy costs of the buildings they occupy – ratios of 100:10:1 are often quoted (see Yudelsen, 2008, p151 for example) – and the potential benefits from relatively small increases in their productivity as a result of an improved working environment, asking for comments is still a relatively rare occurrence. While questionnaires have been developed for this over the years (see Oseland, 2007 for a review of some of these) to the best of the authors' knowledge only two organisations, Building Use Studies (BUS) Ltd in the UK and the Center for the Built Environment at the University of California Berkeley have processes with which they have been carrying out surveys of building occupants over several decades.

Thanks to the generosity of Building Use Studies (2016) - the developer of the questionnaire used in the landmark PROBE Studies (Post-occupancy Review Of Buildings and their Engineering) (BRI, 2001/2) - a large number of researchers have since used the questionnaire in different parts of the world (Jahnkassim et al, 2004; Thomas and Baird, 2006; Turpin-Brooks and Viccars, 2006; Vandenberg and Thomas 2010; Lenoir et al, 2012; Bunn and Marjanovic-Halburd, 2016). The present authors have undertaken such surveys both worldwide and in their home country of New Zealand, and have carried out a range of analyses and comparisons as their dataset has grown. These were mostly based on the building occupants' scores for the 45 factors on which they rank the building's attributes on a 7-point scale mainly.

While these earlier analyses focussed on the occupants' scores, in this paper the focus is firmly on the nature of the occupants' comments on the ten aspects where they were invited to do so. Some preliminary studies had speculated on the potential for the use of these comments in the analysis and prediction of building performance (Baird and Dykes, 2012). This paper looks much more closely at the nature of the comments for each factor, examines their distribution in relation to the scores, and makes comparisons across a range of building types.

2. OCCUPANT SURVEY AND ANALYSIS METHODOLOGY

55 buildings (40 commercial; 15 institutional) were surveyed by the authors and their collaborators. The instrument used was the standard questionnaire developed by Building Use Studies (2016). These were distributed personally, thus ensuring an 80 to 100% response rate from the staff present in the building. The questionnaire asks the

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

occupants to score 45 key aspects of the building on a seven-point scale and invites comment on 10 of these, as follows: building design; needs (in the building as a whole); availability of meeting rooms; suitability of storage; space at desk; noise; lighting; overall comfort; health; and productivity at work.

While the preamble to the questionnaire makes it clear that respondents were not required to score every question, in practice most respondents scored most of the questions (91.6% on average). However, when it came to making comments on the 10 aspects the response rate was much lower at around 30% on average. In terms of the nature of the comments received on each aspect, for the purposes of this analysis they were placed into three categories: positive (extolling the virtues of the building; negative (noting problems attributable to the building); and balanced (where the respondent was neutral about the effect of the building on their work, or made a combination of positive and negative comments).

Checking the validity of the categorisation process for consistency between analysts was carried out by calculating the Cohen's Kappa coefficient to measure the level of agreement between analysts. An overall coefficient of 0.884 was achieved, indicating very good agreement (kappa > 0.8) as defined by Landis and Koch (1977). Virtually all of the individual aspects achieved good agreement (kappa of 0.6 to 0.8) ranging from 0.978 for health to 0.672 for noise – only meeting rooms at 0.520 slipped slightly below this threshold.

In addition to the commercial and institutional building grouping noted above, several other groupings lent themselves to analysis: 39 of the buildings had sustainability credentials while 16 were conventional; 33 were located in New Zealand while 22 were in a range of overseas countries; and of the 40 commercial buildings, 26 were sustainable and 14 conventional.

3. THE NUMBER AND NATURE OF OCCUPANT COMMENTS

Figure 1 indicates, for all ten factors on which comments were invited, the total numbers and relative proportions of positive, balanced and negative comments, as well as the numbers of occupants who made no comment but simply scored the relevant factor. The actual numbers of occupants who either made or did not make a comment on each of the ten factors are shown on Figure 1, plotted on a percentage scale for ease of comparison. There it can be seen that design attracted the highest proportion of comments (42%); comments on desk space were next highest at 35%. Of the questions related to internal environmental conditions it was of interest to see a descending ranking order from noise (32%) through lighting (26%) to comfort with half the comments of design (21%).

The numbers, proportions and natures of comments on each factor are also depicted on Figure 1. Overall, some 30% of occupants took the opportunity to make a comment; of these nearly 60% were negative while approximately 20% each were positive or balanced (58%, 20% and 22% respectively). Storage (or the lack of it) attracted by far the highest number of negative comments (787) and the least positive (79). Design attracted the most comments in total (1433) and the most positive comments (429) but had the third highest number of negative comments (702) as well. However, the ratio of negative to positive comments at 1.6:1 was lowest of the ten factors. At the other end of the scale, storage had the highest negative to positive ratio at 10:1 followed by noise at 5.7:1.

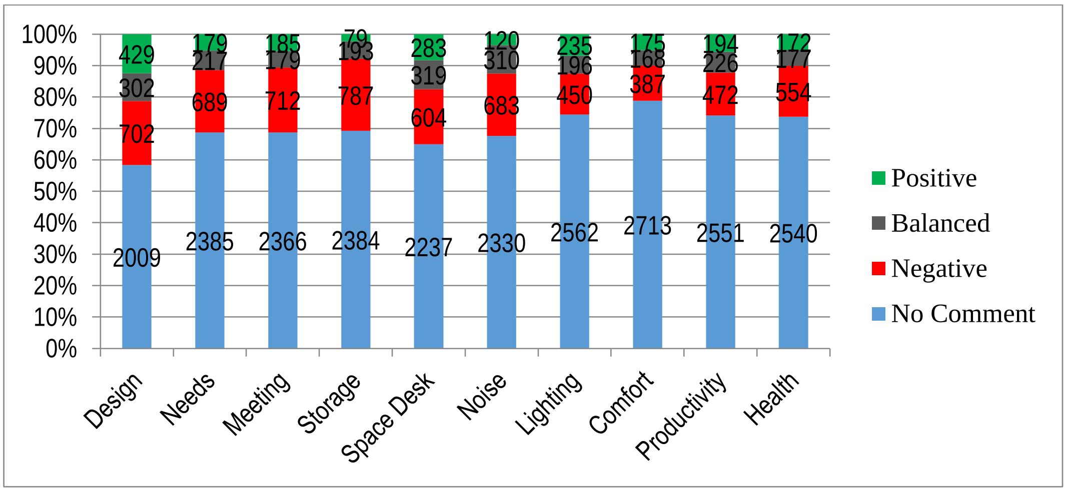

Figure 1: Numbers and percentages of comments on each factor

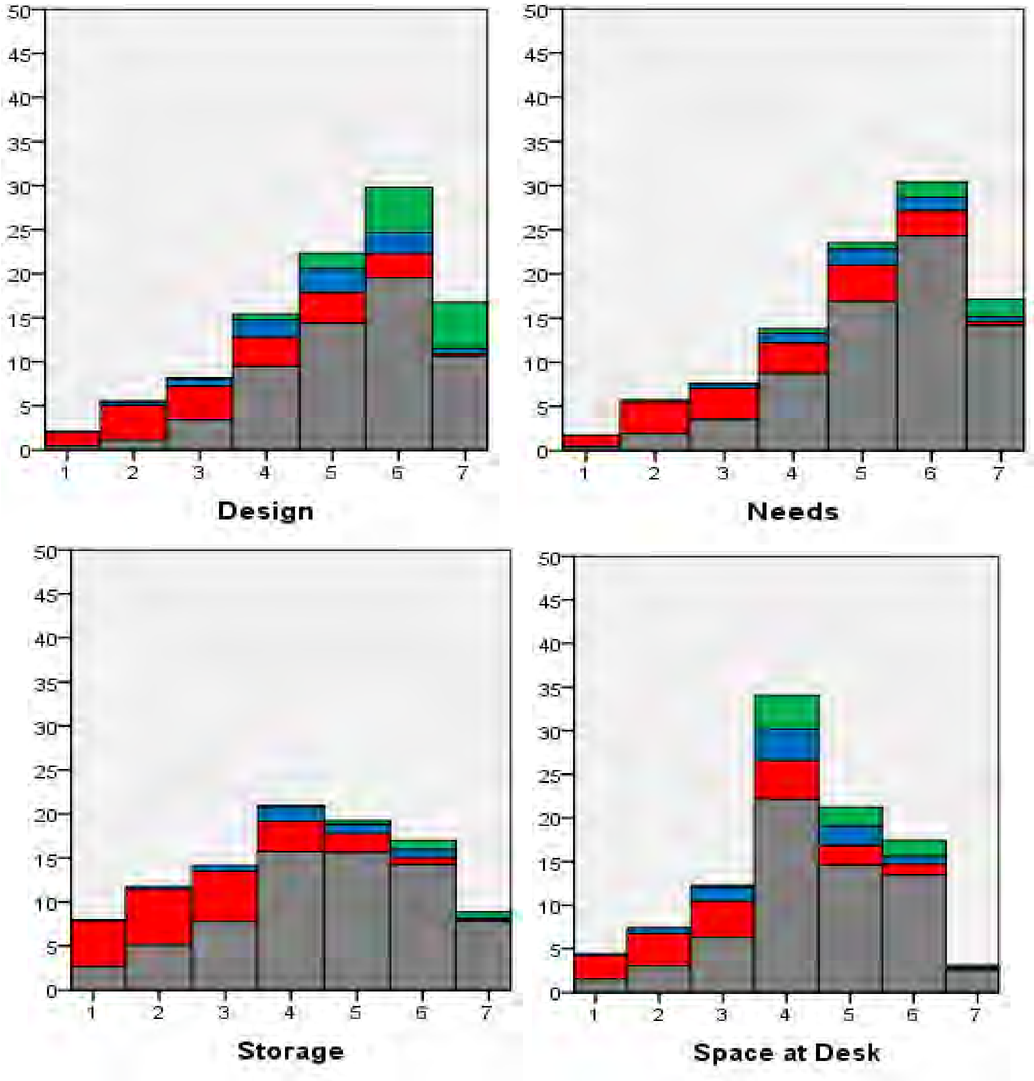
From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4. COMPARISON OF COMMENTS WITH SCORES

The histograms presented in Figure 2 indicate the percentages of positive, balanced, negative and no-comment responses corresponding to each division on the 7-point scale on which individual occupants rated each of the ten factors. Note that a score of 7 is best for all but two of the factors – in the case of desk space the mid-point of 4 is best; in the case of productivity a 9-point scale was used, with a score of 9 best.



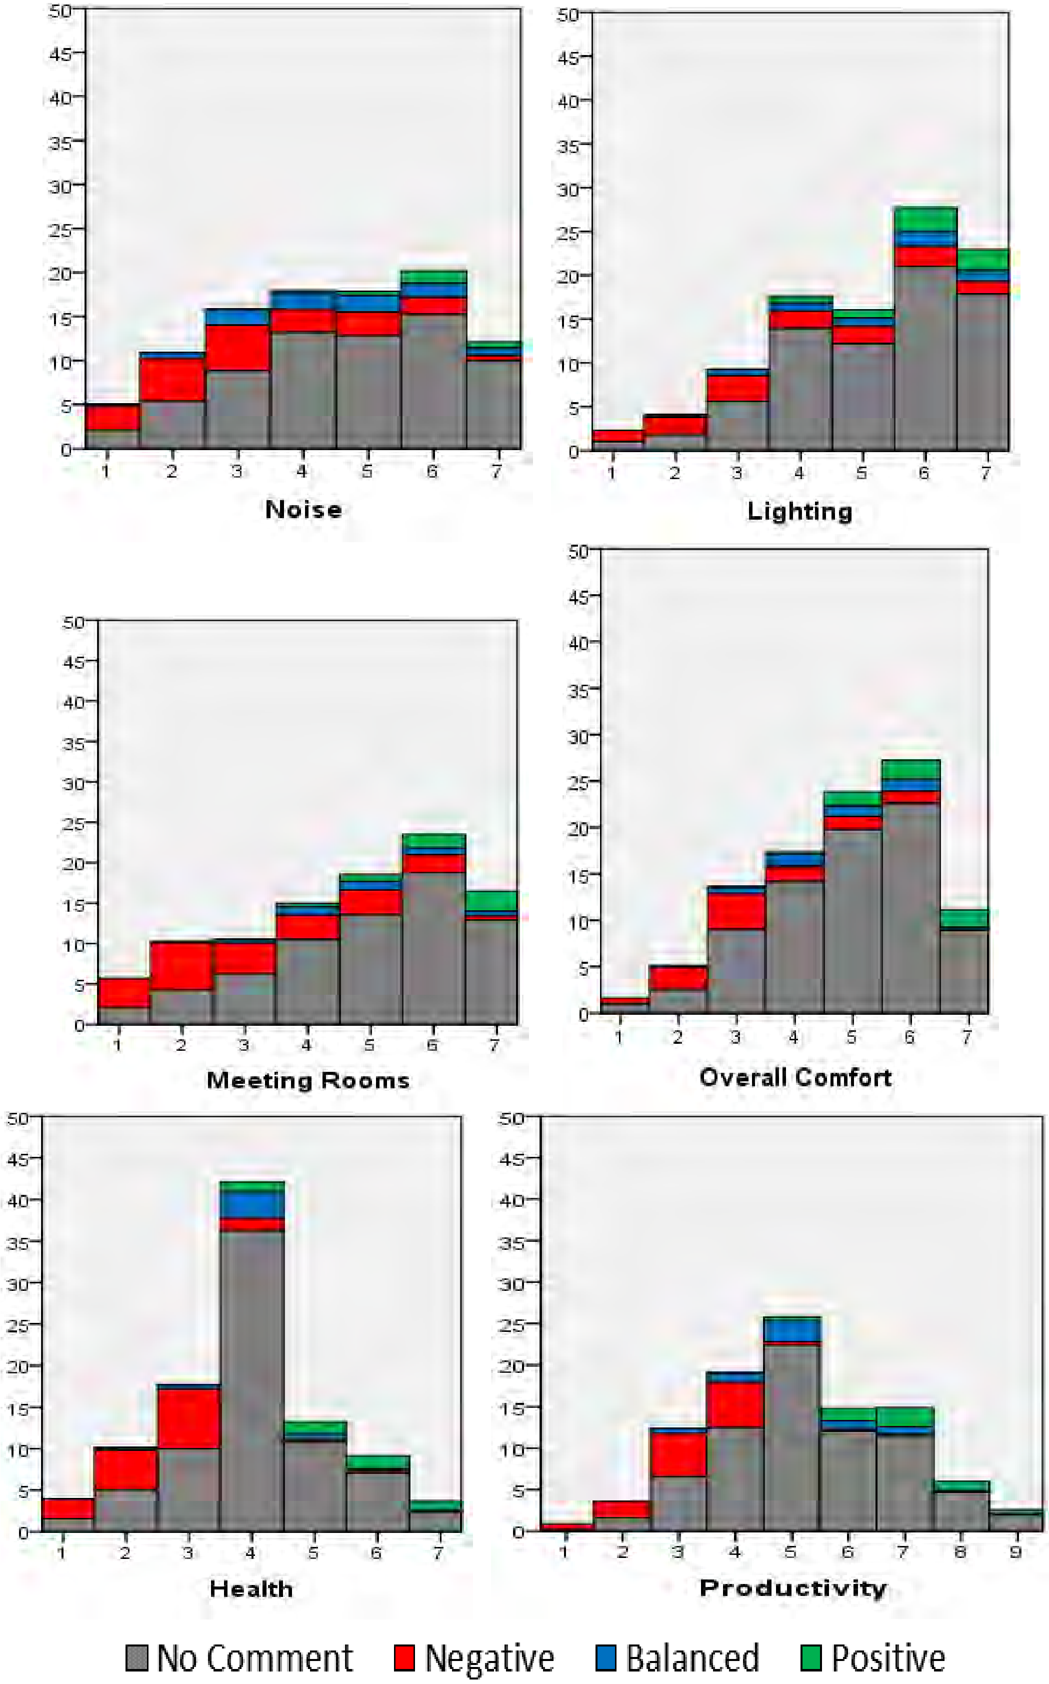


Figure 2: Plots of the nature of the comments vs. the corresponding scores

As might be expected, occupants who scored a factor well, tended also to make positive comments, and vice versa. However, assigning a high score to any given factor did not preclude individual occupants from simultaneously making a negative comment about it. In the case of design, needs, and comfort for example, where the average scores tended to the better end of the scale, individual's scores of 5, 6 or even 7 were still getting some negative comments. However, simultaneous poor scores and positive comments were rare. Negative comments tended to be spread over the whole width of the scale though with more at the lower end.

5. COMPARISON BETWEEN OCCUPANTS OF DIFFERENT BUILDING TYPES

Given the mix of building types surveyed, the opportunity was taken to investigate if this had any influence on the nature or composition of the occupants' comments. The following pairs of comparisons were undertaken (total numbers of comments in brackets): Sustainable buildings (23,890) vs Conventional buildings (17,470): New Zealand buildings (27,300) vs Overseas buildings (14,060): Commercial buildings (35,260) vs Institutional buildings (6,100); and Sustainable Commercial buildings (20,210) vs Conventional Commercial buildings (15,050). Figure 3 displays the numbers, proportions (rounded to nearest whole number) and nature of the comments for each pair of comparisons.

In the case of the sustainable vs conventional buildings comparison the former attracted a higher proportion of positive comments (7.3% cf. 4.4%) and a lower proportion of negative comments (16% cf. 20%) than the latter. Both sets had virtually the same proportion of no-comment (69.6% cf. 69.4%) and balanced comments (6.8% cf. 6.3%).

The aim of comparing New Zealand building occupants with overseas was to see if any country biases could be detected in the nature of the comments. While the proportions of no-comment and balanced comments were very similar to each other, the overseas buildings produced a slightly higher proportion of positive comments (7.4% cf. 5.4%) and a slightly lower proportion of negative comments (16% cf.19%) than their New Zealand counterparts. However it should be noted that while the overseas buildings all had sustainability credentials, the New Zealand buildings were a mixture of conventional and sustainable.

While the number of institutional building occupants was considerably fewer than those for commercial buildings, a higher proportion of the institutional building occupants advanced comments of one kind or another – 35% cf. 30%. Arguably more notable than the actual percentages of negative and positive comments were the ratios of negative to positive - approximately 4:1 in the case of the institutional building occupants; less than 3:1 for their commercial building counterparts.

The final comparison undertaken was between sustainable commercial and conventional commercial building occupants. This was arguably the most statistically satisfactory in terms of the nature of the sample of buildings being compared. The overall percentages of comments made were similar (29% and 30% respectively) but the conventional commercial buildings attracted more negative comments than their sustainable counterparts (19% cf. 15%) and had a much higher ratio of negative to positive comments (over 4:1 cf. 2:1).

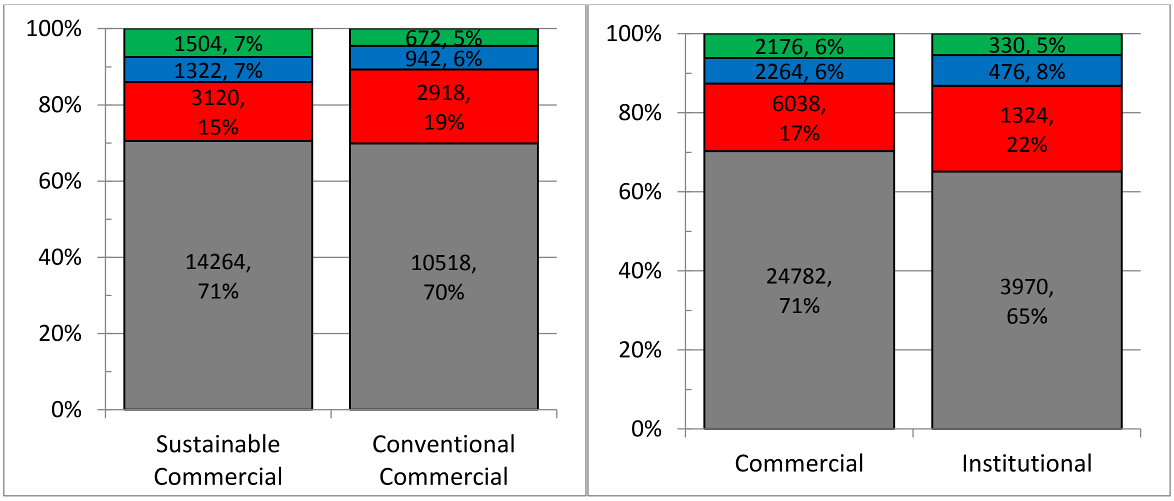

Figure 3: Comparisons based on the building type occupied

6. CONCLUSIONS

Overall, the rate of commenting was 30% of the rate of scoring of the ten key factors. Of these factors, the overall design of the building (42%) and desk/work area (35%) elicited the most comments – clearly matters of particular importance to the occupants; while overall comfort elicited the least (21%) – arguably an indication that the buildings were performing relatively well in terms of this factor.

The ratio of negative to positive comments worked out to be 3:1 overall. This is not seen as an indictment of the performance of these buildings but rather a characteristic of the nature of such questionnaires where respondents are being invited to make a comment in the context of a desire to make improvements. It could also be seen as a benchmark against which to assess the key factors. In this case, for example, the ratio for storage (suitability of storage arrangements to give the full question) was highest at 10:1, while design was lowest at 1.6:1 despite having most comments overall and the third highest number of negative comments. Clearly any benchmark would need to take into account both the ratio and the numbers involved.

While positive comments tended to correspond with high factor scores (and vice-versa) the comparison of individual scores against the nature of individual comments revealed that respondents were quite capable of rating any given factor highly while at the same time making a negative (arguably intended to be helpful) comment. This is particularly well illustrated in otherwise high scoring factors such as design, needs, comfort, and lighting, where negative comments are still evident at scores in the upper ranges. All of which indicates that building occupants can be very discerning in their evaluations – hardly surprising as working in a building they become the experts on its performance.

Comparison between the comments of the occupants of the different building types brought up some matters of interest too. Despite having virtually identical overall comment rates (close to the 30% average), the occupants of the sustainable buildings commented more positively and less negatively than those of the conventional buildings. Unsurprisingly, a similar but less pronounced effect was seen in the comparison of the comments about the overseas buildings (all of which were sustainable) with those of the New Zealand (which were an even mix of sustainable and conventional) – sounding an alert that care should be taken in sample selection.

Comparison of institutional with commercial buildings threw up the interesting findings that the occupants of the former not only made slightly more comments (by around 5%), their negative to positive ratio was higher (4:1 cf. 3:1). One could speculate on the reasons for this – are the occupants of institutional buildings more critical, or are intuitional buildings less attuned to their users' needs? The largest differences were found between the sustainable commercial and the conventional commercial buildings, the former eliciting fewer negative and more positive comments and achieving a much lower negative to positive ratio (2:1 cf. 4:1) – a reassuring outcome for the proponents of sustainable buildings.

7. ACKNOWLEDGEMENTS

Special thanks to Adrian Leaman of Building Use Studies for his inspirational enthusiasm for building evaluation and his generous licensing arrangement of the BUS Methodology for researchers world-wide.

ABSTRACT

This paper represents two research projects with the aim to define what "High Performance buildings" should be and the steps to reach the highest goal, the user satisfaction and contentment with the building.

The quality optimization of buildings demands the consideration of the principles of life cycle assessment (LCA and LCC) and occupant satisfaction, particularly with the aim to create sustainable buildings and high comfort standards. However, these high expectations require expertise to an extent which cannot be covered by an institution or research unit by its own. This paper features the basic principles, the results and findings of two completed government funded research projects. These achievements emerged from a cooperation of several Austrian Universities of Applied Sciences.

The focus of the first research project LQG (life cycle improvement of the building quality) is on developing, analyzing and evaluating methods to assess planning decisions with their consequences on the life time of a building while normally, investment costs often serve as the only basis for decision making. Two main outputs of the project are firstly the creation of a comprehensive guideline on sustainable buildings (= Database of Quality) and secondly a common database of both economical and ecological building life cycle data.

The goal of the second research project MOFNUG (Modular questionnaire for the user satisfaction in buildings) is to determine the whole spectrum of user compliance in buildings by implementing different work packages, ranging from scientific research over purchasing of measurement tools to the improvement and optimization of the questionnaire, which is one of the main topics of the research group at the FH Wels.

The online accessibility of the project's results and tools is important in terms of the usability in research and teaching.

Keywords: cooperative research, life cycle quality, user satisfaction

1. INTRODUCTION

The Topic "quality optimization of buildings" includes a steadily growing number of relevant aspects. Technological advances in product development and building simulation as well as changing relations of influencing life cycle factors often bring institutions and research projects to their limits so that cooperation is needed to cope with the complexity of these issues.

This paper is intended for introducing results and findings of two finished FFG (Austrian Research Promotion Agency) research projects, firstly the project LQG (life cycle improvement of the building quality) and secondly the project MOFNUG (modular questionnaire for user satisfaction in buildings). In the spirit of integration of knowledge and transforming cooperation into action, an association of several Universities of Applied Sciences has explored the complex questions of the topic just mentioned and achieved following results.

2. LQG: LIFE CYCLE ORIENTED QUALITY OPTIMIZATION OF BUILDINGS

Within the FFG research project which has been finished in 2013, five Austrian universities of applied sciences compiled, among other issues, a "qualitative database" which is used as a collection of "tools" for building quality assurance, helping to reach a degree of quality optimization that was hardly achievable before. In addition, a "quantitative database" was created as a practical deliverable, leading to an "energy certificate plus" which is an energy certificate added with life cycle aspects.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The life cycle cost development of sustainably optimized buildings, compared to standard buildings and the effect of decisions during the early planning phases on the cost development gradient is shown in Figure 1.

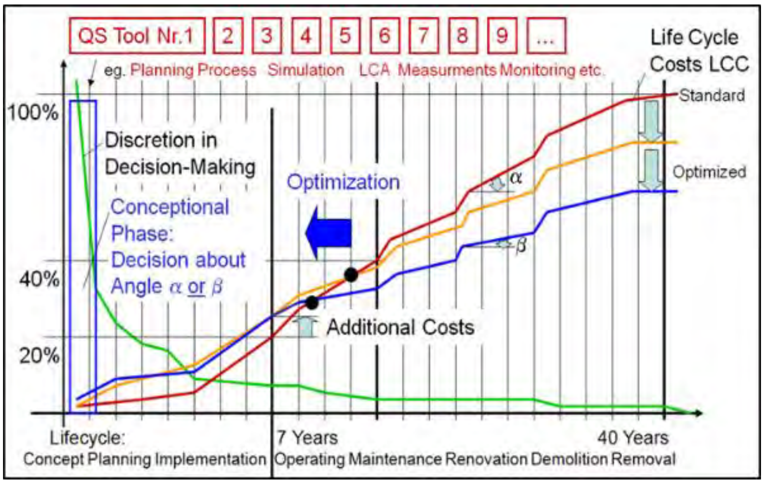

Figure 1: Diagram of LCC and the impact of decisions

2.1 Web based LQG database

This database follows the initial idea that a holistic improvement of the quality of buildings over the entire lifecycle can be achieved by adding a lot of quality assurance methods with one important aim in mind: the satisfaction and comfort of the user of a building. Building certification systems offer a possibility for a high level of quality performance. For this aspect some national and international certification systems – such as klimaaktiv, TQB, DGNB, BREEAM, LEED – have been considered and compared.

The qualitative database has been filled extensively and grouped into five life cycle stages: concept, planning, execution, use and deconstruction whereby these stages were further subdivided. Within the third level, filtration by information out of certain areas, for example project management, ecology, energy, etc. is possible. The fourth level is used to describe different complexes of themes, followed by the fifth level, where the results of the research project can be shown, for example quality assurance tools. Supplementary information like literature, hyperlinks and project-external documents, is provided within the sixth level. The optical appearance and the structure of the LQG-database are illustrated in Figure 2.

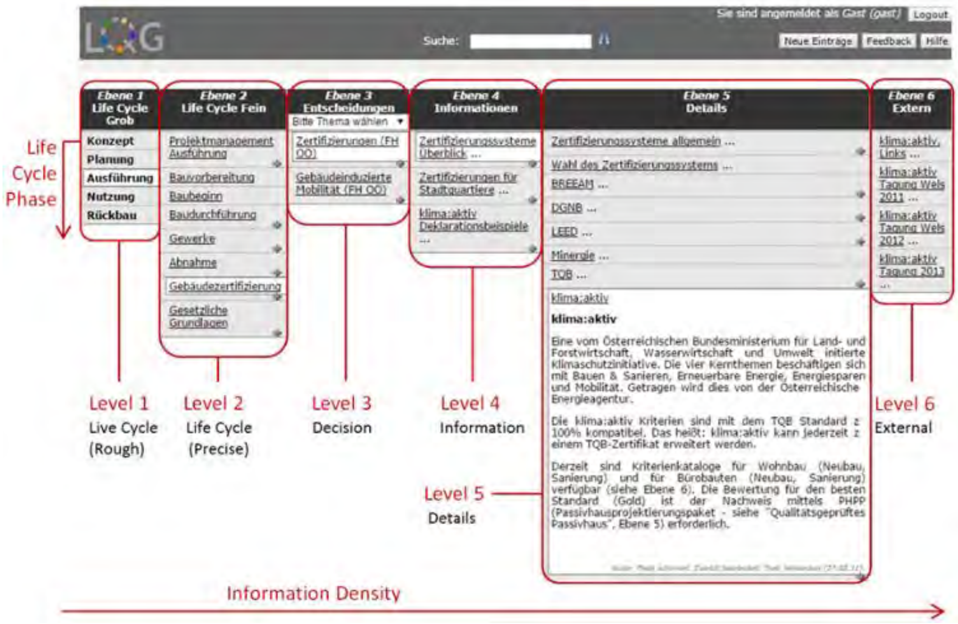

Figure 2: Appearance of the LQG database

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.2 Results of LQG

When complex issues of quality assurance arise, the project partners, as well as the interested persons (limited) can be supported by the online database, which is used on the one hand for commissioned projects, on the other hand also for teaching and research.

3. MOFNUG: MODULAR QUESTIONNAIRE FOR USER SATISFACTION IN BUILDINGS

The idea for the second cooperative FFG-project was born by scientists who worked on the previously mentioned LQG-project. User satisfaction still is the highest and most difficult target during the planning and operation of a sustainably optimized “High Performance Building”.

Because a very wide range of factors, hard to quantify, is covered by the topic “user satisfaction”, four universities of applied sciences where cooperating between 2013 and 2016 to shed light on this issue from different perspectives like marketing, psychology, energy technology and facility management. One main focus has been developing an online survey platform, which is used to “measure” relevant aspects of a building. This tool is able to respond to different circumstances (changing types of buildings or user structures in a flexible way as it is modularly structured.

The participation of the different universities has an impact on the variety of the modules and therefore on the increased platform flexibility. These modules range from aesthetic aspects and social interaction opportunities to building service engineering oriented topics. Improvements of already existing questionnaire parts (so called clusters) and generation of new modules have been done during the whole project (for example different questions for amateurs and experts and several building types).

3.1 MOFNUG online platform

To ensure easy usage of the platform for participants and prospective customers too, a clear and simple structure is necessary. Future customers can extend the questionnaire with minimum effort due to the modular design. Figure 3 shows the current visual appearance of the MOFNUG-project (just available in German). The different Clusters, as well as the number of included questions can be found by clicking “Fragen-Katalog” (questionnaire). If the page is scrolled down, each question of the currently open cluster can be seen.

The cluster “Thermischer Komfort” (thermal comfort) has been checked and optimized by practical measurements, simulations and interviews after comprehensive literature research.

This was followed by an extension of the literature research and an inclusion of additional modules by cooperation partners, for instance acoustic or visual comfort, cleanness or the room layout. For a high degree of visual comfort, an even illumination without considerable disturbance is required as well as individual adaption to the individual user’s needs. A visual connection to the outside world allows the user to inform about daytime, location and weather subconsciously and therefore should not be underestimated in importance. These criteria give a direction for the development of promising questions.

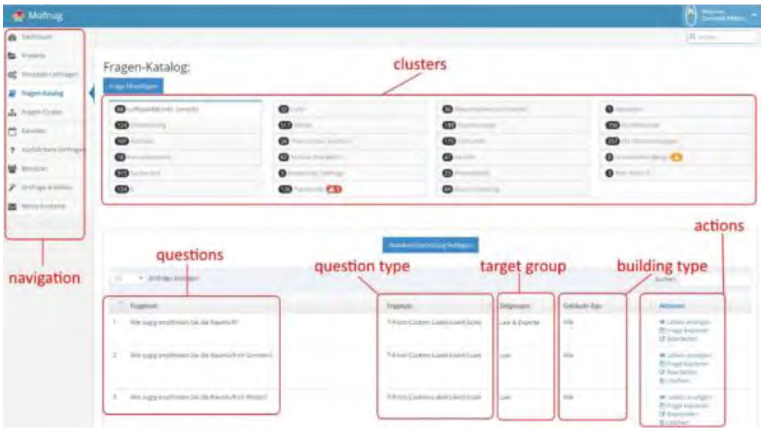

Figure 3: Screenshot of the questions currently available within each cluster of the Mofnug online

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.2 Results of the MOFNUG project

A main goal of the project was to generate an online platform where the modular questionnaire can be used to create surveys, perfectly tailored to the current needs. Each step, from developing an inquiry to its analysis can be done online without leaving the platform.

At the moment, the first surveys have been performed to check and improve the online tool. These surveys were performed within two master theses. The first one is about building automation and user satisfaction. Respondents receive an E-Mail, including a hyperlink which is valid only one time. As soon as the link is clicked, the survey opens and the first cluster is ready to be answered. In Figure 4, a typical survey, added by descriptions and translations, is displayed.

After sending invitations, the survey builder can check how many people already have finished the poll. Moreover, an evaluation of the current results is possible immediately.

It is also possible to generate word clouds with the online tool. If the questionnaire includes questions, answered onto free text areas, the system automatically creates a picture, where often mentioned terms are bigger than less frequent called words- commonly used conjunctions and other words on a “black list” will not be displayed to ensure a maximum degree of relevant data. A question of the first master thesis is what does produce noise at their workplace. The “biggest” answers, shown in Figure 5, are: heating system, conversations, and employees/persons.

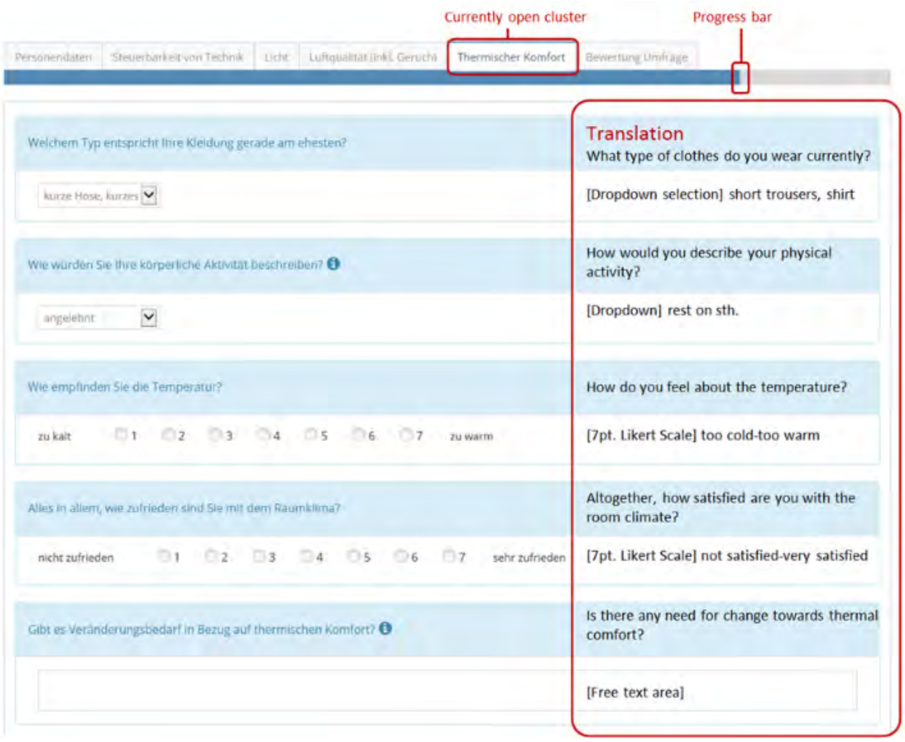

Figure 4: Typical survey on the MOFNUG platform

Figure 5: MOFNUG word cloud about what could be done to lower the noise level

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

A relevant indicator for air quality is the number of persons with health problems at their workplace, what is shown in Figure 6. In this case, multiple answers are possible.

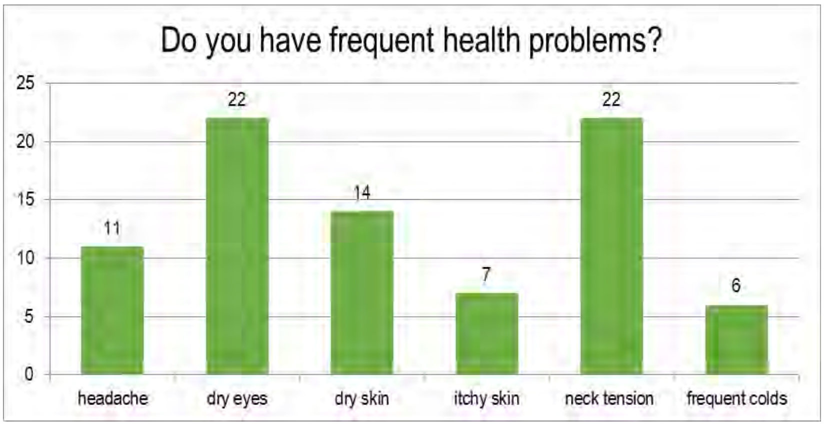

Figure 6: Physical problems of care staff at work

A usual question type on the platform is called "7-point custom Likert Scale" which allows the survey participant to answer the question relatively exact by ticking one of seven possible response options, for example reaching from 1-very bad to 7-very good or 1-too cold and 4- neutral to 7-too warm- shown in Figure 7 (additionally structured into summer and winter).

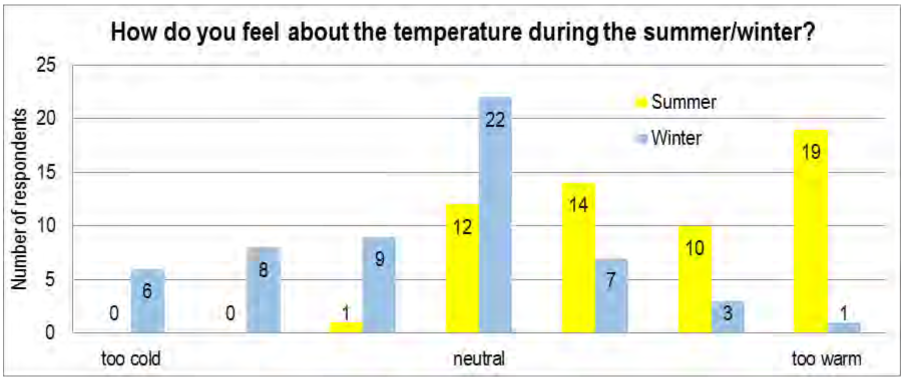

Figure 7: Perceived temperature split up into summer and winter

The second master thesis using the MOFNUNG-tool deals with user satisfaction in retirement homes for both inhabitants and staff.

Overall, the results of this study give a good overview about the preferences of the care center occupants and point out the differences of residents and geriatric nurses about thermal comfort. It is shown that with relatively simple measures the occupants' comfort and subsequently the care satisfaction could be improved significantly. The main discrepancies have been pointed out about the topic of thermal comfort. Whereas the residents feel relatively comfortable at an indoor temperature level of 23°C which is automatically adjusted by the heating system, this temperature is felt as too warm by the employees who have a higher metabolic rate due to their working activity. Additionally, the human thermal model established to regulate the indoor air climate in buildings by using Predicted Mean Vote (PMV) and Predicted Percentage of Dissatisfied (PPD) is not suitable for older people and especially for people suffering from dementia. 60% of the study participants felt that the room air in the building is too dry and 48 % of employees working in the building are suffering from health impairments caused by dry air. The existing spray humidifier installed in the ventilation system of the building is out of service.

For creating a new survey it is necessary to have enough information about the building, its automation systems and occupants as well as if the survey will be received by laymen or experts. If representative results are required, it is also crucial to perform measurements, such as temperature profile, VOC, humidity or CO_2.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4. CONCLUSION

The cooperation of several Austrian Universities of Applied Sciences helped to partly overcome competitive thinking and led to a significant added value at least for the participants, which is higher than just the sum of the findings.

Both LQG database and the MOFNUG platform are available from now on as supportive instruments to push forward the optimization of buildings in a broad range of fields such as life cycle costs, sustainability and user satisfaction. The online presence ensures a successful application in commissioned projects as well as in teaching and research.

ABSTRACT

The social environment and the physical environment at the neighbourhood level have been linked to social interactions and individual wellbeing in different urban populations. However, there is currently no clear understanding about the relative strength and nature of this relationship. This research seeks to better understand the relationship between measures of the social environment and the physical environment (i.e. urban form, including community or "third places") and the frequency of social interactions of older adults (i.e. people aged 55 years and above). From the CSIRO Survey of Community Wellbeing and Responding to Change, we obtained older people's individual views on their social interactions and their perceptions of social and physical environments in six Local Government Areas (LGAs) in inner, middle, outer, and urban fringe areas of Metropolitan Melbourne, Australia. Using multiple regression analyses, we find that perceived social environment measures are stronger predictors of social interaction frequency than the physical environment. In particular, respondents' participation in community events has the strongest association with social interactions, while the presence of, or access to, third places was not a dominant factor and had the weakest association. These findings provide insights into older adults' social interactions, and contribute to planning policy and practice to support ageing-in-place. Further work is required using objective and quantitative measures of the urban form in the context of the respondent's neighbourhood.

Keywords: *urban environment, sustainable neighbourhood, quality of life*

1. INTRODUCTION

The Australian population is ageing due to rising life expectancy, declining birth rates and ageing ´baby boomers´ (Lowen et al., 2015). With *The Intergenerational Report* (The Commonwealth of Australia, 2015) predicting that the number of older Australians will double by 2055, our cities need to be more age friendly. The same trend has also been predicted for other developed and developing countries in the world (Van Cauwenberg et al., 2011).

To address these societal changes, there is a growing interest in the concept of ageing-in-place. This is where people are able to age in their homes and communities in a way that their lives are changed as little as possible over time (Koh et al., 2015). Many older adults prefer ageing-in-place (Yen and Anderson, 2012) because their independence, networks and social connections are maintained (van den Berg et al., 2015). These, in turn, contribute to their overall health, wellbeing and Quality of Life (QoL). Furthermore, ageing-in-place is found to reduce governments' health care costs (Lager et al., 2015).

Many older adults have reduced mobility and energy levels compared with the general population (Buffel et al., 2011), so they tend to spend majority of their time in and around their homes (Wang and Lin, 2013) and immediate neighbourhoods. Face-to-face neighbourhood social interactions are claimed to reduce loneliness that is associated with due to life changes for older adults (e.g. reduced body capital and health, death of partners and friends) and increase their overall wellbeing (Lager et al., 2015). In this research we ask the question: *how can policy, planning practice and urban design provide vital support to allow ageing-in-place to occur?*

In the early 1960s, Jane Jacobs (1961) discussed among other things the influence of urban form on peoples' social relations. However, she never empirically tested her observations. Findings by Lund (2003) and Hickman (2013) confirm that urban form elements (such as density, accessibility and walkability) contribute towards social interactions. However, it is still unclear to which extent urban form influences social interactions and which specific urban form elements contribute most. Some researchers have found that social environment elements, e.g. perceived safety (Delmelle et al., 2013), sense of social or economic opportunities (Argent, 2008) or belonging to social or cultural groups (Kent and Thompson, 2014) contribute more towards social interactions than the physical environment. This lack of clarity creates challenges in neighbourhood planning and in urban design for promoting ageing-in-place, social connectedness, overall wellbeing and QoL of older adults in our communities.

The assessment of urban form explicitly includes neighbourhood third places. Oldenburg (1989) divided places as first places (home), second places (work) and third (community) places. Little is known about social interactions across different types of third places (Hickman, 2013) with the majority of previous research concentrating on examining social interactions in one type or only couple types of places at a time. Herein, we consider eight types of third places: shops, services, cafes/bars/restaurants, public transportation stops, local streets and squares, natural environment, footpaths and community places.

This paper aims to investigate older adults' social and physical neighbourhood environments' contribution to face-to-face social interactions. In the present study, we test the following hypotheses:

H1: More favourable perceptions of social environment are positively associated with more frequent social interactions;

H2: More favourable perceptions of physical environment are positively associated with more frequent social interactions;

H3: Higher perceptions of the importance of social interactions in third places are positively associated with more frequent social interactions.

2. METHODOLOGY

2.1 Survey setting

Self-assessment of social interactions and perceptions of social and physical environments were obtained through the CSIRO Survey of Community Wellbeing and Responding to Change. This survey was administered among residents located in six (out of thirty-one) Melbourne municipalities or Local Government Areas (LGAs) - Melbourne, Yarra, Boroondara, Whittlesea, Greater Dandenong and Frankston as shown in Figure 1. The survey was undertaken in accordance with the Guidelines of the National Statement on Ethical Conduct in Human Research and approved via the CSIRO.

Figure 1: Metropolitan Melbourne in Australia (left) and study LGAs (right - marked with aqua colour).

2.2 Survey participants

Survey participants from the six LGAs were randomly selected by a third party survey company. Overall, 1,072 people participated in the survey, 476 of them were older adults (aged 55 and above) who agreed to participate in this study: with 243 older adults completing computer assisted telephone interviews (CATI) and 233 older adults completing an online survey. It took approximately 30 minutes to complete the survey (McCrea et al., 2015).

2.3 Survey measures

The survey measured different aspects of peoples´ QoL and wellbeing. Most of the measures were sets of multiple items using Likert scales. The original items were designed to be treated as sets; therefore composite measures (instead of single items) were used. Means of each multiple item set were calculated (e.g. mean of all safety items), the means are referred to as a composite measure (e.g. composite measure of safety) and were used in the following analysis. Only measures for density, mix, access and the importance of various third places were single item measures.

Perceptions of social environment were measured with seven composite measures (the individual items for each are listed in the brackets):

- Social Interactions (I stop and talk to neighbors; I stop and talk to strangers in my suburb; I say hello to people in my suburb; I go out socially with others in my suburb; I enjoy simply seeing others in my suburb);
- Safety (It is safe to walk alone in the street during the day; It is safe to walk alone at night; It is safe to leave the car on the side of the road at night; Overall, I feel safe living in this suburb)[1];
- Participation in community groups (You regularly help out a local group as a volunteer; You have attended several community events in your suburb in the past year; You are a very active member of a local organization or club; Overall, you participate regularly in a variety of community activities in your suburb)[1];
- Community wellbeing (This suburb is suitable for seniors; Overall, this suburb offers a good quality of life; Overall, I am happy living in this suburb)[1];
- Community spirit (People can rely upon one another for help; People have friendly relationships; People can work together if there is a serious problem; Overall, I am satisfied with community spirit in my suburb)[1];
- Community inclusion (Suburb is welcoming of newcomers; Suburb is welcoming of people of different cultures; Overall, suburb includes everyone)[1];
- Level of trust (People that you see around can generally be trusted; Overall, I am satisfied with levels of trust in my suburb).

Perceptions of physical environment were measured under five themes:

- General appearance (Cleanliness; Greenery and parks; Walkways and paths; Neighborhoods character; Overall satisfaction with general appearance);
- General environment (Quality of the air; Level of noise; Overall quality of the general environment)[2];
- Density (My suburb is becoming denser)[1];
- Mix (My suburb is becoming more varied, mixed and interesting)[1];
- Access (My suburb is becoming harder to get around)[1].

Importance of social interactions in eight types of third places were also measured: Cafes/bars/restaurants; Shops (shopping malls and specialty shops); Services (like the doctor); Public transport stops and hubs; Natural environments (like local parks); Footpaths; Local streets and squares; Community places (like libraries).

The reliability of the items in the composite measure were tested with Cronbach´s alpha, all the reliabilities were good, >0.7.

2.4 Survey data analysis

The first two hypotheses (H1 and H2) were tested using multiple regression analyses. The dependent variable was the composite measure of social interactions (see first row in Table 1 for mean and SD). Independent variables were added stepwise to the multiple regression model, and we note the changes in R-square values (i.e. indicating

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

how well independent variables are predicting the dependent variable). Firstly, for testing H1, all social environment measures were added stepwise to the regression model. The measures were ordered according to their relevance from literature review, starting with composite measures of safety and participation with community groups and ending with composite measures of community inclusion and levels of trust.

Then urban form measures were added to the regression model, to test H2. The relevance or order of these items was not known; therefore, their order in the regression model followed their order in the survey.

Finally, for testing H3, third places were added to the analysis. They were ordered according to their relevance in literature review, starting with cafes/ bars/ restaurants, shops, natural environment and local streets and squares.

3. RESULTS

A brief summary of the socio-demographic characteristics of the participants are as follows: 56.7% were 65 years old or older, 52.5% female; 57.6% retired; 88.7% were homeowners and 67.8% lived in separate house; about 89% spoke English as their primary language; majority were very satisfied or satisfied with their physical mobility (81.3%) and health (74.0%). On average, respondents spent 5.3 days (during daytime) in and around their suburb.

The means of the measures suggest the majority of respondents were very satisfied or satisfied with their social and physical environment (only the composite measure of participation in community groups and the measure of access had a mean < 3.0) as seen in Table 1.

	Obs	Mean	SD	1	2	3	4	5	6	7	8	9	10	11
1. Social interaction	476	3.53	0.88											
2.Safety	476	3.85	0.88	0.24										
3.Participation in com. groups	475	2.53	1.28	0.38	0.10									
4.Com. wellbeing	476	4.29	0.73	0.44	0.42	0.15								
5.Com. spirit	473	3.67	0.86	0.56	0.33	0.26	0.53							
6.Com. inclusion	469	3.68	0.85	0.36	0.14	0.09	0.34	0.53						
7.Level of trust	467	3.50	0.82	0.44	0.42	0.21	0.50	0.63	0.38					
8.Gen. appearance	476	3.97	0.75	0.32	0.46	0.10	0.60	0.50	0.33	0.55				
9.Gen. environment	476	3.76	0.92	0.26	0.35	0.07	0.38	0.39	0.24	0.36	0.51			
10.Density	472	4.06	1.11	0.03	0.02	0.04	0.01	0.01	0.05	-0.03	-0.08	-0.10

Table 1: Descriptive statistics and spearman correlation coefficients

Community wellbeing (in Table 1) had a mean of 4.3, indicating that participants were satisfied with living in their community. Interestingly, the analysis revealed that 81.0% of older adults strongly agreed or agreed that their suburb was suitable for older adults; this measure was part of community wellbeing measure. Table 1 shows that majority of measures had weak or moderate correlations (coefficient < 0.5). The highest correlation was between composite measure of levels of trust and community spirit (0.63).

The results of the multiple regression analysis are presented in Table 2. Composite measures of community wellbeing added 10.6% to the model and community spirit 9.3% and were the most significant predictors of frequency of social interactions. The least important composite measure was levels of trust (i.e. it removed 0.2% from the model).

We cannot reject hypothesis H1 because half of the social environment measures are significant for predicting frequency of social interactions (composite measures of participation in community groups; community wellbeing and community spirit); and their p value is <0.05. We note, however, that the composite measures of levels of trust and community inclusion are not important predictors of frequency of social interactions, changing the prediction model with less than 1%; similarly, the composite measure of safety changes the model with approx. 6% and the p-values of these measures are >0.05.

In testing H2, we added physical environment measures to the perception model (that already contained social environment measures). Physical environment measures had minimal impact to the model as seen in Table 2. Hypothesis H2 is rejected – the perceptions of physical environment did not influence the frequency of social interactions over and above than the social environment.

Finally, in testing H3, eight types of third places were added to the model. Overall, the third places added 8.7% to the model. Our results showed that cafes/bars/restaurants have the highest impact to the model (3.5%), followed by shops (1.5%), footpaths (1.4%) and natural environment (0.8%), these four types of third places had significant p-value (>0.05). We cannot reject hypothesis H3.

STEP 1. H1: Higher perception of the social environment is positively associated with greater amount of frequency of local social interactions.			
Measure	R-squared	Change in R-squared	p-value
Safety	0.0575		0.54
Participation in community groups	0.1985	0.141	0.00
Community wellbeing	0.3049	0.106	0.00
Community spirit	0.3975	0.093	0.00
Community inclusion	0.4059	0.008	0.12
Levels of trust	0.4042	-0.002	0.19
STEP 2. H2: Higher perceptions of the local environment is positively associated with greater amount of local social interactions.			
Measure	R-squared	Change in R-squared	p-value
General appearance	0.4049	0.0007	0.40
General environment	0.4054	0.0005	0.35
Density	0.4022	-0.0032	0.97
Mix	0.4026	-0.0028	0.70
Access	0.4023	-0.0031	0.95
Step 3. H3: Higher perceptions of social interactions in third places are positively associated with more frequent social interactions.			
Third place	R-squared	Change in R-squared	p-value
Cafes/bars/restaurants	0.4370	0.0347	0.000
Shops	0.4520	0.015	0.002
Natural environment	0.4601	0.0081	0.003
Local streets and squares	0.4676	0.0075	0.018
Community places	0.4723	0.0047	0.121
Services	0.4708	-0.0015	0.769
Public transport stops	0.4744	0.0036	0.844
Footpaths	0.4888	0.0144	0.001

Table 2: Results of hierarchical multiple regression analysis for predicting frequency of social interactions from respondents perceptions of social and physical environment

4. DISCUSSION

Participation in community events was the most significant social environment measure for predicting the frequency of social interactions in older urban residents. This accords with the work of van den Berg et al. (2015) who noted that volunteering (one item of the participation in community events measure) may be an important part of social interactions for older adults because it usually involves other people. Interestingly, approximately 47% of respondents strongly disagreed with the statement "you regularly help out a local group as a volunteer", as seen in Figure 2. Overall, Figure 2 shows that responses for participation in community events are skewed to the right, meaning that participants do not perceive they are participating in community activities, which is an interesting finding in itself.

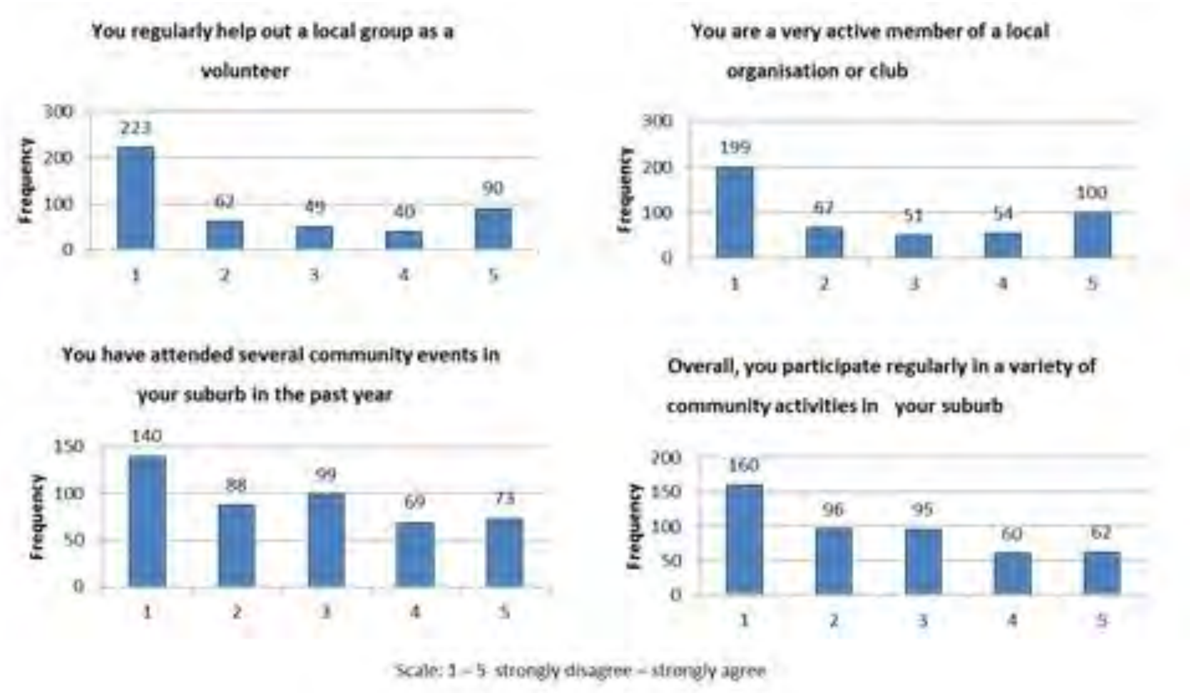

Figure 2: Frequency of ´participation in community events´ responses

Perhaps the most surprising finding is that perceived safety was not a significant predictor of social interactions. This is not in accordance with literature. For example, Delmelle et al. (2013) suggested that safety is a very important aspect for social contacts to occur in Austrian context (and in some cases perhaps even more important than urban form). However, in the case of the 6 Melbourne LGAs, the majority of respondents were very satisfied or satisfied with their overall safety. This could be a general Australian or Melbourne community perception.

Surprisingly, the perceived urban form measures had minimal impact to the model over and above the social environment. This needs further investigation in the next stage of analyses. The respondents' addresses have been geo-coded to enable spatial analysis to be conducted.

5. CONCLUSIONS, LIMITATIONS AND FUTURE WORK

Based on urban older residents´ perceptions of their social and physical environments and their relation to frequency of social interactions, we find that the former is relatively more important than the latter. This means that, to specifically improve older adults' social environment and support ageing-in-place, policies and initiatives that encourage participation in community events and activities and increase their social interactions are important. We note that the survey was a self-reported study and covered only the participants' perceptions of their social and physical environments. The role of neighbourhood planning, place-based design and specific configurations of urban form, including the availability of – and access to – third places, needs further investigation. Since we have geo-coded and mapped the respondents´ home locations and we can have objective neighbourhood measures of urban form and structure, this is indeed the next phase in our investigation.

Furthermore, we did not include digital communication and social media use, which are continually growing and becoming increasingly more important in the developed world; these also need to be considered in future research.

ABSTRACT

Air pollution in China continues to be a major health risk for people across the country, with millions of premature deaths each year linked to the bad air. Continuous exposure to dangerous levels of PM2.5 – or ambient pollution dangerous to health – has also been proven to lower productivity, as well negatively impact talent attraction and retention, making it harder for companies in China to operate under a slowing economy.

With a majority of the PM2.5 outdoors making its way into the office buildings we work at, it is crucial for us to be aware of the fact that we are not safe indoors unless the air inside is properly managed. As China shifts to a service-oriented economy, even greater numbers of people will be working overtime hours in office towers, and thus, the importance of ensuring good air in the workplace will have greater implications ahead.

In the first in-depth industry look at how stakeholders in the China office market can improve indoor air quality by strategically incorporating the use of mechanical systems, professional commercial real estate services firm JLL and environmental consultancy PureLiving China present their findings on the subject. The publication also speaks to the level of action needed to be taken by landlords, tenants, and occupiers to create safer workspaces in China.

By taking the lead in this area, China has real opportunity to not only address the challenges it faces with air pollution head-on, but also to serve as an example for other industrializing nations to follow – as they, too, struggle to cope with bad air. Finally, while we cannot change conditions outside, we can all do something to control the situation indoors, which also happens to be where we spend most of our time working.

Keywords: indoor air quality, China office market, indoor environmental quality

1. **OPPORTUNITY CALLS ON CHINA'S OFFICE MARKET**

In the modern business world, people in China are spending more time indoors than outdoors. At work, employees from 90 percent of the country's industries are clocking in overtime hours on a weekly basis (Beijing Normal University, 2015). Meanwhile, outside of the office, the air in China is a serious problem. Air pollution in China contributes to some 1.6 million fatalities in the country annually (Rohde et al., 2015). While the number of premature fatalities linked to the air that we breathe indoors is difficult to quantify, we know that spending time inside, in places where the air is not properly managed, also exposes us to harmful levels of outdoor pollution – and the ubiquitous PM2.5. The real danger is that 75% of PM2.5 outdoors – or particulate matter sized 2.5 microns or smaller – makes its way into buildings (Wallis, 2015). PM2.5 penetrates deep into our lungs, enters our bloodstream, and has sobering long-term health implications. Consequently, pollution remains at the forefront of public health concerns in the country and continues to be a focal point of China's 13th Five-Year Plan (2016-2020), with targets curbing reliance on coal-fuelled power – a chief source of PM2.5 – reaffirming the Chinese government's deep commitment to the "war on pollution".

As pollution continues to strongly influence China's plans for the future, indoor air quality is a critical issue that deserves greater attention, especially as high public awareness on pollution continues to increase and dramatically change people's expectations toward health. Moreover, pollution is no longer primarily a concern among just foreigners working in China; everyone is worried about the bad air. In just a short time, the general public has gone from a state of near indifference to possessing to world-leading levels of knowledge on air quality indexes, and this is particularly evident in major cities like Beijing and Shanghai. Though China is not that far behind India and Pakistan, which suffer the highest PM2.5 concentrations in the world (World Health Organization, 2014), it is head

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

and shoulders above in both awareness and policy, making it best-positioned to act on indoor air quality in a global context so that other industrialising nations can follow.

While environmental reform in China is a long-term endeavour, we can all take proactive measures now to improve indoor air quality and create office space that employees will want to work in – and choose over others. In this white paper, we explore how sound investments in indoor air quality today pays immediate and future dividends, giving employers an important edge needed in China to attract and retain top talent in the increasingly competitive marketplace. Though our findings are far from providing all of the answers to indoor air quality problems, we have looked at the outside air in China and assessed how it is of concern to both landlords and tenants in the office market. Supported by data analysis of indoor air quality samples collected by our partner for this paper, indoor environmental consultancy PureLiving China, we address indoor air quality challenges for the China office market and offer potential solutions for companies operating in the country.

Our key takeaways include:

- Good indoor air quality correlates with nearly twice the level of productivity compared to average air quality and is of increasing significance for talent attraction and retention in China.
- Good indoor air quality can be achieved by following our three As: Assess, Act, and Assure.
- Investments in indoor air quality further differentiate office buildings from competitors, better enabling them to retain value.

Good indoor air can double productivity levels

While the benefits of a healthy workspace can be difficult to measure in terms of directly correlating gains, new research indicates that working environments with better ventilated clean air helps raise the level of productivity for analytically intensive tasks by as much as twice that compared to just average air quality (see Figure 1; Allen et al., 2015). The study is significant because it suggests that air quality has far more of an impact than previously thought, as previous studies only linked better airflow to a limited improvement of productivity for repetitive tasks such as typing speed (World Green Building Council, 2014). Furthermore, instead of relying on performance of rote tasks, the study measured performance on standardised tests assessing analytical skills highly relevant to professional services firms. This is particularly relevant for China, as it shifts towards a service-oriented economy.

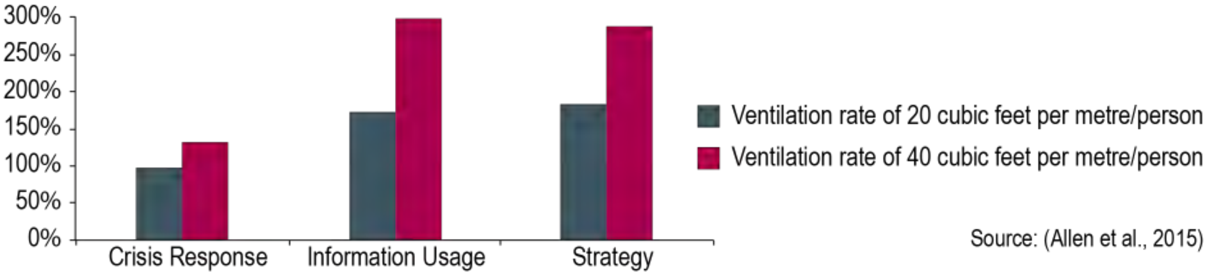

Figure 1: Productivity increases in analytical tasks

A boost for talent attraction and retention

Under a slower economy, productivity gains from good indoor air are also especially significant given that staffing costs make up the bulk of a company's operating costs. Moreover, investments in improving air quality can pay for themselves in as little as three to six months through increased productivity, reduced sick days, and lower health insurance premiums (Wallis, 2015). Though technologically advanced buildings with filtered fresh-air systems tend to be higher rent-buildings, these properties typically only demand marginally higher rent than the market average. Thus, a small premium in office rent could go a long way in creating big cost-savings for firms as greater productivity leads to better performance.

2. OUR 3As STRATEGY ACHIEVES OPTIMAL RESULTS

Achieving good indoor air quality at work is as simple as following our 3 As: Assess, Act, and Assure. While the actions taken by employers to improve indoor air quality in a new or old building will differ, the process undertaken to get there will be the same. Though many employers have a tendency to cut corners at some stage of the process, believing that budgetary requirements will be beyond their reach, this is perhaps unwise. Skipping over a step could lead to serious repercussions – the circulation of dirty and dangerous air – that could prove much costlier and painful to fix at a later date. It is also important to note that not all undertakings to improve air quality are necessarily costly. Moreover, as companies face added pressures to run on lower operating budgets to increase their competitiveness in the market, we expect more employers in China to seek a better a balance between achieving good indoor air quality, energy-efficiency, and cost-savings.

First: assess your workplace situation.

When considering a space for lease, tenants should be proactive in asking landlords about what has been done to provide good indoor air quality in the building. For example, does the office tower have a fresh-air system in place, and what is the effectiveness of its filtration system? The more tenants ask these questions, the better, as it motivates landlords to consider these specifications when they do upgrades. It also applies pressure on them to change their property management practices. Yet, even if a landlord assures you of excellent air quality, it is not possible to detect the indoor air quality of a space solely by relying on their responses. Even in cases where the landlord has answered truthfully, differences in design, operation, and maintenance can produce varying outcomes. Thus, due diligence is important. Having air quality tested not only provides a snapshot of the situation, but also helps to form the basis of a solution to improve the indoor air quality of the space in question. For the best results, PM2.5-auditing should be conducted by a credible third party, not just before occupation as is most commonly done, but actually prior to fit-out commencement to ensure that solutions can be implemented during the fit-out period (or afterwards as a retrofit). This assessment is critical to knowing how to act.

Second: act on that information.

With a sample of 100 data points collected at some 50 commercial offices around the country in Beijing, Shanghai, Chengdu, and Suzhou from indoor air quality testing carried out from 2013-2015, PureLiving China considered almost a dozen factors contributing to indoor air quality. This helped us determine what has the biggest impact on PM2.5-reduction indoors. Surprisingly, several factors, including building height, occupant density, and green certification had little correlation with the reduction of PM2.5 indoors. Statistical analysis revealed that as a group, mechanical systems, specifically the heating, ventilation, and air conditioning (HVAC), and filtration functions, make the most meaningful contributions to cleaner indoor air at offices in China (see Figure 3). Therefore, these should be the prime focus of efforts to improve the air where we work.

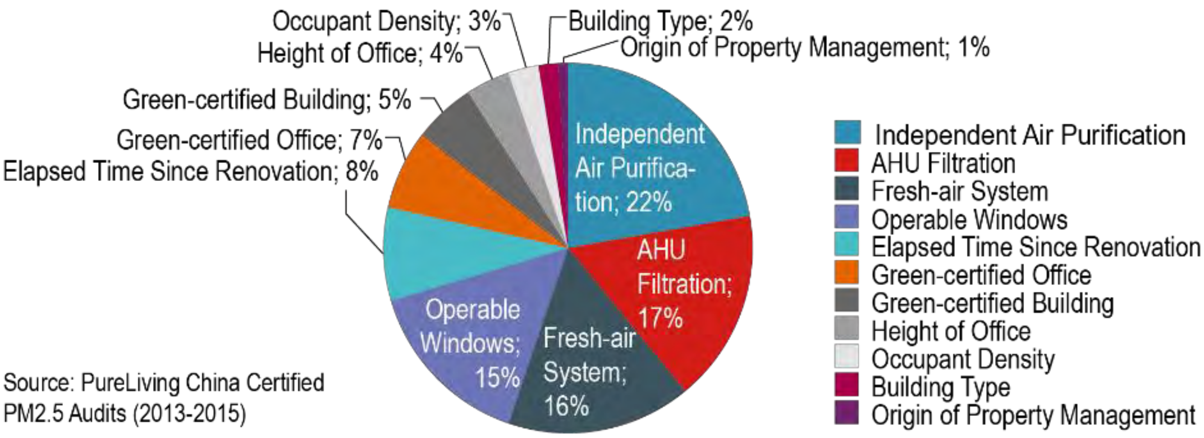

Figure 2: Relative impact of factors on PM2.5 reduction

Improving the indoor air quality of an office can be as simple as ventilating the space with fresh air from an open window. While this may work in other countries, in China, opening a window often means bringing polluted air into the workspace. As a result, many office towers rely on a fresh-air system to ventilate the air within their building. The easiest way to purify the air inside is to exploit existing equipment and retrofit higher efficiency particulate filtration media into existing air handling units (AHUs) of a central HVAC system. AHUs utilising high-efficiency filters deliver large amounts of purified air at a minimal cost, but retrofitting the central ventilation or air conditioning system is not always an option; sometimes, the fresh-air delivery rate is already low and should not be further reduced, or the landlord is unwilling to allow modifications. This leads many tenants to assume that control over their environment is beyond their reach, but is untrue. Tenants can, in fact, significantly benefit from installing independent purifiers that filter the air within their offices. Depending on the size of the space or the time permitted for the upgrade, different methods can be used to filter the recirculating air.

There are two ways to approach this. One is the use of portables, which can be highly effective, but carries cost, maintenance and human error drawbacks. A second option is to install in-ceiling recirculating solutions which our data found to be the most effective and cost-efficient. The in-ceiling approach has been found to be significantly more effective for big areas compared to portable air purifiers at floor level due to their higher capacity and therefore sweeping coverage area. In-ceiling systems can also be spaced apart without any airflow obstructions from furniture. This allows for evenly distributed filtration at a faster rate and minimal sources of interruption. By comparison, portables are frequently found turned off, without a filter, with a dirty filter, or with a filter incorrectly inserted, making it difficult for the machines to work as designed. The results of our analysis (see Figure 4) demonstrate a combination of in-ceiling purification, AHU filtration, and a fresh-air system is most likely to lead to the most meaningful reductions of PM2.5 indoors.

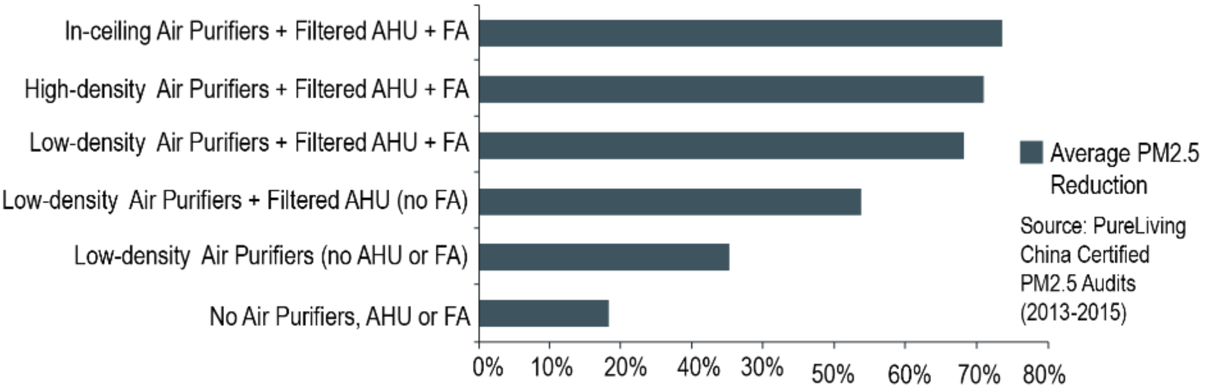

Figure 3: HVAC and filtration combination efficiencies

The use of mechanical systems is most compelling when extreme spells of pollution hit. Figure 4 shows the actual recorded PM2.5 levels in a 1,000-sqm Grade A office in Shanghai during a historic "airpocalyptic" episode in December 2013. This is the true stress-test of the equipment. By using in-ceiling air purifiers to filter the recirculating air, the company's office effectively achieved a 93 percent-reduction. Indoor PM2.5 levels never exceeded 40 micrograms per cubic metre, while outdoor levels soared up to 570 micrograms per cubic metre.

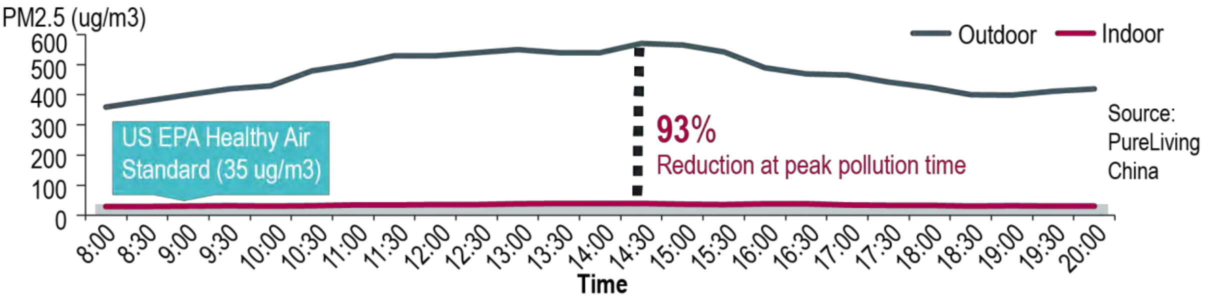

Figure 4: Dec. 2013 Shanghai "Airpocalypse" – PM2.5: outdoor vs. indoor

While portable filtration units are quicker to set up and cheaper by the unit than ceiling units, more portables are required to cover a larger space. Therefore, portables are most suitable for smaller rooms (typically working best in spaces smaller than 20 square metres in size) or temporary offices requiring flexibility in deployment. In-ceiling units, on the other hand, take comparatively longer to set up, but their installation is still relatively quick, and they can be hidden with drop ceilings to reduce their visibility and distraction to employees. Though the capital investment required for these systems is more upfront per unit than portables, they offer greater longer-term cost-savings due to lower maintenance costs and higher coverage per unit (see Figure 5).

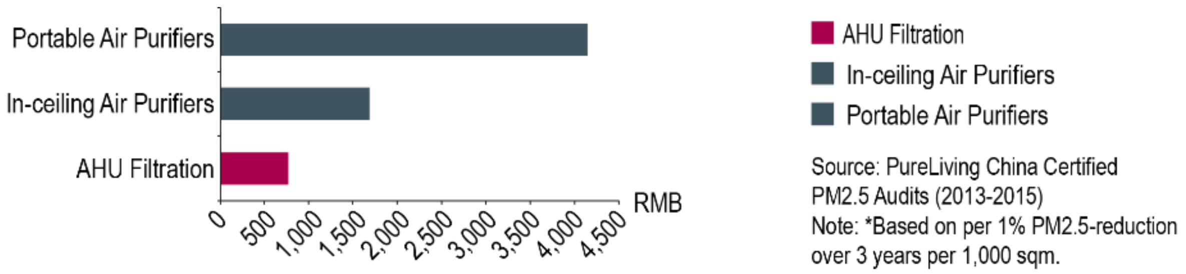

*Figure 5: Relative cost for mechanical system filtration options**

Meanwhile, on-demand automation is the latest tool in the market. Strongly preferred for its ability to reduce human error or mistakes commonly made when it comes to manually operating purifiers, such as cleaners accidentally turning units off on "good-air days" and people fighting over the control switch without understanding how the machines work. On-demand automation is also highly efficient and energy-saving as pre-programmed functions enable air filtration systems to function based on real-time air quality (see Figure 6). Given that the machines do not need to be kept on at all times, on-demand automation also lowers operating costs through energy savings. Therefore, we expect interest in on-demand automation to grow as the number of employers investing in better indoor air quality rises.

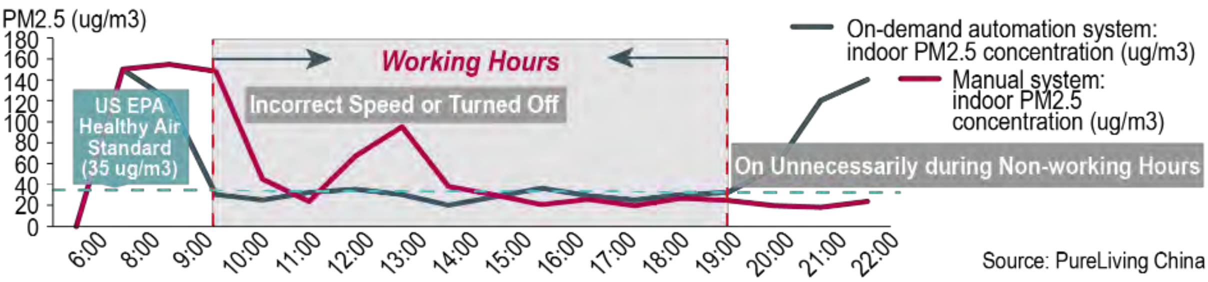

Figure 6: On-demand automation vs. manual operation

Third: assure that good air quality is maintained by continuously monitoring your accredited space.

Many landlords and employers mistakenly assume that once the installation is complete, there remains nothing left to do. In fact, the real work begins after a designated system is up and running. Continuous monitoring of the indoor air quality allows operation teams the ability to fine-turn performance of the equipment and staff operating the machines the ability to improve how the machines are used. It also ensures that landlords, employers, and employees are getting the most out of the systems. The good news is that ongoing monitoring has never been easier, due to the convenience of online applications that are able to capture live indoor air quality readings. This is rapidly driving the industry toward performance-driven solutions, exerting greater pressure on landlords to deliver consistently desirable results as employers are pushed by employees to provide safe air during working hours. In turn, demand for industry certifications like RESET (www.reset.build) or WELL (www.wellcertified.com) is mounting, as these accreditations have been proven to help protect occupant health with specific requirements for criteria affecting indoor air quality. Apart from providing a road map and standard for the creation of healthy spaces, these certifications provide marketing benefits and recognition for those who make the effort and achieve real results. Moreover, real-time monitoring apps, particularly those which allow accredited spaces to be followed online by employees, further offer a high degree of transparency, and thus, these apps also serve as a powerful feedback tool in holding both landlords and employers accountable for the indoor air quality of their space on a regular basis. This ultimately encourages both sides to work together to make certain that problems are rectified quickly as they arise, additionally helping to minimise interruptions to good indoor air quality.

3. MARKET DIFFERENTIATION IS KEY TO SURVIVAL, SUCCESS

Investments in indoor air quality further differentiate office buildings from competitors, better enabling them to retain value in any market. While we have discussed why employers have numerous reasons incentivising them to act quickly, it should also be recognised that landlords, too, have a very persuasive case to be proactive in leading the market. As more landlords consider HVAC upgrades, making the right level of investment in system upgrades will be essential. Under-investing has been the case historically and should be avoided – as should over-investing from an insufficient assessment of the situation. The bottom line is that office towers with food indoor air will only be more appealing to tenants. Buildings without good indoor air quality will provide tenants with less incentive to sign or renew their leases, particularly in older buildings where tenant leases are nearing expiry. In the worst-case scenario, tenants will move into buildings with cleaner air. Even buildings with high occupancy are still susceptible to losing tenants.

Today, office buildings with good indoor air quality are able to set themselves apart from competitors. Later, as more buildings upgrade their systems, those with the best equipment (specifically fresh-air systems and AHU filtration) will be able to maintain their relevance to the market. Moreover, properties with good indoor air quality will be more resilient in periods of economic downturn or slow growth, thus extending their long-term market viability, particularly as health and safety concerns remain a priority for building satisfaction among tenants (BOMA, 2013).

4. WE ARE NOT POWERLESS AGAINST AIR POLLUTION

While we cannot change conditions outside, we can control the situation indoors, which also happens to be where we spend most of our time working. In the interim, this means that the onus will be increasingly placed on landlords and employers to be proactive in providing effective and sustainable solutions to safeguard people from the major health risks that come with the bad air, especially as more employees demand that the welfare of their health be taken seriously in the workplace. With all there is to gain, we are cautiously optimistic that more office stakeholders will act and lead the pack with the delivery of sensible indoor air quality solutions.

In this paper, we have examined the subject of indoor air quality, with a dedicated focus on its relation to pollution in the China office market within the context of commercial real estate. Considering that pollution is an ongoing concern, however, our intent is not to be overly conclusive, but rather to help provide a better understanding of the bigger picture and how the issue is growing in significance for companies operating in China. We have also outlined practical options in our 3 As strategy that are available in the market which can help improve the situation – now. Though more landlords and employers in the office market are increasingly getting on board, the reality of the situation is that those currently acting to achieve good indoor air quality continue to make up the minority, when in actuality, the pursuit of clean indoor air should really be a mainstream priority.

ABSTRACT

The building sector is responsible for approximately one third of Europe's greenhouse gas emissions and thus it is a high priority when aiming to support climate change mitigation. Resource efficiency and energy efficiency strategies can help to reduce the environmental impact of buildings and this article aims to explore if occupancy data can assist their implementation. The influence of occupancy patterns are usually overlooked when consumption in buildings is being discussed. The current method of analysing the environmental impact of buildings is to normalise consumption by building size. This is done for energy, water and carbon dioxide and building size is typically defined by net internal area. However, there is growing call to normalize buildings with patterns of use and with occupancy patterns in particular. Occupancy data was collected in an office building for one month in order to calculate the peak occupancy of the case study area. This also enabled the occupancy and energy consumption patterns to be compared. In addition to this, the energy consumption of the case study building was simulated in order to explore how energy consumption is influenced by different workplace arrangement strategies. It has been shown that daily occupancy curves add valuable information regarding the control strategies of the energy using systems in office buildings. It has also be shown that the peak occupancy rate of the individual building areas is also valuable data as it holds the key to how many desks are needed for a set group of people. It is clear that the amount of space reserved has a big implication on rental costs and energy consumption. The data has multiple uses and can even be used to rent out unused spaces to the public via a growing number of sharing economy websites that focus on spaces in commercial buildings.

Keywords: resource efficiency, energy efficiency, utilisation rate

1. INTRODUCTION

The current method of analysing the environmental impact of existing buildings is to normalise consumption by building size. This is done for energy, water and carbon dioxide and building size is typically defined by net internal area. The simple reason for doing this is that buildings of different sizes can be compared with one another. This practice is reinforced by national building regulations which aim to reduce consumption in buildings and the legal requirements regarding energy efficiency commonly present their target criteria in the format of energy per unit area such as kWh/m^2. The problem with this is that the influence of the occupancy patters are being overlooked when we only consider the amount of energy consumed and the building size.

For example the Finnish national energy efficiency regulations for buildings has defined the maximum amount of energy that new buildings can consume and this is presented in the format of energy per square meter. In order to simplify the comparison for different buildings, the regulation assumes that the buildings are occupied in a standard manner. If office buildings are taken as an example, then the predefined occupancy pattern is 5 days a week from 07:00–18:00 and during these hours it is assumed that 65% of the staff are present. It can clearly be seen here that the influence of the building's individual occupancy patterns are being overlooked. However, there is growing call to normalize buildings with patterns of use and with occupancy patterns in particular . The most comprehensive approaches have called for energy to be normalized by the combination of area and total person hours per year where total person hours per year is the sum of all of the time that each building user spent in the building during the year in question. Furthermore, this intention has been included in European Standard EN15643-1 which advocates that patterns of use should be used in the sustainability assessment of buildings. At present, the legal requirements for energy efficiency are only imposed on buildings when they are being designed or renovated and at this point the energy consumption and patterns of use that are used are estimated and not measured values. There is no legal pressure to conform any post-occupancy energy consumption requirements.

It has been widely discussed that office buildings are only partially occupied during opening hours. The British Council for Offices stated as recently as 2013 that occupancy levels are typically between 60-70%. This means

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

that on average in office buildings 30-40% of the desks are empty during working hours. In addition, there is a wide variation between occupation densities from 7 m^2 of floor area per person to as much as 19 m^2 per person for private offices. According to the British Council for Offices the mean occupation density is 10.9 m^2 per occupied workspace. It is important at this point in the discussion, to note that consumption should be normalised by measured post-occupancy patterns and not the occupancy patterns used in design. Energy consumption has in the past been presented in the form of energy per person where the number of people has been defined by the number of desks in the building or number of staff that the building has been designed for. However, these design numbers are not suitable due to the low occupancy levels of buildings during their use. Also, Dooley points out that energy per person does account for occupation density but does not account for working hours per day which also influences consumption. Thus, energy normalised by the combination of area and total person hours per year is a more suitable metric than energy per person.

Patterns of use have a strong influence on the environmental impact of the existing building stock. If office buildings are on average 30-40% empty during working hours then energy is being consumed by the unused area even if it is empty. It is being heated in winter, cooled in summer, ventilated and background lit all year round. Also, the embodied carbon emissions of the materials used to construct the building are not being optimised if a large portion of the building is consistently unused. Underutilised buildings can contribute to urban sprawl as new buildings are being built on the edge of cities while many spaces that are already constructed are unused. This is similar to how AirBnB has optimized the use of homes and this has resulted in less new hotels being built. Increasing the use of our existing buildings will make the built environment more resource efficient and will reduce the need for new buildings to be built. It also makes sound financial sense to optimise space use as according to a report published in 2014 by Finnish space efficiency experts, Rapal, the average annual cost per annum of a workstation in Helsinki is €9225. The report also notes that Helsinki has only the 15th most expensive occupancy costs in the world and thus the cost per workstation is even higher in a number of other cities.

Public bodies are now beginning to see this error and are starting to increase the use of their buildings. In 2014, it was reported that spaces in government buildings in Seoul, South Korea, were being opened and offered for use by the public. At the time of that publication 970 empty spaces, such as conference rooms and auditoriums had already been used in 22,931 cases. This is part of wider plan in Seoul to promote sharing of unused resources in order to achieve a more practical and sustainable way of living. At this point it should be clarified that the aim for efficient use of space should not compromise the comfort or productivity of the building users and it has been shown by many researchers that it is possible to provide quality and productive indoor workspace environments at high occupancy densities.

The European Commission plans to reduce greenhouse gas emissions by at least 80% by 2050, compared to 1990, with the intention of keeping climate change below two degrees Celsius. In order to achieve this, the building sector must be considered. Previous research has stated that the building sector consumes approximately 39% of the total energy consumption and emits approximately 35% of the total CO_2 emissions in Europe and thus it is an important sector when aiming to reduce global greenhouse gas emissions. This article focuses on office buildings which is the largest commercial building sector in terms of floor space and energy use in most countries. The aim of the article is to uncover: can measured occupancy data assist the implementation of resource efficiency and energy efficiency strategies in existing buildings?

2. RESEARCH METHODOLOGY

In order to collect empirical data on energy consumption and usage patterns, two video cameras were installed in an office building in Helsinki, Finland. The dome video cameras were chosen as they were compatible with a commercial people counting software which is typically used in retail buildings to monitor the number of visitors over a period of time. The studied area was a portion of the third floor of a three floor office building. Its floor area was approximately 650 m^2 and it mainly comprised of a large open office area, three meeting rooms, a small kitchenette and a break area. The case study area can be seen enclosed by a red box in Figure 1 below.

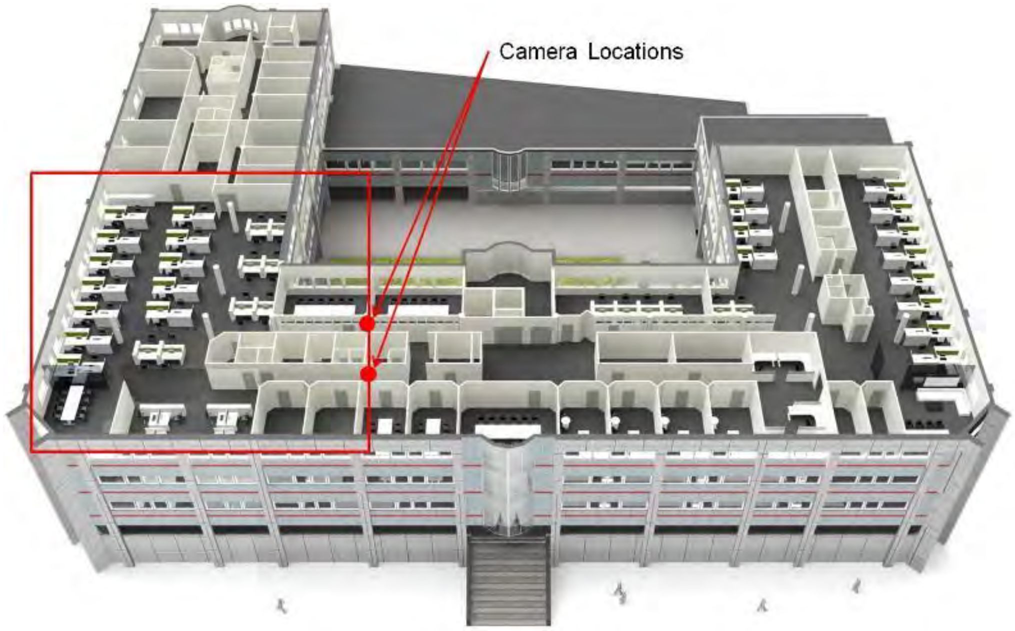

Figure 1: The camera locations and the studied area within the case study office building

This area was chosen as it was the only part of the building that had less than three entrance and exit routes and this greatly simplified the installation and the analysis of the camera data. The analysis of a whole floor could not be done as it was not possible to study people movement at the main entrance to each floor. The reason for this was that the camera software could not function correctly if the cameras were installed inside the door as at this point there was movement in two perpendicular directions (in/ out of the door and movement up/ down the adjacent corridor). In addition to this, there was a fire zone in the stair core outside the entrance to each floor which meant that this location was not suitable for camera installations. Figure 2 shows a camera installed in the ceiling of the case study building and Figure 3 shows an image from the people counting software which displays a real-time view from one of the cameras and the most recent results from that camera.

Figure 2: An installed camera in the case study building

Figure3: An image from the people counting software

The study was carried out for the whole month of May 2016. May was suitable from an energy consumption point of view as it is falls outside the hottest and coldest periods of the year. May was also suitable from an occupancy point of view as it was not affected by the Finnish summer holiday period which generally occurs from June to August. Thus the results for May should be a suitable representation of the whole year. Cameras were installed as the existing building systems were not considered adequate to count the number of building users accurately. A time card system is in place for the building users to clock in and out but it is not used by all employees and it is not used by visitors. RFID cards are used to open the doors to each floor in the building but this system could not be used to count people because of a tailgating problem. Tailgating is when where many people enter or leave the building after one person has unlocked the door with their card. The cameras were installed in the ceiling and pointed straight down so that the faces of the people passing beneath them could not be seen. This meant that privacy was less of an issue when compared to other security camera systems which are pointed directly at people as they approach. This is an important point as it has been claimed by previous researchers that privacy is the main factor that prevents vision based occupancy monitoring from being widely implemented.

The purpose of the software is to count the number of people passing in real-time and also to calculate their direction of travel. The output file of each camera reports the number of people that travel in each direction for each 15 minute interval. The data from the cameras was then combined to calculate the number of people that occupied the case study area for each for each 15 minute interval of the month in question. The case study building is open for 16 hours each day from 06:00 - 22:00 and the counting software was reset to zero at midnight every night. One simple way of detecting error within the results of the counting software was to view the occupancy after 22:00. If the software reported that there was someone still occupying the studied area after 22:00 then it had failed to correctly detect all of the people that had left the studied area during the day and if the combined count was negative after 22:00 then it had failed to correctly detect all of the people that had entered the studied area during the day.

The energy consumption of the case study area during the month of May 2016 has been calculated by using the measured energy consumption for the whole building and proportioning this by area. The building is occupied by only one company and all areas have a similar function and utilisation rate and thus this was considered the best approach in the absence of sub-metering for the case study area. In addition to this, energy simulations were made to further understand the results of the occupancy measurements. The annual energy consumption of the building was calculated in order to examine the energy consumption of the case study open office with three alternative floor areas where each floor area relates to different workplace arrangement strategy. A full dynamic energy simulation was created using the programme IES Virtual Environment.

2.3 Post-processing of data

During the study it was observed that the results continuously reported a positive number of occupants after 22:00 and thus the software was not correctly detecting all of the people that had left the studied area during the day. In order to account for this error, the footage of one full day was observed for both cameras and a manual count was carried out. The comparison of the counting software and the manual count showed that the error was relatively evenly distributed over the whole day. It was observed that the error was not caused by a counting error at the times of the day when large groups of people enter or leave the space simultaneously such as the beginning of the day, at the beginning and end of lunchtime or in the evening. Based on this, following method for error correction was developed. Time periods with higher number of simultaneous passengers are presumed to have higher probability of counting error and therefore higher correction is applied to these periods, while for periods with lower number of simultaneous passengers, lower correction is presumed respectively. This not only removes the error but it also preserves occupancy profile.

3. RESULTS AND DISCUSSION

3.1 Space utilisation of the open office area

The measured peak occupancy of the open office area is particularly interesting with regard to the size of the area and required number of desks. The peak was measured on Tuesday the 10th of May and the occupancy curve for that day may be seen below in Figure 4. The open office area does not operate on a one desk per person policy and instead a desk sharing workplace arrangement strategy has been introduced to the area. In total there are 66 employees and the number of desks is 54. The result is an average desk allocation density of 8.85 m^2. When the peak day is used to compare the measured occupancy with the design occupancy we see that the peak measured occupancy of 44 people is 18.5% lower than the number of desks and that the measured occupancy is 33% lower than the total number of staff. It was also observed that the utilisation for all 5 weekdays is similar as may be seen by Figure 5 below.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

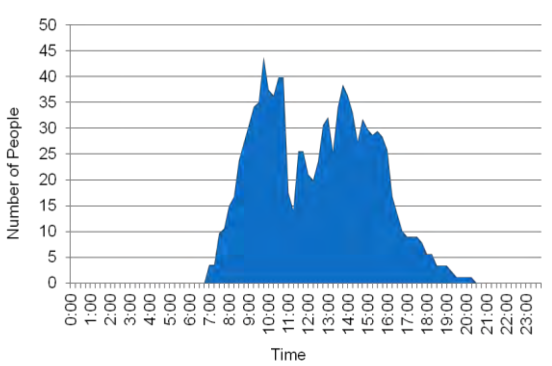

Figure 4: The peak occupancy rate of the open office area

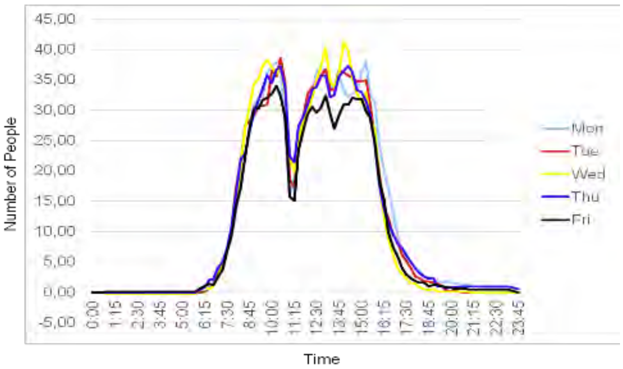

Figure 5: The average occupancy rate for each weekday of the case study area

3.2 Energy consumption for the day of peak occupancy

The collected data also enables the measured occupancy to be compared with the energy consumption of the case study building and this in turn enables the logic of the building management system (BMS) schedules and the overall control strategy of the building's energy consuming systems to be interrogated. By comparing the occupancy curve and the energy consumption curve we can see when energy was consumed and this can be compared to the level of occupancy. This is demonstrated by Figure 6 below. It is important to note that the figure below shows the percentage that each hour contributes to the total energy consumption for the peak occupancy day. The figure below also shows the percentage that each hour contributes to the total person hours for that day. For example, it can be seen that 27.4% of the energy is consumed from midnight to 07:00 and 21:00 to midnight when the area is unoccupied and 34.1% of the energy is consumed from midnight to 07:00 and 19:00 to midnight when the occupancy rate is less than 1% of the total person hours per day.

The breakdown of the energy consumption suggests that the heating consumption is relatively steady over the course of the whole day and this can be explained by a background heating demand in the night-time and a moderate load in the day-time as the internal gains from people, equipment and lighting assist the heating of the building. The electricity consumption has been subdivided into lighting, small power, ventilation and cooling and the comparison of these consumptons with the level of occupany may be seen below in Figure 7.

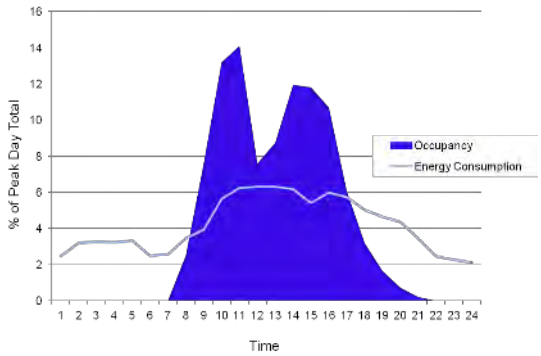

Figure 6: The proportion of total (Heating and Electricity) energy consumption and the occupancy rate for each hour of the peak occupancy day

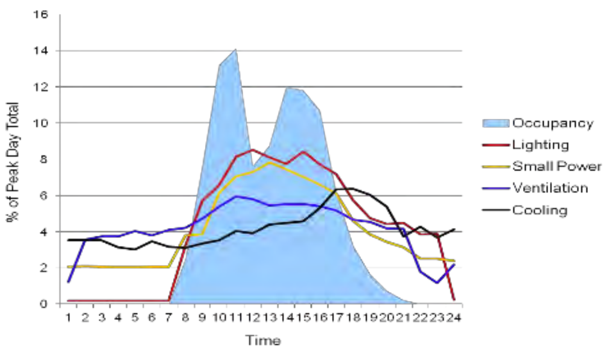

Figure 7: The proportion of the electrical energy consumption and the occupancy rate for each hour of the peak occupancy day

From the evidence provided by Figure 7 it can be deduced that the lighting control systems are suitably configured in the morning (00:00-07:00) but less so in the night-time (21:00-00:00). Also there is surprisingly high small power load, ventilation and cooling load outside of the buildings operational hours (06:00-22:00). It is typical to heat buildings at night-time but it can be expected that the electrical loads are easier to switch off outside the operational hours. Furthermore, if we apply the same comparison to the electrical consumption that was done to the energy consumption above we see that: 23.7% of the electrical energy is consumed from midnight to 07:00 and 21:00 to midnight when the area is unoccupied and 31.6% of the electrical energy is consumed from midnight to 07:00 and 19:00 to midnight when the occupancy rate is less than 1% of the total person hours per day.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.3 Energy consumption for the day of peak occupancy

The desk sharing workplace arrangement strategy of the open office area provided enough desks for 54 of the 66 staff and as a result the office space can assumed to be 18% smaller than if a desk had been provided for each employee. A dynamic energy simulation was used to compare the energy consumption implications of optimising the number of desks in office areas. In all, the energy consumption of three alternative open office areas were simulated. The first office area was 644 m^2 and represented the scenario where each member of staff was allocated a desk and the second office area was 527 m^2 and represented the studied open office area with 54 desks. The final simulation concerned an office area of 429 m^2 which represented the scenario where the number of desks matched the measured peak occupancy of the open office area which was 44 people. The energy consumption of all three areas can be seen in Table 1 below.

The results show that optimising the size of the occupied area has a substantial impact on energy consumption. The current policy of providing 54 desks for 66 people has reduced the energy consumption by 14% compared to the calculated energy consumption of the traditional one desk per person strategy. However, our calculations show that the energy consumption could be reduced by a further 16% if the number of desks were to match the measured peak occupancy.

Simulation	Number of Employees	Number of Desks		Area		Annual Energy Consumption	
#	#	#	(%)	(m^2)	(%)	(MWh)	%
1	66	66	100	644	100	85,6	100
2	66	54	82	527	82	73,2	86
3	66	44	67	429	67	59,6	70

Table 1: The energy simulation results for the open office area

4. CONCLUSION

The original objective of this study was to explore if occupancy data can assist the implementation of resource efficiency and energy efficiency strategies in existing buildings. It is acknowledged that the data is difficult to obtain, however, it was demonstrated that usage patterns are an important factor in understanding the energy consumption of a building.

It has been shown that daily occupancy curves add valuable information regarding the control strategies of the energy using systems in office buildings. The case study building is open from 06:00-22:00 and it is important to understand if the building is occupied for the whole day. It is clear that the building is very likely to be occupied from 09:00-17:00 but without occupancy data it is impossible to accurately know the occupancy rates at the beginning and end of the day. The schedules of the energy consuming systems can be optimised based on the collected data. It is common place for the energy consuming systems to have schedules but maybe the spaces could have schedules too. New workplace arrangement strategies are emerging all the time and they are being driven by the rise of remote working and new hot desking strategies such as coworking. In offices that practice desk sharing it can be assumed that all employees have laptops and can sit at any desk. With this in mind one future area of research shall be to examine the benefits of gradually shutting down the building. For example instead of having the whole building open from 06:00-22:00, two of the three floors could be shut down from 18:00 onwards as at this time the occupancy rate is less than 10% of the peak occupancy.

The peak occupancy rate of the individual building areas is also a valuable piece of information and in a building with desk sharing it can be used to calculate the minimum number of workplaces that should be available. The fact that only providing 44 desks for 66 employees reduces the energy consumption by 30% shows that the amount of area that is reserved is a key driver in the energy consumption of offices. Resource efficient workplace arrangement strategies that focus on space optimisation reduce costs associated with rent and energy and also reduce the environmental impact of buildings through energy reduction and through the reduced need for new buildings.

Another emerging strategy is to rent out unused spaces in commercial buildings to the public via sharing economy websites which essentially act as the AirBnB of commercial buildings. There are already a number of these websites such as Eventup, Splacer, Venuetastic, Venuu, and Flextila. Occupancy data can show the building managers when their spaces are empty and thus are available to be offered online.

One clear limitation of this study was that the area in which occupancy was measured was a small portion of the case study building. If the occupancy of the whole building could have been measured then the energy consumption of the studied area could have been more accurately calculated. The small case study area also contributed to the weekend occupancy being difficult to measure. It was observed that the daily energy consumption at the weekend is approximately 30% of typical weekday total and it is estimated that the peak occupancy is less than 5% but the occupancy could not be accurately calculated. Further studies are required to understand the strategies that could be employed in order to reduce the environmental impact of the weekend days as the building must be able to operate as normal but that occupancy rates are very low.

Session 6.12: Green Buildings – Occupants' Perspectives

Sculpting Socially Sustainable Neighbourhoods

Franklin YU[a]

[a] *Singular Studio Limited, Hong Kong SAR, franklinyu@singularstudio.hk*

ABSTRACT

The paper aims to illustrate, by way of examples, that through careful planning and design in the early stages of developing or renewing a neighbourhood/ building, a socially sustainable outcome can be achieved, and that the key to social sustainability is choice – choice in the activities to pursue, in the ways of attaining environmental comfort, in the modes of transportation, etc. Calling this kind of built environment "architecture of choice", the paper also points the direction in which public spaces like parks and harbourfront promenades can be developed with this "architecture of choice" theory.

Examples used in the paper include the following and other cases, wherein the hardware facilitates users to pursue a multitude of activities with the same or different groups of people in a low-carbon-footprint way and thus helps achieving social sustainability in the neighbourhood:

- In a building for interdisciplinary research, an open staircase links the ground level to the open lobbies on each and every floor as well as the social spaces at G/F, 4/F and the roof garden. Coupled with the open campus policy, the cosy common areas contribute to the community through introduction of the quality public open spaces. Apart from being used for hanging out and having lunches, the social spaces provide comfortable, naturally ventilated gathering areas. They also provide visual cues to induce people to use the open staircase instead of the lifts.
- In a district park, the facilities allow a myriad of active and passive uses, including playing football, roller blading, jogging, lying on the grass, admiring the scenery and water features, climbing a knoll along the stairs or the gentle ramps, learning about Chinese medicinal herbs and traditional exercises in the outdoor areas or indoor exhibition centre, etc. This has encouraged people of different ages having different interests to come together as a community.

Keywords: choice, sustainable neighbourhood, social sustainability

1. INTRODUCTION

Time and expertise are both our valuable resources. While it seems the more we spend time the less it remains, the more we use our expertise the deeper and better it gets. So it seems a good use of our time would be to apply our expertise in bettering the community, in making synergy out of valuable resources.

Have you ever wondered:

Why can't we bike along the Harbourfront in Hong Kong? Why are some of the parks so barren and lifeless, despite being full of plants and seats? Why do most tall buildings in Hong Kong look much alike? Why don't we see green terraces on them, not to mention covered community spaces?

2. HARBOURFRONT PROMENADE

One reason things are not what they can be is that we are bound, in one way or another, by regulations, guidelines, practices, etc. that are simply not suitable for the present time anymore. Involvement in government committees reveals that things would spring to life if we could just loosen the ties. An example: Hong Kong government's current guidelines state that a cycle track cannot be put onto an Emergency Vehicular Access (EVA). This means there is no cycle track along the harbourfront since usually there is not enough width for a separate EVA and a cycle track, and the former takes precedence. It has taken us years, but once we convince the administration departments there are no reasons why the two cannot be combined, a much more vibrant harbourfront becomes

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

possible. In time, hopefully, a lively and inclusive waterfront (see Figure 1 taken at River Garonne in the Bordeaux region in France) can appear in Tsuen Wan, Wan Chai, and other areas in Hong Kong.

Figure 1

3. DISTRICT PARK

Mixing uses can be interesting. In a district park, we have put in the same place different passive and active programmatic elements like pavilions, water features, themed landscape, walking trails, jogging paths, children play equipment, etc. and we have added a lawn with a small knoll (Figure 2). Although this cross-programming configuration was not required in the client's brief, it has enabled a more inclusive use of the park by the community — on a workday, a retired grandpa in a wheelchair brings his granddaughter to play in the park, and while keeping an eye on her, he chats with friends practicing tai chi on the lawn. We could only marvel at the impact on children the players in the nearby skate park have, were it not merely visually connected with but fully integrated into the main area! What makes a park attractive are indeed different people doing what they like harmoniously, and much more than plants and seats, programming plays an important part.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 2

4. CREMATORIUM

Examining the client's brief with respect to specific site conditions can also yield unexpected results. In re-providing a functional crematorium, taking advantage of the sloping topography, we have put the service halls on the lower level and lumped the "servant spaces" on one side, creating a garden on the roof of the service halls at the same level as the adjacent existing footpath, which is 7m above (Figure 3). Freeing up the area on top of the services halls has created a more spiritual setting, with sunlight coming down at the altar from the skylights. At the upper level, people walking on the footpath to and from columbaria can enjoy the view and can actually use the landscaped roof garden, which was not a planned facility at the onset of the project.

Figure 3

5. BUILDING FOR INTERDISCIPLINARY RESEARCH

Given the constraints of economic considerations, most building owners will choose to provide facilities and features that are not "saleable" or "rentable" only if they are not accountable for Gross Floor Area (GFA), as accepted by the government departments. This is why we rarely see in Hong Kong interesting sun-shading devices, double-skin facades, sky gardens, deep overhangs, large voids, slanting walls, etc. — facilities and features that can make a building charming and sustainable both socially and environmentally. In a building for interdisciplinary research, we designed an open staircase linking the ground level to the open lobbies on each and every floor as well as the "social spaces" at G/F (double volume), 4/F (triple volume) and the roof garden (see Figure 4). While not required in the client's brief, coupled with the open campus policy of the institution, the cosy common areas, the roof garden, and the external planters continuous from G/F to the roof have contributed to the community through introduction of quality public spaces. The common areas also serve as semi-open dining areas in the lunch hours, and tables and chairs are put there for people to hang out. The open staircase stands as a symbol inviting the community to go up the building and use it. But all of these are possible only because the client agrees to such a vision and allocate GFA accordingly. In the meanwhile, architects are still working hard to let the government departments understand why the benefits of the above facilities and features far outweigh the potential shortcomings of abuse and why they are worth promoting, much like what has been done in other countries.

Figure 87

6. CONCLUSION

Apart from fulfilling the client's explicit brief, an architect's mission would include providing people with choice—choice in where to go to in a place and how, what to do there, and how to enjoy and use the place (maybe this would not apply to a prison). This architecture of choice is essential, as illustrated above, in creating socially sustainable neighbourhoods. And so in designing places to be more inclusive, in providing auxiliary community facilities without much additional cost, and in extending common and public areas into the community, we may find another layer of meaning to our work. As more clients embrace environmental and social sustainability, we can be optimistic for what lies in the future.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

It is unnecessary to confine using our expertise only in work and straitjacket its usage. On the contrary, good things usually happen when we employ our expertise beyond prescription and extend it into the community.

Thermal Comfort Based Occupancy-driven Building Energy Saving Control Strategies

ZHANG Cheng[a], Mehdi PAZHOOHESH[b]

[a] *Xi'an Jiaotong-Liverpool University, Mainland China, cheng.zhang@xjtlu.edu.cn*

ABSTRACT

Current air conditioning systems often rely on maximum occupancy assumptions and fixed schedules to maintain sufficient comfort level. Having knowledge regarding occupancy situation may lead to significant energy-savings in a building. Therefore, the present research proposes a method to investigate an occupancy-driven HVAC control system based on thermal comfort analysis. Computational Fluid Dynamics (CFD) is used to evaluate thermal comfort through modeling the indoor air distribution and flows. Wind velocity and temperature are simulated in several scenarios and the Predicted Mean Vote (PMV) and the Predicted Percentage Dissatisfied (PPD) are computed. The simulation results are verified through a survey asking for occupants' real feelings and consequently thermal comfort profiles are identified, which are used for possible energy saving. Moreover, a pre-defined working schedule and historical behavior of persons are utilized to develop a pattern for predicting personal occupancy situations. Finally, all variables are imported to an intelligent system to fulfil an intelligent control of air conditioning system. The result shows a good potential to reduce energy consumption while meeting comfort requirements of occupants.

Keywords: thermal comfort, occupancy-driven, HVAC (heating, ventilating, and air conditioning)

1. INTRODUCTION

Increasingly expensive and polluting sources of energy dictate the need of energy conservation in the society. Building sector is responsible for high portion of energy consumption throughout the world (Lajoie et al., 2015; Magdalena et al., 2013). According to the European Union report, 40% of the total energy was consumed in the building sector, while HVAC systems contribute to a significant energy usage in buildings (Lajoie et al., 2015). Therefore, well-designed building ventilation systems can greatly reduce the energy consumption. Meanwhile, about 90% life of an average individual is spent in the indoor environment. A good indoor environment is essential for good productivity, less vacancy, and better health. Thermal comfort is an important factor that is considered to evaluate the indoor environment quality. The assessment of thermal comfort in offices showed that good thermal comfort level delivered more satisfaction for the occupants, and also improved their performance. American Society of Heating, Refrigeration and Air-Conditioning Engineers (ASHRAE) defines Thermal Comfort as the condition of mind which expresses satisfaction with the thermal environment. Well-designed building ventilation systems not only lead to reduction of energy consumption, but also should provide satisfaction for building occupants. However, due to unpredictable locations of the occupants during design stage, the fixed locations of ventilation systems, outlets, doors, and windows give little options to the occupants during operation stage. Therefore, more focus should be put on methods that can maintain the comfort level to occupants with minimum energy usage.

2. LITERATURE REVIEW

A lot of research has focused on energy saving based on occupants' locations. Marshall et al. (2016) investigated different occupancy patterns and calculated energy saving based on these patterns in residential buildings. Klein et al. (2012) introduced a multi-agent based system which also considers the location of users by using RFID tags. However, the above mentioned research did not evaluate the thermal comfort level of occupants which is the main goal of energy usage in a building. The 'feeling comfortable' was very personally and cannot be characterized objectively due to the differences of physiological and psychological for individuals. According to Fanger (1970), there are six major parameters that are needed to be considered to achieve a satisfied thermal level which are, dry bulb temperature, water vapour pressure, air velocity, radiant temperature, metabolic rate, and clothing. These factors are determined by analyzing the whole body satisfaction and local discomfort. Simulation based on relevant parameters is used to analyze and improve thermal comfort. Computational Fluid Dynamics (CFD) is known as the most reliable method for simulation and evaluation in industry sectors, especially for indoor environment. But

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

the accuracy of its predictions is a main challenge as the simulation is based on the highest capacity of thermal loads in each environment and we have some other variables such as occupied areas during a working day. Lajoie et al. (2015) utilized CFD to provide accurate description for the indoor air quality, where three parameters, i.e. wind velocity, indoor temperature and air age, were considered to simulate wall-hanging air conditioning systems. Chiang et al. (2012) evaluated the impact of radiant cooling ceiling and mechanical ventilation systems on the thermal comfort using CFD modeling. Magdalena et al., (2013) discussed the calibrated CFD model in a highly-glazed meeting room with natural ventilation.

Based on the literature review, it is found that an intelligent control is lack of investigation to meet energy saving purpose while providing satisfactory thermal comfort to occupants. Therefore, the present research proposes an assessment of thermal comfort based on the locations of HVAC system and the occupant's location information collected in real time. By establishing CFD models, wind velocity and temperature are simulated in a room to obtain the Predicted Mean Vote (PMV) and the Predicted Percentage Dissatisfied (PPD). A flowchart of intelligent control of the HVAC system is developed based on the comfort areas, occupants' working patterns, etc. to investigate possible energy saving. The integration of occupant's location-based system and thermal comfort assessment provides a deeper view of intelligent energy management systems not only based on energy saving but also considering the comfort level of occupants.

3. METHODOLOGY

The proposed methodology of this research is divided into two parts as shown in Figure 1. The purpose of the first part is to identify thermal zones from the building plan based on thermal comfort models. The geometry data of the area were retrieved from a building information model (BIM). Temperature sensors and location sensors are used to collect environmental temperature and the occupancy situation of persons. All the data are imported to the CFD model and simulation is done to analyze the comfort level at different zones. As the simulation is a time consuming process, it is not possible to model thermal comfort in real time. Therefore, based on the HVAC performances and modeling results, scenarios and corresponding control have been developed. To improve the accuracy of simulation-based thermal zones analysis, a survey has been done to investigate the individual's real feelings and how they match the simulation results, so that the boundaries of thermal zones can be identified.

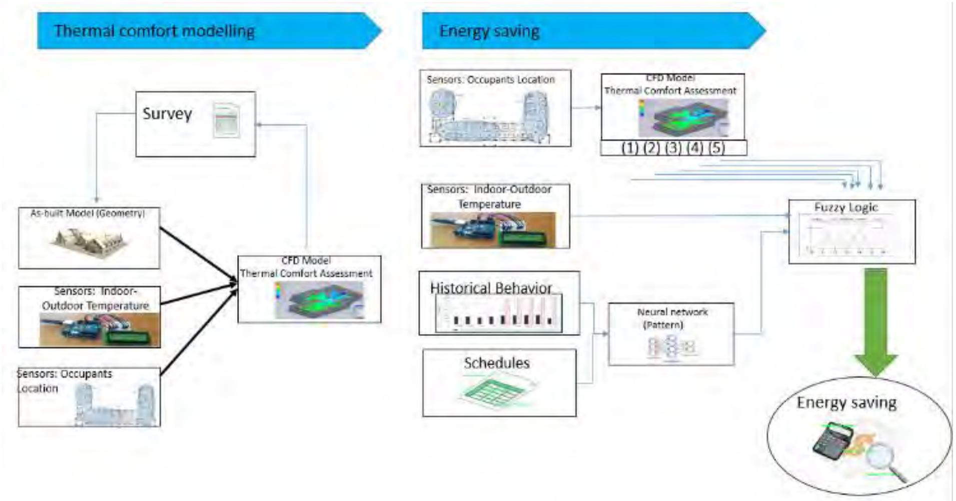

Figure 1: Proposed methodology

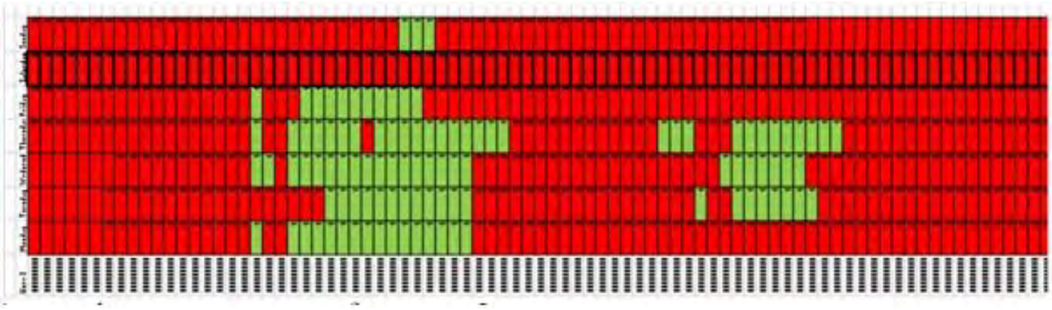
For the second part, four variables are considered to develop the occupancy-driven control strategies, which are: (i) the real-time locations of persons are monitored by using an indoor tracking system based on Zigbee technology. Further details of this localization system can be found in the authors' previous research; (ii) five types of individual situations are considered based on the location of the occupants and the duration of their activities: wandering, working in office, short-term leaving (e.g. coffee room), long-term leaving (e.g. meeting room, class room), and leaving the building. Based on these situations, the system distinguishes whether the occupant leaves the office for a short or long time, and consequently controls the operation of HVAC systems; (iii) indoor and outdoor temperatures are used to control HVAC systems and maintain comfort temperature; and (iv) historical behavior of persons and schedules of working time are also considered. A behavior pattern of individuals is created based on historical data and is combined with schedules of working hours. A neural network pattern is developed to predict individuals' working time and the duration of presence time in the office. Finally, a fuzzy-based system is developed to integrate all variables and control the HVAC systems in a way that meets both energy efficiency and thermal comfort requirements.

4. INTELLEGENT CONTROL

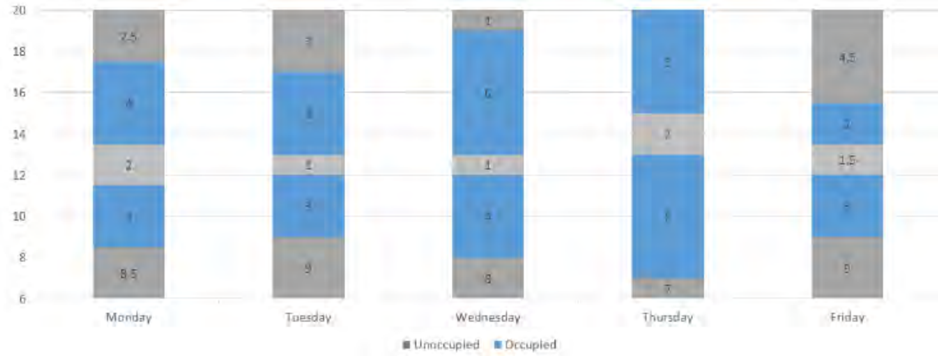
The present paper is to propose an intelligent control of HVAC system based on occupants' locations, behaviors and thermal comfort to improve the energy efficiency; therefore, the awareness of locations of occupants is essential, which is facilitated by a Real-time Location System using ZigBee nodes installed inside the office rooms. The decision of which HVAC system should be turned on/off is taken by the main server at the Facility Management office that is connected with a ZigBee receiver. The details of this system are beyond the scope of this paper therefore not presented here. Based on the thermal zones identified, simple control can be applied to turn on/off corresponding HVAC outlets according to the presence of persons in those thermal zones. Real-time data are collected for persons' presence in the room and combined with their historical behavior to predict the time period of their presence/absence for more intelligent control and energy saving.

Historical behavioral data of occupants

Figure 2 illustrates the occupancy data of office with nine persons. Figure 2(a) represents the occupancy behaviour of one user for one week from 6 AM to 8 PM.



(a) One week occupancy data for one person



(b) One month occupancy patterns of individuals
Figure 2: Occupancy data

The red colour shows the absent periods while green colour shows presence periods. Data collected for one month provide historical data for behavioural patterns development (Figure 2(b)). The pattern of historical behavior of persons is combined with the persons' real-time location and corresponding thermal zones to enable the intelligent fuzzy-based HVAC control. Five types of individual situations are introduced: wandering, working in office, short-term leaving, long-term leaving, and leaving the building. These conditions are considered for the intelligent system to predict the period of time when each person leaves the office. More than 180 rules are developed to utilize the fuzzy decision making.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Intelligent control

Figure 3 illustrates the process of controlling HVAC system based on the person's occupancy situation. Any exit/entrance from/to the room will be monitored. When one person enters into the room or leaves the room, the information of person and related thermal zone are identified. Afterwards, the corresponding behavioral pattern and schedules are considered to predict the duration of this changes.

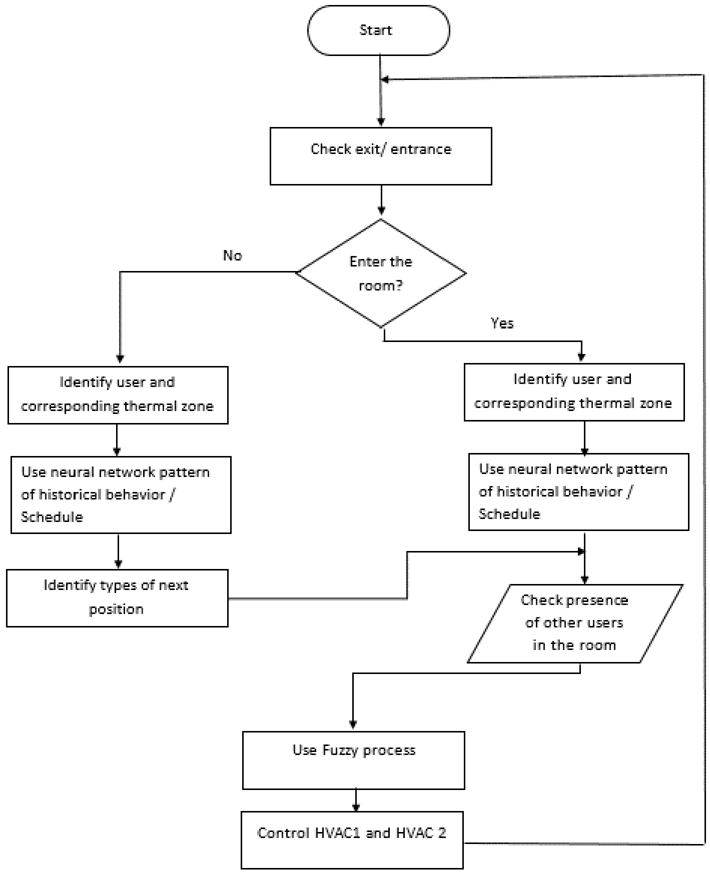


Figure 3: Flowchart of intelligent control

By considering the other persons in the thermal zone and the current situation of HVAC outlets, decisions are made to control the corresponding HVAC outlets. Figure 4 illustrates the HVAC performance during one day. The green and black lines represent the base-line and blue and red lines show the implemented intelligent control result. It is obvious that some times during the day, the controller decided to turn off HVACs based on the introduced rules. For instance, during 12:00 PM to 14:00 PM while all occupants left the room, HVAC 1 was kept on by users which resulted in wasting energy for two hours. However, intelligent controller decided to turn off all HVACs based on data extracted from the real-time and historical information.

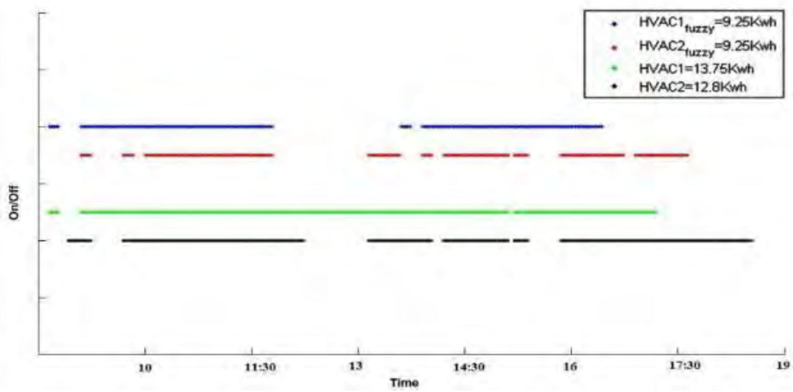

Figure 4: Energy consumption for base-line and occupancy-driven HVAC outlets

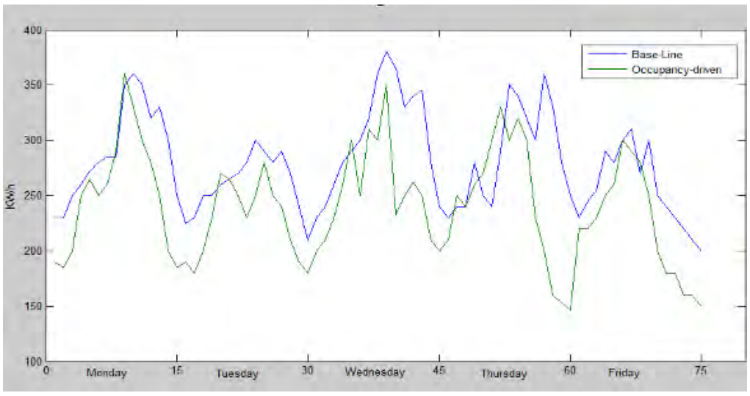

Figure 5: Energy consumption for base-line and occupancy-driven HVAC outlets

Figure 5 illustrates the base-line energy consumption and the energy consumed when applying the occupancy-driven intelligent controlled HVAC system for the test bed office during one week. This graph demonstrates that less energy is consumed by the occupancy-driven system.

5. CONCLUSIONS AND FUTURE WORK

This paper proposes intelligent control strategies by developing a CFD model for the air distribution and flow, calculating the PMV and PPD values, and identifying areas with the higher potential of discomfort and comfort level. Surveys are carried out to investigate the real feelings of the occupants under different situation to verify the simulation results. The test bed area is divided into several thermal zones and corresponding control strategies are developed for intelligent control purpose. Moreover, from historical behavior of persons and their timetables, behavioral patterns are created to predict persons' occupancy situation in the room. The real-time locations of the persons are combined with their historical behavior data so that the persons' occupancy situation in the room can be predicted. The system then evaluates all the variables and controls the situation of corresponding HVAC outlets. The results show the potential of occupancy-driven central air conditioner to undertake indoor heat load and provide suitable thermal comfort. Our future work can be focusing on utilizing different sensors to investigate the passive control of HVAC outlets and providing higher comfort level for persons and saving more energy simultaneously.

The Effect of Occupant Behaviour on Real-time Electricity Consumption in Canadian School Spaces

Mohamed OUF[a], Mohamed H. ISSA[b]

[a] *University of Manitoba, Canada, oufm@myumanitoba.ca*
[b] *University of Manitoba, Canada, mohamed.issa@umanitoba.ca*

ABSTRACT

Studies on sustainable and green buildings reveal mixed results regarding their energy performance. While many of these buildings demonstrate significant savings in gas consumption, previous studies indicated their electricity consumption is increasing in comparison with older buildings. These results highlight the importance of investigating parameters influencing buildings' electricity consumption in order to close the performance gap in new and sustainable buildings. The majority of previous studies focused on commercial or residential buildings emphasizing the need to investigate energy consumption in other building types. Therefore, this study analyzed historical energy consumption in a sample of thirty schools in Manitoba. It indicated the decrease in gas consumption for heating in new schools was counteracted by a statistically significant increase in their electricity consumption. Three cases study schools were then selected for further analysis of electricity consumption. Within each school, one classroom and the gymnasium, as well as spaces with significant community use, were sub-metered to collect real-time electricity consumption data. Occupant behaviour was also monitored simultaneously in these spaces to demonstrate its effect on electricity consumption. Results indicated total electricity consumption increased in the newest school, although sub-metered spaces in older schools showed higher electricity consumption. The study also indicated occupant behaviour influenced variations in electricity consumption between sub-metered classrooms. It is the first to provide in-depth investigations of electricity consumption in Canadian school buildings to identify reasons behind their increased electricity consumption.

Keywords: energy efficiency, school buildings, energy management, sustainability, occupancy and energy performance

1. INTRODUCTION

The building industry accounts for 20-40% of energy use worldwide, representing an excellent opportunity to achieve large-scale energy reductions. Advances in sustainable and green building technologies can help decrease their energy use by improving building envelopes and mechanical systems making them 25-30% more energy efficient on average than conventional ones. However, some studies indicated these buildings use more electricity than conventional ones e.g. [3], [4] which may be attributed to occupants' behaviour. Therefore, closing the gap between actual and expected buildings' energy performance necessitates considering all parameters influencing buildings' energy consumption, including those related to occupancy and usage. Previous studies focused on analyzing energy consumption in commercial or residential buildings, highlighting the need to analyze energy consumption in other building types. School buildings represent an excellent opportunity towards increasing overall energy efficiency as they contribute to a considerable part of overall buildings' energy consumption due to their large number within the building stock. These buildings "can also be used as communication means towards pupils and their families, thus educating many different society groups about sustainability in the built environment".

In order to evaluate energy performance in Manitoba's schools, this study entailed analyzing historical energy consumption in a randomly selected sample of thirty schools over 9 years. The analysis revealed newer schools used more electricity than older ones while using less gas annually, reinforcing the need to investigate their electricity consumption in more detail. Therefore, three case study schools in Manitoba, Canada were selected for analyzing their real-time electricity consumption over a period of 4 months. One of these schools was a new Leadership in Energy and Environmental Design (LEED) certified school built in 2009, a middle aged school built in 1968 and an old school building, built in 1951. The analysis entailed studying real-time electricity consumption in school spaces as well as occupant behaviour using several techniques. Specific objectives of this study involved 1) demonstrating the effect of school building age on their energy performance while controlling for school occupancy and floor area 2) demonstrating differences in electricity consumption between the three case-study schools at the building and space levels 3) demonstrating differences in occupant behaviour related to energy consumption in the three case-study schools.

This study is the first to investigate real-time electricity consumption in Canadian school buildings. The analysis of real-time electricity consumption revealed large variations in electricity consumption between these schools which could be attributed to occupants' behaviour. The study results are, therefore, relevant to school divisions, superintendents and operators looking to decrease schools' energy consumption by targeting specific occupant activities which contribute to wasteful energy consumption. Since existing buildings represent the vast majority of the current building stock, decreasing occupant-related electricity consumption presents a great opportunity for decreasing the building stock's overall energy consumption.

2. BACKGROUND

Several studies found large discrepancies in energy consumption between similar buildings, speculating about the contribution of building occupants to these differences e.g. [9], [10]. Many of these studies showed green buildings may not perform as intended with respect to energy efficiency e.g. [1], [11], [12]. In many instances, actual energy use exceeded design estimates from energy models raising concerns about their accuracy especially when predicting occupants' behaviour. However, relatively few studies investigated the effect of occupants' behaviour on energy consumption and mostly focused on commercial buildings. The majority of these studies monitored real-time energy consumption to estimate occupant behaviour, with even fewer studies directly monitoring occupant behaviour. In these studies, analysis mostly focused on behaviour related to heating, ventilation and air-conditioning (HVAC) energy consumption as opposed to other end-uses.

Studies that measured actual real-time energy consumption entailed sub-metering specific building spaces, mostly with no further breakdown of end uses. For example, sub-metered floors within six commercial buildings and found 56% of their energy was consumed during non-business hours without specifying end-uses contributing to this finding. Similarly, [14] found 23% of the energy consumed by workstations in two office buildings occurred during non-business hours. After providing individual and group feedback to office employees regarding energy consumption, the study indicated power density in individual workspaces could decrease by 7-11% when occupants were informed about their energy consumption. [15] also showed that providing individual and group feedback to building occupants regarding their energy consumption improved buildings' energy-efficiency. Despite their strengths, these studies did not investigate specific end-uses with the highest effect on buildings' energy consumption and consequently their energy-efficiency.

For studies which investigated the effect of occupancy on buildings' energy consumption, they mostly estimated this effect using statistical methods. [16] Investigated energy consumption in a sample of 80 residential buildings over two years by grouping similar buildings into clusters using seven parameters not related to occupant behaviour. Using cluster analysis and grey-relational techniques, the study found significant variations in energy consumption among similar buildings and attributed these variations to occupant behaviour. Other studies used energy modelling tools to determine the effect of occupancy on energy consumption. By modifying occupancy input parameters in energy models, [17] concluded that occupancy could change annual energy consumption by 69 to 177% depending on building type and climate region. [18] found the relative standard deviation due to modelling extreme occupant actions can amount to 47%. Despite the value of these studies, most of them focused on how occupants affected HVAC energy consumption through occupant actions such as the use of blinds, window operations or clothing adjustments. However, these studies did not investigate the effect of occupants on real-time electricity consumption.

3. METHOD

This study entailed collecting data regarding schools' floor areas, dates of construction, number of students and teachers, as well as grade levels from 126 schools in four school divisions in Manitoba. The information was used to randomly select, using stratified random sampling and Neyman proportional allocation technique, a representative sample of thirty schools to be analyzed at a 90% confidence level. This is to create three groups of schools, with thirteen schools representing old schools built on or before 1959, thirteen middle-aged schools built between 1960 and 1989, and four new schools built on or after 1990 including one LEED-certified school. The cut-off dates used for these schools were based on the dates used by the United States Commercial Buildings Energy

Consumption Survey (CBECS 2003) for reporting energy consumption in buildings by year constructed. The study involved collecting and analyzing historical monthly gas and electricity consumption quantities and billing costs for these schools for the period between 2004 and 2013 to evaluate the effect of building age on energy consumption.

One school was then selected from each age category for analysis of total building electricity consumption, as well as space-level lighting and plug load consumption. Simultaneously, several tools were used to study occupant behaviour in spaces where electricity consumption was monitored. These tools included 1) sensors for logging half-hourly durations of light use and occupancy status in classrooms 2) observations of equipment and light use in school spaces 3) daily surveys completed by teachers documenting daily equipment use in classrooms. The monitored spaces were a south-facing classroom between grades 4 to 7, the gymnasium and one space typically used outside regular work hours in each school. Sub-meters were installed to monitor all lighting and plug loads circuits for the selected spaces in order to measure electricity consumption at half-hour intervals for the period between January and June 2015. Total building half-hourly electricity consumption was also obtained by downloading data from advanced utility meters in each school. Figure 1 shows a summary for the data collected for this study.

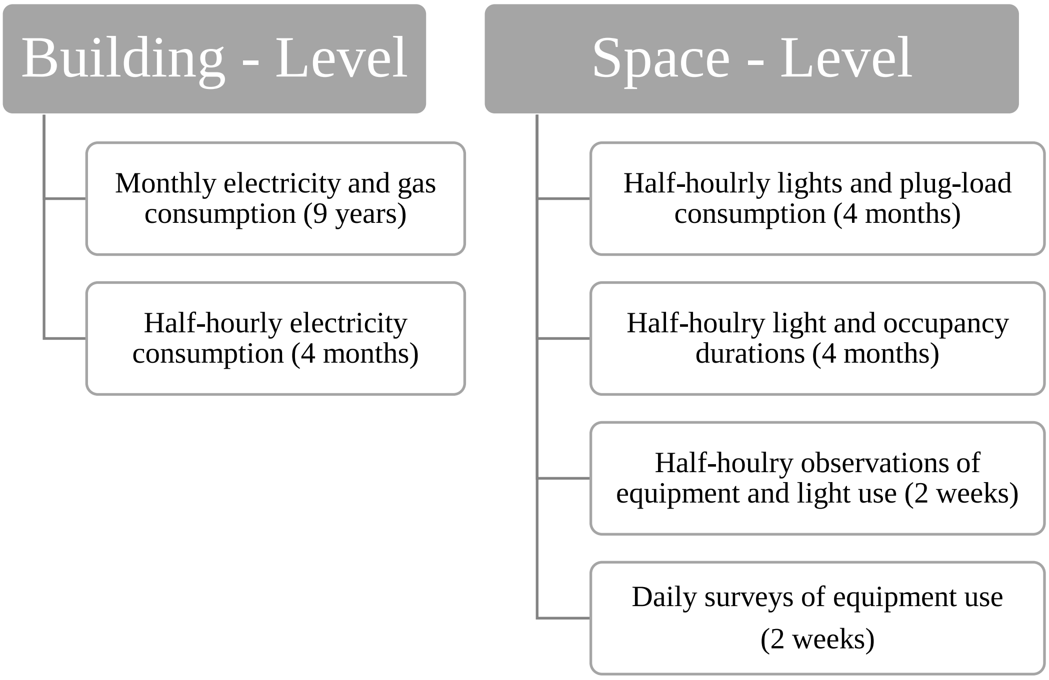

Figure 1: Summary of data collection methods.

Data analysis involved normalizing energy consumption by floor areas at the building and space-levels. Analysis of Covariance (ANCOVA) was used to investigate differences in annual electricity, gas and total energy consumption between the three age categories, after controlling for floor area and the number of occupants. For statistically significant differences, post hoc least significant difference (LSD) tests were used to assess the difference in means between every two age groups. Half-hourly electricity consumption data was used to calculate and compare the average daily electricity consumption for the entire schools, as well as classrooms between old, middle aged and new schools. Non-parametric tests were used to compare half-hourly electricity consumption between the three schools as this data did not follow normal distribution on a frequency plot.

Results presented in this paper focused on 1) analyzing the differences between the three school-age groups regarding their monthly electricity and gas consumption. 2) analyzing the differences in total building half-hourly electricity consumption between the three case-study schools 3) analyzing the differences in half-hourly electricity consumption for classrooms lighting between three case-study schools 4) analyzing the differences in light use durations between the three classrooms.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4. RESULTS

4.1 Historical energy consumption in Manitoba's schools

Figure 2 shows the average annual electricity consumption increased from old (n = 13, 56.57 ± 19.8 KWh/m²/year), to middle aged (MA) (n = 13, 116.26 ± 48.7 KWh/m²/year), to new (n = 4, 126.27 ± 29 KWh/m²/year) school buildings. However, the average annual gas consumption followed the opposite trend where it decreased from old (n = 12, 20.59 ± 9.8 m³/m²), to middle aged (n = 12, 16.58 ± 7 m³/m²), to new (n = 3, 12.66 ± 3.5 m³/m²) school buildings, in that order. These results were in-line with previous studies which also showed new buildings used more electricity than older ones while using less gas annually e.g. [3], [4]. ANCOVA test results showed a statistically significant difference in electricity consumption quantities ($F(2, 25) = 5.22$, $p < .05$), but not in gas consumption quantities ($F(2, 25) = 100.53$, $p = 0.264$) between the three building age groups. Post-hoc LSD tests showed a statistically significant differences in electricity consumption quantities only between old schools and new schools, and between old schools and middle-aged ones, prompting further analysis of real-time electricity consumption.

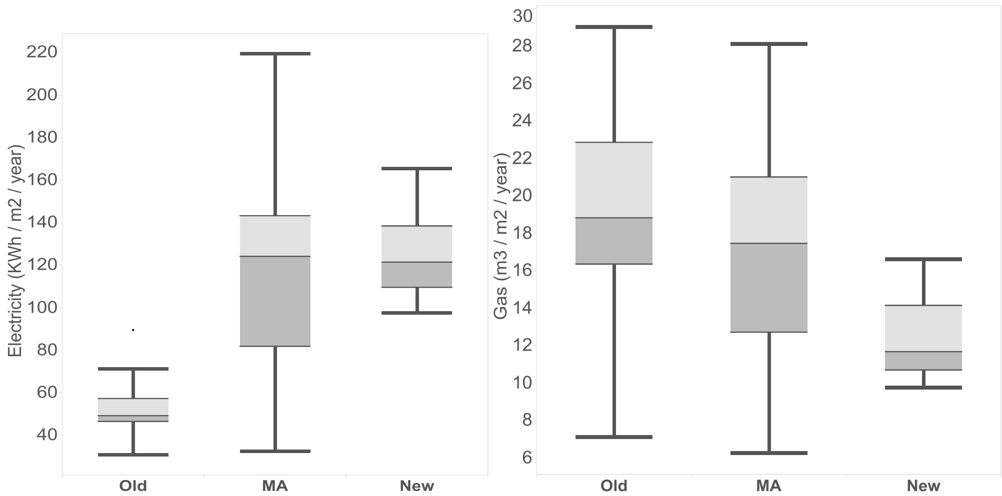

Figure 2: Annual electricity and gas consumption in Manitoba schools.

4.2 Electricity consumption in case-study schools

The analysis of the real-time building electricity consumption in the three case-study schools was in line with findings from the randomly selected school groups as shown in Figure 3. The new school used on average 48% more electricity on a daily basis (0.54 ± 0.24 KWh/m²/day) than the middle aged school (0.31 ± 0.12 KWh/m²/day) which used on average 82% more electricity on a daily basis than the old school (0.17 ± 0.03 KWh/m²/day). The non-parametric Kruskal-Wallis H test showed statistically significant differences in total half-hourly electricity consumption between the three schools ($X2(3) = 279.089$, $p < .005$).

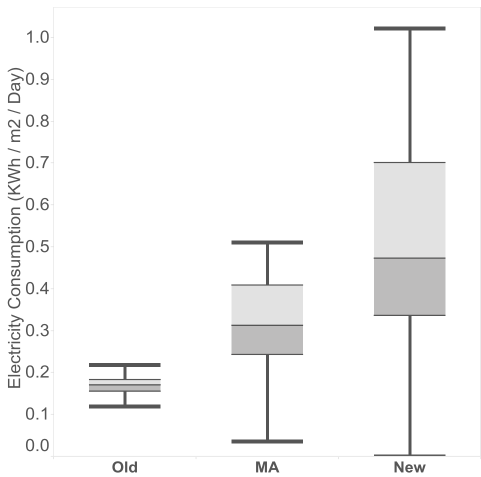

Figure 3: Daily electricity consumption in the three case-study schools.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4.3 Electricity consumption in case-study classrooms

Classrooms' electricity consumption in the three case-study schools did not follow the same trend as their total building electricity consumption. Daily plug load and lighting electricity consumption was highest in the old school's classroom (18.15 ± 12.04 Wh/m²/day, and 32.1 ± 31.02 Wh/m²/day respectively), and lowest in the middle-age school (3.82 ± 4.33 Wh/m²/day and 7.68 ± 10.18 Wh/m2/day respectively) as shown in Figure 4. The new school's classroom, on the other hand, consumed on average 8.88 ± 4.45 Wh/m²/day for plug loads and 11.71 ± 12.23 Wh/m²/day for lighting.

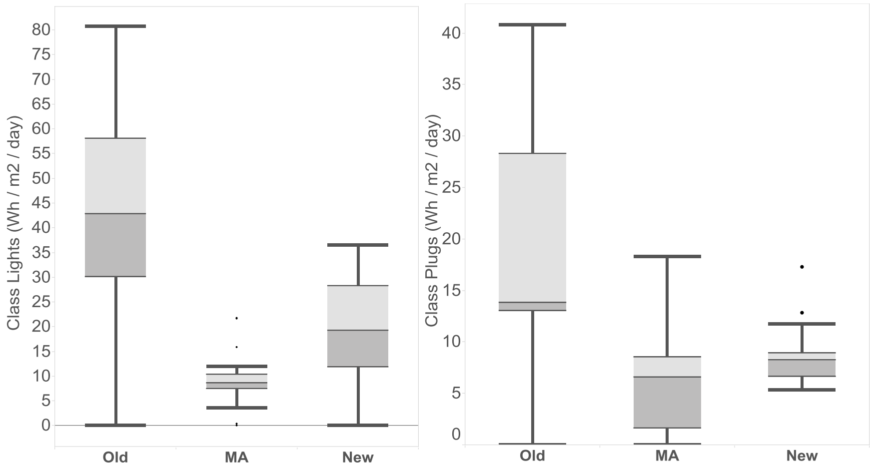

Figure 4: Average daily electricity consumption for classroom lights and plug loads.

4.4 Light sensors data in case-study classrooms

Although sub-meters data indicated the old school classroom was the highest consumer of electricity for lights per unit area, data from the installed light sensors revealed a different story. The average daily duration for which lights were switched on was lowest in the old school classroom (253 ± 163 minutes/day) which increased to 328 ± 212 minutes/day in the new school classroom, and 417 ± 322 minutes/day in the middle aged classroom. Data from light sensors was verified by plotting average half-hourly electricity consumption for lighting in classrooms as shown in Figure 5. These plots indicated lights were typically switched on until 10:30 PM in the middle aged classroom unlike other schools where they were switched on only until around 4:30 PM. School visits also confirmed teachers in the middle-aged school left the lights on for custodial staff, who typically tuned them off at the end of their night shifts highlighting energy saving potential by adjusting occupant behaviour. These results indicated while occupant behaviour may influence light use durations, the type of fixtures and light density within classrooms may have been the ultimate drivers for classrooms' lighting electricity consumption. The results indicate installing energy-efficient lighting systems would result in significant savings in the older schools' electricity consumption for lighting which was at least double the consumption in newer schools.

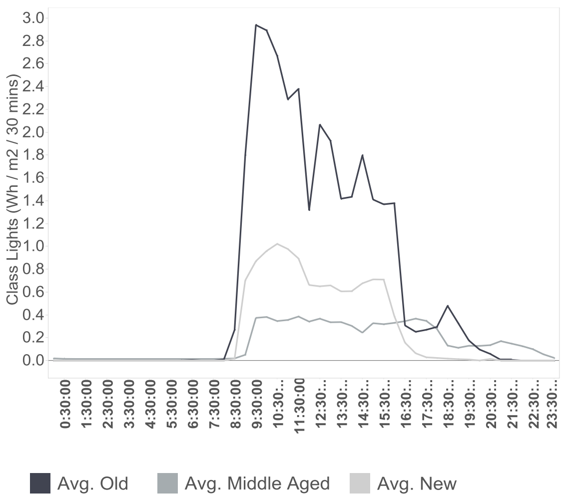

Figure 5: Average half-hourly electricity consumption for classroom lights.

5. CONCLUSION

Results from this study highlighted the increase in electricity consumption in new school buildings in Manitoba although their classrooms' electricity consumption was lower than older schools. Findings of the study indicated occupancy may have played a role in classroom's electricity consumption for lighting. However, fixture types and installed lighting power density may have been the ultimate drivers behind increased electricity consumption for lights in older classrooms. Nevertheless, the study results shed the light on potential opportunities for increasing energy efficiency through occupancy interventions, such as ensuring lights were only used during regular school hours. The discrepancy between total and classroom-level electricity consumption trends indicated other areas of electricity consumption in schools should be investigated. With increased automation and mechanization in new schools, these technologies may have contributed to increased electricity consumption in new schools. For example, electrically controlled blind were installed for all windows in the new school unlike the two older schools.

This study analyzed space-level electricity consumption in only three out of the randomly selected thirty schools in Manitoba due to resource limitations. Therefore, results could not be generalized to the larger population of Manitoba schools. Future studies should focus on investigating electricity consumption in a larger sample of schools and standardizing sub-metering methods to avoid errors in measuring real-time electricity consumption. Increasing the study period to demonstrate seasonal variations in electricity consumption can also help increase understanding of real-time electricity consumption in schools. The shift towards more stringent energy codes for greener, more energy-efficient buildings underscores the need to address new parameters influencing electricity consumption which is increasing in new buildings.

Deep Green Approach to Create Sustainable Built Environment and Neighbourhoods, Case study of Lumpini Place Rama 4- Ratchada Project

Panita VARA-URAIRAT[a]

[a] *Wisdom Consulting and Solution Co., Ltd., Thailand, panita@wisdomcs.co.th, panita.vara@gmail.com*

ABSTRACT

Lumpini Place Rama 4-Ratchada is a low income condominium project owned by L.P.N. Development Public Co., Ltd. located in "Phaisingto district", a low development area with canal side settlement. This area is now facing overcrowding problem and thus results in poverty, polluted water bodies and quality of life degradation which has direct effects on the project. Moreover, community protest against building construction is another major problem. After these conditions evaluation, it was found that light green solutions which applied only inside the project can no more create sustainable built environments. The new goal is how the project can contribute to neighbourhood transformation. As such, a 'deep green' approach taken on a wholly dimension of sustainability; environmental, economic and social aspects, has been incorporated to advocate change at the community level.

Environmental approaches are, for example, 'green construction site program', L.P.N.'s own innovation to mitigate negative impacts from construction activities, passive design strategies such as creating green walls and open spaces to enhance biodiversity, increase storm water infiltration, and improve the microclimate of the area. Also, one part of the site will be dedicated to a community exercising park for social benefits.

As for economic impact, since major community source of revenue is from small retail business, L.P.N. has provided rental retail spaces in the building and launched a cooperative store network program to strengthen community economy.

Social aspect was taken by creating better understanding among local people and condominium's occupants, promoting the project benefits on the community, social activities supporting by the project owner such as trade waste-recycling, walkway and water body cleaning etc. Above all, public relation to stimulate local awareness is a key driver. As long as people have mutual environmental concerns, sustainable built environments can be continually maintained to create a green community and neighbourhoods.

Keywords: deep green approach, neighborhood transformation, green community

1. INTRODUCTION

1.1 'Deep Green' approach; A new dimension of green to provide sustainability in all facets

In the last decade, green building industry expansion in Thailand has appeared to be an accelerating effect which reflected in a rising number of projects applying for green building rating system. This increased interest in green building trend led to a new movement in real estate sector. As such, most developers have started to incorporate green design strategies into their projects in order to create product added values and strengthen their market positions. These green building strategies mostly focus on energy efficiency because tangible and measurable benefits are clearly seen for example, utility savings, operational cost reduction, increases in sale premiums and rental rates. Apart from these, green features such as roof gardens, green walls or solar panels are usually included as fancy items in buildings to promote the projects as 'eco-friendly'. However, key objectives of green building in enhancing quality of life and reducing cost of living may not be achieved only through those features.

The approach that emphasizes only building performance improvement rather than undertaking holistic solution to create sustainable environments was defined by some environmentalists as 'Light Green'. Light green environmentalism believes in green technologies and strongly advocates change at the individual level. This, sometimes, is criticized to be a 'shallow green' since it somehow views architecture as stand-alone objects having no connection to other facets of human life. In this way, wider prospects and impacts to the environment may be overlooked particularly in the larger scale like neighborhood development. Thus, the new shade of green has been addressed as 'Deep green' approach to solve more complex problems such as social issues.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

In contrast with light green, deep green approach values the concept of the triple bottom line or 3p; people, profits, and planets. It pays respect to the interrelation between building and its surroundings in all dimensions and promotes changes at the community level. This approach can be demonstrated in the case study of Lumpini Place Rama 4-Ratchada in which deeper dimension of green strategies is considered as the best answer for the project.

2. A CASE STUDY OF LUMPINI PLACE RAMA 4- RATCHADA

2.1 Problematic issues in Lumpini Place Rama 4-Ratchada project

Lumpini Place Rama 4-Ratchada is located in 'Phaisingto' alley near 'Klong Toey', a low development area with canal side settlement. The project is a low-rise condominium in the land owned by the 'Crown Property Bureau' (CPB), the quasi-government agency responsible for managing the property of the crown of the Kingdom of Thailand. The CPB has mission to be responsible for protecting and managing the royal assets and property as well as supporting other activities for the benefit of Thai subjects and society. It also aims to build sustainable environments for low-income people, and thus had chosen Phaisingto alley in Klong Toey district as a new development project.

Phaisingto alley is located in a prime location in the city center of Bangkok, only 80 m. from underground train station (MRT), and one stop from Asoke interchange station. Plus, Queen Sirikit National convention center is on the opposite site of the project as shown in Figure 1.

Figure 1: Lumpini Place Rama 4-Ratchada location in the city center

Nonetheless, the area has several poor conditions from its surrounding contexts. As Phaisingto district has a small slum called 'Phaisingto Community' which is now facing overcrowding problem and thus results in quality of life degradation. Also, the area is lack of good management and thus results in environmental, economic and social problems. Environmental issue is found in polluted water bodies that emitted obnoxious smell and provided bad scenery instead of city's scenic water way. Local people are confronted with poverty. More importantly, people in the community have to deal with crime issues and downgraded well-being.

With all these circumstances, the CPB planned to transform this area into a better environment by choosing one land to develop a new residential project for low-income people. However, the critical issue lies on a bad perception and violent action from local community against the CPB. Primary cause of a protest derives from physical development and land expropriation in the area. The CPB concerned that this issue might worsen relationship between the project and its neighborhood. Hence, L.P.N. Development Public Co., Ltd., the leader of condominium for low to middle income people in Thailand had been chosen to help the CPB develop this project together.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 2: Site surroundings and contexts

L.P.N. is a real estate developer that has an ambition to deliver sustainability to all its customers. The main goal of the company is to obtain sustainability by emphasizing on the 'Vibrant Community' which has been a signature of L.P.N. for years. Furthermore, L.P.N. had initiated an intensive 'green program' to create a new standard that specifically suits the organization's culture. This ongoing development program has been deployed to all the organization's staff and has been successfully adopted in several condominium projects from the beginning of the entire design and construction process. This integrative strategy causes no additional costs and produces financial benefits from building operating cost reduction. As a result, L.P.N. can provide its customers better performance condominium buildings while simultaneously keeping the projects' selling prices lower than other green projects.

The CPB and L.P.N. also have share business values to create a community where residents can have a good quality of life and a better environment (Figure 2). The CPB, therefore, offered the land in a low rental price, together with L.P.N. know-how in massive construction, maintaining low investment cost to build affordable residential project is not an obstacle.

Figure 3: Crown Property Bureau and L.P.N. business shared values

In Lumpini Place Rama 4-Ratchada, L.P.N. has faced a new problematic situation in which social problems are the key obstruction to this project development. The CPB and L.P.N. had come up with a conclusion that only green standard that mainly concentrates in the project boundary is not enough and can no more create sustainable built environments for the project. Both organizations had to reinterpret conventional thinking method and seek for more profound solutions so that the mutual goal of providing sustainable environment for all residents can be maintained.

2.2 Project specific solutions

Deep green approach was then addressed for the first time among numerous L.P.N. condominiums in order to bring the best and most appropriate solutions that fit these specific site contexts. After conducting a deep research into the site context, 3 main resolutions which are social psychological, physical, and economic approaches have been undertaken.

Figure 4: 3 pillars of deep green approach resolution

Social psychological approach

Social psychological method is the most challenging aspect in this project. The key driver that can build a sustainable development which interrelated to its environments relies on people perception. Although Phaisingto community is in a degraded condition and seems to lack of proper management, it has appeared to be a strong community with close relationship among each other. This reflects in the mutual activities such as community settlement groups or some social events. Therefore, the first and foremost strategy is to create better understanding among local people and Lumpini Place Rama 4-Ratchada condominium's occupants, follow by promoting physical and economic benefits provided by the project. This is to create better perception and cooperation between the project and the community. Lastly, enhancing mutual environmental concerns is crucial. As long as people have awareness, sustainable environments where residents and neighbours can happily live together can be last long.

Physical approach

This approach started from passive design strategies such as creating green walls to enhance biodiversity in the project boundary, L.P.N. 'green construction site program' to lessen negative impacts from construction activities, and surrounded security system improvement. Accordingly, outdoor lighting fixtures and CCTV cameras will be installed at the site boundary and some areas nearby. This plan is to improve security within the project neighbourhood and to prove that having the project located at the area can also enhance living quality of people in Phaisingto community. Moreover, one part of the site will be dedicated to the community playground and exercising park for children and elderly to spend time together.

Economic approach

Major community source of revenues are from small retail business, thus L.P.N. planned to provide rental retail spaces in the condominium common areas and launch a cooperative small store network program. The ideas of this program are to collect existing store information and advertise condominium residents about various local products and store locations. Besides, L.P.N. also has housemate training program with an aim to create jobs for disadvantaged women in the community. All of these strategies have been incorporated to offer more job opportunities and revenues for local people and to strengthen community economy.

2.3 5 steps of implementation to change the project and its neighborhood into a sustainable environment

To ensure that the project can resolve all 3 issues mentioned above and reach its goals, implementation is a key success especially in community participation process. To give highest chance of success, an integrative process has been incorporated in the project. In Lumpini Place Rama 4-Ratchada project, all team members have gotten involved and developed action plans all together from the start. Each department has clear scope of work, responsibility and implementation periods. This is shown in the diagram of project participants and responsibilities of each working step in Figure 5.

Figure 5: Relationship of project participants and responsibilities comprises of environmental consultant, R & D, designer, contractor, marketing, and community management

After a brainstorming session, 5 following steps of implementation process were addressed as corresponding plans that cover all aspects.

Step 1: Conducting a site survey

Carrying out a site survey and analysis to explore all circumstances at the beginning of project planning process had helped in problem identification and thus, provided more precise solutions. Also, local people satisfaction survey had been taken to collect community feedback and apply in the project current operation assessment.

Step 2: Implementing sustainable construction strategy in the project during construction to prevent pollution from construction activity

L.P.N. has implemented its own' green construction standard' which is the company's vision and mission to build condominiums with least negative impacts to the workers, residents, neighborhoods and environments. The company has sent a team to conduct monthly site inspection to ensure that green construction strategy is regularly implemented during construction period.

Step 3: Community development in physical, economic and social aspects

Several plans have been initiated to help in neighborhood development for example, physical improvement of site surrounding area by L.P.N. construction team, security system installation, provision of community common spaces for activities etc.As for economic facet, a cooperative store network program has been introduced to stimulate community economy. L.P.N. also planned to arrange social activities and facilitiessuch as trade waste-recycling program, walkway and water body cleaning program, children education program local and workers' children etc.

Step 4: Create community participation

The project is opened for comments andadvocates local people to participate in the community development plan. People can give recommendation to the plan if they feel it will not be fit with the community. The main purpose of this process is to encourage partnership among the community and build positive attitude about the project.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Step 5: Public relation of the project operation

Public relation campaign was planned to be launched after the project construction is completed, in order to communicate to the public about L.P.N. approaches and operation to resolve all dimensional issues of this project. This is to build confidence and a positive attitude to the community. Additionally, it can influences public to have awareness about environmental concerns in a wider and deeper facetsapart from building performance and green strategies only within the project boundary.

Above all, to accomplish all these steps of implementation, an intensive integrative process that all parties set mutual agreement and work together at the beginning of entire project process is crucial.

3. CONCLUSION

This project has proved that the challenge of sustainability and green design is more a matter of local interpretation than of the setting of universal goal. The important thing is to consider existing issues and integrate achievable practices into the project in all dimensions. Intensives approach that advocates changes in all scales of social, physical, and economic aspects is significant and need to be considered since the very beginning of project entire process. The key seed of success is how we can raise awareness, create mutual understanding and cooperation among all project participants, and drive everyone to deeply engage in the project. Ultimately, it is important to keep in mind that creating change is never easy, especially in a delicate issue like social consequence. It always takes time and patience to create sustainable development, however; the outcome of a better living is worthwhile. As such, we can finally create communities that people could live comfortably and securely while having the least impact on the environment.

ABSTRACT

M+ Museum (M+) will, upon completion be a globally leading museum with exemplar sustainable credentials. Designed for performance throughout, M+ will provide a high quality environment whilst significantly reducing energy consumption and potable water consumption. The roof podium provides landscaped and a publically accessible garden where the microclimate is refreshed by the harbour breeze. Internally, pockets of daylight animate selected gallery spaces reducing artificial lighting use and architectural shading minimises heat gain and cooling energy. The remaining building loads are served by district cooling and supplemented by solar hot water panels to supply sustainable energy.

Sustainability in modern museums is essential, however this should always be considered alongside the environmental requirements of art galleries, art work storage, staff and visitors.

This paper presents the sustainable engineering processes, analyses and findings which underpin the design of M+. Particular focus has been given to the areas of design which required specific solutions to be engineered beyond those found in conventional commercial buildings in Hong Kong, and how these designed solutions are creating a high performance, highly sustainable building.

Keywords: high-performance building, museum design, integrated design approach

1. INTRODUCTION

M+ Museum (M+), shown in Figure 1, is a globally leading museum with exemplar sustainable credentials. This high-performance sustainable building uses passive and active design strategies to minimise energy, material, water and land use. By making use of ambient energy sources such as daylight, breeze and solar energy, the external microclimate is improved, energy demands lowered and operating costs reduced.

The building envelope incorporates architectural shading over well placed windows to minimise heat gain and cooling energy. Internally, pockets of daylight animate selected gallery spaces reducing artificial lighting use. The remaining building loads are in part served by district cooling with solar hot water panels. Where required bespoke designed cooling delivery system provide low energy solutions whilst maintaining specific environments.

The extensive roof podium will provide a lush publically accessible garden where the optimised microclimate is refreshed by the harbour breeze, this type of usable outdoor space reduces the need for conditioned buildings. All together this enabled M+ to be awarded a Provisional BEAM Plus Gold rating. BEAM Plus is Hong Kong's sustainable building rating system (BEAM Society Limited 2012) and is equivalent to other rating systems such as the internationally recognised LEED v2009.

This paper presents the sustainable initiatives that have been designed into M+ and required specific analytical assessment to balance the requirements of sustainable design, visitor experience and art work preservation.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure1: Rendered Image of M+

2. SITE AND OUTDOOR ENVIRONMENT

Situated overlooking Hong Kong's Victoria Harbour, in The West Kowloon Cultural District, M+ will be a key asset of the district and city. The large publically accessible podium garden was designed to be comfortable for visitors throughout the year. During the hotter months in Hong Kong local microclimates are enhanced by sun shading, breezes and reducing surface temperatures with planting. This is particularly important along pedestrian circulation routes and areas designed for sitting and enjoying outdoor space.

2.4 The podium

To analyse visitor comfort the metric of thermal sensation was used. Thermal sensation is the combined physiological response to solar radiation, air temperature, wind, radiant temperature, metabolic rate and clothing (Givoni et al, 2003). The local wind speed was simulated using computational fluid dynamics which considered the neighbourhood massing and influential building features. The solar radiation was simulated using Radiance ray tracing tools which take into account local building massing. The other thermal sensation factors were included as typical values for the corresponding period of the year, the results are shown in Figure 2.

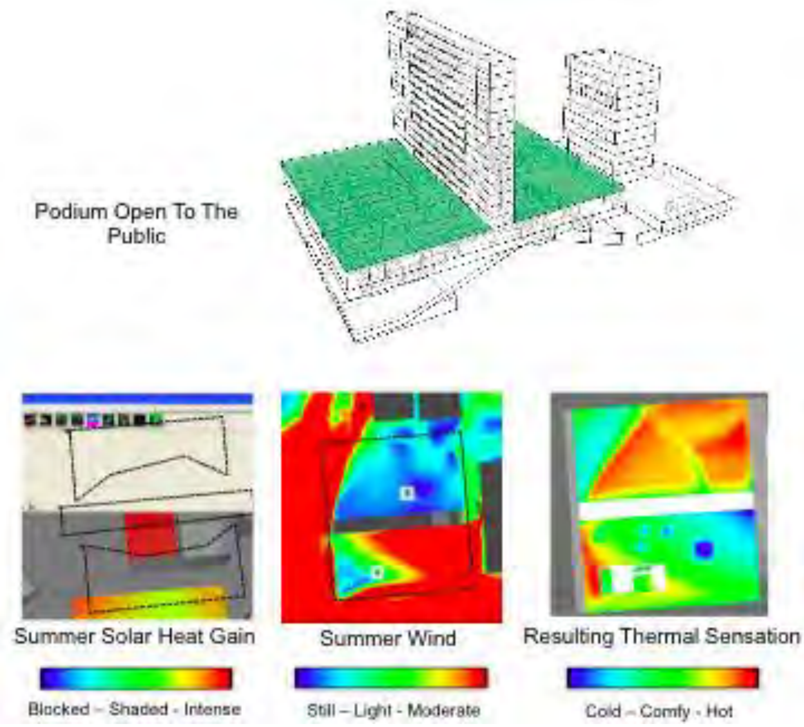

Figure 2: Thermal sensation analysis

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Based on the results of the analysis, the podium was configured to make the best use of the outdoor space. The spaces with a comfortable thermal sensation are more suitable for pedestrian circulation areas, outdoor spaces and exhibitions spaces. Permanent planting and none accessible north lights were also included more extensively towards the north east where thermal sensation was hottest. This is shown in Figure 3.

The planting also provides a thermal and acoustic buffer for the gallery spaces, this lowers cooling energy and enhances visitor comfort. The planting predominantly used species native to Hong Kong and was chosen to vary in height to enhance bio-diversity and provide habitats for insects and pollinators.

This podium garden includes over 50% planted area. Rainwater is harvested from the roof, treated and stored in the basement before being used to serve over 50% of the annual irrigation demand.

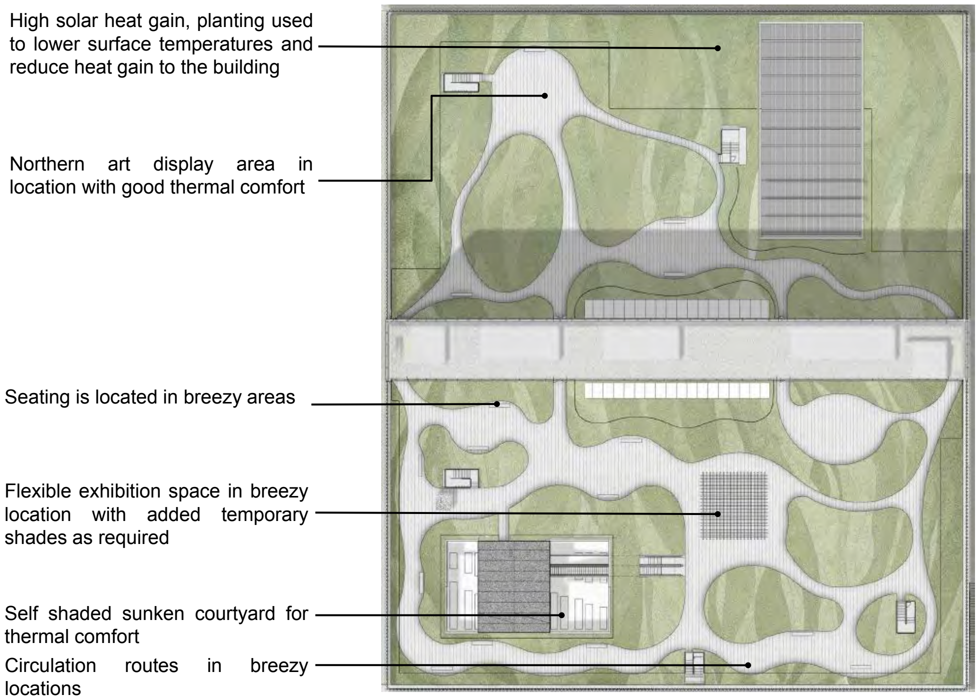

Figure 3: The resultant podium space planning. Background image courtesy of Herzog & de Meuron

2.5 Pedestrian circulation routes

Direct sunshine in the summer in Hong Kong will rapidly lead to thermal discomfort particularly for pedestrians walking between buildings or from transportation drop offs. The building was designed with setback at the ground floor façade. This allows the podium to provide shading to pedestrian routes. The setback also encourages breeze to flow around the building. Figure 4 shows the extent of the overhang in red.

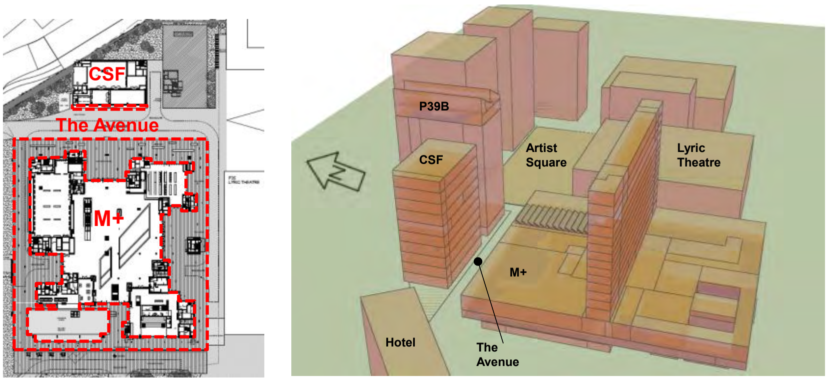

Figure 4: Shading of pedestrian routes with particular emphasis on "The Avenue" which transects the site

To ensure the shading environment is optimised ray tracing simulations were carried out to assess the hours of direct sunlight the pedestrian areas receive. These are shown in Figure 5.

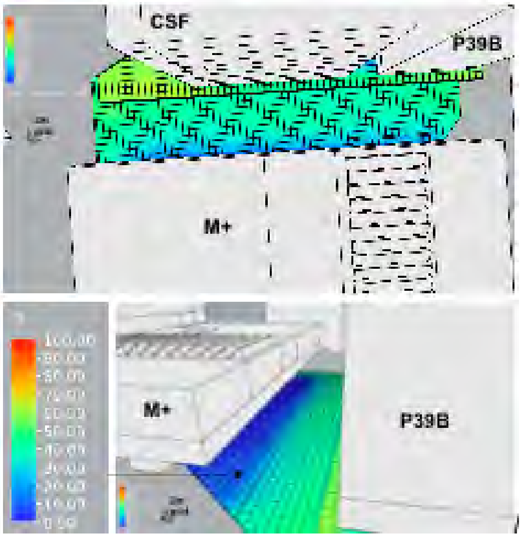

Figure 5: Simulation result highlighting that M+ massing enables large areas of pedestrian circulation routes with minimal hours of direct sunlight throughout the year. (Scale is % of daylight hours which experience direct sunlight across the year)

3. INTERNAL ENVIRONMENTAL QUALITY

The people that visit M+ and the artwork on display have specific environmental requirements. Key parameters are light levels (artificial and daylight), temperature, temperature distribution and humidity. As such the design embeds a number of passive and active systems into the building which ensure that strict environmental conditions can be maintained and energy use minimised. This section of the paper reviews the elements of design that presented specific challenges relating to M+.

3.1 Heat gain

In a sub-tropical climate such as Hong Kong, solar heat gain will drive up cooling loads and the associated capacity and energy consumption of the cooling plant. M+ minimised solar heat gain, by reducing glazing areas, locating more glazing away from the hotter east and west facades and providing shading for the tower portion of the building alongside north lights and extensive overhangs at the ground floor. The combined effect reduced annual solar heat gain by over 66% for the office portion compared to the statutory requirement for commercial offices in Hong Kong (note there is no statutory requirements for museum or archive stores). The shading elements are pre-cast concrete which reduces material wastage on site.

3.2 Daylight

Using natural light creates an alternative lighting ambiance and vibrant spaces for works of art (those which are not damaged by light). Daylight provides excellent colour rendering and a subtle dynamism which is favoured by curators. It also reduces the energy consumption associated with artificial lighting which is typically 2~3 times that of a typical office or school environment. This must be balanced with light exposure limits for sensitive artwork where both artificial and daylight must be controlled. As such, M+ lights certain galleries or parts of galleries with natural light and others with controlled artificial light. This enables freedom of curation for a variety of galleries. The use of daylight also plays an important part in creating a low-energy building and providing visitors and staff a valuable connection to nature with the associated health benefits.

The design guide, Lighting For Museums and Art Galleries (CIBSE, 1994), set limits for art work exposure which are as low as 150,000lux hours per year for sensitive art work. As direct unobstructed light can result in instantaneous illuminances of well over 50,000lux it follows that galleries should minimise or block direct sunlight completely if light sensitive artworks are to be displayed. In practice, due to Hong Kong's solar geometry blocking direct light completely is challenging and limits general daylight levels. Figure 6 shows a south – north section and a Radiance simulation of "The Skylight Gallery". This gallery uses north lights to block over 90% of direct light,

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

however, blinds are still required to ensure art work is not damaged for the instances when the sun is in the north of the sky. During the design process precise Radiance ray tracing tools were used to guarantee building performance and artificial lighting demand was reduced by over 5% compared to Hong Kong Building Energy Efficiency Codes (EMSD, 2012).

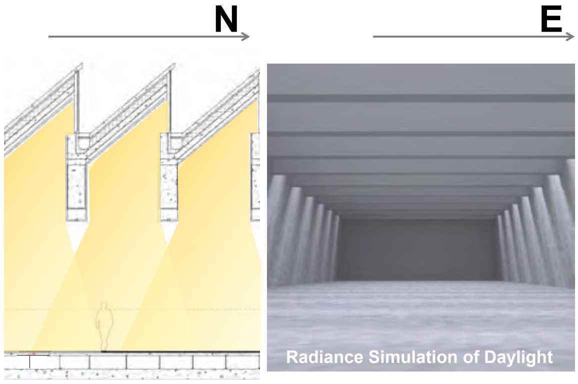

Figure 6: Section through the skylight gallery and Radiance simulation of daylight

3.3 Temperature distribution

Museums demand a lot from internal environments; temperature and humidity must be carefully controlled to preserve artwork, visitors must have best in class comfort and typically the HVAC systems must be sensitively integrated into architecture. For a museum to be sustainable this must be achieved with minimal energy and water expenditure, easily maintainable systems and high levels of adaptability. One of the more challenging spaces to design was the skylight gallery.

Due to requirements for subtle supply and extract locations underfloor air delivery was preferred; from the energy view point this was favourable due to reduced fan energy associated with higher temperature differences between supply and extract. The key environmental requirement for a minimal temperature gradient across the surface of art work also favoured this solution. Underfloor systems rely on natural buoyancy effects whereby room heat loads warm the air which then moves upwards towards the exhaust louvers. In this process warmer air will pool at the ceiling creating a stratified layer, below the layer the air temperature will be constant at the design set point. In the case of this gallery, this stratified temperature layer cannot drop below 5m into the art work zones else the art work will experience a temperature gradient. The heat gains and HVAC cooling delivery with computational fluid dynamics (CFD) to asses this. The simulation was conducted using k-ε turbulence computation for the gallery space. Figure 7 shows the input parameters and the results.

Case	Predicted Temperature Difference (°C)	Supply Air Volume Rate (L/s)	Supply Air Volume Velocity (m/s)	Occupied Zone Temperature (°C)	CFD Temperature Plots
1	4	9800	0.25	19.0 – 20.0	
2	6	6550	0.25	19.5 - 20.5	
3	8	4900	0.25	20.0 – 21.0	
4	8	4900	0.4	Not Stable	

Figure 7: Optimising the HVAC for environmental control and energy efficiency

The results show that as the air flow rate decreases the stratified layer lowers, hence the design looked to minimise air flow whilst ensuring the stratified layer does not infringe on the art work zone (with a suitable buffer). This minimises fan energy consumption and increases overall sustainable performance. As such Case 3 was taken forward as the optimised solution – supply air volume (and energy) is minimised to the point where the stratified layer cannot go any lower.

Case 4 highlights an optimisation exercise which was carried out to assess the feasibility of reducing the number of supply louvers. In case 4 the supply louvers were almost halved hence the supply velocity almost doubled. It is clear from the CFD plot that this increase in velocity led to short circuiting whereby the supply air jetted straight to the exhaust with insufficient room mixing. This is not a workable design solution.

4. OTHER SUSTAINABLE FEATURES

M+ has included a number of sustainable features to ensure that the building performs across multiple parameters, whilst not the focus of this paper they are listed here for reference.

A key aspect of M+'s sustainability is energy consumption. As close environmental control relies of extensive mechanical servicing, energy consumption is typically higher than other building types. The major energy consuming systems of a museum located in the sub-tropical climate are cooling, lighting and humidity control. Total energy consumption of M+ was reduced by almost 20% compared to Hong Kong Building Energy Efficiency Codes (EMSD, 2012).

M+ uses daylight and occupancy sensors to provide only the necessary light which is served by highly efficient and high quality (high colour rendering performance) fittings, lighting energy is reduced by over 23% compared to Hong Kong Building Energy Efficiency Codes (EMSD, 2012).

The cooling loads are served from a district cooling system with open loop sea water heat rejection. The district systems makes use of diversity across the site with the sea water heat rejection providing a lower average rejection temperature compared to the ambient air. In the archival and gallery spaces where close humidity control is needed (mould will develop quickly over 60% RH), desiccant dehumidification systems are used. The reheat from these systems is in part supplied by solar thermal hot water panels and heat recovery chillers, solar energy accounts for almost 1% of total building energy.

Energy consumption however cannot be driven down to the lowest levels as to provide an excellent environment, the air quality inside M+ must be excellent. With the use of high rated air filters and increased fresh air rates (with associated increased fan energy consumption) Hong Kong's indoor air quality standard of "excellent" is achieved.

M+'s toilets are flushed with seawater displacing the use of potable water and sanitary fittings are all low flow saving over 35% potable water compared to the BEAM Plus baseline.

5. CONCLUSION

The paper has primarily presented a selection of the analytical assessments which were carried out to deliver a modern, sustainable museum design. Often in this design process requirements for art work preservation and visitor comfort required more energy to run systems compared other building types. As such it was essential to carry out detailed building physics analysis to ensure the systems would perform optimally. A key example of this is the under floor air delivery which was optimised across multiple parameters to deliver the required environmental conditions with minimal energy consumption.

Session 7.12: Multi-facet Considerations of Urban Regeneration Policies

The Role of Stakeholders in Masterplan Regeneration Decisions

Hannah BAKER[a], Alice MONCASTER[b]

[a] University of Cambridge, United Kingdom, heb51@cam.ac.uk
[b] The Open University, United Kingdom, alice.moncaster@open.ac.uk

ABSTRACT

Brownfield sites often contain existing buildings and during regeneration the decision to demolish or adapt them should consider sustainability principles. This paper discusses decision-making criteria obtained through a literature review and primary research including 18 interviews, 2 workshops and 2 focus group discussions. The most frequently mentioned criteria including building condition; heritage value and capital costs are evaluated. Criteria are then analysed from different stakeholder perspectives and the paper identifies where stakeholder values align. The paper forms part of a three year research project which aims to develop a decision-making framework to assist with integrated and holistic decision making.

Keywords: urban regeneration, building adaptation, decision-making

1. INTRODUCTION

Worldwide there is an increasing population and a pressure for housing in a number of countries (Karantonis, 2008). In 2015, the UK Conservative Government's manifesto stated that brownfield land (Previously developed) should be used as much as possible for new development (HM Government, 2016; Smith, 2016). When redeveloping brownfield land, independent of scale, the decision needs to be made to demolish or adapt the existing building(s). This should consider the benefits and drawbacks of adaptation and demolition; alongside several decision-making criteria and sustainability principles (Love and Bullen, 2009). In general, the decision is not made by one person as it is complex and requires the expertise of a range of stakeholders (Bullen, 2007; Kaklauskas et al., 2005). This paper discusses decision-making criteria identified through a literature review and supported by primary research methods including 18 interviews, 2 workshops and 2 focus groups. Criteria are then discussed from different stakeholder perspectives to show where stakeholder interests may align or differ. The research is beneficial as the paper forms part of an ongoing three year research project which aims to develop a decision-making framework for the adaptation or demolition of existing buildings on masterplan regeneration sites to assist with integrated and holistic decision-making.

2. LITERATURE REVIEW

2.1 Brownfield redevelopment, adaptation and demolition

The decision to demolish or adapt is not 'black or white' (Baker et al., in press). There are different forms of adaptation and a building can be demolished in its entirety or part. Wilkinson et al. (2014) outlines the different options for decision-makers including: demolish; strip out and maintain the building shell; maintain the building in a vacant state; part demolish and adapt; modify, refurbish and adapt; part extend; let all or part; or sell.

2.2 Decision-making criteria

Through an in-depth literature review, seventy criteria used to evaluate building's and whether they should be adapted or demolished have been identified, collated and 'mapped' into three separate tiers: an overarching theme, 1st tier and 2nd tier. The overall themes include: technical; planning; environmental; economics; masterplan design; legal; heritage value; corporate objectives and the construction process. The most commonly cited criteria in the 1st tier are displayed in Table 1 and the most frequently referenced criteria in the 2nd tier are in Table 2.

Technical criteria are regularly mentioned including the buildings' layout and dimensions; condition; regulations; structure and function. Baker et al. (In press) identified poor building condition as a key disadvantage of adaptation, thus favouring demolition because it can increase the capital costs of the project. Although problems affecting the

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

condition can be identified in the structural appraisal stage, a key concern related to existing buildings in comparison to new-build is the risk of discovering unknown problems during construction (Bullen and Love, 2010; Remøy and Van der Voordt, 2006; Yung and Chan, 2012). Building regulations are regularly cited because of the safety of occupants and threat of prosecution if not met (Garrett, n.d.). Fire safety must always be adhered to (Table 2), whereas there is more lenience for other regulations such as the thermal performance (Energy efficiency) of listed buildings, scheduled monuments and buildings in conservation areas to avoid irreversible damage to the buildings' fabric (Historic England, n.d.).

Wilkinson (2011) conducted a quantitative analysis of building permits to identify trends in previous adaptation projects and what features enable adaptation. For example, concrete frame buildings were found to be more adaptable than load-bearing brick, stone or concrete wall and the optimal building height was 11-20 storeys. Clark's (2001) case study investigation of historic naval buildings also found columnar structures to be more flexible because of their grids and larger spans. Building height is a factor related to land value and potential profits. Been et al. (2016) discuss that if buildings have low heights and low amenity values, the whole area should be redeveloped because it is not reaching its full potential.

Alongside the technical criteria, qualitative values should be considered for holistic and sustainable decision-making (Bullen, 2007) and are regularly cited in the literature. Table 1 shows that heritage incorporates a range of intangible values including: aesthetics; historical importance and architectural significance. Baker et al. (In press) identified 'heritage value' as a key benefit of adaptation over demolition and that there is a growing appreciation for heritage retention because of concepts such as place-making and providing a sense of identity to the community.

Table 2: Most frequently cited criteria at 2nd tier level

2.3 Stakeholder roles in the decision-making process

Mok et al. (2015) discuss the complexity of mega-construction projects including the involvement of numerous decision-makers who will have different interrelationships and conflicting viewpoints. The Engineering Council's inter-institutional guidance on sustainability (Bogle, 2010) says that engineers should "seek multiple views to solve sustainability challenges" (Ashley, n.d.). This is applicable to other decision-makers to ensure integrated decision-making. Wilkinson (2011) identifies decision-makers as: investors; producers; marketeers; regulators; policy-makers; developers and users, which then have a range of sub-categories. The general public may be stakeholders or decision-makers dependent on their influence and power in the process (Langston and Smith, 2012; Yang et al., 2014).

The criteria identified in Section 2.2 can be integrated into frameworks as decision-makers go through different processes to assess adaptation and demolition. There is inevitably a difference between the ways an engineer would assess a structure to a heritage consultant, but both processes need to be considered for holistic decision-making. For example, engineers are often responsible for analysing the building's condition and the Institute of Structural Engineers provide guidance and flow charts to show the suggested paths of appraisal, which include various stages of qualitative and quantitative analysis (IStructE, 2008). Heritage consultants aim to understand the contribution of various heritage values but these are often critiqued because of their perceived subjectivity. To try and overcome this, Historic England have recently published guidance on conservation principles and polices to ensure there is consistency between decision-makers (Drury and McPherson, 2015, p.38).

Fundamental decision-makers include the building owners and developers. Geraedts and Van der Voordt (2007); Langston and Smith (2012) and Wilkinson et al. (2014) have created tools for asset owners to assess a portfolio of office buildings with the aim of determining what intervention is required. An analysis by Baker et al. (In press) using case study sites found that adjustments are required if using the tools on masterplan sites rather than individual buildings.

3. METHODOLOGY

3.1 Thesis overview

This paper forms part of an ongoing three year research project, which aims to understand the decision to demolish or adapt existing buildings on masterplan regeneration sites. Results from the 1st year are outlined in this paper. The objective was to identify key decision-making criteria through general interviews with different stakeholders. During the second year of research these preliminary results will be used to assess case study sites, with the overarching aim of developing a holistic framework to assist in decision-making. During the 1st year, the use of social research methods, such as interviews and focus groups, was informed by previous studies (Referenced in the literature review) regarding adaptation. As shown by Bullen and Love (2011, p.35), an interpretive research approach "can capture information about the beliefs, actions and experiences of stakeholders involved".

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.2 Interviews

The participants for the 'general interviews' were chosen through opportunistic and purposive sampling methods (Given, 2008). Interviews conducted so far represent: property consultants, heritage societies, building surveyors, engineers, private planners, local authority planning officers and conservation officers – see Table 3. Once the interviews were transcribed, they were analysed through a coding software called HyperResearch. The initial set of codes established through the literature review were used as an introductory guide.

Stakeholder	Number of interviews
Engineers and building surveyors	4
Heritage societies	7
Property consultants	4
Town planners and conservation officers	3

Table 3: Interviews conducted to date

3.3 Focus groups and workshops

Two focus groups, containing eight people from academia and industry discussed "How can embodied energy be incorporated in the decision to demolish or retain existing buildings?" as part of an Embodied Energy Symposium. Conversations were recorded, transcribed and coded in the same way as the interviews. In addition, two workshops were hosted with post-graduate and undergraduate students on courses related to the built environment. Classes were separated into stakeholder groups of four to five people (Design team; planners; end-users and developers) and asked to determine what criteria were important from their stakeholder's perspective. These were recorded in Excel and mapped to the codes identified in the literature review.

3.4 Limitations

The current results should be treated as preliminary findings. Further iterations of coding analysis are required to refine the criteria being used as only one iteration has been completed to date. The research currently does not represent all stakeholders in the decision-making process and there is a higher representation of heritage societies, which may create a bias.

4. RESULTS

4.1 Decision-making criteria

Table 4 displays the decision-making criteria extracted from the interviews, focus groups and workshops and the number of people mentioning them.

Ws = no. of stakeholders groups from workshops (n=9). In = no. of respondents from interviews (n=18). Fg = no. of focus groups (n=2)

Theme	1st Tier	2nd Tier	Ws	In	Fg

Table 4: Criteria identified from interviews and focus groups: Theme, 1st tier and 2nd tier

The most frequently mentioned technical criteria were those related to the building's condition; layout and dimensions; services and function. The building condition was regularly mentioned, similar to the literature review because of the effect it can have on costs. One interviewee stated: "If you are an asset owner - it's all about capital costs and running costs". Alongside this, four interviewees discussed unforeseen problems occurring during the construction process and issues associated with warranty.

It is vital for a building to have a use: "without a use, there is no point regenerating these buildings". The feasibility of adaptation is affected by floor areas, floor to ceiling heights and service provisions. If a building needs to have specialised floor-plates it may be more complex to adapt. Whereas, a factor which emerged during the interviews was the desirability of start-up companies and knowledge economies to accommodate within existing buildings. One building surveyor stated that "Groovy start-ups want to go into groovy little buildings". These businesses do not necessarily require open floor spaces and can utilise the "nooks and crannies".

One of the most commonly mentioned criteria in all three methods was whether or not a building was designated. If a building is listed in the UK, interviewees suggested that the de-listing process can be time-consuming and increase the risk of not obtaining planning permission. Despite some of the interviewees stating that retention was not dependent on designations and that non-designated heritage assets can still be desirable, one conservation officer said: "it's much harder when you're talking about undesignated assets".

Although embodied energy is a commonly cited benefit of building retention in the literature (Baker et al., in press) and was recognised as a benefit of retention in the interviews, the overall perception was that it is currently not a major factor to consider in the decision-making process because "it doesn't appear on balance sheets". During the focus groups, the general consensus was that for embodied energy to be considered in the decision-making process there needed to be tax incentives or legislation in place. At the moment this is difficult due to uncertainties associated with the measurement. This emphasises an important point - what is currently done, is not necessarily what should be done from a sustainability perspective. Future research will establish what should be changed in the decision-making process and which criteria should have a higher weighting of consideration.

4.2 Criteria in a masterplan context

Decision-making criteria may be considered differently for buildings in a masterplan context rather than individual buildings. In some situations it would not be economically viable to retain an individual building, however this may change within a larger site. This was discussed by a property consultant who said "when you look at the benefit of knocking that building down and replacing it in the scheme of the masterplan, it's miniscule…any space that we could have grabbed by knocking it down, we could catch up with elsewhere". When considering the economic

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

viability of a large scheme, it is important that the phasing of the development is considered. For example, the perception of three interviewees was that the scheme at Kings Cross, UK was successful because the historic buildings were completed first which created a hub of activity early on within the process. However, this may not always be possible as raising the funds to adapt existing buildings can be more complicated than new build because of the associated risks and uncertainty. Both the accessibility and the density on site were regularly mentioned as it is vital individual buildings work within the masterplan vision and this includes their location on site and if they are easy to access.

4.3 Stakeholder viewpoints

The primary research showed that there are differences in opinion between stakeholder groups and even within them. Currently there have not been enough interviews to conclude a criterion is only important to one stakeholder group, but it is interesting to acknowledge where stakeholder interests may align.

During the workshops the criteria mentioned by all stakeholder groups were building function and accessibility but were important for different reasons. For example, developers wanted to establish if a building was fit for purpose (1st tier = building function) to ensure development was economically viable. The design team were concerned with function as they are responsible for "space-planning" and designing the building for the intended use. The end-users were interested in whether the "space was practical" and "whether there were enough toilets and cafes" to meet their needs and the planners had a general interest to ensure the area is effectively used. The workshops emphasised that there can also be a difference of opinion within stakeholder groups. In the first workshop, the students chose to be 'social developers', whereas in the other they chose to be 'profit-driven', which meant they had different attitudes towards the scheme.

In the interviews, the criteria identified within all stakeholder groups (Figure 1) included: designations, planning policies, capital costs, building structure and building condition. As would be expected, engineers and building surveyors were interested in technical criteria as their role is to assess the robustness of the structures. Property consultants were interested in the technical aspects as they affect the cost of a project, whilst heritage societies and town planners recognised that non-economic viability can sometimes be used to justify demolition. This has to be balanced with heritage values. Designations were regularly mentioned because of the protection they can offer. Although property consultants recognised that heritage could add value (Economically and socially), they did express concern regarding constraints caused by designations which can lead to delays and extra costs.

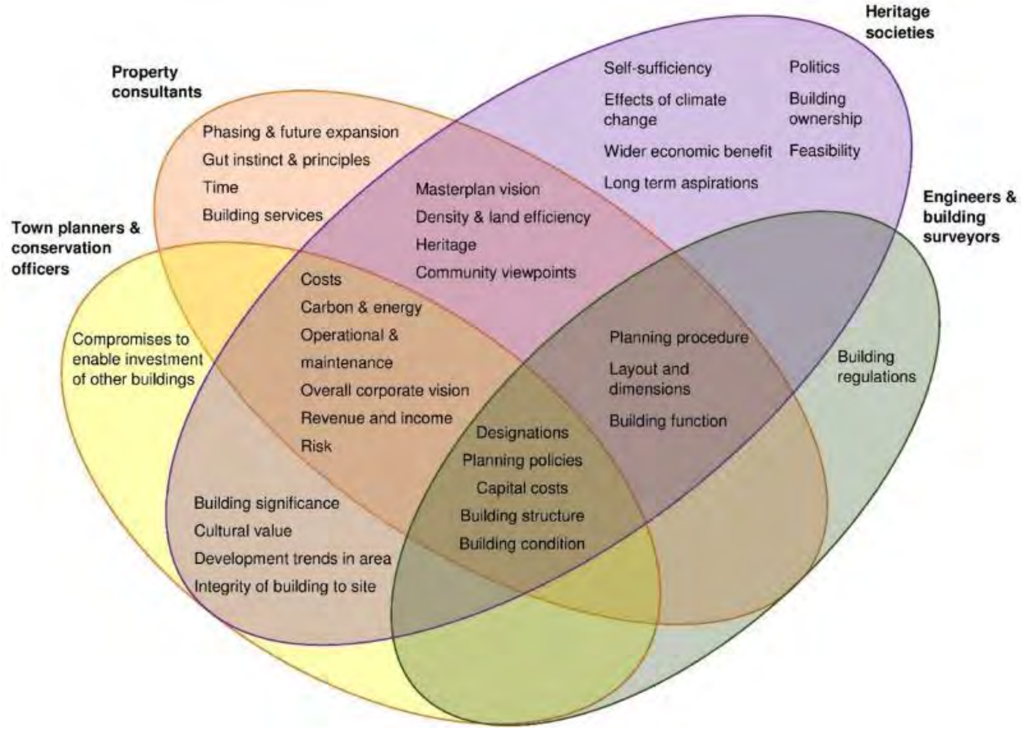

Figure 1: Criteria mentioned by stakeholder groups in the interviews

5. CONCLUSION

This paper has identified criteria currently used in the decision to demolish or adapt existing building on masterplan regeneration sites through a literature review, interviews, focus groups and workshops. Frequently mentioned criteria include: technical issues such as building function, condition, layout and services; economic viability; designations; and issues specific to masterplan sites, for instance accessibility, density and phasing.

Different stakeholder attitudes to the same criteria were discussed and the findings begin to show that it is vital to consider these differing viewpoints in the decision-making process. This includes a diversity of opinions between and within stakeholder groups. For example, an engineer may be concerned with designations for a different reason to heritage societies. The criteria outlined show an understanding of what currently happens when making adaptation and demolition decisions. Future work will establish if this is the most sustainable way of thinking and what needs to be changed. The criteria will be refined and contribute towards a decision-making framework which will aid holistic decision-making and collaboration between stakeholders.

ABSTRACT

Since 1960s building typologies in Hong Kong demonstrated significant variations in their geometry and size responding to plot ratio amendments. Majority of residential buildings prior to 1990s were of square or rectangular plan form. Since mid-1990s under Comprehensive Development Area policy, "hyper podium tower" typology which consists of a 15m high podium with quasi-cruciform plan residential towers above was introduced. Our previous research indicates a reduction in wind speed from 2.97 m/s in 1950s to 2.27 m/s in 1990 (Authors et al. 2016). A sharp drop in the wind speed was evident from 2.27 m/s in 1990 to 1.88 m/s in 2000 which may be attributed to the emergence of "hyper podium tower" residential typology.

The study further investigates the impacts created by these quasi-cruciform towers on urban wind environments comparing them with three different residential tower geometries considering two factory estates in Tsuen Wan as prospective redevelopment areas. Hyper podium developments with square towers, cylindrical towers, cruciform towers and cruciform towers with balconies were examined for their impact on urban wind speed. Wind speed was measured at 2m, 30m and 50m heights using a three dimensional urban model of Tsuen Wan as of 2015 development scenario testing with Computational Fluid Dynamics ANSYS Fluent platform.

Cruciform towers and cruciform towers with balconies outperformed wind speed around square and cylindrical towers. Cylindrical towers indicate the lowest wind performance due to the laminar wind flow facilitated by the smooth building envelope. These findings also support the positive impacts created by balconies in residential buildings as a green feature promoting urban ventilation. Findings from this study provides references for designing sustainable and liveable neighbourhoods.

Keywords: urban regeneration, sustainable neighbourhood, building geometries, urban air ventilation

1. BUILDING TYPOLOGIES IN HONG KONG

Evolution of building typologies in Hong Kong is discussed generally and also taking Tsuen Wan new town as a case study. Tsuen Wan is one of the first satellite towns in Hong Kong which is currently undergoing rapid revitalization.

Hong Kong building regulations have been evolving responding to factors that promote health and well-being of citizens and therefore plot ratio amendments. In mid 1930s permissible depth of buildings were reduced to 10.7 m with building height capped at three storeys. In the early 1950s, public housing programmes were introduced to accommodate increasing influx of returning residents. Initial public housing typologies were massive blocks with increased floor area. Private developers entered the market in 1956 and building regulations were further changed allowing taller buildings up to 24.4m high. Realizing the increased density by the massive blocks and their consequences, new building ordinance in 1966 reduced the plot ratio to 8:1 with options to choose higher plot ratio with lower site coverage or lower plot ratio with higher site coverage. Podium and tower typology became a popular option due to 100% site coverage for non-domestic portion.

Since early 1980s, industrial areas in Hong Kong have been transforming from manufacturing to a service and knowledge based economy due to the decline in industrial sector's contribution to Gross Domestic Production. With the relocation of industrial estates to Pearl River Delta Region, most these factory buildings were adopted for non-manufacturing and residential purposes. In 1988 Hong Kong inherited approximately 12 million ft^2 of flatted factories (Colliers, 2011). Tsuen Wan developed as an industrial hub accommodating some of the largest factory estates that exist even to date. In the past fifteen years, Tsuen Wan has been undergoing rapid transformation of these industrial estates and old buildings built in the 1950s. With modified zoning requirements, stand-alone developments have been progressively replaced by mixed use large scale redevelopments which are classified as

'Comprehensive Development Areas (CDA)'. Out of 136 factory zones in Tsuen Wan 52 have been transformed into non-industrial zones (HKSAR, 2011). Old wide roads made for container vehicles and factory blocks were amalgamated and transformed into large blocks with development Plot Ratio of 5 to 6. These modifications to plot sizes and plot ratios adversely impacted on the urban porosity.

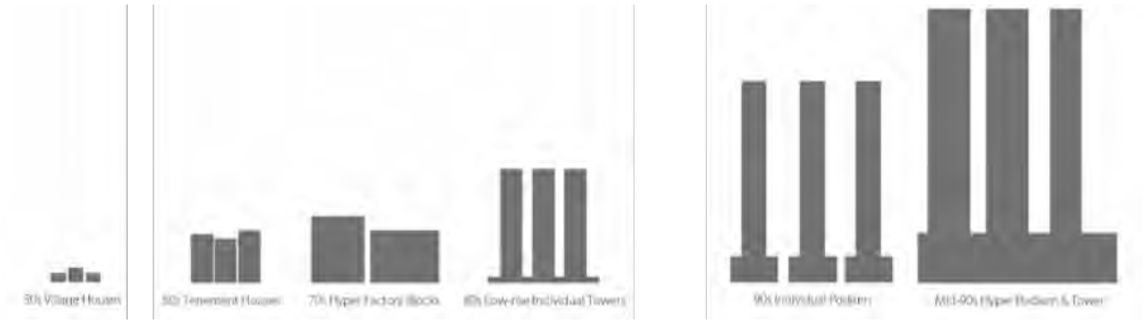

Figure 1: Evolution of building typologies in Tsuen Wan from 1950s to 2015

In Hong Kong distance between building blocks is governed by the vertical light angle requirement of 71.5 for habitable areas with a minimum 10% glazing area out of the floor area. As a result, distance between buildings became narrower resulting on lack of air and light penetration into lower levels.

1.1 Emergence of cruciform and quasi-cruciform residential typologies

In private residential developments, in order to maximize the gross floor area within given plot ratios, residential typologies began to evolve into plan forms that deliver higher spatial efficiency and daylight and natural ventilation penetration. Hong Kong building regulations stipulate minimum perpendicular distance between windows of habitable rooms in different blocks within the same site. Cruciform plan form and its mutations were the most feasible option; staggering building envelope of cruciform plan eliminates perpendicular obstruction between towers although adjacent towers are closely built. Most these developments also consisted of external features such as protruding drying racks, bay windows, planter boxes etc.

Most developments adopted bay windows instead of balconies as bay windows were exempted from the gross floor area (GFA) calculations. In 2001, GFA exemption was granted for balconies; 50% of balcony area that is not less than 2 m^2 became a value added sustainable feature in many new developments (Buildings Department, n.d.). Majority of hyper podium residential towers in Hong Kong are of cruciform geometries in order to increase number of flat units per floor that have daylight access.

For the purpose of this study, we calculated building volumes of square, rectangular and cruciform plan tower developments in Tsuen Wan as of 2015. Figure 2 indicates the predominant presence of quasi-cruciform towers in Tsuen wan compared to square plan form and rectangular plan form building volumes. Cruciform developments consist of 19.16 million m^3 whilst square representing 5.6 million m^3 and rectangular plan form towers representing 12.6 million m^3.

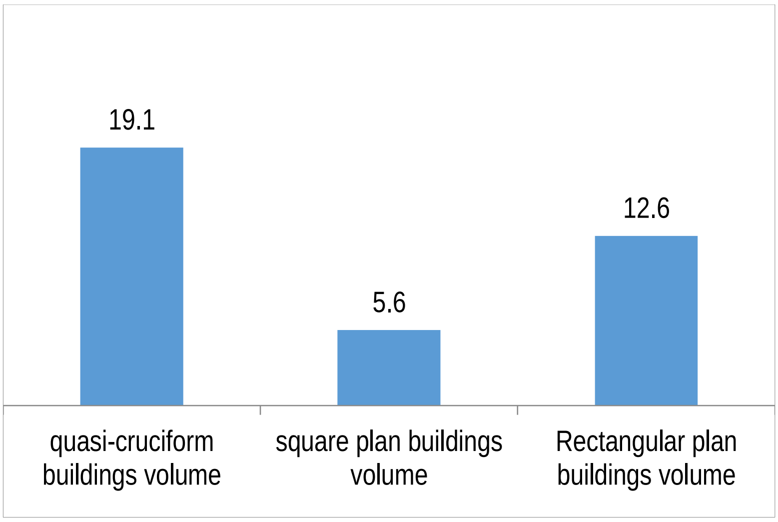

Figure 2: Building volumes three different building geometries in Tsuen Wan in 2015 in million m³

2. RESEARCH DESIGN PARAMETERS

A factory estate within Tsuen Wan that has prospects for redevelopment was considered as the experimental site: this existing factory estate was hypothetically replaced with eight podium developments that consists of 37 towers. These towers represented four variations of building geometries that were simulated for wind performance. These four variations are: square plan towers, quasi-cruciform plan towers, cylindrical towers and quasi-cruciform towers with balconies (Figure 3). Wind performance at 2m pedestrian level, 30 m and 50 m height above ground level was measured. All buildings were approximately similar in floor plate area and distance between towers.

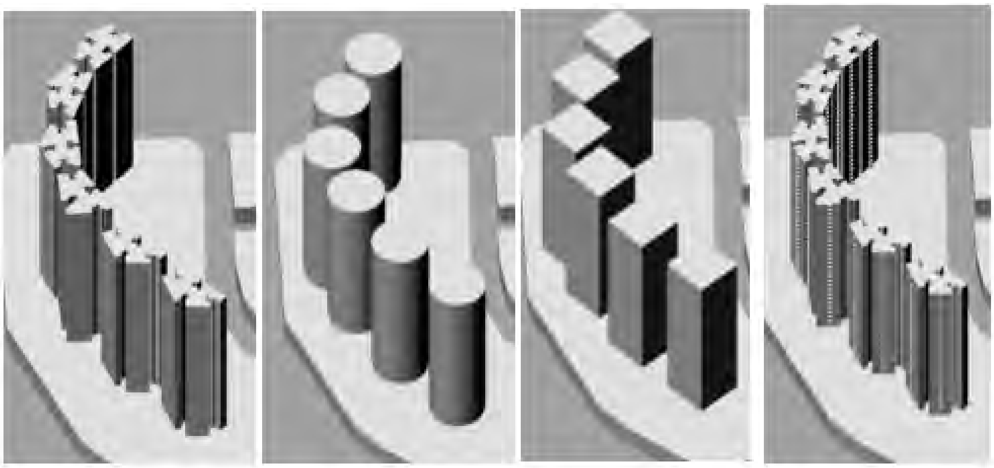

Figure 3: Four different building geometries tested for their impact on urban ventilation

2.1 Wind simulation parameters

All protocols stipulated in Hong Kong Air Ventilation Assessment Framework were followed in setting parameters. Simulations under seven strongest wind directions (E, ESE, ENE, NE, SE, S, and SSW) that represent over 76% of annual wind frequency were carried out for each case.

Inflow wind profiles are adopted from RAMS data from Hong Kong Planning Department's website. Inflow turbulent kinetic energy profile and corresponding dissipation rate profiles are estimated using the following equations where u* is the frictional velocity, Cμ =0.09 and κ=0.4.

$$k = \frac{u_*^2}{\sqrt{C_\mu}} \qquad \varepsilon = \frac{u_*^3}{\kappa(z+z_0)}$$

Equation 1

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Computation Fluid Dynamics ANSYS FLUENT solver (Fluent Inc., 2006) with the Realizable k-e turbulence model was used for wind simulation adhering to the parameters described in Hong Kong Air Ventilation Assessment framework. Strength of the Reynolds number is referred to explain laminar and turbulence air flows. The model spans a distance of 2700m with inflow wind velocity of 6 m/s at boundary layer height, as for the formula of Reynolds number

$$Re = \frac{UL}{\gamma}$$

Equation 2

In which, U = Length Scale (Order of 102 to 103) for Tsuen Wan district, the length scale is around 2700 meters for our study area.

L = Flow Velocity (Order of 100) from our wind velocity profile, around 6 m/s for inflow wind velocity at boundary layer height.

γ = Kinematic Viscosity of Air (1.72* 10-5). Therefore, the simulations were carried out under high Reynolds number of order of magnitude of 109

Unlike in a building scale AVA study, in a city scale study it is important to adopt a practicable and reasonable resolution and a scale for simulation. Typically recommended 8million cell resolution did not facilitate smooth operation of the software for this city scale analysis warranting an increased resolution of 15million cells. Selection of an appropriate turbulence model is crucial in CFD simulation studies. RANS k-ε k-εfamily steady turbulence model are commonly practiced for carrying out parametric studies on wind flow problems. Out of the three variations of RANS k-ε k-εmodels, 'Realizable k-ε model' proposed by Shih et al. (1995) were adopted due to its ability in predicting more physically realistic turbulence properties with a varying model coefficient of C_μ which modifies the turbulent viscosity term. Following the recommendations in CFD guidelines (Franke, 2007; Tominaga, et al. 2008; Mochida et al., 2002), the study adopted a rectangular computational domain with symmetric boundary conditions at the two side boundaries and the upper boundary. For our computation, the inflow boundary condition is set as the velocity inlet boundary condition and the outflow boundary as the outflow condition. Unstructured tetrahedral cells of approximately 8-15 million with maximum expansion ratio were created in the mesh with other settings as referring to the COST Action C14 (Franke et al., 2011) and the Architectural Institute of Japan (AIJ) guidelines (Tominaga et al., 2008; AIJ 2007).

3. EFFECT OF BUILDING GEOMETRIES ON WIND SPEED

3.1 Urban ventilation trends from 1960 to 2015

This study examined the effect of building geometries on urban wind speed taking into consideration three different plan form variations and one variation with balconies. In order to establish a rational and scope, this study also developed historical wind profiles from 1960 to 2015 considering urban fabric changes in every ten years and historical wind profiles from 1997 to 2015 to verify results with every three-year development changes in Tsuen Wan city centre (Figure 4).

Progressive developments in Tsuen Wan new town resulted in the reduction in urban porosity from 51% unbuilt area in 1960 to 6.1 unbuilt area in 1990 negatively impacting on the pedestrian zone wind speed. Weighted average scores from fifty strategically placed test points within the study area reported a decline in pedestrian wind speed in parallel to reduction in unbuilt areas. However, the reduction in wind speed was 0.7 m/s from 1960 to 1990 in parallel with approximately 45% reduction in urban porosity, compared to the sharp drop in the wind speed from mid 1990s onwards (Figure 5).

Two significant development typologies attributed to this noticeable decline in the wind speed; a decline from 2.97 m/s to 2.5 m/s with the introduction of 'hyper factory blocks' in the 1970s followed by another sharp decline from 2.27 m/s to 1.88 m/s with the introduction of 'hyper podium and tower' developments in mid 1990s. Approximately 1.1 m/s reduction in the wind speed can be observed in the year 2000

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

compared to 1960s (Figure 5). Alarming impacts from hyper podium developments calls for attention to the way we design buildings.

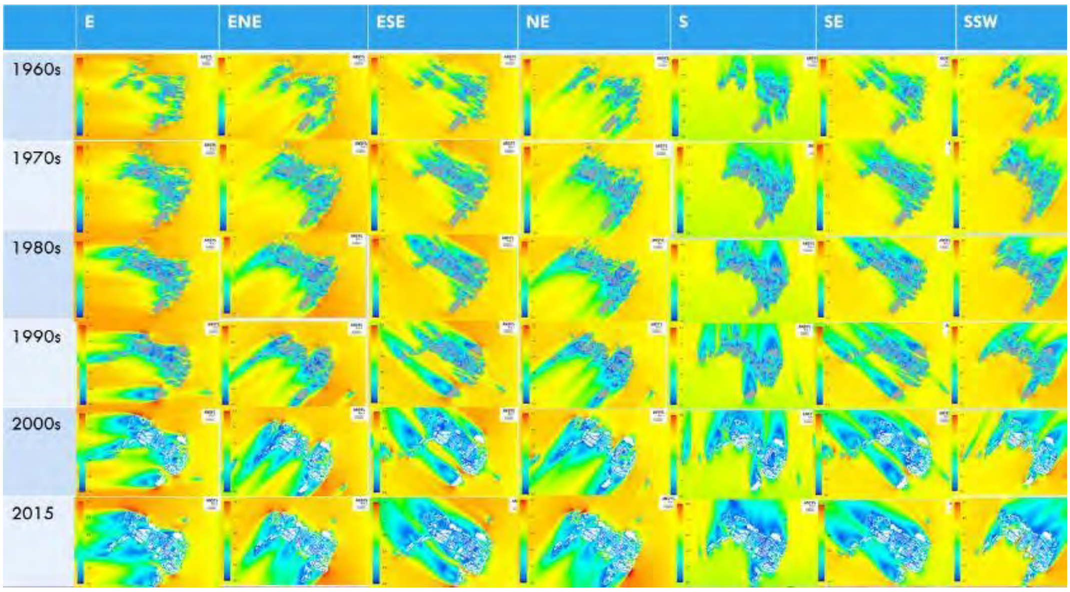

Figure 4: Ten year interval historical wind profiles from 1960 – 2015

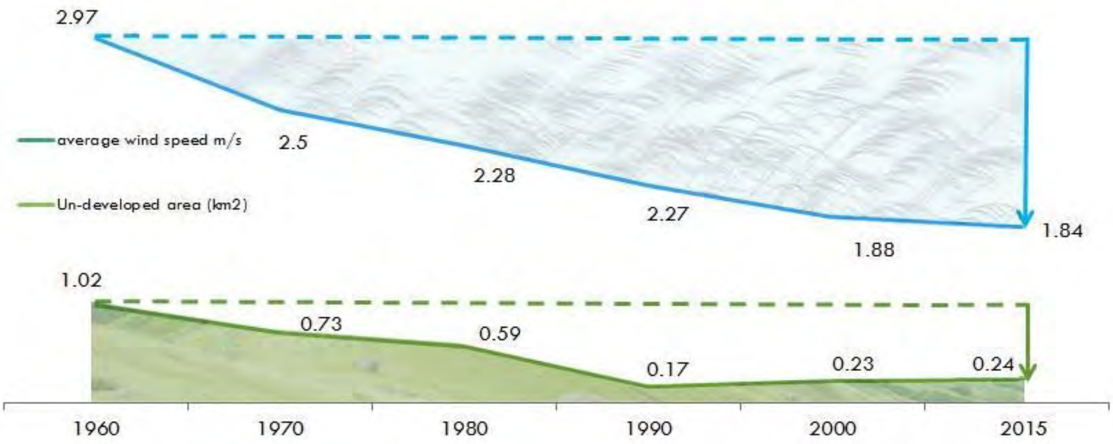

Figure 5: Correlation between pedestrian level ventilation and reduction in undeveloped land area in Tsuen Wan from 1960 – 2015

3.2 Creating sustainable neighbourhoods with better urban ventilation

Thermal comfort is a key consideration when designing liveable and sustainable neighborhoods. Poor air quality, urban heat island effect and extremely high humidity levels are some of the factors attributed by stagnant urban ventilation levels effecting liveability in urban Hong Kong. Effect of building geometries have been studied as a means of manipulating urban ventilation (Norberg, C.1987, Williamson, C. 1996). Findings reported distinct wind behavior patterns around these four building geometries with cruciform towers and cruciform towers with balconies reporting higher wind speeds around them compared to cylindrical and square towers. Results were consistent at 30m height and 50m height. These findings are supported by a study conducted by Montazeri, H. et al. (2013) which reports the contribution of uniform second skin façade to equalize wind pressure in balconies in high wind zones. Cylindrical forms facilitate more steady streamlined flow or laminar air flow around the surface. Whereas cruciform geometries facilitate erratic air flow around the edges due to resistive forces thereby creating air turbulence increasing wind speed around the buildings. In cruciform geometry, the envelope is rougher and therefore the friction between air and the envelope is higher; greater the friction between the layers, greater the drag. Results also indicate improvement in wind performance at upper zones compared to lower zones due to ground level friction which behaves differently from building envelope friction. Wind speed at the pedestrian zone can be unpredictable due to urban roughness variations; however, wind speed results at 2m high zone is seemingly consistent with 30m and 50m high zones.

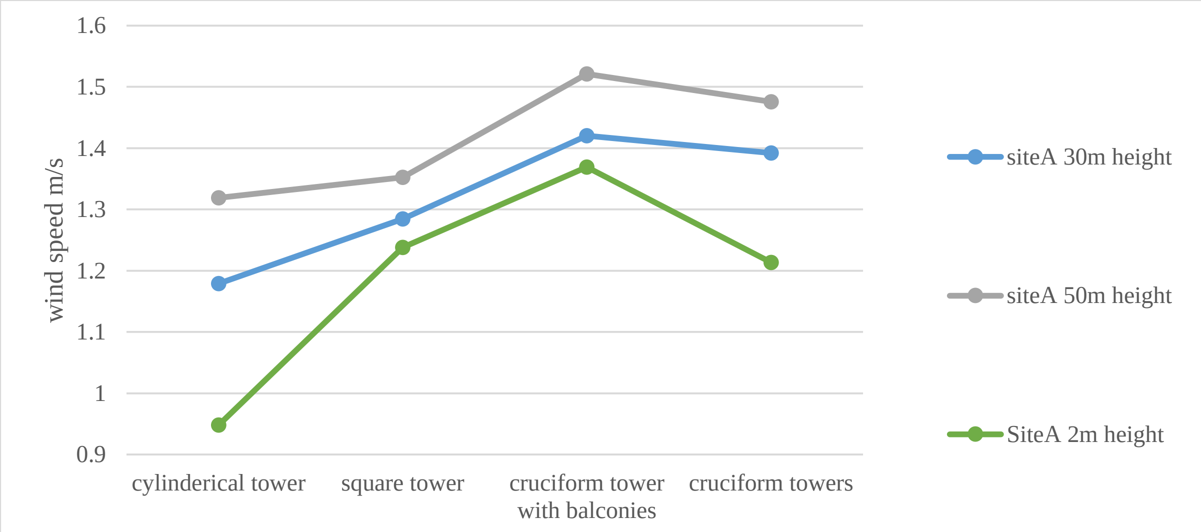

Figure 6: Building geometry impact on wind speed at different height zones

4. CONCLUSIONS

This study established a correlation between urban porosity and urban wind speed and the impact from various building typologies on wind speed since 1960 until 2015. Wind simulation results in the year 2000 indicated adverse impacts on wind environment by hyper podium tower developments emerged in mid 1990s. Adverse impacts were also notable around massive podiums due to wind amplification on the windward side. Cruciform towers reported better wind movement around them, however the gap between these towers influence ventilation levels.

This study contributed to the advancement in built environment knowledge by developing historical wind profiles from 1960-2015 and identifying the effect of development trends and building typologies on urban ventilation. Results from 3 year interval analysis and 10 year interval analysis confirm the adequacy of 10 year interval analysis for development of historical wind profiles at city scale. These findings may serve as a reference for future development of sustainable and liveable neighborhoods with improved outdoor thermal comfort.

Findings from this study established the contribution from cruciform towers and balconies as a green feature in improving urban ventilation speed thereby their creating sustainable neighborhoods. Findings also call for review of residential development and CDA policy in order to create desirable pedestrian wind environments and thermal comfort levels.

ABSTRACT

Purpose: Evidence suggests that in the area of public health, action on climate change can bring multiple health co-benefits. In Australia, while the 'co-benefits approach' is adopted by local governments in pursuing low carbon policies, the approach is limited in targeting certain 'energy-related' monetary benefits. 'Non-climatic and non-energy-related' benefits, which include significant health-related gains, rarely enter climate change-related policy discourse. This paper addresses the gap by contributing to current understanding of the 'co-benefits approach' in the Australian local government context. The aim is to determine whether, how and to what extent local governments' low carbon policies embrace the public health needs of their communities by targeting health-related co-benefits as an integral part of broader sustainable development strategies. The paper also provides an insight into the Australian local government policy context to enable better understanding of how to plan, generate and promote health-related co-benefits for urban built environments.

Methodology: The research methods comprised a comprehensive online survey and review of NSW councils' climate change-related policies, as well as interviews of selected council officers.

Findings: The findings show that NSW local governments' climate change-related policies rarely consider whether their greenhouse gas reduction strategies also yield health co-benefits. In many instances, the net co-benefits of health are not identified, let alone measured by local governments. In the majority of councils, climate planning activities and work on public health are happening separately and in parallel, rather than through an integrated approach.

Conclusions: The results of this study suggest the need for a clear policy direction from the State to local governments to link climate change planning with health; inter-agency coordination and training to conduct health analyses; development of tools, methods for identifying, quantifying, and incorporating health-related co-benefits; and regulatory or statutory changes to support actions in certain areas which are currently beyond local governments' sphere of control.

Keywords: Australia, built environment, climate change, health co-benefits, health and wellbeing, liveability, local government, low carbon policy, urban planning

1. INTRODUCTION

While climate change continues to be the hotly contested around the world, the 2015 Paris Climate Agreement has shifted the focus of this debate. There is now acceptance of the scientific certainty of climate change but disagreement identifying appropriate policy responses to mitigating climate change (Lewis, 2015). An urgent, high-priority global response is required through international negotiation of coordinated national policies for large-scale reduction in global emissions. At the national level policy-makers are now faced with the challenge of balancing the immediate interests of development needs with the long-term interests of stabilising the global climate.

On the one hand, climate change is a global commons problem that warrants a coordinated global response (Edenhofer et al., 2013; Ostrom et al., 1999). On the other hand, its source, greenhouse gas (GHG) emissions, is increasingly seen as being produced and most readily controlled at the local level (Revi et al. 2014). Achieving particular mitigation goals, such as limiting warming to 2°C, is most cost effective when approached from a worldwide perspective and results in high long-term international benefits at considerable short-term costs (Clarke et al., 2009). However, most climate policies are increasingly formulated at national and even local levels, where many of the non-climate objectives are often more salient as policy drivers (Dubash et al., 2013; Seto et al., 2014;

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Somanathan et al., 2014). Because most co-benefits, unlike the primary benefit of greenhouse gas mitigation, are enjoyed typically at regional or local scales, are closer to the agents bearing the mitigation costs (typically the taxpayers and/or the consumers), have more immediate welfare effects (Markandya and Rübbelke, 2003) and easier to measure. Hence, they provide incentives for decision makers to engage in stricter climate action and are considered more politically feasible.

Hence, local governments are uniquely positioned to create large reductions in GHG emissions because of their impact on local patterns of urban development, economic activity, transportation infrastructure, and energy use (Rosenzweig, et al. 2010; Anguelovskik and Carmin 2011). However, the primary focus on cost minimisation at the local government level has largely limited climate policies targets to reducing GHG emissions cost, together with the attainment of 'energy-related' monetary savings. In Australia, while the 'co-benefits approach' is adopted by local government in pursuing low carbon policies, the focus is largely economic. Non-climatic and non-energy-related benefits, which include significant human health outcomes from better air quality, active transport uptake, improved 'liveability' and the creation of local jobs (IPCC 2014, Woodcock et al. 2009; and Hickman 2013), rarely enter climate change-related policy discourse. Indeed, there is limited understanding of these co-benefits in the Australian context (Philp, Taylor and Thompson 2015).

The purpose of this article is to determine whether, how and to what extent Australian local governments' climate change-related policies consider the public health needs of their communities. Do policies target health-related co-benefits as an integral part of broader sustainable development strategy? The paper also provides an insight into the Australian local government policy context to enable better understanding of how to plan, generate and purposively promote health-related co-benefits in planning urban built environments.

1.1 Emergence of co-benefits in climate change mitigation

The 'co-benefits concept' emerges internationally as an important paradigm for analysing, developing and implementing policies and strategies that simultaneously contribute to tackling climate change whilst addressing local environmental and developmental problems. The concept is not rigid with clearly identifiable boundaries and there is no common definition of 'co-benefits' in the academic literature. In policy discourse, positive impacts of policies and programs that occur in addition to the intended primary policy goal are commonly considered as co-benefits. However, in climate change-related policy discourse co-benefits are widely understood as the collection of benefits accruing to actions linking climate change and other development priorities. This understanding is based on the definition of co-benefits found in the Intergovernmental Panel on Climate Change (IPCC)'s Third Assessment Report where co-benefits are defined as:

"the benefits of policies that are implemented for various reasons at the same time – including climate change mitigation – acknowledging that most policies addressing greenhouse gas mitigation have other… equally important rationales" (Metz et al., 2001).

This definition focuses on simultaneous effects of policies specifically introduced with explicit intention to integrate climate change response benefits with other fields. According to this definition the 'explicit intention' and integration of policy measures are considered essential in order to qualify for a 'co-benefit principle'. We adopt this definition of 'co-benefits' as it appropriately suits the scope and objectives of this paper.

Over the past two decades, a growing number of studies have demonstrated that a 'co-benefits approach' could prove more cost effective than managing climate and development issues in isolation (Davis et al., 2000; Pacala et al., 2010; Burtraw et al., 2003). With increasing global attention and interest in mitigating GHG emissions since the 1990s, several studies indicated that GHG mitigation policy co-benefits could be the same order of magnitude as the cost of implementing the policies (Davis et al., 2000, Pacala et al., 2010). Several studies around the turn of the millennium found that co-benefits could significantly reduce the net costs of GHG reduction efforts (Burtraw et al., 2003). These studies demonstrate that 'Co-benefits approach' has the strength to reframe climate change mitigation in a positive and constructive 'win-win' way and thereby prevents framing issues in terms of trade-offs. In this respect, 'co-benefit approach' has the potential to become more relevant as an alternative paradigm which can be positioned complementarily to the post-Kyoto evolving global climate policy regime. Co-benefits are relevant not only for the economics of climate change mitigation, but also for the politics of climate policy-related decision making.

1.2 Climate change and health in Australian local government

In Australia, there are unique challenges to addressing climate change with respect to health and wellbeing. There is limited understanding and public awareness of the link between health and climate change, although this is changing with the work of The Climate and Health Alliance (Woodcock et al., 2009). Nevertheless, the health implications of climate change have been given a relatively low priority in climate change-related policy debate (Smith and Capon, 2011).

Climate change is unlikely to cause new health problems for city populations, rather, it will exacerbate existing urban health problems (Bambrick et al., 2008; Friel et al., 2011). The health impacts of climate change will be influenced by a range of factors such as environment, socioeconomic circumstances (at country, regional and personal levels), infrastructural and institutional resources, underlying physical vulnerabilities and local preventive (adaptive) strategies (IPCC, 2014).

This will be significant for Australia as it already experiences climate extremes in temperature and rainfall that are projected to become even more extreme (Climate Commission, 2011; Bureau of Meteorology, 2012; CSIRO, 2007; Climate Commission, 2013). Further, Australia is one of the most highly urbanised countries in the world with over 89% of the population living in cities (Commonwealth of Australia 2010a). With the population projected to grow 40% to 35 million by around mid-century, the way Australian cities perform environmentally, socially, economically and physically will largely determine the magnitude of the health impacts from climate change (Commonwealth of Australia, 2010b).

While the health system will have its role to play in planning services to mitigate these health impacts (Burton et al. 2014; Ebi et al. 2006), the local councils collectively tasked with planning the nations' cities, will need to play a major role in mitigating the health impacts of climate change (Capon 2010; Frumkin 2002) working in collaboration with health agencies across government, private and the not-for-profit sectors.

Although local government has limited power and resources to provide health services, many councils provide a range of direct health services to their communities which respond to varying local needs and conditions. Councils also provide a number of services generally not considered to be directly related to health, but they nevertheless deliver clear and demonstrable local health benefits. For example, council health associated services include, but are not limited to: municipal waste collection; food inspection; (in some states) the provision of maternal and child health centres; immunisations; programs to encourage community health and fitness, such as nutrition awareness and healthy weight loss programs; the establishment and/or maintenance of sports and recreation facilities, bicycle paths, and walking tracks; and traffic calming measures (CoA, 2010; NSW, 1993).

The link between climate change and health is not however well recognised at the local level. For example, the NSW government identified the roles local councils could play as key actors in adapting to the local impacts of climate change in the NSW Greenhouse Plan (NSWGHP). The NSW Local Government Act 1993 provides councils with an extensive list of functions, many of which could potentially be affected by climate change. For example, councils control land use, development and building in their areas; and they manage and maintain infrastructure, such as roads, bridges, public buildings, recreational areas, storm water systems, water supply and waste facilities. Thus, councils are considered ideally placed to provide a localised response to the climate problem (CoA, 2010; NSW, 1993) but the potential to address health issues in this context is not broached.

Within this context, from a local government perspective, environmental services, health services, health promotion and preventive health policies, should not be seen in isolation. Climate and health policy and programs at the local government level, therefore, must be integrated to address climate change with respect to health and well-being.

2. METHODOLOGY

This research used a combination of qualitative and quantitative methods. Qualitative research involved documenting and critiquing information from the literature, a desktop review and analysis of policy documents available in the public domain, and conducting in-depth interviews. Quantitative research involved assessment of data from a comprehensive on-line survey questionnaire.

The geographic area of investigation for this study was the Sydney Greater Metropolitan Region (GMR) and surrounding localities (See Figure 1). The investigation focused primarily upon policy processes at local government level, but the research also looked into the links of local to state, and broader national processes.

The research comprised three distinct phases. Phase one was a comprehensive online survey. Phase two comprised the desktop review and analysis of the selected council policy documents. Phase three was the in-depth interviewing of selected council officers.

Table 1: Distribution of participated councils in on-line survey

2.1 Selection of councils with local climate change policies

The first stage of phase one was a targeted on-line survey of councils using a comprehensive questionnaire. This was conducted from July to December 2015. Based on the policy responses to climate change found in the survey, participating councils were categorised into three distinct groups. Councils who have:

Category A: Specific Climate Change Policy;

Category B: Climate Change Addressed Broadly Under 'Sustainability' (but no specific policy for climate change); and

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Category C: No Climate Change Policy (but measures adopted mainly to reduce energy consumption which results in GHG reduction and other benefits). (See Table 2)

Subsequently, a data-driven set of three indicators were developed to assess the extent of policy responses to climate change and targeted policy benefits. These indicators are: i) Types of mitigation measures; ii) Policy integration; and iii) Targeted co-benefits. This information was then used in two ways in analysing the findings.

First, the total number and percentage of councils undertaking measures related to each indicator were calculated. This information is collectively presented to give an overall picture of the extent of adoption of a 'co-benefits approach' across the three categories of councils. This gives a broad quantitative picture rather than an assessment of the quality of each measure under the three indicators (see Table 2).

Councils were then selected from the three categories to evaluate in detail their climate change policies. The objective was to determine whether, how and to what extent, these policies target health-related co-benefits alongside other benefits (see Table 3).

2.2 Evaluation of council climate change policies for health co-benefits

In phase two, a qualitative review of selected council (as identified in phase one) climate change policies and plans was undertaken. The purpose of this review was to examine specific climate change-related and emissions reduction measures and their associated health-related co-benefits. An assessment of all aspects, actions and benefits of each policy document was not undertaken.

In phase three, in-depth interviewing of selected council officers (n = 11) was conducted from February to May 2016. The investigation specifically focused on exploring and understanding the variation in council policy responses to climate change across NSW. Of particular interest were the range of benefits obtained through the policies and council perceptions of the 'co-benefits approach', especially with respect to health-related co-benefits in the climate policy making process.

This study was approved by the University of New South Wales (UNSW) Human Research Ethics Committee.

3. RESULTS

In this section, findings are presented from the data generated by the online survey. This reporting is supported with analysis from the review of policy documents identified in the survey and key findings from interviews of selected council officers.

Out of the 152 NSW councils, 75 participated and completed the survey. Among the 75 councils: 38 are from the GMR of Sydney (out of total 41 GMR councils) and the remaining 37 councils are from across the surrounding areas beyond the GMR (see Table 1).

3.1 Variations in council climate change policies and targeted co-benefits

In terms of policy responses, the overwhelming majority of councils in NSW (i.e. 86.3% or 63 of the 73 respondents) reported they have some form of policy in place to address climate change. Conversely, only 13.69% (n = 10) reported they have neither a policy nor any action plan to address climate change. Only 56.16% (n = 41) councils reported that they have a 'specific climate change policy' (see Table 2).

COUNCILS' RESPONSES TO CLIMATE CHANGE		LOCATION OF COUNCILS		TYPES OF MITIGATION MEASURES			INTEGRATION WITH OTHER POLICIES		TARGETED CO-BENEFITS			
					Non energy related				Climatic and Energy related		Non-climatic and non-energy related	
		GMR (n = 38)	Beyond GMR (n = 37)	Energy related	Waste	Active transport	Integrated	Not Integrated	Economic	Environmental	Health	Social
CATEGORIES OF COUNCILS	**A. Specific Climate Change Policy** (n=41)	22	19	40	37	33	25	16	41	39	07	09
	B. Climate Change Addressed Broadly Under 'Sustainability' (n=22) (but no specific policy for Climate Change)	11	11	22	19	11	13	09	21	21	04	05
	C. No Climate Change Policy (n=10) (but measures undertaken to reduce energy consumption that also result in GHG reduction)	05	05	08	06	03	01	07	07	05	00	02

Table 2:

It was found that councils who perceived climate change as a major policy issue by adopting a specific or dedicated climate change policy (n=41, 56.16%), managed to enhance their climate change actions by targeting more areas. This is evident from the data which show that councils with a specific climate change policy more effectively integrated climate change actions across different sectors in a consistent manner. This results in achieving maximum policy benefits compared to councils that do not have a dedicated climate change policy (n=22, 30.13%) (see Table 2. row A, B). Councils which do not have either a dedicated policy or strategy for climate change, generally address 'climate change' under the term 'sustainability' as one of the many components of their Community Strategic Plan (CSP) (see Table 2, row B).

Generally, it is observed that councils located in the GMR with higher populations (over 50,000 inhabitants) are undertaking more climate change-related activities which result in more benefits than councils which are located outside the GMR with smaller populations (less than 15,000 inhabitants) (see Table 3).

Table 3: Targeted co-benefits of councils' climate change policies

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.2 Preference for 'climate- and energy-related' co-benefits over 'non-climate- and non-energy-related' co-benefits

While councils in NSW generally do not purposively adopt a 'co-benefits approach', nor explicitly mention this in any of their policies, adoption of a 'co-benefits approach' is clearly evident in the wide range of benefits resulting from these policies (see Table 2, column - Targeted Co-benefits). The response of one of the interviewed council officers illustrates this well:

… anything that we [council] can do is to refer to the objectives in the community strategic plan… [and]… these are related to environmental and social objectives… when we are producing policies we have to give alignment to these objectives and… all [are] about [technically] environment, efficiency with use of resources, caring inclusive communities… that's the main avenue to demonstrate how a proposal is proposing to align with those objectives we need to deliver as a council… it [co-benefits approach] is not formalised. There is no clear tool to say what the co-benefits are. You are simply putting words together to have a strategic reason to implement a policy and then whether the policy gets delivered or not that is another question. (Council officer interview 2016)

Irrespective of whether councils have any specific climate change policy or not, most were found to pursue measures that relate to climate change. Many of these measures relate to mitigation (see Table 2, column – Types of Mitigation Measures). While these measures are not always 'explicitly intended' to reduce GHG emissions, their adoption generally results in reduction of emissions as a 'co-benefit' along with the specific benefits targeted by these measures.

The indicator for adopted 'Mitigation Measures' (n = 179) illustrates a clear preference for 'energy-related mitigation measures' (n = 70; 39%) among the majority of councils compared with other mitigation measures such as 'active transport' (n = 47; 26%) (see Table 2). The potential for reducing consumption of energy, and therefore, GHGs, as well as making significant monetary savings, predominantly motivated this adoption of 'energy-related mitigation measures'.

As councils predominantly consider 'financial savings' as the main criterion for the selection of measures to reduce emissions, when considering the benefits from these measures the emphasis is overwhelmingly on 'financial benefits' (see Table 2, column - Targeted Co-benefits). This is mainly due to the current nature of local government policy discourse which stresses the need for quantification of results and concrete outcomes. In such a context, policy measures are negotiated mainly within an economic frame of reference. This is reflected in the following statement by one of the interviewed council officers:

…investment in mitigation is primarily seen as bit 'meeting a business case'… maybe reducing the 'operating over-heads' of the building, for example, it's utilities of the building or maybe some driver in terms of efficiency… there is a need to demonstrate a 'business case'. Sometime that 'business case' could be quite marginal. Only then other 'non-monetary benefits' factor comes into it. (Council officer interview, 2016)

This clear preference for certain (quantifiable) monetary benefits only reflects GHG abatement and its associated fiscal savings as the main outcome from reduced energy use. Non-climatic benefits also result from these measures. They include 'non-energy-related benefits' such as health benefits from better air quality, active transport use, improved 'liveability' and access to locally created jobs. And while all of these have potential monetary savings for the health budget, they are not explicitly considered in the decision making process.

3.3 Consideration of health co-benefits in councils' climate change policies

In reviewing the councils that have climate change policies (n = 41), only seven (17%) have specific plans that explicitly consider the health co-benefits of adopted mitigation measures (see Table 3). However, nearly all these councils qualitatively describe health co-benefits in their relevant policy documents through graphic icons and bullet points. The graphics simply describe that the measures are selected for their potential to improve local air quality, decrease obesity, improve public health, and create a healthy living environment. This qualitative evaluation lacks a methodology as well as reference to evidence to support the claimed health co-benefits. Health co-benefits are also listed qualitatively alongside quantitative matrices that analyse the potential of these councils' climate change-related measures to reduce GHG emissions and achieve cost savings. These observations are echoed in the comments of the interviewed council officers. As one said:

Measuring those 'non-monetary health benefits'… it's a difficult one and it's one that I am not sure that we as a Council successfully measure that well. It's still like an evolving field. It's a bit like the issue of the active transport. There is a body of theories which says that if you make any area more attractive for pedestrians and cyclists that the local economy would benefit rather than having traffic going through the area. And that's an emerging body of evidence. But we don't necessarily at the local level yet really quantify some of those things. So when we invest in cycle paths we say that's good for people to get them out of their cars and there is health benefit for it. It makes people happier, it gives people sense of pleasure, it reduces the stresses of sitting in a traffic jam and but it's also maybe benefitting local economy because people riding pass may stop, shop and buy something… but we have not quite got there yet in terms of measuring the 'non-monetary' side of things. (Council officer interview, 2016).

4. DISCUSSION

The findings of this research indicate that while local governments in NSW purposively consider certain 'climate- and energy-related' co-benefits of their climate change-related policy measures, these are in the main quantifiable. 'Non-climate- and non-energy-related' co-benefits that also result from these measures are not considered, quantified, or even identified by local governments. This totally misses a swathe of health co-benefits arising from better air quality, active transport, improved 'liveability' and local job creation which are outcomes of climate change-related policy measures. This means planning for climate change and improved public health in the majority of NSW councils are currently not happening through an integrated approach. While this study identified limited number of local governments with specific climate change policies (n = 41; 56%), those policies can be easily judged as modestly effective due to their failure to incorporate health co-benefits. This study has identified a number of critical issues which have significant bearing on the possible incorporation of health co-benefits in the climate policy making process for NSW local government.

The existing regulatory framework within which local government currently operates determines the level of authority and control they can exercise over certain areas or sectors (NSW, 1993; CoA, 2010). This influences councils in their choice of mitigation measures. While councils have effective control over their buildings, vehicle fleet, other assets and facilities, and therefore achieve significant GHG abatement in emissions through adopting energy-related mitigation measures (see Table 2, Column – Types of Mitigation Measures), the same is not the case for emissions from the community. Councils generally have relatively little control over its citizen's energy consumption patterns and a host of other areas such as major land-use planning decisions, transport infrastructure, energy supply and addressing the demand for energy. This limited authority causes frustration among local government policy makers as evident in this officer's statement:

… I find that local government does not have that much planning control... I think that's another push back! When I was drafting this document [climate change strategy] I was looking at different actions that we could do... if I talk to the planners, the transport planners or transport engineers or the infrastructure people – they be like 'Oh! That's with State Government, our hands are tied... we can't do anything... that's State Government, that's State Government, that's State Government!' So any kind of change we want to make - lot of the time it's just 'That's not us, that's State Government' (Council officer interview, 2016).

Given that local councils operate with limited resources and there is no immediate return from prioritising limited expenditure to undertake such measures, the majority of councils lack incentives to pursue health benefits. One of the councils participating in the online survey clarified the position in this way:

Many of the additional benefits that can or will accrue to the community are not the responsibility of local government [i.e. health, employment]. Even if the 'monetary quantification' of these benefits was known or could be estimated, there is no return available to local government for prioritising our limited expenditure.

The above findings suggest that councils' over reliance on 'monetary considerations' and 'monetary quantification' in targeting benefits, coupled with their reluctance to undertake certain 'non-energy-related' mitigation measures that are not perceived to have any positive budgetary impact at the local level, excludes a wide range of environmental, social and health benefits from incorporation in the policy process. These 'non-climatic and non-energy-related benefits' include the most important and significant category of health-related benefits such as those from better air quality, active transport, improved 'liveability' and local job creation. Exclusion of these benefits from

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

incorporation in the policy process limits the potential for councils and their communities to achieve maximum policy benefits from climate change-related policy measures.

In terms of policy responses, this study has found that currently there is no clear direction for local governments from either Federal or NSW State Government with regards to climate change. In the absence of such direction, local government mainly leverages state government's energy-related policies and limited funding available for addressing climate change. As one of council officer noted:

There is no directive from Federal or State for us to have a climate change strategy. They are not forcing us to do that. So in that sense there is no direction. However, there are different levels of support and documents we can look to… (Council officer interview, 2016).

In this context, planning for climate change at local government level is primarily driven by the dual objectives of reducing GHG emissions and energy consumption. At present NSW State's climate change-related policies provide local governments with neither any direction regarding how to consider health in planning for climate change, nor any necessary tools or funds to conduct more extensive analyses of the health co-benefits of their climate change-related measures. As such, many councils consider public health benefits too far removed from their sphere of influence or benefit. This means that the focus of their climate change policy remains on reducing GHG emissions in a cost effective way and targeting monetary savings from reduced energy use.

A broader climate change policy agenda is needed to shift climate change-related activities at the local government level. Climate change and public health need to be addressed in an integrated and holistic manner. For this to happen, local government requires a clear policy direction from the State. Based on our assessment of local government climate change-related polices and interviews with local government officers, three policy areas are proposed. This is where the NSW State and local governments can focus to incorporate health co-benefits in climate change policies at the local government level.

First, State Government should mandate local councils to develop dedicated local climate change policies. As part of this, the State needs to provide adequate funding for conducting full health co-benefit analyses of the resultant climate policies. The challenge for such a task is the resourcing required to generate substantive public engagement programmes and cross-sector/multi-dimensional impacts analyses. However, the benefit of undertaking such a task is likely to more than compensate the initial investment for this purpose. This will enable local governments to broaden their focus to consider health co-benefits in their climate policies, alongside energy-related benefits. This will help local governments extend a co-benefits approach 'beyond energy efficiency and monetary savings' incorporating broader co-benefits of low-carbon policies to include 'non-climatic and non-energy-related benefits' of low carbon measures.

Second, this research shows a limited understanding among policy makers about the 'co-benefits approach', particularly in terms of how to frame climate change policies to include and quantify health-related co-benefits. The motivation behind a limited adoption of the co-benefits approach is currently driven by the monetary benefits to be gained from emissions reductions, though the potential for achieving better air quality, creating local jobs, improved health and urban 'liveability' are also considered. However, these very difficult to calculate long term benefits get side-lined in a policy discourse that stresses the need for immediate quantification of results and direct outcomes. Accordingly, co-benefits research should focus on developing tools and methods (including calculators, indicators and indices) to help policy makers estimate, quantify and monitor health and other non-energy-related co-benefits of different policy interventions.

Finally, the findings of this research demonstrate that while adopting co-benefits approach local governments can construct climate change mitigation as a local issue which can be reconciled with local priorities (i.e. energy efficiency and monetary savings) that reduce greenhouse gas emissions. However, the extent to which co-benefits approach can work beyond the bounds of local government is a crucial question for research. This is particularly relevant when scaling up the emission reduction targets and extending a co-benefits approach to include non-energy-related health benefits. These involve actions in areas such as land-use planning, transport provision, and addressing the demand for energy that require deeper policy shifts, which in turn entail legislative changes.

5. CONCLUSION

This article has provided an insight into the public health aspects of NSW local government climate change-related policies. The specific objective has been to understand the extent to which local councils are currently considering the public health needs of their communities and targeting health-related co-benefits in planning for climate change. The findings show that local government climate change-related policies in NSW rarely analyse whether their GHG reduction strategies also produce health co-benefits. This suggests a need for a broader policy direction from the State to local government to link planning for climate change with health. This direction will need to embrace inter-agency coordination and training to conduct health analyses; the development of tools and methods for identifying, quantifying, and incorporating health-related co-benefits; and legislative changes to support actions in areas currently beyond local governments' sphere of control.

This paper has also provided insight into local government policy makers' perceptions about targeting health-related co-benefits in their climate change planning. More research is needed to understand how individual councils are engaging with their communities and health agencies to establish explicit inter-connections between climate change and public health. Such research can examine how and why particular councils develop linkages between climate change and population health. A detailed investigation of how local governments' climate change-related policies across Australian states are developed in practice will provide a more strategic understanding of the particular agendas, politics, motivations, and expertise that influence the development of these policies and their health-related outcomes.

Bai Wan Zhuang, A Beijing Community at The Crossroads - An Analysis About the Sustainable Update of Chinese Old Distinctive Residential Areas

WANG Liang[a]

[a] *CAUPD, Mainland China, 24911622@qq.com*

ABSTRACT

Bai Wan Zhuang (BWZ) residential area, one of the excellent residential space designs during the early time of PRC's founding, had deeply influenced over people's life style in China. However, BWZ has turned into a poorly maintained community today with old houses, broken facilities, and disorganized outside environment. It had been listed in the Beijing City Renovation of Dilapidated Buildings Projects several times and should be renovated entirely earlier. However, due to the extensive controversy, the government temporarily stopped the BWZ's renovation project, and they waited for a more optimized alternative which focuses more on the balance of improving the living quality, protecting the historic buildings, respecting the householders' choices and economic success.

The way of BWZ's renewal will represent the fates of many Chinese distinctive old residential areas, particularly in the New Urbanization period. And this article commits itself in the most important topic of discussing how to foster the sustainable update for the BWZ.

Keywords: Baiwanzhuang, distinctive residential area, sustainable update

1. INTRODUCTION

1.1 The origin of the Issue

(1) Urban renewal and the sustainable development

Sustainable development refers to meet the current people's needs without hazards to the later generation's development abilities. It promotes the relationship between the environment and human existence in a sustainable approach. In 1992, the World Commission on Environment and Development (WCED) published the report "our common future" to formally state the concept and discussed it on commonly concerned themes. Then it has spread heavily all around the world.

The sustainable development in the context of urban renewal takes a city as an organism in a continuous process with quantities of historical information and reflects the city's life cycle. Thus, the urban renewal needs a more moderate way, in order to keep clues and characteristics of various development periods, including physical forms, local culture, composition of residents, etc. rather than the full replacement.

(2) The sustainable update of distinctive Residential Areas in China

Residential Area is one kind of modern living physical environments. In China, it appeared after the country's establishment and flourished with the rapid urbanization from the late of 1970's. In various period, there have been born some excellent residential areas taking the period's signals and become special heritage for present citizens. However, many of them are facing sustainable update issues.

(3) The sustainable update of the Bai Wan Zhuang (BWZ) Residential Area

The BWZ Residential Area, with the glory of "the first residential community in the new capital," was built in the Nation's establishment period. The project was started in 1953 and completed after 3 years. It is considered as a typical case of modern residential areas and published in the college subject textbook. Characteristics such as the red brick wall, slope roof, large area of green spaces, children' playground and the quiet living environment make it one model for activities of designs, developments and constructions in the following multiple decades in China.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Today, a large portion of BWZ suffers deteriorated houses and the environment. BWZ has become the object needing to demolition. But the government shows prudence due to the strong public opposition. The earlier voice rose from the local community residents. After 2011, many urban planners and construction experts joined the group. With the knowledge of BWZ's historical and cultural value, they claimed that BWZ's update should be in a sustainable way. Without a satisfactory explanation of the sustainable way, the old BWZ still has no formal development plan. Doubtless, the future of BWZ is full of variables.

1.2 The Current Condition of BWZ

(1) Position, administration and the population

BWZ is settled to the West of 2nd Ring Road, between the Chegongzhuang Street and Banwanzhuang Street. The east boundary is 400 meters from Zhanlan Road, while the west boundary is 80 meters to Sanlihe Road. Its whole shape shows a square with the size of 500m*420m, equivalent to 21 hectares. (Figure.1)

Figure 88: Location of BWZ.

It is administrated by two Residential committees, Baixi and Baidong, in the Xicheng District. They take charge of basic affairs such as the social and economic data, rent registration, cleaning stairs and passageways. In accordance with the governmental data, Baixi has 1864 households, 6218 residents; whereas 1932 households, 5777 residents in Baidong. And the gross population of BWZ is 11995.[1]

(2) Land Use

BWZ includes 10 housing clusters. The center is the Baiwanzhuangzhongli cluster which is surrounded by the other nine clusters. A primary school two parts of a primary school stand separately on the east and south of the center cluster. On its northwest, there are one engineering company and one community life-service center with a supermarket, a restaurant and a parking lot. On the north of the BWZ erects a building belonged to China National Nuclear Corporation (CNNP). Several simple dormitory buildings stand along BWZ's east edge. In two yards near the north, a retirement center and a disability-nursing center stay separately. (Figure.2)

Figure 89: Landuse of BWZ.

(3) Living quality

Many surfaces of bottoms of the eaves are broken and fall-off, exposing inner wood structure. Moreover, without the thermal insulation layer, the buildings' walls lose heat easily, which make the rooms extremely cold in winter days, special before and after the heating period. Some walls are eroded due to the seepage from the aged pipeline, causing moss growth. Residents have to clean the sewer system frequently after it jams. Electric wires twist and fly here and there. Some furniture are abandoned in the corners, covered with thick dust. During summer, weeds grow thickly, and the apartment rooms becomes warm and humid. Mosquito attacks on the residents continuously. Besides, there are many illegal constructions in the yards between the buildings, which consumes a large amounts of open spaces. They rose up in the 1970s as earthquake shelters, and sprawl in the later years.[2] (Figure.3, Figure.4)

Figure 90: One water room.

Figure 91: The illegal houses.

On another angle, BWZ also keeps advantages: Buildings with only three-floor height hide behind the trees, which creates a comfortable space dimension for the resident. As a comparison, the too high buildings in Beijing's new residence area convey heavy pressure. For the reason that buildings are shorter than trees, plus a large area of greening, the temperature in BWZ is often 2-3 degrees lower than the adjacent communities in summer. Closing to the elementary school and life-service center provides BWZ a convenient daily life. The special 3m room height design increases the interior brightness and the flexibility of indoor activities. (Figure.5, Figure.6)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

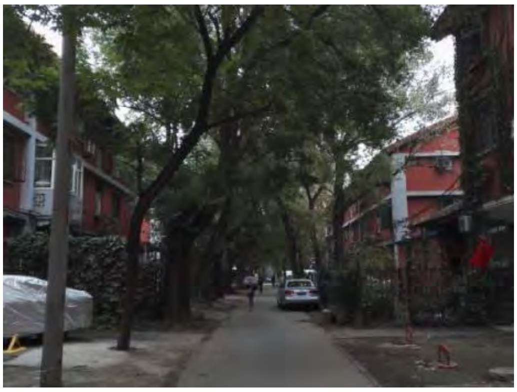

Figure 92: The scene in the alley.

Figure 93: The scene of one yard.

(4) Historic value

Researches for BWZ's historic value begin from 2010, the main points are:

- The earliest residential area design samples in China. BWZ's designer had learned a lot from the international forefront planning concept - "expanding neighbourhoods" (aka. the European or American "neighbourhood" concept) from the Soviet Union. With this concept, the clusters are planned to surround the center green park (where Baiwanzhuangbeili cluster is. It was built after 1975). And daily service facilities, stores, kindergartens, elementary schools, etc., can be reached within a five-minute walk. The most important is no need to cross the traffic road.
- The buildings' arrangement suitable to local climate. The majority of the residential buildings faces the north and south directions in order to receive more sunshine; whereas a small part of the buildings faces the east and west, to achieve enclosure and thus to get better resistance against the winter wind. (Figure.7)

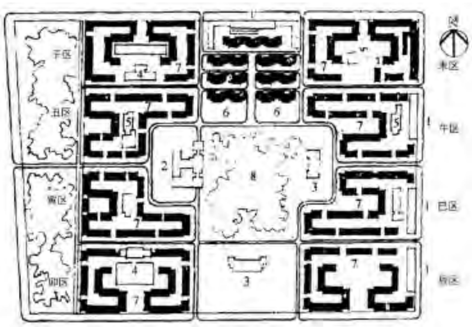

Figure 94: Master plan of BWZ.

- The building's form is on behalf of the era characteristic. All the buildings are three-floor height, with red brick walls and double-slope roofs. The special red color conforms the style of both Soviet Union and

China's Forbidden City. The white beam-column construction for seismic resistance sharpens this character. The independent kitchen and restroom with 3 meters height have referenced to Soviet Union too. The special "circling" pattern can be seen easily in the balcony wall between windows, in the stair arms, and in the heads of gate posts, which displays a "modernist" style. Many buildings still maintain doors and windows made of redwood from the northeast of China, which explain the traditional patterns in 1950 period. (Figure.8)

Figure 95: Concise design.

- Celebrity residents. Many country leaders, famous scholars and writers have spent their lives in BWZ, such as Li Peng, Gu Mu, Wen Jiabao, Qian Qichen. These celebrities add fascinating legends to this area.[3]
- Traditional taste. Names of the 9 clusters (not including the center one) come from the traditional earth branches system, which makes them heard unordinary. With the arrangement of a circle, the whole pattern of BWZ looks like a big peaceful Bagua image. An interesting explain for this special design is in order to squelch bad affections of BWZ's history as a grave before the country's foundation.[4]

1.3 Key Problems for BWZ Sustainable Update

Lack of maintenance entity leading to acceleration of BWZ's deterioration

Over 50 years, BWZ had to face its quality problems in the 1990s. Many residents had ever plotted detailed plans to improve their room's quality and beautify their decorations. However, they gave up finally because the government declared the BWZ demolition project, not only once. Once the demolition project was carried out, the residents would receive monetary compensations or new apartments by calculating the room area. But the expense on reinforce and decoration has no payment, which means the householders' investments on their houses are waste. Considering this reason, in the past 20 years, most households only have spent minimal expenses on their houses.

Another reason comes from the residential house's ownership system. In the early time, many BWZ residents worked for the national "four departments and one committee" (national planning commission, ministries of geology, heavy industry, first and second machinery industry) . All of the houses belonged to these government institutions. In 1994, the state council published a reform policy on urban and town housing system in order to transit the urban housing system from the institutions into the open market. People could obtain their houses' ownership by paying at the original construction cost price or the standard price. Before, the maintenance work of buildings and the environment was part of the institution's duty. After the ownership's shift, institutions dropped out. Most of the maintenance affairs needed to seek special facility companies. However, the market has no interests at collective affairs. Original institutions' retreat had created troubles to perform the thorough maintenance works such as buildings' repair, which accelerated the deterioration.

(2) Out of the city protection system, short of policy support

The earliest professional protecting voice was claimed by its designer Zhang Kaiji in 2004, in a letter to the Beijing Administration of Cultural Heritage. In the same year, in the tenth meeting of 3rd Beijing Political Consultative Conference, Lu Huai'an provided a proposition (No. 0633) to advice protection for BWZ in time. At the same year, Ministry of Construction issued a document to demand protections of excellent modern buildings. After that, Beijing announced more than 70 modern buildings in the preservation list (without BWZ).[5]

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Beijing is one of the first batches of Chinese historical and cultural cities. It finished its own protection plan in 1990s and has published 21 batches of historic and cultural resources. During the 11th and 12th five-year periods, Beijing had formulated the protective construction plan to conduct all the related works with necessary support on fund, technique and research. However, this plan only focused on the traditional cultural resources scattering in the old town scope (the 2nd Ring), plus some historical and cultural towns, villages and other cultural sites in the suburb. The most similar category to BWZ is cultural relics and modern architectures which is related with individual buildings. So BWZ gains no help from the Beijing’s protect system.

(3) High proportion of the elderly and tenants reducing the community vitality

The population structure of BWZ has affected its community vitality. According to Zhanlanlu Street Office, among the gross population 11995, people over 60-year-old is 3058, and the tenant is 3292. The proportion of the two kinds is calculated to 25.4% and 27.4%, respectively, with a sum of more than 50%.[6]

Generally, a higher elderly proportion generates a higher participation rate in community activities.[7] Different from the young people suffering a lot in daily work, the elder people enjoy retirement life and tend to devote more in the community. However, most of the aged population in BWZ is more than 75 years old. Their self-care ability is relatively weak, which leads to low participation rate in community activities. Besides, taking care of the much old people also cuts down the younger generation’s energy and enthusiasm into community lives.

Tenants are short-term users of the community’s facilities and environment. The higher tenant percentage means less motive force on the improvement of the community. Most of BWZ tenants run their business in a large wholesale market nearby. This market is planned to move out of the downtown area in 2017, which adds uncertainties to the tenants’ future. They only pay for temporary stay, not to mention the participation of the BWZ’s sustainable update.

1.4 The sustainable update path of BWZ

(1) To push forward the city protection system advancing more.

Although BWZ does not belong to Beijing‘s historical and cultural city protection system at present, it should be noted that this protection system advances itself in a constant process and has not solidified. In 1983, Beijing established the status of the historical and cultural city with an urban construction planning scheme. Since that time, the protected objects have expanded from single cultural relics to the entire historic and cultural field, from material entities to intangible cultures, including particular courtyard buildings, historical and cultural town and village, underground cultural relics buried area, excellent modern buildings, and industrial heritage. This evolution reflects the gradually increasing awareness of the historical preservation.[8]

In other cities, researchs and protections of distinctive residential areas, like BWZ, have already begun. Shanghai Chaoyang First Village, for example, was created in the 1950s. As a classic worker new village mode, it served as the national reception sites for foreign affairs, taking the role of the" working class" living room. It became a typical architectural style of the settlement for industry workers for the next following 30 years. In 2004, Chaoyang First Village was rated as "the fourth batch of excellent historical preservation building in Shanghai". The topic of how to protect it to achieve sustainable update has always been the social focus.[9] Another case comes from Shenyang, a city with many “worker village” dwelling units. The units explained well at "new China's working class becomes the master", with deeply marked features as "upstairs and downstairs, lights and telephones” of that time.[10]

Preservation in Beijing also possess the dynamically developing character. All of the valuable objects should be protected in this city, covering each period. BWZ, which represents outstanding designs in the early time of China, have the qualification to be paid attention on, in spite of many research and work needed.

(2) To apply for urban renewal projects and take items selectively.

Beijing launched a comprehensive improvement plan for old residential areas in 2012, including areas built in and before 1990, with low construction-standard buildings, backward facilities, incomplete function and lack of long-term management mechanism.[11] In 2013, Beijing renamed it shantytown renovation and planned to complete all the projects within the 4th Ring Road before 2017, and complete all the projects before 2020. It is free totally to the residents. A special national capital policy for this plan is exerted. Beijing also will invest a large amount of capital for this. 40 billion Yuan will be paid for the 35000 households' renovation task in 2016.[12]

BWZ doubtlessly fits the definition "shanty". According to "implementation opinions" of the renovation, detailed items cover reconstruction of walls for energy saving, changing aged facilities and equipment, cleaning and painting walls, and collective works such as building elevators, changing air conditions, rearranging electric wires, repairing utility pipes, etc. There are also many items in yards, concerned with accessibility, fire protection, greening, landscaping, alleys, lights, etc. All of these are urgent for BWZ. Considering the valuable historic information on the surface, items such as the reconstruction and painting of walls may be canceled. Therefore, Rather than worrying about destruction of the shantytown renovation, BWZ should actively apply its project, exert the beneficial items, to grasp this opportunity to advance a great step in its sustainable update lifetime.

(3) To explore the property management and eliminate the illegal constructions.

Property management brings seasonable maintenance to buildings, facilities and related sites. Old residential areas, like BWZ, seldom achieve property management services because of the unclear property rights, the long-term rent or idling, frequent delay for the payment, etc. In addition to the sanitation task which belongs to the residents' committees, residents consult different professional municipal companies to solve their daily troubles. Affairs, especially the common affairs, are hardly to be carried out. For example, the parking. Many cars park in BWZ every day, which affects residents' activities. Safety is another problem. There are numerous hidden-risk locations exist in the outdoor, which is a danger to the people living here.

Suitable ways of the property management should be explored in BWZ. A good choice may combine it with the resident autonomy, which means semi property management. In Chaoyang District, a new property management with the "resident autonomy" characteristic is working. Local residents manage themselves in some service fields.[13] Concerned about the municipal services have been completely open to the market, the property management of BWZ can run in fields of the parking, electronic surveillance, public green space design, fitness places arrangement, stairs corridor repairmen, etc.

As historical causes, the existing illegal buildings are used as living or storage rooms by householders and tenants, which makes them hard to dismantle. However, they really make the environment worse. Determination is needed for these illegal constructions. Paralleled with strong demolition activities, some trade mechanism is possibly plotted to compensate some reasonable affection.

(4) To gain social support to enhance the inner sustainable development ability.

In spite of the old appearance, it is still reckless to say BWZ is experiencing decay. From a long-term statistic data, the population of BWZ at its birth is 8176, while the newest data is 11995. Getting rid of people in the later buildings, BWZ's population has increased more than 2000 people. Simultaneously, the householder's update keeps going on. On the basis of HOME LINK company's data, there are 43 deals in the whole year of 2015, and 41 deals before October in 2016.[14]

On the other side, as a distinctive residential area, BWZ has already won attentions a lot. Some research articles are typed in journals and spreading in the internet, some professional urban planners and architects have shown wills of joining the sustainable update process of BWZ[15]. Obviously, BWZ needs outer force for its better future. With professional supports, BWZ's historical and cultural value can be displayed thoroughly. By careful designs and constructions, BWZ would gain its charming outer space. The local recognition will created gradually and the community vitality will recover.

2. CONCLUSION

In China, the urban historical and cultural protection system has established early, but still not perfect. The distinctive old residential areas, which have significant values for cities' history, are neglected in the majority of cities. As a typical case, BWZ is suffering update dilemma. The protection of its valuable historical and cultural information is facing challenge from the physical decline, uncertainty renovation plan, lack of maintaining service, low community vitality, etc.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

However, positive factors are also growing. After analysis to BWZ's conditions, the sustainable update path is finally pointed out with four measures: (1) to push forward Beijing's protection system advancing and cover BWZ in the new system; (2) to apply for Beijing's urban renewal policy and take items selectively; (3) to explore the proper property management and eliminate the illegal constructions; (4) to gain social support to enhance the inner sustainable development ability.

ABSTRACT

Accelerated urbanisation in developing countries is creating an unyielding pressure on existing urban areas. This reality is leading to the widespread growth of informal settlements, that is, urban areas without infrastructures and property titles. According to the United Nations, Sub-Saharan African Region are showing the worst scenario, with 55% of the population still living in informal settlements in 2014. Different approaches and strategies have been applied but the scale of the problem, the lack of financial resources and the political instability are the major constraints. Urban regeneration actions is fully dependent on the State's decisions and resources, which delay the process and, sometimes, show inadequacy to economic, social and environmental conditions. Yet, developing countries represent a "tabula rasa" opportunity for the implementation of good practices within the urban and built environment. After a literature review on urban regeneration approaches, this paper sets out the analytical and methodological framework applied to Luanda metropolitan plan (Angola). Understanding the importance of a practical perspective, a Geographic Information System (GIS) approach, based on the delimitation of urban cells, is adopted as tool for regeneration dissemination process across the city. The aim is to combine strategy and action into a model where the State is the promoter of regeneration programs that are developed by the private sector and the population, considering mechanisms to implement a self-empowerment process. This research aims to support the design and implementation of sustainable solutions for urban regeneration in developing countries.

Keywords: informal settlement, urban regeneration, GIS, urban cells, dissemination units, sustainable development

1. INTRODUCTION

Sustainability has been defined as the concept of meeting the needs of the present without compromising the ability of future generations to meet their own needs. Different definitions emphasize sustainability issues, related to economic, social and environmental analysis, as one interacting reality since the final objective requires a fair balanced approach within the management of all the resources. Sustainability is synonymous of complexity, since collects a huge group of interactions between human activities and the natural environment. It integrates the related phenomena of adaptability, resilience and flexibility as well as the need to assess responses to optimize system-wide effects and to minimize the impacts of localized actions and decisions. This framework places sustainability as an emergent subject, connecting food scarcity, floods, landslides, water availability and energy access with the sprawl of urban settlements boundaries. Such relations lead to models that political and governance institutions can also use to address to potential climate change effects and mitigation of cities' impact on climate. The translation of these concerns into practice fosters social and economic development toward a new way of thinking about sustainable urban regeneration that has established itself in developing country as a fundamental research subject. But, what do current trajectories of research suggest for future practice? Here, new ways of living, renewable energy, green and nature engineering, ecological design, manufacturing and products, reflect major scientific and technological pursuits endorsed by sustainability principles. According to the UN-Habitat latest reports, about 881 million people are currently living in slums in developing countries. This emergence is due, in large part, to the rapid growth of urban areas which leads to a shortfall in many sectors, especially in housing, since the cities cannot meet the huge demand and needs of population. Abrams argued that the informal city is a result of lack of shelter in a context where the formal channels are inaccessible to the poorer. Payne postulates that the growth of these settlements is inevitable in developing countries. Today, the proliferation of slums and squatter settlements are examples that government or public authorities deal with dynamics that are still uncontrolled or uncontrollable. This is a consequence of an instable and weak economic sector, aggravated by an insufficient education policy. Indeed, Sub-Saharan Africa continues to have the highest prevalence of slum conditions of all regions, estimated at 55 per cent in 2014. Informal settlements are marked by unhealthy conditions,

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

due the lack of basic infrastructure, overcrowding, environmental vulnerability and land tenure issues. However, some authors identify the potential of these informal settlements within its transformation. For instance, Turner identifies the informal settlements as a successful solution for the shelter of the urban poor, that is, people find their own ways to create shelter with few material and financial resources. Steyn, reinforces this perspective by saying that, besides the low quality and uncomfortable layouts, informal settlements are a viable response for the social and economic conditions of these populations. Both generally agree that the self-build housing linked to the application of local materials (composite and natural) are an important feature if not a sustainable approach. The inhabitants of today's settlements do not only need food but proper housing accommodation, adequate living space and healthy environment. The benefits linked to a better conditions of living in urban areas have a relation with the preservation of nature. Environmental psychologists have examined and concluded that, generally, such contact with the nature has been determined be necessary for human health and wellbeing and to quality of life. All of these issues are basic human rights and constitute the central framework to project sustainable development of future societies. Such features, together with the self-determination and the capability to "do more with less", should be used within the regeneration process as a social and economic way to provide shelter. The local governments often lack the necessary funding and resources to implement long-term strategies able to promote sustainable transformation of the urban environment. Without an integrated approach this is a closed-loop problem. Regeneration process needs to be complemented with coherent policies and incremental strategies supported by both the State and private entities. Therefore, inclusive, universal and adaptive solutions that help to determine informed development strategies at local scale, represent an explicit challenge to innovate conventional urban regeneration models. This paper discusses a methodology for sustainable urban regeneration for the informal settlements of Luanda, Angola, within the Luanda's metropolitan plan. Thus, the main challenge of this work relies on the fact that 80% of the population (5 million people) of this city lives in informal settlements and are currently exposed to environmental risk and with precarious conditions that might compromise their lives.

2. URBAN REGENERATION

Many authors have focused on the meaning of urban regeneration. Robert and Sykes, consider that urban regeneration refers to urban rehabilitation or urban renovation to solve urban problems and simultaneously provide a long-term solution for the social, economic, physical and environment contexts. According to Sahin, urban regeneration includes urban redevelopment, revitalization, replacement and rehabilitation. However, it is commonly agreed that strategies that consider urban regeneration fully dependent on State are no longer viable. When the public sector is fully responsible for the project, problems such as bureaucracy, lack of financial resources and corruption might occur. Indeed, public actions based on economic premises, lead to severe consequences in the social context and promotes, in the end, social exclusion. The new settlements are commonly located in peripheral urban areas where the land is cheaper. This result in "urban dorms" without services or economic opportunities for employment, worsening the poverty situation of these populations besides the growth of collateral problems such as crime and thus insecutiry. According to Turner the urban poor need to solve a difficult equation by getting shelter near employment opportunities centres. Even the informal economy (e.g. street vendors) need to occur in areas where consumers exist. Therefore, the public sector has the political responsibility to provide infrastructures and affordable housing for those with no means to acquire a house at all, that is, single parent families headed by women, elders or handicapped people for example. The site-and-service scheme is another solution that emerged in response to the failure of fully public initiatives. This approach can be considered as an indirect public initiative combined with self-help, where the State provides subdivided greenfield land with basic infrastructures and social facilities while the population build their own houses. One of the good examples of such approach is the Chilean experience on regeneration that evolves the incremental housing process. This process started with the State actions in providing land and infrastructure, where the people would build their houses, and then evolved within a more controlled process. During the first years of this experience, people built their houses as they knew which lead to precarious conditions similar to informal settlements but with access to water, sewage and energy. Later, an assisted process was introduced through a technical team that would help and support the population within the building process to provide better housing solutions and thus ensure quality. Some of these experiences lead, however, to the problems previously mentioned: most of the land provided by State was far away from economic centres; On the other hand, speculation triggered escalation of land prices. Site-and-service approaches are remarkable by integrating people within the process to, simultaneously, reduce costs and better solve the population needs. Moreover, the State is seen as a support instead of a direct provider which improved the viability of these kind of projects. However, such approach needs coordination between the whole stakeholders or otherwise will be unable to provide a social and economic viable solution. Besides the site-and-service strategies that are commonly applied, upgrading informal settlements is also a current strategy considered by non-governmental organizations. This approach starts with the transformation of the urban environment through the participation of the State with the self-determination of the population. In fact, the process is similar to the site-and-service strategies but applied in the informal settlements instead of relocate people in other locations. The public sector provides basic infrastructure (roads, sewage, water, energy) and the community is responsible for the building upgrading. To do so, public sector needs to empower local authorities through legislation (policies) as well as human, financial and material resources. The absence of this support might compromise the whole purpose: people have indeed infrastructure but the building stock still precarious similar to what was mentioned in the incremental housing in Chile. In these approaches, the partnership between the State, the private sector and the population is the common premise. The public sector facilitates the regeneration process by creation the conditions for the private investment and people self-determination. This conditions can be through the management and monitoring the housing market, land provision and policies. Tax relief is commonly used in India and Morocco while in Egypt the State provides land and lower the housing standards through legislation. In Turkey, a counterpart is added: The State provides land but the private sector must accommodate a percentage of social housing. Politica lintentions but with a weak economy hampers the problem thus an incremental and local-based approach, supported by a partnerships scheme that involves the State and the private sector, is required. Therefore, the local features are important aspects to be considered to better accommodate the needs and create a viable solution for each case.

3. URBAN CELL AS DISSEMINATION UNIT

Despite the general complexity of informal settlements, when they empirically and theoretically studied, some general global patterns tend to emerge in response to land use patterns, urban system parameters and population density. Therefore physical-geographical approaches to the urban form and land use analysis are commonly used to deal with this kind of complexity. Many of these approaches are used to analyse different aspects of urban development at a macro spatial scale such as urban shape, city size distribution, population density and thus involving an array of interrelated methods and tools. The widespread use of geographic information systems (GIS) has shifted the emphasis to new forms of analysis and planning at a fine spatial scale. One of the most effective methods is the implementation of urban models, based on the principles of cellular automata (CA). The concept of CA was introduced in the 60's by Von Neumann as a formal model of self-reproducing biological systems, later, computer science, mathematics and physics began to study CA for modeling their respective domains. In 1979, Tobler introduced the concept of CA to geography and made the first application in the study of urban systems. In 1995, Clarke created a land use change model called SLEUTH (Slope, Land use map, Excluded area, Urban area, Transportation map, and Hillside area) that simulates the urban growth process showing the real value for planning and GIS application. The SLEUTH model is capable of modelling the complex urban growth dynamics and a land use system changes, providing a set of spatial variables such as topographic slope, road networks, land use maps. Other CA-based models, incorporating analysis of linear dimension of urban infrastructures, number of buildings densities and uses with the number of years and population growth, have also been propose. Related with these issues, the MOLAND (Monitoring Land Use/Cover Dynamics) model has been applied to European cities to assist spatial planners and policy makers to analyse a wide range of spatial policies and their associated spatial patterns. In this regard, the grid-based approach is the recognition of an alignment between the urban complexity and its study by means of units of space that are conceived as smallest urban units available: the cells. White reports that at the latter scale, cells may represent cadastral units (i.e. actual land lots), which may have any shape. More recently, the GUUD (Geographical Urban Units Delimitation) model emerges to deal with cellular approach to the urban form, land use analysis and solar potential and energy consumption estimation. The potential relationship between the GUUD model approach and the concept of dissemination units for urban regeneration are the theoretical boundaries that inspired the present research. Therefore, the paper describes the methodology for a sustainable urban regeneration, based on urban cell as dissemination unit considering an incremental long-term process.

4. METHODOLOGY

Within the scope of the Luanda's metropolitan plan, urban regeneration is a crucial aspect for the success of the planning action, not only due to the precarious living conditions but also because people are exposed to many risks, that is, floods, landslides and lack of mobility facilities which, all together, compromised both their life and development. The methodology developed in this paper combines several aspects of the aforementioned urban regeneration approaches, adding the sustainable component. The latter is achieved by considering the local features (social, economic and environmental) as primary aspects. The research framework addresses three complementary categories: 1). physical-geographical approach to urban form and land use analysis; 2). recent data from the public entities and fieldwork and local surveys developed between 2014 and 2015; 3). relationship between urban planning and housing deployment. Therefore, the methodology follows five steps that interrelate policies and physical scale through an integrated process (Figure 1).

A partnership model between public and private sector is also established where land valorisation and tax benefits are the key elements to attract private investment. The public sector is responsible to create the conditions for development. These conditions are not only physical, through the creation of major infrastructure and social facilities, but also at the policy level through incentives (inclusionary zoning and density bonuses), rights transfer and a tax benefit programme. Moreover, the State is also responsible in providing social housing within the national housing programme but it is mandatory that the private sector contributes for housing provision through the creation of affordable housing. This will result in fewer costs and direct and indirect revenues for the State and thus a viable solution for both stakeholders in working together for the housing deficit and city development.

Figure 96: Flowchart describing Luanda's methodology of urban regeneration

Step 1 - Definition of the intervention area

Definition of intervention area is firstly based on three main criteria according to its priority: 1). areas located in flood and landslide areas, that is, locations that compromise human lives; 2). areas where are programmed development projects (such as roads or main infrastructures); 3). Areas with precarious conditions (absence water, sewage and energy). The intervention area definition should also consider a dimension for its transformation of a neighbourhood unit of 5000-10000 people. This dimension was based in empirical and theoretical evidence of the

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

territory and its densities (about 350pph living in single-family homes in the city centre). This step is fully led by the public sector, regarding its development programme and intentions for the territory.

Step 2 - Urban analysis

Urban analysis refers to the development of a criteria framework that will work as the main core for the regeneration process. In this step, land tenure must be clearly defined to support the rights transfer model and establish the compensatory mechanism where buildings improvements may be added as compensation, according to the following parameters: existing roads, social facilities, cultural or historic heritage, commercial activities, agricultural area, vacant land. Regarding these uses, land tenure number of floors and materials should be also assessed. This phase is strongly supported by the State within the land tenure assessment that is the most bureaucratic and time-consuming task.

Step 3 – Delimitation of urban cells

The delimitation of the urban cell is implemented according to the urban analysis criteria by working with the physical parameters that might structure and organize a potential homogeneous neighbourhood. This step provides an opportunity for the management and monitoring process led by public sector because has a smaller operational unit, easier to operate, within the regeneration process.

Step 4 – Land valorisation

This step refers to the public sector effort to attract private investment, that is, land valorisation through the creation of conditions such as: major infrastructures (mobility corridors and basic infrastructure – water, sewage and energy); provision of social facilities (creation and upgrading of the existing ones) and open space; management of the urban plots according to the land tenure as well as the creation of social housing within the national housing programme. These are the main conditions for development and will provide the basis for the urbanization process lead by private sector in step 5.

Step 5 – Urbanization

Step 5 refers to the urbanisation process that envisages the creation of services, commerce, free market and affordable housing promoted by the private sector. This step is crucial for the effectiveness of the process as far as the private sector must contribute to the housing deficit, that is, a percentage of its investment must be affected to affordable housing. Indeed, this type of housing aims the low-income population that could pay for a house (in a rent or rent-to-buy scheme) based on the consumer-pays principle. The possible flexibility in gross floor area within the intervention area (density bonus) will actually encourage land transformation. Thus, private sector will take on a more significant role within the urbanization process through the transfer of building and/or land rights /the latter might involve another location).

5. CONCLUSIONS

Literature review shows different perspectives on informal settlements as well as different approaches to their resolution. The main outcomes of these strategies are identified and analysed. Therefore, a mixed-strategy that combines site-and-service and settlement upgrading, as well as a partnership model between public and private partnerships are crucial aspects for its effectiveness. Within the urban development process, urban cells can disseminate regeneration to surrounding areas not only physically but also in terms of social and economic impacts. The application of CA models supports the transition from macro-scale to micro-scale offers more and better data to understand the relationships among a range of key aspects of informal settlement such as urban form, built environment, land-use, densities and infrastructures across the city. This process helps on the definition of urban cells for regeneration, assuming that the problem can only be solved incrementally and with local operations. However, this research does not deny an holistic approach but consider that the intervention must be divided into phased components (cells) Therefore, the dissemination unit aims to be a small area that can be easily managed and monitored by the public sector. The definition of this intervention scale permits to control the viability of projects due the lower costs that are concentrated on a small urban area. This intervention combines a five-step process that integrates the transformation of the territory through physical actions and policies, where the State has an important role. Such policies are based in financial benefits and incentives to attract private sector and thus become the main operative stakeholder. The support of the private sector on the creation of affordable housing, regarding a rights transfer model, will also have impacts on public budget by contributing to solve the housing deficit. This model aims the self-empowerment of the private sector in urbanising the land which might encourage to further interventions. In a long-term perspective, cities in developing countries can gradually transform its informal character into formal environment.

ABSTRACT

Pingtung City, Pingtung County, Taiwan is an old city, and villages started to be established there around 1684. In 1836, defensive walls were constructed to prevent thieves and fights. The county was developed very early and is the central city on Pingtung Plain. During the Japanese Occupation Period (1907), Pingtung City, due to the establishment of railway station and sugar factory, attracted population and gradually formed the prototype of its urban plan. However, as time changes, Taiwan sugar industry loses its advantages. The extensive land owned by Taiwan Sugar in the south of Pingtung experienced slow transition. The previous Front Station and Back Station areas of the plane railway station are situated in the south and north of Pingtung City. Also, the urban development is featured by non-homogeneous growth. Besides, with the enhanced urban disaster-prevention awareness in recent years, the central hinterland of Pingtung is small but is an area where tons of dilapidated buildings are erected, suggesting that the space development of Pingtung City shall be renewed and reviewed.

“TRA Kaohsiung-Pingtung Chaojhou Rapid Transit Systematization Construction Project” brings new opportunities for the urban renewal of Pingtung City. To empty the land for the new project in the railway station, eliminate urban level crossing, implement the concept of resilient city, work with related major construction projects to continue to produce synergy, and respond to extreme climate and vulnerability in the earthquake zone, the Pingtung County government has embarked on overall and systematic planning and strategy planning of Pingtung's urban renewal, reviewing the land surrounding the Railway Station and planning transfer stations to integrate the railway and highway transit system. Also, it connects the traffic arteries of Front Station and Back Station and develops the business district in Front Station and Back Station in the form of urban renewal, hence fueling local sightseeing, leisure and business activities and guiding sustainable development and environmental optimization of Pingtung city.

Keywords: urban regeneration, resilient city, sustainability

1. DEVELOPMENT OF RESILIENT CITY

1.1 Global sustainable development framework - addressing disasters caused by climate changes

At the end of the twentieth century, mankind gradually realized that the environmental destruction had already begun to result in counterattack on the nature. Therefore, in order to reach a consensus on environmental protection, in 1983, the Brundtland Commission (formally known as the World Commission on Environment and Development, WCED), which probed into environmental issues, was convened in the United Nations.

This commission suggests that human beings formally explored environmental issues and formulated processing framework for the first time. In 1987, the Brundtland Commission published the well-known report “Our Common Future” (also known as the Brundtland Report), which for the first time gives a complete definition of sustainable development:

“Development that meets needs of the present without compromising the ability of future generations to meet their own needs.”

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

After the idea of sustainable development had been proposed in the United Stations, in 1992, the United Nations Conference on Environment Development (UNCED) held the Earth Summit in Rio de Janeiro, Brazil, and put forward a comprehensive proposal on how to address climate change, i.e. “Agenda 21”.

“Agenda 21” is an unprecedented sustainable development program and seeks to provide a blueprint for the sustainable development of mankind as a whole. It presents more than 2,500 proposals for action plans, including detailed proposals for how to reduce waste and consumption patterns, protect the atmosphere, marine and livelihood diversities, and promote proposals for sustainable agricultural development (Lin, 2005).

The Agenda mainly focuses on four aspects, that is, society and economy, conservation and management of resources, to promote development, strengthen the roles and major groups and means of implementation. Additionally, the Agenda also defines three respects of sustainable development: environment, economy and society. Pope and Parkin later developed the three respects into the current well-known interconnected three-respect development framework, and the development framework is detailed in Figure 1.

In 2005, the United Nations adopted the “Hyogo Framework for Action 2005-2015: Building the Resilience of Nations and Communities to Disasters, HFA”. The framework preliminarily constructed the planning idea centering on handling disasters -- Resilient City, and confirmed the importance and development framework of resilient city. Presently, HFA has become the most important guiding principle of implementing resilient city planning of the world's governments and sustainable development organizations.

1.2 Definition of resilient city- adaption and recovery of cities despite complex disasters

According to the planning framework of the resilient cities “City Resilience Framework” published by the promotion organization of resilient cities the “100 Resilient Cities” (100RC) in 2014, it put forward the following concept of resilient cities: “The resilience of a city refers to the capacity of individuals, communities, institutions, businesses, and systems within a city to survive, adapt, and grow no matter what kinds of chronic stresses and acute shocks they experience.”

“Resilience” is recovery and adaptability

Resilience is a term that emerged from the field of ecology in the 1970s, to describe the capacity of a system to maintain or recover functionality in the event of disruption or disturbance. It is applicable to cities because the urban environment and ecological environment are complex systems that are constantly adapting to changing circumstances (ARUP, 2014). Therefore, the concept of resilient cities not only emphasizes the ecological of urban entity construction by disasters, but also stresses the disturbance to social system.

Resilient cities focus on “multiple hazards”: including chronic stresses and acute shocks

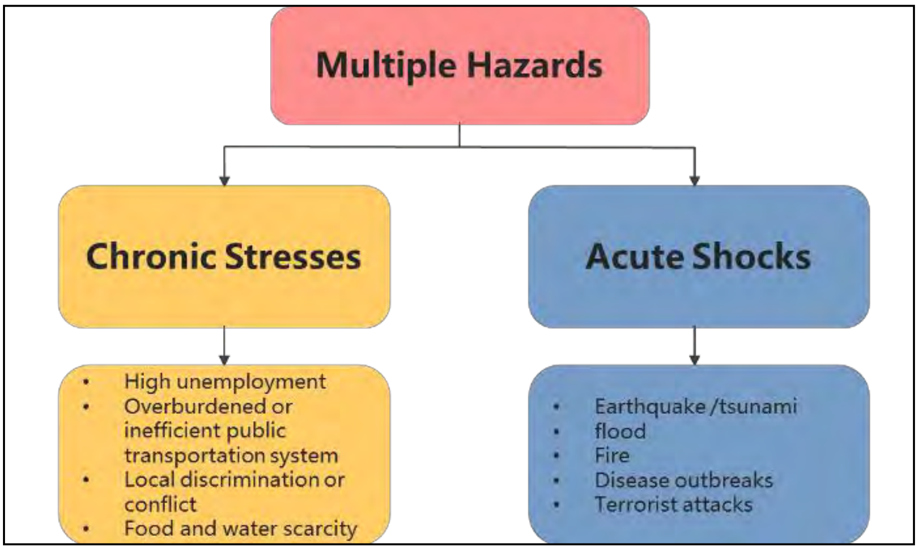

Figure 1: Composite structure of multiple hazards

(Source: 100RC, en.wikipedia.org, CNN, www.panoramio.com, Telegraph Media Group)

In addition, the 100RC also points out that resilient cities move away from traditional disaster risk management, which is founded on risk assessments that relate to assessment and reduction of specific hazards. Instead, resilient cities take multiple hazards as the strategic objectives, including the chronic stresses and acute shocks faced by the cities. Therefore, resilience focuses on enhancing the performance of a system in the face of multiple hazards, rather than preventing or mitigating the loss of life and assets due to specific events.

2. PRESENT STATUS, DEVELOPMENT AND PROBLEMS OF PINGTUNG CITY

2.1 Information on present status of Pingtung City

Pingtung City is the largest city in Pingtung County, and the county government is also situated there. It is located in the west of Pingtung County, and borders Kaoping River and Kaohsiung County. It covers an area of 65 square kilometers, accounting for about 2.43% of the county.

Pingtung urban planning area is located in the east of Pingtung City, covering 61 villages like Anle Village and part of Xiangyang Village, Changzhi Township, and representing 27% of Pingtung City area. Changzhi urban planning and Linluo urban planning are located within 5 kilometers of Pingtung City, so this planning intends to regard the Pingtung urban planning areas of Pingtung County as the planning area with a planning area of about 1,760 hectares. It is planned to develop the Pingtung urban renewal program and review the scope of Pingtung urban renewal areas. The relevant laws and regulations of Pingtung urban renewal are formulated and completed as the basis for Pingtung County to promote future urban renewal.

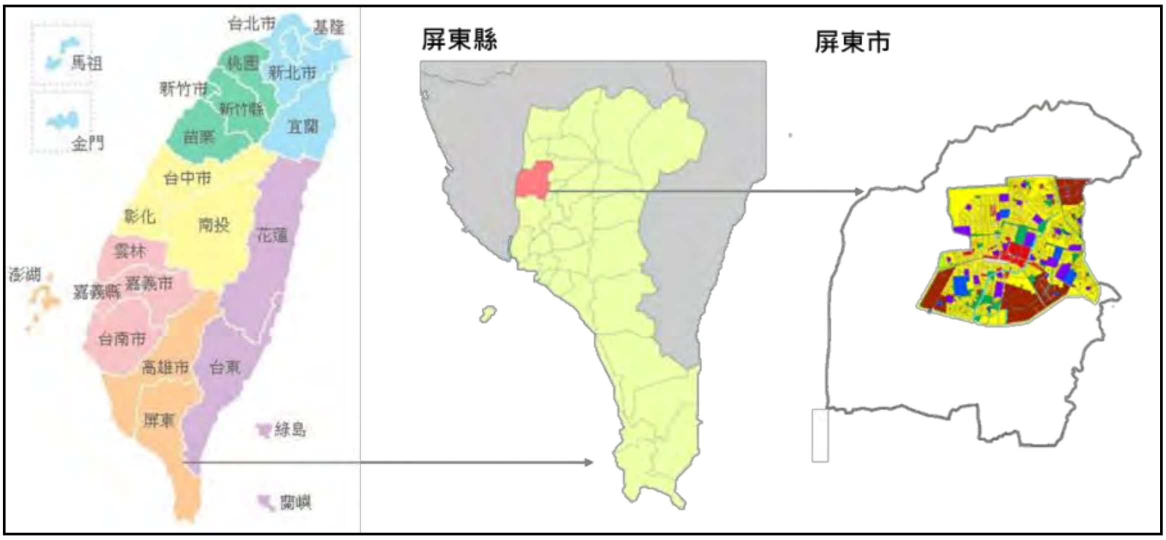

Figure 2: District map of Pingtung City

2.2 Overview of development status and current major construction plans

The business district of Pingtung City is concentrated in Pingtung Front Station with a development rate of 95%. The edge of the city is dominated by an industrial area with a development rate of 13% only. The remaining area is residential area with a development rate of 85%. Besides, although the buildings of Pingtung City are primarily situated along the street and are town houses, the five-floor dilapidated buildings of more than 20 years total 215 in Pingtung County, 153 of which are located in Pingtung City, accounting for 72% of all buildings.

Besides, in recent years, the Pingtung County Government invested in large numbers of major construction projects, such as elevated railway stations and reconstruction of station areas, renovation and construction of green belts in Wannian River, review of public facilities and reserves, lease of public land in Dawuying and industry introduction, connection of green-ways in Shengli Road, widening of Gongyong Road, and re-planning and renewal of old winery urban land (see Figure). Among them, elevated construction of railway stations is the most important construction for Pingtung in one hundred years, and brings new opportunities for urban development. The details are as follows:

- The original space on both sides of plane railway was mostly crossing traffic (such as land bridge), idle land, temporary business districts and old settlements. After the railway was elevated, the Pingtung train station was reviewed and the land development texture surrounding the corridor was elevated, and the space image of entrance to Pingtung City was planned as a whole.
- Railway corridor is the pulse of the development of Pingtung. After the railway was elevated, new appropriate functional orientation shall be detailed to offer new opportunities for the development of Pingtung City.
- To meet the overall needs of future urban space development, the urban renovation of the existing Pingtung Railway Station and the areas along the railway corridor must substantially increase the value of the station area and its surrounding land and encourage regional development.

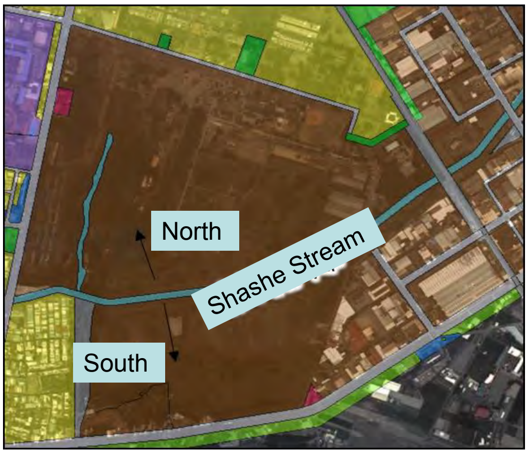

Figure 3: Urban plan of Taiwan sugar industrial area

- About 80 hectares to the south of the railway corridor is the idle land owned by Taiwan Sugar, where the Taiwan Sugar's pulp plant is located. Since the 1980s, the land has been idle, so it can serve as a model of brownfield regeneration by means of overall planning and revitalization of low-use land.

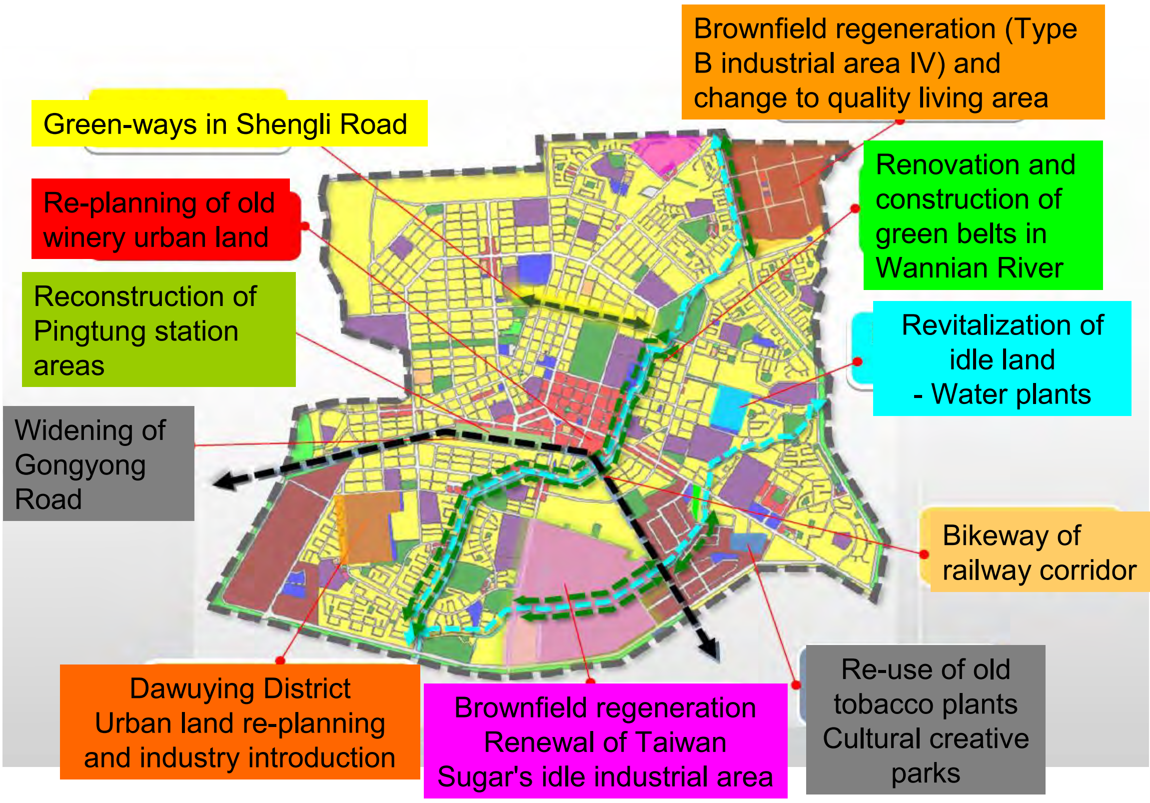

Figure 4: Schematic diagram of Pingtung urban planning land use partition and major construction distribution

Additionally, the earthquake on February 6, 2016 captured people's attention to disaster prevention. The dilapidated buildings in Pingtung City account for 72% of the total buildings of the county, demonstrating that Pingtung City is the area with a heavy demand for disaster prevention in the county. Given the local characteristics of Pingtung City, Pingtung City has a low demand for the bulk reward for urban renewal. The traditional urban renewal method by reconstruction is not competitive in Pingtung City, so only the elevated railway facilities can bring new opportunities for improving Pingtung City's urban landscape and building of public facilities. This study plan attempts to respond to the global trend of resilient urban planning and disaster prevention urban planning, expand the construction synergy, integrate into the overall spatial planning and put forward integrated strategies to use as the guiding principles of Pingtung City's future urban renewal.

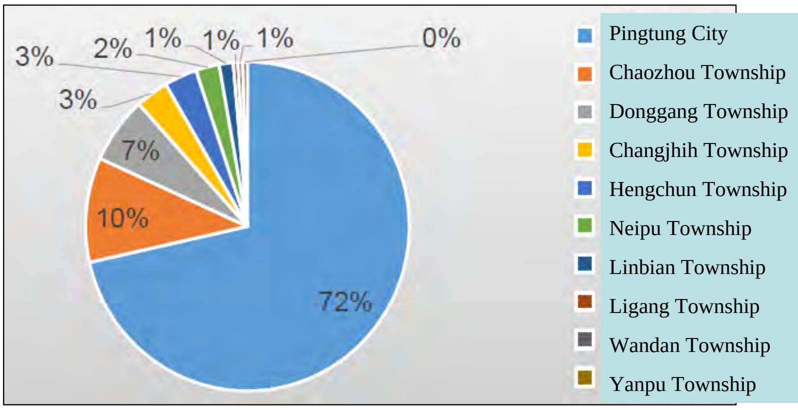

Figure 5: Proportions of dilapidated buildings of more than five floors in townships, Pingtung County

3. EXPECTED RESULTS OF THIS PLAN

This study plan expects to last for two years, and intends to start from investigation into basic information. After analysis, it will set the city's development goals and strategies, and formulate local self-government regulations according to local circumstances. The details are as follows:

Preliminary investigation into basic information and feasibility assessment

Background environment of the plan scope and basic information analysis include: Master plan and major construction plan of the adjacent areas, policy and ordinance analysis, analysis of physical environment (socio-cultural environment and current urban plan), land and building ownership analysis, survey and analysis of land use status, traffic system analysis, surrounding public facilities, etc. Besides, the preliminary work also includes the real estate market survey and analysis (including analysis of related development cases), development potential and restriction analysis.

Redevelopment goals of Pingtung County

This plan's key renewal scope shall be the entrance portals of Pingtung County, and covers the commercial and transportation centers of Pingtung City, such as Pacific Department Store, Global Market, Central Market, Pingtung Station, etc. To continue the synergy of elevated major construction projects, it is intended to develop an overall plan of urban renewal of Pingtung City. It is expected that through the planning and implementation strategies of key demonstration areas of urban renewal and through the specific city-wide implementation programs of urban renewal, the old urban areas of Pingtung City can be connected, the life quality of citizens in old urban areas improved and the regional environmental landscape enhanced. Moreover, the Pingtung urban environmental space can be re-shaped and the Pingtung urban portal intentions and industrial development can be activated.

- Formulation of determination criteria or identification scope of the urban renewal areas, and of the benchmark of determining urban renewal units and the self-government ordinance of Pingtung County's urban renewal.
- Substantive redevelopment strategies

Disaster-prevention urban renewal strategies

Given that the dilapidated buildings of over 20 years in Pingtung City tops Pingtung County and given the "2016 Annual Earthquake-resistant Inspection of Existing Buildings (Old Building Inspection Plan) funded by the central government in Pingtung County in 2016, this study plan provides strategies of promoting disaster-prevention urban renewal in Pingtung City, puts forward the criteria for determining disaster-prevention urban renewal areas with local characteristics of Pingtung County, gives priority to determining the urban renewal units, and assists independent application for renewal, reconstruction and maintenance through consulting groups of independent application for renewal.

Development strategies of resilient cities

Regeneration and development strategies of brownfield in Taiwan Sugar industrial areas

Type B (II) industrial area in the south of Pingtung Railway Station covers an area of 92 hectares, and owned by Taiwan Sugar. Currently, except some land that is maintained by the government and Pingtung City Office as open space, the remaining land is idle industrial land. It is suggested that by working with the overall urban development direction of Pingtung City, new development concepts are planned and land redevelopment strategies and plans are proposed. Furthermore, there are no detailed planned roads within this industrial area, so by referring to the urban renewal and the urban plans and procedures, the implementers are required to plan and build public Utilities.

4. CONCLUSION

Since Pingtung City was developed earlier than other areas, currently, there are numerous dilapidated and shabby buildings, and especially, those around the railway station are mostly dilapidated buildings of more than 30 years. In the future, after the completion of the "TRA Kaohsiung-Pingtung Chaojhou Rapid Transit Systematization Construction Project", the railway will be elevated, and the original railway land will be released and connected with the adjacent land as part of the city, hence bringing new opportunities for the renewal of dilapidated buildings. In response to the opportunities and challenges brought by the elevated railways, and to the new urban development issues like climate change and urban disaster prevention, this study plan intends to implement the concept of "resilient city" through the proposal of this urban renewal plan of Pingtung City, stimulate the urban

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

development of Pingtung City and bring a new look for the city via extensive urban renewal ways and revitalization of national land.

ABSTRACT

Taiwan often built campus gymnasiums to hold large gathering events and physical education activities in rainy, extremely hot and other harsh weather days. In recent years, based on the considerations of the rationalization of construction investment efficiency and building operation energy-saving, semi-outdoor gymnasiums, a covered playground, have been proposed as the corresponding program. However, whether the covered playground can meet the needs of the users remains yet to be verified. Therefore, this study took the covered playgrounds of elementary schools in Taiwan's Yilan area as the research objects. The method of post-occupancy evaluation is used to explore the status and operation issues related to covered playgrounds' spatial planning, physical environment, building facilities, and the use of spare parts.

The research results show that five categories of common activities are usually carried out in covered playgrounds, including physical education activities, sports competitions, performances, exhibitions, and gatherings. The most serious problem in terms of the spatial capacity of covered playgrounds is the inadequate buffer space and it also suffers the insufficient space height of the main ground for sports activities. There are also problems related to physical environments of covered playgrounds; sound environment related problems are caused by background noise interference; lighting environment related problems are caused by inadequate illumination and glare light interference; thermal environment related problems are caused by sunlight interference; and water environment related problems are caused by wind-driven rain. Besides, building facilities of covered playgrounds primarily comprise two types of equipment, namely, the electrical equipment and the AV equipment. Further, there are two types of spare parts, namely, spare parts for sport and those for gathering events.

Finally, based on the above findings, this study also made recommendations corresponding to architectural programming of elementary school covered playgrounds and as the reference for building or renewing the covered playgrounds in the future.

Keywords: architectural programming, post occupancy evaluation, sport activity

1. OVERVIEW

Gymnasiums are often seen in Taiwan campuses, which are used for large gathering or gym classes held in bad weathers like rainy or hot days. However, the funds required for building gyms are enormous. Recently, in consideration of reasonable architectural investment and energy-saving for the operation of buildings, a concept of semi-opened covered playground was proposed as a countermeasure.

The so-called covered playground denotes a simplified sport field with rooftop but no wall, in order to facilitate ventilation as well as reduce maintenance cost (Sports Affairs Council, 2008). Yilan area, where the researcher is located, has been budgeting since 2010 for building covered playgrounds for the schools in the county which have no large sites for indoor activity, so as to reduce the impact of harsh weather on student's learning activities and improve the issue of limited activity space for students during raining days as well as provide a good place for community residents to have leisure activities (Yilan County Government, 2012). As of the end of 2015, 11 elementary schools in Yilan area have completed building covered playgrounds. However, could the building satisfy the usage requirements of schools? Is there any issue in using? These are worth of further exploration.

Therefore, this research based on the needs in practical activity usage of covered playground to explore the current situations regarding spatial planning, physical environment, building facilities, spare parts and other issues, and dig out related problems. In the end, corresponding architectural programming recommendations were proposed accordingly.

2. RESEARCH METHODOLOGY

Two research methods were introduced in this research: literature survey and current situation investigation, which are described as follows:

- Literature survey: The literature survey includes issues such as sports facility planning guidelines, sports space planning standards and physical environment standards. The summary of literature survey result is used as a reference baseline for the content definition and review of current situations.
- Current situation investigation: The current situation investigation includes work items such as administrator interview, spatial surveying and mapping, activity observation and physical environment measurement, etc. The content of current situation investigation covers school basic information, practical activity status, spatial planning, physical environment, architectural facilities, spare parts, etc.

The investigation result shows that among a total of 77 elementary schools in Yilan area in 2014, there are 11 schools have covered playgrounds, which are used as the research objects in the case study of this research (Figure 1). The class number of all these 11 schools is between 6 to 12 (1-2 classes a grade), and the average student number for a school is 144 students (standard deviation: 61.6 students).

Figure 1: Appearance of research cases

3. Discussion

3.2. Practical activity status in covered playground

In the practical activities taking place in covered playgrounds, 50 activities were collected through interviews, which can be categorized in the following five major types: physical education activities (24 items), sports competitions (2 items), performances (5 items), exhibitions (4 items), and gatherings (15 items). Furthermore, though the index of "strength of activity occurrence", the activities that are likely to occur in covered playgrounds were selected for the analysis basis of follow-up explorations on spatial planning, physical environment, architectural facility, spare part and other issues. The "strength of activity occurrence" is derived from multiplying three types of data: "average number of people in activity", "average activity time" and "average time of usage in a year". The principle for selecting the activities that occur more frequently in covered playgrounds is by choosing the activity with the highest "strength of activity occurrence" in all 5 types of activities, and the single activity that is 5% higher in "strength of activity occurrence" than the sum of that of all activities.

The research result shows that the activities frequently occurring in covered playground include 9 activities as follows: sports education - basketball (taking up 16.26% of overall strength of activity occurrences), dodge ball (8.95%), badminton (5.52%), Tee ball (5.29%), healthy exercise (5.14%); sports competition - basketball (0.34%); performance - comprehensive performance activity (1.19%); exhibition - mobile public library activity (3.14%); gathering - gathering event for school anniversary (2.59%).

3.3. Spatial planning

The current status and issue on the spatial planning of covered playground are explored via 5 approaches, which are overall architecture, unit space, space organization, space size and space material, respectively.

- Overall architectures: The covered playgrounds of elementary schools in Yilan area are all of one-story buildings, with average building area of 674m^2 (standard deviation of 244m^2). The building orientation, with regards to the long axis of court, is mainly in east-west direction. Half of the cases are with performance stages in the field and mainly locate at the long side of the court. The floor of the covered playgrounds are marked with court-lines of 2 to 3 types of ball games, among which all cases are marked with basketball and dodge ball court-lines. Nearly 40% are marked with badminton court-lines but only one case is marked with volleyball court-line.
- Unit space: The unit space of covered playground is divided into three major categories: main space, secondary space and service space, and 9 items. According to the frequency of occurrence in all cases, the sequence is as follows: Main ground (100%), covered corridor (54.5%), performance stage (45.4%), maintenance catwalk (45.4%), storeroom (27.3%), facility control room (18.2%), parking lot (18.2%), bleacher (9.1%) and restroom (shared with adjacent school buildings).
- Space organization: Regarding the above mentioned 9 activities that are often held in covered playgrounds, the space organization analysis of covered playground were executed for the spatial items that are required to be used in the proceeding of each activity.
  - Main space (including main ground, performance stage and bleacher): The main ground is used as the main space for the operation of all kinds of ball games; the performance stage is used for health exercise teaching, basketball competition, comprehensive performance and gathering of school anniversary; while the bleacher is used for basketball competitions only.
  - Secondary space (including storeroom and facility control room): The facility control room is used for the operation and storage of switches, controls and relevant facilities for electrical equipment and AV equipment, while the storeroom is used for the storage of spare parts related to physical education and gathering events.
  - Service space (including covered corridor, maintenance catwalk, parking lot and restroom): The maintenance catwalk is used for the inspection and maintenance of lightings and other equipment of the court; the covered corridor is used to connect the covered playground with other school buildings.; the parking space is used for mobile public library cars; while restrooms are used for teachers, students and community residents.

It was found in the research that some cases suffer inconvenient issues for using covered playgrounds causing by lacking performance stage, bleacher, covered corridors and other spaces. For example, due to no storeroom, the moving of physical education or gathering event related spare parts of a long distance is a headache in using covered playgrounds.

- Space size:
  - Main space: The space of main ground is capable to arrange courts of 4 different ball games, among which the basketball court takes up the biggest space. The basketball court is possible to contain one dodge ball court or two badminton courts, or one volleyball court. The basketball court takes up the space of 26 x 14 meters. Moreover, the bottom line buffer space of the court is about 0.25~3m, the side line 0.25~2m and the net height of 5.2~8.6m. In addition, the width of performance stage is between 7.8~15.9m and 3.75~4.6m in depth. And the bleach space appears only at one side for about 60m^2.
  - Secondary space: The area of facility control room is around 13~13.5m^2, and the storeroom is around 27~67m^2.
  - Service space: 80% of maintenance catwalks are configured as a C shape, while the rest 20% are configured as a square. The width of covered corridor space is between 1.5~2.5m. The parking space is 6m in length and 2.5 in width. The restroom space in all cases is commonly used with adjacent school buildings.

It was discovered in this research that in parts of the cases, as the main ground space is used for basketball court, the buffer space for bottom lines and side lines is only 0.25m, or the ceiling height is only 5.2m, both of which are

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

lower than the recommendation value (Sports Affairs Council, 2008). Furthermore, there are also insufficient size and space issue in performance stages, bleaches, storerooms, covered corridors, etc.

- Space material:
  - Floor material: There are two kinds of floor material seen in this research, with over 90% have monolithic finish flooring and less than 10% has acrylic flooring. For most of the cases that use monolithic finish flooring encounter problems such as insufficient slip friction resistance, poor elastic force and pulverization of surface layer. However, there is no foregoing issue in acrylic flooring.
  - Ceiling material: There are three kinds of ceiling material seen in this research, with 54.5% of the cases uses galvanized steel, 36.4% uses galvanized steel + polycarbonate lighting board, and 9.1% uses galvanized steel + presensitized insulation foam board. The ceiling material in all cases is presenting a good condition.

3.4. Physical environment

- Sound environment: Noise from cars and motorcycles around the school were considered affecting the usage of covered playgrounds by the administrators in 70% of the cases. According to a field investigation result, all cases present a environmental background noise of 45~55 dB(A) in daytime and 40~55 dB(A) in night time, which complies to the standard of 55 dB(A) (Lai et al., 1991). On the contrary, it was also discovered that the noise generated by the activities held in covered playgrounds is possible to become a source of noise for other spaces in the vicinity, which is worth of attention as well.
- Lighting environment:
  - Illumination: The average illumination of the main ground in covered playgrounds is 700~6,000 Lux in daytime, while in night time the average illumination of artificial lighting is 100~300 Lux, from which we know that parts of the cases cannot meet the usage standard of 300 Lux in artificial lighting in case of activities held in night-time (Architecture and Building Research Institute, 2010). And nearly 50% of the cases reflected the insufficient artificial lighting illumination issue in the interviews. In addition, there was also 81.8% of the cases reflected that the natural illumination in covered playgrounds is extremely imbalanced which caused troubles in using.
  - Glare light: In this research the most popular activity in covered playgrounds, the basketball game and performance activities, were used for the evaluation of glare light problem. The result shows that under the natural lighting in daytime for basketball game, there was 63.6% of the cases have troubles with the glare caused by the over-brightness of the background behind the basketball board or performance stage and affect the use. Furthermore, there was 45.5% of the cases have troubles with the glare caused by the artificial lighting on the basketball board or performance stage, which is worth of consideration as well.
- Thermal environment: Insufficient shading of the covered playground will lead to direct sunlight on the main ground space, and causes troubles to users for exposing under the burning sun. The interview result shows that 45.5% of the cases reflected the foregoing issue. On the other hand, a computer simulation was conducted in this research, which shows a direct sunlight interference in 5%~65% of the area of main grounds (3~5m in depth) from 9 am to 11 am; while there is 6%~60% from 1 pm to 3 pm (3~5m in depth).
- Water environment: The issue of covered playground in water environment is mainly caused by strong wind that blows raindrops into the main ground space, and results in a slippery condition of the ground that comes with safety concerns in holding activities. The investigation result shows that the eave at the long side of the main ground space in covered playgrounds have an average height of 7.5m, which is subjected to the wind-driven rain at the windward side by 3m in depth, and by 1.5m at the lee side; the eave at the bottom line has an average height of 7.7m, which is subjected to the wind-driven rain at the windward side by 2m in depth, and by 1m at the lee side. According to actual statistics result, there is over 30% of the cases are under severe impact by wind-driven rain.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.5. Building facilities and activity spare parts

- Building facilities: Lighting and power sockets are the building facilities that installed in all cases. There are less than 20% of the cases installed with lighting for stages, AV equipment and other facilities. Almost in all cases the insufficiency of power socket during performances, gatherings and such like was proposed by administrators.
- Spare parts: Basketball stands, basketballs and dodge balls required for physical education activities as well as folding chairs and tables for gatherings are equipped in all cases. And then, over 60% of the cases have badminton, Tee ball, mobile AV equipment, timers, score boards and movable stage. In addition, less than 30% of the cases have badminton nets and poles, whiteboards, bleach chairs, notebook PCs, podiums and other spare parts. Also, parts of the cases were found having headaches on moving folding chairs and tables for long distance for performances or gathering activities, as there is no storeroom prepared in the covered playgrounds.

4. Recommendations for architectural programming of elementary school covered playground

According to the investigation result of current status as well as referencing relevant recommendation standards, the following suggestions for architectural programming of elementary school covered playground were proposed.

4.1 Spatial planning

- The space organization of covered playground shall have three unit spaces at least: a main ground space that can accommodate a basketball court, a storeroom for storing necessary spare parts required for physical education and gathering activities, and a covered corridor connecting other adjacent school buildings. Furthermore, according to the expected activity types, schools can plan for performance stages, bleaches, equipment control rooms, maintenance catwalks, parking space for mobile public library cars and other unit spaces in covered playgrounds. The relative position of the above unit spaces are recommended as Figure 2.

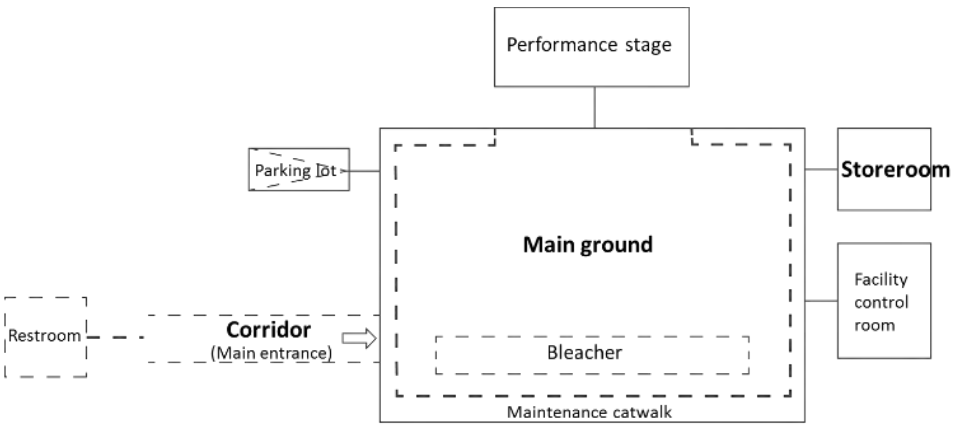

Figure 2: Typical space organization of covered playgrounds in an elementary school

- Unit space size:
  - o The main ground space shall accommodate a basketball court with sufficient court-side buffer space plus weather buffer space of proper depth, whose spatial size is around 34mx22m, area is about 748m2 and net height is at least 7m.
  - o The storeroom shall be about the size of a general classroom with area around 75m2, which can be increased or decreased according to the needs of spare parts for physical education and gathering.
  - o The size of a performance stage space shall be at least 8m x 4m, and is better located at the long side of main ground space.
  - o The area of bleach can be estimated by 0.4m2/ people, which shall be located at the opposite side of the performance stage and the line of sight shall be able to go through the whole basketball court.
  - o The area of facility control space shall not be less than 10m2.

- o The width of a covered corridor shall not be less than 1.8m.
- o The installed height of a maintenance catwalk shall not be lower than 4.5m with the width above 0.5m and the railing height above 1.1m at least.
- o The parking space shall be of the size of 6m x 2.5m at least.

4.2 Physical environment

- The artificial lighting shall reach an average illumination of over 300 Lux, and to avoid uneven illumination the main ground space shall be better allocated with over 12 sets of lightings.
- To avoid the glaring interference of sunlight in daytime, it is better to install glare-shields above the 4m height from the ground behind basketball boards and main stage. Artificial lightings shall be avoided from being installed on the wall along the short side of main courts as well.
- To avoid direct sunlight or wind-driven rain into the main ground space, the main ground space shall have at least additional 3m of depth for weather buffer space in addition to the original required space for activities.

4.3 Space material

- The flooring material of main ground space can be acrylic or synthetic rubber that prevent sport injury due to insufficient friction and elasticity of the floor. If concrete flooring is chosen due to cost concern, the surface shall be cut for expansion joints after the smoothening of the surface layer, which can reduce powder generation due to floor cracking.

4.4 Building facilities and spare parts for activities

- The building facilities of a covered playground shall include court lighting and power sockets (over 6 sets). In addition, if necessary the stage lighting and AV equipment can be considered for installation.
- Regarding the spare parts for activities, there shall be enough quantity of spare parts for basketball, dodge ball, badminton and Tee ball for at least 20 people to use as well as spare parts for basketball games, and at least 100 folding chairs and 20 folding tables for gathering activities. Furthermore, whiteboard, bleach chairs, podiums and other spare parts can also be considered.

ABSTRACT

This study is an initial attempt to investigate public mood in the city by revealing relationships between opinion mining from online sources and real world phenomena based on sentiment analysis. The aim of the study is to determine potential of geo-tagging social media data, as well as offering possible new directions for city planners. We analyzed data from social media i.e. Twitter and generate a sentiment map of the city. We developed classifier tweets and emoticons to determine the mood of each tweet. We selected the city of Bandar Lampung as the case study. Bandar Lampung is the capital of Lampung Province with the population of over one million people. Moreover approximately 10% of the population in Bandar Lampung is within the age of 15-19. In Indonesia, this group of age represents 80% of the internet users. Therefore we would argue that the citizens of Bandar Lampung could provide sufficient social media data for this study. Sentiment analysis on social media data can offer better information for city planners and developers that can be used to improve planning and quality of life in the city.

Keywords: sustainable neighbourhood, city, sentiment analysis

1. INTRODUCTION

Social networking websites are the new era of expressing views. Today every person put their opinions, views, comments on these micro-blogging and social sites like Twitter, Facebook and many more. Social networking sites have provided an easy and attractive way to exchange ideas, opinions, knowledge and lots more. People can update status which gives a picture of what's going on in their minds. These statuses can reflect an individual's mood, their achievement or failure. Further, the comments on the same can help to gather other people's opinion on the same, thus, providing an overwhelming and valuable piece of information on a particular subject.

Twitter makes it easy for users to communicate, collaborate, interact and share data. The ease of access so as to provide the online reaction to everything that happens around them. Mood someone usually poured in posting their tweets. a person's lifestyle can be drawn from their tweet. Some of research studies have linked the use data from twitter. Twitter use of data related to public health surveillance. The large volume of data in Twitter approximately 5000 posts per second, it can help the extent to which the data twitter support public health surveillance and provide results that support for exploration of the future. Social media can be leveraged to provide greater understanding of the well-being and health behaviours of community's information that has been previously difficult and expensive to obtain consistently across geographies. More open access neighbourhood data can enable better design of programs and policies addressing social determinants of health. From retagged twitter data, a national neighbourhood database with area-level indicators of well-being and health behaviours.

Sentiment analysis or opinion mining is the process of understanding, extract and process the textual data automatically to get the sentiment of information contained in an opinion sentence. In this paper we analyse data from the micro-blogging site Twitter and generate a sentiment map of cities. We develop a classier Twitter messages, or tweets, using key words, phrases and emoticons to determine the mood of each tweet. We combined with geo-tagging provided by user. We can find the public mood is based on the level of sentiment in certain locations. Based on the results of data classification twitter we tried to take a variety of issues related to the environment, sustainable development and climate change.

We use Twitter to study of the cities based on geography and dynamics of sentiment in the greater area of the city, identifying areas and times of positive and negative sentiment. We built a sentiment classifier in order to assess the mood of the twitter.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The aim of the research is to determine potential of geo-tagging social media data based on sentiment analysis, as well as offering possible new directions for the research community for city planners. Sentiment analysis on social media data can offer city planners and developers better information that can be used to improve planning and quality of life in cities especially in the areas of environment, climate and sustainable development.

2. METHODOLOGY

2.1 Data collection

Twitter is a microblogging site created in 2006 that is used by over 500 million people worldwide. Twitter tweet are used for our research work which is our primary focus. They will be further use for mine opinion on the basis of features contain in the tweet extracted. We use Twitter to study of the cities based on geography and dynamics of sentiment in the greater area of the city, identifying areas and times of positive and negative sentiment.

We selected the city of Bandar Lampung as the case study. Bandar Lampung is the capital of Lampung Province with the population of over one million people. Figure 1 show in Map of Bandar Lampung, Latitude and longitude coordinates are: - 5.450000, 105.266670.

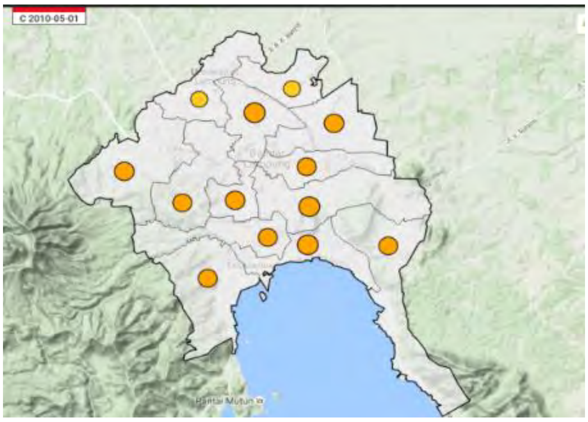

Figure 1: Map of Kota Bandar Lampung
Source: Badan Pusat Statistik, Republik Indonesia (web)

Table 1 shows of population in Kota Bandar Lampung. Bandar Lampung is large city. With its almost 900,000 population, the city is considered to the third most populous one in the country.

Name	Status	Population Census 2010-05-01
Kota Bandar Lampung	City	881,801
Kedaton	District	88,314
Kemiling	District	71,471
Panjang	District	63,504
Rajabasa	District	43,257
Sukabumi	District	63,598
Sukarela	District	70,761
Tanjung Karang Barat	District	63,747
Tanjung Karang Pusat	District	72,385
Tanjung Karang Timur	District	89,324

2.2 Sentiment Analysis

Figure 2 depicts a typical sentiment analysis model. The model takes a collection of tweets as input, and processes them using three core steps, data preparation, and review analysis and sentiment classification. The results produced by such a model are the classifications of the public mood.

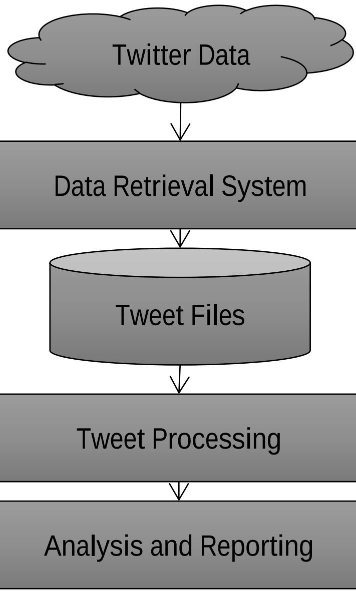

Figure 2: Sentiment analysis model

2.2.1 Data preparation

Text preparation is nothing but filtering the extracted data before analysis. It includes identifying and eliminating non-textual content and content that is irrelevant to the area of study from the data. The retrieved data was cleansed by removing: symbols, punctuations, special characters, URLs, and numbers Bag of Words approach was used for sentiment analysis.

- Stemming: Each tweet was stemmed into the group Indonesian words
- Matching: A match of each word was searched in the lexicon database
- Scoring: Positive and negative matches were summed to define a score of each tweet
- Polarity: (P-N)/ (P+N), where P=total sum of positive sentiment words; N=total sum of negative sentiment words

2.2.2 Naïve Bayes classification

Naive Bayes classifier is a simple model for classification. It is simple and works well on text classification. It is a probabilistic classifier based on applying Bayes' theorem with strong independence assumptions. This is the simplest form of Bayesian Network, in which all attributes are independent given the value of the class variable. This is called conditional independence. It assumes each feature is conditional independent to other features given the class. A Naive Bayes classifier is a technique that applies to a certain class of problems, namely those that phrased as associating an object with a discrete category. We make two classes positive and negative tweets.

A conditional probability is a probability that event X will occur, given the evidence. So, our initial formula looks like this:

$$P(sentiment|sentence) = \frac{P(sentiment)P(sentence|sentiment)}{P(sentence)}$$

We can drop the dividing P(line), as it's the same for both classes, and we just want to rank them rather than calculate a precise probability. We can use the independence assumption to let us treat P (Sentence | Sentiment) as the product of P (Token | Sentiment) across all the tokens in the sentence. So, we estimate P (Token | Sentiment) as:

Count (This token in class) +1/ count (All tokens in class) +Count (All tokens)

The classify function starts by calculating the prior probability (The chance of it being one or the other before any tokens are looked at) based on the number of positive and negative.

3. ANALYSIS RESULTS

We collected 53389 tweets from September-October 2015. We built a sentiment classifier in order to assess the mood of the twitter. Here we use Twitter to study the fine-grained geography and dynamics of sentiment in the greater Bandar Lampung City area, identifying areas and times of positive and negative sentiment. Figure 3 shows tweets collected from Bandar Lampung city during September-October 2105.

Figure 3: Tweets collected from Bandar Lampung during September-October 2015

We collected tweets by name of user, text tweets, date, time, longitude and latitude. From this data we classification which tweets positive or negative based on location.

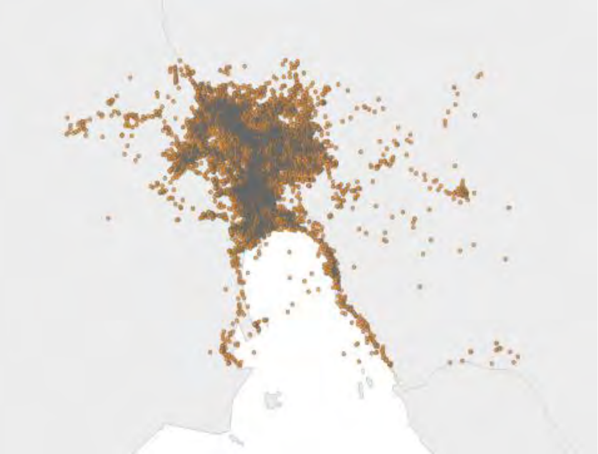

Figure 4: Map of tweets collected from city of Bandar Lampung during September and October, 2015

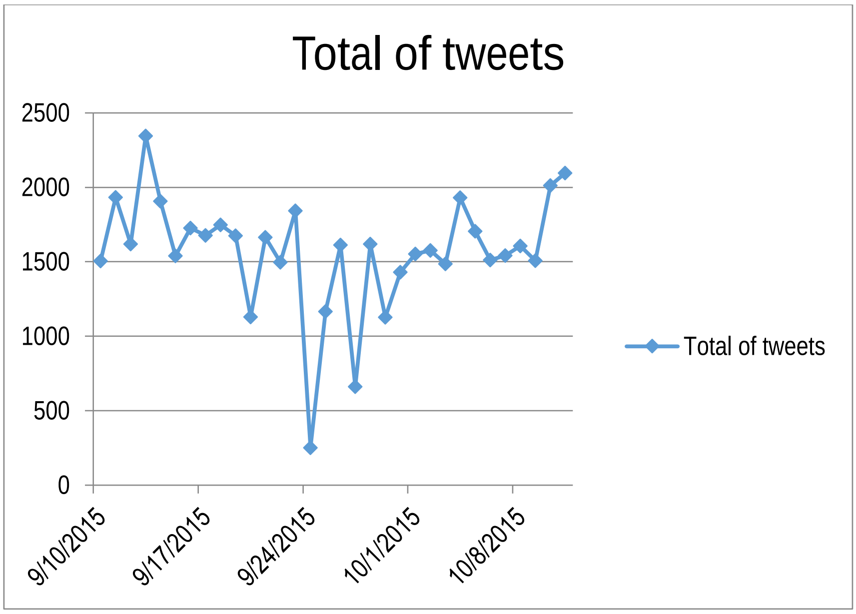

Figure 5: Total tweets per day

We have analyzed the geo-tagging social media data based on sentiment analysis in Bandar Lampung during a period September and October 2015. By building classifiers based on tweets mood, we are able to map the general trends and identify areas of strong sentiment.

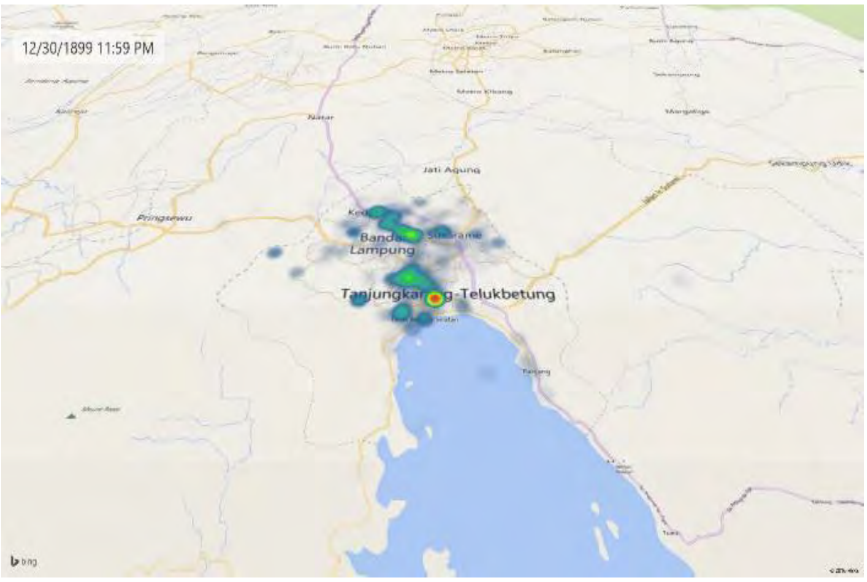

Figure 6: Map of tweets data based on tweets frequency

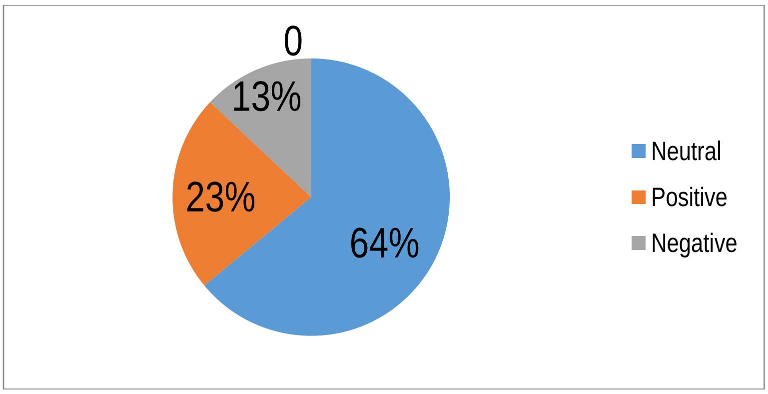

Figure 7: Overall sentiment classification

Figure 7 shows overall sentiment classification, this data we can use for find what the problem make user negative tweets. After the classification process of positive and negative tweets, then we will filter the data based on the issues relating to the environment, sustainable development and climate change. For the future work we are trying to collect as many words related to the environment, sustainable development and climate change that can support better filtering tweets again.

4. CONCLUSION

This study is an initial attempt to investigate public mood in the city to reveal relationships between opinion mining and real world phenomena based on sentiment analysis. This study establishes a methodology for using opinion mining social media and sentiment analysis to understanding cities. This information could be help city planners plan future developments. Our method of public mood analysis has several strengths. For Future work we plan to collect more tweet data to get specific mood about city. We hope this paper will contribute to the research of the built environment and is based on a complex network analysis based on social media from Twitter.

ABSTRACT

Rural Regeneration is the most prominent national policy project of the Council of Agriculture, Executive Yuan of Taiwan. According to the Agricultural Development Regulations issued for implementation in Aug.4, 2010, 150 billion NT dollars of the rural regeneration fund would be allocated to ten-year budgets to boost rural developments for fishermen and farmers. Located in the most southern part of Taiwan, Pingtung County is the most important agricultural county in the south and Pingtung government has dedicated to the rural regeneration policy to improve the life conditions there. Among the 381 agricultural communities, 238 participated in incubation programs, of which 37 communities were granted for rejuvenation. This project aims at depicting how a local government of Pingtung County complies with the central government to promote rural regeneration policies and to innovate their governance.

Keywords: rural regeneration, landscape axis, vital action project, live and work in peace and contentment

1. INTRODUCTION

To meet the need of the entire rural development, rural regeneration is settled. With current agricultural communities in the center, participating from bottom to top, agricultural villages are holistically established to better residents' life. Besides, related industries, natural ecology, and living environments are also planned and constructed for conserving the cultures and sustain a green environment. Therefore, Pingtung County Government (PCG) established Rural Renewal Project Office (RRPO) on Mar.3, 2016 to specifically and directly deal with rural regeneration matters; related resources can hence be integrated effectively.

In 2016, PCG has implemented the incubation programs, vital action projects, rural rejuvenation plan reviews, annual implementation plans, farmhouse inspection and management, excellent rural community competitions, and other related plans. To achieve the goal of "work and live in peace and in contentment," rural regeneration is able to be carried out with sufficient resources and appropriate content. RRPO is led by the deputy governor along with each bureau to voluntarily take charge of a township as a team and to assist each agricultural community involved in the project. It is expected that through in-depth interviews and counselling, strategies for promoting regenerations can be found. Cross-bureau integration on the basis of "communities" contributes to effectiveness of resource combinations for the interests of people in the communities.

2. AGRICULTURAL REGENERATION POLICIES OF PINGTUNG COUNTY

Given more modernized areas in Taiwan, more and more people have begun to recollect a simple rural life of friendly people, without hustle and bustle of cities. In view of the fact that some communities, after receiving subsides, have started to build their own communities with their plans, or others copy some successful communities in form but neglect local features, the agricultural regeneration project was initiated by the Bureau of Soil and Water Conservation of the Council of Agriculture. A bottom-up promotion policy has been adopted and trained residents through the Bacon Project for them to comply with their community regulations and create a distinctive community from the perspectives of life, production and ecology.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

As a leading position to promote the overall construction of the domestic communities, PCG makes good use of the resources from the central government to boost regeneration. Since 2015, PCG, by the principle of innovative management, has integrated actual demands and development plans. In 2016, PCG even took the lead in setting up the first RRPO in Taiwan, with a single window linking the central and local resources to help the communities promote rural industries, train professionals, explore local cultures and inject new elements to local resources. Via resource integrations, the direction of rural regenerations is in line with other major projects of PCG.

3. SEVEN AREAS OF RURAL REGENERATION

The promotion of rural regeneration in Pingtung County is an entirely new administrative subject and experience. Especially in the 21st century with the aim of conservation as a way of life, we identify existing landscape types from the past, in search of a new development link among life, production and ecology. Apart from local characteristic of each village, high-quality, safe, recreational, and ecological communities must be built as well as gathering rural manpower in teams to increase self-reliance. The rural landscape structures of Pingtung County can be divided to seven areas: (1) the valley living production area, (2) the multi-agricultural production and living area, (3) the Tinan large-scale open production and living area, (4) the Pingtung City core development area, (5) the production and living area of Pingnan traditional tribes, (6) the fishing village area of living, and (7) the Peninsula humanities and natural ecological living area. The division is based on the historical changes in life. Through the environmental investigation and analysis, the rural areas of Pingtung Country are spatially evident with a goal of reconstructing the unique rural landscape and its sustaining systems.

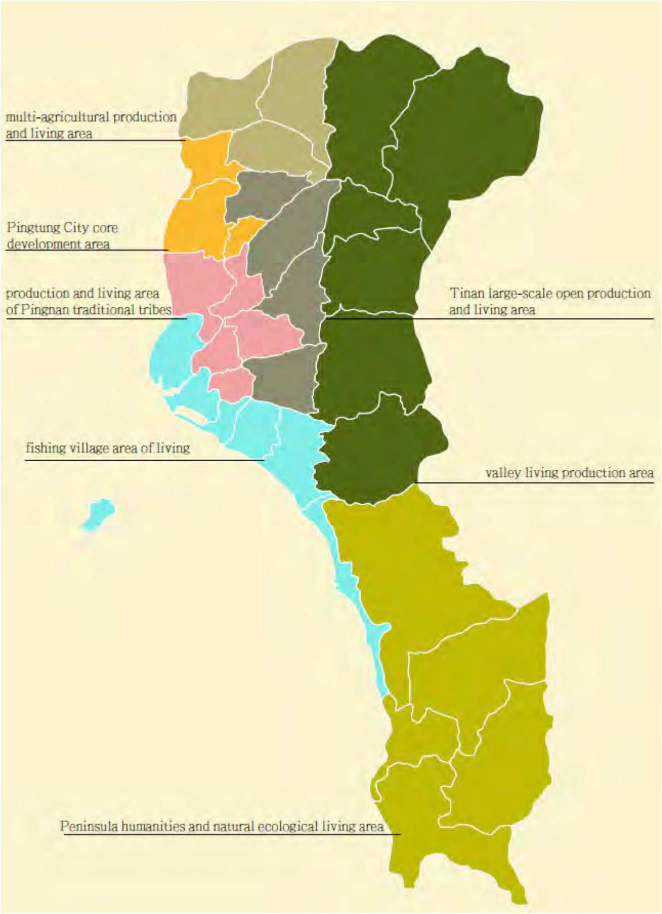

Figure 1: Seven areas of rural regeneration

4. THE VISION AND PROSPECT OF THE DEVELOPMENT OF THE SIX ZONES OF AGRICULTURAL REGENERATION

There are six areas for development in Pingtung County on the basis of different visions. Respectively, they are "pro-mountain ecological corridor", "characteristic agricultural development area, ""high-quality new life town,"" metropolitan core life area,"" marine recreation development area," and "Peninsula sustainable tourism area." These sixe zones for development correspond to (1) eco-tourism, environmental preservation, cultural preservation, humanistic values, (2) I-center cross-area values for agricultural regeneration, (3) liveable city+ investment promotion +green living +low carbon transportation, (4) Sightseeing fisheries, low carbon sustainability, marine recreation and convenient transportation, (5) cultural creativity, sightseeing recreation, ecological conservation and ecotourism. The six visions of the development are combined with the seven areas of the geographical division of rural regeneration, which results in a prosperous development of Pingtung County.

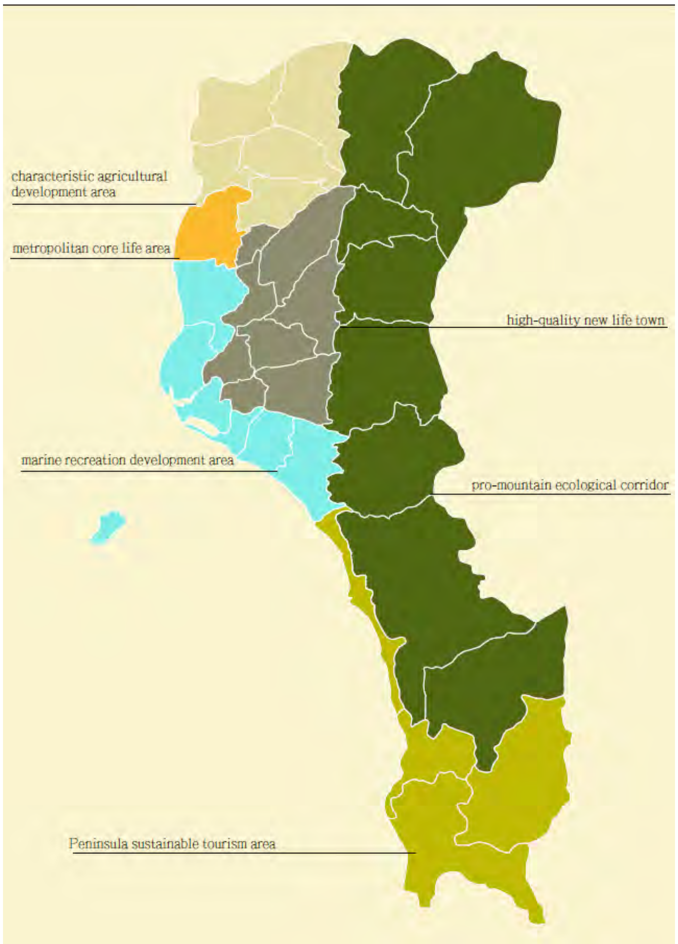

Figure 2: Six areas for development in Pingtung County on the basis of different visions

5. INNOVATIVE GOVERNANCE OF RURAL REGENERATION IN PINGTUNG COUNTY

On March, 3, 2016, the first Rural Renewal Project Office was officially established in Pingtung County to initiate the rural regeneration programs and promote rural sustainable development and rural revitalization. Through the matrix-based organization mode, a platform for the rural regeneration program will be constructed by a dedicate staff, and resources of the central and local governments will be associated to take a big leap ahead. Pingtung County and Yilan County have been at the leading position to boost the overall development of community building in Taiwan. Moreover, the special budget under the Rural Renewal Regulation offers a new energy for rural transformation. However, the rural regeneration program was developed by the community itself after stages of discussions and its effect was less significant. As a result, starting from 2015, the county government, led by the Deputy Mayor, Wu Lixue, has integrated the actual needs of the communities and development plans. For example, along the line of County Rd.185, resources are combined to build up a featured agricultural village of culture, industry and tourism.

When local governments have been entrusted by the Bureau of Soil and Water Conservation under the Council of Agriculture to promote rural regeneration businesses, it is imperative for a special project office to integrate and plan them. PCG established the first Rural Renewal Project Office as a single window linking the central and local resources to assist the communities in promoting rural industries and personnel training. Furthermore, a multi-faceted integration of people, culture, farm, production and landscape is complete to link marketing and tourism to vitalize rural lives. As a result, the Rural Renewal Project Office was set up to help the communities incorporate sustainability policies into their respective rural regeneration programs. Through resource integration, the rural regeneration project complements the overall plan of PCG as to comprehensively implement the project, empower the community resources and sustain the community development.

County Rd. 185 landscape axis

County Rd. 185, from Dajin to Fangliao, is about 68.885 kilometers long and is the fifth longest county road among all in Taiwan. Along the line by the west side of the central mountain range of Taiwan, it is also named Yanshang Road for its location along the mountain side and is considered the main contact road among the eight mountain townships in Pingtung County, forming a multi-ethnic convergence axis. The majority of the population in Pingtung County are Taiwanese, but the proportion of Hakka people accounts for 23 %, indigenous peoples, including Rukai, Paiwan, and Pingpu, are about 6.85%, and immigrants from China, including veterans, Dachen immigrants, Burmese immigrants are about 8.4%. Due to the diversity of cultures, County Rd. 185 goes through and integrates different ethnic groups in terms of life, ecology, production, culture and other regional categories.

Pingtung rural tour of the six arts

The term “rural six arts” refers to an action plan of arts in rural areas to create an artistic community. Through a multi-resource mixture of County Rd. 185 and Rd. 189, coupled with the marketing of PCG, emerging tourist attractions and experience-based recreation modes are established. With the theme of the rural regeneration program, the “valley living production area” uses eco-urban and rural constructions as the future blueprint. Using the six arts (performing arts, toys art, agriculture, crafts, travel art, and stone craving art) as the main elements, the plan fuses the previous outcomes of the industrial development, ecological conversation, cultural preservation, and the software and hardware construction. Within the theme of Six Arts Tour in Pingtung Rural Area, cultural tourism is implemented with the residents’ participation and with a rural image. The landscape along the axis can be shaped then to promote a travel package in the future.

Along County Rd. 185, the targeted communities of the rural regeneration which are equipped with the six arts and have been granted as the included communities in the project or have developed well include: Xinfeng Community, Anpo Community, Dewen Community, Sandi Community, Maer Community, Qingye Community, and Wanjin Community. The seven communities have been chosen as the main constructs of this proposal. After the integration, installation arts and signboards will be settled. Concrete constructs will be done through the “Exploring Experience Area” and the “Native Community Environment Beautification of the Xinfeng Community, for instance. In the following, small country tours, environmental improvements, industrial brand planning and design, deepening and upgrading industries, eco tours, conservation and improvement of ecological environment, cultural heritage and learning can be all implemented to highlight the features and visions of this project.

Tribes, starry skies, and fun of camping

Modern people have urgent needs to approach the nature and the earth in the leisure time due to pressure from work, family and so on. In order to mediate and ease their minds, camping in the wild provides a way out to balance the body and the mind. Given this, Maer Community and Qingye Community create a spotlight for camping in tribes under the starry sky.

On the other hand, these two communities have a theme of “myth art village” and “traditional horse-riding arena to corporate ecotourism, post space, star camping, traditional folk, tribal i-center as community highlights. The landscape planning and design style can be improved, and new features and opportunities are shaped in rural areas along with tribal characteristics, and marketing camping.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

County Rd. 189: Six arts axis

The six arts innovation and management plan on the left bank of Gaoping River will be carried out from 2017 to 2019. The spirit of the plan lies in the mastery of the merits and opportunities of regional and geographical conditions and a further integration of urban and rural areas in the prospect of co-prosperity. The concept of "living circle," "production circle,"" Ecological circle,"" and "cultural circle" will be implemented to arrange a sustainable landscape.

In a cycle of annual plans, the Bureau of Soil and Water Conservation connects directly with PCG to implement the rural regeneration policy. In 2017, townships along County Rd. 189 and 185 will be united and extended as a vertical landscape axis, encompassing "Pingtung Six Arts Life Museum." A bright spot of six arts via a cross-domain integration will build up agricultural communities through resources of people, culture, geography, specialties, landscape, and so on.

Action plan of rural revitalization

Based on the characteristics and needs of individual rural communities, the rural revitalization plan is to broaden the concept of rural residents' bonds and co-participation. They take part in practical courses, practices of life, production, conservation of ecology and culture, and even bring about a concept of community consensus. The establishment of rural communities leads to self-development awareness and create new features to them.

The plan subsidizes NT$250,000 for each rural community. Programs or courses will be offered and conducted through a consensus meeting, a proposal, qualification and content review, workshop experience sharing, write-off instruction and guidance. A dynamic, systematic action play will be carried out to create bright spots in a multi-dimensional landscape in a new community. Integrated with six arts, the features of each community are highlighted and new opportunities are created for community life.

6. CONCLUSION

Pingtung County lies in a place of green mountains and blue seas. During the day time, the sun shines to rural communities with full energy. At night, starry skies are seen in Qingye Community and Maer Community, camping venues. Along the landscape axis of County Rd. 185, granted revitalized villages corporate six arts into their lives to display individual features. The "six arts," are assimilated to the six arts of Chinese Confucianism," rites, music, archery, riding, books, and art." But now the six arts refer to performing arts (Maer Community), toys art(Anpo Community), agriculture (Qingye Community and Dewen Community), crafts (Sandi Community), travel art (Xinfeng Community), and stone craving art (Wanjin Community), altogether comprising Pingtung Six Arts Life Museum. Through qualia in the six arts of rural communities and those of the action plan of rural revitalization, a new journey to Pintung has been linked like a string of pearls, leading to a new era, a new appearance and a new energy.

The rural revitalization policy and innovative governance is a complete, sustainable development and management of rural communities along a landscape axis. Regeneration is promoted to improve the ecological environment, to maintain agricultural cultures, to enhance country lives, and to construct new villages. With the help of the Rural Renewal Project Office of Pingtung County, related businesses are integrated on a single platform or window to directly link to the central government, including the Bureau of the Soil and Water Conservation of the Council of Agriculture and its affiliated divisions. Therefore, horizontally and vertically, related departments are able to be associated and contacted. Special personnel are responsible to contact them and implement their tasks. Meanwhile, the project of value-added strategies for rural revitalization is proposed to integrate the resources of each department or office to comply with their current administrative and project promotions. Finally, other resources will also be put in related rural constructions or revitalization to add values with this project for more concrete effects, realizing the governmental vision of Pingtung County, "work and live in peace and contentment."

[e] 2030 Districts, jli@architecture2030.org

ABSTRACT

As of 2016, fifteen 2030 Districts® have formed across North America to implement the carbon reduction targets set by Architecture 2030 for existing buildings through energy, water and vehicle emissions reductions.

2030 Districts® are unique private/public partnerships that bring property owners, managers and developers together with local governments, businesses and community stakeholders to provide a business model for urban sustainability through collaboration, leveraged financing, and shared resources. Together they engage local community stakeholders to benchmark, develop and implement creative strategies, best practices and verification methods for measuring progress towards common goals.

The majority of 2030 Districts are located in downtown commercial cores and city centres, which typically have the highest and most concentrated energy and environmental impact. There, the reduction of energy and water consumption, transportation emissions, and improved indoor air quality provides the additional benefit of increased competitiveness in the business environment and owner's returns on investment. Several of the Districts that are vulnerable to environmental threats such as flooding also focus on community and economic resilience. This paper will explore the achievements of the 2030 Districts in meeting their carbon reduction targets, and their impact on raising awareness of climate change and mobilizing community action. It will also explore some of the challenges of fighting climate change at a community level and provide guidance for emerging 2030 Districts and/or cities interested in establishing 2030 Districts.

Keywords: design process, green rating tool, high-performance building

1. 2030 DISTRICTS

"Without a dramatic change in the way built environments are designed, constructed, and operated, the world has no chance of adequately addressing climate change." - Architecture 2030

On December 12 2015, the world came together and reached a monumental climate change agreement. At the heart of the agreement is a "long-term goal" to limit global average temperature increase to

"well below 2°C above pre-industrial levels and to pursue efforts to limit the temperature increase to 1.5°C."

To realize this goal, the scientific community estimates that the world must peak total greenhouse gas (GHG) emissions by 2020 and reach zero fossil fuel CO2 emissions by about mid-century. [1]

COP 21 in Paris also provided an opportunity for the building sector to address the critical role it must play in reducing carbon emissions worldwide. Urban environments are responsible for over 70 percent of global energy consumption and GHG emissions, mostly from buildings. [2] Over the next two decades, it is estimated that a staggering amount of building area will be newly built or rebuilt in cities worldwide to accommodate a projected 1.1 billion new urban inhabitants – a number equivalent to the current population of the entire western hemisphere. [3] These trends reveal an important opportunity to address the climate change crisis through the design and operation of the urban built environment. This requires leadership, ingenuity, and new types of partnerships.

1.1 2030 Challenge

Architecture 2030 defined the connection between climate change and the global building sector in 2003 when it revealed that buildings are responsible for 48 percent of total U.S. energy consumption and greenhouse gas (GHG)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

emissions, and 77 percent of total U.S. electricity consumption. [4] It followed that architects and other building professionals, who design our buildings and specify materials and equipment for new projects, have a direct stake in lowering the level of carbon emissions from buildings, particularly in dense urban areas. Architecture 2030 partners and collaborators have been instrumental in framing the discussion around the decarbonization of the global built environment.

In 2006, Architecture 2030 issued the 2030 Challenge, asking the architecture and design community to commit to using design strategies and specifications that would gradually reduce GHG emissions in all new buildings, developments, and major renovations, to make them carbon-neutral by 2030. Since the Challenge was issued, thousands of design professionals, firms, and organizations have committed to meeting the 2030 Challenge in their work.

Delving deeper into energy use and GHG emissions in cities, Architecture 2030 issued the 2030 Challenge for Planning in 2008. The 2030 Challenge for Planning goes beyond reducing carbon emissions from individual buildings, integrating transportation, infrastructure, planning and climate resilience into its focus. This challenge comprises a set of incremental reduction targets for energy, water and vehicle emissions, and includes 2030 Challenge targets for new construction while adding targets for the existing building stock. The 2030 Challenge for Planning has attracted stakeholders from both the private and public sectors, including engineers, building owners and managers, institutional and civic leaders, and businesses.

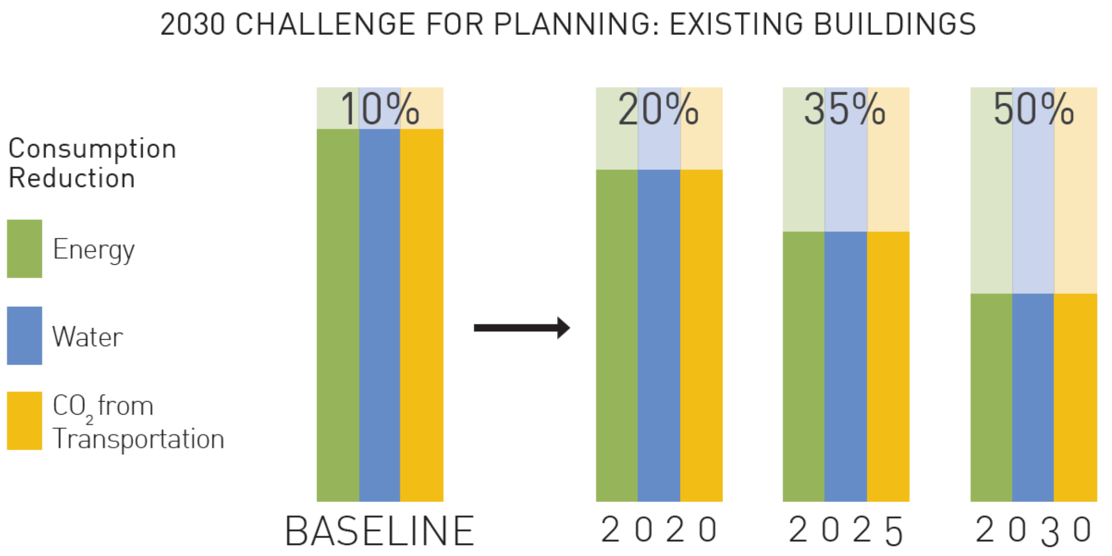

Figure 1: District 2030 reduction targets for existing buildings

1.2 What is a 2030 district?

The 2030 Districts movement began as a collective response to the 2030 Challenge for Planning. A 2030 District is a locally organized, private/public partnership among stakeholders within a concentrated commercial or institutional urban core. 2030 Districts demonstrate that reductions in energy, water, and transportation emissions called for by the 2030 Challenge for Planning can be achieved through collaboration, leveraged financing, and shared District Member Resources. 2030 Districts bring together local property owners, managers and developers, government officials, businesses, and community institutions. Together they develop and implement creative strategies, best practices and verification methods for achieving progress towards a common goal.

Across North America and beyond, 2030 Districts are forming to meet the emissions reduction targets called for by the 2030 Challenge for Planning. Emissions reduction solutions and strategies vary among cities, depending on climate and geography as well as the local economy and community goals and priorities. For this reason, 2030 Districts are unique in their flexibility, while consistent goals and performance tracking strategies across Districts allow for the collaboration and success of the entire 2030 Districts Network.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2. THE NEXT STEP: CONVENING A 2030 DISTRICTS NETWORK

Architecture 2030 organized the first annual 2030 Districts Summit in August of 2013, which was attended by representatives of all established Districts and those from cities interested in creating a District of their own. The outcome of the Summit was consensus among District leadership of the value of forming a Districts Network.

In October of 2013, Architecture 2030 drafted a comprehensive business plan to implement future expansion of the Network and its benefits to members. The multi- pronged vision of the 2030 Districts Network included attracting new cities to the 2030 District model, supporting peer exchange among Districts, aggregating the purchasing power of Network membership, and creating national partner relationships. Architecture 2030 launched a 2030 Districts Network website, with online technical tools provided by Lawrence Berkeley National Laboratory, and a number of toolkits for existing and emerging 2030 Districts and their members.

Beginning with Seattle in 2011, the 2030 Districts Network has grown to fifteen (and counting) in 2016. Through the current 2030 Districts Network, all 2030 Districts benefit from collaboration and services, including technical support, fundraising guidance, access to national partners, and participation in 2030 Districts Network conference calls, summits, webinars and capacity building workshops

Figure 2: Representation of the established Districts 2030

3. WHAT HAVE THE 2030 DISTRICTS ACHIEVED SO FAR?

To date, the 2030 Districts have made tremendous progress towards meeting their goals and targets. The Seattle 2030 District's Strategic Plan presents a vision for a high performance urban area that dramatically reduces the environmental impacts of building construction and operations while contributing to the growth of Seattle's economy. [5] This vision has taken hold within Seattle's City Council, which has launched the Living Building Pilot to incentivise and implement the construction of buildings that capture and treat all stormwater and produce as much energy as they use. Meanwhile, Seattle 2030 District energy achievements include five whole-building retrofits that achieved an average 17% energy reduction, and more than 8.2 million kWh total energy savings for the District as a whole. [6]

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The Cleveland 2030 District, which joined the initiative in 2011, has brought together 168 buildings comprising 40 million sq. ft. Sixty six percent of these properties now report their energy consumption in Portfolio Manager, an ENERGY STAR tracking software developed by the US Department of Energy. With the help of District programs and initiatives these buildings are currently operating at a 24.2% reduction from the district baseline, saving an average of 107,752,188 kWh (367,665,725 kBTUs) per year – equivalent to the total energy use of almost 3,000 single family homes in the Midwestern US. The Cleveland 2030 District is also working with the Water Department and local transportation agencies to understand historic consumption trends and define water and transportation baselines. [7]

Pittsburgh, one of the most aggressive Districts to pursue the 2030 goals, has involved 85 property partners who have committed 438 buildings totalling 68.2 million square feet. Pittsburgh 2030 District has held 44 one-on-one meetings with property partners and held 32 educational events and presentations. Partner building achievements to date include 12.5% energy reduction, 10.3% water reduction and 24.2% transportation emissions (CO2) reduction. [8]

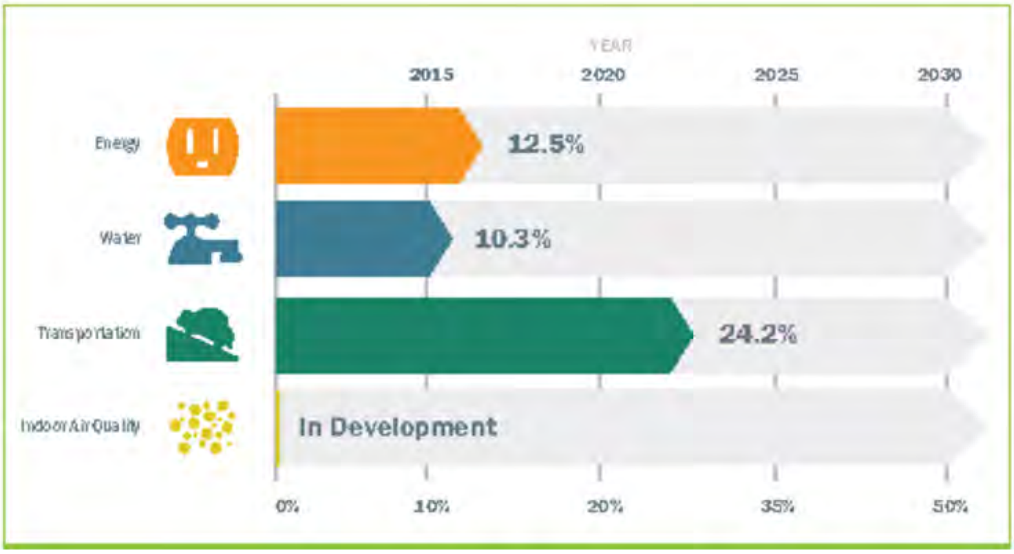

Figure 3: Pittsburgh progress toward the 2030 goals

The San Francisco 2030 District, with an aggregated member building area of over 12 million square feet, has recently been awarded $5 million in grant funding from the California Energy Commission. The grants are targeted at two of San Francisco's most prevalent, and therefore most environmentally impactful, building types: mixed use and small (under 50,000 square feet) commercial. The funding will support the San Francisco 2030 District both in proving the business case for Zero Net Energy (ZNE) retrofits for these building types as well as in developing tools and resources for ZNE retrofits throughout the city and country.

The 2030 Districts effort is not limited to larger cities, and has garnered the participation of smaller cities such as Stamford and Ithaca. Though it is one of the newest and currently the smallest 2030 District, Ithaca has secured funding from both the New York State Energy Research and Development Authority (NYSERDA) and the Park Foundation, supporting the District in proving the model's viability in smaller markets. And in its 2015 annual report, Stamford demonstrated an improved energy performance of 23.9% for 2030 District members, compared to the baseline. [9] In addition to the key District 2030 goals of energy, water and transportation, Stanford has identified resilience as one of its key objectives. To assess Stamford's vulnerability to coastal storms, the District is working closely with the City of Stamford to complete a preliminary review of the UNISDR Disaster Resilience scorecard and is actively working with CIRCA, C2ES and other organizations to determine which meaningful actions will make Stamford a more resilient city.

4. CONCLUSION

2030 Districts have emerged as an effective bottom–up, community-driven mechanism to fight climate change. For local government, 2030 Districts provide an opportunity to collaborate with communities on implementing increasingly critical climate change policies. For participating businesses and commercial partners, particularly the real estate sector, 2030 Districts provide an opportunity to document organizational commitments to social responsibility and act as a driver for improving operational performance, reducing energy and water costs, and participating in a green economy. Nationally and globally, the 2030 Districts Network is proving to be an effective mechanism for aggressively reducing carbon emissions at the scale necessary to meet our climate change goals.

A Critical Discussion on the Role of Architectural Practice in Development of Rural China: For Living Sustainably

LI Ke-han[a], Edward NG[b]

[a] *The Chinese University of Hong Kong, Hong Kong SAR, likehan@link.cuhk.edu.hk*
[b] *The Chinese University of Hong Kong, Hong Kong SAR, edwardng@cuhk.edu.hk*

ABSTRACT

Worldwide sustainable development advocates sustainable living for all. The increasing architectural construction in China has become an irreversible force in rural development. Judging and conducting architectural practice based on analysis of living sustainably in rural China is urgently needed. The developing of rurality should show sustainability through the lenses of institutions, capital, and ecosystem services, with the aim of achieving well-being and maintaining ruralite-centred development. Such a perspective will facilitate the development of a conceptual framework of sustainable rural living. Architectural practices can advance sustainable living. Contextualisation sustainable living in rural China can identify the current needs of a decent and endogenous life, which is also open-source and universally beneficial to all. Prevalent problems in architectural practice in rural China such as house demolition, inefficient use, inadequate sustainable concern, and the recently unveiled top-down working pattern are challenged. An alternative framework of architectural practice pattern should be adopted to promote sustainable living in rural China. Such a framework should include context specification and should consider functional, procedural, material, and managerial sustainability.

Keywords: rural architectural practice, living sustainably, community empowerment

1 INTRODUCTION

The rural architectural practice emerging in China over the last decade should be re-examined from the lens of sustainability because sustainable development has become a worldwide consensus for human development. China has promoted sustainable development as a national strategy since the 1990s, but modernisation and industrialisation remain the ultimate goal of development. The Sustainable Development Goals (SDGs) in 2015 signify the global movement towards sustainability. Given the announcement of SDGs and the inevitable domestic structural transformation, China intensifies its effort to reduce carbon emissions and advance balanced urbanisation. Thus, rural architectural practice requires extensive knowledge on sustainable rural development and must promote sustainable approaches. The broad concept of sustainability provides varied perspectives on particular contexts and needs. Rural life in China is discussed using a conceptual framework of sustainable living. Targeting this, appraisal on the current situation and the latest empirical results of rural architectural practice reveals the problems and limitations. The role of sustainable architecture practice is also contextualised.

2. LIVING SUSTAINABLY IN THE RURAL CONTEXT

2.1. Rurality and rural space, sustainability, and well-being

Rurality provides a scope for the development of a conceptual framework of living sustainably. Rurality is related to the physical or emotional characteristics that are interpreted and reinterpreted by people living or working in rural areas (Bosworth, Somerville 2013, Cloke 2003). These features guide ruralites' life, practice, and choice (Van Assche, Hornidge 2015). Three theoretical lenses are used to conceptualise rurality (Adapted from Bryant, Pini 2010, p.4-5): the functional lens refers to the rural land use, landscape, and identities of living on land (Cloke 2006); the lens of political-economy indicates the domestic relationships and global connections of rural places based on networks such as production, economic activities, social structure and relations (Cloke, Goodwin 1992, Friedmann, McMichael 1989, McMichael 1996, Redclift et al., 1991); the lens of social constructionism shapes identities of place by rural idyll and the "interconnection between construction of rurality and nature" (Cloke 2006, p.21). These three lenses of rurality are applicable to a certain location, space, or place that support rural life. Location indicates specific topographic positions, whereas space pertains to human and non-human activities in a location; place possesses identities and boundaries which may be impermanent, permeable and blurred, indicating the socio-cultural and environmental values (Cloke 2006, Bosworth, Somerville 2013). A triad model of rural space (Halfacree

2006, p.51) includes rural localities, which are "inscribed through relatively distinctive spatial practices," formal representations, which frame rurality "within the (capitalist) production process," and everyday lives of the rural, which "incorporates individual and social elements ('culture') in cognitive interpretation and negotiation." which emphasise "materiality, representation, and imagination" (Harvey 1996, p. 322) respectively when learning rural space.

The development trends or needs of a certain area influence the perception of rural life and future rurality. Sustainable development became a primary development model worldwide because of its global appeal. Necessary adjustments help to match sustainability to differential development paths of countries and regions. Knowledge of sustainability should be grasped from perspectives of locals and experts, and consider locality while internationally learn, share, and innovate. In a bottom–up approach, sustainable living starts by adopting small changes in daily life (United Nations 2016), which are easy to practice by any individual. Increasingly interdisciplinary studies and practice continue expanding the concept of sustainability. Sustainability incorporates problems, solutions, and responses at a systems level, which contains three key concepts, namely, institutions, capital, and ecosystem services (Jacques 2014). Institutions indicate the rights, rules, procedures, and features of governance (Young 2013). Development efforts must be resilient to changes. Thus, governance must be capable of providing effective rules to coordinate differential participants and modify the inappropriate rules at a proper time. Capital determines livelihoods and living style and comprises natural, physical, human, financial, and social capital, among most of which can change with varying conditions (Ellis 2000, Jacques 2014). Ecosystem services, a component of natural capital, refer to the critical ecological goods and service for human life and society "in four types: provisioning, cultural, regulating, and supporting" (Jacques 2014, p.9): provisioning services address direct needs; cultural services meet the spiritual and recreational demands; regulating services provide stable spatial and temporal conditions; supporting services are crucial for the operations of other services. The interaction and evolution of elements of rurality and rural space within development can be determined based on institutions, capital, and ecosystem services.

Rural institutions, capital, and ecosystem services influence local life and livelihood through which sustainable lifestyle can be introduced. According to the theory of rural livelihoods, the diversification and access to capital and capital-based activities can help people learn more skills, broaden their minds, and promote regional economy, which in the long run improve healthy, self-recognition and self-esteem of individuals and stimulate them to obtain decent work and pursue life goals (Jahan 2015). Institutions and ecosystem services vitally enable people to access desired capital and develop activities. The well-being of rural residents should be the most important goal and evaluate criterion for improving rural livelihoods. Human well-being encompasses security, the basic material for good life, health, good social relations, and also freedom of choice and action (Millennium Ecosystem Assessment 2005). Rural areas usually suffer from the effects of industrialisation, such as environmental degradation, low economic competitiveness, and disintegration of moral values, which weaken the capacity of local development and result in dissatisfaction in rural life. Resilient approaches that provide universal basic social services and enhance opportunities and capacity for choice can promote happy and healthy living, particularly lifelong and cross-generation well-being (Malik 2014). Sustainable operation and optimisation of rural institutions, capital, and ecosystem services can maintain the provision of public goods, strengthen the capability of individuals and communities, and provide additional options on what and how lifelong development can be achieved.

2.2. Ruralite

The concept of sustainable living in the rural context must be established based on the scope of institutions, capital, and ecosystem services and the achievement of well-being. The stakeholders of rural sustainable living should then be prioritised. Stakeholders include permanent or the long-term rural residents, particularly the underclass, the vulnerable, and the marginalised population. Approaches of diversifying the rural economy by intensive agriculture, tourism or other forms of business usually ingratiate urban customers and benefit rural middle-class and urban-rural migrants who have a higher education level, favourable living conditions, and high disposable income to pursue non-farming jobs (Ribeiro, Marques 2002). Uncertainty is another factor that increases the vulnerability of rural residents. Sources of rural income are usually unstable. Market and climate influence agriculture. Rural tourism suffers seasonal non-income and non-employment. The growth of rural businesses depends on external investments. Also, climate change and catastrophes can easily alter rural life and production. A liberal market causes alienation between people and land in regions with low labour-intensive production regions, result in segregation of land function that may adversely influence sustainable rural landscape management (Vos,

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Meekes 1999). Migration between rural and urban is highly affected by the changing conditions of social welfare and services in the two regions (He 2014) thereby causing instability of rural human capital. People who live most of their life in the countryside have the right to benefit from development fairly and equally.

2.3. Role of rural architectural practice

Assessing the architectural effects on rurality is kind of moot because the current architectural practice is partially driven by rural residents' needs and problems in development, which also reflect and influence rurality. Rural architectural practice enables developers or builders to visually and rapidly realise their aspirations. The locals or outsiders shapes a location, space, or place, affects the evolution of rurality, and manifests through the spatial changes and transformations of rural lives. Thus, changes in rurality shaped by architectural practices to a certain extent indicate the willingness of rural residents to alter their lifestyles because they interpret rurality, but also show the imagination of rural life and interventions by the outside practitioners. The quality of built environment and rural landscape determines the quality of the well-being of ruralites, particularly their health, means of sustenance, functionality of the social and ecological system, and mental satisfaction. Rural architectural practice should help rural residents to optimise their built environment to enable them to live sustainably and achieve short- and long-term improvement of their well-being.

3. RURAL DEVELOPMENT AND LIFE IN CHINA

Rurality in Chinese context cultivates moderation and forbearance because rural life and society accept good or bad things as human nature, and such acceptance showcases the Chinese philosophy of perceiving and pursuing humanity (Village Diary 2013). Exploring Chinese rurality and rural identity entail following this nature of Chinese countryside because it roots the sense of belonging to rural residents who share a common social culture. Stories in a certain rural place that people remember and pass on indicate specific semiotic meanings. During decades of development after 1949, rural China is shifting from a society based totally on the familiar and a differential mode of association (Fei 1992) to a society with disassembled traditional social institutions and association based on mutual interests or profits (He 2013). The Chinese government dominates the country's rural development. The Three Rural Issue raised in the late 1990s identified the increasing poverty, unguaranteed rights of the peasantry, and their dissatisfaction with rural livelihoods, instability of agriculture, and food insecurity. To address these concerns, national policies have started enhancing rural development through rural governance reform, infrastructure and housing construction, industrial development, and urban-rural integration. Designated rural regions or groups receive sufficient political support and resources, whereas the less favoured areas or the marginalised groups are left behind. This situation results in the unstable expectation of rural life. Later, the improvement of social welfare in the rural areas accompanied by the decline of urban employment during the economic transformation gradually decreases the rural-urban migration (He 2014). The tendency of young adults to stay in villages increases rural human capital. Given this issue, life in the countryside should provide Chinese ruralites with increased choices on the means and direction of development, guaranteed rights, and increased capacity and confidence to grasp local development, which is, living sustainably in rural areas.

The constitutions of well-being can demonstrate the need to improve sustainable life in rural China, stabilise governance, and achieve balanced development. In contrast to the hard and disrespectful life in cities, when the physical living condition, infrastructure, and social welfare in the countryside are gradually improved, rural residents begin to aware of and pursue a decent life (He 2014). Decent living is achieved when the rights of rural residents are realised. Such realisation empowers them and also provides them with freedom, accessibility, and appreciation. Rural China must improve its endogenous life, respect diverse livelihood, and protect nature in response to the modernist development model and the top-down governance approach. The advocacy towards endogenous development in Europe (Woods 2011) emerges for rural China. However, Woods (2011) also states the three significant limitations of endogenous development model: first, the model is inefficient in foundational or structural disadvantaged areas where must be urgently improved; second, rural middle-class residents gain more benefits than the poor and vulnerable; last, this model strengthens rural elites and professionals and creates exclusion, internal inequalities, and oppressions (Shortall 2008, Árnason et al., 2009, Shucksmith 2000). Thus, promoting endogenous development in rural China needs critical contextualisation and adjustment. Also, updated knowledge and modern techniques must be made available to people and easy to be inherited locally. High-science low-tech rural architecture, which led by Edward Ng (Wan et al., 2011) and Hsieh Ying-Chun (2015), and public science services such as that provided by Public Lab (2016), are examples of researches and innovations cater to people.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Lastly, rural development must be universally beneficial. SDGs emphasise fair and universal development, suggesting that the priorities of different groups should be addressed in a fair, timely, and continuous manner. The term universally beneficial means provision of benefits to different groups in the same developing process according to each specific need, while the results may differ that not all should meet a unified standard. Living sustainably for Chinese peasantry refers to decent living where one can endogenously live with open-source and universally beneficial development.

4. RURAL ARCHITECTURAL PRACTICE IN CHINA

In China, the rural architectural practice has gradually arisen since the early 2000s due to the political and economic changes that aim to bridge the significant rural–urban disparity. Since 2005, the implementation of the New Socialist Countryside resulted in various cases of entire village relocation, large-scale residential demolition, and evictions. Thus, the official initiative of traditional village preservation established in 2012 and the Beautiful Countryside Construction movement enacted in 2013 advocated the conservation of rural locality and nostalgia. These actions encourage growing rural architectural practice by the third sector (Zhou 2016). Also, the saturated market of urban construction that proliferated because of rapid urbanisation but declined after 2013 (Hewitt 2016) impels architects to target rural regions. The permeation of market economy also results in the widespread rural construction. The rural symbols and meanings that satisfying rural consumers but detaching from rural residents and referent (Cloke 2006) emerge during the modernist and market-oriented Chinese rural development. Certain rural areas with pleasant climate or environment face excessive commercial development. The new middle-class rural residents prefer building multi-storey houses with industrial materials as a display of affluence or a sop to urbanite. This feature also causes the marginalisation or elimination of remote, less favoured, or common villages. Rural architecture is currently one of the most crucial domains when intervening rural development in China.

The widespread and rapid growth of rural architectural practice focuses more on short-term results than on systematic development planning and long-term benefits. The obliterated conventional livelihood and lifestyles must be re-built through community engagement and organisation in new villages (Liu et al., 2015). However, this process is difficult because re-establishment entails substantial resources and significant time, and to adapt to new conditions and neighbourhoods usually fails. Foci of the government and the public on the inefficient use of new cottages remain inadequate. Various factors cause the vacancies and idleness of new village residences, including oversized or inconvenient indoor or outdoor space (Liu et al., 2015), the low comfort level of built environment, and improper land planning that are primarily attributed to urban bias or unconformity of rural life. A systematic strategy of rural construction in China based on investigation and experience of crucial projects was first proposed by China Architecture Design Group (2016) on a public forum under the theme of 'Remember the Nostalgia' by Architect Su Tong. Su firstly summarised the current problems related to rural construction in China as follows:

- Economic backwardness
- Social disintegration
- Ecological degradation
- Loss of identity and locality
- Fail to reach consensus between rural community, local government, and architect
- Convergence of business model (mainly refers to tourism and related services)
- Inadequate transmission of vernacular knowledge and tectonics

Similar to the findings of many current rural architectural projects, Su pointed out that the same externally supported architectural projects are inapplicable in all the areas in rural China. This finding means that bias may exist and project sites must be carefully examined and selected at an early stage. Su emphasised the market-oriented development supported by the external capital and based on the negotiations coordinated by local government, and stated the five stages under this rural construction strategy as follows:

- Intensive and professional investigation
- Identity clarification and planning initiation
- Localisation of development and spatial planning by targeting specific conditions
- Integration of multi-level and multi-element planning for operationalisation

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Space categorisation and design in line with three types of functions, namely, ordinary buildings, demonstrating and gathering buildings, and semiotic buildings and rural landscapes

The rural construction strategy proposed by Architect Su methodologically represents most perceptions on current rural construction in China and the future development, most of which are based on actual projects and other domestic experiences. However, challenges can be established through the lens of living sustainably in rural areas, which is discussed before. The rural construction strategy of Su is highly biased towards a top-down approach under which typical predicaments in land tenure or rural governance are easily compromised or avoided. This rural construction strategy lacks architectural innovations to sustain rural cultures and ecosystems. This strategy also implies urban bias to some extent in selecting sites, planning, designing space, and proposing development. Participation of rural residents is concerned in this strategy but inclines to requests local governments to persuade residents to accept plans and designs by architectural teams composed of outsiders. This process fails to enhance professionalisation of construction of the villagers or promote collective labour for bonding community.

More generally, most current architectural practice in rural China fails to consider the multi-dimensional aspects of sustainability. Most practice acknowledges the values of vernacular tectonics and traditional knowledge but barely contribute directly to the inheritance of vernacular architecture by local generations. Simplifying problem-oriented methods produces a common construction style and similar features in different rural areas and results in the loss of vernacular knowledge and techniques. The knowledge exchange and local education during the architectural practice are scarcely noticed. Mature planning strategies and climate change preparedness at a bottom level are not systematically provided. The locals usually cannot sustain the contributions of architectural practice on social and environmental dimensions. And the economic functions of new-built space serve less except rural tourism and concomitant services. In terms of professionalisation, weaknesses indicated currently primarily relates to the inadequate capacity to plan and design sustainable built environment. Interdisciplinary cooperation and study of instruments for assessing, maintaining, managing, and operating rural built environment has been seldom conducted. From another angle, all these limitations also inspire the alternative approaches.

5. **ALTERNATIVE FOR CHINA’S RURAL ARCHITECTURAL PRACTICE TOWARDS LIVING** SUSTAINABLY

General strategies proposed for the identified issues in rural China construction are developed below. A well grasp of a rural space depends on deep experiencing the local through lenses of materiality, representation, and imagination. Based on a proper understanding of the local, innovation and practice in rural architectural will enhance the spirit of place, reduce urban bias, and modify capitalist or materialist orientation. Sustainable architectural practice in rural must gradually apply bottom-up approach. Investigations and engagements should figure out the situations and working patterns of local institutions, capital, and ecosystem services and then scrutinise possible opportunities to change local mind and build cooperation during designing and constructing. This approach should allow the locals to express their opinions and respectfully provide them low-cost but sustainable choices according to their ability and resources when they encounter problems in sustaining decent life. A local consensus of ecological conservation is crucial, though difficult to establish, based on which architectural tectonics obtain evolution sustainably. Attempts of adopting a systems level on the local and regional social-economic changes help to identify local priorities and adjust architectural approaches. Allowing rural residents to dominate architectural practice is possible, which requires learning from the locals and subsequently encouraging them to learn. Architecturally targeting sustainable well-being should particularly enable the left-behind rural groups or regions to improve their way of living and shape particular sense of place and belonging endogenously. A framework of local architectural practice pattern is proposed by contextualising sustainable living in rural China, which is described below:

- Context specification: Establishing the concept or idea of design for the local by spatially and temporally reflecting on the past, grasping its potential of development and enhancing foresight;
- Functionally sustainable: Planning and designing space while appreciating locality, showing accountability of increasing engagement and developing potentials;
- Procedurally sustainable: Improving local human capital, maximising usage of local resources, exchanging or generating knowledge, and transmitting culture and value while planning, designing and building;

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Materially sustainable: Choosing materials that showcase identity and care for habitat, challenging consumerism, and exploring more ways of reusing or recreating;
- Managerially sustainable: Operating projects cost-effectively, advancing social connections and community participation, and catalysing governance breakthroughs.

6. CONCLUSION

Dynamic changes occur in rural areas in China because of decades of rapid industrialisation and urbanisation. A proper perception of Chinese rurality provides architectural facilitators practical directions to grasp local contexts and establish understandings. Learning rural institutions, capital, and ecosystem services in a certain place will promote the engagement with local networks and establish proper bottom-up approach as a response. To help rural residents perceive well-being ensures that rural architectural activities concentrate on enhancing the capacity and providing access for the locals to lead and maintain a sustainable life. A methodological discussion establishes an alternative framework for the rural architectural practice pattern in China that specifies context and considers functional, procedural, material, and managerial sustainability. More theoretical supports and empirical strategies should add to improve this architectural practice pattern further.

Towards a Holistic Methodology: A Practical Approach to Local Energy Planning

Thomas SCHLUCK[a], Matthias SULZER[b]

[a] *Hochschule Luzern, Switzerland, thomas.schluck@hslu.ch*
[b] *Hochschule Luzern, Switzerland, matthias.sulzer@hslu.ch*

ABSTRACT

Within the energy strategy 2050 the Swiss Confederation decided upon the nuclear fade-out and the reduction of CO_2-emissions. The hereof derived ambitious sub-goals are to consecutively increase the share of renewable energy sources, improve energy efficiencies, enhance the domestically added value and finally reduce the dependency on foreign supplying countries.

The realization of these goals and the final implementation of this self-decreed policy drop down on local stakeholders and especially the local communities. They often understand the need for action, but have neither a sufficient knowledge in this field nor the set of skills to oversee, let alone develop a local energy plan by themselves.

To cope with the different aspects during the planning process and to empower communities, local stakeholders and local planers, a modular and thus adaptive method is in ongoing development.

Here we present the core module for local energy planning and the module for monitoring and assessment of the planning process. Both modules were developed in cooperation with a local energy utility and a local community based on state-of-the-art systems engineering and systems thinking principles.

As the target audience was chosen to be diverse in knowledge, resources and skill-sets the modules were designed to be as coherent and adaptable as possible. The local energy planning for instance allows for both: a hands-on planning approach as well as the integration of sophisticated optimization approaches (Like the energy-hub concept or similar).

Further planned modules comprise stakeholder engagement / collective learning, business modelling (ongoing) and information quality assessment.

Keywords: community empowerment, design process, transit-oriented development

1. BACKGROUND

In 2007 the Swiss government decided to base its energy policy on four strategic areas: efficiency, renewable energy sources, replacement and rebuilding of large power stations and its foreign energy and trading policy. In 2011, under the impression of the Fukushima disaster, the nuclear fade-out was decided and the focus was strongly set on the efficient use of energy and the dissemination of renewable energy sources (BFE-website, 2016). Besides all efforts on the federal level, it still is ambiguous how to reach these ambitious goals. Many measures to effectively achieve these goals must be realized at the local level and involve local stakeholders. Especially the development of a holistic energy plan is normally an overwhelming task for a community as it needs the coverage of a wide range of topics and expertise in conjunction with a systemic approach. However, the idea of resorting to a national wide decreed infliction of general measures on the communities will very probably not be an effective solution. Communities are too diverse and face different challenges, pursue different goals and find themselves in individually unique situations with distinct stakeholder constellations and thus interest. A federal infliction, which takes all these aspects into account, firstly would certainly render infeasible and secondly would be perceived as a massive political interference with the communities' sovereignties.

Today the Swiss government's main approach is to raise awareness, to support and bundle existing effective measures, to fund research and to drive the dissemination of new and existing measures. Due to the complexity and interdisciplinarity of these tasks comprehensive research networks, like the SCCER FEEB&D, were established that pool academic competencies and establish a strong link to industry and economy. But the key question is still to be answered: How to empower local communities, their stakeholders, and especially

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

local energy planer to find locally feasible solutions and help to reach the national superordinate goals in the long term? A first step to address this question was taken by developing a flexible method, which will be described in detail in chapter 2.

1.1 Related work

In 1994 the EBC – Annex 22 (Jank et al., 1994) addressed the question how to develop economic and ecological energy concepts for communities and larger regions. Annex 22 collected knowledge from different countries and looked at different available tools, models, public acceptance and proposed planning processes which were summarized among the term "Local Energy Planning" (LEP). The follow-up Annex 33 (Jank et al., 2000) then picked up on its predecessor's proposal of a more holistic approach to LEP, which resulted in the "Advanced Local Energy Planning" (ALEP) method. At its core ALEP is based on comprehensive computer modeling of the communities' whole energy systems, but also allows for the optimization of subsystems. Due to its descriptive and general generic approach in necessary combination with a sophisticated computer tool local administration, stakeholders and planers cannot directly apply these findings, but must still develop their own approaches. Finally, the aspect of stakeholder analysis and involvement and the difference in overall strategic and operative LEP was addressed in the subsequent and last Annex 51 (Jank et al., 2013). These research programs represent about two decades of dedicated work on Energy Planning and are not only a valuable resource of knowledge, but in its entirety a testimony how the field of Energy Planning developed into a more and more complex and systemic field of research.

Handling complexity and making at least the conceptual design more manageable is the dedicated goal of recent projects. Some projects like TABULA focus on the definition of energetic building archetypes in a country, which allows for an easy mapping of the energy demand of entire areas (TABULA website, 2016) (Loga et al., 2015). Other projects like the UrbanReNet (Hegger et al., 2012) work on comprehensive model kits that use archetypes in combination with sophisticated optimization approaches to find a representation and solution for the demand and supply side.

All these projects share the common approach to make their methodology available in specially developed tools, which thereby become an integral part of the method itself. This progressing entanglement between methodologies and their tools make them more and more indistinguishable.

1.2 Underlying criteria to the developed method

The given premise to this work was to provide practitioners with a methodology to develop energy concepts for their community and region and monitor the process in the run. The method should consider principles (see (Winzer, 2013)) and latest findings in systems thinking, systems engineering and research on method development (Haberfellner, 2012) (Winzer, 2013). In accordance to these principles the method aims to provide a conceptual model that acts as a frame and guidance to the developmental process.

The method should be versatile, i.e. applicable on different communities and adaptable in technicality. The planning group should be able to decide whether to use sophisticated modeling and simulation approaches or a rather hands-on approach using more familiar engineering tools and techniques.

To cope with the varieties of individual tasks and to take into account that holistic approaches vary from system to system the method is sought to be modular in design. Different topics should be treated in separate methodological modules that can be subjoined as is considered necessary.

2. A METHOD FOR LOCAL ENERGY PLANNING

2.1 The module for energy planning

Here we will present the core module of the method for local energy planning and the module for the assessment of the planning process. Initially these modules were developed for a joint project between a local Swiss community, the SCCER FEEB&D and a energy utility to develop a holistic energy concept that will accomplish the given national goals until 2050 (Kellenberger et al., 2012).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

An overview of the core module, i.e. the energy planning module is given in figure 1.

It is organized in seven layers and each layer comprises between on to four subunits. The module starts with an understanding of the initial situation and ends with the final recommendation for an energy concept. The depiction in figure 1 is held in similarity to a classical cascade approach to help the planning groups map and visualize their overall progress, but also to provide guidance through the process. Iterations and feedback between layers are accepted and actually considered as a crucial part of the method.

The methods main target groups are planning engineers, architects, community staff members and the like. To keep the method flexible and adaptable and to provide the using groups with a proper framework in which they can orient but also find enough freedom to develop their ideas, the method was designed to be prescriptive in its general design and descriptive in its subunits. The above also implies that the method keeps its neutrality, i.e. must separate its design from any utilized tools.

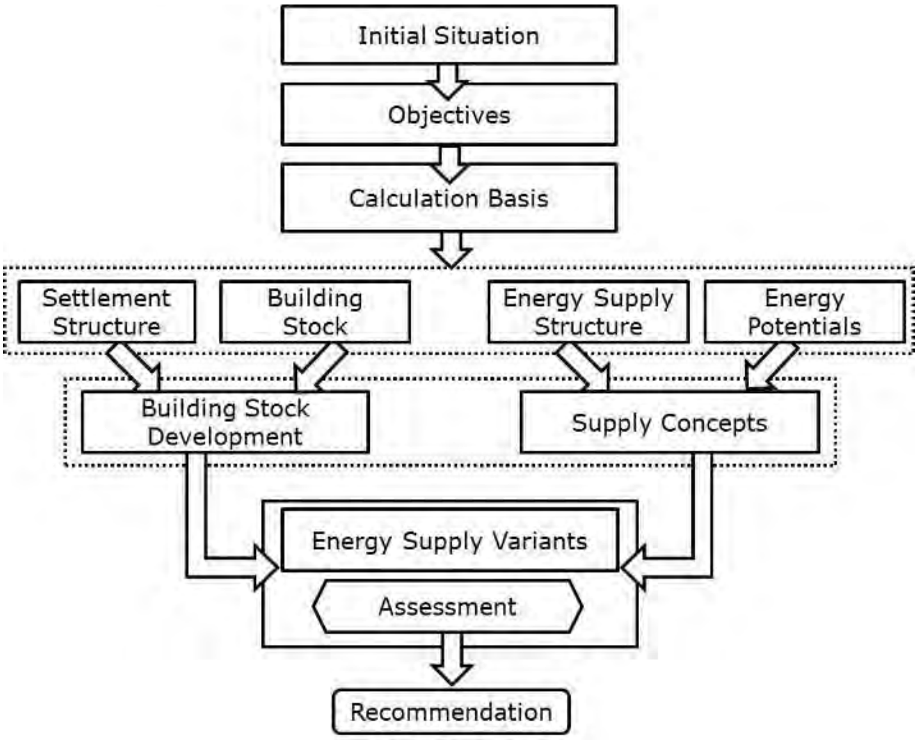

Figure 97: Concise representation of the methods core module for energy planning.

2.2 Layers and subunits

Here we will shortly present the different layers and subunits. A more detailed overview can be found in (Schluck, 2016).

Initial Situation: In this layer and subunit the community's situation is examined in regard to existing visions, goals and developmental plans but also in regard to the possibly different interests and the stakeholders in the community. All involved stakeholders agreed upon the considered system's boundaries, especially in terms of geography, the forecasting horizon and the balancing boundaries. Finally, the structure of the planning group and their ways of communication are defined.

Objectives: Based on the insights from the previous layer a system of objectives is established which comprises a definition of the goal, measurable indicators for the fulfillment of the goal and the method how the indicator is measured. This approach corresponds to (Jank, 1994). If too few is known about the community and a final definition of objectives seems not to be feasible yet, preliminary objectives must be set. The method is then advanced until layer four – the analysis of the community's current situation. After the analysis the method comes back to this layer.

Calculation Basis: The procurement of information is one of the fundamental issues in any form of planning. In energy planning information quality varies strongly such that deductions drawn from it may be more or less conclusive and must be interpreted with some wariness. Thus this layer and subunit was explicitly introduced to stress this point and to deeply embed information quality assessment and quality gap analysis in the method. In addition all assumptions made and all tools planned to be used must be listed at this point. All these measures help later on to clarify on what bases the final recommendation was elaborated.

Analysis: This layer consists of four subunits, which do not have to be worked on in any particular order.

Analysis – Settlement Structure: In this subunit the settlement's topology is examined. Is it a rural or urban structure? What kind of areas – like residential, industrial or business – can be found? Does a centre exist? These and similar questions are addressed.

Analysis – Building Stock: Here the building stock is analyzed in detail. Parameters like the energy reference area, the building building period, renovation period, usage, and energy demand are determined.

Analysis – Energy Supply Structure: In this unit the existing energy infrastructure is examined. What kind of infrastructure is already present and will be influential in the further planning process? For instance, if district heating is an option the location of the sewage channels must be taken into account. What temperature levels must be obtained for room heating and domestic hot water? What capacities of the electrical grid are still unused and available for further installations? And so forth...

Analysis – Energy Potentials: This subunit encompasses the analysis of local energy potentials like wind, solar gains, geothermal usage, ground-, sea-, waste- or lake-water usage, waste heat or the like.

Synthesis I: This layer combines the information from the units "Settlement Structure" with "Building Stock" and "Energy Supply Structure" with "Energy Potentials" to develop forecasting scenarios. The main objective of this layer is to define the solution space.

Synthesis I – Building Stock Development: The findings in the previous units "Settlement Structure" and "Building Stock" are combined with available statistics to forecast the community's development for the given time frame.

Synthesis I – Supply Concepts: The results from the units "Energy Supply Structure" and "Energy Potentials" are merged together to determine all possible energy supply solutions.

Synthesis II – Energy Supply Variants and Assessment: In this forelast layer the optimal solution within the solution space is determined.

Recommendations: The planning group presents a collection of solutions it sees fit.

2.3 The module for planning assessment

Key-performance indicators (KPIs) are best known from quantitative economics, but they also found their way into the field of sustainability (Epstein et al., 2001) (Ugwu et al., 2007). KPIs are ordinarily developed to obtain some kind of metrics for either measuring the overall success or the influence and sensitivity of a taken action. Thus they are often divided into "operational" and "strategic" KPIs. Normally any method based on a systemic approach demands for measurable and specific objectives and thus implicitly demands a set of strategic KPIs. The same is true for the previous presented energy planning method. So the question obtrudes why to dedicate a separate module to the assessment via KPIs.

The definition of operational KPIs is not part of the core module, while the definition of strategic KPIs can overlap with the objectives defined in layer two. By transferring the definition of KPIs into a distinct module process management and the substantive work are kept separated and thus clearer. Thereby each unit in the energy planning method can be assessed.

Two approaches can be taken to develop KPIs. On the one hand all available data can be collected and archived and subsequently an explorative analysis of the data on sensitive parameters is performed. This means that the analyst looks at the process in retrospect and must thoroughly handle a vast amount of diverse data. When methodologically supporting local stakeholders to develop an energy concept for their community this approach is infeasible as the concept would have to exist already. This is why this module develops KPIs based on key-performance-questions (KPQs) (Marr, 2015). For each subunit (besides “Initial Situation” and “Recommendation”) a KPQ is broadly formulated but in relevance to quantification of the subunit’s goal. This approach creates the necessity to rethink each step before any substantial work is done and can help to eliminate uncertainties. Figure 2 shows an example how KPIs for one subunit are obtained. Thus the interface between the core module and the module for planning assessment are the key-performance-questions. At present the module only loosely sums up all derived KPIs, which then must be controlled separately and independently. However in a next step extending the module to a performance management system (PMS) (Rodriguez et al., 2009) with inherent KPI management, advanced assessment and interconnection is aspired.

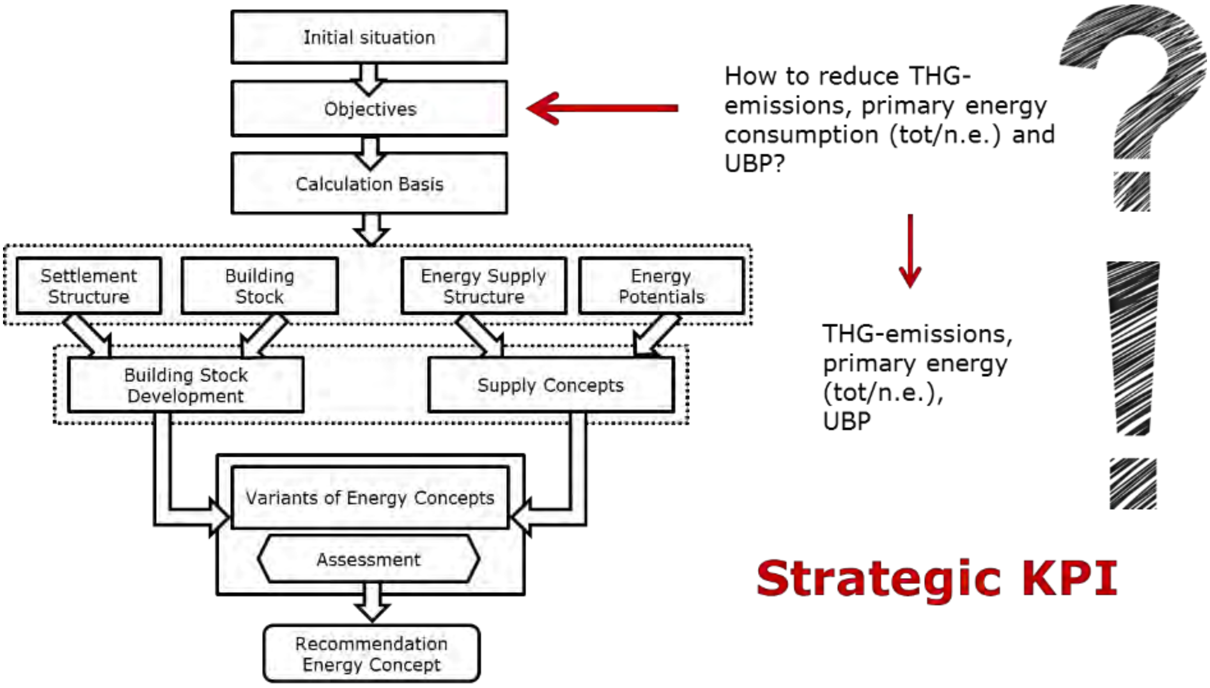

Figure 98: Exemplary KPI development for the “Objectives” subunit. Key-performance-questions are the interface between the module for planning assessment and the core module. (UBP: Measure of the Swiss Ecological Scarcity Method)

3. DISCUSSION

Twenty years ago local energy planning focussed on energy savings in production plans and it were raising opportunities of available optimization tools like MARKAL/ TIMES (MARKAL, 2016) that led to sophisticated methods capable to address the energy system in a more holistic fashion. Today hundreds of such tools are available (Connolly et al., 2010) and each of them needs knowledge and expertise, which is offered by academia. Realizing that this expertise did not disseminate as hoped for over the last years, research was emphasized on socio-economic aspects (Jank et al., 2013). Tools became more and more developed and designed with regard to practitioners and in a similar spirit the here presented method was developed. Although the method allows for a hands-on approach in energy planning it is compatible to modern optimization approaches like the Energy-Hub concept (Geidl, 2007) (Parisio et al., 2012) (Orehounig et al., 2015). Indeed such an approach is still recommended. An important aspect during the development of the method was to consider modern findings in generic systems engineering and help in handling complexity. This was one of the main reasons why a possibly strict separation between substantial and methodological work and between method itself and the used tools was sought. For the same reason different aspects are purposely addressed in its original module. However this methodological approach is still very young and although successfully tested on a project there will be changes and improvements made. For instance our experiences showed how important a sound understanding of information’s quality is. An assessment and an extended gap analysis – treated in a separate unit – could be considered. Another experience was that the economic calculations, which are now distributed over the different subunits, should also rather be condensed in one single unit.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The module for planning assessment also should be consolidated and developed into a full performance measurement system.

The modular methodological approach offers the clear benefit of adding and removing modules for each communities need as they see fit. Ideas for further modules are:

- A dedicated module for stakeholder analysis and involvement
- A module addressing mobility
- A module to incorporate life cycle analysis (LCA)

In this article recommendations on tools, useful visualizations, details in balancing, and information gathering were purposely excluded as they specifically address the circumstances in Switzerland. Information on these topics can be found in (Schluck, 2016).

4. CONCLUSION

A method for developing local and holistic energy concepts was presented in short. The method is modular in design and at its core stands the module for Energy Planning. A separate module was elaborated to accompany the planning process and develop operational as well as strategic key-performance-indicators using key-performance-questions. These also represent the interface to the core module.

When designing the method key findings of generic systems engineering were considered. Despite its novelty it had already proven successful in one large project. In a next step the method will be refined as already discussed in chapter 3.

A module for the development of business cases was not presented here, but partially exists and is in further active development.

ACKNOWLEDGMENTS

We would like to thank the Swiss Commission for Technology and Innovation (CTI) that partially funded this work within the research framework of the SCCER FEEB&D.

Session 4.13: Community Empowerment (2)

'Pride the Civilians Motivator for Resilient Sustainable Cities' Results of the 2016 Questionnaire Research Under Dutch Amsterdam Council Members

Fred SANDERS[a]

[a] *Delft University of Technology in the Netherlands, The Netherlands, f.c.sanders@tudelft.nl*

ABSTRACT

Dutch practice shows that cities will only become UNFCCC 2016 Paris Agreement sustainable proof when civilians besides government are willing to take responsibility for these cities too. Motivation feelings and neighbourhood conditions seem the key success factors. Many of these factors and conditions have become clear in recent years. Feelings of 'Pride' though is very often called as the motivation factor of importance although less is known of this phenomenon. To make the role of 'pride feelings' more clear exploring research on feelings of 'Pride' is done in the Dutch city of Amsterdam recently. Therefore the 100 council members of the Amsterdam city and its 7 city areas are questioned on their vision on pride as the motivation factor of civilian initiative and responsibility. Besides there were asked to give best practices examples actual in Amsterdam. The analysis of literature search show that 'pride feeling' knows the four stages: proportional pride, shared pride, self-esteem and shared identity. The case-study analysis shows based on homogeneous outcome unless the small sample of data, that civilian initiatives are seen as important (74%) for city development and that 'pride feeling' of importance for the success of civilian initiative is (72,5%). Besides the analysis shows that 'shared pride' is the most common stage for civilian initiative. Recommended is that civilian initiatives should be more inventoried whereby 'pride feeling' can be deeper examined being the important motivator for the participants and factor for success.

Keywords: pride-feeling, civilian-initiative, sustainable-cities

1. PRIDE THE DIFFUSE CIVILIAN INITIATIVE MOTIVATOR

Pride is the diffuse motivator for civilian initiative. Knowing more about this motivation factor will help to understand civilian initiatives better. Therefore in succession explanation is worked-out concerning: the role of civilian initiatives for resilient sustainable cities (1.1) and its motivation factors (1.2), the function of pride as motivation factor (1.3), the need and set-up of the additional 2016 research on the pride motivation factor done in the seven Amsterdam city areas included the research question (1.4).

1.1 Civilian initiative for resilient sustainable cities

Urbanization is increasing worldwide and in the Netherlands the Amsterdam city is in special growing too (UN, 2014). Recent forecasting predicts that Amsterdam will grow with 300.000 houses from 850.000 towards 1.500.000 inhabitants in the coming 25 years (manucipality, 2015). This trend of urbanization growth is a trend of global magnitude including new cities on all continents. Dutch practice shows that cities will only become UNFCCC 2016 Paris Agreement sustainable proof when civilians besides government are willing to take responsibility for these cities too (Sanders, 2014). In the Netherlands stimulated by national government and its municipalities civilian initiatives has become though a growing phenomenon. Civilian initiatives show to be social and cooperative of nature, reasonably often into producing of renewable energy on the neighbourhood scale. It feels a realistic hypothesis that by increasing urbanization the existence of civilian initiatives and therewith civilian responsibility becomes more important to reduce the need for governmental control (Hajer, 2011). Civilians can make the difference bringing cities on a higher state of resilience. Recent developments proof that Dutch governmental organizations have become more successful by facilitating and stimulating civilian initiatives in recent years. For the civilians themselves these initiatives should be attractive enough for the group and each of the participating individuals. Motivation feelings and neighbourhood conditions are the key success factors. Many of these factors and conditions have become clear in recent years. Feeling of 'Pride' though is very often called as the motivation factor of importance although less is known of this phenomenon (Sanders, 2014). Insight on pride feelings therewith is necessary to understand civilian initiatives for building resilient city populations that have that social defensibility that they invest in sustainability of their city.

1.2 Civilian initiative and their municipalities

At the SBE16 Conference in Utrecht the Netherlands the 2015 research done with focus on civilian initiative in a number of Dutch IKS energy-neutral projects was presented (Sanders and Timmeren, 2016). It concerned the Dutch 2010 innovation program for speeding-up the transition of cities towards climate neutrality 2010 (IKS) (Ministerie-VROM, 2009). This program contained 20 projects at the start (IKS1) from which 8 projects ended-up in project realization (IKS2) being innovation project realistic enough for execution and 4 projects concerning neighbourhood coupled renewable-energy sustainability projects.

The 2013 evaluation of this IKS program (Boon et al., 2013) scanned all climate neutral activities in 55 of the 400 (2009) municipalities working on climate neutrality. The conclusion of this 2013 research was that municipality civil servants and civilians by acting together can make the difference between failure and success. To make the picture more clear these 4 IKS2 are given a closer research for this SBE16 Conference.

Based on my dissertation (Sanders, 2014), research concerning the relation forms of citizin initiatives with local governments (Tonkens, 2009) and governmental evaluation research on societal participation (WRR, 2012) a hierarchy for civilian participation is used as input for this research. This hierarchy showed the following three stages: thinking-along (a passive civilianship, civilians reflect and advice by accepting governmental initiatives), joining-in (a passive civilianship, civilians participate in and support government initiatives) and investing-in (an active civilianship, civilians take responsibility for initiatives dealing with government) all stages of exceeding civilian empowerment.

Analysis of these four IKS 2 projects in 2015 for the SBE16 Conference is done using these three stages of civilian participation. This diversity of stages helped to make the differences of civilian participation in the projects clear and made it possible to couple the renewable-energy results to these. The result is showed in Figure 1. The conclusion was that project dominated by local government the municipality and civilian initiative both can be successful. Hybrid cooperation's of both are less successful.

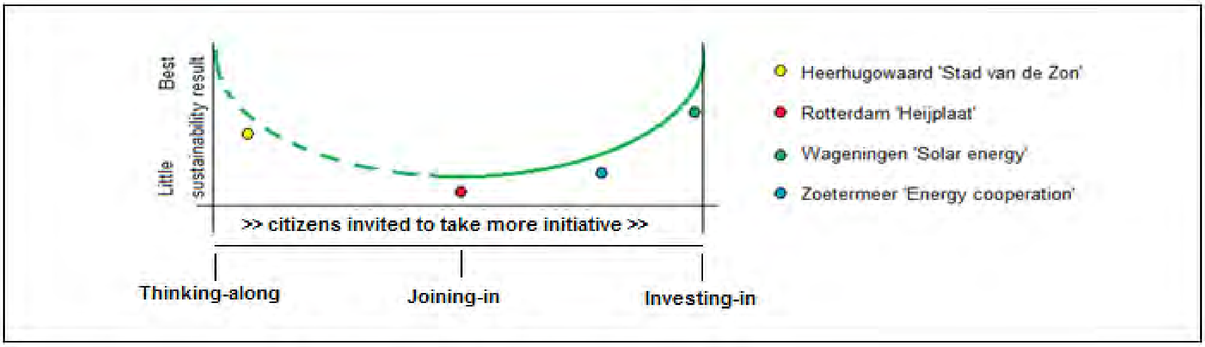

Figure 1: Square diagram of the 4 IKS2 sustainability neighbourhood project .

Remark 1: Unfortunately the sample of these 4 IKS2 innovation projects was little of number. However these concern interesting Dutch examples of 'Climate neutral' innovations coupled to civilian initiative for the period that such initiatives started-up at the beginning of this century. Therefore these projects are analyzed in 2015 on the moment that the evaluation report became available. The casestudy research is done by file-search, key-person interviewing with the the above mentioned dissertation as the 'body of knowledge' for the research methodology, analyzes and conclusion making.

Remark 2: The result of this research stresses that civilian sustainability initiatives are worthwhile to make succesful, in the IKS 2 selection they scored the best results.

1.3 Pride feeling literature search

Pride feelings show to be related to feelings of self-esteem (Cooper, 2003) and identity (Mercer, 2014). According to Cooper prideful activities give people self acceptance and sin giving factors founding feelings of self-esteem. pride can have positive benefits enhancing creativity, productivity and altruism according to Cooper too. Mercer found that people functioning in a group doing collective activities, by which they share culture, interaction, mutual

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

interests create themselves identity. He also found that such group emotion is more powerful then light coupled group activities. The lightest form of pride seems to be proportional pride, pride feelings of something, a son, a house, an ability (Davidson, 1976). This basic feeling of pride is there with a self-directed pleasant sensation (Taylor, 2012). These are the topics of numerous of research and publications on pride feeling thought this selection concerns insights from recent data. Analysis of these forms of pride feeling shows a hierarchy although this is not given in the literature involved. Although the base for such an hierarchy is little, these can be used as a hypothesis for analyzing pride feeling in case situations, with reservation. This hypothesis is that the hierarchy of pride conceptions form a circle that suggests a accelerator for people's group initiatives, see Figure 2.

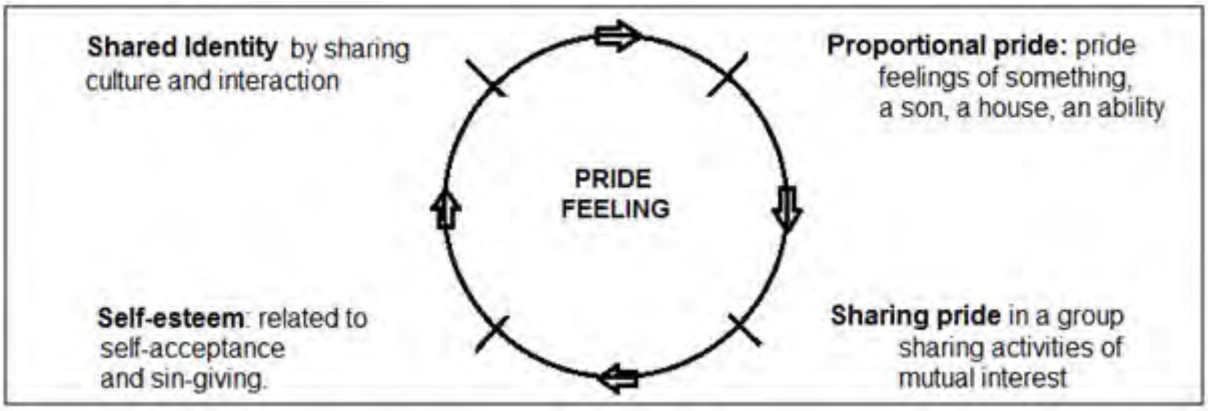

Figure 2: Pride feeling circle containing four stages and continuous stages.

Explanation: The first stage of pride feeling concerns proportional pride a personal group-loose feeling attached to things and persons and own achievements. Sharing pride the second stage develops when people share activities of mutual interest. Self-esteem the third stage is a pride feeling that people develop in reflection with others giving self-acceptance and sin-giving. The fourth stage of pride feeling develops when people share culture and interaction with group members become part of the group by which they share mutual feelings of pride. These stages are outlined I a circle with the reason that group feelings become part of personal pride afterwards with the effect that following the circle feelings of pride become stronger and stronger the longer a person deals with group related activities.

1.4 Pride feeling researched

To make the role of 'pride feelings' of civilian initiative more clear exploring research on feelings of 'Pride' is done in the Dutch city of Amsterdam. The research is done to make the function of 'pride feelings' as motivator among participant of civilian initiative more clearly, there were research from the past lacks this special focus.

The underlying research question for this research therewith is: 'How important and with what impact are feelings of pride for civilians initiatives of importance'.

Therefore additional to the literature search done with the results given in this chapter, the 100 council members of the Amsterdam city and its 7 city areas are questioned on their vision on pride as the motivation factor of civilian initiative and responsibility. The choice for questioning council members is grounded in the idea that these people know many civilians, that they know how they think and how they feel taking group initiatives.

Remark: The response was little and some council members reflected that they are too busy for even short questionnaires. In total 17 out of 99 council members reacted from which four gave a blank reaction by which 13 reactions remain, no 15% yet. Therewith the questionnaire gave no chance on a significant result. The answer at the other hand were homonymous. So the questionnaire results therewith gives a direction of the council members their opinion on civilian initiatives. Secondly they were asked to give best practices civilian initiative examples. The 11 suggestions given are used as case study material. For the results and analysis see chapter 2.

2. PRIDE FEELING IN AMSTERDAM CIVILIAN INITIATIVES

For the questionnaire research on pride feelings of civilian initiative among Amsterdam city area council members the elaboration is presented in this chapter: the questionnaire and results focusing on the importance of pride

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

feelings (2.1), the given best practices and analysis focusing the impact of proud feeling (1.2) and the general analysis (2.3).

2.1 Questionnaire on pride feeling and results

The questionnaire touched four questions scanning the existence of civilian initiative (the first question) in relation to the importance of pride feeling for the success of civilian initiative (the next three questions) concerning the city area for which the council member carries responsibility for. These four questions are:

- What is the density of civilian initiative in your city area, with the average of one initiative on a 1.000 residents as the reference, +/- 0-10-100%.
- How important are civilian initiatives for development of your city area in
- general, 0-10-100%.
- How important is pride feeling for the success of these civilian initiatives in your city area, 0-10-100%.
- How often are negative motivation stimulant (contra question) for civilian
- initiatives in the city area you are responsible for, 0-10-100%.

With the low percentage of reactions a sustainable conclusion cannot be the result. Though the reaction were so homogeneously (see appendix 1) that these are useful for the exploring attitude of this research answering the first part of the research question 'How important are feelings of pride for civilians initiatives of importance'. The results are.

Density Civilian Initiatives,

The city area council members show to have little impression of the density, the number of civilian initiatives, in their city area. In relation to the average density of one initiative on a 1.000 residents many could not gave a deviation percentage (8 out of 17) and the other reactions differed enormous from -65% to +150% with estimations of -5%, -30%, -10%, -3%, +1%, + 10% and +30% in between.

Importance of Civilian Initiative,

The city area council members were reasonably unanimous that civilian initiatives are an important stimulant for development of their city area's a). Their estimation showed an average of 74% importance on the scale of 0-100% leaving the one deviation of 5% behind.

a) Amsterdam counts 7 city areas with own town councils varying from 12 to 15 council members with an average o 120.000 inhabitants.

Importance of pride feeling for civilian initiatives (and contra question),

The city area council members their reactions reacted with an average of 72,5% leaving the two deviations 10% and 20% apart. This reasonably fits to the contra question asking the estimated percentage of initiatives in with negative motivation plays a role b) what gave an average result of 38,5%. What gives the result that the importance of pride feeling for civilian initiatives estimated by city area councilors lays around 67%.

b) The two questions asking for the influence factors of proud feeling and negative motivations are not exact contrary questions though in the practice and vocabulary of citizens initiatives they can be seen as.

2.2 Amsterdam best practices on pride initiatives

Secondly these Amsterdam city area council members were asked to give best practices examples of proud feeling driven civilian initiatives in their city area. A number of 11 civilian initiatives were mentioned, from which 5 meeting of people oriented, 3 green activities producing food or plant zones, and 3 of other product.

The reason for this questioning is connecting and categorizing these best practices in perspective of the forms of civilian initiative presented in paragraph 1.2 and the four stages of proud feeling illustrated in paragraph 1.3. To discover how deep proud feeling in these best practices civilian initiatives is anchored, see paragraph 2.3.

These best practices civilian initiatives are:

1. Centrum, ‘Canon van de Zeedijk’ (Story of the Red Light Zeedijk)

Inhabitants from the ‘Zeedijk’ being the central oldest street in the red light district of Amsterdam, started an association being an neighbourhood network with pride feeling stimulating activities. The underlying reason is that many of the locals are negative about their neighbourhood because of the negative attitude of outsiders related to the prostitution activities in their streets. One of these activities is presenting the interesting neighbourhood past by a ‘canon’ a sequential line of historical pictures suggested and selected by the inhabitants. The idea is that this will change the inhabitants attitude to the neighbourhood and each other with the positive spin-off that they will be more willing to meet and do joint activities. Therewith it show to be a project of ‘sharing pride’ the second stage of the ‘pride feeling circle’. See Figure 3.

2. New-West, ’Studiezalen’(Study Rooms)

A platform of students started a study room to help new and isolated students to great and meet each other on the level of the city area New-West. Their motivation was that many students newcomers in Amsterdam live to spread in the area and the degree of interaction is so little at the universities, that too many students suffer from loneliness. By starting study rooms in the area students should meet others that live nearby enough to stimulate more frequent contact and breaking open isolation. This initiative shows to be an example of the fourth stage ‘sharing identity’.

3. New-West, ‘Beer met kussen’ (Bear with pillow)

Welfare organizations active in the ‘Staalmans’ neighbourhood asked the artist Florentijn Hofman to make a artwork with non-active youngsters ‘loiterers’ to create a meeting-place, stimulate place-attachment and proud feeling among them. The results was the creation of a statue representing a ‘beer with a pillow’. The youngsters participating fist rejected the idea. The final result is that the statue excite so much discussion concerning the choices for the place in the park and the figure of a beer, that not only the youngsters but also children, older people and local immigrants started the dialogue with each other. The artwork showed to be an instigation of meeting and talking among the neighbourhood residents. This project shows to be an example of the second stage ‘sharing pride’. See Figure 3.

4. North, ‘Noordoogst’(Northern harvest)

Neighbourhood resident started a city garden for ecological food production in a deserted piece of land near sport field accommodations. Fellow believers in the need for such homemade food were invited to join the project. Also local volunteers en entrepreneurs joined the initiative. The city area loaned the land for a starting period of ten years. Spinoff activities were theater festivals, a kindergarten and food producing workshops. This temporary project shows to be an example of the third stage ‘self esteem’ sharing sin-giving. See Figure 3.

5. North, ‘Kadoelenweg 360’ (Kadoelen street 360)

The initiative concerns homeless youngsters taking an empty office for temporary housing without permission, without permission of the owner and the city area council. Ten years after the toleration of this action the youngsters were set-out of the office for making the parcel free for new to built housing. The youngsters defended their temporary shelter and acted as a group although they weren’t. The happening shows a situation similar to the first stage ‘proportional pride’.

6. East, ‘Fonds voor Oost’ (Funding for East)

A committee of befriended civilians started a fund for neighbourhood activities of any kind with the goal that residents meet in activities, to learn and know each other better, to stimulate spinoff relations and activities. Locals are asked for crowdfunding and others can start projects with the financial result of this. The initiative seems an example of stage 2 ‘sharing pride’. See Figure 3.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 3: Initiatives Zeedijk, Bear with pillow, Noordoogst and 'Fonds van Oost'.

7. West, 'Domela Nieuwenhuis Plantsoen' (Domela Nieuwenhuis Park)

In de spirit of Domela Nieuwenhuis (1846-1919) a socialist Amsterdam citizen in 1972 a park was applied in de 'Spaarndammer' neighbourhood. From the start this was an initiative of the neighbourhood residents. When the city area council in 2010 planned to built houses on part of the park these residents started an opposition movement against these plans because of the importance of this park for meeting an identity in their neighbourhood. The result is that the city area changed the plans in building outside the park in a way that the function of the park will become stronger. The situation gave an impulse to the group strength too. This initiative shows to be an example of the fourth stage 'sharing identity'.

8. West, 'Leefstraat' Hugo de Grootkade (Liveability street)

Liveability streets is an initiative of the city area council to give the Hugo de Grootkade one month at August 2016 free from traffic and parking cars to give the street inhabitants the freedom to organize new and personal neighbourhood activities. In fact the street inhabitants organized activities for children, created meeting places for all and started a street library with donated books open for each other. Target was that the residents make new meetings, learn to know and help each other in Dutch called 'mantelzorg' care giving. This month free street zone shows to be an example of the second stage 'sharing pride'. See picture 4.

9. Zuid, 'G250 Hallo de Pijp' neighbourhood summit

In March 2015 residents, entrepreneurs, politicians and civil servants started talking about their neighbourhood, about what could be done or organized new or better. This talking delivered 52 realistic ideas to explore. Afterwards a new project called 'G250 works'(G250 werkt) started to make these ideas come true. The city area council donated a fund for use on a 50/50 base. Target of the project was bringing people together for more self initiative for the benefit of each other and themselves. A typical example of stage two 'sharing pride'. See picture 4.

10. Zuid, 'Watertuinen' (Water gardens)

From 2000 on residents of two Amsterdam city canals created 200 floating gardens to create meeting places, be active together and to make the city more green and healthy. Additional projects started like a picture competition to share the good feeling among the residents. In 2015 by a mistake the city area organization destroyed a number of these water gardens. That happening showed how pride the participants were on their project and new initiatives developed afterwards. Therewith the project showed to be an example of the fourth stage 'shared identity'. See picture 4.

11. Zuid- East, 'Straatschoonmaak' Holendrecht (street cleaning-up)

On a regular base neighbourhood ambassadors (local civilian volunteers that try to know residents, speak and connect them) do organize street cleaning up activities with school children. Parents and local entrepreneurs are asked to organize food and small presents to honor the children for their work. These spinoff activities show that this project is an example of stage three 'self esteem'

Figure 4: Initiatives DN park, Hugo de Grootkade, water gardens and G250 de Pijp.

2.3 General analysis of Amsterdam questionnaire results

The revealing of the best practices by city councilors mentioned civilian initiatives (paragraph 2.2) should be a help to learn which stages of 'proud feeling' (as illustrated in paragraph 1.3) are actual in the nowadays practice of Amsterdam initiatives. Secondly, by categorizing these Amsterdam initiatives to the by SBE16 presented diversity of civilian initiative forms (paragraph 1.2). To learn from the possible coupling between 'proud feeling' and the working form of the civilian initiatives. This all to answer the second part of the research question 'what's the impact of pride feeling on the success of civilian initiatives'.

For the analysis is chosen for using the visual methodology of a diagram in which these stages of 'proud feeling' and 'civilian initiative forms' form the axis of a table in which the 11 Amsterdam civilian initiatives can find its place. Another reason for this choice is, there was to less data on the initiatives available for cross-data relation analyses, and secondly this choice of analysis makes the SBE17 research a interesting deepening of the SBE16 research in 2016 presented. Additional can be argued that the simplicity of the diagram approach suits an exploring research as this is.

The result of this analyses is the diagram shown in Figure 5, containing the 11 civilian initiatives by city area counselors mentioned, categorized towards the two axis of stages of 'pride feeling' (x-ax) and forms of civilian initiatives (SBE16) (y-ax). Advanced to that the initiatives are given in the diagram three colors categorizing the kind of initiative if this is of 'meeting people' (red), 'green plants' (green) and others (blue), this because these categories are mentioned in the dissertation concerning facets of civilian group cohesion behaviour (Sanders, 2014). Thirdly the cloud of initiatives in the diagram is given a circling (purple) to visualize which combinations of categorizing are the more actual for the 11 civilian Amsterdam initiatives.

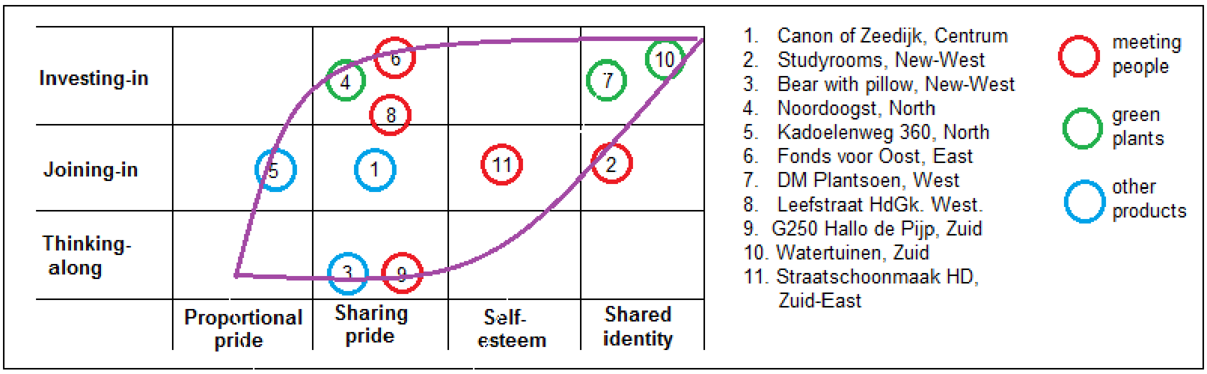

Figure 5: Diagram categorizing 11 Amsterdam civilian initiatives.

The following conclusions can be adopted:

- Most of these civilian initiative a 55% concern 'sharing pride' stage two.
- These 'sharing pride' initiatives are found in all forms of civilian initiatives
- These initiatives do not combine basic and further developed stages and forms.
- Green initiatives concern 'investing-in' mostly and match all 'pride feeling' stage.
- Initiatives other then 'meeting people' and 'green plants' are mainly of 'sharing pride' stage and 'joining-in' form.
- The initiatives of 'shared identity' stage and 'investing-in' form are both green.

3. PRIDE FEELING THE CIVILIANS INITIATIVE MOTIVATOR CONCLUSIONS

In special preparation for the SBE17 Conference this advanced research following-up the SBE16 research on successful models of sustainable civilian initiatives concerning the importance and the impact of 'pride feeling' is examined during autumn 2016. The result must be marked as exploring research having the characteristics of a quick. At the other hand the research is done as a spinoff of my dissertation. And there with this exploring research suits in the new tradition of quick and divers research deepening facets of this dissertation, widening the scope around the subject of civilian initiative more than focusing as in the dissertation, more to build-up a body of knowledge facilitating new long term research in time on civilian initiative.

With this reserves the following conclusion can be presented:

- Based on literature search 'pride feelings' an be given four stages namely: proportional pride, sharing pride, self-esteem, sharing identity. By analyses the idea is suggested that these ca form a closed circle that can be followed additional times, this is not proven and not rejected by this research.
- The Amsterdam city area counselors do high estimate both the importance of civilian initiative for the development of the city and the importance of 'pride feeling' for the success of these civilian initiatives, respectively 74% and 72,5%. At the other hand they show less to know how many initiatives there actual are in the city of Amsterdam. Because of the homogeneous reaction of the counselors on this subject the result can be seen as a direction for conclusion. An sophisticated inventory of civilian initiatives in combination with research on the drivers for success is recommended.
- The analysis of the 11 best practices 'proud feeling' civilian initiatives delivered the insight that 'sharing pride', sharing activities and mutual interest, is the most common stage actual for Amsterdam initiatives. The more interpersonal stages being 'self-esteem' and 'sharing identity' are less common. Here can be suggested a parallelism with one of the conclusion of my dissertation that Dutch civilians avoid tight forms of social cohesion, they prefer social togetherness instead.

The cloud of categorized initiatives in the diagram of paragraph 2.3 show that the less (and the most and intermediate forms) developed stages of 'pride feeling' and forms of cooperation of the civilian initiative show matching to the most. Thereby can be suggested that this can be the case because of the difference of light and tight structured networks of the participants (Weick, 1979). It can be an obvious combination that within civilian initiative in which the participants take more own government-loose responsibility for which they have to work more intensive together, proud feelings becomes more breeding ground and urgency from the participants. It would be interesting to research such best best-practices further when a significant number of cases is available.

APPENDIX

Civilian Initiative Factors		Density to 1/1000	Local development factor	Proud Feeling factor	Negative Motivation factor

ABSTRACT

Sustainability is the most sought after topic in the contemporary built environment. The fundamental concept of modern sustainable building emphasizes on a holistic approach to reduce negative environmental impact of man-made structure, and this is coincided with the ancient Chinese knowledge of Feng Shui that aims to creating harmony between heaven, earth and human. Previous studies have already indicated that there are many similarities between ecological sustainable design and principles and practice of Feng Shui. The purpose of this paper is to explore these similarities through BEAM Plus, the sustainability rating system in Hong Kong. This paper will compare the five categories of BEAM Plus with the Chinese traditional Feng Shui concepts to enhance public awareness of sustainability in the built environment amongst the Chinese communities. The results indicate that two categories of BEAM Plus: Site Aspects and Indoor Environmental Quality are the major concern toward Feng Shui concepts. This study enhance the general public in Hong Kong to aware the importance of sustainability from the Feng Shui perspective.

Keywords: Feng Shui, sustainability, BEAM Plus, public awareness

1. INTRODUCTION

Feng Shui is the traditional wisdom of the Chinese art of building design that aims at creating a harmony between environment, buildings and people. Sustainable design emphasizes on a holistic approach to eliminate negative environmental impact through skillful and sensitive design. The goal of sustainable design is to look at all the systems together and to make sure they work in harmony. This integrative design process is similar to the Chinese holistic view and the Feng Shui approach to the built environment (Humphreys, 1976). It is suggested that interpreting Feng Shui knowledge would embrace the western concept of sustainable design. This paper explores the relationships between the concepts of sustainable design and Feng Shui in environmental design. Firstly, the principles and practices of sustainable design and Feng Shui in environmental design are briefly explained. Then, a set of five concepts of sustainable design and five Feng Shui concepts in terms of environmental design are identified and compared. Finally, the five categories of BEAM Plus for New Buildings, the sustainability rating system in Hong Kong, are compared with the traditional Feng Shui practice.

1.1 Sustainability design in Hong Kong

The original concept of Green Buildings emphasizes "the increasing efficiency with which buildings and their sites use water, energy and material; and reducing building impacts of human health and the environment, through better siting, design, construction, operation, maintenance and removal throughout the complete life cycle" (Office of Federal Environmental Executive, 2003). The concept of Green Buildings has been extended on a larger scale, focused on "Sustainability" or "Sustainable Development". According to the World Commission on Environment and Development (WCED), it is defined as "forms of progress that meet the needs of the present without compromising the ability of future generations to meet their needs" (Brundtland, 1987). With the latest sustainability commitment in Paris 2015, "Transforming our world: the 2030 Agenda for Sustainable Development", every single country and all human in the world should change their life a little bit to protect our planet.

In Hong Kong, HK2030 Campaign provides a vision for a low carbon, sustainable built environment in Hong Kong by 2030. BEAM Plus – Building Environmental Assessment Method is a renowned green building labelling tool in Hong Kong certified by the Hong Kong Green Building Council (HKGBC) to evaluate the environmental performance of buildings. It contributes significantly towards sustainable development in Hong Kong. The marking scheme process the rating on five categories: Site Aspects, Material Aspects, Energy Use, Water Use and Indoor Environmental Quality, and credits on Innovations and Additions on design solutions. It will be classified in the rating of Bronze, Silver, Gold and Platinum.

1.2 Feng Shui – The traditional Chinese wisdom

Feng Shui, the ancient Chinese knowledge that aims at creating a harmony between heaven, earth and human has influenced most traditional built environmental design in China for thousands of years. Since the late 1960's, the impact of western civilisation and technology has grown to global proportions, with more western scholars becoming aware of the limitations of modern scientific paradigms that fail to explain the whole realm of natural phenomena and beginning to realize that there are similarities between modern science and eastern philosophy (Capra, 1975).

However, it was not until 1956, when Joseph Needham published his book series "Science and Civilisation in China", that western readers began to appreciate the scientific context in which Feng Shui flourished. Needham tried to identify relevant aspects of western science and their applications to traditional Chinese counterparts. He began to appreciate the value of Feng Shui in ecology and landscape aesthetics. According to Needham (1959, p.361) Feng Shui "embodied ... a marked aesthetic component, which accounts for the great beauty of the siting of so many farms, houses and villages throughout China".

Anderson and Anderson (1973) recognized that Feng Shui is an aspect of Chinese cultural ecology. They investigated village siting in Hong Kong of Feng Shui configurations with modern planning practice on site planning, land use and natural resources, especially those of ecology. They recognized that Feng Shui is "basically a very practical system whereby a village is situated such that it does not take up farmland or lay itself open to floods and typhoons… based on sound pragmatism" (Anderson and Anderson, 1973, p.45-50). They called Feng Shui "the traditional Chinese science of site planning", containing "an organized body of knowledge, intensely practiced in application, and of specific intent" (Anderson, 1973, pp.127-128).

2. COMPARISON OF SUSTAINABLE DESIGN AND FENG SHUI

The sustainable development concept includes many areas such as waste and recycling, energy, water, building design, emission, indoor environmental quality (IEQ), alternative transport, landscaping, and about everything that revolves around human activity, and aims to eliminate negative environmental impact while continuing to be completely ecologically sustainable through skilful and sensitive design (McLennan, 2004). It can be summarized to a set of five fundamental concepts for sustainable development (Dong and Zuehl, 2009):

- Constructivism – to create more enjoyable space that build knowledge and skills for the end users
- Circular design (McDonough's "Cradle to Cradle" concept) – to reduce, reuse, recycle through the intelligence of natural systems
- Energy efficiency – reduce consumption of natural resources to increase environmental satisfaction
- Balance between natural and the built environment – bring natural elements (sunlight, plants, water, etc.) to improve the behaviour of the user in the environment
- Thinking global and buying local – acquire from local markets to increase the environment's overall well-being

The principles and practices of Feng Shui are aimed at creating a harmonised built environment for people to live in, and it represents a traditional Chinese architectural theory for selecting favourable sites, as well as a theory for designing cities and buildings (Lee, 1986). The five fundamental concepts of Feng Shui in terms of environmental design (Mak & Ge, 2010) are:

- Unity between heaven and human – to create a balance and harmonious environment between natural and man-made structures
- The five elements cycles – productive and destructive relationships of five observed natural phenomena (Fire, Water, Metal, Wood and Earth)
- Yin and Yang harmony – to create balance space from engaging two opposing parts (positive and negative) in nature and human
- The form school model – an arm-chair position from five geographical configurations (Dragon - supporting mountain, Sand - surrounding hills, Water – flow of water, Cave - front open space, Direction – orientation)
- Balance between interior and exterior spaces – create a harmonious space amongst surrounding environment, external layout, internal layout and interior arrangement

The five fundamental concepts of sustainable design can be compared with the five Feng Shui concepts in terms of environmental design. When comparing the concepts of sustainable design with Feng Shui, there are both similarities and differences. Firstly, the concept of constructivism translates well into the principles of harmony between universe, earth and human in Feng Shui. The ideal environment for Feng Shui is that these three aspects intersected and overlapped. These three circles can also be found in sustainable design as social contexts, environmental and human as shown in Figure 1.

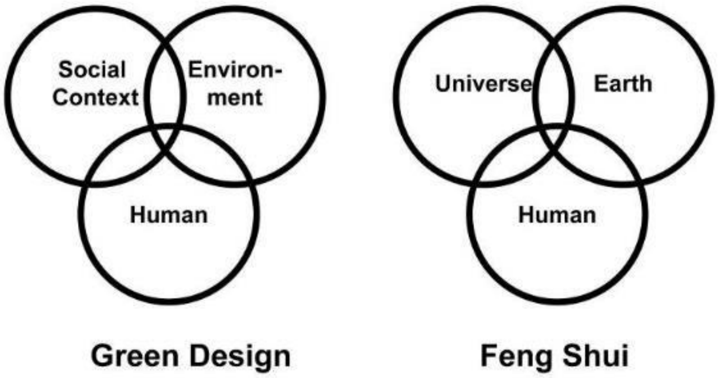

Figure 1: Comparison of the principles of green design with Feng Shui (Source: Dong and Zuehl, 2009)

The second principle of Feng Shui is the productive and destructive cycles of five elements, which is similar to the circular design or McDonough's "Cradle to Cradle" concept (McDonough and Braungart, 2002). The third Feng Shui concept is the balance and harmony between Yin and Yang, which also matches with the concept of sustainable design of balancing between natural environment and the built environment. In sustainable design, the third and fifth concepts, energy efficiency and buying local concepts are focused explicitly on the sources and consumptions of natural resources. However, the Feng Shui concepts of Form school model and balance between interior and exterior spaces are focused on the physical form and spatial arrangement of the built environment. Table 1 summarized the comparison of sustainable design concepts and Feng Shui concepts.

Sustainable Design Concepts	Feng Shui Concepts
Balance and Harmony	
(1) Constructivism	(1) Unity between heaven and human
(4) Balance between natural and the built environment	(3) Yin and Yang harmony
Cycles Pattern	
(2) Circular design	(2) Five elements cycles
Sources and Consumption of Natural Resources	*Physical Form and Spatial Arrangement*
(3) Energy efficiency	(4) Form school model
(5) Thinking global and buying local	(5) Balance between interior and exterior space

Table 1: Comparison of sustainable design and Feng Shui concepts (Source: Mak and So, 2015, p.152)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. COMPARISON OF BEAM PLUS AND FENG SHUI

There are five categories of BEAM Plus rating system: Site Aspects, Material Aspects, Energy Use, Water Use and Indoor Environmental Quality (while credits on the Innovations and additions are measured separately). In the BEAM Plus for New Buildings Version 1.2 published in July 2012, there are a total of 80 considerations (BEAM Society, 2012). The following Table 2 to 6 highlighted those considerations which are similar to the Feng Shui concepts.

Site Aspects (SA)	Sustainable evaluations	Feng Shui concepts
(SAP1) Minimum Landscape Area	Planting on site equivalent to at least 20% of the site area.	(2) Five elements cycle of the natural phenomena (Wood element)
(SA1) Contaminated Land	Conducting a site contamination assessment and implementing measures for rehabilitation, and/or proper preparation of sites and structures adjacent to landfill sites.	(1) Create a balance and harmonious environment (Natural environment must be restored to create a balance space)
(SA4) Site Design Appraisal	To achieve greater integration of site planning and design issues	(4) Create an arm-chair model formed from five geographical configurations (Dragon - supporting mountain, Sand - surrounding hills, Water – flow of water, Cave - front open space, Direction – orientation)
(SA5) Ecological Impact	Appropriate design measures have been implemented to contribute positively to the ecological value of the site.	(1) Create a balance and harmonious environment (Balance between natural and man-made environment)
(SA7) Landscaping and planters	Using pervious materials for a minimum of 50% of hard landscaped areas, and appropriate planting on site equivalent to at least 40% of the site area.	(3) Create a balance space from two opposing parts (hard and soft landscape)
(SA8) Microclimate Around Buildings	(a) Wind Amplification - No pedestrian areas will be subject to excessive wind velocities caused by amplification due to the site layout design and/or building design. (b) Elevated temperatures - Providing shade on at least 50% of non-roof impervious surfaces on the site and roof material that meets the Solar Reflectance Index (SRI) of 78 or vegetation roof covering at least 50% of the total roof area.	(4) Create an arm-chair model with balance geographical configurations (Sand - protected by surrounding hills, and Direction – orientation) (3) Create a balance space from two opposing parts (open area and roofed area)
(SA9) Neighborhood Daylight Access and Lighting Pollution	The access to daylight of neighboring sensitive buildings is maintained to the prescribed level. Also, obtrusive light from exterior lighting meets the specified performance for the environmental zone	(5) Balance external environment with interior environment (From surrounding environment to internal layout for natural and artificial lighting)
(SA11-SA15) Air pollution, Noise and Water pollution During Construction and from building Equipment	Providing adequate mitigation measures for construction dust, air emissions, noise and water pollution.	(1) Create a balance between natural and built environment (Balance between natural and man-made features)

Table 2: Comparison table of sustainable and Feng Shui in site aspects

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Materials Aspects (MA)	Sustainable evaluations	Feng Shui concepts
(MA4) Adaptability and Deconstruction -Spatial adaptability and structural adaptability	Providing spatial flexibility that can adapt spaces for different uses, and allows for expansion to permit additional spatial requirements	(3) Create a balance space with two opposing parts (space requirements for different users, different timeframe)

Table 3: Comparison table of sustainable and Feng Shui in material aspects

Energy Use (EU)	Sustainable evaluations	Feng Shui concepts
(EU13) Energy Efficient Building Layout	a) Consideration of built form and building orientation; b) Consideration of optimum spatial planning; c) Consideration of building permeability provisions of building features to enhance the use of natural ventilation; d) Provision of fixed or movable horizontal/ vertical external shading devices; e) Provision of movable external shading devices for major atrium facade windows or skylights.	(4) Create an arm-chair model with balance geographical configurations (Dragon - supporting mountain, Sand - surrounding hills, Water – flow of water, Cave - front open space, Direction – orientation)

Table 4: Comparison table of sustainable and Feng Shui in energy use

Water Use (WU)	Sustainable evaluations	Feng Shui concepts
(WUP1) Water Quality Survey	Ensure quality of water delivered to building users is satisfactory.	(4) Create an arm-chair model with balance geographical configurations (Water – flow of water)

Table 5: Comparison table of sustainable and Feng Shui in water use

Indoor Environmental Quality (IEQ)	Sustainable evaluations	Feng Shui concepts
(IEQP1) Minimum Ventilation Performance	With the minimum requirements of Outdoor Air Quality; and Minimum Ventilation Rate	(4) Create an arm-chair model with balance geographical configurations (Sand - protected by surrounding hills, and Direction – orientation)
(IEQ2) Plumbing and Drainage	Reduce the potential for transmission of harmful bacteria viruses, and odours.	(3) Create a balance space with two opposing parts (Balance between nature and human)
(IEQ13and 14) Thermal Comfort in Air-Conditioned Premises and Naturally Ventilation Premises	Room air diffusers satisfy the Air Diffusion Performance Index. The thermal performance, and the internal wind speeds, of the occupied/habitable rooms fall within the 80% acceptability range for the tropical climate conditions of Hong Kong.	(4) Create an arm-chair model with balance geographical configurations (For natural ventilation, Sand - protected by surrounding hills, and Direction – orientation)
(IEQ15) Natural Lighting	Normally occupied spaces is adequately lit with an average daylight factor	(5) Balance external environment with interior environment (For natural lighting, balance of external layout and internal layout)

Table 6: Comparison table of sustainable and Feng Shui in indoor environment quality

From the above tables, Site Aspects consist 8 items that are similar to Feng Shui concepts, which is half of the list above. Other than that, there is only one item each in Material Aspects, Energy Use, and Water Use. In Indoor Environmental Quality, there are 4 items similar to Feng Shui concepts. Overall, in the BEAM Plus – New Building category, Site Aspects and Indoor Environmental Quality are the major concern toward Feng Shui concepts.

These results indicated that BEAM Plus rating system is focused on the tangible measurements in Material Aspects, Energy Use and Water Use. However, Site Aspects are most related to the architectural and urban planning, which is classified as passive sustainable design and it should be planned at the very beginning of a development project. Feng Shui concepts focused on physical form and spatial arrangement of the built environment provides intangible evaluation in these aspects. Performance measurements of BEAM Plus in Indoor Environmental Quality suggested to provide a comfort condition for human to live. This is similar to the Feng Shui concepts that aim to creating harmony between heaven, earth and human, with the emphasis of human potential through the built environment.

4. CONCLUSION

This paper has compared and contrasted the concepts and practices between western sustainable design and Chinese Feng Shui through investigations of five categories of BEAM Plus rating system in Hong Kong. The findings have suggested that both concepts are the same in terms of focusing sustainable development, that is, to provide a balance and harmonious built environment. The distinct feature of sustainable design put greater emphasis on the measurement of physical attributes such as the efficient use of material, water and energy, whereas Feng Shui is unique and the emphases are on the balance of Yin Yang, exterior and interior, the relationship between physical form and spatial arrangement of the built environment. Through the analysis of five categories of BEAM Plus rating system for New Buildings in Hong Kong, Site Aspects and Indoor Environmental Quality are the major concern of the Feng Shui concepts. These results indicated that BEAM Plus focus on tangible measurement of sources and consumptions of natural resources, whereas Feng Shui concepts focus on intangible factors of surrounding environment and well-being conditions. Based on this comparison between Feng Shui and the BEAM Plus rating system in Hong Kong, it can enhance the public awareness on sustainability amongst the Chinese communities. This analysis also provides a framework for Feng Shui concepts to be considered and applied into the modern sustainable buildings that will enhance the effectiveness of sustainable development.

ABSTRACT

The Hong Kong Housing Authority (HKHA) develops and implements one of the world's largest public housing programme and is committed to providing adequate and affordable quality housing services to people who are in genuine need.

Over the decades, HKHA has been embracing the core values of "Caring, Committed, Creative and Customer Focused" in delivering the sustainable public housing in Hong Kong. Since 2002, we have changed our modus operandi from basic levels of "informing", "consulting", to tertiary levels of engaging the public to "decide together" and "acting together" in drawing up of plans and design briefs to meet common objectives, and in providing feedback and suggestions for long-term maintenance. Public engagement processes result in socio-economic benefits and the aggregate of changes enhance the surrounding built environment, local character and social identity of its neighbourhood. In this Paper, we focus on the community aspects, namely, a) Community engagement; b) Sustainable lifestyle; c) Socio-economic impact, and d) Corporate social responsibility, to share our experience on how HKHA creates sustainable communities in public housing estates –

- Public consultation at planning stage engaging the District Council, Concern Groups and Stakeholders in the neighbourhood;
- Integrated knowledge management and feedback system covering not only the design stage but expanding also to building completion and occupation. Under the system, we conduct resident surveys and organize post completion review workshops for newly completed projects to gauge residents' satisfaction level on the estates in which they live, and capitalize their feedback for continuous enhancement of our design standards;
- Setting up Estate Management Advisory Committees with tenants' participation - to decentralize estate management to local level; and
- Total Maintenance Scheme features proactive in-flat inspection, timely arrangement of maintenance works and education for tenants.

Keywords: sustainable community, community engagement, public housing

1. INTRODUCTION

The Hong Kong Housing Authority (HKHA) develops and implements one of the world's largest public housing programme. As a progressive public sector developer underpinned by the core values being caring, customer-focused, creative, and committed, HKHA is committed to providing happy and harmonious homes with caring and stable communities for the people of Hong Kong. The ensuing paragraphs share HKHA's experience on community participation through case studies and summarize tangible results and benefits in the recent endeavors.

2. FROM INFORMING, CONSULTING TO ENGAGING

Sherry Arnstein, former Executive Director of the American Association of Colleges of Osteopathic Medicine, mentioned about a "ladder" of participation, reflecting different levels of power exercised by communities, and there are five different kinds of participation as follows (Lister, Perry & Thornley):

1	Informing	Telling people about what is planned and engaging their interest in it
2	Consulting	Offering people options, getting feedback from them and taking account of their views
3	Deciding Together	Encouraging people to develop ideas or options, and giving them some influence in deciding the way forward
4	Acting Together	Joint decision-making on action to be taken, and forming partnerships with residents' groups to carry it out
5	Supporting Independent Community Initiatives	Helping residents to carry out their own plans or initiatives, whilst leaving them in charge of what happens

Table 1: Five different kinds of participants

Since HKHA's development has major impact on the lives of our tenants, we make every effort to ensure that our residents will enjoy a sustainable community life and have a sense of belonging in the communities they live in. So have we done enough for our tenants and community in terms of tenants' participation and public engagement?

Towards this end, we have a long-standing practice of informing the community, consulting various concerned groups and District Councils (DC) at the early stage of planning and design of new estates. That is to say, "Informing" and "Consulting" have long been our common practice across the board. Following the turn of the millennium, we ventured to test the route for higher levels of involvement by partnership with stakeholders. In our recent endeavours, we took a step ahead to engage the community in "Deciding together", "Acting together" as well as helping he residents to carry out their own initiatives.

3. CASE 1 – REDEVELOPMENT OF PAK TIN ESTATE

Since the announcement of the redevelopment of Pak Tin Estate in April 2012, HKHA has conducted over 150 events to communicate with the local residents and stakeholders, to collect their feedback and concerns so as to optimize the redevelopment proposal. We believe that "Strengthening of communication and understanding will strike a balance between the expectations of both sides and alleviate grievance."

The 150 events included:

Regular level of consultation (over 130 events)
- DC & Estate Management Advisory Committee (EMAC) consultations
- Meetings & site visits with Legislative Council (LegCo), DC members, concerned groups and residents' representatives
- HKHA members' meeting with concern groups

Figure 1: Over 130 events of regular level of consultation including consultations, meetings & visits

Advanced level of consultation (over 20 events)
- Arranged briefings and attended residents' forums held by DC members
- Arranged community engagement workshop
- Distribution of pamphlet & newsletters to tenants, Non-Government Organizations (NGOs) and schools, to brief and respond to concerned redevelopment issues e.g. closure of public transport interchange and temporary transportation arrangement
- Broadcasting video at domestic block entrance lobbies to brief residents on redevelopment information

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 2: Advanced level of consultation events e.g. forum, workshops, pamphlets, newsletters

Through public consultation, basic and consistent development information and principles were conveyed to stakeholders, and stakeholders' views were collected. This strengthened communication between community and HKHA and enhanced the planning and design of the redevelopment project with incorporation of their views.

4. CASE 2 – URBAN GREEN HOME – KWAI SHING CIRCUIT

Kwai Shing Circuit Development was the last part of a major redevelopment project at Kwai Shing East. The project scope comprised the demolition of the former Block 12 of Kwai Shing East Estate and construction of two domestic blocks as well as an integrated lift tower and the communal open space.

Figure 3: Image and location of the former Block 12 of Kwai Shing East Estate

At the planning stage of the project in late 2008, objections from stakeholders were received on the disposition of the proposed development, i.e. one of the domestic blocks was at a locality right next to an existing school. Management of expectation of the school was crucial as complaints arose from the school might jeopardize the construction programme. A series of activities and workshops were conducted to engage stakeholders in the design of the development. Until April 2009, based on the comments collected from the public consultation activities, disposition of the two domestic blocks was re-arranged to the lower and the upper platform, where the adjoining space of existing school was planned to be an open space.

Figure 4: A series of activities and workshops have been conducted to allow stakeholders to get involved in design of the development

During demolition of the existing block, a green hoarding design competition for students of the nearby schools was organized with "green living" as the main theme. The awarded design entries were posted on the hoardings.

Briefing meeting and workshop were also conducted to brief the nearby school users on the demolition procedure, hoarding design, noise and environmental management and safety measures.

Figure 5: Green hoarding drawings competition and briefing meeting and workshop had also been conducted during demolition of the existing block

The community engagement process in Kwai Shing Circuit project is a manifestation of “informing”, “consulting”, “deciding” and “acting together”

- Stakeholder, were invited to community engagement workshop to give ideas for conceptual design of the community garden
- They were also actively involved in design development and construction stage to assure that the final deliverables met their requirements
- The project has best addressed needs and wish of stakeholders. Resistance from stakeholders was minimized and project delivery was accelerated

5. CASE 3 – CONVERSION OF CHAI WAN FACTORY ESTATE TO PUBLIC RENTAL HOUSING

The Government announced the conversion of the Chai Wan Factory Estate (CWFE) into public rental housing in 2012 as one of the short term measures to address the needs of singletons and small families for small-sized housing units in urban area. Being the only surviving example of H-shaped factory building in Hong Kong, CWFE was granted Grade II Historic Building status by the Antiquities Advisory Board in 2013.

Figure 6: A series of community engagement activities and display area in the public rental housing estate sharing collective memories from ex-tenants and local residents

HKHA conducted a series of community engagement activities to introduce the heritage value of the CWFE, to share the collective memories from ex-tenants and local residents and to collect opinion from the district on the preservation of CWFE. In the workshop, design concept of the display area in the future public rental housing estate was also introduced and the valuable contents to be included in the display area discussed.

The participatory processes of “consulting” and “deciding together” described above have taken into account the interests and assets offered by an existing well established community. We have successfully built up the estate identity, ownership and a sustainable community synergistically. We believe that “It is important to recognize the asset and potential that local people, building fabric and service provider offers and to creatively extend them into exciting new potential.”

6. CASE 4 – HAND IN HAND – ACTION SEEDLING

Action Seedling initiated in 2007, is a Community Participatory Scheme to enhance our partnership with contractors, public housing tenants and the community at large. Through Estate Management Advisory Committees, schools and community organizations, seedling plants are given out by HKHA and its building contractors. The participants would nurture the seedling plants at their home until the plants are fit for transplanting into the planters of the newly constructed estates.

Figure 7: Action seedling

The initiative allows our contractor to play their part in greening and environmental protection as part of their corporate social responsibility. Action Seedling is a manifestation of "acting together". It effectively accomplishes our mission towards green and sustainable community. Besides, the programme helps to foster a greater sense of belonging amongst the resident and the community.

7. CASE 5 – ESTATE IMPROVEMENT PROGRAMME FOR KWAI SHING WEST ESTATE

HKHA selected Kwai Shing West Estate completed in 1975 for pilot implementation of BEAM Plus for Existing Buildings. Various improvement measures had been tied in with the Estate Improvement Programme to enhance the environmental performance and promote sustainable living in the estate community. Kwai Shing West Estate had achieved Final Platinum Rating under BEAM Plus EB Version 1.2 in October 2015 and it is the first existing building to receive this award under the existing building category.

7.1 Creating thriving communities

Innovative services and educational components brought the estate improvement in Kwai Shing West Estate to a new height. Under "Total Maintenance Scheme", we put un-precedential emphasis on customer services and education. In serving Kwai Shing West Estate and other estates under management of HKHA, some 140 specially trained inspectors, who not only perform technical building inspections, but also act as landlord's ambassadors, help motivate and educate the tenants in bringing building defects in their homes to the landlord's hands. This holistic approach, which brings peace-of-mind, has been very well received by our tenants and customer satisfaction has stayed high since introduction. With the Scheme as foundation in promoting a defect reporting culture, the "Responsive In-flat Maintenance Services" has been launched to provide enhanced and responsive in-flat maintenance services for all tenants with frontline staff register maintenance requests directly from tenants and set repair process in motion quickly. The estate communities are well engaged and educated which contribute to the success of estate improvement in Kwai Shing West Estate.

7.2 Fostering community goals

Energy saving is one of the common community goals to promote sustainable living in Kwai Shing West Estate. Alongside with building improvements using energy-saving light fittings and water-saving installations in common areas, we strive for continuous improvement by regularly monitoring the energy consumptions of the estate. To arouse tenants' environmental awareness and nurture their sense of belonging, ten LCD panels had been installed to display the periodic consumption of electricity, gas and water consumptions at all domestic blocks.

7.3 Engaging the communities

To strengthen social cohesion and sense of belongings, public engagement was conducted in formulation of its estate improvement projects of Open Space Design and Improvement of Elevated Walkway. Through proactive

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

publicity in DC and Estate Management Advisory Committees meetings, partnership functions with Non-Government Organizations and open forums organized by political parties, about 60 representatives from various stakeholders including estate tenants, nearby schools, NGOs, local District Councilors were invited to participate in the Community Workshop. A total of twelve meetings were held to gauge stakeholders' views and interviews were conducted with our tenants in which all participants were able to freely express ideas and enthusiastically contribute constructive ideas. The elevated walkway was finally designed as an Art Gallery displaying old estate photos and students' drawings, whereas the Open Space was adopted as a fitness and children recreational area. We have successfully fostered neighbourhood spirit and achieved harmonious relationship with good community network in Kwai Shing West Estate.

Figure 9: Photo (From Top): Community engagement workshop, open space design and improvement of elevated walkway, community workshop

8. POST-OCCUPANCY CONSIDERATIONS

We treasure the views of our residents and have conducted independent Residents Surveys for all newly completed estates since 2004. The major objective of the Residents surveys is to gauge residents' satisfaction level on the design and provisions of the estates in which they live, as well as to collect opinion on hypothetical design and provision scenarios that we would like to explore. Satisfaction level on "estate as a whole" from each Residents Survey conducted within a year will be aggregated to compile the Customer Satisfaction Index for that financial year. At the onset, our Key Performance Indicator was pitched at 70%. In light of the consistently high satisfaction obtained from these surveys over the years, the Key Performance Indicator has been uplifted to 80% from 2011/ 12 onwards. With engagement of the residents in the planning and design of our estates, the Customer Satisfaction Index is continuously on the rising trend, reaching 95% in recent years.

9. CONCLUSION AND WAY FORWARD

In all cases mentioned above, there is better communication, better understanding, better consensus, and with a better product or services where participating stakeholders have a sense of ownership. Forget about bureaucracies and impossibilities for a while, and be a good listener.

"Seek first to listen and understand, before one could be understood." Start from scratch and look at the world from a different view, listen and accommodate others' views, work with them to arrive at the final conclusion – and on a road less traveled we can derive more satisfaction during the journey towards a win-win destination.

The Application of Social Innovation in Designing an Aged Care Centre in Malaysia

Thomas TANG Sek-khuen[a]

[a] *Kuala Lumpur Centre for Sustainable Innovation, Malaysia, sk.tang@klcsi.com*

ABSTRACT

Social innovation is the commercial application of ideas and technology towards improving societies. Of key importance, social innovation works best when the community concerned is empowered to help co-create the innovation. In this paper, social innovation is considered in a Southeast Asian context and how a bottom up approach improves the sustainable design of public buildings such as schools and community centres. A living lab case study is used to demonstrate how identifying and analysing community needs by consulting the latter is fundamental to the design of a community care centre for the aged. The centre incorporates assistive technologies, access design and care features as well as sustainable design such as urban gardening, rainwater harvesting, waste recycling and energy efficiency. The building is also designed for intergenerational use as it is intended to have other users of different ages so that the elderly will be encouraged to interact with them thereby promoting the benefits of active ageing.

Keywords: social innovation, living lab, aged care, community centre

1. INTRODUCTION

Social innovation is the commercial application of ideas and technology towards improving societies and works best when the community concerned is empowered to help co-create the innovation. In this paper, social innovation is considered in a Southeast Asian context and how a bottom up approach improves the sustainable design of public buildings such as schools and community centres. To take this idea further a living lab approach was applied in Kuala Lumpur to design an aged centre in a suburban area.

2. BACKGROUND

2.1 Social innovation

Social innovation can be defined as, "new solutions (products, services, models, markets, processes etc.) that simultaneously meet a social need (more effectively than existing solutions) and lead to new or improved capabilities and relationships and better use of assets and resources. In other words, social innovations are both good for society and enhance society's capacity to act." Social innovation, much like technical innovation, involves creative ideas and problem solving skills with the aim of improving social conditions.

Five core factors for social innovation are:

- Novelty: Social innovations are new to the field, sector, region, market or user, or to be applied in a new way;
- From ideas to implementation: Social innovation focuses on implementation and application of new ideas, rather than just inventing new ideas;
- Meets a social need: Social innovations are explicitly designed to meet a recognised social need;
- Effectiveness: Social innovations are more effective than existing solutions – they create a measurable improvement in terms of outcomes; and
- Enhances society's capacity to act: Social innovations empower beneficiaries by creating new roles and relationships, developing assets and capabilities and/or better use of assets and resources.

Thus, social innovators are individuals who have come up with product or service solutions for a specific social problem. For instance, a person who has developed an app for translating an aboriginal dialect into English to improve communication between indigenous tribes and health workers could be considered to be a social innovator. Another example could be an engineer who has invented a way of low cost construction for housing the homeless.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

In these cases, the innovator may or may not be seeking a profit out of his or her work. But commonly social innovators would want to see some commercial return on their ideas but not necessarily as a business. Government too sometimes comes up with social innovations e.g. providing free or subsidized bicycles for school children whilst making the school zones car-free to avoid traffic jams around schools. Some NGOs have also provided social innovations such as using cookery or art as a means for the mentally disabled to express themselves.

Over the past decade social innovation has been applied to sustainability and to encourage sustainable living as a lifestyle and behaviour change. The very nature of social innovation, which is community-driven, ensures that institutions, enterprises, non-profit organizations and networks of collaborative persons are able to find common platforms to work together generating a variety of initiatives such as community-supported agriculture, co-housing, carpooling, community gardens, neighbourhood care, talent exchange and time banks. These initiatives propose viable solutions to complex problems e.g., social cohesion, urban regeneration, healthy food accessibility, water and sustainable energy management and, at the same time, they represent working prototypes of sustainable ways of living.

2.2 The living lab approach

Living labs are platforms like a building or a community for user-centred products before they are commercially available. As living labs usually involve partnerships, they are appropriate mechanisms for social innovation. Such partnerships can involve government agencies, companies and research institutes to pool their research on built environment and city management, urban mobility, IT and info-communications, public safety, waste and water management and clean energy. Members of communities are furthermore invited to contribute and shape the tested product.

Social innovation applied in a living lab allows:

- Unprecedented connectivity and networking, which means new possibilities for competition as well as cooperation;
- Global awareness (e.g. about climate change), thanks to information from other citizens and sensors alike, which can enable access to culture and inclusion;
- New solutions for sustainability, based on collective intelligence, including not only new financial and economic models, but also support for a true low-carbon economy, and renewable energy production.

Living labs have the potential to strategically frame co-production processes in two ways. First, consulting users and stakeholders allows complementary sets of projects to be strategically planned that offer holistic solutions to sustainability challenges. Second, by emphasising the iterative process of experimenting and learning from year to year they provide a more coherent basis for action over time. Living labs are emerging as a form of collective urban governance and experimentation to address the sustainability challenges and opportunities created by urbanisation. Five key characteristics are identified:

- Living labs are situated in a real urban context where the process in focus is taking place. This may be a region, an agglomeration, a city, a district or neighbourhood, a road or corridor, or a building.
- Living labs represent a specific form of experimentation, whereby processes of innovation and learning are formalized, unlike policy experiments, and enable the co-production of knowledge and ideas with the users.
- Participation and co-design with stakeholders such as residents and users is at the core and appears in all stages of the living lab approach – from identifying stakeholder needs, deciding upon living lab goals, planning and designing to developing, implementing, evaluating actions and updating.
- A clear leader or owner is crucial for a living lab to be effective, although a fine balance exists between steering and controlling. The living lab needs to be flexible for different stakeholders to engage in its development and direction.
- Finally, evaluation of the actions and impacts of a living lab is important to feed back the results, and revisit and refine the goals and visions over time. Evaluation underpins the ability of living lab projects to facilitate formalised learning amongst the participants.

3. CASE STUDY: AGED CARE CENTRE LIVING LAB

3.1 Ageing populations

Globally, the population of persons aged 60 and above is projected to double to more than 2 billion by 2050 or 21% from 11.7% in 2013. By 2047 the number of older persons is expected to surpass the number of children for the first time. Not only are the numbers of older persons increasing substantially, they also have longer and healthier lives due to higher standards of living and advancements in healthcare. Population ageing is found to be more prominent in developing countries due to the rapid decrease in fertility rates in recent years compared to developed countries. Asian countries stand to face the biggest growth in their ageing population, as one in four Asians will be over the age of 60 by the year 2050.

Malaysia, one of the modern nations in ASEAN, faces an ageing problem. Compared to European countries which took 100 years to double their populations aged 65 and above, Malaysia will take only 23 years to double from 7% in 2020 to 14% in 2043. This is a reflection of longer life expectancy, good public healthcare and lower fertility but the downside is that the country does not have much time to prepare for a new set of issues that come with ageing.

Firstly, care and attention for the elderly will be critical. The old are more prone to chronic diseases, sleep disruption, psychological problems and cognitive decline. Healthcare models will have to be reconfigured to cater for the aged who have spent a lifetime of modern living with all the associated stresses. Housing will be another challenge as homes designed for the young and active become difficult for the elderly to cope with. Whilst ageing in one's own place is the best approach for a greying population, the practicalities of stairs and toilets will become physically insurmountable with ageing. Moving to aged care homes is a possibility but affordability will be an issue and many elderly will probably end up in aged homes of a basic nature unsuited for their needs. Other problems include physical and psychological degeneration. Even with extended retirement ages, there will come a time when people can no longer work and rapidly deteriorate through emptiness and boredom. Deprived of human company, aged decrepitude becomes synonymous with being abandoned or ignored.

3.2 Intergenerational community centre case study

The KL Centre for Sustainable Innovation has been involved in the design and development of an innovative community centre in Kuala Lumpur as a social innovation and a living lab that will cater to the needs of the immediate local community - the elderly, adults, youths and children. The centre's facilities and programs will cover health, social, recreational and educational purposes. The community centre is a model for intergenerational care that can be easily replicated across other communities in urban areas across Malaysia.

The basis of this approach comes from intergenerational housing models where the young share living quarters with the elderly. In Japan, 40% of older people live with their adult offspring and over 17% live with their grandchildren in contrast to the UK where less than 10% of those aged 70 and over live with their adult offspring and around 2% live in multigenerational households with offspring and grandchildren. Home sharing is where an older person offers accommodation to a younger person at a reduced rate in exchange for support with basic tasks such as shopping or gardening. Co-housing is the development of private households with shared facilities that invoke a sense of community. The best example of an intergenerational model is in Alicante, Spain where 200 affordable, intergenerational housing units were created in central urban areas and populated by older persons over the age of 65 and young people under the age of 35 in a ratio of 80:20 respectively. On the basis of a 'good neighbor agreement', each young person had responsibility for four older people in the building with resulting positive feedback from the elders (increase in well-being and independence within a family-like environment) and the young people (knowledge gaining and the opportunity to nurture real relationships of friendship with the older persons they assisted).

KLCSI in conjunction with Kirk Architects came up with a design to apply the intergenerational concept for a community centre in a suburban setting. This centre was to be designed specifically with the local community in mind, after a study of the demographics and lifestyle patterns in the area and identifying any gaps or needs not being fulfilled from the perspectives of a wider community. Factors to be taken into consideration include:

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Inclusivity. The community centre will be designed to meet the basic needs of the local community regardless of age, beliefs and social standing. These include a safe environment, modern technology, adequate facilities and open spaces.
- Active. The community centre will provide products and services that the community need or want like classes, activities and assistive tools. These will be provided at a discount through sponsorship.
- Adaptability. The centre will be able to adapt to the changing needs of the community over time through regular stakeholder focus groups.
- Sustainability. The centre will be a showcase for sustainable living that the community members can adapt and apply in their own homes such as urban gardening, waste recycling and energy efficiency.

3.3 Living lab design

Survey

KLCSI conducted a survey on elderly users on their preferences for a community centre. Working with a group of senior adults, the following findings emerged:

- 97% of the respondents prefer that a medical centre should be nearby, and 91% want to live close to their children.
- All of the respondents prefer well trained caregivers (staff or nurses), 97% want swift response and accessible means of summoning help in emergencies, and 97% agree that a 24/7 ambulance service is crucial.
- 94% of the respondents want wheelchair accessibility and 96% want safety features in the buildings. Green technologies received 73% of votes.
- 87% of respondents feel that the reputation of the developer as well as the care centre operator is important, 93% want security features and 96% agree that street lighting is crucial. Gardening and sports received 54% and 48% of the responses.

Architectural design

Kirk Architects produced a pavilion-based design using a reinterpretation of a traditional Straits shop house that was adaptive, viable and flexible with a framework to support a wide range of uses, and allowed multiple modes of management and operation for different generations (see Appendix). Key features include:

- Broad space typologies of activity space, office, amenity and service spaces and circulation in combination with passive strategies to deal with the tropical environment for natural light and ventilation, shading and glare, views and privacy.
- The modular structure of the pavilions allows a loose fit model using structural simplicity and open span functional areas that offer flexibility for a multitude of configurations depending on the particular program requirements whether for elderly or non-elderly use. These include larger spaces suitable for dining, exercise studio, arts and crafts, seminars, celebrations and libraries to smaller configurations suitable for counselling, medical consultation and more personalised services for the elderly such as health planning and management, and non-invasive therapies, and at the same time can be used for playrooms or youth activities if needed.
- The central courtyard forms the key space of the building to connect the community. Security and safety would be ensured in all public spaces and the courtyard acts as a spine to allow easy movement and clear way for the elderly and non-elderly community. The building is permeable allowing continuous connection to landscape elements such as roof top gardens, water, window seats and informal social breakout spaces.
- Utilitarian functions are located each end of the pavilions for vertical circulation, amenities, offices, stores and plants etc. This planning arrangement and the modular nature of the pavilions allows for a building model that can scaled and sized for different sites.
- Technological advances through internet communication allow for remote access for people to online specialist counselling and medical care. This unlocks opportunities for medical screenings, health and nutritional management, counselling and rehabilitative training close to home at the local community facility.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

From a sustainable building perspective, sustainability is considered holistically in the design whereby the building responds to climatic conditions such as high rainfall, solar and sky glare, reflective and radiant heat. Features such as natural diffused daylighting and thermal massing, renewable energy such as solar panel and solar air cooling systems, and rainwater collection and harvesting are incorporated. A roof garden serves as an edible food source using rainwater for irrigation and food waste for compost. The centre furthermore utilizes intelligent building systems and real-time software to verify building performances. It is possible that through use of durable, resilient and low maintenance materials, innovative and sustainable building technologies (including glue laminated and cross laminated timber technologies) together with low energy demand that the building could be a leading exemplar as a zero carbon footprint building and act as a catalyst for growth and regeneration in the neighbouring community.

4. DISCUSSION

Although the intergenerational model of aged care has been shown to be successful elsewhere, there are inherent challenges in Malaysia. Other than family ties, it would be justified to say that the model has not taken root in any large measure, possibly due to the unpopular notion of having to share facilities with strangers. There are further issues to do with the fact that Malaysia is quite diverse in its population mix through ethnicity (Malays, Indians, Chinese), religion (Muslim, Christian, Buddhist, Hindu) and culture. But the benefits exist - older people can benefit from reduced levels of loneliness and isolation and increased levels of civic participation, while younger generations can also gain in similar ways and through the learning of new skills and experiences.

In the living lab example presented, the social innovation lies in tackling three issues simultaneously: (1) Creating an intergenerational centre for sharing of knowledge and well-being; (2) Active ageing to enrich the quality of life for the elders; and (3) Sustainable design to lower the footprint of the building and at the same time provide an educational tool to highlight a sustainable lifestyle. The living lab itself benefits from stakeholder consultation and it is planned to do further community profiling to determine potential users.

The architectural design is a creation taking traditional ideas interwoven with more contemporary ones. The application of the modular approach is key to the design as it allows flexibility for the different age groups and their interests, while at the same time does not neglect the needs of the elderly and the potential for active ageing. With further opportunity spaces for interaction (like the urban garden and activity rooms for cooking and dancing) the intergenerational aspects can be tested to see which ones work best. The use of passive strategies like ventilation and natural light provide a degree of comfort and sustainable living, and the overall design further imbues character to the place and a sense of belonging to the users.

To develop the living lab there still remains further exploration of ideas to be completed:

- More community outreach to assess the needs of the non-elderly users – the original idea was that the centre could be used for elderly and very young i.e. toddlers so that it becomes a one-stop shop for families to leave their dependents there during the working day. Surveys need to be done for parents and youths (18 - 24) who may want to drop by the centre to enrol on courses to learn skills from the elderly.
- The modular design needs to be refined to allow interchangeability of units for different purposes. At this stage, the operators of the centre will need to be consulted on the types of service offerings and the fixtures needed to deliver them so that the units can be designed accordingly.
- The active ageing element provides an opportunity to try out new assistive technologies that can help elders still maintain a level of mental and physical ability to be able to socialise and contribute. Further research needs to be done on what types of technologies are available, particularly leveraging on ICT and smart building and personal technologies.
- The sustainability aspects can be further developed. Life cycle costing can be carried out to establish the economic benefits as well as the environmental benefits for each measure. There are other innovative applications that can be incorporated like water recycling and zero waste.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

5. CONCLUSION

Social innovation is the commercial application of ideas and technology towards improving societies. Linking social innovation with a living lab allows the idea to be taken to a live demonstrable example which can be replicated to achieve greater impact. An example of this is how to provide for ageing populations. Use of an intergenerational approach could be a social innovation, coupled with active ageing carried out in a sustainable built environment. A case study is used to demonstrate this effect. Further research, in particular on user needs, is recommended.

APPENDIX

Ritualized Place and Community Empower

Wasana DE SILVA[a]

[a] *University of Moratuwa, Sri Lanka, wasanade@yahoo.com*

ABSTRACT

Traditional cities and settlements in Sri Lanka, are dynamically re-enacted through regular performances and rituals. People, place, rituals, landscape and architecture are inter-connected in these processes making harmonized relationships between built elements, architecture and nature, in contrast to many contemporary developments. The research questions how people understand these places, through these performances and communal engagement and reflect harmonized relationships between people, landscape and architecture. This paper examines the notion of sustainable built environment from phenomenological point of view. Kandy city is described within this performative phenomenon in order to understand the sustainable nature of the place. Phenomenology is the research methodology. A theoretical framework, synthesizing key concepts of place, sense of place, dwelling, *chora*, becoming, non-representational landscape theory and performance theory and body theories, is developed and utilized to examine performance of the Asala perahera ritual process in Kandy city. In these ritual performances people form unique relationships with the immediate and wider landscape by means of walking, dancing, parading, connecting natural elements, topographical locations and historical places with the city. Communal engagement and ritual behaviour are highlighted and re-enacted in these place making processes. Case study analysis illustrates that, Asala perahera marks geometrical patterns, in the landscape inter-weaving different locations, rituals, people and the invisible dimensions of the place which reflect in the place, landscape and architecture as emerging patterns. Ritual behaviour establishes embodied relationships and specific state of mind-body condition in the space and time, true sustainable understanding of the place, significant with specific behavioural approaches throughout the process in natural-cultural setting and body performances.

Keywords: ritual behaviour, performing place, Asala perahera

1. INTRODUCTION

1.1 Asala perahera and spirituality of the place

This paper examines the notion of ‘sustainability’ from phenomenological point of view. The study examines the Asala perahera performing in traditional cities and settlements in Sri Lanka, where these places are dynamically re-enacted through regular performances and rituals. These ritual ceremonies are happening within the similar time period of the year in all traditional settlements with the participation of large number of people actively, in some places and some events more than two hundred thousand people. The most significant in these ritual ceremonies are people do not recognize any speciality or extra ordinary of these events; people experience these rituals as part of their life and daily routine. Despite contemporary social, economic trends highlight the tourist attraction of these festivals, through social media, emphasizing the dramatic beauty of the performance, the main concern of temple priests, is to perform these rituals as original as it was happening during the past days, experiencing spirituality of the place and ritual performances. Hence, do these ritual performances reflect the essential nature of the humans, associated with culture and nature of the place where they occupied; as a process of place making related to human nature and ontology?

1.2 Research aim and methodology: traditional vs. contemporary

People, place, rituals, landscape and architecture are inter-connected in these traditional processes making harmonized relationships between built elements, architecture and nature, in contrast to many contemporary developments (De Silva,2014). The research questions how people understand these places, through these performances and communal engagement and reflect harmonized relationships between people, landscape and architecture; whether this ritualistic communal behaviour could be utilized to explain sustainable approaches: more in-depth versions of sustainability of the place and cities and settlements. Although Kandy city is under world heritage list, many contemporary developments are a question, whether these forms, styles and tectonics are fitting to the historical and natural context of the Kandy, to the mountainous landscape and to the spirit of the place; how

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

far these could be explained as sustainable with the landscape, social, cultural, religious context . Among the new developments, new life patterns, and new values how do people understand the value of these traditional rituals? The large number of people, who are not tourists, gathered as participant observers is an evidence of recognizing the human sense and continuing meaning of these performances for their contemporary life. How do these historical ritual performances decide human nature and the place? Can these be a mechanism to understand the notions of 'sustainability' and 'authenticity' of the place in contemporary city developments? Therefore, it is realistic to examine the notion of sustainable built environment from phenomenological point of view. The research aims to investigate the role of body and performances of communal engagement of these rituals, among the relationships of people, ritual performances, place and architecture and landscape, employing case study Kandy and Asala perahera ritual performance. It questions how people experience the place; what relationships are developed between groups of people in these performances. How do these performances 'establish' specific phenomenological situation in the space-time-body framework? How do 'bodies' of communal group engage, empowering the place? Phenomenology is the research methodology. A theoretical framework, synthesizing key concepts of place, sense of place, dwelling, chora, becoming, non-representational landscape theory and performance theory and body theories, will address these questions.

2. SUSTAINABLITY AND AUTHENTICITY OF THE PLACE

2.1 New trends

The modern concept of sustainable development urged from Brundtland report (1987), advancing some earlier concepts around 'forest management'. Today, 'sustainability' evokes vital forum all around the world encouraging research fields, policy making, International and national conferences, forums, academic curriculum, and recognizing different approaches for sustainability. In the built environment it flourishes many pathways with the adjective of 'sustainable' - green architecture, green buildings, sustainable cities, sustainable materials, sustainable construction, sustainable tourism, waste management, sustainable energy consumption, eco tourism, are some of these. Some words and approaches are stylish such as; minimalism, green concepts, adjective of 'eco' describing many nouns, reflecting modern trend of commercialize approaches. However, all these modern trends arise to achieve one goal of sustainability, directly or in directly focusing on natural environment, climate, and human well-being. However, it is true that all around the world these kinds of concepts were not useful and meaningless before 20th century. Traditional settlements reflect multifaceted sustainable approaches to live with nature in harmony, because the life attitudes and nature of understanding the place differ from modern concepts (Borgmann,1987). Sustainable developments as a process is identified and methods, approaches and assessments are developing in many research areas. However, in-depth understanding of 'sustainability' is still unclear, ambiguous, gaps, and incomplete.

2.2 Sustainable place and authenticity

The 'process' described by Brundtland, implied direction and orientation of human needs and aspirations. Miller (2013) defines as 'procedural sustainability', an understanding of sustainability as a process for identifying important societal values and pathways for a desirable future. Dynamic properties of sustainability (Leach et.al) are described as stability, durability, resilience and robustness which could be further described as the properties of material culture. The pathways approach describe STEPS (social, technological and environmental pathways to sustainability) – Leach, where this orientation and direction could be happened in order to achieve material culture. However, processes and approaches are still ambiguous in nature. Although place concepts are identified, case studies which fulfil all the parameters are less regarded. In this context, the notion of 'place' in phenomenology of architecture, is a useful concept to describe the harmonize relationship between buildings, people and the context; dealing with human experience of the place. In this view, authenticity of the place(Relph,1976 is described as how place flourish with people and from their needs, how people attached to the place and experience 'sense of place' as the essential nature of dwelling (Heidegger, 1962). Placelessness is where people detached from the context, where place is the result of outside agents and aspirations which could be described as a threat to the authenticity of the place, largely reflect on many new developments. Norberg-Schulz(1980) describes how place responds to the natural landscape and the spirit of the locality as a process of dwelling. Place has a direction and dynamic nature, therefore, more useful in describing sustainable approaches to understand the in-depth orientation of material culture.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. SUSTAINABILITY AND PERFORMING PLACE

3.1 Performing place

Performance approaches (De Silva, 2014) are more useful to describe dynamics of the place and process to understand the orientation, which leads to the sustainability; performing place is developed to describe the process of sense of place and dwelling, how place emerge and re-emerge with people and their activities, by employing actor network theory (ANT), performance theories and advancing ideas on performance approaches in landscape research. ANT describes that people by acting and walking make a network of relationships around them, which produce place and space (Lefebvre, 1991); landscape which represent the material environment as more than representative, as lived practice in terms of relational views, actions and processes (Lorimer,2005). Therefore, performing place which represents dynamics of the place is an interesting approach to understand 'sustainable nature' of the place and material culture of cities, settlements and landscape of people within the changing attitudes of people and the place: a phenomenological approach.

The embodied place is evident in sense of place, dwelling and performing place in experiencing the place, architecture and landscape. Surrounding as an extended body; as a lived body; as worldhood understanding and perception of the world (Merleau-Ponty) describe how body reveal the place in acting and performing in surrounding place and landscape. Recent Neuro-scientific research is focusing on finding the gaps between the body and the surrounding reveals how people experience around them as extension of their bodies . All these describe establishing specific space-time-body framework in dwelling and performing place.

3.2 Ritual behaviour

Performing life and celebrating place is common in traditional and primitive cultures, identical with ritual behavior which is characterized by seasonal journeys, walking, ceremonial parades, celebrating places, events and natural landscape features and the making of cultural theatre. According to neuro-scientific explanations, a kind of sharing of sensitivity and understanding happens between people through such rituals. It is also described that emerging place is not always visual; it can also be mythical. It could be involved in making temporary/ permanent structures (built elements/ architecture), making mythical stories about landscape features, singing and playing sounds, dancing/ body gesture, decorating, drawing pictures and images, crafting (varies from farming lands to arts and crafts), and narrating stories: multifaceted nature. According to Eliade(1961) ritual bebaviour is identical and revealing inside, center and divine/ spiritual experience within mundane performances, which reveals the orientation of the place towards spirituality. All discussed above theoretically prove that ritual behavior involving with producing space and place, identical with acting and making network of relationships, embodied place, and sharing bodily experiences strengthen the place and place attachment among group of people, attached with invisible dimensions, chora of the place. Following section illustrates and examines how it practically happens by employing case study Kandy and Asala perahera ritual performance in Sri Lanka; how these traditional notions of place understanding could be utilized to understand the sustainability of these places.

4. CITY AS A PERFORMATIVE PLACE

The cultural, religious, social aspects of Asala perahera ritual performance has been studied from various perspectives (Seneviratne, 1978; Seneviratna, 2009). How city is re-enacted and re-experienced through a process of place making, by employing performance approaches of Asala perahera is explained more in-depth place attachments associated with performing, and dwelling (De Silva,2014). Kandy is the last kingdom of Sri Lanka has been taken under the British power in 1815AD and city and city life has been exposed to major changes hereinafter. However, it is recognized by temple priests that rituals in Kandy including Asala perahera still continue without any major changes in the changing face of social, cultural, political history and even today in the contemporary globalization. It is an evidence of how place understanding still continues within the pure domain of phenomenology of the place and architecture, clues of more in-depth sustainable approaches to the place. Asala perahera in Kandy is performed annually making celebrative atmosphere in the city and other villages during July/ August and ended on a full moon day. Sounds of traditional drum beats, dynamic movement of dancers, elephants wearing traditional cloths in the parade are common happenings in the city, making vibrating atmosphere. In Kandy the beginning of the festivals are declared by planting kapa ritual performance held at four temples; temple of god Natha, temple of god Vishnu, temple of god Kataragama and temple of goddess Pattini, the locations of these

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

temples are same as it was in 1815 A.D. It is noted that although origins of these temple deities are Hindu, in Kandy appears in Buddhist context and interpretations, thus boundaries between religions are unclear, as an evidence of phenomenological place notions. After planting Kapa ritual process, inner parade is performed around these temples for five continuous days; temple priests, flag bearers, drummers and temple assistants participate in this event. Thereafter outer parade known as Kumbal perahera a long processions of people of different villages belong to four temples; dancers, pipers, drum beaters, elephants, traditional administrative heads and temple priests parade along the streets of old city for ten continuous days. Each day parade becomes much longer and much glamorous and in the fifth day temple of the tooth relic also participates in the parade. The final night parade is more elegant, and performed until midnight of the full moon night, then followed by 'diya kapeema' parade which connects city to the river; where the place where this ritual happens is related to several mythical and historical stories. The following day afternoon, the parade revisits the city, at an auspicious time: rejuvenating the place (Figure1). The most important in these ritual performances are active participation of large number of people, who are not traditional or belong to the period before 1815 A.D., they belong to the today's context. How they participate in these events and method of performing involved illustrate that walking barefoot across the landscape marking network of relationships with temples, specific places, with villages, with people, landscape features, city and the river as common and significant, re-producing the place. The common methods of performing are; walking, dancing, playing music, clockwise movement/ circumbulation and repeating the events. The marking of centers and insides/ enclosed domains are significant aspects in these performances where spiritual experience is significant in all these performative processes, revealing the invisible dimensions of the place. These performances and network of relationships are reflecting on art and architecture, natural landscape and with the city and social/cultural/religious place of the Kandyan kingdom. It is explained that city is emerged as an 'inside' within the triangular shaped valley enclosed by mountains (De Silva,2014), re-enacting the city through network of relationships of ritualistic communal engagements, reflecting upon social/cultural/religious aspects of the place and physical dimensions of the place in material culture.

H – Hindu kovil

Figure 1: Revisit the city

5. RITUALIZED PLACE AND COMMUNAL EMPOWER

How repeating events of ritual behavior ritualized the place and establishing communal power of the place is evident in these performing processes.

5.1 Embodied place and communal empower

It is observed in Asala perahera the significance of body performance and methods of performance taking central role with the dynamic movement of the parade. There are a number of actions, which takes simultaneously while concentrating on the actions, such as listening, jumping high above, circling around the body, and performing and dancing according to the rhythm of hewisi, as lived practice of producing place are common and communal engagement is highlighted. According to historical documental evidences, Asala perahera is a more than cultural display and highlight body abilities and body performances, is an important clue about communal engagement and sustainable understanding of the place through these performances. Very small children , five and six years of age take part in fire ball circling/ rotating and dancing , displaying the importance of the body in making and sensing the place and space, establish the human nature of place understanding. It is evident that inter-related network develops between the body and with the other bodies, performances, with the action, space, city and landscape producing new space and place as discussed in earlier sections.

It is evident that people experience embodied relationships between the body and the surrounding, a worldhood experience – body, action and surrounding as one spatial extension (see Table 1). In these ritual behaviors all people are engaged in the same repetitive actions of walking, dancing, playing, drumming, singing, rhyming and other activities. According to neuro-scientific explanations, a kind of sharing of sensitivity and understanding happens between bodies of people as one communal body in space, embodied in the performing place. Also the repetitive nature of these body performances strengthens the sense of place and attachment to the place, art and architecture, bounded by social/ cultural/ religious norms as important notions in sustainable approaches and authenticity of the place discussed in earlier sections.

Behavior and attitudes of performers	All of them are non-alcoholic and vegetarian during the entire ceremonial period.
Relationships between performers and perahera	Perahera performance becomes the first priority among all other commitments. People take leave from their jobs, who involve in self business temporary suspend for this period.
Their feelings about performance	They are in a great feeling of present themselves in the perahera, wherever they are, feeling of they are as part of the performance.
Feeling of body and performance	Tireless feeling of their walk and performance Feel free and less weight of the body Never fall ill during the participation period.

Table 1: Performers experiences and attitudes

5.2 Sustainability of the place

Performing Asala perahera and its experiences vibrates between myth and reality, between historical/ mythical events, stories of the place, divine experience and through direct relationship of the body with the landscape experience such as walking barefoot, sensing topography, wind and rain and bathing in river. These ritual performances are socially organized and culturally transmitted; flourishing among natural landscape, shaping the place and architecture. Ritual performance re-enact the place and strengthen the place attachment empowering the place and community. Therefore, communal empower in ritualistic behavior of Kandy city highlights the notions of sustainability of the place, its processes and manifestation of the place through performing place, experiencing invisible dimensions of the place, chora. As these places are a result of people and community engagement with direct experience of the landscape implies from inner orientation of the place, more in-depth understanding of the places, provide evidences of orientation of the sustainability of the place which is deeply rooted in the place significant with spiritual experiences.

6. CONCLUSION

The current trend 'sustainable built environment' focuses on natural environment, climate and human well-being: humans to be in harmony with nature. The methods, approaches and assessments are developing in many research areas, around the globe, focusing on the material culture, the end product. The sustainable developments as a 'process' describes direction and orientation of human needs and aspirations, while pathway approach describes where this orientation and direction could be happened in order to achieve sustainability in built environment, however, still unclear. This research proposed the phenomenology and 'performing place' concept to understand the orientation towards sustainability, utilizing performance of Asala perahera ritual festival still continues in its traditional form in Kandy. Theoretical discussions reviewed that ritual behaviour involving with producing space and place, identical with acting and making network of relationships, embodied place, and sharing bodily experience strengthened the place and place attachment among group of people, attached with invisible dimensions, chora of the place. Further, this is proved by case study and observed that even in contemporary globalization of the world, Asala perahera in Kandy continues without any major changes and people experience the value of these performances and authenticity of the place and place attachment. The repeated events of ritualistic behaviour and communal engagement ritualize the place, empowering the place and people, highlight notions of sustainability of the place. The orientation of the sustainability of these traditional places is deeply rooted with community empower of ritual behaviour and with the place and significant with spiritual experience.

ABSTRACT

Providing housing for about one third of the territory's population, the Hong Kong Housing Authority (HKHA) has committed to continuously improving the environmental standards in providing public housing and related services. With our wide spectrum of services from design, construction, to management and maintenance of our estates, apart from the endeavour of our own staff, we have empowered our stakeholders to join hand with us to promote healthy living and a green environment in our housing estates.

In the planning and design stage, we have been collaborating with the construction industry, material suppliers, and academia to research and develop environment-friendly design, green building products and construction technology. The micro-climate studies, w-trap drainage system, twin-water tank system, LED bulk-head, were some of the examples. On the other hand, we have also encouraged our staff to take initiative to innovatively develop the most suitable provisions for our stakeholders, such as the Zero Irrigation System for water saving, acoustic window or balcony to mitigate noise pollution, a two-level lighting system to reduce energy use; as well as the Carbon Emission Estimation, and energy estimation to ensure low carbon footprint design.

We also empower our tenants to help upkeep the green environment. We organised the "Let's Join Hands to Reduce Waste", Source Separation of Domestic Waste Programme, tree planting days, and developed community gardens. Since 2005, we have been partnering with Green Groups for a community environmental education programme to raise environmental awareness among public rental housing residents and to instil a culture of environmental concern.

We believe that habit change is instrumental in achieving a green living environment, and empowering the community to work in synergy is the key to its success.

Keywords: green management, stakeholder empowerment, Hong Kong Housing Authority experience

1. INTRODUCTION

The Hong Kong Housing Authority (HKHA) is responsible for producing and managing one of the world's largest public rental housing programme, helping low-income families gain access to adequate and affordable housing. Our public housing programme has been successful in providing homes for over two million people and it has been well recognized as one of the solid foundations upon which the prosperity of Hong Kong is built.

We are committed to continuously enhancing the environmental standards in providing public housing and related facilities. With our wide spectrum of services from design, construction, to management and maintenance of our estates, apart from the endeavour of our own staff, we have empowered our stakeholders to join hand with us to promote healthy living and green environment in our housing estates.

Throughout these years, we have been actively engaging our residents and the community-at-large, as well as our many stakeholders and our own staff, to join hands together in supporting, executing and underpinning the work of the Housing Authority. The result provides vivid evidence of the tremendous benefit of empowering the stakeholders in providing sustainable public housing. In this paper, we will illustrate with examples to show what we have achieved in empowering our stakeholders to provide a green and sustainable public housing programme.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2. EMPOWERING THE INDUSTRY

Starting from year 2000, we have the leverage to partner with our stakeholders in the construction industry, including the contractors, material suppliers, academia and regulators through regular meetings, participation in local/ regional/ international seminars, exhibitions, journals and conferences, to undertake research and development. These activities and discussions drive the industry to think for innovations towards greener, safer, more efficient and sustainable construction operations and system. With their support, we have been driving innovations in the use of green materials, design and site management tools, and construction systems. All these enhancements have reaped a bountiful harvest in delivering quality and sustainable housing.

2.1 Micro-climate studies

Starting from year 2004, the HKHA has been applying micro-climate studies to facilitate designers in passive design from the planning and design of all new projects in order to provide comfortable living environment in sub-tropical climate. We enhance the design, orientation and disposition of the building blocks through the optimal use of natural resources such as local wind breezes, natural ventilation, daylight and solar heat gain, by applying proven scientific technologies including computational fluid dynamics analysis, wind tunnel tests, daylight simulation tools etc. Apart from using the computational simulation tools at design stage, we also carry out verification studies to validate the results of our studies; these include model calibration and on-site measurement at the construction and post-occupation stages, applying to both outdoor and indoor public spaces for both winter and summer seasons. For major estates planned and designed after July 2006, we conduct air ventilation assessment to compare the environmental performance of different design options and select the optimal planning and design solution as required by Planning Department.

2.2 W-trap drainage system

The outbreak of SARS in March 2003 aroused public concern over the problem of dried up floor traps in the drainage system. Public health will be jeopardized due to the possible transmission of virus through these short circuits in the bathrooms/ kitchens from contaminated soil and waste stacks. HKHA in collaboration with City University of Hong Kong conducted the study on the use of Common U-traps in the drainage system in 2004. After vigorous research and laboratory tests verifying the operational stability and mock-up installation, we finally came up with the innovative Common W-trap system.

2.3 Twin tank system

Water supply interruption during tank cleansing once every 3 – 6 months often causes inconvenience to residents. Residents may need to store fresh water for temporary use or use fresh water to flush toilets during those periods. There is also considerable wastage when water remained in the tanks has to be drained away for tank cleansing. A solution was in place with the introduction of the innovative "twin tanks system" to all new public housing projects since 2008. Originated by HKHA, the system not only allows continuous water supply to residents during regular tank cleansing, but also facilitates maintainability and helps conserve the environment by saving water.

2.4 LED bulk-head

To further enhance the energy efficiency in lighting, we have tried some types of LED bulkhead lightings in the corridors of typical domestic floors since 2011 and have implemented a large scale of trial installation at the corridors, staircases and lift lobbies of a domestic block in Kai Tak Site 1A project in 2013. The performance of LED bulkhead lightings in these trial installations has been satisfactory.

3. EMPOWERING OUR STAFF

One of the most precious resources in the Housing Authority is our dedicated staff. We empower them to take initiatives in developing innovative ideas to serve the community. We encourage them by means of incentive schemes, awards, and provide necessary resources to assist them. In the aspect of providing sustainable housing, the followings are some examples:

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.1 Rainwater harvesting/ Root zone irrigation/ Zero irrigation system

As early as 2008, HKHA had started exploring means to harvest rainwater for irrigation to help reduce water consumption. Two pilot Rainwater Harvesting Systems (RWHS) in Eastern Harbour Crossing Site Phase 5 and Lower Ngau Tau Kok Estate Phase 1 were put into use in July 2011 and March 2012 respectively.

A root zone irrigation system has also been tried out in Kai Ching Estate with polyethylene dripping tubes wrapped with specially designed fleece to form the Root Zone Irrigation Mat installed about 100mm below soil surface. The irrigation system achieved water saving of 38% while maintaining healthy plant growth.

HKHA further devises Zero Irrigation System "ZIS" to achieve 'zero irrigation'. ZIS is a sub-irrigation system comprising a wicking mechanism which is a self-sustained and passive design to deliver storm water stored in sub-soil retention box to the vegetation and minimize topsoil evaporation through capillary action. The system is found more efficient in water conservation and less mechanical part for maintenance when compared with RWHS. Refer to Figure 1 and 2.

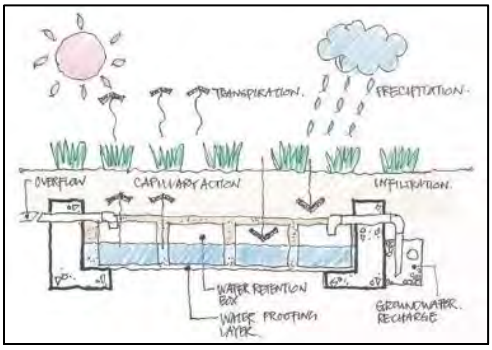

Figure 1: Illustration of ZIS

Figure 2: Construction of ZIS at trial planter

3.2 Acoustic window and acoustic balcony

Hong Kong is renowned for its high density living environment. With limited land sources, residential developments, including public housing developments, may usually be located in close proximity to heavily trafficked roads or other noise sources. To tackle the most severe noise challenge without compromising the performance of natural ventilation for the flats, HKHA has come up with the innovative acoustic windows (refer to Figure 3) and acoustic balcony design for shielding noise impact. These innovative designs could secure comfortable environment whilst maintaining the valuable natural ventilation at the living areas.

In 2015, we developed the second generation of Acoustic Balcony which amalgamates the acoustic window concept with slide screen in front of the balcony door, acoustic window plus subsisting features like sound absorptive material at the wall and ceiling of the balcony and inclined projecting panel from the parapet, all to be determined on a site-specific basis (refer to Figure 4).

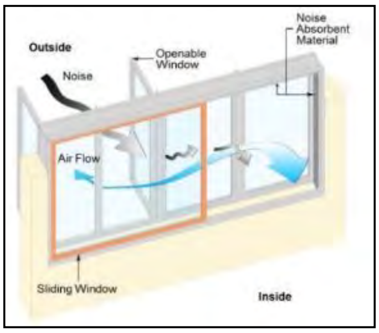

Figure 3: Configuration of acoustic window

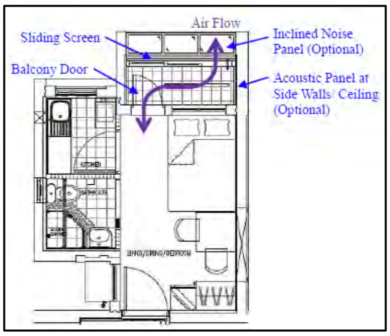

Figure 4: Layout of enhanced acoustic balcony

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.3 Precasting and prefabrication

As early as 1980s, HKHA has already been pioneering the use of precasting techniques in construction of its domestic blocks using precast facades, staircases, tie beams, refuse chutes, semi-precast slabs etc. to enhance site safety, built quality, save timber, reduce CO_2 emission and sustainability. After nearly two decades of application, we develop the Enhanced Precast and Prefabrication System in 2008. One major breakthrough achieved is the development of large scale volumetric precast components, which signifies a great advancement from planar to volumetric precasting. The invaluable precasting knowledge and experience gained in public housing developments will continue to be a prime mover for sustainable construction in the industry and will certainly contribute to the quality, saving of labour on site and sustainability of public housing developments hence better living environment for the public.

3.4 Two-level lighting system

To strike a balance between energy conservation and adequate illumination meeting the need of users at large, we adopt a 2-level lighting control system for public area of domestic buildings with illumination level maintained normally at 50 lux at lift lobbies and 30 lux at corridors and staircases around the clock, while the illumination level can be elevated to 85 lux, zone by zone, for a pre-set period of time once triggered by users on a need basis. With this control system, the energy consumption of the lighting installation can be saved by approximately 30%. This design approach is considered practicable, cost effective and environmental friendly.

3.5 Recycling and re-use marine mud

Marine mud is a stiff, moist, dark brownish grey, slightly sandy silt or clay, containing occasional small shell fragments. They have little engineering value due to its low strength and high compressibility but the disposal of large volumes of marine mud in landfill sites or marine dumping facilities is costly, time consuming and most important of all, burdensome to the natural environment. Our Structural Engineers have developed an innovative and inexpensive engineering method to re-cycle the materials, through mixing with a certain proportion of cement and granular materials, to strengthen, stiffen, and stabilise the mud. The cement-stabilised marine mud can be used for backfilling as well as turning them into eco-paver blocks.

3.6 Carbon emission estimation

Since February 2011, HKHA have conducted Carbon Emission Estimations (CEE) for all domestic blocks of new public housing developments. We have developed a user-friendly CEE methodology to holistically evaluate the carbon emission of our new public housing developments throughout the building life cycle. The CEE model consists of six aspects, namely (i) materials consumed during construction, (ii) materials for building structure, (iii) communal building services installations, (iv) renewable energy, (v) trees planting, and (vi) demolition. This provides an effective design verification tool for us to gauge the overall performance of a public housing development in terms of carbon emission throughout the life cycle of the buildings. We have achieved an estimated reduction in carbon emission of around 980,000 tonnes for the whole life cycle of these domestic blocks, representing an average of 13% reduction as compared with the baseline figure of New Harmony 1 block in terms of CFA.

3.7 Building information modelling (BIM)

In the past decade, we have devoted ourselves to integrating the use of Building Information Modelling (BIM) to enhance design efficiency, improve environmental performance, and advance the quality and safety of our built environment for the entire life cycle. With the concerted effort by staff at all levels, we have successfully integrated BIM at all stages of our work, including:

- Feasibility and planning stage – Integration of BIM and geographic information system (GIS) to facilitate a variety of studies, including visual impact assessments, ridge line, vantage point and shadow analyses as well as site appraisal studies.
- Scheme design stage - Use of BIM for site specific design and value management
- Detail design stage - Integrated use of BIM and environmental analysis software to achieve energy saving (refer to Figure 5 and Figure 6).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Construction stage - Use of BIM for site safety and construction planning.
- Post completion stage - Use of BIM for facilities and asset management.

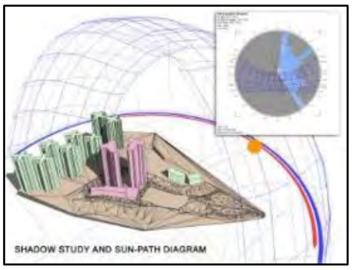

Figure 5: Daylight analysis for site specific block design

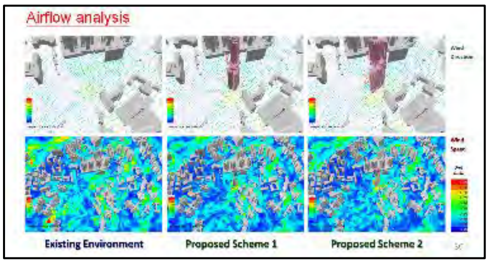

Figure 6: Testing of new software for airflow analysis

4. EMPOWERING OUR HOUSING TENANTS

Apart from the construction partners and our delegated staff, housing tenants are another important stakeholder of the Housing Authority. After all, they are the end-users to enjoy the green living we provide. We empower them to upkeep the premises and make themselves their own master in building a healthy and happy life in the estates. To achieve this, we partner with the tenants' association, the Estate Management Advisory Committee (EMAC), as well as local Non-governmental Organisations (NGO), schools, to organise green activities engaging estate tenants.

4.1 Green delight in estates

Since 2005, we have been partnering with green groups for the "Green Delight in Estates" (GDE) programme, which aims to raise environmental awareness among Public Rental Housing residents and to instill a culture of protecting and improving the environment.

There are also in-depth educational and promotional programmes for about 30 selected PRH estates each year which focused on special themes and activities, such as green living carnival, green living quiz competition, flower bed design competitions, waste reduction and recycling, waste separation at source, etc. The in-depth programmes have eventually covered all existing PRH estates and we have trained up over 15,000 green ambassadors who are volunteers within the estates to spread environmental messages to other tenants.

Various activities have been well received by the estate tenants, Estate Management Advisory Committees, local schools and Non-Governmental Organisations and the programme has raised the environmental awareness of the tenants and improved on their environmental habits.

4.2 Waste separation and recovery

Since 2005, HKHA have been actively implementing a number of waste management programmes across our PRH estates, including the Source Separation of Domestic Waste Programme. To facilitate our collection of recyclables, collection points have been established in all PRH estates. Tenants are encouraged to bring recyclables to the collection points in exchange for cash or daily household items.

4.3 **"Let's Join Hands to Reduce Waste in Our Estates"** campaign

From July to December 2014, we launched a campaign "Let's Join Hands to Reduce Waste in Our Estates" in all PRH estates. A series of activities engaging our tenants were arranged to encourage reduction of municipal solid waste. We have also engaged Non-governmental Organisations (NGOs) and other government departments in organising environmental activities. For instance, we sponsored the venues for the Waste Reduction Campaign held at Domain, our biggest shopping centre, in September 2014 to line-up tenants of restaurants and supermarkets to adopt food waste reduction and management practices. With all these activities and campaigns, our residents generate 30% less domestic waste than HK average (refer to Figure 7).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

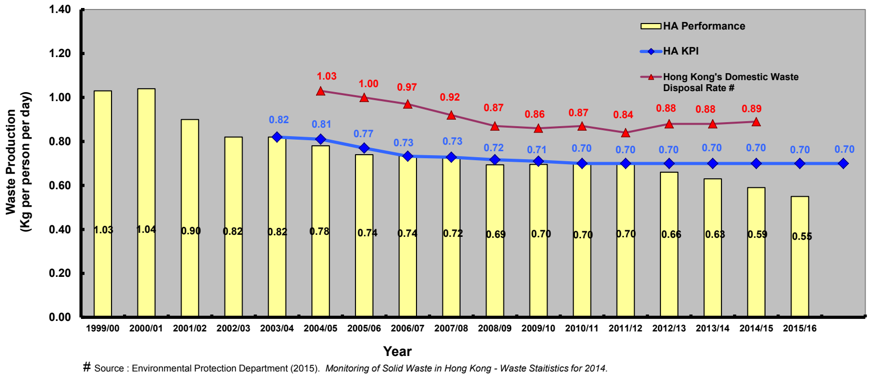

Figure 7: Average domestic waste production

5. CONCLUDING REMARKS

The roles and functions of Housing Authority are unique in many aspects which spread from design, construction, maintenance and management. To provide sustainable housing that can be enjoyed by about two million people, environmental awareness and habit change of our stakeholders are instrumental in achieving a green living environment. With engagement of the residents in the planning and design of our estates, the Customer Satisfaction Index for our newly occupied projects is continuously on the rising trend, reaching 95% in 2014/15 (refer to Figure 8). We cannot work alone as the effect will be limited; we believe that empowering the community to work in synergy with us is the key to its success.

Figure 8: Customer satisfaction index

CoLLaboratoire Montreal: Living Experiments for Climate Change Awareness

Carmela CUCUZZELLA[a]

[a] *Design and Computation Arts, Concordia University, University Research Chair IDEASBE, L.E.A.P, Canada, carmela.cucuzzella@concordia.ca*

ABSTRACT

This paper introduces a new research initiative called CoLLaboratoire, a community embedded project with the goal of realizing a series of art-architecture installations that communicate some critical theme of sustainable living in the city. This project links together academics, students, community, and business leaders to address sustainability challenges together. It therefore serves as a medium for transdisciplinary scientific research requiring citizen-engagement while also creating a measurable impact with regards to sustainable living.

The goal of this initiative is to stimulate Montreal's collective intelligence by recovering memories of place and environment while serving as a model project of a sustainable city. CoLLaboratoire has adopted the urban corridor of Sherbrooke Street, a street that runs 31km from east to west in the city of Montreal, Canada. This research project has been adopted as an organizing principle for these urban installations, where each public art piece will have its own story. The resulting narrative from the collection of installations along the length of Sherbrooke Street will be at once, educational, interactive and experiential. The intent is to foster public awareness of natural systems and resilient urban infrastructures through community engagement, both during the design process and during the use of the public artwork after it has been installed. This may have the benefit of invigorating life in the city while addressing pressing problems of today. By using one of the city's main east-west axis we can disseminate the idea of context-specific sustainable living throughout the various communities.

In this paper, we will present our first design challenge/experiment in Montreal, in terms of its process, its outcome and our analysis. This project's main research questions are: What type of art-based installations can help heighten community awareness to issues, questions, or solutions regarding climate change? How can participation in the design of these art installations contribute to a deeper understanding and embodiment of sustainable practices for participants in the long term?

Keywords: sustainable neighbourhood, design process, community empowerment

1. INTRODUCTION

CoLLaboratoire is a research-creation initiative, which started on September 2014, in Montreal, Canada. The aim of this project is to better understand how the collaborative design of public art-architecture installations can contribute to a critique, deeper understanding and/or embodiment of sustainable urban, professional, community, and even human practices in the long term. It focuses on the design of art-architecture for public spaces as a practice in which the resulting representation and narrative can contribute to todays' imperative questions by pushing its disciplinary boundaries.

Through design experimentation, citizen engagement, and the construction of working prototypes installed in Montreal, these designs are intended to lead to scalable and measurable environmental benefits, such as green energy and food production, water conservation, greater community involvement, etc. It is a project under the auspices of the Concordia University Research Chair Integrated Design, Ecology, and Sustainability for the Built Environment (IDEAS-BE), of which I am chair. This research project is also directly related to the worldwide initiative called Future Earth. Future Earth is a global platform for sustainability research serving as a vehicle for communicating knowledge between sustainability sciences, business leaders, policy makers, and community leaders. The location of the United Nations Future Earth global secretariat is in Montreal. Montreal, a UNESCO city of Design, with its hybridity of cultures, languages, urban dynamism, and its leading place in the history of sustainability, is a fertile place for such an experiment in sustainable living.

Through this initiative we are planning, designing, and building public space urban installations with the intent of heightening climate change awareness, while also building capacity in citizenry to address issues together. The aim is to successfully make connections between academics, community members, artists, designers, architects, professionals, and business leaders, etc., in order to better address sustainability challenges. This research project has the inherent benefit of communicating the research directly to the community involved, and therefore also acts as an outreach project.

All installations are context sensitive, taking into consideration the concerns of the community in which they are intended. CoLLaboratoire has adopted the urban corridor of Sherbrooke Street, which runs 31km east to west across the city of Montreal in Canada as an organizing principle for all urban interventions and/or installations. This iconic Montreal street runs from the Parc Delphis Delorme and Paroisse Marie-Goretti nature area in the east to just west of Concordia University's Loyola Campus in Montreal Ouest. Along this corridor we will identify roughly 12 sites or hubs for artistic-architectural installations and interventions. The resulting narrative from the collection of these designs along Sherbrooke Street will be at once, educational, interactive and experiential.

One of the main goals for CoLLaboratoire is to stimulate Montreal's collective intelligence by recovering memories of place and environment and to serve as a model project of a sustainable city. These interventions serve as elements of a path to a sustainable, resilient future. In addition to the creation of site-specific interventions, we expect the broader societal impacts of this project to include greater networks for mobilization at the community level, better public understanding of solar energy, concept development for potential product commercialization and toolkits for effective participatory design.

The research questions that are at the core of this research project are: What type of art-based installations can help heighten community awareness to issues, questions, or solutions to climate change? How can the inclusion of the community in which the installation is embedded contribute to a deeper understanding and embodiment of sustainable practices for the long term? Specific installation sites are constantly investigated based on their historical importance, natural features, availability, and future possibilities. The site for our first design challenge was Concordia University's Loyola campus, which sits on the far west end of Montreal. We selected this site because we wanted the community of students, especially at Concordia to be deeply involved in our inaugural design challenge.

This paper is organized into three main sections. We will first introduce the historical context and theoretical canvas for CoLLaboratoire. Here we consider the transdisciplinary approach of designing art-architecture for the public realm. We will then present the details of our first design challenge on the Concordia Loyola campus, in terms of the process we adopted, the projects resulting from the design challenge, and our analysis. We conclude with insights on this first experiment and suggest a variety of ways forward.

2. THEORETICAL BASIS OF RESEARCH PROJECT

Although the scientific discovery of climate change began early in the 19th century when changes in the climate were first suspected, these ideas were met with disbelief at the time. It was becoming known only in the late 1950s and early 1960s that questions of human emissions were causing not only environmental degradation but were also disrupting climates around the world. It was at this time that radical designers entered the conversation of environmental degradation.

Since the 1960s designers have been ardently working towards addressing the complexity of the pressing questions of their time. The discourses related to environmental design started at this time, and have shifted since. In the 1960s, the drive towards holistic approaches of public and individual human settlements gave rise to the idea of environmental design, as a mean to transcend the boundaries between various design disciplines: architecture, landscape, urban and product design. This first “environmentalism” culminated, amongst other manifestations, in the formation of the *Environmental Design Research Association (EDRA)* founded in 1968 . In the 1970s, environmentalism started to shift towards an ecological ideology soon dominated by technical solutions. This coincided with the energy crisis and so environmental design soon shifted from a holistic approach to the search for new methods that would help designers reduce energy used in all phases of their designs. This technological turn was driven by highly structured principles, many of which were in the search for ever-more efficiency.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

At the turn of this century, the technological emphasis for efficiency systematically developed throughout the 1980s and 1990s, started to reveal its limitations. The limitations faced by the emerging methods and tools developed specifically at the time to address both global and local environmental degradation can be categorized in three general areas. First, the prescriptive or normative nature of the tools being developed left little room for profound exploration in innovative solutions. We have seen in our previous researchers on large-scale sustainable projects, that it is the tried and tested proposals that go ahead rather than the experimental. Second, their predisposition to fragment the given problem through very rigorous and numerous analyses tools for the various portions of the project, resulted in very little or no thought given to the encompassing situation. This disconnectedness between the analyses of the many parts and the whole project was problematic especially in terms of synergies and of coherence. Third, the profound problems facing humanity at the time could not be solved through technology alone, since questions of the social or cultural conditions could no longer be ignored.

Facing a problematic integration of both social and cultural dimensions, this approach revealed a contradictory opposition between form and meaning, between aesthetics and ethics, between process and content [6]. Numerous scholars now underline that these missing inter-subjective dimensions may be compromising the very idea of a holistic environmentalism in various realms of knowledge and action. Such is the case in the design disciplines, where a series of paradoxes are being identified at varying scales. We focus on three paradoxes related to how design today deals with environmental degradation and climate change mitigation. These three paradoxes are:

- Human behaviour is hardly considered in environmental evaluations yet behaviour is at the core of environmental degradation and specifically resource consumption;
- Predicted performance measurements of design projects rely on managerial and eco-deterministic approaches, yet there is a large gap between these promises based on best case scenarios and actual performance; and
- Representations of 'green' design are often added to spaces or buildings to communicate the 'greenness' of these projects rather than integrating actual effective environmental processes or characteristics not necessarily visible to the general user if these spaces or buildings.

An example demonstrating the first paradox is when smart buildings are adopted as a way to design energy efficient buildings. The 'intelligence' designed into the buildings is often quite disconnected from actual human behaviour, to such a point that energy promises at the design phase, are rarely met at the post-occupancy phase.

An example demonstrating the third paradox is that it is commonly observed that some uses of solar panels have more to do with communicating (green) than actually reducing environmental impacts. This phenomenon has been observed in contemporary Canadian public spaces, where there is evidence that designers tend to bypass the race for efficiency through strategies of communication.

It has now become critical to better understand how the dominant doctrines of managerialism, environmental efficiency, eco-determinism, among others, as systematic approaches, are resulting in a series of contradictions and 'demonstrative devices' which influence collective intelligence while deceiving the public that real action has been taken.

Today the question of climate change and its projected catastrophic impacts worldwide requires a rethinking of some of the predominant international discourses and approaches, so that human behaviour and collective intelligence regarding issues of climate change becomes a priority rather than a residual thought. Our hypothesis states that the critical and reflective design of art-architecture installations for the public space can address collective intelligence for the longer-term by helping to shift human behaviour. The CoLLaboratoire research project is focused on this approach.

3. INAUGURAL DESIGN CHALLENGE OF COLLABORATOIRE

For the inaugural experimental design challenge, CoLLaboratoire organized a design competition open to only young designers, artists, architects, creative or critical thinkers, and therefore preferably students. We heavily targeted our own students at Concordia University since the site of first design challenge was the Concordia University Loyola campus. The challenge called for an augmented bus shelter that students can use during the week as a bus shelter, but would have an augmented program during evenings, weekends and especially the summer. Solar energy was to be used in the project in creative ways, for collecting, storing, using, as well as displaying a variety of metrics to users of the shelter. The projects were expected to consider the role of public art and design in increasing awareness of, and engagement in, issues around climate change at the local level.

This competition was anonymously judged. The jury was made up of an art historian, a gallery director, an expert in solar energy, two architects, an interdisciplinary designer, and a doctorate candidate in sustainable business practices comprised the jury. A public vote was also included in this challenge as a way to get the members of the community involved in the conversation.

The main criteria for the challenge was the following:

- Imaginative shelter design (form, materiality, spatial qualities, etc.);
- Innovative interpretation of the idea of 'shelter' for the Loyola campus site;
- Incorporate solar energy and provide details of its use;
- Consideration on how the impact of your project might be measured over time (eg.: the number of mobile devices being charged per day using the solar power).
- The maximum allowable budget for the project build-out is $23,000.

Anonymity was ensured since all young contributors to the challenge had to preregister and obtain a code to include on their design panels. Because of the requirement of solar energy and the creative interpretation of the shelter, multi-disciplinary teams were highly encouraged.

3.1 Results from design challenge

This first design challenge was launched on April 2016. In this challenge, which was geared towards young designers only, we received 26 design proposals from Brazil, Canada, France, Iran, and USA. Three proposals were selected as originally announced, but the jury decided to add two honourable mentions. We present a short description of the awarded projects.

The first prize went to a project that displayed a bold architectural proposition, with an elaborate, yet clear reinterpretation of the 'bus shelter'. The solar panels could be integrated into the floating canopy, which glows at night. The proposal collects energy in order to create a night-time beacon, providing a feeling of security for users of the shelter over the darker months of the school year.

The second prize also proposed a poetic gesture for the site, alluding to a lighthouse in its design. The proposal, which included the addition of a subtle installation for social gathering adjacent to the original, refurbished shelter had great symbolic potential as a landmark.

The third prize was innovative in form and composition and extended the program of the bus shelter by proposing a structure that might also be useful as a weekend market. The proposal stood out for its distinctive, flexible form.

The two honourable mentions were selected for their pragmatic approaches. One of these doubled the capacity of the shelter, thus allowing for an extended interior program, such as the inclusion of a sharing library within the shelter. The second designed a series of modular shelters that can be combined in a variety of permutations to increase the capacity of the shelter while revealing perhaps too directly the solar technology.

With the winning project selected, a supervised design process is now ongoing. The winning team is currently collaborating directly with research groups, researchers and students from Concordia University, as well as other professional bodies in order to construct the project for the summer of 2017 on the Loyola Campus of Concordia University. The construction of the winning project is expected to begin by in early spring of 2017 for a completion date by August 2017. The launch of the constructed project will be done concurrently with the 375th Montreal celebrations in 2017.

4. DISCUSSION OF RESULTS OF CHALLENGE

With 26 projects submitted to this design challenge, the diversity was high and therefore the selection of the winning project was difficult since the criteria had to be reinterpreted for each special case. The projects can be categorized into a series of polarities, which ranged from:

- Projects that chose to focus on symbolic gestures to those that were completely pragmatic in their approaches;
- Easily buildable projects to overly complicated parametric designs - let's keep in mind that the competition was for a bus shelter;
- The visible exhibition of solar panels on elementary architectural forms to the elegant use of new solar technologies inconspicuously concealed in clean forms;
- Projects that focused on sites and their spatial compositions to projects that focused on the composition of the artefact (bus shelter) alone.

The winning project provided a symbolic gesture, that is buildable, with solar panels obscured in the materiality of the canopy, focusing on the spatial qualities of the site while also the designing an artefact that can act as a beacon for the entrance of the university. It also proposed a playful and theatrical lighting approach for displaying the level of energy stored, used and left in the shelter.

The theatricality of this gesture for displaying such dry information allows reaching a broader spectrum of users of differing ages, backgrounds, etc. The designers provide a shelter that is didactic and interactive, informing the user of the energy saved from the grid. As the user activates the elements that use the stored solar heat, they will immediately see the indicators of stored solar energy decrease. This playful gesture is meant to communicate to the users, or the passer-by as to the solar energy that is being collected, stored, and used on a daily basis for cooling, heating or charging portable devices.

Furthermore, the clever manner in which the solar panels (harsh engineered components) are concealed in the canopy of the shelter presents two key outcomes: (1) the clean integration of effective environmental processes is possible; and (2) the expression of 'sustainability' or 'green design' does not equal green design, since the winning design is not embellished with demonstrative environmental gadgets.

The winning project addresses the main goal of CoLLaboratoire, which is to recover memories of place and environment and to serve as a model project of a sustainable city.

5. CONCLUSION

This first inaugural project for CoLLaboratoire helped reflect on how architecture and more broadly, spatial practices, through its autonomous structures, formal procedures and even representational approaches, enables designers to expand out towards other discourses such as virtual technologies, sustainability, spatial practices, in order to address pressing questions of today, such as climate change issues. This project allows architects to bridge the gap between different modes of knowledge, and this is especially evident in practices of sustainable architecture. This project is also key in highlighting its contribution to the expansion of today's architectural interdisciplinary practices.

This community-academic experimentation through public art-architecture installations, helped in finding unconventional ways to allow designers and community to better reflect on questions of climate change. Such a project may also bring to light some of the contradictions of the prominent practices of what is termed 'sustainable' design today - but this is only observable once the installation is adopted and used by the community over the course of the next few years. So such a project is not only a cultural production for the community, it also is a living lab, a dissemination project of innovative technologies and uses of technologies. Such a critical practice is key to help bridge the gap of collective intelligence so deeply needed for moving towards sustainable cities.

ABSTRACT

The built environment is responsible for significant environmental impacts. It is therefore a central research area to balance ecological and built systems and allow them both to thrive. While the majority of previous and existing attempts have targeted minimising environmental impacts, regenerative development goes beyond reduction and aims to restore and support environmental, social and economic flows. Yet, very few projects to date have been able to demonstrate a regenerative outcome. This is because few consulting firms currently offer regenerative design thinking, which is in turn linked to a lack of understanding of processes that support decision making in regenerative development projects. This paper uses a 680 hectares regenerative development project in Gippsland, South East Australia as a case study to investigate how implementing a regenerative development approach from the onset affects the decision-making process. A series of workshops were facilitated by the authors with the local community, indigenous elders, design experts, academics, scientists, government and industry partners and other stakeholders. An online survey consisting of 10 questions was sent to the 40 actors involved and 28 responses were collected (N = 28 and a response rate of 70%). This study provides a contribution to the understanding of both the processes that can support the implementation of innovative regenerative concepts in the built environment and their benefits. It covers aspects ranging from the personal motivation of participants, to the performance of the workshops in facilitating a regenerative design. The knowledge gained from this study will inform the future use of regenerative development and associated facilitation tools.

Keywords: regenerative development, design process, sustainable neighbourhood

1. INTRODUCTION

The built environment is responsible for a significant portion of the environmental impacts humans are having on the planet. Yet the built environment is critical to human development. How do we reconcile this when past practice has always privileged human progress above ecological (Steffen et al., 2007). The solution to this is to understand the interconnected nature of our planets systems (Pretty, 2011). In the long term humanity will only thrive if the systems on which it depends thrive. As such our built environment should be designed to support the viability and vitality of social and ecological systems and enhance the ability to adapt constructively to change. That is, cities designed to provide net ecological and social benefits; no longer minimising environmental impacts but actually aiming to heal, connect and strengthen them. An approach to doing this is termed Regenerative Development, which aims to restore and support environmental, social and economic flows.

This contributive approach to designing the built environment is relatively new with very little long term research underpinning it. It has been practiced by a few consultants internationally (Mang and Reed, 2012) and case studies found on practitioner pages from Regenesis and Institute for the Built Environment (IBE), Colorado State University) but rarely as part of a research led process. While regenerative practices provide insights into the outputs of regenerative development projects; there is a need to better understand the process that supports regenerative thinking by contrasting it to business as usual.

The aim of this paper is to evaluate the experience of stakeholders during a regenerative design charrette facilitated using LENSES and applied to a large scale regenerative development proposal: Seacombe West, Gippsland, Victoria, Australia. This contributes to our understanding of the process of regenerative design and the effectiveness of facilitation tools such as LENSES. LENSES is a framework which supports design thinking towards regenerative goals. There are other tools or frameworks used by Regenesis, and it could be argued that any consultation process could incorporate regenerative outcomes, if the underpinning ecological thinking is present. That is, thinking that determines the potential of place, looks that the flows that bring a place to life, enables design

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

to enhance the relationships between flows and the place and therefore the ability for a place to be more resilience and to constructively adapt to change (Hes and du Plessis 2015). The LENSES framework was chosen as it nicely support this approach to regenerative development.

1.1 Site

Seacombe West is a proposed 680 hectares (6.8 km²) development on Lake Wellington (or Murla in the Gunai aboriginal language), the largest of the Gippsland lakes in Victoria, Australia which cover 340 km² (Roberts et al., 2012). Some areas along the lakes are protected under the Ramsar convention (Ramsar, 2016) and other wetland and birds protection agreements. The Gippsland lakes are therefore a significant natural feature and generate a large economic activity, mainly in terms of agriculture and tourism. However, these lakes were artificially connected to the sea at Lakes Entrance in 1889 and since then the salinity of their waters has steadily increased. While Lake Wellington is the least saline of the three lakes, its salinity is increasing and its biodiversity has simultaneously declined over the last decades. Salty flood waters have also blighted the Seacombe West site which can no longer fulfil its past ecological or farming functions. The owners of the site decided to regenerate the site through a development that would provide stable habitats while also regenerating its ecological functions and enhancing its socio economic activity.

2. METHOD

This section presents the LENSES regenerative development framework assessed. The overall research strategy and the project timeline are also described before detailing the survey used to assess the facilitation process.

2.1 Case study and LENSES description

LENSES stands for Living Environments in Natural, Social and Economic Systems. Plaut et al. (2012) state that LENSES aims 'to facilitate tangible, actionable and contextually based solutions that support and create healthy, natural, social and economic systems'. Error! Reference source not found. shows that LENSES is represented by three overlaid lenses. The outermost lens (the Foundation Lens) outlines the guiding principles of the project. The intermediate lens (in blue) is the Flow Lens and represents the flows across the project. These can be physical or abstract. Both the flows and the guiding principles of the project have been defined by the stakeholders during Workshops 1 - 3 (see Figure 1). In the centre of the framework lays the Vitality Lens which includes the two spheres of degenerative and regenerative design and incites a workshop participant to focus on regenerative outcomes for each flow. Artefacts of this model are generally printed or made for workshops. This visual representation is a tool that helps structure the thinking during the workshops and allows the stakeholders to have all the key flows and principles in an organised manner.
