On acoustics quality, noise from internal equipment (printers, telephones, keyboards and computers), vibration (including air conditioning), colleagues, noise coming from the building's external environment and user's satisfaction with the level of noise were evaluated. (Barreto and Silva, 2010)

About interior layout and ergonomics, privacy at the workstation, density of people in the office, pain in hands, back, legs, neck, arms and malaise, the existence of areas to make private phone calls, rest, comfort and information about the chair, computer screen adjustment possibility, if the occupant spends most of the day sitting or standing, sufficiency of space activity implementation, and the level of the user's satisfaction. (Ulrich, 1991)

Regarding green areas and views, the research evaluated: occupant's feeling about the existence or lack of plants and flowers in the office; visibility of trees, green areas, gardens and sky through the window and user's satisfaction level in this regard. (Lohr et al., 1996)

Questions about the aspects and perceptions involved cleanliness and organization of space, the occupant's feeling about the shapes, colors and textures of the walls and floors of the office and the user's satisfaction level in relation to this category.

Transportation category evaluated the means of transport to get to work, the distance from user's residence to a public transport station, availability of complimentary transport provided by the employer, if the user has no other choice to commute to work, how long the commute takes, user's stress due to commute and level of the user's satisfaction with transportation.

Finally, the access to amenities category assessed the existence of car and bicycle parking in the workplace, bicycle storage, existence of a pantry or cafeteria in the office, if there are restaurants, day care centers, parks or plazas nearby the workplace and the occupant satisfaction level regarding the category.

For the analysis of this research, only companies that registered over twenty respondents were considered, in order to avoid biased samples. Participating companies received a full report with diagnosis of their results, which can be used as a basis for the implementation of improvements.

The evaluation of perceptual method results enabled to identify, in company number 5 (see the matrix importance x satisfaction), that acoustic quality was the greatest dissatisfaction factor to occupants. With this finding, the IPT conducted measurements of sound inside two participating companies. Measurements were carried out during a typical work day, approximately, from 9 am until 3 pm, using two meters of the sound pressure. One equipment was kept fixed at one point considered critical in terms of exposure to noise generated internally, others piece of equipment were allocated in various office points, including meeting spaces areas and collective rooms, with five minutes duration measurements.

3. RESULTS

Questionnaire sent to participating companies considered nine factors of interest in literature: air quality and ventilation (1), thermal comfort (2), daylighting and lighting (3), acoustics quality (4), internal layout and ergonomics (5) green area and views (6), aspects and perceptions (7), transportation (8) and access to amenities (9). Besides questions related to each subject factor, there was also questions about the importance the respondent attributed to each factor, and how pleased he was. With data collected from these responses a matrix of importance and satisfaction was prepared for each company, which can be seen in Figure 1. (Slack, 1994) Each survey were answered only by occupants office staff per company, a total of four buildings were surveyed.

These nine factors represent the structure and workplace physical conditions that most interfere in occupants comfort and wellbeing. Seven factors are related directly to the built environment of the green building and two factors are regarding building location and surroundings.

Likert´s qualitative scales were used to measure the answers thus the data analysis was necessary to make a numerical association replacing degrees of importance "Worthless", "Not very important", "Important" and "Very important" by the values 1, 2, 3 and 4 respectively; and replacing the satisfaction levels "Totally dissatisfied," "Dissatisfied" "Satisfied" and "Totally satisfied" also by 1, 2, 3 and 4 respectively.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

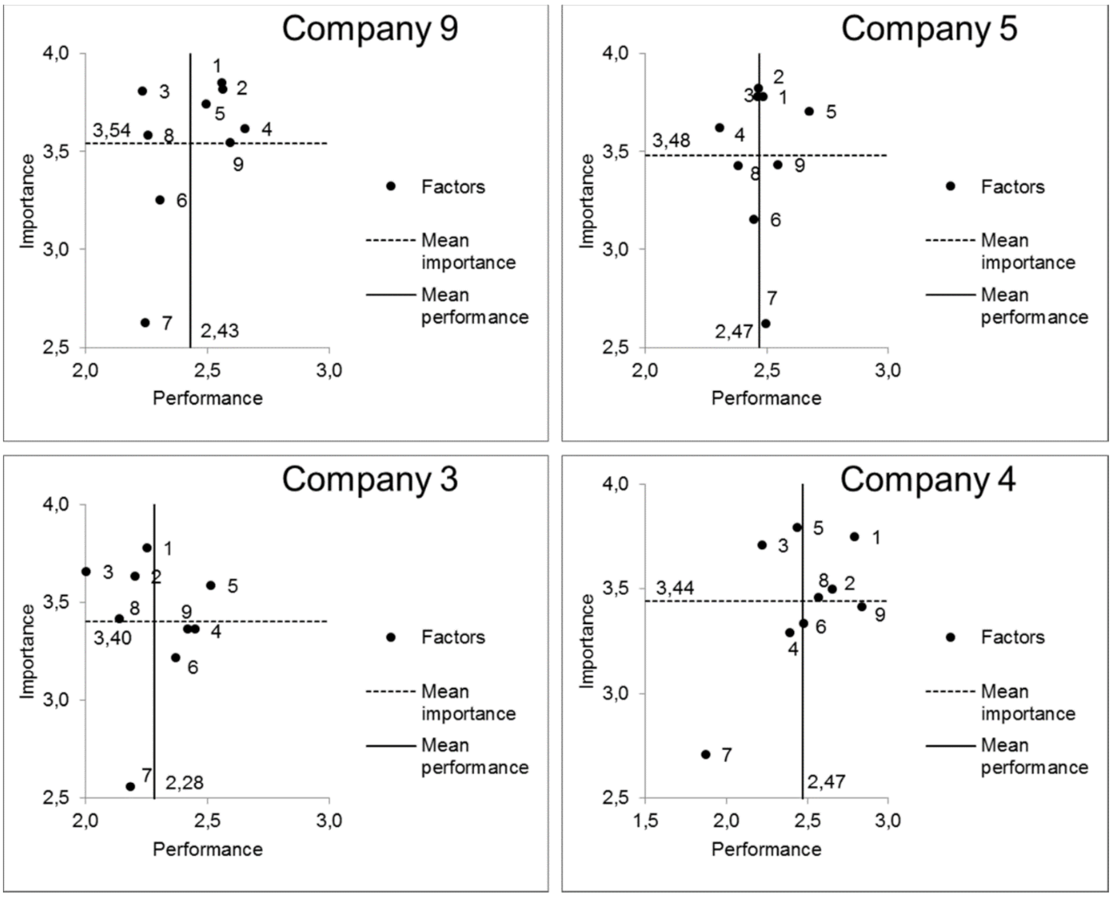

Figure 1: Matrix importance/ performance of seven factors separated by company

Matrix was constructed by placing on abscissa axis the average satisfaction of all respondents for each factor and on ordinate axis the average of importance. (Martilla and James, 1977) Also plotted are the points of satisfaction and importance regarding all nine factors so factors comparisons can be done. (Pavot and Diener, 1993)

Regarding Company 3, the factors 1, 2, 3, 5 and 8 were considered more important than the factors 4, 6, 7, and 9; and respondents are more satisfied with the factors 4, 5, 6 and 9 than with the factors 1, 2, 3, 7 and 8. Highlighting the factor aspects and perceptions (7) that was considered least important in all four companies.

Regarding Company 5, the factors (1, 2, 3, 4 and 5) were considered more important, except for the factor 4 (acoustic quality) that was considered below average in terms of satisfaction, although three of them (1, 2 and 3) were situated close to the limit.

Regarding factor 4 (acoustic quality) of the office, 23 of the 116 respondents complained of noise with comments like "Coworkers talk very loudly on the phone", "People should respect the open space," "During the night, when turn off the air conditioning is noticeable the noise it makes and in the morning when they turn it on.

During the day, I think he got used to it."," Open space contribute to inconvenient noise, requiring a higher concentration at work and increased stress at the end of the shift "and even more damning phrases like" I just cannot work when two people are on the phone next to me "or" noise is one of the factors that affects me more than any other factor. Often I have to go to the quiet zone ". This company has a soundproof room called "quiet zone" where people can go at any time and stay as long as they want, when they feel disturbed by office noise.

Specific questions showing users perceptions can be seen in Table 1.

	Never (%)	Sometimes (%)	Many times (%)	Always (%)
I feel distracted/ annoyed by noise from phones, printers, computers, keyboards, and other equipment.	12,96	42,59	24,07	20,37
If windows are opened, there is too much street noise.	61,54	12,09	10,99	15,38
I feel distracted/ annoyed by machine noise from outside.	78,79	17,17	3,03	1,01
I can hear vibration noise	64,42	28,85	2,88	3,85
I feel distracted/ annoyed by speaking people noise at office.	8,41	29,91	28,97	32,71
I feel distracted/ annoyed by air conditioning vibration noise.	56,19	34,29	6,67	2,86

Table 1: Noise level perceptions at workplace

It was also asked about people's satisfaction regarding noise level, and the answers were: 7.41% were totally satisfied, 50% satisfied, 30.56% dissatisfied and 12.04% completely dissatisfied.

To improve the analysis of company acoustic quality, a physical measurement of sound pressure in the workplace was made. All respondents work in a single floor of a LEED CI certified building, and seventeen points were chosen to be measuring points. One point, considered the noisiest, was monitored during all working day, from 9:13 am until 14:53 pm, and others sixteen points were measured for 5 minutes each. At the noisiest point were measured 65 dBA and it is acceptable within offices limit, according to ABNT NBR 10152, Brazilian acoustic code standard. Sound pressure levels can be seen in Figure 2.

Measurement every half second was conducted amounting a total of 7200 measurements per hour. To better understand the sound pressure levels, measurements during lunch time are represented by the solid line, and one hour later is represented by the dotted line, were organized by frequency and sound pressure level. As an example, the average sound pressure levels were calculated of 20 Hz frequency which resulted in 44.54 dBA for lunch hours and 53.07 dBA outside this time (Figure 3). It appears that during lunch break all measured points were below the audible line, except for the frequency point of 125 Hz and sound pressure 58.28 dBA both during lunch time and outside it can be perceived. During working hours, all measured points above 200 Hz are capable of hearing.

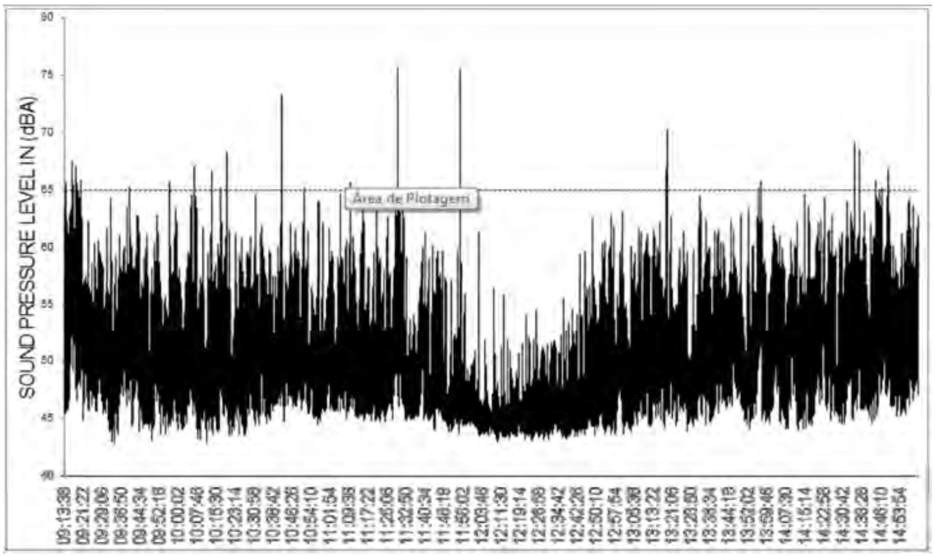

Figure2: Sound pressure level in dbA

At Figure 3 can be seen the frequency band normally used by spoken voice that goes from 500 to 2,000 Hz and the noise perception limit of air-conditioning equipment noise depending on the frequency and sound pressure provided by the equipment manufacturers.

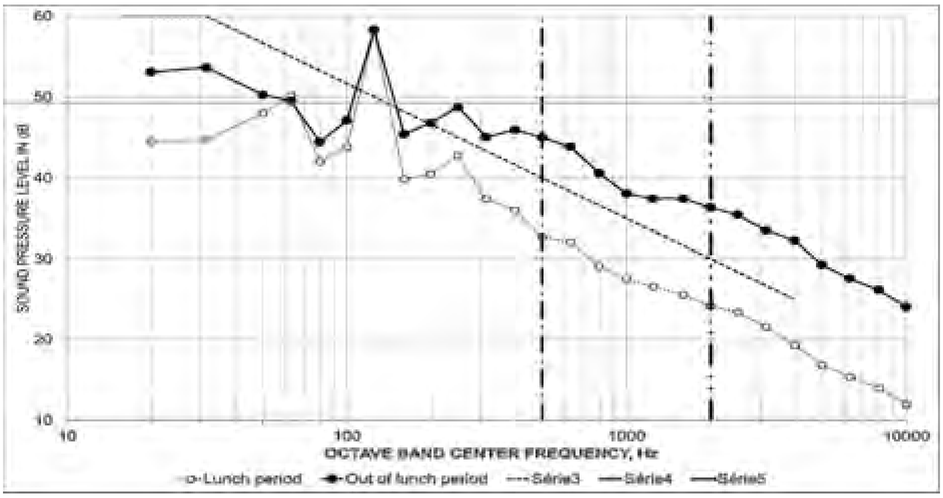

Figure 3: Sound pressure level by frequency during one hour

4. CONCLUSION

As shown on results, offices´ acoustics affect people wellbeing in the workplace. Brazilians workers are loud even for LEED CI certified offices. The participant offices have been planned considering acoustics protection, for common offices the results would be really worse. Brazilian culture with the latin root is talkative, passionate, friendly and loudly sometimes! That is why not only the built environment but also the behavioral habits need to be aligned. This research aims to collaborate with the sustainable community of green buildings focusing on people. Training and sustainable courses can help to reduce the disturbance in Brazilian offices, consequently improving workers health and wellbeing and also their productivity. Brazilian sustainable facility managers really need to integrate with human resources managers to benefit all, planet, people and profit.

Development of a Home Indoor and Outdoor Environment Visualization System

Yusuke NAKAJIMA[a]

[a] *Kogakuin University, Japan, yusuke@cc.kogakuin.ac.jp*

ABSTRACT

In recent years, HEMS (Home Energy Management Systems) have garnered attention as an energy-saving measure, and are being adopted in an increasing number of cases in smart houses and smart apartment complexes. As the name indicates, their main focus is energy management functions such as operation/control of appliances, and measurement/display of electric power. On the other hand, adjustment/maintenance of the indoor environment is an important factor for comfortable living in the home, but it is extremely unusual for indoor environment characteristics such as temperature and humidity to be displayed. Therefore, the authors' laboratory has previously developed an "indoor and outdoor environment visualization system" as a means of raising interest in the indoor thermal environment, and promoting use of passive technology suited to the skills of the resident and the season. Energy-saving effects and effectiveness in improving the indoor environment have also been confirmed through trial operation in housing complexes.

As the next step in development, for this report the authors improved the versatility of the equipment by packaging devices more compactly, and developed a system with additional innovations in sensing items and information transmission techniques to take into account factors of health and safety. The utility of the system was verified, and issues identified. In the means for transmitting information, small LED light which color and blinking changes with indoor environment was incorporated. From the results of test installation of this kit in a number of houses, passive activities were promoted and the effects of improvement of indoor environment were confirmed.

Keywords: energy saving, indoor environment quality, HEMS

1. INTRODUCTION

In recent years, HEMS (Home Energy Management Systems) have garnered attention as an energy-saving measure, and are being adopted in an increasing number of cases in smart houses and smart apartment complexes in Japan. Japanese government aims to put HEMS into every home in Japan until 2030. As the name indicates, their main focus is energy management functions such as operation/ control of appliances, and measurement/display of electric power. On the other hand, adjustment/maintenance of the indoor environment is an important factor for comfortable living in the home, but it is extremely unusual for indoor environment characteristics such as temperature and humidity to be displayed. Therefore, the authors' laboratory has previously developed an "indoor and outdoor environment visualization system" as a means of raising interest in the indoor thermal environment, and promoting use of passive technology suited to the skills of the resident and the season. Energy-saving effects and effectiveness in improving the indoor environment have also been confirmed through trial operation in housing complexes.

As the next step in development, for this report the authors improved the versatility of the equipment by packaging devices more compactly, and developed a system with additional innovations in sensing items and information transmission techniques to take into account factors of health and safety. In this research, the result of a subject experiment using that visualization system kit were reported.

2. OVERVIEW OF INDOOR/ OUTDOOR ENVIRONMENT VISUALIZATION SYSTEM KIT

Based on the results of previous operation experiments using a prototype system, the authors developed an indoor environment visualization kit that can be easily installed in existing homes. The main concepts are indicated below.

- Improved awareness of the indoor/ outdoor environment (Measurement items and screen innovation)
- Health and safety warnings (Heat stroke alerts, etc.)
- Convenience of installation (Can also be installed in existing homes)
- Power-saving design (Long-term drive using batteries)
- Simplification of data gathering (Use of Internet line in each home)
- Screen for comparison between homes (Continuation of interest)

Figure 1 shows the configuration diagram of the system. It was decided to adopt the following measurement items for the prototype kit: (1) Indoor temperature/ humidity and globe temperature, (2) Wall/ floor surface temperature (radiation temperature), (3) Carbon dioxide concentration (+ temperature/ humidity), (4) Dust concentration, (5) Outside air temperature/ humidity, and (6) Electric power consumption (main + 2 branches). It was decided to adopt specifications making it possible to ascertain the indoor vertical distribution of temperature by installing the sensor terminals for (1) – (3) at three different heights (high, medium, low). (1) – (4) are installed in a typical room (living room), and in addition one more sensor terminal for (1) was prepared for installation in any desired room by the resident. Measurement of the thermal environment is conducted every 30 seconds, and measurement of electric power every minute. In addition, the view count is collected for each page.

The indoor environment and electric power consumption are sent from each wireless base unit to a web server via the in-home Internet line, and the data is processed into easy-to-view graphs and the like. These can then be viewed from a smartphone or PC. An existing product was used as the power consumption measurement device. Compact boards (Arduino) were used for the sensor terminals newly developed and fabricated this time, and ZigBee communication was used as the communication standard with the system's base unit (Raspberry Pie). Power-saving design was carried out for each board, and dry cell drive was adopted in the sensor terminals for (1) and (5).

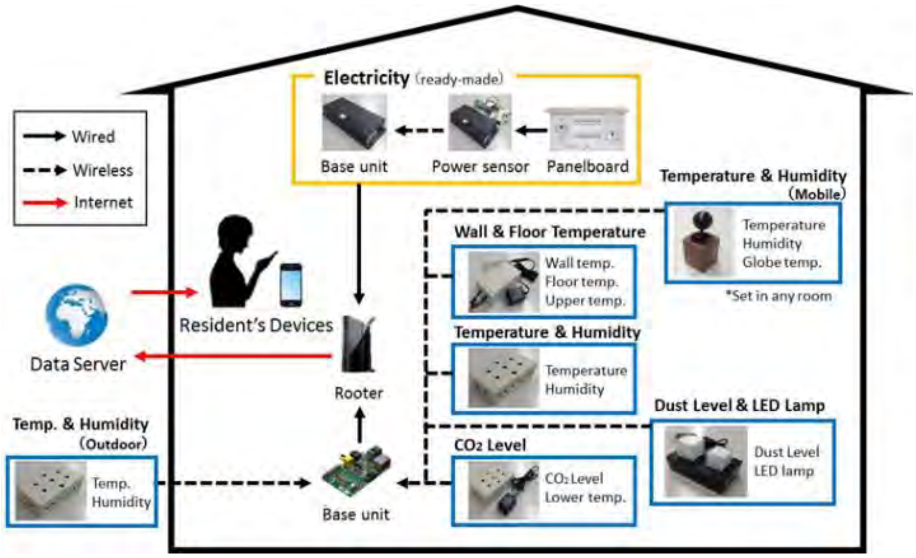

Figure 1: Configuration diagram of the system

Figure 2 shows the functions of the "LED lamp indicator" which is a major distinguishing feature of this system. This indicator provides a real-time display of the measured indoor/outdoor temperature information using the color level of an LED lamp. This allows the user to intuitively ascertain the indoor/outdoor thermal environment even without looking at a smartphone or other device. In addition, the system has a function to enable display of various alerts for ventilation, heat stroke and dryness using a flashing LED display when measurements of temperature/humidity, CO_2 concentration or other values exceed a fixed threshold. Internally, the system has a built-in dust concentration sensor.

Figure 3 shows a sample screen from the "Uchi-Repo" viewing site. The home screen displays the weather forecast for 3 days starting today and real-time values for measurement data, and the system is designed so that information on the indoor environment can be understood at a glance. At the room temperature screen, graphs are displayed of the indoor temperature, window/floor surface temperature, vertical distribution of temperature, and outside air temperature, and at the humidity screen, graphs are displayed of the indoor humidity and outdoor humidity. This enables indoor/outdoor comparison, comparison of times series for 1 week from the current day, and so forth. Time series graphs are also displayed for CO_2 concentration and electric power consumption. Also, using the comparison screen, it is possible to compare the indoor environment and electric power consumption with other households, and to ascertain the whether the indoor environment in the home is good or bad, and where power usage is high or low. The system is designed so that an LED flashes simultaneously when sensor measurements exceed fixed thresholds, and warnings on ventilation, heat stroke, and dryness are displayed on the home screen of the "Uchi-Repo" site. This helps promote quick response. To ascertain differences in the sense of heat/cold in each household, a function is also provided to enable reporting of the current degree of comfort.

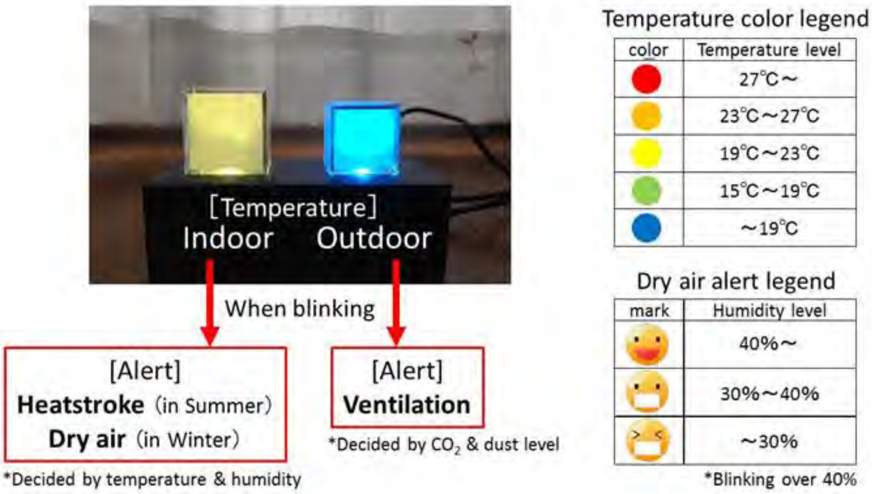

Figure 2: Functions of the "LED lamp indicator"

Figure 3: Sample screen from the "Uchi-Repo" viewing site

3. SUBJECT EXPERIMENT USING VISUALIZATION SYSTEM KIT

3.1 Overview of experiment

Table 1 provides an overview of the homes for the subject experiment. Experiments were conducted by installing 4 of the systems improved and developed in the previous section in 4 households. Data was only collected for about 1 week subsequent to installation of the equipment. After that the viewing site “Uchi-Repo” and how to use it were explained, and then data was collected again for 1 week while performing visualization. The experiment period was November 11 – 25, 2015, at the start of winter. After the experiment was finished, a questionnaire survey was administered regarding how the subject usually spends the same period each year, changes in awareness due to system adoption, and views on the system itself.

	Location	Number of residents	House type	Construction type
A	Machida city, Tokyo	5	Detached house	Wood
B	Hiratsuka city, Kanagawa	5	Detached house	Wood
C	Machida city, Tokyo	4	Detached house	Wood
D	Saitama city, Saitama	4	Apartment	RC

Table 1: Overview of the homes for the subject experiment

3.2 System viewing and evaluation

Figure 4 shows screen viewing counts for each day and time band in each household, and Figure 5 shows the viewing percentage for each type of screen. It is evident that there are differences in the view count and percentage depending on the lifestyle, interest and concern of the subject. As can be seen, in homes with a high view count (A and D), viewing is done periodically in the morning in A and in the evening in D. From Homes B and C with a comparatively low view count, comments were obtained on the questionnaire such as “the graph screens are hard to see” and “the information I want to see is hard to understand.” In terms of screen types, the percentage for the “home screen” where the full set of real-time data can be viewed is high for all households, and it is presumed that interest is high in current value data on the thermal environment and amount of electric power. The “comparison screen” received the next most views. In this regard, there was a comment that “it is interesting to compare with other households.”

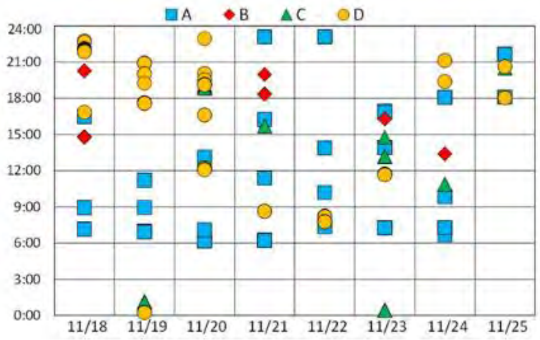

Figure 4: Screen viewing counts for each day and time band

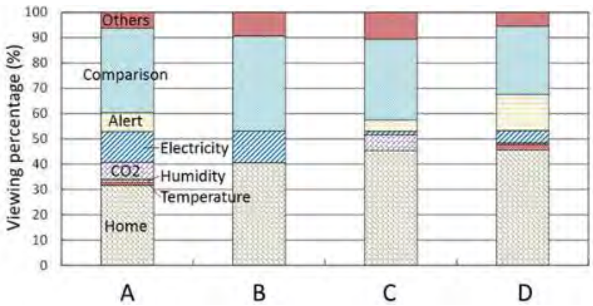

Figure 5: Viewing percentage for each type of screen

3.3 Changes in environment awareness due to visualization

Table 2 shows results regarding the changes in environmental awareness of each household according to the questionnaire. In all households, the item “I began to worry about ventilation” pertained often, and this can be regarded as confirmed by the results of interviews indicating that the subjects periodically engaged in the ventilation behavior of opening/closing doors and windows while looking at the flashing display of the LED lamp. In households where power consumption decreased, it was confirmed that subjects began to worry about use of the TV and other appliances, but it was ascertained that bothersome techniques such as unplugging generally were not translated into action even if they were effective. In addition, among households which responded that they became able to predict the current temperature and humidity, they all responded that information communication using an LED

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

lamp is effective. In addition, there were also comments such as "I confirmed with the LED color that maybe the current room temperature was too cold for children," and "I determined the timing for using heating based on the LED color." This can be regarded as confirming that this sort of visual device has high potential to aid in proper prediction and regulation of the indoor environment.

Classification		Questionnaire list	A	B	C	D	Point
Temperature	a	I began to worry about temperature control.	○	△	△	△	5
	b	I learned to be able to predict current indoor temperature.	○	×	○	○	6
	c	I learned to be able to know my comfortable temperature.	○	△	×	○	5
	d	I could control indoor temperature without heating.	○	×	×	△	3
	e	I began to get sunlight from the window.	△	○	△	○	6
	f	I began to worry about opening and closing curtains.	△	×	△	○	4
Humidity	g	I began to worry about humidity control.	○	×	△	△	4
	h	I learned to be able to predict current indoor humidity.	△	×	○	○	5
	i	I could control indoor humidity without humidifier.	×	×	×	△	1
Ventilation	j	I began to worry about ventilation.	○	×	○	○	6
Indoor climate	k	I began to worry about indoor climate from the outside.	×	△	×	○	3
	l	I began to worry about indoor climate before going out.	△	△	×	△	3
	m	I began to worry about indoor climate before going to bed.	△	△	△	△	4
Electricity	n	I began to worry about using appliances.	○	○	△	○	7
	o	I began to reduce wasteful electricity use.	○	○	△	△	6
	p	I began to turn off the TV when no one is watching.	○	○	○	○	8
	q	I began to disconnect the plug of unused appliances.	△	○	×	△	4
LED lamp	r	I did environment control behavior by LED lamp indicator.	○	×	○	○	6

Table 2: Questionnaire results regarding the changes in environmental awareness

4. EFFECTS OF IMPROVING INDOOR ENVIRONMENT

4.1 Passive techniques

All of the households have a custom of shutting curtains at night and opening curtains to let in light, and no practical actions were seen based on an understanding of the effects of direct gain and heat accumulation. Also, during the period of the experiment, the air temperature was comparatively high, and this may be one reason why passive behaviors were not actively carried out. However, based to the questionnaire results, it can be said that the system provided greater awareness and interest in the indoor environment, such as "I was able to adjust my clothing to suit the temperature by viewing the LED lamp" and "I noticed the difference between my body temperature and the actual temperature."

4.2 Ventilation behavior

Figure 6 shows changes in CO_2 concentration and CO_2 screen viewing on the 18th at Home A and the 23rd at Home C. At Home A, the living room is used for sleeping, and the CO_2 concentration rises to a high level at night. It is presumed that, due to the flashing of the LED lamp every morning, the subjects viewed the CO_2 screen, and this was connected with periodic ventilation behavior. In Home C too, it was confirmed from the questionnaire that the subjects viewed the CO_2 screen and shifted to ventilation behavior when they noticed flashing of the LED lamp.

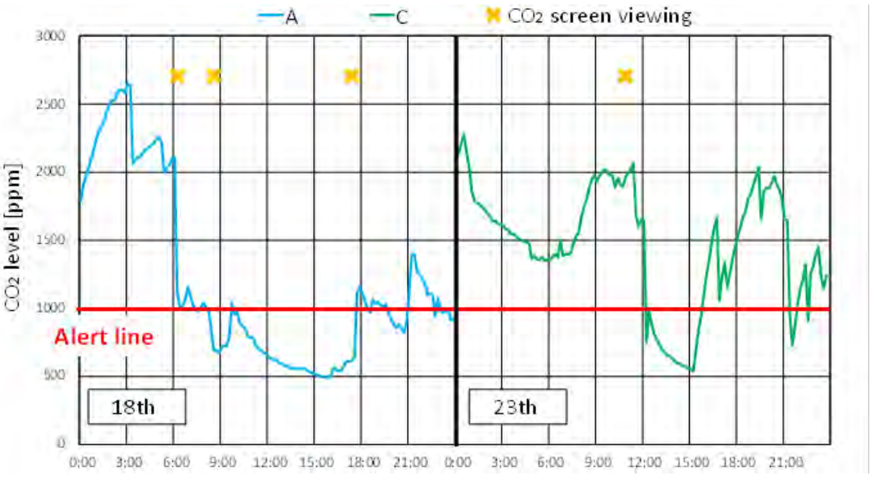

Figure 6: Changes in CO_2 concentration and CO_2 screen viewing

4.3 Energy consumption

Figure 7 shows the daily average of electric power consumption before and after adopting the system at each home. This experiment was done at the beginning of winter, but there was still not much use of heating equipment, and partly for that reason no major overall change was evident. However, in households where the rate of viewing the electric power screen was high (Home A), it was possible to confirm a certain degree of reduction.

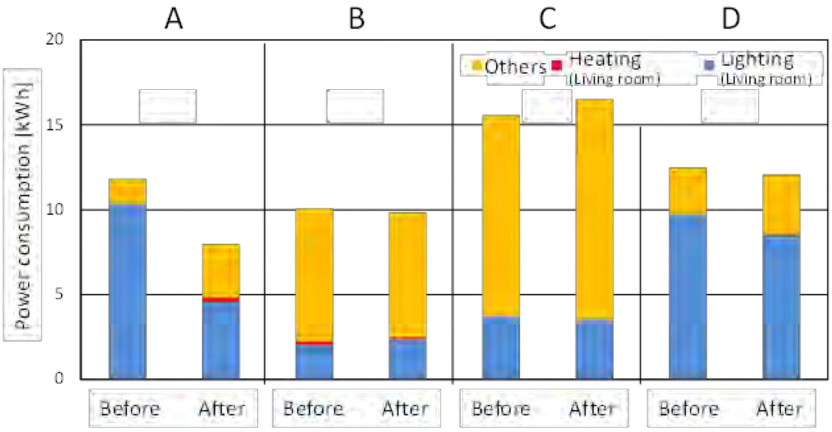

Figure 7: Daily average of electric power consumption before and after adopting the system

5 CONCLUSION

This research is a PILOT project, but the following summarizes the main findings obtained as a result of a subject experiment with the developed kit for visualization of the indoor environment.

- A tendency was evident for use of the system kit to lead to various types of awareness, interest, and concern toward the indoor/ outdoor environment, and cases were seen that were linked with specific passive behavior.
- It was confirmed that the LED lamp indicator promoted routine awareness of the indoor/ outdoor environment in almost all households, and helped to warn about alert items.
- A trend was evident of high interest in the screen comparing with other households.

Going forward, the authors will increase the number of subjects, lengthen the experiment period, conduct detailed verification of the results of improving the environment through communication of information such as warning displays, examine effective comparison screen content, improve to a system and design with less trouble and resistance to installation, and so forth. The author's plan is to proceed with development to make this a system for promoting energy-saving behavior and environment adjustment behavior, and a tool for management of energy consumption, and safety, health and comfort.

ABSTRACT

The World Health Organisation (WHO) stated that air pollution is the world's largest single environmental health risk, and this risk is particularly high in urban areas (WHO, 2014). Heavy traffic, high population density and packed city morphology with deep street canyons have resulted in a very high level of harmful outdoor pollutants in major cities like Hong Kong. Nevertheless, buildings still need to take in "fresh air" from the outside for their occupants. As the outdoor air remains unhealthy, the impact of bringing it into the indoor air environment needs to be further clarified.

This study focuses on the relationship between indoor and outdoor air quality, and examines how outdoor air quality varies with height in the urban street canyon. Field measurements were conducted in a high-rise office building located in a densely populated district in Hong Kong. Using the data collected, analyses were performed to check if the indoor air quality could meet the WHO daily average PM2.5 standard of 25 $\mu g/m^3$ and CO_2 concentration of less than 1000 ppm.

Our result shows there can be an effective reduction of PM2.5 from outdoor to indoor, and a satisfactory CO_2 level in the building. Outside the building, our measurements show complex vertical variations of PM2.5 with the height that are different from what is expected from simple boundary layer theory. This may be related to the complex urban morphology and the vigorous vertical mixing within the urban street canyon. Nevertheless, even with such complexity, our results also show that it is still possible to have a building operate properly to provide a healthy indoor environment for the occupants, despite the relatively polluted outdoor environment.

Keywords: indoor environmental quality, dense urban environment, street canyon, particulate matter, CO_2 concentration

1. INTRODUCTION

With the release of hourly PM2.5 data in China in 2013, the public's concern for poor air quality has grown substantially. The improvement of local air quality has become a top priority in cities around the country. The air pollution problem is the most serious in major cities, where rapid urbanization and vehicular traffic in deep street canyons have led to serious deterioration of air quality.

Apart from outdoor pollution, one also needs to worry about indoor air quality, as people spend most of their time indoors. Indoor air quality relates to the health and comfort of the occupants inside a building. The US Occupational Safety and Health Administration estimated that poor indoor air quality costs employers US$15 billion annually, including death, sick leaves and worker inefficiency (Black, 2014).

2. METHODOLOGY

2.1. Site description

This study focuses on an 18-storey commercial building with a combination of shopping mall and commercial offices, located in Tsim Sha Tsui, one of the earliest districts developed after the British took control of Hong Kong in the 19th century. Tsim Sha Tsui has since evolved into a major commercial, shopping and tourist district, with a lot of shopping malls, restaurants, residential and office buildings, and heavy traffic throughout the day. The 18-floor building examined in this study is of average height in Tsim Sha Tsui, with both higher and lower buildings in its vicinity. This building is one block away from the main transport route, and hence the roads surrounding it are neither too quiet nor too congested. It is therefore a good candidate to study in order to understand the typical indoor impact of outdoor air pollutants in the district. Moreover, the building adopts a floor-based central air-conditioning system, and each floor has an individual fresh air-intake and distribution system. This enables us to also examine the variation of outdoor air quality as a function of height in the vicinity of the building.

2.2. Parameters

CO_2 and PM2.5 are the pollutants selected in this study. In the absence of indoor combustion sources, CO_2 levels in an enclosed environment are related to the number of occupants and the effectiveness of the ventilation system. Although there appears no long-term health impact from CO_2 at levels typically found in the urban indoor environment, an elevated level of CO_2 may cause drowsiness, headache and lower productivity. In Hong Kong, the Indoor Air Quality Objectives for Office Buildings and Public Places classify indoor CO_2 level lower than 1000 ppm as 'Good', and those under 800 ppm as 'Excellent' (HKEPD, 2003).

PM2.5 refers to airborne particles with aerodynamic diameter less than 2.5 micrometers, including dust, soot, smoke and liquid droplets. Their small size allows them to penetrate deep into our bodies, including our lungs, heart and other major organs, causing serious health impacts. Hence, PM2.5 is one of the most significant pollutants to be monitored. The WHO Air Quality Guidelines recommends that the 24-hour average PM2.5 concentration should not exceed 25 μg/m3 (WHO, 2005). In urban areas, vehicular emission is the main source of PM2.5 outdoors, and fuel combustion (e.g. cooking) is the main source indoors. In office buildings without combustion sources, indoor emission of PM2.5 should be quite limited.

2.3. Measurement protocol

In this study, the TSI Model 7575 Multifunction IAQ Meter with IAQ Probe 982 (QTrak) was used to measure CO_2, and the TSI DustTrak Aerosol Monitor 8530 (DustTrak) was used to measure PM2.5. In our study, these two portable pieces of equipment were placed together in a backpack, and two backpacks (i.e. two QTrak and two Dustrak sensors) were used in the field measurements. One backpack was used to measure the air quality outdoors and the other was for indoors.

To ensure data reliability, all the portable instruments were first calibrated against stationary, research-grade air quality instruments at the university. The PM2.5 and CO_2 measurements from the DustTrak and Qtrak were compared with corresponding measurements by the Thermo Scientific Synchronized Hybrid Ambient Real-time Particulate 5030 Monitor and the Teledyne Gas Analyzer 360E System, respectively.

During each day of the field measurements, two researchers collected the two backpacks at the university laboratory early in the morning, started the recording, and then carried them side-by-side to the building site via public transport. At the end of each day's work, the two backpacks were also placed side-by-side for an hour in the building, and then they were carried back together to the laboratory for data download and equipment charging overnight. This protocol dictates that there would be three extended periods of collected data measurements by the two backpacks in different microenvironments. The accuracy and precision of the air quality data (PM2.5 and CO_2) from the portable sensors can hence be obtained. This protocol allows easy detection of drift and/or failure that is quite common for such portable sensors. Agreement of the collocated measurements at the beginning and the end of a day's work can also assure us of the quality of the measurements when the backpacks were placed separately to measure the air quality indoors and outdoors. Finally, the researchers were also asked to keep logs of their positions, and to take pictures and log remarks if they come across events that may affect local air quality.

2.4. Measurement design

Figure 1 shows the typical floor plan of the sampled building. There was a fan room with louvers to allow air intake into a central air-conditioning system on each floor. In this study, measurements taken near the louvers in the fan room were used to represent the outdoor air quality, and measurements taken at the lift lobby were used to represent the indoor air quality for that floor. Moreover, measurements taken at a 2/F terrace were used to indicate the near ground outdoor air quality.

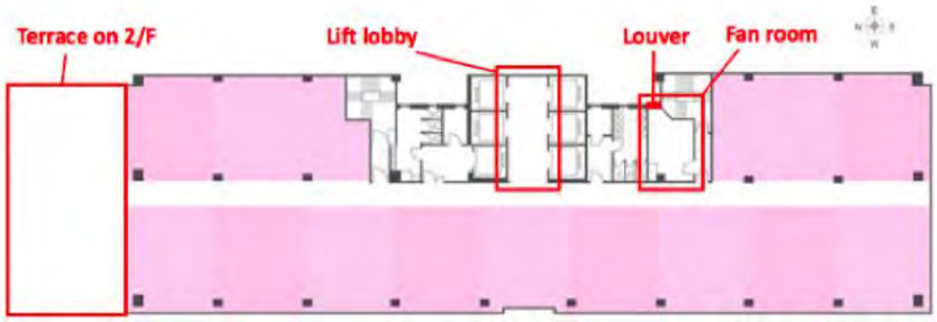

Figure 1: Floor plan of the sampled building

Two measurement programs were designed for the two objectives. For the indoor to outdoor ratio study, backpack 1 was used to measure indoor air quality at the lift lobby and backpack 2 was used to measure outdoor air quality in the fan room. The two backpacks started at the 4/F and moved up to 6/F, 8/F, 10/F, 12/F and 15/F in pairs every one hour. For the study of vertical variations in outdoor air quality, backpack 1 was placed at the 2/F terrace to measure the outdoor air quality at the reference floor throughout the measurement period, while backpack 2 was used to measure the outdoor air quality in the fan room from 4/F to 6/F, 8/F, 10/F, 12/F and 15/F for an hour each. These measurements were completed during the regular office hours from 9 am to 5 pm. Then, the two backpacks were placed together at 2/F for an hour of collocated measurements at the building site. Measurements were also carried out during the trips to and from the sampling site to allow rigorous data quality checks of the portable equipment throughout the measurement period.

3. ANALYSIS METHODOLOGY

3.1 Indoor to outdoor ratio

For both CO_2 and PM2.5, an hourly indoor to outdoor (IO) ratio and the five-day averaged IO ratio are calculated for each floor.

3.2 Vertical variations of outdoor air quality around the building

Vertical variations of outdoor CO_2 and PM2.5 concentrations as a function of height were determined by normalizing (dividing) the measured concentrations at different floors against those measured at the 2/F. Ratios greater or smaller than one indicate that the measured concentrations at the higher floors are larger or smaller, respectively, than the corresponding concentration at the 2/F. The Student's t-test with *p*-value 0.05 was used to check the statistical significance of data.

4. FINDINGS

4.1 Indoor to outdoor ratio for CO_2

Floor/ Date	18/01/16	19/01/16	20/01/16	21/01/16	22/01/16	Average
4/F	1.3	1.6	1.6	1.4	1.5	1.5
6/F	3.0	2.2	2.8	2.3	2.4	2.6
8/F	1.7	1.5	1.5	1.5	1.4	1.5
10/F	2.3	2.1	2.3	2.1	2.0	2.2
12/F	2.2	2.3	2.3	2.0	1.9	2.2
15/F	2.2	2.2	1.9	2.3	--	2.2*
18/F	2.1	1.9	2.1	1.8	--	2.0*

-- Equipment failure * 4-day averages

Table 1 Summary of the indoor to outdoor ratio for CO_2 in different days

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Our results show that the CO_2 concentrations in indoor areas are higher than that of outdoor areas, and the averaged IO ratio for CO_2 ranging from 1.5 to 2.6. This is consistent with our understanding that indoor CO_2 concentrations should be higher as a result of the respiratory production of CO_2 by the building occupants.

Furthermore, we found that almost all the indoor CO_2concentrations were in the Excellent (< 800 ppm) or Good (< 1000 ppm) class (HKEPD, 2003), except for one case for the 6/F on 18th Jan, when the indoor CO_2 concentration was recorded as 1350 ppm. Our observation log noted heavier-than-normal human traffic during that morning, which may have contributed to the higher CO_2 concentration recorded.

Nevertheless, the CO_2 levels at all floors are considered safe and unlikely to cause adverse health impacts like headache, nausea or dizziness, as these symptoms are not expected for CO_2 concentrations less than 5000 ppm.

4.2 Indoor to outdoor ratio for PM2.5

Floor/ Date	18/01/16	19/01/16	20/01/16	21/01/16	22/01/16	Average
4/F	0.34	0.24	0.25	0.16	0.28	0.25
6/F	0.37	0.42	0.37	0.50	0.36	0.40
8/F	--	0.34	0.42	0.36	0.45	0.39*
10/F	--	0.24	0.25	0.25	0.21	0.24*
12/F	--	0.27	0.33	0.32	0.47	0.35*
15/F	0.41	0.41	0.51	0.36	0.48	0.43
18/F	0.21	0.17	0.38	0.19	0.29	0.27

-- Equipment failure * 4-day averages

Table 2: Summary of the indoor to outdoor ratio for $PM_{2.5}$ for different days

Our measurements show that all IO ratios of PM2.5 are significantly less than 1, showing substantial reduction of PM2.5 through the central air-conditioning and filtration system in the selected building. We further note that the hourly outdoor average PM2.5 levels were mostly above 25 $\mu g/m^3$, while all of the hourly indoor average PM2.5 levels were below 25 $\mu g/m^3$; the highest hourly indoor PM2.5 concentration of 17 $\mu g/m^3$ were measured on the 6/F on Jan 20th. 25 $\mu g/m^3$ is the WHO daily average Air Quality Guideline for PM2.5 (WHO, 2005). Our results showing that all the hourly average indoor PM2.5 concentrations were below this guideline value indicate that the central air-conditioning and filtration system in the sampled building has been effective in maintaining good air quality with respect to PM2.5 during our measurement period.

4.3 Vertical variations of outdoor CO_2

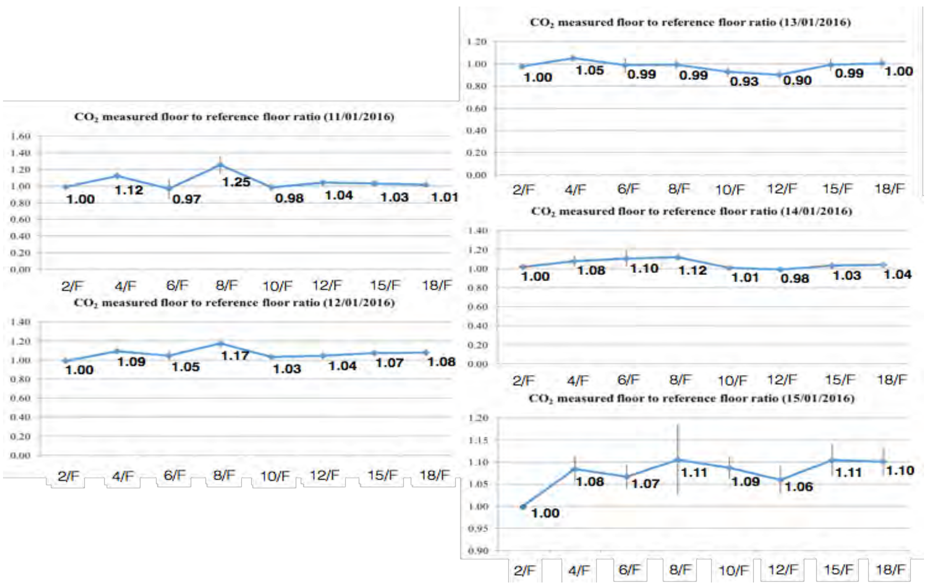

Figure 2:Normalized plots of CO_2 levels in measured floors to reference floor in different days (Error-bars denote ±1 standard deviation)

Figure 2 shows the average ratios of outdoor CO_2 concentrations at different floor heights with respect to the corresponding outdoor CO_2 concentration at the reference level on 2/F for different measurement days; error-bars at one standard deviation are also shown. It is found that the ratios were all very near one, suggesting that in the urban environment surrounding the selected building, the vertical variations of CO_2 from the surface to the top of this 18-storey building is very limited, if any.

4.4 Vertical variations of outdoor PM2.5

Figure 3 shows the average ratios of outdoor PM2.5 concentrations at different floor heights with respect to the corresponding outdoor PM2.5 concentration at the 2/F reference level for different measurement days; error-bars at one standard deviation are also shown. Different from CO_2, there appears more vertical variation with height in the outdoor PM2.5 concentrations, and the variations are quite complex.

In particular, there was an apparent concave shape in the vertical variations of PM2.5 concentration with height, with maximum PM2.5 level occurring between the 8/F to 12/F and lower PM2.5 concentrations above and below these levels for most days, except on the 13th Jan 2016 when the maximum PM2.5 level occurred around the 4/F. This is quite different from what one would have expected from simple boundary layer theory that predicts a gradual drop in PM2.5 with height.

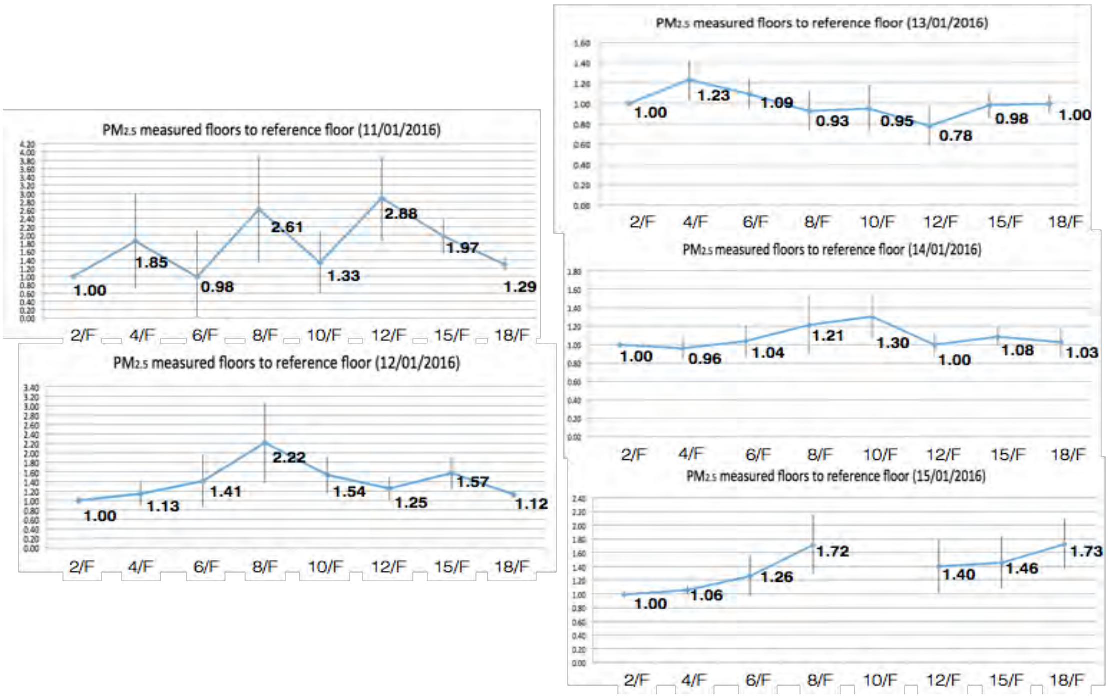

Figure 3: Normalized plots of $PM_{2.5}$ levels in measured floors to reference floor in different days (Error-bars denote ±1 standard deviation)

To better understand the possible cause(s) of this unexpected vertical variation in PM2.5 concentration, we examined the built morphology around our sampled building. Figure 4 shows the building heights of our sampled building (shown in grey) and a few buildings around it along an east-west cross-section. We noticed that there is a shorter building to the immediate east of our sampled building and its roof is approximate at the same level as the 8/F of our sampled building. We also note that from Figure 1 that the fan rooms are on the eastern side of our sampled building.

These configurations make us suspect that the wind circulation may have become more complicated and have affected the average vertical distribution of PM2.5 on the eastern side of the sampled building. To assess that possibility, a computational fluid dynamics (CFD) run using the built morphology shown in Figure 4 was conducted. Average wind data recorded at the Hong Kong Observatory over the measurement period was used as background wind to drive the CFD model.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The prevailing wind direction during our sampling period was easterly, and the average wind speed simulated in the CFD model is shown in Figure 4, which shows a recirculation cell next to our sampled building and on the top of the roof of the shorter building to the east. Under the influence of such a recirculation cell, the wind speeds around the 8/F floor on top of the adjacent building would be reduced, and trapping enhancement of pollutants like PM2.5 could occur there.

Further, the recirculation cell can help re-suspend particulates deposited on the rooftop of the adjacent building, leading to a high concentration of PM2.5 just above its roof top level of 8/F in our sampled building. Lastly, we have not checked whether there was any exhaust on the rooftop of the shorter building, which (if exists) could also increase the local PM2.5 around that level.

In summary, our measurements show that, near our sampled building, the vertical variation of outdoor PM2.5 is complex, with maximum PM2.5 concentration between 8/F to 12/F, which is different from a decreasing distribution from the ground expected from simple boundary layer theory. The complex built morphology, the re-entrainment of pollutants from nearby rooftops, or exhaust emissions from nearby rooftops may have contributed to this difference.

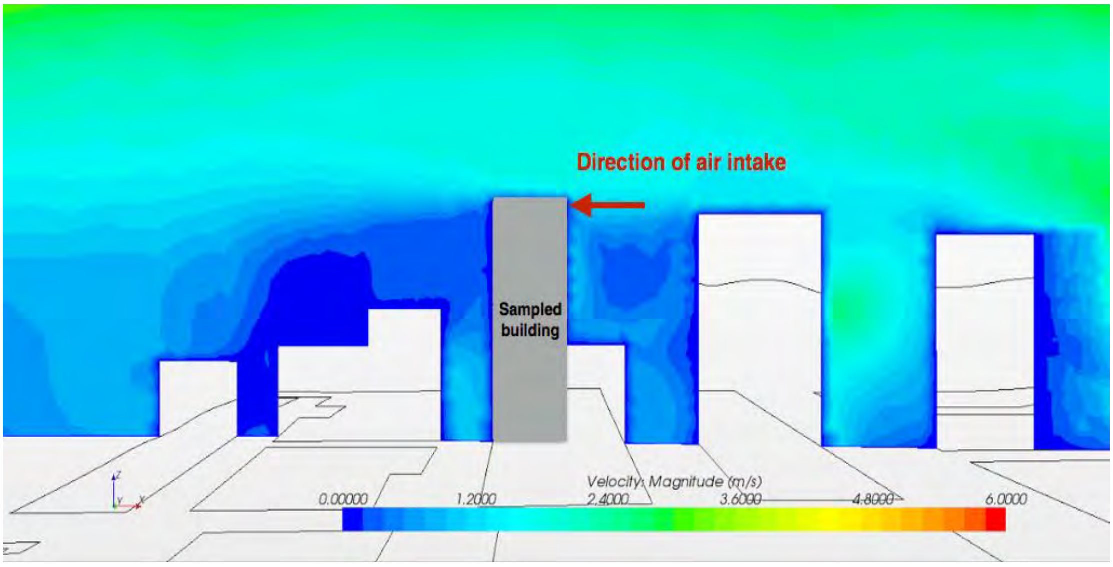

Figure 4 Simulation of wind motion at the sampled building during 11/1/2016-15/1/2016

5. CONCLUSION

This study examines the indoor to outdoor ratio of CO_2 and $PM_{2.5}$ in a typical commercial building in a densely populated urban metropolis. We found that the average indoor to outdoor ratio for CO_2 ranged from 1.5 to 2.6, and the average indoor to outdoor ratio for $PM_{2.5}$ ranged from 0.24 to 0.43 in our sampled building.

Moreover, the air-conditioning and filtration system of the building was able to keep most of the indoor CO_2 concentrations below 1000 ppm, and the hourly indoor $PM_{2.5}$ concentration below the WHO daily guideline for $PM_{2.5}$ at 25 µg/m^3, despite the outdoor $PM_{2.5}$ concentrations that exceeded this guideline level most of the time. These results show that it is possible to have a building managed properly to provide a healthy indoor environment for the occupants despite a relatively polluted outdoor environment.

Taking advantage of the fan rooms at different levels, we also examined the vertical variations of CO_2 and $PM_{2.5}$ in the outdoor environment. We found little vertical variation in CO_2 concentration from the ground to the top of our sampled building. On the other hand, we found that the vertical distribution of $PM_{2.5}$ around the sampled building to be more complicated (with highest $PM_{2.5}$ concentration between 8/F to 12/F) and different from what is predicted by simple boundary layer mixing theory. Subsequent CFD analysis suggests that this may be related to the microenvironmental flow created by the complex urban morphology. Hence, our results suggest that one should not assume pollutant concentrations must be decreasing with height in complex urban environments. More detailed analysis and simulations are needed.

Redesigning Long-Term Senior Care: Design Solutions to Facilitate Different Levels of Care Needs in Senior Housing - Using Hong Kong's Latest Senior Housing as Example

Bryant LU[a]

[a] *Ronald Lu & Partners, Hong Kong SAR, bryantlu@rlphk.com*

ABSTRACT

Over the next two decades, between 2017 and 2037, China will see an enormous increase in its population of senior citizens (people over 65). This increase will result in two hundred million seniors needing to be accommodated. In Hong Kong, the issue of an aging society is even more critical: in just 15 years, the city will need to accommodate another one million seniors, one-seventh of its current total population.

Thanks to advances in healthcare and technology, today's seniors are expected to enjoy a dynamic and high-quality lifestyle for a much longer period of time after they retire. The extended lifespan of these "new generation senior citizens" poses a number of uncertainties and unprecedented challenges in terms of the design of senior housing and the provision of sustainable elements – these designs need to be adapted to help seniors enjoy their dynamic lifestyle as well as assist them through the aging process.

This paper explores how the different stages of life and aging are categorised in different countries and which long-term senior care needs are associated with these categorisations. It also investigates the country-specific regulations and guidelines formulated for the needs of seniors, and discusses how design solutions can facilitate their implementation. Japan, Australia and Canada have comprehensive pension and senior care policies. Their long-term care systems were studied in this paper.

Lastly, the paper discusses two senior housing projects in Hong Kong, Harmony Place and The Tanner Hill, as case studies. The paper concludes four design strategies that will help achieve sustainable long-term senior care in housing developments in China and Hong Kong.

1. THE AGEING TREND IN THE POLULATION OF CHINA AND HONG KONG

1.1 Rapid ageing

The ageing of China's population has become more apparent as it enters the 21st century. According to scholar Florian Coulmas' definition of an ageing society in his study on Japan, a country is an 'ageing society' when its seniors (aged 65+) account for 7% of the total population. It becomes an 'aged society' when the percentage rises to 14%, and a 'hyper-aged society' when the percentage reaches 21% (Figure 1). According to the census and forecast data of the World Health Organization, China became an ageing society in 2000, and will become a hyper-aged society come 2040.

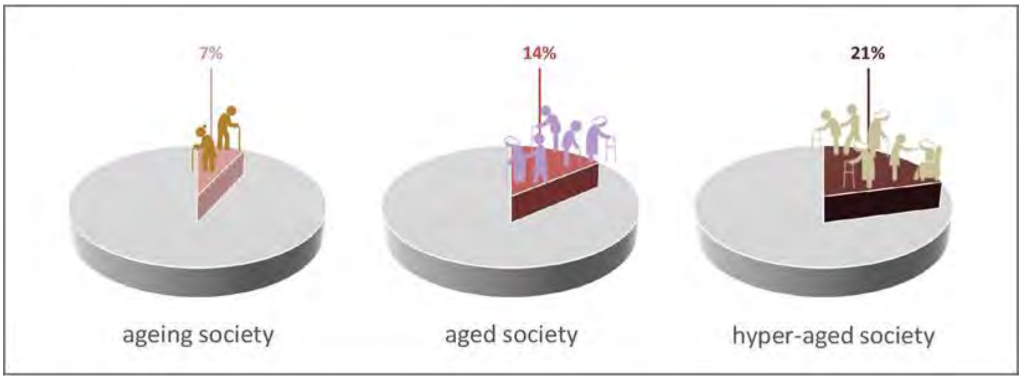

Figure 1: Definition of "ageing society", "aged society" and "hyper-aged society"

Based on the ageing rate, China will enter a period of rapid ageing after 2030. It takes 30 years (2000 - 2030) for an ageing society to become an aged society, but it takes only 10 years (2030 - 2040) for it to move further into a hyper-aged society. As far as the senior ratio is concerned, it takes merely 22 years (2010 - 2032) for it to double to 25%. It is estimated that by mid-century, China's senior ratio will reach its peak, with one-quarter of its population aged 65+. This ratio is higher than the definition for a hyper-aged society, and far higher than the world average (Figure 2).

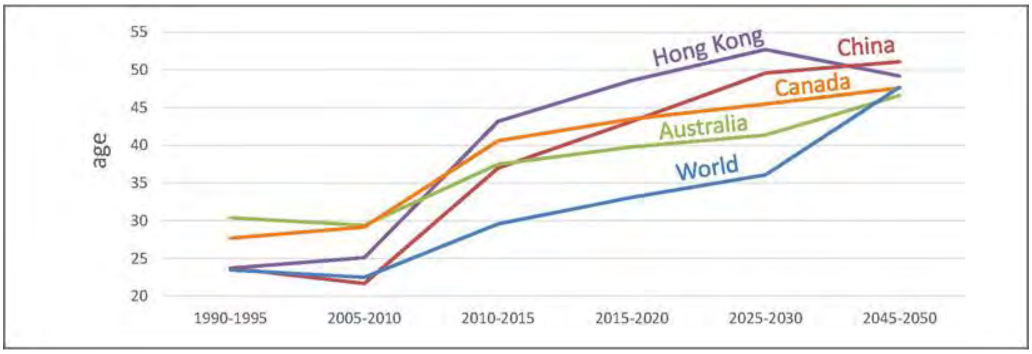

Figure 2: Median age of population in China, Hong Kong and other countries
(Source: United Nations, Department of Economic and Social Affairs, Population Division (2015). World Population Prospects: The 2015 Revision. New York: United Nations)

Although the senior ratio at its peak in China is still far lower than some of the developed and developing countries (such as Japan and Singapore, etc.), in terms of absolute numbers, it still represents an enormous growth, and the number of seniors has long topped the global league. It took Hong Kong and China merely 30 years from the end of the last century to evolve from an ageing society into an aged society, a speed that far surpasses the ageing process of developed countries at the beginning of the last century (Figure 3).

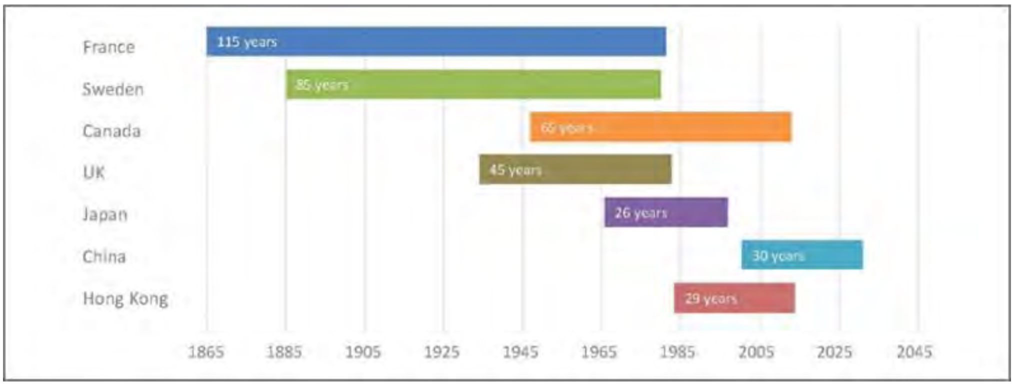

Figure 3: Time required for seniors of various countries to grow from 7% to 14%
(Source: United Nations University, and WHO Kobe Centre. "The Wisdom Years: Ageing into the 21st Century". http://wisdom.unu.edu/en/ageing-societies/index.html and United Nations, Department of Economic and Social Affairs, Population Division (2015). World Population Prospects: The 2015 Revision. New York: United Nations)

So what are the implications for the economy of a rapid rise in population and an enormous number of seniors? Statistically, China will, within the next two decades (2017-2037), have an added 200 million seniors (aged 65+), which is equivalent to Japan's current population x2 (Figure 4). This means society must now make provisions for the many challenges brought about by these 200 million seniors.

Compared with China as a whole, Hong Kong's ageing population problem is even more serious. Its senior population will grow by close to a million within 15 years (2014-2029) (Figure 5). Seniors numbered 1 million in 2014, accounting for 15% of the population, but rapid growth will take the numbers to 2 million and 26% respectively in 2029. It will be a serious challenge to provide housing and related senior care services for these additional 1 million seniors in the next 10 to 15 years.

1.2 The extension of senior living

Following the ageing in the population, there is also an extension in the period of senior living. As the general retirement age in China is around the age of 60, related rule and regulations and definitions on senior care are also based on 60 years of age. Consequently, the drastic changes in the lifestyle of a senior actually precede his physiological changes.

Due to historical reasons, and using 60 years of age as the cut-off point, the growth in the ratio of younger seniors will be more rapid than those in the 65+ group. At its peak, one-third of the population could be over 60 years of age. Therefore, the number of people approaching or entering a senior lifestyle could exceed the number based on physiological grounds.

There is a continued rise in life expectancy in China, exceeding the age of 80 at mid-century when the number of seniors reaches its zenith. In other words, seniors will, in future, enjoy more than 20 years of old-age living. The situation in Hong Kong is even more pronounced, as its general life expectancy will remain on top from now until mid-century (Figure 6). Between 2045 and 2050, its life expectancy is close to 90 years of age, meaning that Hong Kong seniors will enjoy almost 30 years of old-age living. The extension of senior living creates different demands on senior care services and housing facilities.

2. DIFFERENT LEVELS OF SENIOR CARE IN OVERSEAS COUNTRIES

2.1 Levels of care based on age in Canada

In the population ageing process, the speed of ageing and the physiological changes vary based on age. The speed of physiological decline varies from person to person, but is largely related to age. The decline in body functions must be matched by an appropriate level of care, therefore different age brackets are often used to determine the level of care. According to the Canadian Department of Health definitions in the 1990s, 60+ senior care is divided into three categories:

- Independent self-care: Generally refers to from retirement to 75 years of age (varying according to individuals). Seniors in this category have not experienced serious decline in their body functions, and may only require simple assistance for certain activities. They can choose to live independently, or in nursing homes that provide only basic lodging facilities. They can seek limited care services as required. From the age point of view, independent self-care is the most important stage of senior care.
- Semi-independent: Generally refers to 72+ of age. Seniors in this category have undergone certain levels of decline physiologically, and would find it difficult to stay fully independent. They would be recommended to choose nursing homes that provide basic care services.
- Full care 1: Generally refers to 79+ of age. Seniors in this category have experienced a higher level of decline. A full-service nursing home would provide the needed care.
- Full care 2: Generally refers to 84+ of age. Depending on individuals, seniors in this category may need to live in a nursing home or an associated medical care facility indefinitely.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.2 Different levels of senior care and daily assistance facilities in Japan

In 1997, Japan introduced standards for long-term senior care needs. The assessment divided senior living self-care capabilities into 7 categories, viz, independent, assistance needed, and care services needed (class I to V). 'Independent' seniors refer to those who can live independently without any assistance. 'Assistance needed' seniors refer to those who can basically live by themselves, but may need assistance for social activities. 'Care needed' seniors class I refer to those who need some care; class II refer to those who need a low level of care; class III refer to those who need a medium level of care; class IV refer to those who need a high level of care; and class V refer to those who need the highest level of care.

In 2006, Japan revised the standards from the original 7 categories into 8 categories by splitting the 'assistance needed' category into class I and II. It also re-confirmed that all 'care services needed' categories require care services.

The long-term senior care classification is not solely based on the individual's health condition, but also on the time needed for the care services, and the level of care needed. Initially, Japan adopted a method of measuring the degree of care per minute for the sake of standardization. They assigned a bar code for each type of care services, and then recorded two consecutive days of care services data. After electronic processing, they worked out the degree of care on a per minute basis, and came up with the time required for individual care services, and hence the basis for classification.

However, the resultant data can show a significant difference from the actual time, and tend to push the services onto a higher category. By using a number of other approaches, the Japanese government improved on the original software in 2003. They put all the care services through a statistical analysis, and based on their inter-relationships, devised a tree-like model in order to measure the care time. In deciding on the classification, they take into consideration the seniors' physical and psychological well-being, and their medical diagnosis.

Based on the time required for the care services, the classification works out as follows: independent - below 25 points; assistance needed: 25 - 32 points; care needed - class I: 32 - 50 points, class II: 50 - 70 points, class III: 70 - 90 points, class IV: 90 - 110 points, and class V: 110+ points (Figure 8).

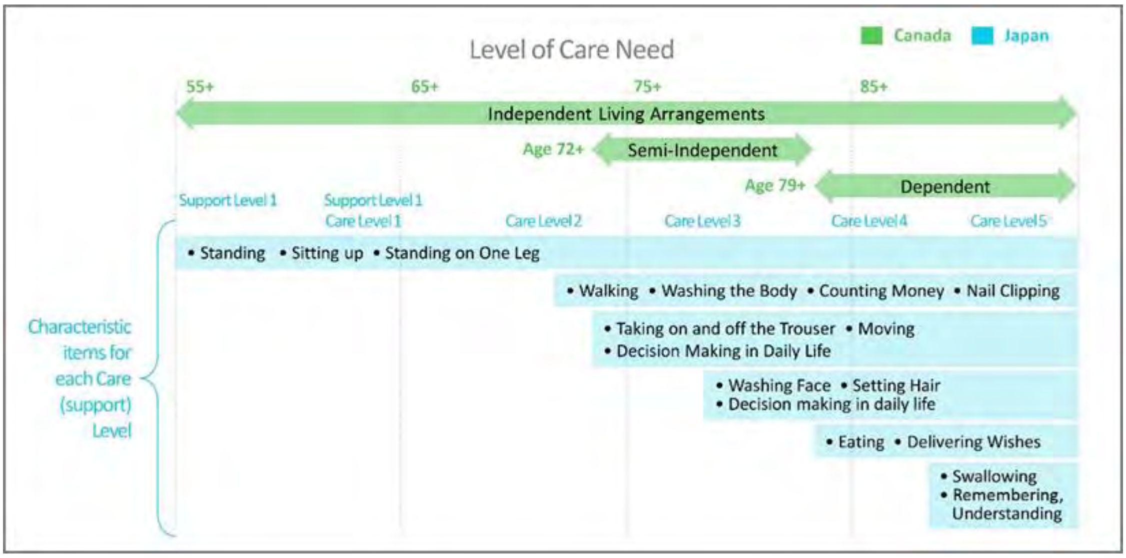

Figure 8: Canadian senior classification and Japanese senior care classification

2.3 Different levels of senior care system and policy in Australia

Based on different levels of senior care needs, Australia divides its hostel type of senior care, or the traditional nursing homes, into three categories. Its low level care allows the seniors to lead an independent life, but receive, at the same time, assistance with meals, washing, personal matters and care. The typical mode of operation is the specialized serviced apartments for seniors. Its high level care provides 24-hour care, in addition to meals, washing, cleaning, health care and personal care. The typical mode of operation is the traditional nursing home. Hospice

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

care provides for specialized care and medical attention for seniors with a terminal illness, making sure that patients enjoy a quality life to the very end.

As the majority of seniors opt for a low level of care and only parts of the high level care, a substantial portion of Australian seniors prefer to remain at home, or live in the local community with access to care services. Some seriously ill seniors or those with Alzheimer's disease also share the same preference. In order that these people can receive the same level of care services as in nursing homes, the Australian government has, in recent years, reinforced its support for community care services, and has, since August 2012, included community care services for Alzheimer's disease sufferers in the National Health Priority Area.

Currently, Australia has a very comprehensive community care service, and can provide for bespoke services to meet specific needs. Therefore, seniors can enjoy a longer period of independent living. This not only leads to very obvious social benefits, but also alleviates the pressure on nursing homes, thereby reducing social costs.

Based on different classes of care, Australia's community care services include:

- Home and community care (HACC): It includes seniors' daily care and health care services, home services, meals, transport, and repairs & maintenance.
- Community aged care project (CACP): It provides a variety of care services for seniors or those in weak health, and seniors with more complex needs.
- Long-term home care project: It provides for more flexible and personal services than CACP for those who need a high level of care.

2.4 Classification of current senior care policy in China

Currently, China's "Basic Policy of Social Welfare Agencies for Seniors" divides the care needs of people of 60+ years of age into three categories:

Self-care: Fully independent in everyday life without relying on others;

Device-aided: Relies on railing, walking stick, wheelchair and elevator in everyday life;

Nursing-cared elderly: Relies on care services in everyday life.

Based on the care needs of different age groups, the policy provides guidelines on the range of specific services (Figure 9).

For self-care seniors: Daily cleaning to ensure there are no flies, mosquitoes, rats, cockroaches and bugs; provision of clean, proper clothes plus washing (weekly in winter, spring and autumn, and more regularly in summer); maintaining a flow of fresh air; assistance with bedding management; weekly replacement of blanket cover, bed sheet and pillow cover (including immediate replacement as necessary); 2 bathing sessions per week in summer, one in other seasons; reminders on washing and cutting hair, and nail clipping; 24-hour care services based on established procedures; and adjustment of services depending on circumstances.

For device-aided seniors: Daily cleaning to ensure there are no flies, mosquitoes, rats, cockroaches and bugs; provision of clean, proper clothes plus washing (weekly in winter, spring and autumn, and more regularly in summer); maintaining a flow of fresh air; assistance with bedding management; weekly replacement of blanket cover, bed sheet and pillow cover (including immediate replacement as necessary); 2 bathing sessions per week in summer, one in other seasons; assistance with washing hair and nail clipping; regular barber service to ensure proper grooming; regular washing of towels and cleaning of wash basin; weekly toilet disinfection; assistance with visits to the toilet; 24-hour care services based on established procedures; and adjustment of services depending on circumstances.

For nursing-cared elderly: Daily cleaning to ensure there are no flies, mosquitoes, rats, cockroaches and bugs; provision of clean, proper clothes plus washing (weekly in winter, spring and autumn, and more regularly in summer); maintaining a flow of fresh air; assistance with bedding management; weekly replacement of blanket cover, bed sheet and pillow cover (including immediate replacement as necessary); assistance with dressing in the morning and undressing at night; 2 bathing sessions per week; regular hair washing and nail clipping; dental care; regular barber service to ensure proper grooming; regular washing of towels and cleaning of wash basin; weekly toilet disinfection; meal delivery and feeding; assistance with visits to the toilet; provision of walking stick, wheelchair and other devices as needed; assistance with personal cleaning in the morning and feet washing in the evening; weather permitting, accompanying the elderly daily for a one-hour session of outdoor activities; 24-hour care services based on established procedures; adjustment of services depending on circumstances; assistance with purchasing tickets for travel; special protection for females, the intellectually handicapped and those suffering from mental illness; and special provisions for elderlies with communicable diseases, including isolation arrangements and treatment, based on the principle of maintaining their dignity and consideration for others.

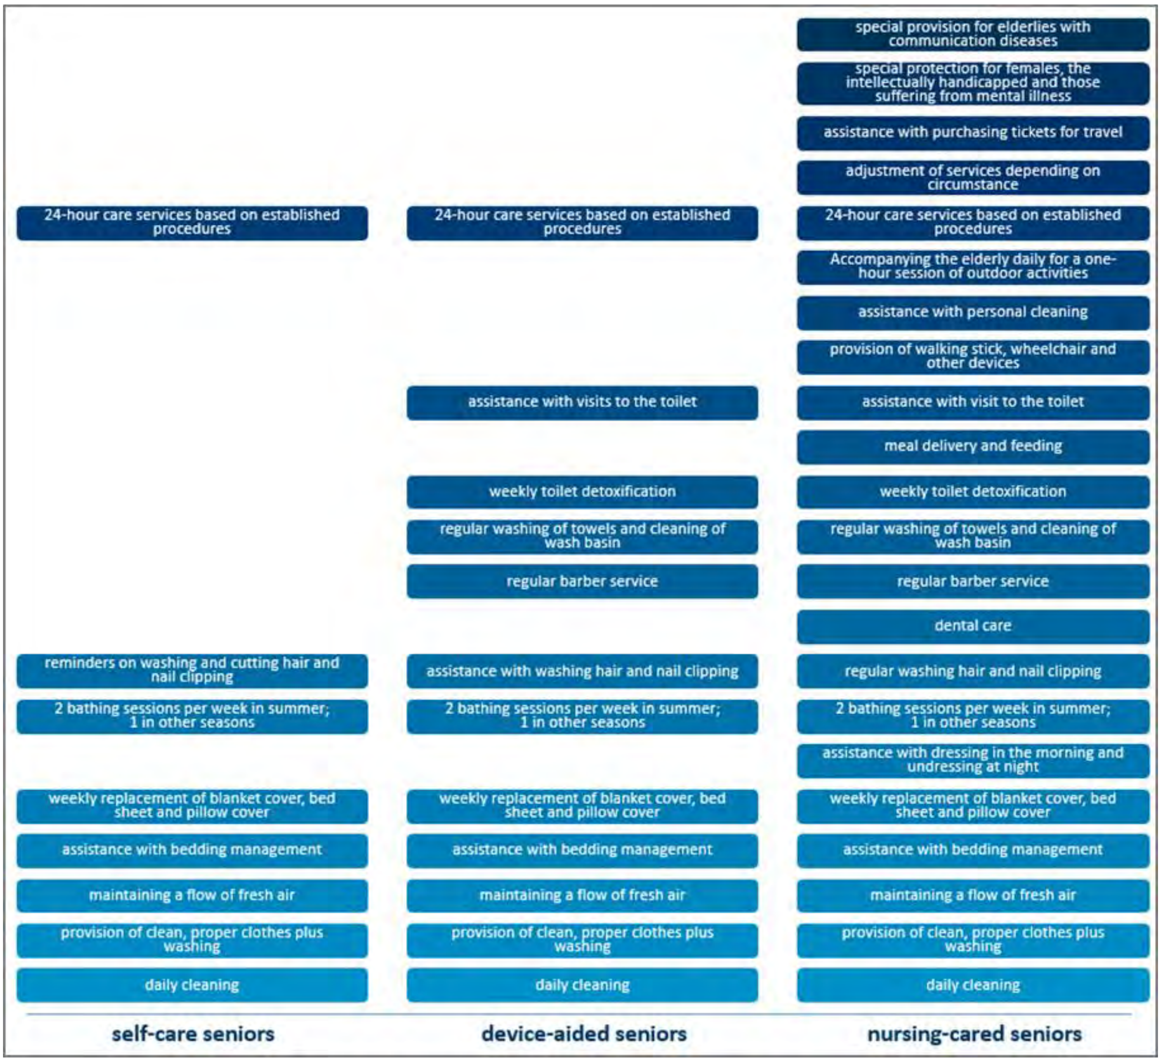

Figure 9: Guidelines on the range of specific services to be provided to different age groups with different care needs

To meet the different levels of care needs, China's senior care facilities feature different modes:

- Homes for the Aged: Cater to seniors who are independent, need assistance or care. They provide lodging, entertainment, rehabilitation and medical care services.
- Hostels for the Elderly: Provides communal living facilities for the elderly, including meals, hygiene, entertainment and medical care services.
- Homes for the Device-aided Elderly: Provides assistance to the elderly, including lodging, entertainment, rehabilitation, and medical care services.
- Nursing Homes: Provides care services to the elderly, including lodging, entertainment, rehabilitation, and medical care services.

- Homes for the Elderly in the Rural Areas: Provides services for those without certified volunteer helper, or with certified volunteer helper who does not have the capability to provide care services; those who are incapable; and those who have no sources of income. Services encompass meals, clothing, lodging, medical care and funeral services, in addition to entertainment and rehabilitation.
- Nursery for the Elderly: Provides short-term (day care, full care and contingency care) services, including lodging, entertainment, rehabilitation, and medical care services.
- Center of Service for the Elderly: Provides a comprehensive range of social services, including entertainment, rehabilitation, medical care and home visit services.

3. ASSISTANCE AND DESIGNS GEARED TO THE NEEDS OF CHINESE SENIORS

3.1 Senior assistance principles

3.1.1 Evolution of the concept of senior care

Ageing population has become an important social issue in both China and Hong Kong. Census data show that China is fast becoming an ageing society, and the trend will intensify in the first half of the 21st century. But with the advances in medical science and the improvement in the physiology of seniors, the definition of old age is becoming out of sync with the actual rate of physiological decline.

Old age is the final stage of a person's life when physiological decline no longer allows the person to handle the demands of social activities. While a person can live with complete independence in his youth, he will begin to need special care as he gets older. Therefore, old age demands adjustments in one's lifestyle. The normal work life gives way to a complete withdrawal from work into a lifestyle that requires assistance. In other words, a retirement lifestyle.

But this concept is beginning to veer from actual practice. China established the retirement age at between 50 to 60 (for special jobs, it could be as early as 45), which no longer matches the actual rate of physiological decline. The majority of retirees at age 50 to 60 are still bubbling with energy, and physically they can keep up with the younger set both in lifestyle and, to some extent, in work. This situation looks set to continue for 10 to 20 years.

Nowadays, many people who have just entered the old age bracket choose to continue to live at home, until they become incapable of looking after themselves, because traditional hostels and nursing homes tend to focus on the physiological decline in seniors, and overlook their social and psychological needs. In providing a certain degree of medical care, these establishments should also respond to these demands, so that seniors can live their life to the full independently in the post-retirement period which may last for 20 years.

3.1.2 The psychology and social needs of younger seniors

Like their younger counterparts, seniors have a host of psychological needs that must be satisfied, in addition to their basic survival needs. They include:

A sense of security and affection: They long for care and attention; they would like to live in a familiar environment where everything is agreeable, or at least bearable.

Social recognition: They look for respect from people that matter.

Personal values and dignity: They look for the ideal life.

Besides physiological decline due to ageing, the change in his social role also triggers a psychological impact on the senior. This is especially apparent in the early stage of ageing when the abrupt change in his social role causes discomfort. Retirement leads to a change in lifestyle and the loss of his old circle of friends, personal values and social status. The decline in physique and consciousness, and the reduction in income lead to a progressive decline in a sense of security. Other traumas in life, like the loss of spouse, also demand a transition period of adjustment.

Traditionally, senior care facilities focus on medical services without sufficient attention to psychological adjustments and care for the seniors. Accommodation-wise, we need to create a comfortable and secure living

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

environment for them. On a social level, we should ease them into a new chapter of their lives by maintaining as much as possible their pre-retirement social life. If we prematurely limit their new lifestyle and social circle to their contemporaries, or even older people, as practiced in most nursery homes, they would find it very hard to make the necessary adjustments. Senior care establishments should encourage them, health permitting, to at least maintain a part of their previous lifestyle, continue to work to a certain degree, and to actively participate in community activities.

3.1.3 Medical care

When a senior falls ill, its severity could vary by a wide margin, so the best way is to send him expeditiously to the nearest medical facility for treatment. A senior, no matter he is living by himself or with his family normally could not afford a 24-hour medical care service, so senior housing should aim at being able to send the patient to hospital within a specified time, and providing the doctor with accurate and detailed data.

A doctor from resident medial services of a local private hospital points out that when they treat emergency cases of seniors, the crux lies in early detection and in whether those who accompany the patient can accurately determine its degree of seriousness. Doctor needs to know the patient’s condition to facilitate diagnosis and treatment. As time if of the essence, the trip to the emergency ward of the hospital must be as short as possible.

3.1.4 Domestic safety and convenience

Statistics shows that the majority of seniors who have had a domestic accident, such as slipping, would sustain a degree of injury. With their physiological decline, some of these injuries could cause serious harm, and it is often very difficult to recuperate. Therefore, domestic designs for seniors should take into account not only the convenience factor, but also the safety factor. The decline in physical capability means that seniors cannot independently deal with certain household chores, and require an appropriate level of assistance.

- Decline in memory and consciousness: Seniors are slow to react to changes in the domestic environment because of weakened sensory functions and memory, leading to accidents when they engage in day-to-day household matters and activities. Most younger seniors live alone, and even if they have company, they often perform certain functions by themselves, like taking a bath or going to the toilet. Therefore, there must be warning signs for any steps in the domestic environment. When accidents occur, such as a fire, an additional alarm system would minimize casualties.
- Decline in mobility: Seniors are physically not as strong as young people, and with ageing and/or illness, they would need a walking stick or wheelchair to facilitate movement. When there is insufficient support or the standing duration is too long, accidents will happen. Toilets equipped with railing support and anti-slippage designs will reduce the incidence of accidents.

3.2 Design strategy for senior housing

Ageing population has become a social problem that must be faced squarely in both China and Hong Kong. The composition of the senior population and the new trend of their health status mean that traditional senior care facilities lag far behind current needs, stretching into the next 50 years. The new generation of seniors are looking forward to a new model in senior care facilities, something that can provide assistance for 10 - 20 years of high-quality retirement living. Given proper assistance, seniors can maintain a lifestyle that is not vastly different from their youth. If their previously neglected psychological needs are met in addition to their physiological demands, they can make a smooth transition to a more advanced stage of ageing. In response to seniors’ multifarious needs, housing designs can make specific adjustments to provide for a high-quality senior lifestyle.

3.2.1 Private and social space

The abrupt change in the social role after retirement often causes discomfort for seniors, so social activities can maintain their contact with society and the community, thereby easing the feeling of loneliness. Seniors also feel that the private space they enjoyed while they were young have now been reduced to a certain extent, because of the need for care and assistance due to their physiological decline. As long as their safety is in place, we should let them enjoy as much of their serene private space as possible. At the same time, we should, through the provision of convenient space for social activities, meet their psychological desire for company or for participation in group activities (Figure 10).

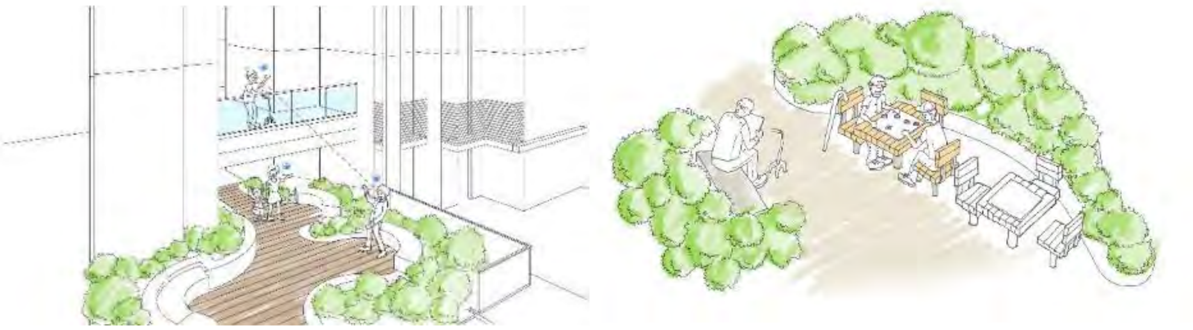

Figure 10: Social infrastructure and stimulation for establishing new friendships and interaction with peers

3.2.2 A comfortable and agreeable environment

Your submission must provide the details of the work to readers. It should be clearly divided into sections, with heading/ sub-headings, so that readers can follow the logical development of work. Using headings is a great way to organise the paper and to increase its readability, so make sure to format them correctly.

Seniors are comparatively more sensitive to environmental impacts such as noise and light pollution. The abrupt change in their social role and their ageing body have created a sense of insecurity, making them yearn for a comfortable and predictable living environment. If their building makes use of natural materials like timber, and opts for a warmer palette, they will nurture a more homey feel, and, at the same time, reduce the sensory impact and feeling of loneliness. Natural lights, ventilation and greenery not only improve the general hygiene indoors, but will also enhance the overall tranquillity and comfort level. Conditions permitting, we should let seniors come into contact with a green outdoors environment as much as possible (Figure 11).

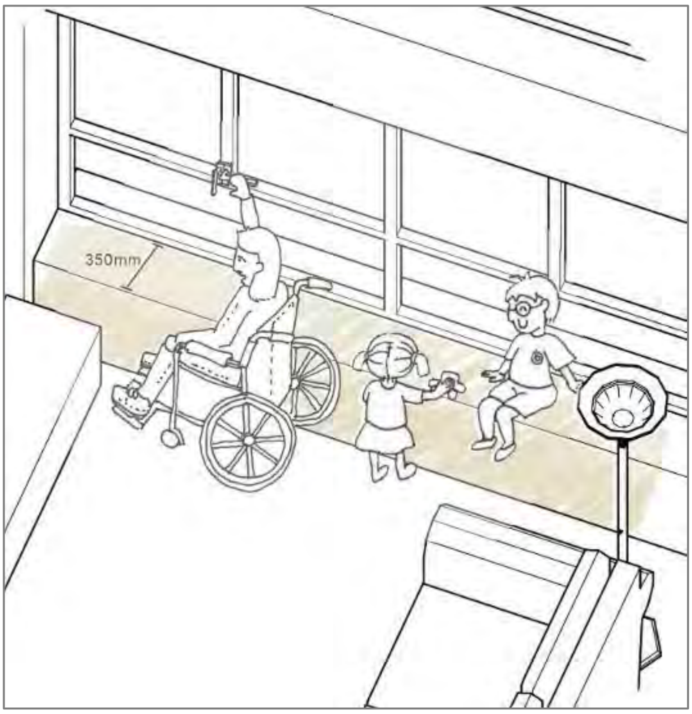

Figure 11: A shallow bay window and appropriate window designs would facilitate lighting and ventilation, and enables seniors to open/ close them more easily.

3.2.3 Prominent signage

To enable seniors to familiarize with their living environment and understand any changes, both interior and exterior signage should be bold and clear. For example, each floor level and emergency exits should be marked in bigger fonts and in strong colours, so that those with poor eyesight can easily read them (Figure 12). The front door peep-hole should be installed at both standing and wheelchair levels, so that seniors can identify visitors at various stages of their mobility (Figure 13). Corridors and partitions should be installed with built-in night lights, so that seniors do not have to grope for the light switch; and they should be soft enough as not to affect sleep. Other safety installations, like smoke sensors and fire alarms, should be set at levels that are visible to wheelchair users.

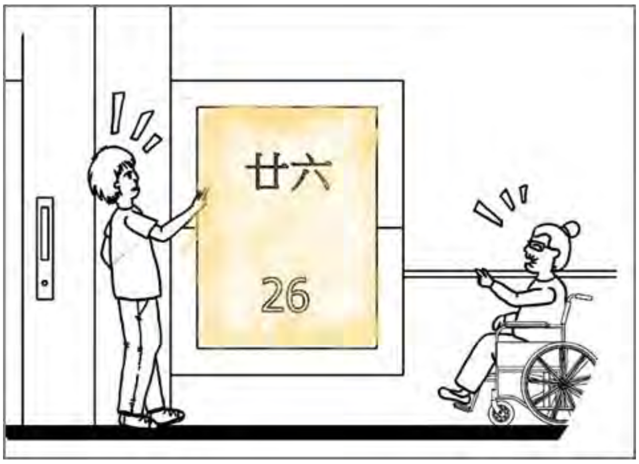

Figure 12: Seniors will be able to read the signage more easily if it is in bigger fonts and stronger colours

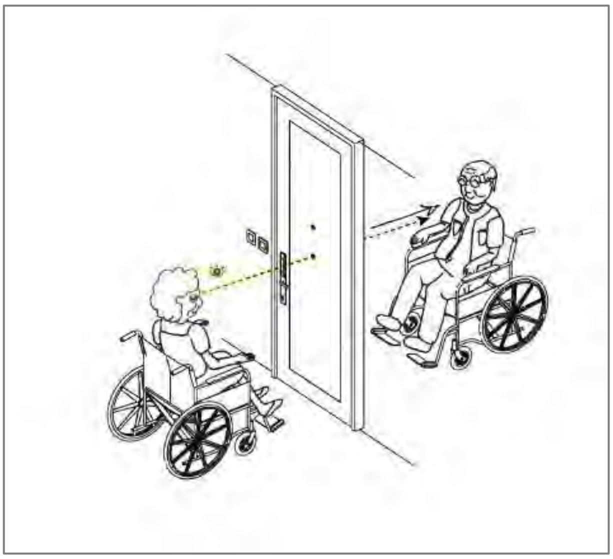

Figure 13: Peep-holes in front doors should be installed at both standing and wheelchair levels.

3.2.4 Smooth emergency passage

Your submission must provide the details of the work to readers. It should be clearly divided into sections, with heading / sub-headings, so that readers can follow the logical development of work. Using headings is a great way to organise the paper and to increase its readability, so make sure to format them correctly.

Accidents and sudden illness could have very serious impact on seniors, and they must receive prompt medical attention. Therefore, the trip from home to the hospital should be as short as possible. Senior homes must be so designed as to enable the early detection of sudden changes in the senior’s health. Seniors who live by themselves or in private rooms should install a motion detector, so that if there is no movement for an extended period due to illness, his family can be alerted as early as possible.

In private spaces like the bathroom or the toilet, they should install sliding doors that can be opened in emergencies, to facilitate entry without hitting the senior who may have fallen or fainted (Figure 14). In order that patients may reach the hospital as soon as possible in emergencies, senior housing should be sited close to medical facilities with pre-determined transport routing and arrangements. There should also be provisions for ambulance loading/unloading. The lobby and lifts in the building must be able to accommodate mobile beds or stretchers, so that whether lying or in wheelchair, the senior who needs urgent medical attention can directly access the ambulance (Figure 15).

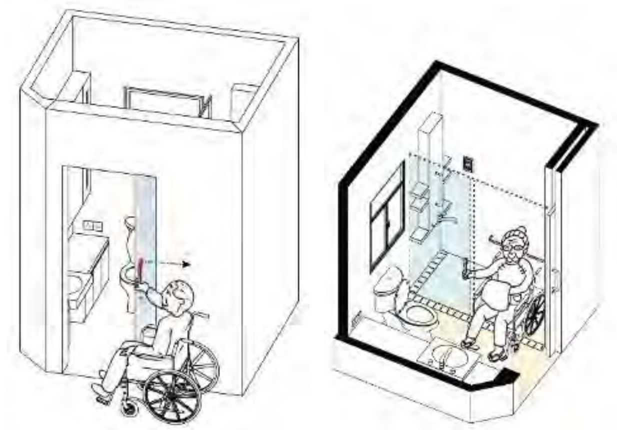

Figure 14: Bathrooms and toilets should install sliding doors that can be opened in emergencies.

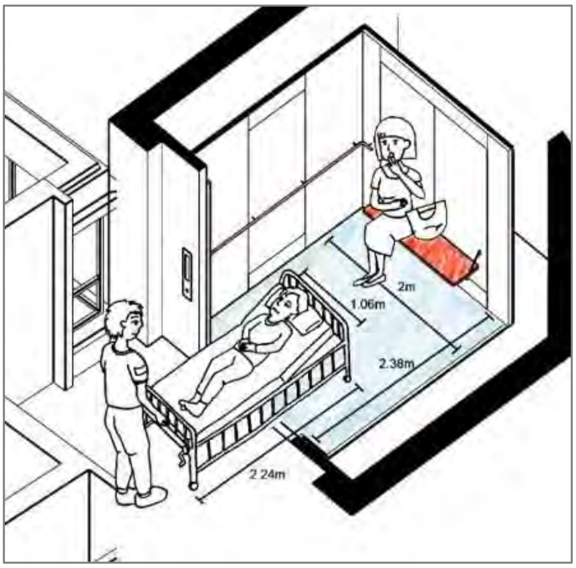

Figure 15: Lifts that can accommodate mobile beds.

3.2.5 Convenience and safety considerations

Senior housing should be designed to assist occupants in their daily lives so that, despite their physiological decline, they can still conveniently accomplish a majority of household tasks free of accidents. Owing to their failing physique, seniors often require additional assistance and support. Therefore, corridors should be installed with railings that seniors can avail of, whether standing or in wheelchairs. The same principle applies to public spaces, including lifts and passageways (Figure 16).

There could be provisions for a bench in lifts for tired legs to minimize the danger of falling due to weakness or movements. As some physically handicapped seniors may need a wheelchair on a short-term or long-term basis, building designs should cater to their special needs, for example, lowering the height of furniture. Kitchen benchtops should be lowered by 0.8 meters, and microwave and cupboards should be installed below 1.3 meters (Figure 17).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

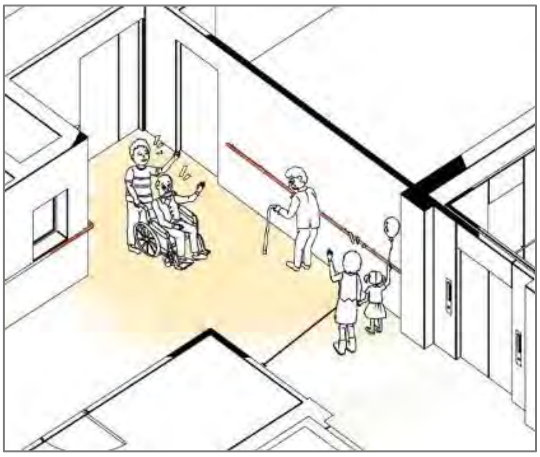

Figure 16: Public spaces should install support railings.

Figure 17: Household designs that cater to wheelchair users.

3.3 Senior housing development in a high-density city environment

China's ageing population has created a heavy demand for senior housing that meets their specific needs. To meet this rising trend, different countries are exploring a variety of options. In the Asian region, a senior care community model that adapts to a high-density city environment is probably the answer. This model should be based on a 'family first' concept, and re-create the living environment of a traditional family mansion in the spatial context of a high-density city environment.

China's cultural tradition has always been based on the family and its close relationships as the bedrock of society, with the older generation enjoying a lofty position in the hierarchy. This characteristic is reflected in China's traditional housing designed for extended family living together. A typical example is seen in the rectangular garden mansions (Si He Yuan 四合院) commonly seen in northern China, where family elders live in the main house, and the younger generations live in the subordinate blocks, creating a central open compound for family bonding and communal activities. Different generation members look after one another, providing spiritual support and nurturing a sense of belonging among their members.

The Chinese society has, over time, undergone modernization. As more and more people congregate in the cities, the urbanization process has ushered in high-density cities as major hubs of habitation, and traditional family mansions have been replaced by units stacked vertically on top of one another. The old extended family concept has evolved into individual families creating their own nucleus of living, posing a threat to traditional family values. As a result, seniors not only face new difficulties with their physiological decline, but also a loss of spiritual and physical support and sense of belonging, because of the separation with their children in their habitation. This situation is even more pronounced in high-density Hong Kong and in China's other major cities.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

However, this traditional practice of extended family living and respect for elders runs deep in Chinese culture, and most families are still prepared to share the load of looking after the older generation. We may be able to solve the problem of senior care brought about by ageing population through the study of two approaches in spatial utilization in a high-density city:

3.3.1 **Vertical 'generational integration' model**

In a multi-storeyed, high-density development, the building can be divided into zones on a vertical basis. The lower-level zone is devoted to senior hostels, with special provisions in the design to meet their needs, while the higher-level zone is made up of normal apartments, together with related communal facilities. This configuration allows members of an extended family to live in different zones of the same building. Each generation has its own private space, but can maintain communication and meet in communal spaces. It is, in reality, the remake of the traditional garden mansion in a vertical mode.

3.3.2 A consolidated model with diversified lodgings

A second approach features a small community that comprises a diversity of lodgings to suit different families. Seniors would live in low-rise terrace houses/units, while the younger generation would live in adjacent high-rise blocks because of their smaller number of family numbers. The two types of lodgings would share the same outlook and communal facilities. It is, in essence, a modern version of extended family living which promotes inter-generation interaction and mutual care.

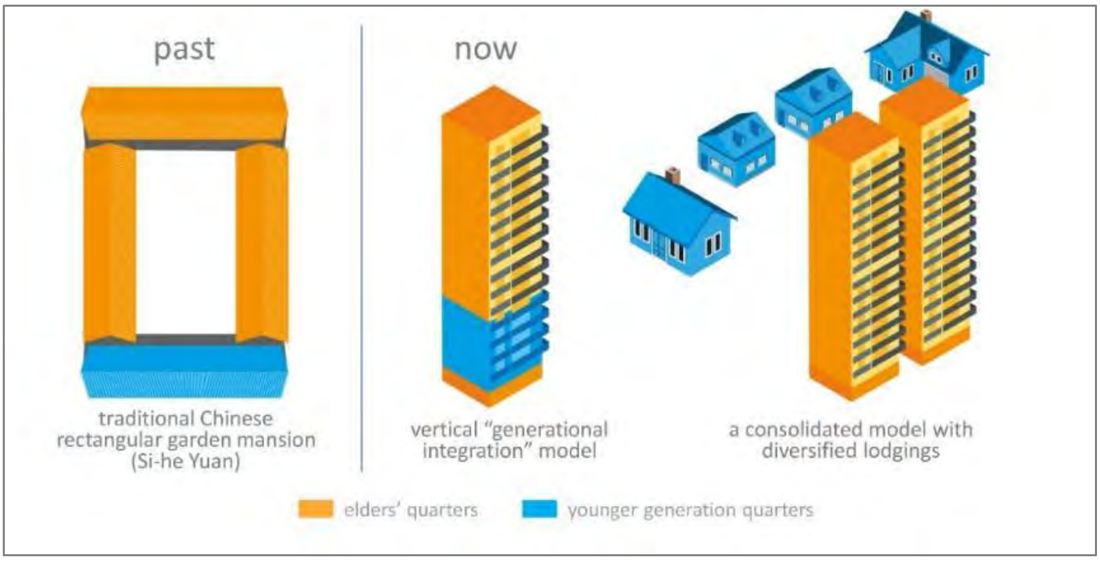

Figure 18: Harmony living in Asia

3.4 Case studies

3.4.1 **Vertical 'generational integration' model**

Located in Shau Kei Wan on Hong Kong Island, Harmony Place is an urban renewal project completed in 2015. It comprises a multi-function block and a 42-storey residential block. The project aims to promote a senior care mode with the senior living close to other family members, and addresses the current trend of ageing population. About 30% of the development is made up of senior apartments for lease, while the rest are private residential units for sale (Figure 19). Residential unit owners have priority in leasing the lower-level apartments for elders in the family, so that seniors and their family members each have their own private space, and are close to each other. The multi-function block is designed with seniors in mind, and comprises retail shops, clinics and senior service centres.

Generational integration design aims to encourage younger family members to live with the older generation, and provides support to seniors suffering from physiological decline. Although retirees these days are physically much fitter than previously, improvements in the finer details of interior design would lift their quality of life. More importantly, a number of ancillary medical facilities and household services, like clinics, can provide basic medical services to seniors from their retirement to a more advanced hostel-bound stage of their old age, a period that could span nearly 20 years.

A senior hostel obviates the need for a senior who lives in an ordinary apartment to make a move to a nursing home as he grows older and suffers from physiological decline. The older one gets, the lower the ability to adapt to new circumstances. The abrupt change in the living environment impacts heavily on seniors both physically and psychologically. Senior hostels have adequate basic facilities which can be adjusted to meet changing needs, enabling seniors to continue living in a familiar and caring environment for as long as possible. It is a blessing for both the senior and his family members.

Generational integration also dovetails with the new trend of an extended retirement life and a new breed of healthier and more agile seniors. It not only effectively looks after their health, but also provides private space for both parties in spite of their physical closeness. This mode of living largely maintains their original lifestyle, including family gatherings, reunion with friends, and to a certain extent their previous work. Therefore, it meets the seniors' two psychological needs: the care of family and friends, and their social status and recognition. Living close to family members in a semi-independent mode can effectively alleviate the feeling of loneliness, and of isolation from society due to retirement.

Figure 19: The generational integration design of Harmony Place comprises lower-level senior hostel for lease, and higher-level private residential units for sale.

3.4.2 Thoughtful interior designs: The Tanner Hill

Your submission must provide the details of the work to readers. It should be clearly divided into sections, with heading/ sub-headings, so that readers can follow the logical development of work. Using headings is a great way to organise the paper and to increase its readability, so make sure to format them correctly.

Located in North Point on Hong Kong Island, The Tanner Hill comprises two 24-storey towers and a 29-storey tower, offering a total of 588 units that range from 344 sq ft to 1,231 sq ft. The lower-level podium comprises the residents' clubhouse and medical services centre that offers entertainment and medical services respectively. There is also a day-care centre, a cognitive training centre and a nursing home, providing rehabilitation treatments, plus day care and 24-hour care as needed.

The residential units have been designed with seniors in mind, and incorporate many detailed considerations. The unit entrance is deliberately wide and free of doorsteps. The front door is fitted with a U-shaped handle at an appropriate level, as well as two peep-holes at two levels. The interior signage and alarm systems have taken into account the decline in sensory sensitivity of seniors. Therefore, the fire alarm adopts an audio-visual approach to enable hearing or sight impaired seniors to detect such mishaps as early as possible. All rooms and corridors are installed with night lights so that seniors can find their way with ease; and there are stripe designs on the sliding door of the shower.

As seniors grow older, some of them may have to resort to wheelchairs, therefore the positioning and measurements of furniture and fittings in bathrooms and toilets have been adjusted in accordance with the height of wheelchair users (Figure 20). Cabinets in the open kitchen and specified bathrooms are movable for their convenience. Kitchen amenities have also been adjusted so that they can easily manage, while the shower sliding door can be replaced with shower curtains. All light switches and sockets have been enlarged and conveniently positioned. For the sake of safety, interiors, and especially the bathroom and showers, are equipped with emergency call buttons.

Figure 20: Kitchen cabinets and benchtop have been adjusted to suit wheelchair users.

The interior design concepts are extended to the exterior public places. For example, there are clear signage and alarm systems. Each floor level is clearly labelled in bigger-than-average fonts to help residents identify their own abode (Figure 21). The lift lobby, the lift interiors and corridors are all fitted with support hand railings at an appropriate height; and the lifts all feature seating for those weak on their feet. To prevent slipping, the floors feature anti-slippage designs.

Another important consideration in the design of public open space is to ensure that ambulances can arrive at the scene promptly in the event of accidents or other unforeseen circumstances. After the application of first aid, they must be able to transport the patient to the hospital as quickly as possible. The crux lies in the design of the lifts, the residential unit and the lobby of the building. The Tanner Hill has made provisions for special jumbo lifts that can accommodate stretchers or mobile beds. In the event of an emergency, the senior patient can be transported in these lifts directly to the ambulance with a minimum of delay.

Figure 21: The Tanner Hill features clear level signage and appropriately positioned lift buttons.

Figure 22: The Tanner Hill provides extra common areas for leisure and social gathering.

ABSTRACT

Accounting for human behaviour while striving to improve energy efficiency has been brought to the fore in recent studies since occupant behaviour impacts energy use in buildings. Maintaining occupant satisfaction with indoor environmental conditions can promote their wellbeing and productivity especially in office buildings. In order to improve efficiency and maintain occupant satisfaction indoors, it is important to capture actual occupant-energy-related behaviour and occupant preferences in buildings. Some of the parameters that influence occupant behaviour indoors are the environmental conditions such as the ambient temperature, lighting levels, and air quality.

Preliminary results obtained from monitoring an office building in Qatar are presented. This study seeks to capture occupants' indoor preferences and behaviours to give an insight into how they impact energy use or may be impacted by the indoor conditions. To achieve this, measurements of energy use (lighting, plug load devices, space conditioning), indoor environmental parameters and occupant feedback (satisfaction, preferences, behaviour) are collected using a combination of approaches including sensors, power meters and surveys. The preliminary findings show that the occupants took action to improve their comfort with the temperature and airflow. The highest energy consumption was when the building was not fully occupied which could provide an opportunity to improve the building operation and achieve energy savings while taking into account occupant needs, preferences and behaviour. Observations made regarding the lighting use pattern are also highlighted. It is intended that this study will provide an important contribution to understanding building occupant behaviour in a hot climate region like Qatar.

Keywords: indoor environmental conditions, occupant behaviour, building energy monitoring

1. INTRODUCTION

Sustainable high performance building strategies have been increasingly adopted by various countries as the building sector seeks to improve efficient use of resources. Due to the high environmental impact and the amount of energy consumed by this growing sector, there is an increasing need to ensure the environmental footprint is minimized by ensuring new buildings are energy efficient, improving existing building performance, using renewable energy sources and identifying and cutting down areas of wastage. Statistics from different countries emphasise the need to conserve energy. The US, for instance, is one of the top energy consumers in the world even though it is about one-fourth the population of China, about 40% of US energy is used by the building sector. In Hong Kong, about 90% of the electricity produced is consumed by the building sector (The Energy Efficiency Office, 2016). Qatar is a very small country in the Gulf region and one of the top crude oil producers in the world. It has the highest GDP per capita in the world and one of the top energy consumptions per capita in the world with growing electricity and energy demand (EIA, 2015) as technological advances and population increase. The building sector needs to continuously make efforts to improve its energy conservation efforts.

The main drivers for energy monitoring and energy use measurements are the need to mitigate climate change, to comply with legislation and better understand how energy is used in buildings to improve performance (Ahmad, Mourshed, Mundow, Sisinni, & Rezgui, 2016). While reducing building energy consumption, the industry has begun to recognize the need to ensure occupants have an environment that is conducive and promotes their health and productivity. People could also impact the way energy is used in a building through their behaviour. As various countries strive to meet the energy reduction targets, the needs of the occupants should be taken into consideration. In order to assess and better quantify the impact of people on buildings and be able to provide preferred indoor conditions, their needs and preferences including their actions should be captured. Energy simulation tools oversimplify their representation of occupants and do not properly account for their behaviour.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

This study investigates energy consumption, indoor environmental conditions and occupant behaviour in an office building in Qatar. Qatar has a dry subtropical desert climate and also experiences high temperatures in the summer (around 40°C) and cooler winters (around 15-25°C) (WeatherOnline, 2017). There are a number of strategies in place to ensure resource conservation in Qatar buildings such as imposing fines for wasting water, leaving exterior lights on during the day, promoting the culture of energy conservation (Meier, Darwish, & Sabeeh, 2013). In order to capture different occupant-related characteristics, values, preferences and behaviour indoors, experimental approach using sensors, metering devices and a survey application for the occupants to provide their feedback on the indoor conditions and their level of satisfaction with the indoor environment are used. The indoor environmental monitoring includes temperature, relative humidity, air quality, and light intensity measurements, sub metered energy use for the lighting, plug loads and space conditioning, and occupant behaviour and satisfaction tracking through sensors and a Preference Monitoring Application (PMA) survey that was administered to the occupants. The study could provide an insight into occupant-related energy use and occupant preferences in an office. Preliminary results from the study are presented focusing on a few of the parameters.

2. BUILDING ENERGY USE AND OCCUPANT FACTORS

Occupants should be accounted for as energy efficiency strategies are implemented in buildings since people majority of their time indoors. Identifying the needs of the occupants and their energy use habits can help with providing preferred indoor conditions and reducing energy wastage associated with individual efforts to improve their comfort. Studies have suggested that occupant behaviour can significantly increase energy consumption by about 90% (Hong & Lin, Occupant Behavior: Impact on Energy Use of Private Offices, 2012). Investigating energy use behaviour can help with identifying the wasteful habits and possibly encourage a change in behaviour through education or other indirect means such as providing access to energy use information through dashboards.

Data collection techniques for building energy monitoring were explored by (Hong, Taylor-Lange, D'Oca, Yan, & Corginati, 2016). Buildings are different and identical buildings sometimes exhibit different energy consumption patterns, using a context-aware approach enables the actual building characteristics to be captured, though the results may not be generalised or directly applicable to other office buildings but there are lessons that can be learned and applied to a larger number of buildings. There are very limited studies on building energy consumption and occupant-related factors in Qatar. About 80% of the energy use in buildings in Qatar is for air conditioning (Meier, Darwish, & Sabeeh, 2013).

Studies have addressed occupant values (what they consider is of importance) and mentioned their effect on the indoor environment. The values are thermal comfort (temperature and humidity), lighting/ visual comfort (light intensity), indoor air quality (airflow/ ventilation), perceived health and personal productivity. Hong, et al. (2016) mentioned the parameters needed for occupant behaviour studies have been discussed. Human behaviour is dynamic so gaining better understanding could give a better understanding of their preferences and behaviour indoors. Occupants engage in adaptive or non-adaptive behaviour indoors. They could adapt the environment to their needs like adjusting thermostats or adapt to the environment by wearing additional clothing.

Actual occupant-related energy use data is beneficial to improve estimates from building energy simulation tools. Machine learning algorithms could also be used to learn occupant behaviour and predict their needs and provide preferred indoor conditions that minimize energy wastage.

3. METHODOLOGY

An academic office building located in Doha, Qatar was selected for the case study due to its availability and the willingness of the occupants (professors and instructors at the college) to participate in the study.

3.1 Building characteristics

On average the occupants spend about 20 hours in the office since most of their tasks involves teaching. Additional information about the building is presented in Table 1. All the occupants are in private offices and are able to control their thermostats within 6°C (18-24°C). The building has an automation system that controls the whole ventilation and air conditioning system, which is a single variable air volume (VAV) system.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Building Type	Medium-sized office
Year of Construction	2005
Size	680 m^2 (zone monitored)
Number of Floors	2 (ground floor, west zone monitored)
Climate	Subtropical dry hot desert climate
Cooling System	Single variable air volume system
Energy Source	Electricity
Power Distribution	Three-phase
No of Occupants	22 in the zone monitored

Table 10: Case study building characteristics

3.2 Instrumentation

The monitored zone in the office building is presented in

Figure 53. Each room has a temperature and relative humidity sensor. Three air handling units serve the zone and each one has an air quality sensor. Ten illuminance sensors were installed in 10 of the 22 offices in the zone the selected rooms represent different areas of the office namely the interior offices at the core, and a few offices at the perimeter of the building with access to daylighting and some with interior shading devices and others without shading. There is also shading on the exterior of the building (

Figure 53). The sensors were also placed based on whether the occupants were interested in taking part in the study.

Figure 53: Floor plan and exterior of case study building

The set point temperature varies for each office and is between 18 and 26°C. Occupants can control the lights manually to turn them on and off. The sensors were placed close to the occupants' working spaces on their desk

Figure 54. The illuminance sensor measures light intensity as seen by the human eye. The energy use by three major end use categories- lighting, plug loads and space conditioning are considered. The lighting and HVAC energy consumption are measured with power meters while the plug loads are measured virtually. The sensors were tested and calibrated before they were installed.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

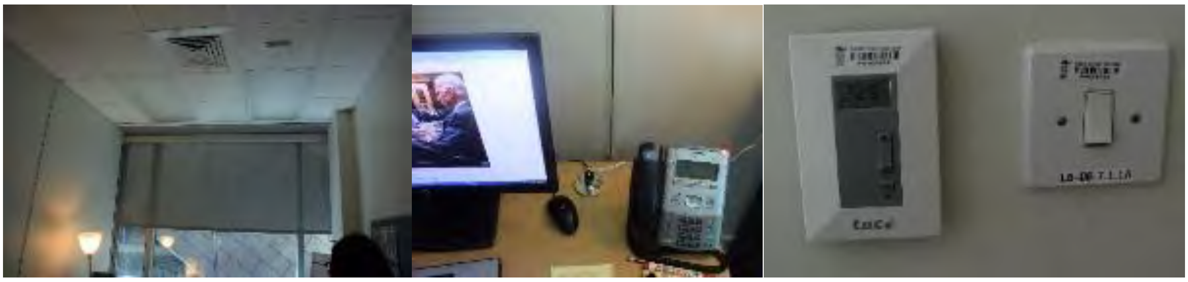

Figure 54: Office interior, illuminance sensor placement and thermostat and lighting controls

Occupant satisfaction with the thermal (temperature and airflow) conditions, lighting and indoor air quality are monitored through the Preference Monitoring Application (PMA) which is a survey provided to them which can be completed daily and is accessible on mobile devices and computers. It is a 3-5 minute survey for occupants to provide feedback on their perception of the indoor environment, their satisfaction and actions related to energy use.

The indoor conditions and energy use measurements are monitored with sensors and stored in the data acquisition system. The data is retrieved from the vista workstation on-site every other week to check the quality of the data and ensure there are no technical problems. Remote access to the workstation was not granted due to security concerns. Information on outdoor weather conditions are collected from local weather stations some of which are available online. Occupant feedback is retrieved online. The study is still ongoing and the total duration is for one year.

4. RESULTS

Preliminary results from the case study are presented in this section. The monthly energy consumption for major end use categories show that the energy use for space conditioning was the highest which is attributed to air conditioning accounting for over 75% of energy consumption monthly (Figure 55).

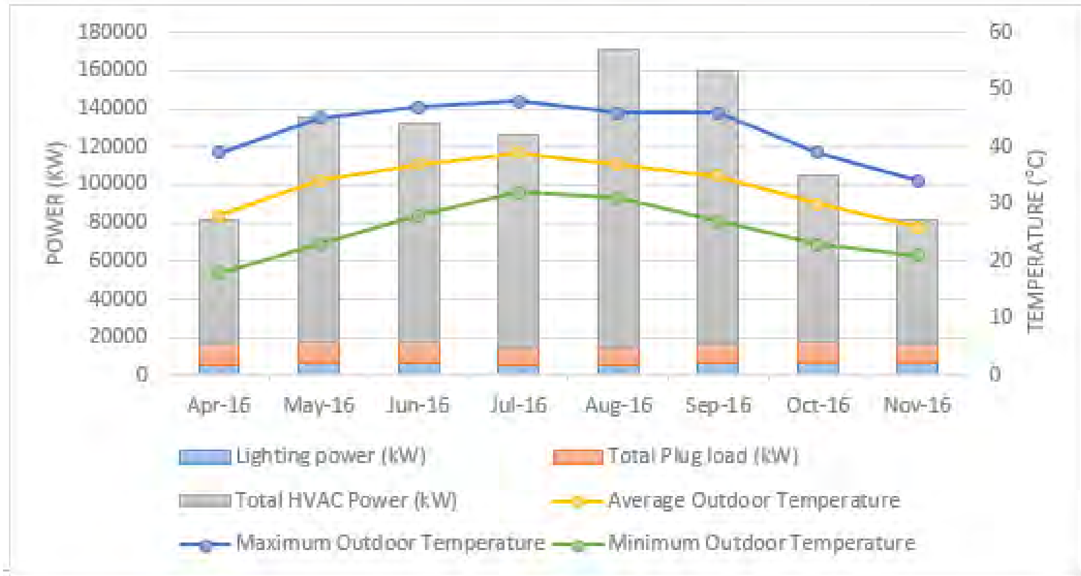

Figure 55: Monthly power demand and average outdoor weather

The peak temperature from April to November 2016 was about 48°C in July. The building was partly occupied in June, unoccupied in July and unoccupied for most of August due to the extremely high temperatures and the college being closed for the summer holidays. The peak average temperature was about 40°C in July while the peak overall power consumed in August (Figure 55). The minimum power measured was in April and November which were not as hot as the average temperature in July.

The response on the PMA surveys from April to October are presented in Figure 56 below, 343 responses were collected from 14 occupants over that period. The feedback rates from the occupants vary from daily to weekly depending on how often they choose to respond.

Figure 56: Monthly responses from occupants

A few parameters were considered from the feedback of the occupants. Figure 5 shows that they were mostly satisfied with the lighting, and indoor air quality. They were moderately unsatisfied with the thermal comfort. They took more action on their temperature and airflow than on the lighting levels as seen in Table 2 below.

	Took no action (%)	Took action (%)
Temperature	33.4	66.6
Humidity	100	0
Airflow	42.2	57.8
Lighting	61.1	38.9

Table 11: Response on Actions

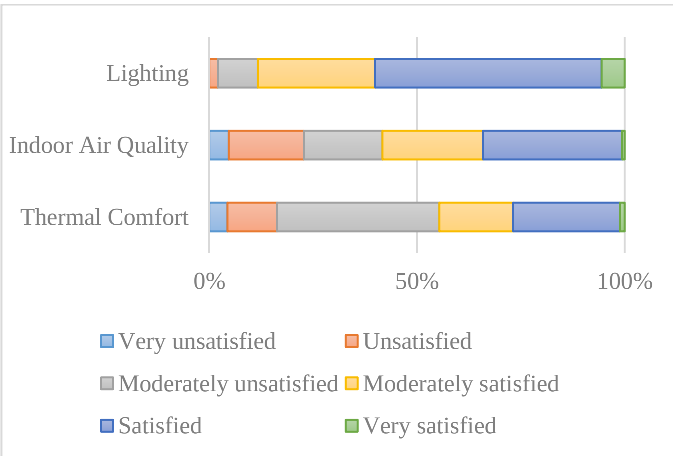

Figure 57: Satisfaction with indoor environmental parameters

Focusing on the occupants' perception of lighting, most of the time, they felt neutral about the lighting but a few other times they felt it was slightly bright (Figure 58).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

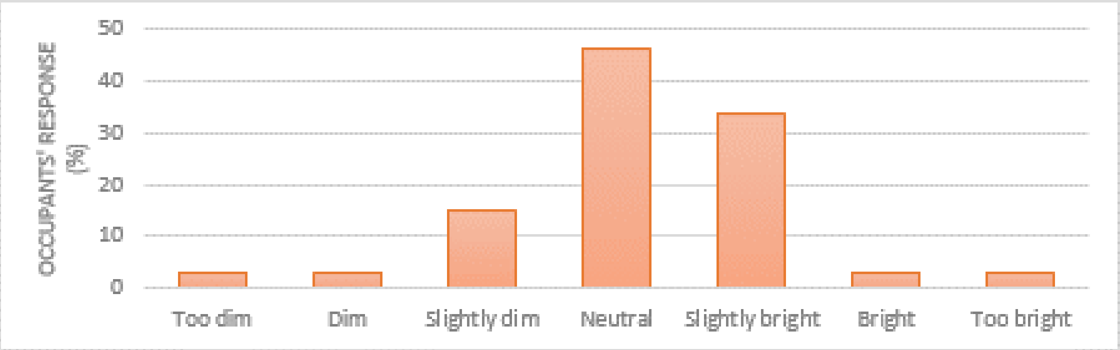

Figure 58: Occupants' response on their perception of lighting indoors

From Figure 8, we observe a strong correlation between the illuminance levels and the lighting energy consumption which is expected. The average illuminance of the 10 rooms was plotted against the overall lighting energy consumption over a working day in April (Figure 7) which also showed a close correlation even though not all the rooms have sensors installed but the rooms selected seem representative of the entire zone.

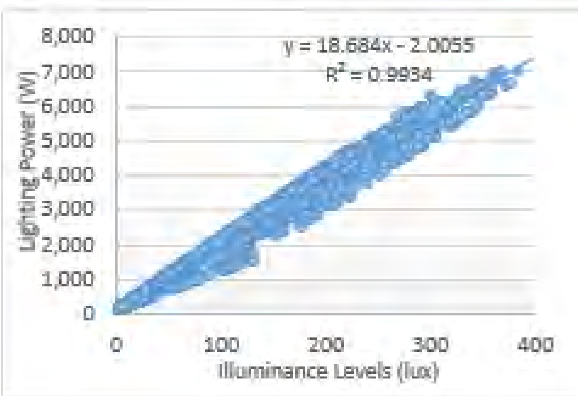

Figure 59: Lighting profile from a working day

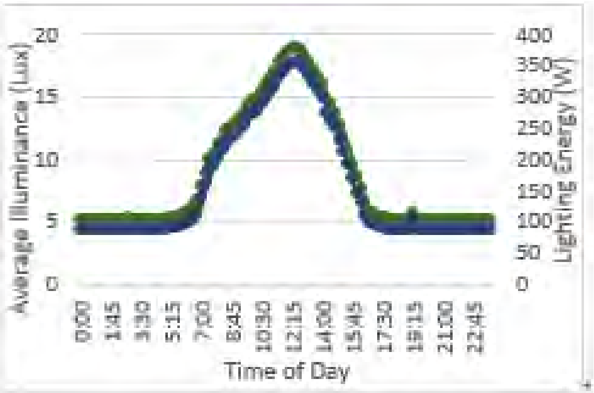

Figure 60: Lighting power vs average illuminance (April- November 2016)

The illuminance by natural daylighting was not separated from that by artificial lighting since the sensors measure how a human perceives light, this might introduce some errors. Overall, the occupants seem more satisfied with the lighting levels than with thermal comfort and indoor air quality.

5. DISCUSSION

July was the hottest month but August had the highest energy consumption overall. Energy consumption was lower in some of the hottest months since the building was unoccupied but it was still cooled for the equipment in the offices. The most obviously fluctuating energy use category is for space conditioning, which was the highest in

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

August perhaps because people were returning to work in the extremely hot weather and their cooling demand increased.

The strong correlation between the illuminance levels and the lighting energy measurements could indicate that natural lighting has very little contribution to their interior lighting which could be because of the associated heat gain through the large windows. Also since they felt the lighting was too bright at times, it could be reduced to achieve energy savings due to the strong correlation between the illuminance level and lighting energy while also maintaining satisfaction levels. Some offices had additional plug-in lamps without the room lights to dim the environment, these may increase the illuminance but the energy use is measured as plug loads but this does not seem to adversely affect the results since only a few of the offices use the lamps. The illuminance measurements also closely reflect the occupancy patterns and the occupant's lighting use.

6. CONCLUSION

Occupants should be considered in energy efficiency improvements since their behaviour can impact energy consumption. Gaining an insight into not only the energy consumption but also the indoor environment conditions and the occupant behaviour and can bring into focus how occupants impact energy use in buildings and help to identify areas for energy improvements while maintaining occupant satisfaction using actual energy use data. The paper covered some aspects of an ongoing energy monitoring project in an office building in Doha, Qatar. The PMA provides more insight into occupant behaviour, preferences and their satisfaction indoors. The indoor measurements and the energy use measurements also display the building energy use profile. This is still a preliminary analysis of a portion of the results since the study is still ongoing. A more robust analysis will be completed for conclusive findings while translating occupant factors to be included in analysis to predict energy consumption.

ACKNOWLEDGMENTS

The authors acknowledge the support of Qatar National Research Fund (QNRF), a member of Qatar Foundation (Grant No. 6-1370-2-552). We will also like to thank Ke Xu for his advice on the instrumentation and the building owners and occupants for providing access to their buildings and for their help with this study.

ABSTRACT

Worsening air pollution poses a large and growing public health problem. More than 80% of people currently live in urban areas with air quality levels that exceed WHO particulate matter (PM) concentration limits. They are subjected to a higher risk of cardiac arrests, peripheral vascular disease (PVD), lung cancer, respiratory diseases, and asthma. Poor air quality is mainly caused by rapid urbanisation and industrialisation, which require high energy consumption and transportation flow. Air pollutants are emitted from power plants and vehicles, and are trapped in the built environment, to which people on the street are exposed all the time.

In view of the pressing need to combat roadside air pollution, Arup and Sino Green have developed a novel, patented system called the City Air Purification System (CAPS) that won the second prize of the Construction Industry Council (CIC) Innovation Award 2015. The prototype, a stand-alone system with a ventilation system that filters out pollutants and purifies air for pedestrians in proximity to the system, has been tested in Hong Kong and Beijing and has effectively reduced air pollutant (PM2.5 and PM10) concentration within the system by 30% to 70% under various ambient conditions. This paper focuses on the simulations and analysis showing the improvement of roadside air quality resulting from CAPS when it is incorporated into buildings located in a busy district in Hong Kong.

Keywords: air pollution, purification, roadside health, public transportation

1. INTRODUCTION

In many Asian cities, pollutants emitted from vehicles permeate through the crowded city roads, poor air quality has become a threat to pedestrians or roadside stores. Air pollutants emitted from vehicles in densely-built cities such as Hong Kong, where streets are narrow and bounded between high-rise buildings, cannot be naturally circulated and diffused to the atmosphere; instead, they accumulate at the bottom of the street due to the Street Canyon Effect. This poses health problems to urban residents using nearby pedestrian walkways. Chinese cities like Beijing and Shanghai share similar difficulties in maintaining acceptable air quality level on the street. On a high-pollution day in Beijing, the roadside monitor could record over 600 Air Quality Index (AQI), which is twice the index level considered hazardous to human health. In the 2016 Environmental Performance Index (EPI) developed by Yale University and Columbia University, China, India, Myanmar, South Korea, and Vietnam ranked 170-179 out of 180 countries in the air quality category. Other than pollutants emitted from vehicles, smoke coming out from chimneys of coal power plants and factories worsen air quality by raising the ambient pollution level. If the layer of heavy pollution and the ambient pollution level are not treated and continue accumulating, the risk of respiratory disease of pedestrians would increase.

The main purpose of the CAPS innovation is to develop a solution that could mitigate major air ventilation difficulties in urban areas with the Street Canyon Effect, and to study the feasibility of different roadside ventilation systems for improving roadside air quality.

1.1. Street canyon effect in built environment

One main difficulty in ensuring natural ventilation in urban areas is the massive number of high-rise buildings on narrow streets and roads. Pollutants emitted by heavy traffic do not have sufficient energy to rise up to high attitudes to escape the containment of surrounding buildings. As a result, air quality worsens as pollutants like particulate matters and nitrogen oxides accumulate at the pedestrian level of the street canyon. The geometry of the street canyon, along with the wind direction and wind speed, are the major parameters that affect the air pollution's dispersion in the area. In a dense and compact cosmopolitan city like Hong Kong with population of over 7 million, the aspect ratio between the building height and the street width ranges from 3 to number larger than 10. A study showed that an increase of 30% to 80% on the retention time of pollutants in the street canyon was due to the air ventilation impact from the high-rise buildings and its 'wall effect'. The air pollution problem in a mega city like Beijing with a population of over 16 million, which has an aspect ratio of 2 to 4.5, is also affected by the effect. Beijing's building development is comparatively less compact, but it faces more severe ambient air pollution in general. Hong Kong and Beijing have different characteristics in terms of city development and environmental conditions, but both are affected by air pollution due to the Street Canyon Effect.

Figure 1: A Typical street canyon in an urban area

Street Canyon Effect, as shown in Figure 1, represents the inability of normal wind channel to flow into and ventilate the road and the formation of a primary vortex of wind circulating inside the area between buildings. Both characteristics of the Street Canyon Effect reduce the chance for pollutants to escape; as a result, they accumulate to a hazardous level of concentration, which is harmful to human health. Over-exposure to highly polluted air would lead to a greater risk of allergies and respiratory diseases.

2. CITY AIR PURIFICATION SYSTEM (CAPS)

2.1 Engineering design

To mitigate the immediate and pressing air pollution problem due to the Street Canyon Effect in cities like Hong Kong and Beijing, Arup and Sino Green developed a patented innovation called the City Air Purification System (CAPS). Since its debut in March 2015, CAPS has gained attention from international and professional media, including: Forbes, Bloomberg, The Guardian, China Daily, Architect Magazine and Global Construction Review. The main goal of the innovation is to provide purified air for pedestrians through a ventilation system that filters out pollutants and generates cleaner air in proximity to the system.

Figure 2: City air purification system (CAPS)

The innovation, illustrated in Figure 2, was designed with fluid mechanic principles so that it could build up an air curtain and a positive pressure to create a cleaner environment. The polluted air is drawn into CAPS at a low level, which is then filtered and recirculated to improve the air quality of the space inside CAPS. Purified air is supplied at the top of CAPS at a high velocity that serves as an air curtain, or an invisible barrier, isolating the occupied space inside CAPS from the adjacent polluted ambient. The purified air emitted through the fan chamber creates a positive pressure inside CAPS and pushes the polluted gas away. CAPS is equipped with a quiet and high energy efficiency fan and a High Efficiency Particulate Arrestance (HEPA)-type (medical-level) filter that is capable of filtering away up to 95% of PM2.5 and larger suspended particulate matters (PM) in the ambient air. With CAPS, people who are standing or waiting in the outdoor polluted roadside environment will be able to breathe in cleaner air.

2.2 Engineering simulation

Based on the design of CAPS, a computational fluid dynamics (CFD) model was developed to study the effectiveness, practicability, usability, and flexibility of different design solutions. Furthermore, the CFD modelling technique was used to optimise the system operating conditions that maximise the overall filtration effectiveness, while minimising energy consumption.

In the CFD model, a wide range of different scenarios and operating conditions were simulated and investigated. The scenarios covered various system variability and ambient factors such as external wind and background ambient pollution level at the system and city-wide levels. Sample results, shown in Figure 3, verify that CAPS is effective in maintaining a cleaner air zone (blue in the Figure) and to keep away from the surrounding pollution (green to red in the Figure). Under different ambient conditions, simulations were carried out to investigate the impact of different system operating parameters on overall filtration effectiveness and fan requirement. Using the results, the optimised system operation in terms of air pollutant level inside the system area, air balance of the air delivery system, and fan operating speed were determined.

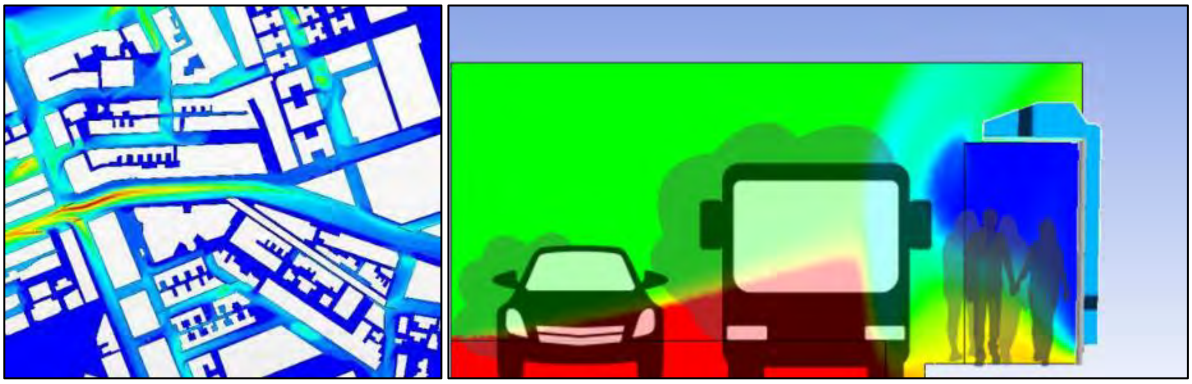

Figure 3: City-wide CFD simulation (left) and system CFD simulation (right)

2.3 Roadside testing

To demonstrate the effectiveness of the system, CAPS was first placed in Wan Chai, Hong Kong for two months and then relocated to Tsinghua University in Haidian district of Beijing. During the demonstration, continuous performance data logging and on-site manual measurements were conducted. The testing results showed that CAPS is able to provide clean air within its covered area, which achieved an air quality that complies with the World Health Organisation (WHO)'s PM2.5 guideline values.

Roadside testing in Hong Kong was conducted from March to May 2015 to analyse the real system performance with respect to the ambient air quality data inside the system area. CAPS was installed in Queen's Road East in Wan Chai, one of the busiest districts in Hong Kong situated between two official government roadside air monitoring stations located in Central and Causeway Bay. The collected data were compared to the published data. After verifying performance in Hong Kong, CAPS was relocated to Beijing for roadside testing in different environmental conditions from July 2015 onward. A similar approach, including continuous data logging and manual on-site measurements, was adopted. Similarly, the collected data inside CAPS were compared to the ambient data in Beijing.

Different system operation settings were tested using a set of testing protocol for on-site measurements. After the air quality inside the system was measured, the fan speed and the air delivery angle were adjusted for studying different design scenarios. The maximum power for the system was 13A and it cost HK$16 per day for continuous operation. The measurement was also used to identify the filter conditions. Owing to particle blockage and aging of the filter, filter performance deteriorates when the flow rate reduces. The measurement results provided alerts for when to clean or replace the filtration system. Depending on the roadside conditions, the filter is expected to be replaced every two to six months. Further testing details can be found in.

Based on the collected data in Hong Kong and Beijing, a correlation analysis was conducted using measured data from roadside testing and simulated data from the CFD model. As shown in Figure 4, results showed that the simulation model is able to predict the real situation with a difference of less than 10%. Based on the current data analysis, CAPS is capable to reduce the PM2.5 concentrations by 30%-70%, depending on the ambient pollution level.

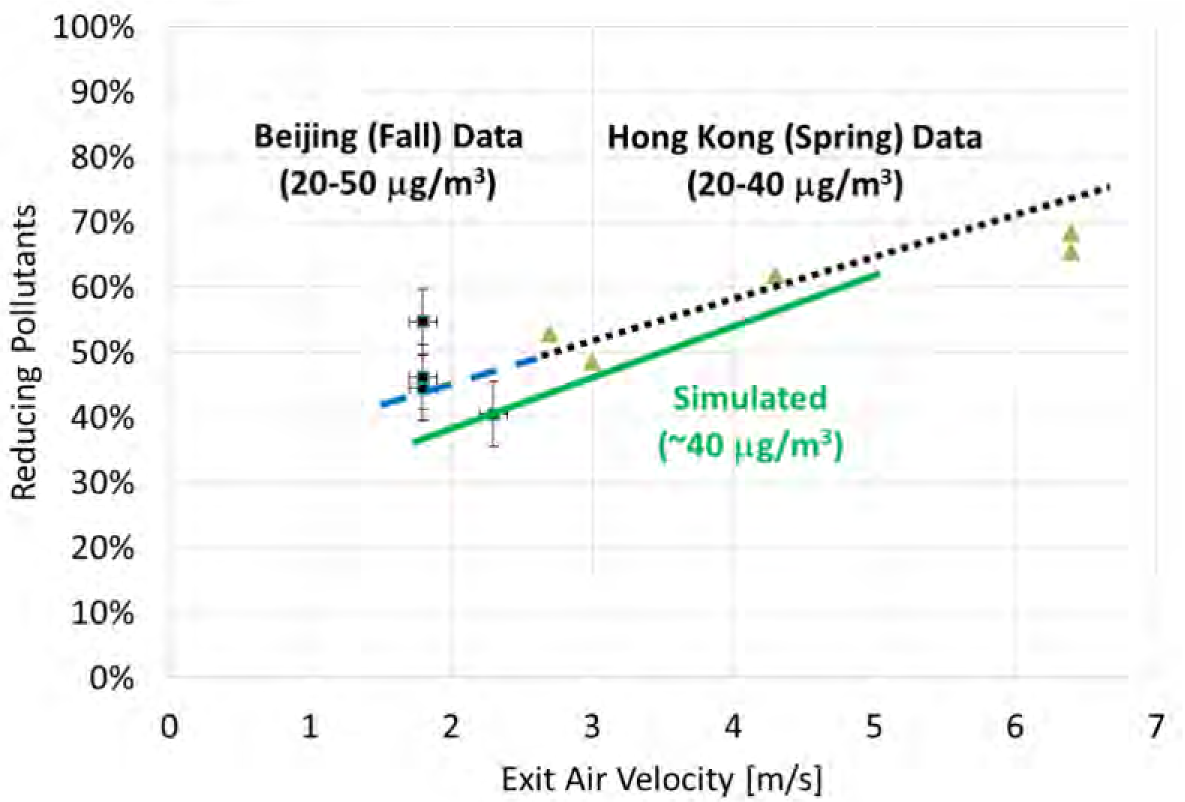

Figure 4: Correlation results between measured and simulated data for Hong Kong and Beijing roadside testing

2.4 Economic benefits

Many researchers have also attempted to quantify the economic cost due to the air pollution problem. One such analysis for Hong Kong case is done by Hedley Environmental Index. Accounting for deaths, hospital visits, and productivity loss, the Hedley Environmental Index estimated about HK$41 billion economic losses due to pollution-related health problems in 2013.

If 200 CAPS are implemented in the 10 districts most impacted by poor air quality, as shown in Figure 5 (base map from [18]), CAPS would be saving HK$330 million per year for Hong Kong, which is four times of the social benefit relative to the initial cost of the system. The benefit is achievable even with the assumption of only about 30 minutes of protection inside CAPS per day while waiting for the traffic, and the benefit can be observed by 60% of the entire population in Hong Kong in those mentioned 10 districts (1. Central & Western, 2. Wan Chai, 3. Eastern, 4. Kwun Tong, 5. Kowloon City, 6. Yau Tsim Mong, 7. Sham Shui Po, 8. Kwai Tsing, 9. Tuen Mun, and 10. Yuen Long).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

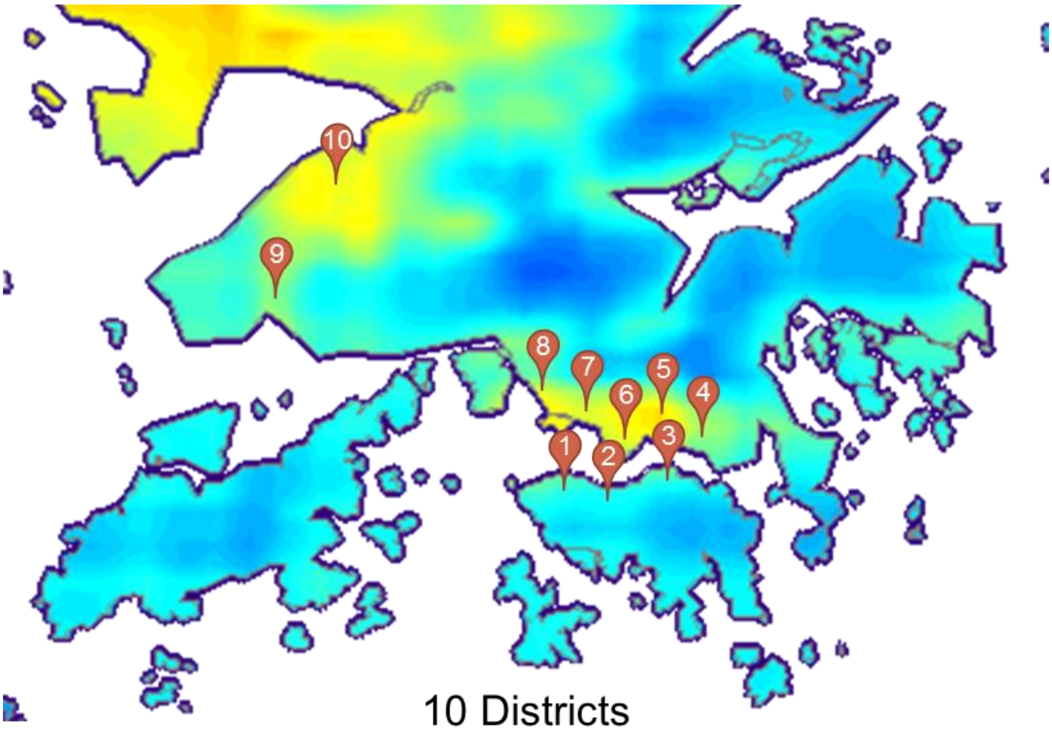

Figure 5: Most polluted districts in Hong Kong

3. CONCLUSION AND FURTHER DEVELOPMENT

Based on the analysis and tested data, the CAPS can reduce the air pollution level of PM2.5 by about 50% on average under various ambient pollution levels. Figure 6 shows CAPS's demonstration model in Hong Kong and Beijing during the testing period.

Figure 6: Demonstration in Hong Kong (left) and Beijing (right)

CAPS has wide ramifications and applications. For instance, given that Hong Kong has a well-established public transport network, the system can be adopted for bus shelters, tram stations, and other applications to improve air quality. The patent covers different forms of CAPS, including building canopy, outdoor kiosk, and central underground filtration system. For example, buildings canopy could supply fresh air to the pedestrian level and keep clean air recirculated right in front of the building entrance to improve the overall air quality around the area. The ideas can work for new designs; it is also possible to retrofit existing bus shelters and buildings. With such

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

appealing performance data, CAPS could be produced in mass and applied in major Asia cities, such as Beijing, Shanghai, Ho Chi Ming City, etc., all of which suffer from severe air pollution problems.

As the measured data reveal that CAPS can effectively reduce pollutant levels to a recommended level of PM2.5 according to WHO standards, CAPS can be developed into next-generation systems in the future. The major objective of developing the next-generation systems is to further improve its effectiveness, so as to make it low-carbon or even zero-carbon, in order to improve air quality inside the system area.

4. ACKNOWLEDGEMENT

The patented City Air Purification System (CAPS) was developed by Arup and Sino Green.

ABSTRACT

The vision of LOHAS (Life of Health and Sustainability) is to enrich and live up to a healthy lifestyle which has become a trend worldwide. Health and Sustainability are the two major elements of LOHAS. In the past decades, we were more focused on sustainability for the physical living environment, but may have overlooked the importance of healthy lifestyles. In the concept of LOHAS, a healthy living lifestyle and its environment has again become the core spirit of design.

Mental and physical health are inextricably connected in terms of the health of LOHAS. It discovers beyond the healthy spaces and facilities, but also the relevant activities organized in order to satisfy residents both mentally and physically which are compliant with interests and local context.

The Waveland, consisting of three 14-floor RC mixed-use buildings with residential units, shopping mall, art village, and sport club. It is not only a stylish construction with integrated design, it is also injected with LOHAS spirit throughout the entire site, from exterior to interior, from large scale master planning to furniture details; it represents an organic carrier providing smart living. There are three parts of LOHAS design concepts introduced in the development.

- For sustainability, the building orientation and landscape are conducted by computer simulations for a comfortable environment filled with daylight and natural ventilation to reduce energy consumption.
- For health, organic gardens are inserted into green roof and landscape. All residents can obtain food ingredients planted by themselves, and visitors can also enjoy healthy foods in the restaurant.
- For wellness, diverse venues with nature and a pedestrian path winds between and around buildings like a hillside trail to encourage social interactions throughout the site.

This paper will discuss the concept of LOHAS designs and the details in design development stage.

Keywords: sustainable neighbourhood, wellness design, Taiwan

1. INTRODUCTION

In most of modern cities, people live a fast-paced life under various pressures. The convenience that human get from modern life may not be a healthy one as it usually accompanies along with pressure, pollution, and the feeling of alienation. Even though the threat to health is recognizable, the majority of the public could not just leave where they are at, and therein lays the problem. Thus, some of them started to look for the possibility of new urban lifestyle, which may be relatively inconvenient but more importantly, healthy.

In order to build a healthy and sustainable building, style or form should no longer be the only thing architects care about. There are numerous issues to be responded in the design such as nutrition, fitness, and wellness. In the coming chapters, a newly designed community following the concept of LOHAS will be a demonstration that showcases a living space where metropolitans would be desired to live in.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

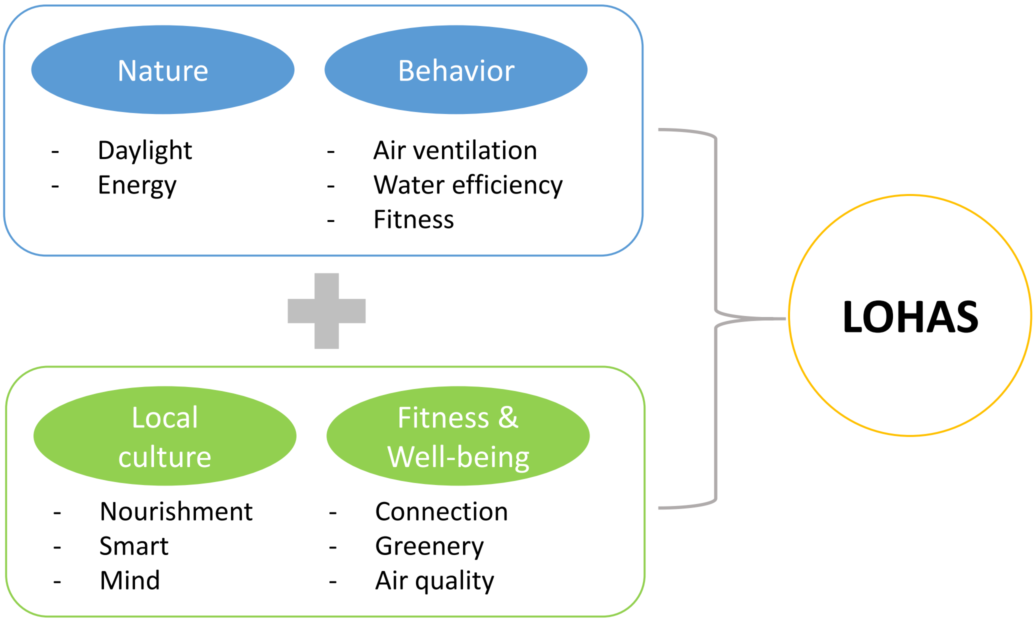

Figure 1: LOHAS concept

1.1. Design Trend

Since the Industrial Revolution in the 18th century, architecture and construction had got into a vast evolution. New materials and the change of the society had driven urbanization to bloom in that period of time. In the 20th century, the world was already occupied by lots of modern buildings constructed by concrete. People soon recognized that this was growing to become a threat for which themselves were the causes, so they began to talk about building sustainability. In the past 20 years, green building took the spotlight in this industry. Energy savings and environmental friendly design was the key topic that architects use to sell their designs. During this design trend, the needs of occupants were pretty much ignored.

Discussions and topics regarding the health of occupants emerged after the sustained debate of building sustainability. Engineers, scientists, and researchers have all joined the design team to contribute on the pursuit of healthy and sustainable designs. Nowadays, architectural designs not only emphasize solely on the importance of energy saving but also the impact on the human health and welfare.

1.2. Taiwan lifestyle

The economy and society of contemporary Taiwan was built upon agriculture. Looking back 50 years from now, the life was regular and simple in Taiwan. In that agricultural society, the economy was mainly dependent on crops productivities. Physically, people were healthy due to the daily works in the farmland; mentally, Taiwanese were happy because of the close interpersonal relationship in the small villages. The air was clean and the environment was full of greenery in that period of time.

As time goes by and along with the industrial development, most people left the farmland and moved into major cities as a metropolitan such as Taipei and Kaohsiung. Today, they can only experience the fresh air either in the countryside or in front of the air purifier. If you choose to live in the countryside, the life will be a bit dull due to the isolation of the location. Therefore, Taiwanese who live in big cities are used to and keen to have a weekend in the countryside to take a breath mentally and physically. That is one of the main reasons for the growing trend of stylish villas in Taiwan.

Figure 2: Life in modern city Taipei is tense and fast

1.3. Next generation of lifestyle

In consideration of the advantages of both urban and rural life, a new design concept is inspired - A LOHAS community that benefits the natural environment and the occupants at the same time. The environment is one point which shows human's care to others like biodiversity indicator in Taiwan green building system. Convenience would be another key point for which this design should also consider advanced systems, social activities, and interpersonal relationship that enables the occupants to feel like they are still living in an urban area and not isolated.

In addition to the points described above, the next generation of lifestyle should be affordable and able to blend into the daily life rather than a weekend holiday mode only. In this kind of community, people are able to actually enjoy their life with anything they need, as if they were still in urban areas.

In the following chapters, a newly designed community, the Waveland, consisting of three 14-floor RC mixed-use buildings with residential units, shopping mall, art village, and sport club will be an example to show what a LOHAS living space is.

Figure 3: The Waveland (Highlighted) is surrounded by nature

2 SUSTAINABILITY

Meanwhile, Sustainability remains a key in the contemporary building designs. More and more designers have recognized the importance of the environment, and thus more and more sustainable strategies have been invented and implemented in the design and construction process. For a community intending to support a LOHAS lifestyle, the practice of environment friendly design plan is essential.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.1 Nature

2.1.1 Daylight

A successful lighting design not only aids to achieve energy saving in lighting but also in HVAC. Daylighting diminishes the demand for artificial lighting, and the accurate control of daylight penetration helps to minimize the impact of solar radiation, for which it may lead to the increases of energy consumption required for indoor thermal comfort if solar heat gain is not properly addressed. In the Waveland, retail lobby and residential flat unit have applied computational daylight simulation to information daylight design.

2.1.2 Energy

Low carbon and energy efficiency design is the primary element in LOHAS. The Waveland applies the energy conservation hierarchy – first, make use of the natural environment to have passive design; second, optimise the efficiency of building services system; lastly, apply renewable technology to further offset the energy use. The technology development of renewable energy is on the cutting edge of trend day by day, and as a result, higher acceptance and usage in the architecture design. On-site produce and on-site consume is recommended for renewable energy planning as to minimise energy loss during the delivery process.

2.2 Behaviour

2.2.1 Air ventilation

Taiwanese are welcoming natural ventilation, and they generally have a behaviour to accept the slightly higher indoor temperature in naturally ventilated environment. This can greatly increase the usable period of natural ventilation. Advanced natural ventilation design reduces the energy consumption for air-conditioning equipment, and also provides sufficient fresh air to improve the indoor air quality. In this case, advanced computational fluid dynamics (CFD) technique is used to enhance the mountain shape design figure to maximize natural ventilation.

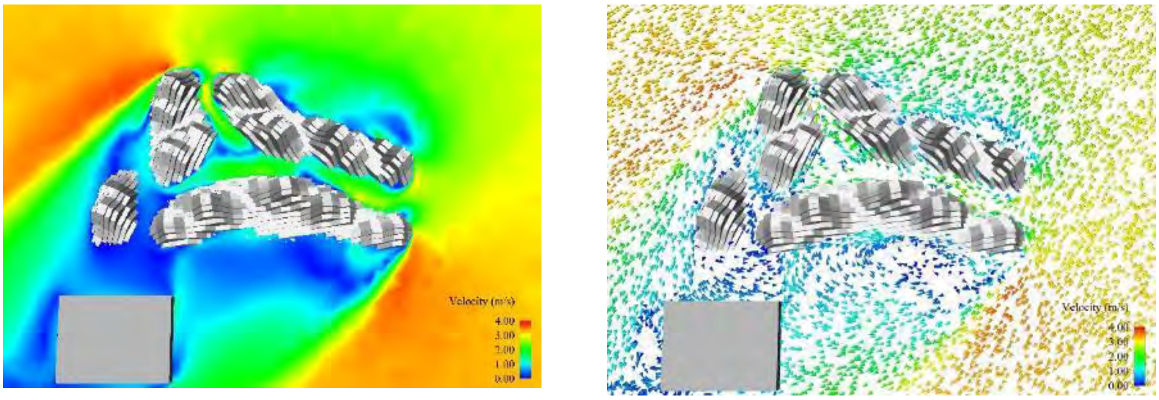

Figure 4: CFD air-flow simulations facilitate the wind environment design

2.2.2 Water efficiency

Waste water and the demand of potable water are two major issues to influence the environment on the water resource aspect. The uses of water efficient fixtures are common now, but this implementation is not good enough to reduce the impact and burden on the environment. Water recycling design should be the most significant strategy to deal with these issues such as gray water treatment and rainwater recycling systems for irrigation and flushing. However, in Taiwan, people have the perception to avoid using recycling water with human contact. In Waveland, the rainwater recycling is applied, and sufficient educational panels and facilities are provided to drive for users' behavior change.

2.2.3 Fitness

In urban cities nowadays, advanced transportation and labor-saving jobs has provided us a convenient life but at the same time threats has been brought to impact the citizen health. A high portion of the citizens cannot reach the suggested daily activity hours, which may cause obesity and cardiovascular diseases. It has been proved that sufficient exercise everyday benefits both physical health and mental health for humans. Some special fitness design ideas are inserted into this case such as horse riding, windsurfing, jogging path, and stair promotion.

Figure 5: Fitness concepts are applied into the design to provide a healthy living space

3 HEALTH AND WELLNESS

Human health issue was easily neglected in contemporary sustainable design. In the past 20 years, architects and designers paid more attentions on the outdoor built environment and building energy efficiency, but have ignored the indoor occupants and their needs. The new lifestyle, LOHAS, emphasizes the balance between outdoor and indoor living qualities. Today, a healthy living space, both mentally and physically, has become a core that cannot be ignored anymore.

3.1 Local culture

3.1.1 Nourishment

Food is the main source that humans obtain their nutrients and therefore has a direct impact to human health. Nowadays, the industrialized agriculture has altered the quality and quantity of food we take. There are more and more processed foods and artificial ingredients on the dining table, and it is either difficult or expensive to have a healthy meal. In the LOHAS community, the nutrition information of foods are to be shown clearly and those unhealthy products should be limited. On-site farming with local species is encouraged to control the quality of foods to be served in the community.

Figure 6: Organic farm and restaurants provide a healthy and local choice to occupants

3.1.2 Smart

One of the distinctive attractions of urban life that people nowadays can’t live without is convenience. For example, U-bike, the public city bike rent system provides an easy way to ride and explore in Taipei City. A smart and convenient transportation system encourages citizens to take public transportation for their daily move to reduce carbon footprint. In addition to smart transportation, a smart building system which is based on the advanced information and communications technology (ICT) in Taiwan effectively influences occupants' behavior to avoid energy wastes like daylight sensor, information dashboard, and demand control. Smart Home concept is implemented in the Waveland.

3.1.3 Mind

The mental status somehow influences the physical health both directly and indirectly. Anything that makes occupants happy and peaceful in mind benefits their health status too. In the concept of LOHAS, nature and beauty are two key points to evaluate design level in this category. A design linked to local context and culture is highly probable to be recognized as beauty. Plants, animals, arts are all included in this aspect.

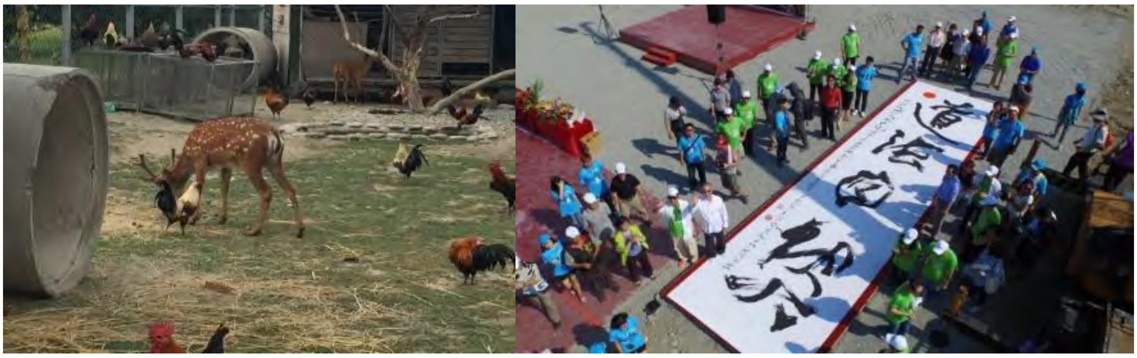

Figure 7: In terms of beauty, nature and culture are two major factors

3.2 Fitness and well-being

3.2.1 Connection

The feeling of alienation is common in the urban life which may lead to negative impact on mental health. In this LOHAS community, the architect designs many meeting corners such as coffee station, vanilla garden, and links them together by a jogging path which winds between and around buildings to encourage social interactions throughout the site. There are also many courses and activities arranged for all residents to improve the connection in the community with the intention of providing a living environment as close as they were in urban area, or even better.

Figure 8: Specific space design links occupants together and improves interpersonal relationship

3.2.2 Greenery

Greenery benefits a lot in reducing urban heat island effect. Additionally, it is one of the key points to recover the natural habitat and to reduce energy consumption. A new thinking for greenery is to have the awareness on the plant species selection which influences the water demand of irrigation and the efficiency of cooling down the ground or roof temperature. For example, in this case, the roof is 100% recovered by greenery and the roof temperature is lower than concrete roof.

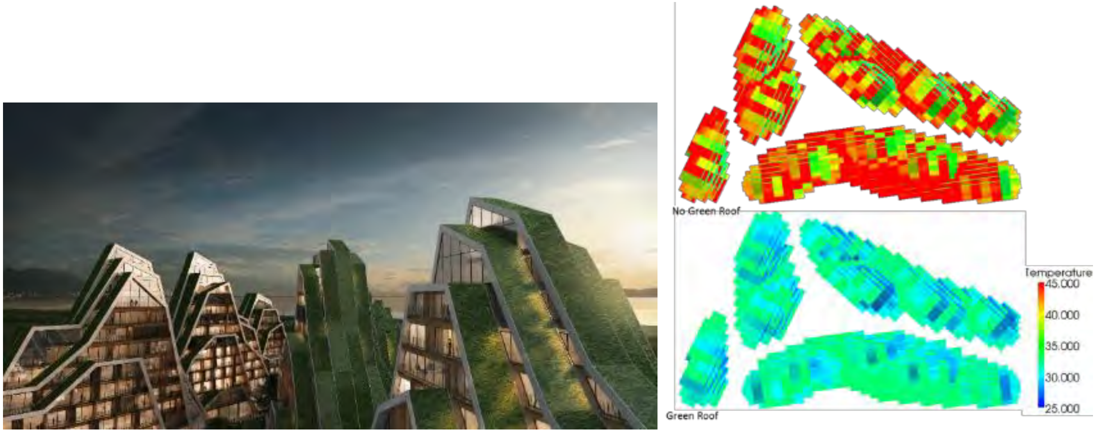

Figure 9: Maximum green roof design efficiently reduces urban heat island effect

3.2.3 Air quality

Urban residents in Taiwan would drive for hours just to go to the countryside to spend their weekends, in search for clean fresh air. The air pollutants such as PM2.5 and PM10 have been threatening human health tremendously in big cities. That is why natural ventilation may not be welcomed in the urban area. Before the outdoor air quality is improved in big cities, a high efficient air filter and indoor air quality monitoring are recommended to maintain the occupants' health, integrated with the Smart system. People spend 90% of their time indoors like in workplace, home, shops, restaurants, and therefore the indoor air quality is the first priority to ensure a healthy living space.

4 CONCLUSION

The two core values of LOHAS are "sustainability" and "health and wellness". According to the study of Taiwan society, there is an obvious and strong trend of demand for new lifestyle that combines the advantages of urban and suburban area. This situation is believed to be common in the modern cities around the world, and LOHAS may be one of the best solutions to this.

LOHAS represents a balance between the environment and its occupants. The human health, including both physical and mental parts, is as important as building sustainability. Nowadays, if a building only focuses on sustainability aspect would not be good enough to meet the public desire of life. Thus, a healthy and sustainable living space where the designers pay more attentions on the health issues such as nourishment, fitness, and interpersonal relationship could be an exemplary approach to response to the desires of residents in the modern cities, and it is expected to soon become the standards for future building industry.

ABSTRACT

Place making is one of Swire Properties' key strategies in integrating our sustainability commitment in our business. Brickell City Centre is our latest project in Miami, United States, which showcases our commitment and brings sustainable neighbourhood design into reality.

Brickell City Centre is a 5.4 million square feet mixed-use development comprising shopping mall, two office towers, one hotel and two residential towers across four city blocks. The buildings are inter-connected by the 150,000 square feet Climate Ribbon™ forming an inviting central concourse and semi-open space for people to gather. We believe we have introduced a vibrant and connected community hub for Miami city.

Climate Ribbon™ provides a naturally lit, covered, naturally cooled environment for pedestrians. This pedestrian-friendly design is complemented with its connectivity with surrounding pedestrian walkways, bike paths and a site-integrated Metromover light rail station, allowing our properties to connect to mass transit networks. A two-storey parking garage spans the entire underground area beneath the development site, freeing up above-ground surface area and allowing for more traffic control.

Brickell City Centre incorporates various planning and design elements from LEED Neighbourhood Development (ND), and is targeted to achieve LEED ND Gold certification. Various new green building design features and needs from the neighborhood have been adapted.

As a symbol of sustainability, Climate Ribbon™ encourages natural breeze, water recycling and visual connectivity. Its "scoops" at the eastern end of the development collect the southeast trade winds which are guided through the central concourse and ended with "spoilers" at the western and northern ends by creating low pressure. This passive design eliminates the need for mechanically ventilating the large volume of the multi-story, multi-block shopping concourse. Significant energy savings as well as more efficient space planning and a quieter environment without all the mechanical equipment are significant benefits from the outset.

This paper will further explain the details of the environmental design and how the community can be influenced in a better way.

Keywords: sustainable neighborhood, microclimate, rainwater recycling

1. INTRODUCTION

1.1 Place making as a transformative idea for improving neighbourhood

Place making is a multi-faceted approach to the planning, design and management of spaces. It improves the gathering places within a community covering its streets, sidewalks, parks, buildings and other spaces1, and invites greater interaction between people and the build environment and therefore creating a living space2. This aligns with Swire Properties' Sustainable Development 2030 Strategy where Place, People, Partner, Performance (Environment) and Performance (Economic) are identified as the five important pillars. We aim to transform places while retaining their character to support communities and enhance people's lives.

Mixed-use development is one of the key elements in successful place making. It creates a hub for people's different needs and become a self-sustained neighborhood. This translates to Swire Properties classic urban proposition – all uses in one place: retail, restaurants, office and hotel. This proposition replicates in Hong Kong (Cityplaza, Citygate, Pacific Place), mainland China (Indigo and Taikoo Li Sanlitun in Beijing, Taikoo Hui in Guangzhou, Sino-Ocean Taikoo Li in Chengdu) and now in Brickell City Centre (BCC) in Miami, United States.

1.2 Brickell city centre

Located at the centre of South Florida's international trade and finance corridor, Brickell City Centre comprises 5.4 million square feet of office, residential, hotel, retail and entertainment space. The building compositions are two condominium towers, two office buildings, a EAST hotel and a 500,000 square feet open-air shopping centre integrates shopping, dining and public space.

The Climate Ribbon™ is part of Brickell City Centre's overall people-centred, human-scale design. It is an elevated trellis of steel, glass and canvas placing above the main pedestrian thoroughfare of the shopping centre, binding each building together.

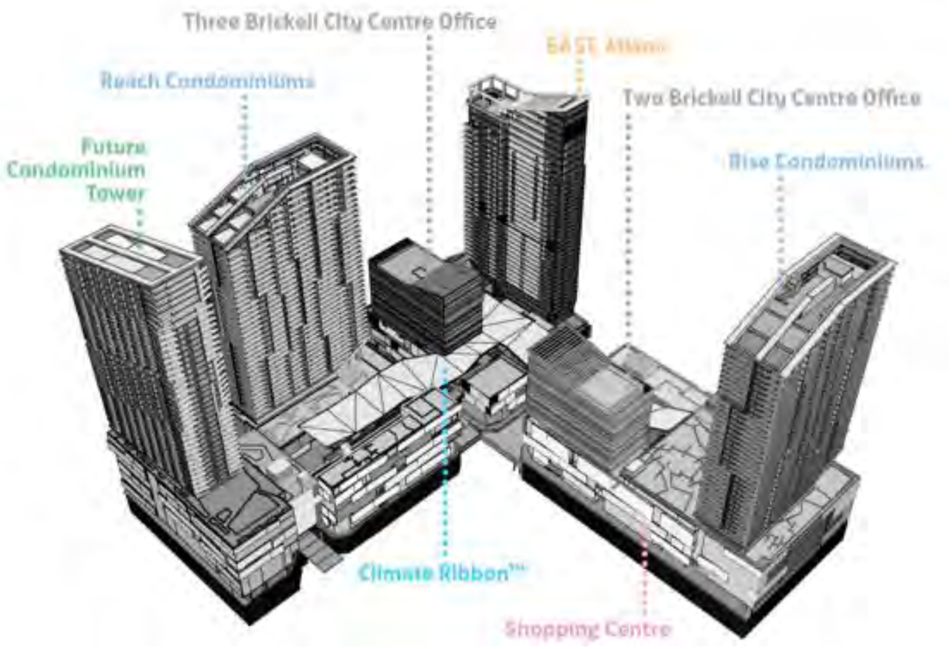

Figure 1: Overview of the Brickell City development

- Reach and Rise are twin luxury condominium towers comprising 780 total units
- EAST, Miami is one of Swire Hotels' lifestyle business hotels
- Two Brickell City Centre and Three Brickell City Centre together offer over 260,000 sq ft of prime office space
- The 500,000 sq ft open-air shopping centre integrates shopping, dining and public space
- The 100,000 sq ft Climate Ribbon™ improves the microclimate of the public spaces

2. CREATING A SUSTAINABLE NEIGHBORHOOD

Integral to the design and development of Brickell City Centre is a commitment to sustainability principles within its neighborhood. These include improving connectivity in multiple ways (to public transportation, minimized vehicular circulation for a project this size, increased pedestrian circulation); improved neighborhood micro-climate as per heat island effect; and the overall improvement of having a thriving mixed-use development energizing the neighborhood and providing new places to live, work and play where before there were empty blocks. From the initial concept for the project, BCC was designed to improve the neighborhood by factoring in the multiple layers of connectivity. The objective was to create an urban retail environment that is linked to the surrounding streets, sidewalks and public transit; BCC's precedents were Rockefeller Center instead of a suburban mall. This was

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

done by having multiple entry points as well as by creating pedestrian promenades along the center of each block on multiple levels, so they could cross the streets without conflicting with vehicular circulation. The expensive commitment was made to have two levels of below-grade parking for 2600 cars, allowing retail and lobbies to face the streets at the podium levels instead of the typical Miami parking podium. Access to the parking and loading docks was designed from the beginning with the goal to get cars/ trucks off the streets as quickly as possible, circulate within the building in order to exit where it was most expedient to leave the neighborhood, all efforts that reduces vehicles circling the city streets. Neighborhoods and retail thrives when there is connectivity, with people flowing through BCC as it becomes the city's centre, located at the historic crossroads of Tamiami Trail (South 8th Street) and Brickell Avenue.

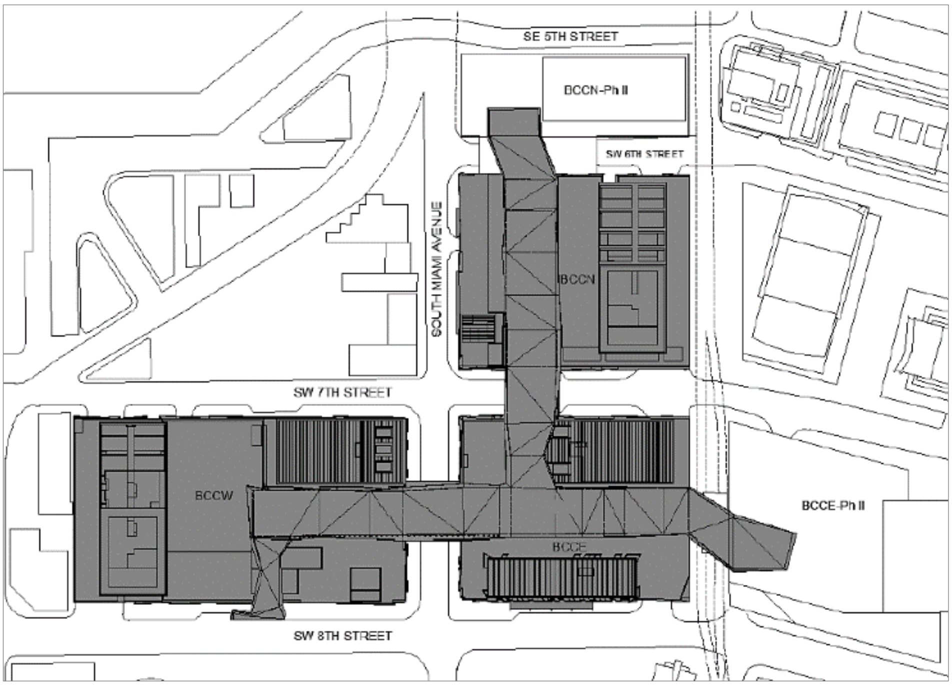

Figure 2: A layout map showing the location of BCC and its vicinity

BCC expanded the adjacent Metromover Station, adding escalators and extending the elevator to connect to the main concourse level above the light-rail platform. Integrating with this station allows easy access to the city light-rail transit network, including the nearby Metrorail, which will soon connect to the high-speed All-Aboard to Orlando. Other public transportation includes surrounding Metrobus stops and new Miami Trolley stops. This encourages BCC residents and visitors to adopt efficient transportation modes and move away from extensive use of single-occupancy vehicles and their heavy reliance on petroleum.

The Climate Ribbon™ above the central shopping concourse connects five towers (residential, office and hotel) across five city blocks, providing interconnected walkways at multiple levels, open civic spaces, active street fronts and tree-lined sidewalks, making it a pedestrian-friendly project. The connectivity with bike paths also allows BCC occupants and visitors to commute in a healthy and environmentally friendly way.

In addition, minimal parking footprint is achieved as the retail and office parking is in two levels of below grade parking. This enabled there to be more pedestrian friendly walkaway and sidewalks, articulated building fenestration and the elimination of the bulky above grade parking typical of development in Miami. The pedestrian safety is also considered and improved by multiple access points. This below grade parking allows access from one location and egress from another, working with the one way street system, and thus, reduces traffic congestion and accidents.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 3: Brickell City development

Brickell City Centre is further enhanced by its greenery extended over all concourse levels, amenity decks and streetscape with plant selection primarily of drought-tolerant native species. The landscape design by ArquitectonicaGEO includes regionally appropriate plant communities that transition from coastal dunes, to hammock and tropical foliage. The cumulative effect of BCC's extensive landscaping, with nearly half (46%) of the total roof area landscaped, reduces the ambient temperature within Brickell City Centre and the surrounding neighborhood as the landscaping absorbs the sun's warmth instead of deflecting it, an exemplary example of the heat island effect at work. The landscaping also improves everyone's physical and emotional well-being. Simply the sight of all the variety of landscaping, as biophilia studies have shown, reduces stress, lowers heart rates and increases a calm mood. The scents and leaves moving in the breezes also benefit the senses of smell and hearing, soothing everyone amidst the landscaping.

These sustainable elements in BCC are aligned with the principles of Smart Growth oriented development, for instance, promote mixed land uses serviced by a variety of transportation modes and create walkable site. These enable BCC to obtain recognition from Smart Growth Partnership. Along with the same sustainable neighbourhood concept, BCC is designed with the goal of achieving LEED Neighbourhood Development Gold certification for the mixed-use development complex.

3. CLIMATE RIBBON™

The Climate Ribbon™ acts like a shelter to improve the environmental performance for the general public mainly addressing 3 issues through passive design approach:

- Enhance natural ventilation
- Provide sun shade
- Promote rainwater harvesting

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 4: A 100,000 sq ft faceted canopy of steel and glass undulates between the mall, hotel, offices and residential towers

Detail scientific analysis and modelling simulation have been conducted before optimizing the current final design.

3.1 A breeze path

One of the common design practices on ensuring thermal comfort in pedestrian area is by mechanical ventilation or air conditioning system. However, Climate Ribbon™ strives to take the passive design approach which is more environmental friendly. The challenge is how we can introduce a feasible design with respect to the local prevailing wind condition and providing a comfortable condition for public walking underneath the canopy structure in summer time.

Figure 5: The semi-open space underneath the Climate Ribbon™ in retail concourse

The degree of thermal comfort is expressed as Standard Predicted Mean Vote (SPMV) which is a thermal comfort index with consideration on humidity, temperature, wind speed, solar exposure and human activity level in predicting pedestrian comfort levels.

Microclimate simulations have been conducted on the public area underneath the canopy structure, under 5 time slots of day and 4 seasonal periods.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

After various canopy designs and corresponding CFD simulations, an optimized design was agreed as indicated in Figure 6 below. The results below indicate that the overall thermal comfort underneath the Climate Ribbon™ in summer time is significantly cooler than the surrounding sidewalks.

Figure 6: Thermal dynamic simulation results showing the thermally comfortable zone created underneath Climate Ribbon™ [At mid-day in summer period]

Furthermore, we have simulated the breezing flow pattern under different prevailing directions. Figure 7 below indicates a 3D result with breezing flow from South East 8th Street into the pedestrian street from the south side. Wind will split and leave the pedestrian street at the north and west ends. The sectional diagram (Fig. 7) shows how the wind flow pattern and magnitude from east to west. The simulated results indicate that air flow will be maintained at approximately 3 to 4.6 m/s at all times throughout the centre. The thermal conditions at approximately 90% of the locations studied in the public realm under the Climate Ribbon™ will be better than outdoor ambient levels.

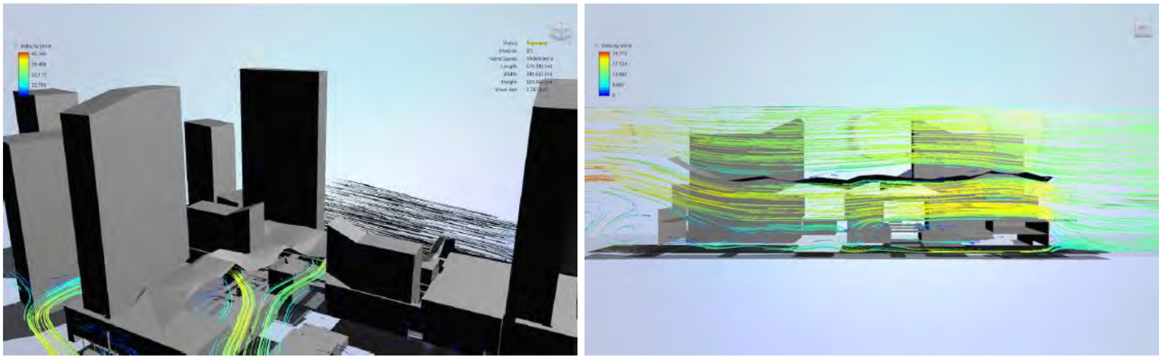

Figure 7: Simulate the breezing flow pattern under different prevailing directions

The reality of the micro-climate is also improved by BCC's lush and extensive landscaping designed by ArquitectonicaGEO. It contributes to the physical micro-climate by reducing solar heat gain. With nearly half (46%) of the total roof area landscaped, including multiple green roofs, the ambient temperature within Brickell City Centre

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

and the surrounding neighborhood is reduced as the landscaping absorbs the sun's warmth instead of deflecting it, an exemplary example of the heat island effect at work.

In addition to the contribution to micro-climate, this passive design in the semi-open area eliminates the need for mechanically ventilating the large volume of the multi-story, multi-block shopping concourse. Wind breeze flowing along the concourse also leads to significant energy savings as well as more efficient space planning and a quieter environment without all the mechanical equipment are significant benefits from the outset.

On top of computer simulation, physical model using wind tunnel test has been conducted to measure building performance under various dynamic buffeting conditions. Figure 8 below indicates the model created for wind tunnel test with a gust wind speed of almost 300km/h, which results in up to 6.5kN/m^2 wind load. The blade structure has been modelled to demonstrate the structural liability even under strong wind condition.

Figure 8: Wind tunnel test to measure building performance under various dynamic buffeting conditions

3.2 A sun shade

During the design stage of the Climate Ribbon™, we faced another challenge on daylight issue. We intend to provide shading for the pedestrian street while maintains suitable degree of sunlight.

3D shading analysis using typical meteorological year (TMY) data for Miami has been conducted to determine the solar exposure at each location on an hourly basis. Annual sun path (Figure 9) for the site with consideration of the surrounding buildings has been simulated.

In addition, we manage to limit the amount of sun projecting directly into shop fronts. It is now demonstrated that the Hotel East can shade the North South Street from noonday direct sun. Furthermore, the west BCCW condominium tower can shade the East and West Streets from late afternoon direct sunlight.

Regarding the blade angle design of the Climate Ribbon™, Figure 10 shows a mapping of annual direction and intensity of sun exposure for the pedestrian street and shop fronts. Optimized design is achieved with longitudinal blades perpendicular to the sun angles.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 9: Providing optimal alignment for sun protection by simulating the annual sun path for the site

Figure 10: Modelling on effect of different blade angles

3.3 A rainwater collector

Apart from natural ventilation and sun shading, we also considered the possibility of rainwater harvesting, with the end result of capturing all the water in a total of 6 cisterns that is needed for BCC's irrigation as well as some mechanical functions (see attached cistern location plan). Since the CLIMATE RIBBON TM is connecting the hotel, office and the residential towers with an area of 100,000 ft2, we have introduced interesting contour with a fluid ceiling beneath of sinuous blades of architectural fabric shading. Quantity of rainwater collected and the corresponding pipe sizes have been predicted accordingly. With the local rainfall data available, it is predicted that 4.3 million gallons of rainwater for reuse annually. The harvested rainwater provides 100% of the irrigation water and cooling tower make-up water. Figure 11 provides an image of the contour with Climate Ribbon™ angled planes directing the rainwater to the cistern collection points, for information.

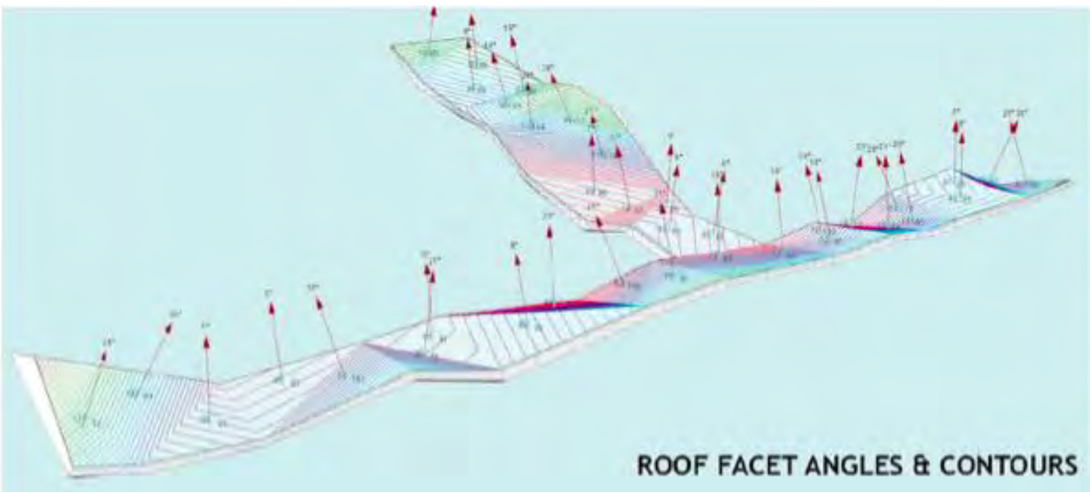

Figure 11: 3D model of the roof facet angles and contours

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4. CONCLUSION

Climate Ribbon™ provides a naturally lit, covered, naturally cooled environment for pedestrians and becomes an innovative solution to creating a favourable microclimate for the neighbourhood. It also connects five building blocks, providing interconnected walkways which leads to a pedestrian-friendly development. Integral with its connectivity with a site-integrated light rail station, Brickell City Centre becomes a vibrant and connected community hub in the heart of Miami.

ABSTRACT

Nowadays, urban greening is a popular program within urban cities with an ultimate objective of improving the environmental quality. Urban greening in form of parks have been shown to provide numerous benefits like mitigating urban heat island (UHI) effect and improving thermal comfort in urban areas. However, there is a lack of guidelines to inform how park should be designed in order to improve the thermal environment inside parks. This study aims at investigating how different types of paving materials will affect the temperatures of different areas inside an urban park. In addition, it also aims to investigate the cooling ability provided by trees in the park. To this end, a series of field measurements were conducted with the assembled monitoring system and infra red camera. Our results found that the type of paving materials significantly influenced their surface temperatures at different time periods of a day. The shading effect provided by trees could significantly lower the surface temperatures of the park. The findings arising from this study should provide valuable insights on park planning for maximizing the cooling ability within the park environment.

Keywords: urban parks, urban cooling effect, paving materials

1. INTRODUCTION

Nowadays, urban greening is a popular program with an ultimate objective of improving the environmental quality in urban areas including roadside environments. Urban greening can mitigate the urban heat island (UHI) effect and improve thermal comfort by moderating micro-climatic conditions (Taha 1997; Park et al. 2012; Shashua-Bar et al. 2009) and provide shading (Ali-Toudert & Mayer 2007; Shahidan et al. 2012). Also, it can bring other benefits including the ability to attenuate noise levels (Van Renterghem et al. 2012; Islam et al. 2012), improve air quality (Nowak et al. 2006; Jim & Chen 2008) and reduce urban storm water runoffs (Armson et al. 2012).

The cooling effect beyond boundaries of parks is influenced by the physical setting of urban parks, e.g. park area (Lin et al. 2015; Feyisa et al. 2014), park geometries (Kong et al. 2014), type of plant cover (Lin et al. 2015; Cheng et al. 2015), and land cover (Feyisa et al. 2014), and the proportion of vegetated surface versus paved surfaces within a park (Feyisa et al. 2014). Fragmented greenspaces could also provide effective cooling (Kong et al. 2014) and large parks were found to be cooler than smaller ones. Quite often, a park's cooling effect could extend beyond its boundary into the surrounding streets and buildings (Feyisa et al. 2014), and the extent of influence was also affected by the nature of area around each park despite being related in part to park area (Kong et al. 2014).

In addition, urban greening can provide cooling effect inside parks. The cooling ability is influenced by area of shade, geometry of parks and tree characteristics (Shashua-Bar & Hoffman 2000). Trees and vegetation lower surface and air temperatures by providing shade and through evapotranspiration (Doick & Hutchings 2013; Landscape 2016). The surrounding air temperature can be 3°C lower and the surface temperature can even be 8°C lower than the unshaded areas (Lin & Lin 2010). A single tree could moderate the climate (Jauregui 1990), and a tree with a wide canopy could even reduce the surrounding air temperature up to 3.5°C during daytime (Potchter et al. 2006). However, the cooling effect of trees may vary from time to time and may vary due to difference in radiation condition (Yu & Hien 2006; Oliveira et al. 2011).

Besides the ambient air temperatures within a park, the surface temperature of different areas within parks should also be an important design consideration as park visitors may have close contacts with the ground surface. In fact, surface temperature has been proposed to act as one of the indicators for investigating the cooling ability of park since reasonable correlations were found between surface and air temperature (Widyasamratri et al. 2013; Li et al. 2008). As a park often embraces many different functional areas, both the ambient air and surface

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

temperatures are anticipated to vary with the types of paving materials (Santamouris et al. 2012; Santamouris 2013; 2014). Accordingly, this study aimed at investigating the cooling effect provided by trees in an urban park. It also aimed at investigating the cooling ability of different types of paving materials under shaded and unshaded condition.

2. METHODOLOGY

2.1. Studied site

A urban park in Tsim Sha Tsui (Kowloon Park (KP)) was selected for conducting measurements. The park was surrounded by high-rise buildings and medium trafficked roads. Its location and major characteristics are shown in Figure 1 and Table 1 respectively.

Figure 1: Location map of the studied park

	Kowloon Park (KP)
Area	317m x 417m
Tree coverage inside park	90%
With water features in parks	Yes
Height of Surrounding buildings	100-120m
Distance between the parks and building	30m

Table 1: Characteristics of the studied park

2.2. Field measurement campaigns

Two mobile microclimatic stations had been assembled for recording the microclimatic conditions under shaded and unshaded areas of the center of the park. The mobile stations embraced sensors for measuring and recording air temperature, globe temperature, wind speed, relative humidity and solar radiation. All instruments are compiled for the specification details stated in WMO, No.8 (2008).

2.3. Geographic Thermal Environment Information

Thermal camera with a resolution of 320*240 pixels (Testo 875-1i) (see Figure 2) was used to measure the surface temperatures for different areas within the park by taking remote sensing images. The photos were then further analyzed by the computer software IRSoft after inputting the emissivity, air temperature, relative humidity and wind velocity values of the measurement points. Measurements were carried out in an hourly interval from 12:00 to 23:00 for about ten days from October to November 2015. In addition, the geographic information of the park such as the total park area and the proportion of greenery areas were determined from GIS-System (Holux M-241) (see Figure 3).

Figure 2: Thermal camera

Figure 3: GIS-System

2.4. Measurement locations and materials

Both natural and synthetic paving materials like sand and grass, clay, concrete, brick, rubber used in different functional areas of a park were chosen for investigation in this study. Table 2 shows the photo images and the emissivity values of different types of paving materials. The emissivity values for different types of paving materials were extracted from Mills (1999) and the instruction manual of the thermal camera. Figure 4 shows the designated measurement routes for all the ten measurement days. One of the selected survey spots contained a banyan tree located in the Banyan Court so as to investigate the cooling ability of a tree. As there were sufficient open areas around the tree, the cooling effect of a tree could be observed directly (see Figures 5 and 6). The ground temperatures at 2m, 4m, 6m and 8m away from the center of Banyan tree were measured at different orientations (South, West and North). However, the temperature changes were not monitored at the East orientation because surrounding buildings might have influence on the cooling effect on that side. Infra-red photos were taken in an hourly interval from 12:00 to 23:00 for ten different days so as to analyze the cooling effects of the park during both daytime and night time.

	Type of Material	Emissivity Value	Photos of the materials		Type of Material	Emissivity Value	Photos of the materials
A	Clay	0.91		F	Concrete	0.91	B	Clay	0.91		G	Concrete	0.91	
C	Brick	0.90		H	Sand	0.75	D	Clay	0.91		I	Grass	0.92	E	Rubber	0.89

3. RESULTS

3.1. The cooling ability of different types of paving materials under shaded and unshaded condition

Figure 7 shows the surface temperatures for nine different types of paving materials under shaded and unshaded condition at different periods of a day. Dotted lines denote the surface temperatures of the paving material measured under shaded condition (Material *A* to *I*), while solid lines denote the surface temperatures of material measured under unshaded condition (Material *A* to *I*).

Highest surface temperatures of Rubber (Material E) were observed in Children Playground while lowest surface temperatures were observed in natural environment containing Sand and Grass (Materials H and I) under both shaded and unshaded conditions during afternoon periods. The surface temperatures of paving materials like Clay and Concrete could reach 40-45°C while Brick could reach 50°C in the afternoons.

For all types of paving materials under shaded condition, the surface temperatures fell below 37°C during the afternoon periods. For those materials without shade, the surface temperatures rose over 37°C and could even rise up to 65°C or above. The surface temperatures of all the materials showed a decreasing trend with time period after 1pm under both shaded and unshaded condition. For the same type of materials, the surface temperatures under shaded and unshaded condition after sunset were nearly the same, i.e. around 25 - 30°C. The gradients of temperature difference before and after sunset for those materials under shaded condition were small, between 0 and 5°C. However, the gradients of temperature difference before and after sunset for those materials under unshaded condition were large, which could be more than 10°C and could even go up to 40°C.

Even with a significant difference in surface temperatures during daytime, the results showed that the surface temperatures after sunset were almost the same for shaded and unshaded condition. This suggested that shading could lower the surface temperatures substantially during the afternoon periods. The decreasing trends of surface temperature for all different types of paving materials slowed down and became stabilized at night time. Furthermore, the ambient air temperature measured at the clay surface was linearly correlated with both surface temperatures under shaded ($r=0.716$) and unshaded areas ($r=0.653$), which further confirmed that surface temperature can be used for portraying ambient air temperature.

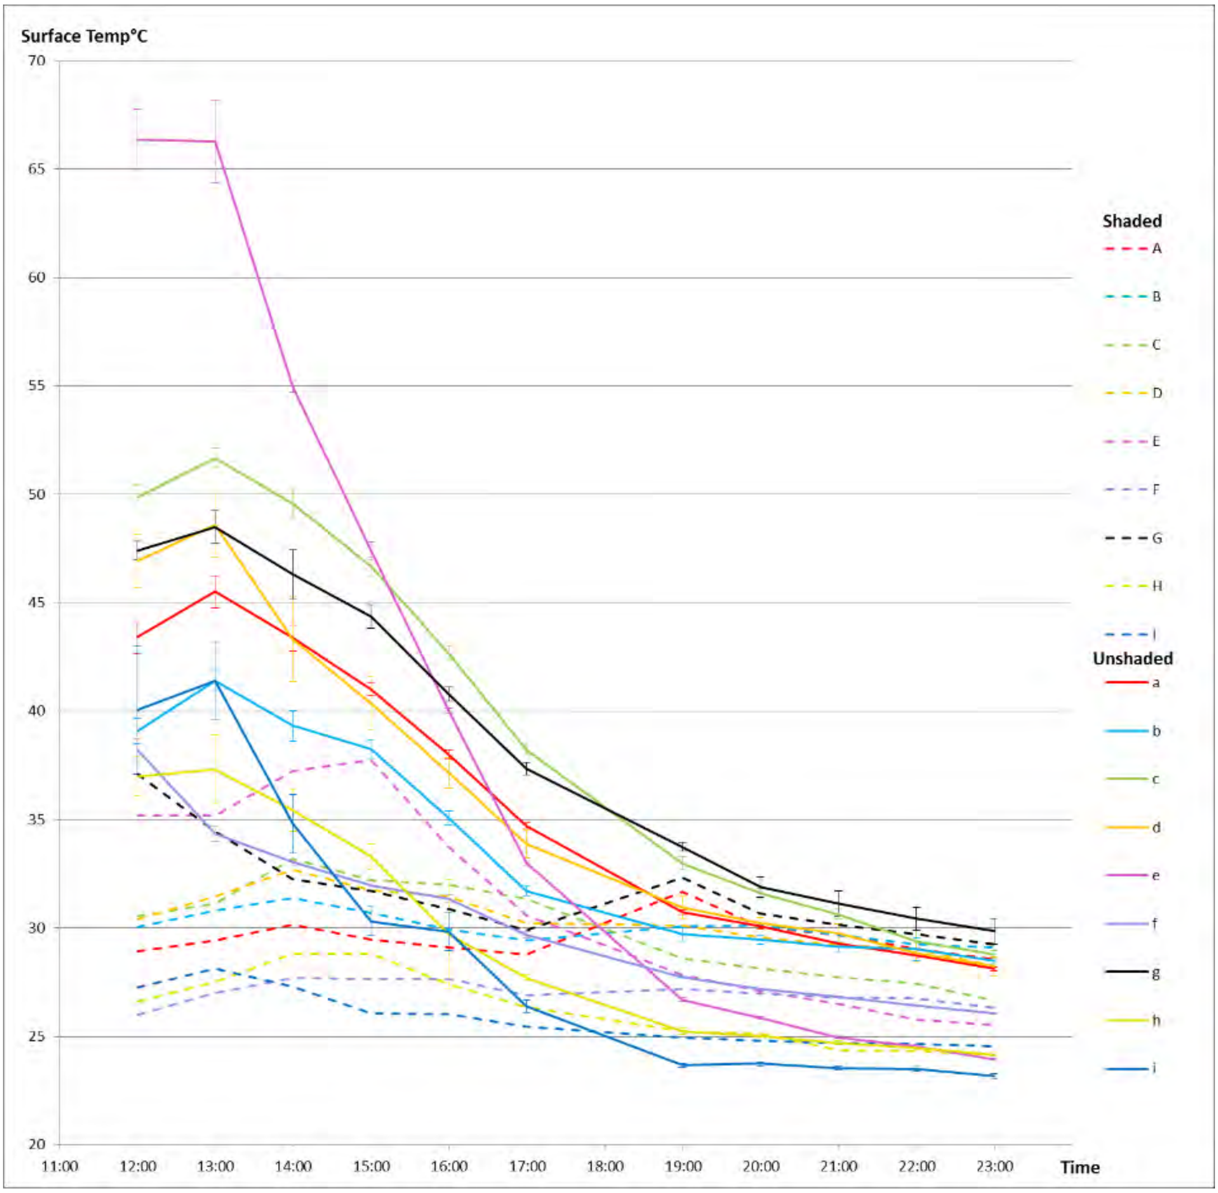

Figure 7: Surface temperatures for nine different types of paving materials located in shaded areas and unshaded areas

3.2. The cooling effect provided by the greenery area in the urban park

The ground surface temperatures at various distances (2m, 4m, 6m and 8m) away from the center of the Banyan tree were measured at three different orientations (South, West and North). Locations 1 and 2 (2m and 4m away from the center of the tree respectively) were mostly shaded by the tree, while Locations 3 and 4 (6m and 8m away from the center of the tree respectively) were not shaded.

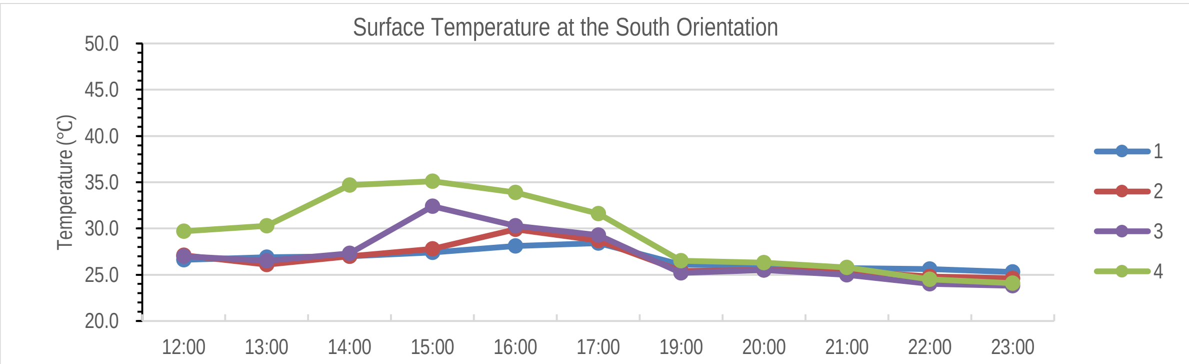

Figure 8: Surface temperatures at the South orientation

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

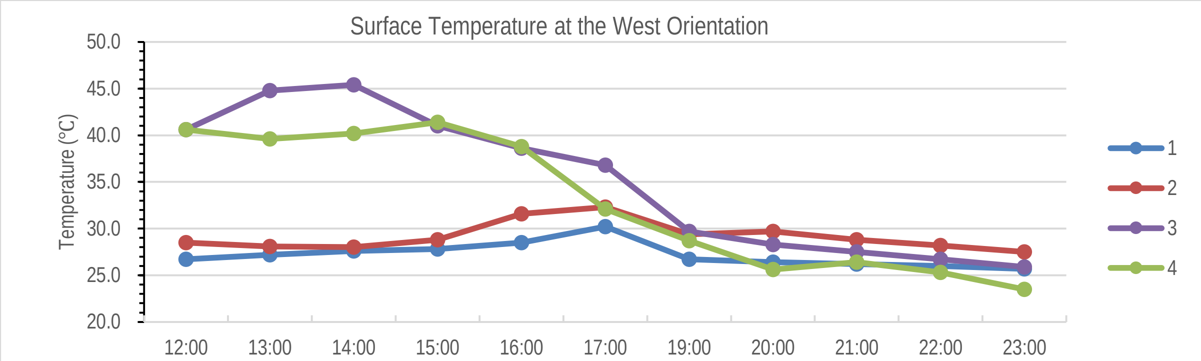

Figure 9: Surface temperatures at the West orientation

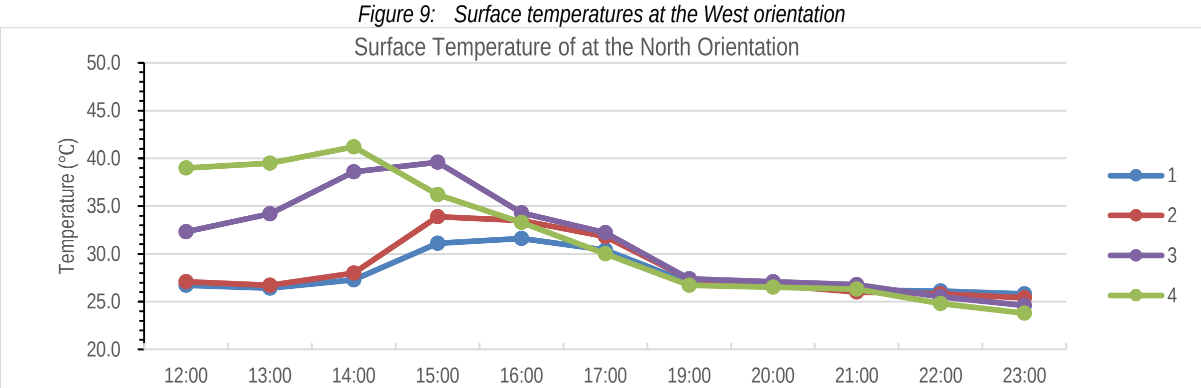

Figure 10: Surface temperatures at the North orientation

Figures 8, 9, and 10 show the surface temperatures at various distances away from the center of the tree for different periods at different orientations. All these 3 figures show that the temperatures at Locations 1 and 2 shaded by the tree were generally lower than those at the corresponding unshaded counterparts (Locations 3 and 4). However, the cooling ability of tree varied with orientation. At the West orientation, the surface temperatures remained around 40°C till 4pm as less amount of shade was provided by the tree due to the sun direction, while the surface temperatures at South and North orientation dropped with time after 2pm. Figure 11 show the effects of shade on temperature variation with and without shade over a 24-hour period. Shade provided by trees could lower the surface temperatures by at least 15°C during afternoon periods, while the presence of tree would not change the cooling efficiency at the nighttime.

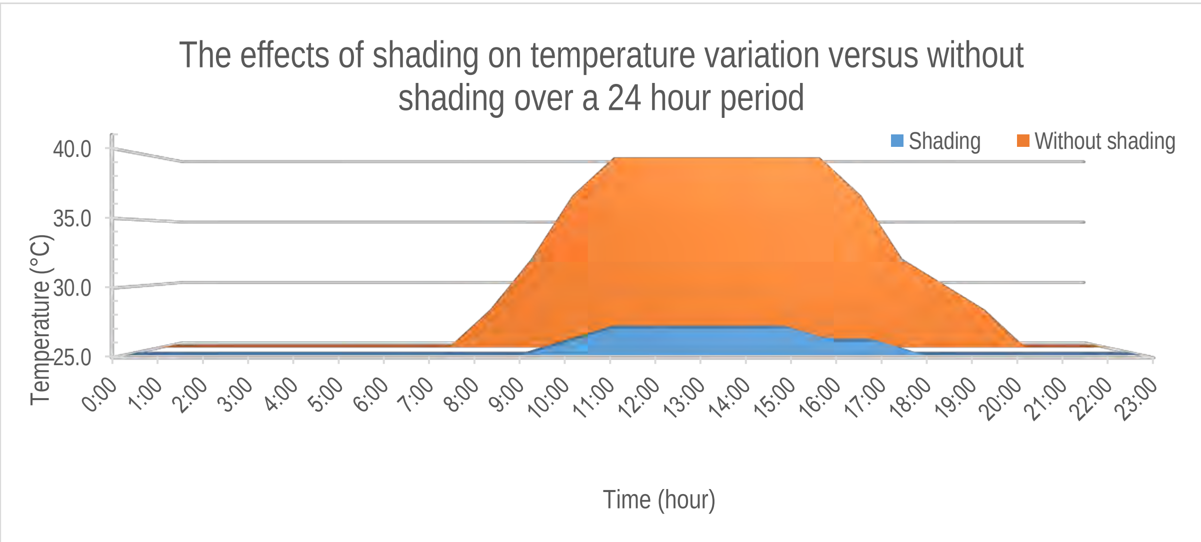

Figure 11: The effects of shade on temperature variation over 24-hour period

4. CONCLUSION

In this study, surface temperatures of nine different types of materials under shaded and unshaded conditions were measured within an urban park in Hong Kong. Basically, it was found that shade was an important means to lower the ground surface temperature inside a park in the presence of sunlight. The more natural the paving material, the cooler the ground surface was. The surface temperatures of clay and concrete (about 40°C) were comparatively lower in the afternoon periods, with higher surface temperatures being detected for bricks (up to 50°C). Alarmingly higher surface temperatures were determined for the rubber paving in children playground (up to 65°C or above), which can pose health threat to children playing inside the playground. These results should provide valuable insights for urban planners when designing parks as paving materials do not only affect their functional uses but also greatly affect the surface temperatures inside parks.

ABSTRACT

Human wellbeing in architecture is highly influenced by its site and climate; there are methodologies that suggest the correct orientation of open facades, depending on pre-existing weather condition, which seek to ensure the user environmental comfort. In tropical cities like Medellin - Colombia, the absence of stations generates a relatively homogeneous climate that allows the use of passive design strategies to naturally condition spaces and to adapt the interior space, according to a particular function or activity; however, the rapid growth of cities and the lack of sustainability criteria in urban planning has limited the orientation of buildings to the pre-existing urban design, narrowing the design options and the use of resources. This article aims to develop a tool for architects, which provides design premises for building envelopes with under bioclimatic criteria, according to the orientations of open facades, on the basis that any orientation can be imposed by the urban setting. For this a hypothetical model, with pre-set parameters and the possibility of opening only two facades, was evaluated. Sunlight incursion, natural ventilation and natural lighting simulations were made, which gave us inputs for the development of the tool. In order to illustrate its use, the premise obtained in the design of the facades of the hypothetical module were applied on an example located in the city of Medellin, in two different orientations, achieving through different facades, a similar indoor environmental conditions.

Keywords: bioclimatic architecture, human well-being, environmental comfort, passive design, building orientation.

1. INTRODUCTION

In the city of Medellin, Colombia, during its development, the rapid growth of the population and the industry, gave way to an slow process of urbanization and legalization, with a lack of sustainability criteria. In the literature on bioclimatic architecture, studies indicate which is the ideal orientation of open facades according to: climatic factors, the latitude, prevailing wind currents and availability of lighting resource (Olgyay, 2002). However, given the urban configuration of the city, in some cases it is not possible to choose the orientation of the open facades.

This research seeks to provide a tool for architects to design envelopes with bioclimatic criteria. The importance of this tool lies in promoting and encouraging the construction of buildings designed with bioclimatic criteria that favor human well being in inner spaces and decrease environmental impact. The research studied the behavior of a hypothetical model in eight different orientations, starting from the north and rotating 45° degrees each time to complete 360°, as illustrated in Figure 1.

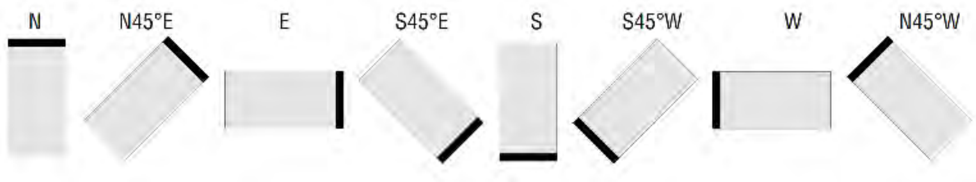

Figure 61: Orientation of the analysed open facades

2. RESEARCH BASELINE

2.1 Geographical location and climatic characterization

The study was developed in the city of Medellin, Colombia, at latitude 6°13'55"N and longitude 75 ° 34'05"O. Its temperature ranges between 12°C and 32°C having an annual average temperature of 22°C. The average relative humidity is 68% and the predominant wind direction is north (23%) - South (14%), with speeds between 1.5 m/ s and 7.9 m/ s (IDEAM, 1999a).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.2 Hypothetical model properties

It was specified a hypothetical model of a rectangular shaped, 6m wide, 12m long and 3m high, located in a central block, whose areas of intervention are the main facade and the roof. The selected building typology was an “office space”, as this are environments that require prolonged stay and in which complex activities with high requirements for sun protection, lighting and ventilation are developed.

2.3 Environmental factors

Solar incursion: To calculate solar incursion into the model, a solar chart for latitude 6.13°N was used. This type of diagrams are easily obtained (Arquitectos, n.d.) or can be built (Bermudez, 1969).The dates chosen for the diagnosis were December 21th and June 21th (solstices); and March 21th and September 21th (equinoxes). According to the spatial typology, it was determined that between 8:00h and 16: 00h, direct sunlight should be avoided on the open facade.

Natural Lighting: Daylighting simulations were performed with the Velux Daylight Visualizer 2.8 software, under partly cloudy conditions, on December 21th, June 21th and March / September 21th at 8: 00h, 12:00 and 16: 00h. This software, presents the amount of lux present in the space at the level of the work plane (0.75 m from the floor surface) in order to identify areas that are over-lit or poorly lit.

To define the required lighting levels in office spaces, this study took as a reference the "technical regulation lighting and street lighting. RETILAP"(Ministerio DeMinasYEnergía, 2015). For office spaces, the lightning levels required on the work plane should be between 300 lx and 1.000 lx.

Natural ventilation: To determine the size of openings necessary to naturally ventilate the space, "The Florida Solar Energy Centre Method 1" was used. This method calculates total opening area (TOA) required, considering an inlet and an outlet located in opposite facades, of equal area, and taking into account the effect of wind, regardless of the temperature. This formula was chosen as it proposed corrections to the wind direction and surroundings characteristics.

$$TOA = \frac{1{,}16 \cdot 10^{-3} \cdot V \cdot ach}{W \cdot f_1 \cdot f_2 \cdot f_3 \cdot f_4}$$

Equation 1

Where TOA = total opening area in m^2 (the sum of both the entry and the exit); V = volume of the building in m^3; Ach = air exchanges per hour; W = wind speed in m/ s; f1 = coefficient determined by wind angle of incidence; f2 = site correction factor; f3 = surroundings correction factor; f4 = height multiplication factor.

According to the chosen spatial typology, 10 Ach were considered as the minimum required and 30 Ach as the optimum air changes per hour (Tobar Arango, 2004).

3. DIAGNOSIS

Once the parameters were stablished, a diagnostic analysis was performed assuming the main facade is entirely open.

3.3 Solar incursion

Based on the criteria established in the research base line, a solar incursion analysis was conducted for each orientation. In Figure 2, the areas on the floor that receive sun during the set dates and times, are indicated.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

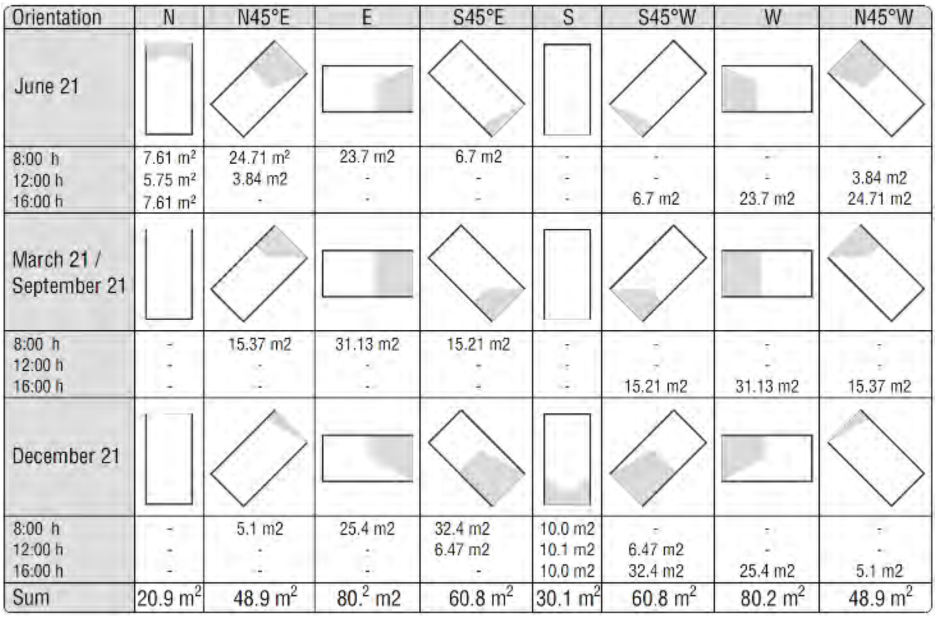

Figure 62: Summary of the floor areas that receive sun during the studied dates and times

At the end of each column the sum of the sunny areas is presented, obtaining as a result that the facade with the lowest solar incursion throughout the year is the one oriented towards the north (N) and the sunniest are the Eastern (E) and western (W) facades, both presenting the same value.

3.4 Natural ventilation

In order to calculate the required ventilation open areas, for each module, the f value (correction factor) were determined according to the facade orientation.

(f1) Wind incidence angle: Considers the loss in efficiency presented when the wind enters a space depending on the inclination of the facade with respect to the prevailing wind direction, thus: 90°=0.08, 80°=0.14; 70°=0.2; 60°=0.25; 50°=0.3; 40°=0.35; 0°=0.35. Two directions of the wind were set, the predominant direction, north (3.23 m/ s) and the second predominant, south (2.5 m/ s) (IDEAM, 1999b).

(f2) Correction factor due to side location: the chosen site location was "great city center", 24 hours a day. For these two conditions a value of 0.47 was determined.

(f3) g (distance)/ h (obstacle height) relation: For all orientations, it is considered that the open façade faces an obstacle (h) corresponding to a three story building (9 m high), located at a distance (g) for the urban section between buildings: sidewalk 1.2 m + street 5 m + road divider 1 m + street 5 m + sidewalk 1.2 m = 13,40 m, being the g/ h ratio equal to 13.4/ 9, 1.49, equivalent to an f3 of 0.63.

(f4) Multiplication factor due to the height: Only one level; f4=1.

Table 1 shows the result of opening areas required for minimum air exchange (10 Ach) and the optimum air exchange (30 Ach). The area presented corresponds to a single opening, the inlet and the outlet must each meet the area indicated.

Opening areas required for ventilation in office space(m^2)					
Facade	N	N45°E - N45°W	E y W	S	S45°E - S45°W
10 Ach	2,17	2,53	9,50	2,81	3,27
30 Ach	6,52	7,60	28,51	8,42	9,82

Table 1: Opening areas required for ventilation purposes

The open facade of the module has an area of 18 m2 which prevents the east (E) and west (W) facades from meeting optimal air exchanges. For this reason, the minimum air exchanges (10 Ach) as the comparison parameter.

3.5 Natural lighting

Simulations were performed according to the parameters outlined in the research base line, considering the following materials for each system: walls = semi-gloss white paint; floors = semi-gloss white finish; blinds = wood; profiles = aluminum and glass = clear glass. In Figure 3, three (3) different values are identified at the work plane height (0.75 m from the floor surface), the areas of it that over lit, those that are properly illuminated and those that are poorly lit. Columns show the orientation of the open facade and the rows show the dates that were evaluated. At the end of the table the sum of the optimal lit areas was performed to identify the areas, which have lighting independence throughout the year. The orientations with the highest and lowest area in the final count are the N45°W and N45°E facades, respectively.

Orientation	N	N45°E	E	S45°E	S	S45°W	W	N45°W
June 21th								
over-lit area	7.1 m²	10.9 m²	7 m²	7.3 m²	7.2 m²	7.3 m²	7.1 m²	7.2 m²

4. CONSTRUCTION OF THE TOOL

The proposed tool, was developed by building a calculator that allows to obtain basic outputs to generate solar control strategies, to identify areas of ventilation and promote the balance of the light curve according to the space needs.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

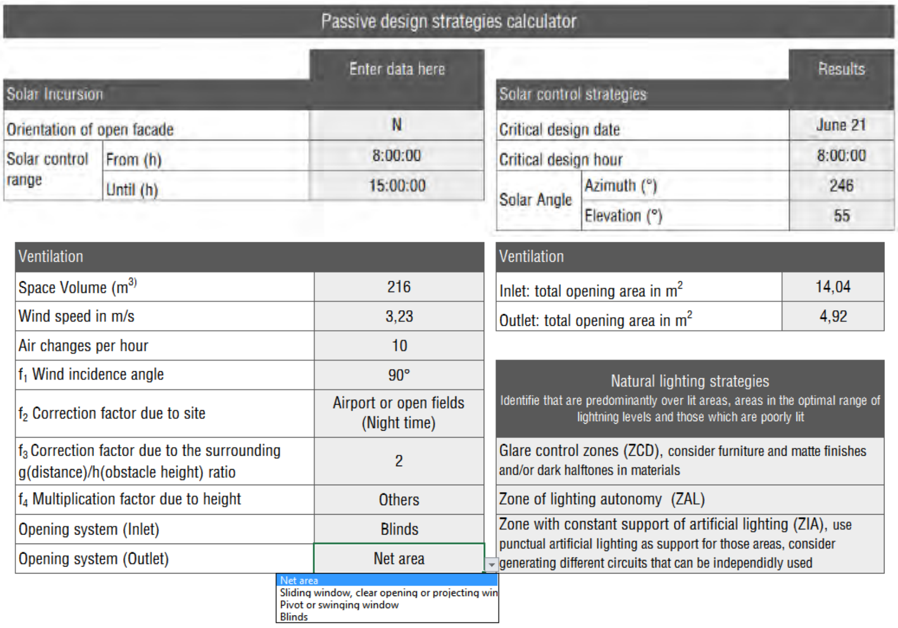

Figure 4: Passive design strategies calculator

To use the calculator, the designer should enter the data requested in the first column. Once the data is entered, the second column will display the design criteria, as shown in Figure 4. Table 2, shows the instructions on how to read the results obtained in the calculator.

Solar protection strategies		
Critical design date	Indicates the date with the highest solar exposure according to the given orientation	
Critical design hour	Indicates the hour with the highest solar exposure according to the selected time range	
Solar Angle	Azimuth	Angle of solar exposure in the top view
	Elevation	Angle of solar exposure in the section view
Ventilation		
Required inlet area in m²	Opening area required in facade according to its efficiency	
Require outlet area in m²	Opening area required in facade according to its efficiency	
Observation: The efficiency of the type of opening will depend on the particular characteristics of each system, for this exercise the following efficiencies are assumed. Net area: 1; Sliding or projecting window open at 90°: 0.8; swinging or pivoting window: 0.6; and blinds: 0.3. If you have a different window system, take the total opening area and divide by the systems efficiency.		
Lighting		
Due to the multiplicity of factors that affect the behaviour of natural lighting is recommended to identify the areas that are over lit, illuminated in the optimum range or poorly lit, and implement the recommendations included in the calculator.		

Table 2: How to read the tools results

5. APPLICATION EXAMPLE. CASE STUDY MEDELLIN

This chapter contains an application example of the use of the calculator. Passive design strategies are chosen for two (2) facade's orientation, the (N) and the (W), which represented the most favorable and critical conditions, respectively, during the diagnosis of solar and wind exposure. As an architectural approach, a flexible, modulated facade was chosen, dividing it into a basic grid with divisions of 1m in the horizontal and 0.6m in the vertical 0.6m. Each module is a projecting. This element is made of wooden slats framed in metal profiles, and inside, a clear glass that has no solar protection coefficient. The opening angle, density and size of the slats depend on the requirements for solar control of the facade's orientation; the windows operation will be defined according to the ventilation needs. Inside the space, 0.75 m from the floor surface (work plane height) is taken as the evaluation height, and the dimensions of the Latin-American population are taken as a reference for comfort analysis purposes (Ávila, Prado, & González, 2007).

5.1 Solar protection criteria

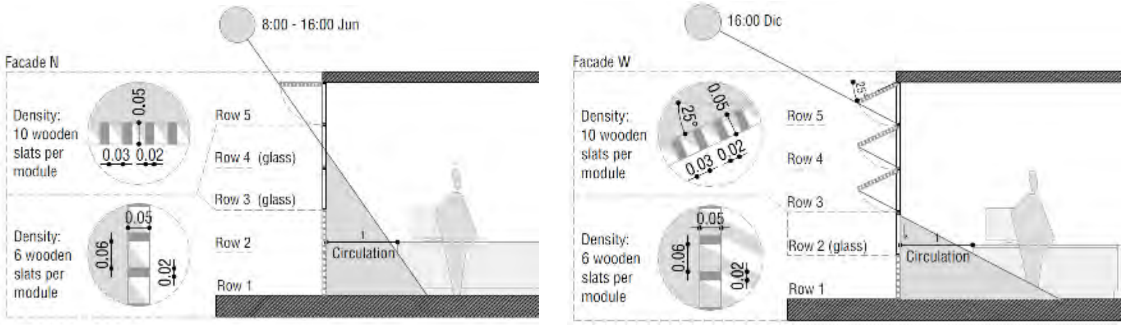

Figure 5: Application of elevation angles for defining elements of solar shading

The facades were divided into rows. According to the defined range of solar control, Figure 5 presents the design strategies apply for both facades, where rows that require solar protection are identified, and for those rows where protection is not needed, the dimensions of the wooden slats and densities of them are given.

5.2 Natural ventilation criteria

The method used to calculate the areas required for ventilation, assumes two openings of equal size, one as an inlet and the other as an outlet. Table 2 gives the total opening area required, which is modified by the loss of efficiency, depending on the chosen opening system.

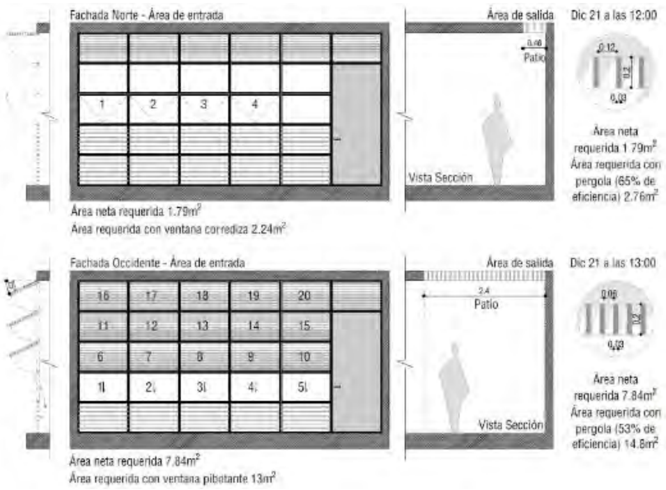

Figure 6: Distribution of the required opening areas in the N and W facades

The facade is assumed to be the inlet location, and a patio is located on the back of the module as the outlet. The space under the patio is not considered as a "useful area" and can receive sun and rain. Figure 6 shows the application of this element in the hypothetical model.

5.3 Daylight criteria

The lighting simulations were performed considering the new composition of the facade. For each sample orientation the work plane areas which were over lit, illuminated in the optimum range of lightning levels or poorly lit, were identified. Based on this information, a zoning of electrical circuits was outlined in order to achieve a balance in the light curve, generating visual comfort for the space users and reducing energy consumption by preventing the unnecessary use of artificial lighting.

The space is classified into three zones: areas of lighting autonomy (ZAL), areas with constant support of artificial lighting (ZIA) and glare control areas (ZCD). The first category includes all areas that present appropriate lightning levels within the optimal range required by the spatial typology; the second one gathers the areas of the work plane that are poorly lit and do not reach the minimum required lighting levels at any time of the year; finally, the third category refers to those areas that exceed the maximum levels, and therefore require glare control strategies.

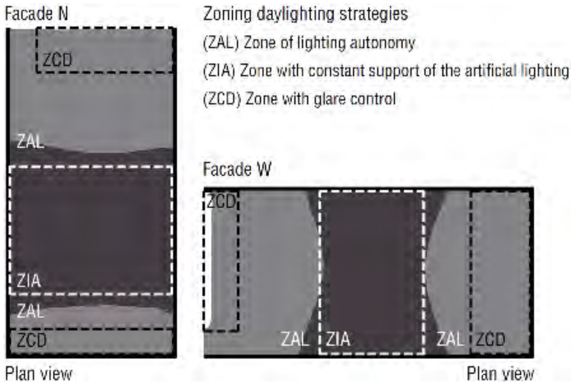

Figure 7: Space zoning to apply lighting strategies, for the modules orientation towards N and W.

6. CONCLUSIONS

As it was shown in the application example, for the architectural typology analyzed in this exercise, all orientations can get the same level of solar control, although the E and W facades require greater design efforts to obtain the same results, than those required by facade N. This refers only to solar shading, in future applications the influence of other variables, such as the thermal behavior, materials and different envelope compositions, should be evaluated.

In the model and the studied space type, it is not possible to achieve optimal Ach (30), when the space's main open facade is parallel to the wind direction.

According the lighting diagnosis which was performed, between 40% and 50% of the total area of the work plane, have lighting autonomy, in both resulting inner environments. This value represents a significant portion of the area, which with a proper distribution of the electrical circuits, can be translated into energy savings by having a lower consumption due to artificial lighting use.

Having a tool that allows unfamiliar architects with the subject of bioclimatic and solar passive design, obtain basic guidelines to integrate the principles of this discipline to their designs, allows to develop an architecture with a greater environmental quality for space users, which in return, decreases environmental impacts. This tool can be applied in the city of Medellín, additionally this methodology can be replicated in cities located in the tropics, which have similar climatic conditions.

ABSTRACT

The energy performance of an urban building is depended on its surroundings, such as the cast shadows of the nearby buildings, variable air temperature due to radiative trapping in street canyons and anthropogenic heat sources. Existing building energy models are limited in the consideration of the micro-scale variations of the surrounding environment, which can be significant for high-density cities like Hong Kong. In this paper, an integrated urban microclimate and building energy model was developed to assess the energy performance of a cluster of buildings in high-density cities. Results are evaluated by the field measurement data conducted in the Sai Ying Pun neighbourhood in Hong Kong. Measured air temperature, wind speed, and building wall temperature are compared with those simulated by the model. The study enriched modelling literature at the scale of building clusters and contributed to the methodologies of integrated simulation in urban microclimate and building energy. The model has potentials to support building design and urban planning at early stage.

Keywords: building energy simulation, urban microclimate, numerical modelling, high-density cities

1. INTRODUCTION

A building modifies its surrounding microclimate, sunlight, wind, and temperature. This modification affects its own energy performance and those nearby. Overshadowing by neighbouring buildings affects solar radiation; temperature fluctuation of external wall surfaces modifies long-wave heat exchanges. Air temperature in street canyons can rise 4 - 6°C above those of the rural areas (Nichol 2005, Chen et al. 2012), which will affect building energy performance. This effect modifies localized microclimate, thermal comfort, and the use of outdoor spaces (Huang et al. 2016). This interdependency calls for better coordination in the design of a cluster of buildings. Hong Kong's high-rise towers, however energy-efficient they may be, can create the 'wall effects' (Wong et al. 2011) which stagnate airflow (Lau and Ng 2013), raise air temperature (Nguyen et al. 2011), increase the use of air-conditioning in nearby homes. This phenomenon has concerned urban planners and policy makers in recent years (Chen and Ng 2011).

In practice, most buildings are not designed to operate in the actual surrounding microclimate. Most building energy models uses meteorological data that are obtained from rural weather stations; some take into account the urban climate effect at city-scale (Bueno et al. 2013). Rarely can a building energy model account for the modifying effect of both solar radiation and air temperature. This gap in research literature is critical at the scale of building clusters and the space in-between (50 - 500m) in which most planning and development projects are commissioned. Building energy models such as EnergyPlus (Crawley et al. 2001), Ecotect (Li et al. 2014), or IES VE (Crawley et al. 2008) do not account for localized microclimate; Instead, designers rely on weather data measured at remote rural stations which differ considerably from those of an urban site. Urban climatology models often look at city-scale (>1km) which is less useful for the design of buildings.

Currently, there are no tools that can assess the interactions between urban microclimate and building energy performances (Bouyer et al. 2011). The Computational Fluid Dynamics (CFD) method is the primary tool applied in urban microclimate analysis (Chen and Srebric 2000; Bruse and Fleer 1998). It is computationally expensive which cannot be easily coupled with other simulation platforms (Novoselac and Srebric 2002) and it is unsuitable to assess large districts and complex urban configurations (Yang and Li 2009). Recent urban energy assessment tools such as CitySim (Robinson et al. 2009) and UMI (Reinhart et al. 2013) made great progress in European and North American context; yet both accept simplified assumptions in airflow or air temperature which may limit their application in high-density cities.

We developed an integrated model by coupling a multizone airflow network model for urban microclimate with the building energy model (HTB2). To the best of our knowledge, this is the first fully-coupled model between urban microclimate and building energy. Results are evaluated using field experiment conducted on a site of 100 buildings in Sai Ying Pun, Hong Kong. Model results agreed reasonably well with measurement data. Major contributions of this research lies the following aspects: 1) We developed and evaluated an integrated model that can describe the energy performance of a cluster of buildings in place of the surrounding microclimate; 2) The research contributed to the literature of environmental modelling at the scale of a cluster of buildings (50 - 500m) in which most buildings and urban design projects are commissioned; 3) The integrated model can be a useful tool to support sustainable design at early stage.

2. METHODS

The integrated model is based on the Urban Microclimate Model (UMM) (Huang et al. 2015) and a Building Energy Model (BEM) of HTB2 (Jones et al. 2013; WSA 2014). The UMM provides localized external air temperature to BEM, while external building surface temperature and HVAC exhaust data, calculated by BEM, will be provided to UMM in return. The conceptual strategy for the integrated urban microclimate and building energy model is illustrated in Figure 1.

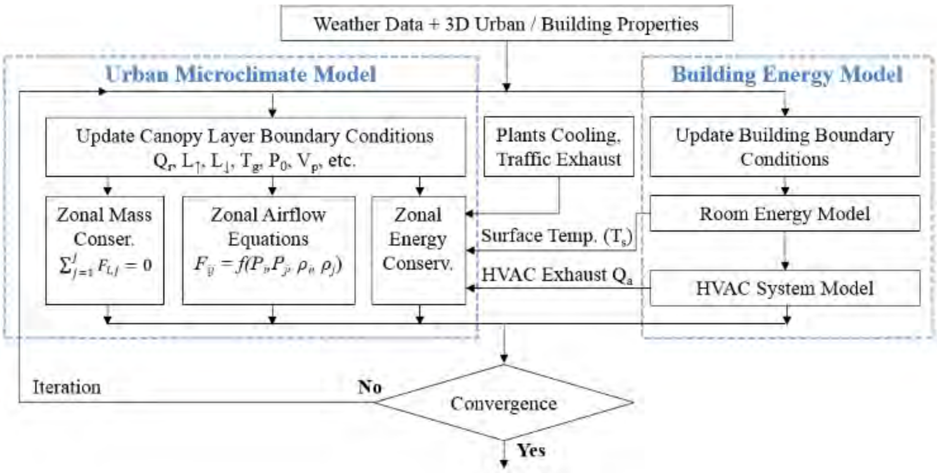

Figure 1: Conceptual strategy for the integrated urban microclimate and building energy model

2.1 Building energy model

Energy performance of individual buildings was modelled using HTB2, an established building energy model (Lewis and Alexander 1990). HTB2 describes energy exchanges among buildings, the external environment, and the heating/ cooling systems in heat fluxes as well as the movement of air and moisture (Figure 2 (left)). The model simulates the dynamic exchanges of mass, energy and moisture exchanges among space. The model takes input information of weather data, 3D spaces and building elements, i.e. walls and windows. Virvil (Figure 2 (right)), a software plugin for SketchUp, has been developed to process 3D geometries spaces and building elements (Jones et al. 2013) in order to simulation energy performance at urban scale.

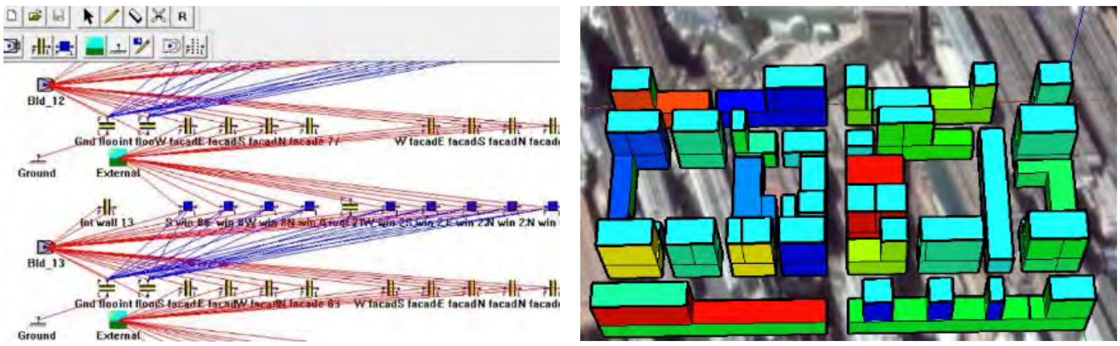

Figure 2: Schematic of HTB2 building energy Model and the Virvil Plugin (HTB2 User manual 2.10)

2.2 A MultiZone model for urban microclimate

We use a multizone airflow network model (Huang et al. 2015) to assess mass and energy in the air of the outdoor space, a simplified approach first developed to describe indoor environments (Musy et al. 2001). We divide the urban canopy layer into a series of semi-enclosed 'zones' resembling a roofless building. The air within the UCL exchange mass and energy with urban surfaces, anthropogenic heating/cooling sources, the Urban Boundary Layer (UBL) above, and the Rural Boundary layer (RBL) on its side (Figure 3 (left)). To simplify, we assume airflow is driven by pressure, temperature and density differences, upholding mass and energy conservations while relaxing the momentum conservation equations. We hypothesize that this relaxation works in high-density cities where wind-drive flow are stagnant yet buoyancy flow dominates (Yang and Li 2009).

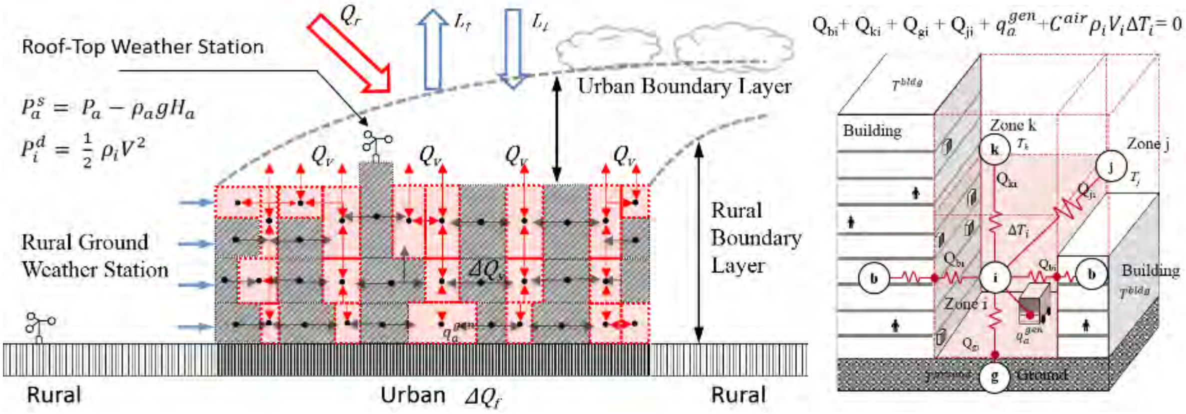

Figure 3: Schematic depiction of the urban microclimate model

The air within each zone is characterized by a uniform temperature (T_i) and density (ρ_i). The zonal air pressure (P_i^e) at any given height (e) is expressed as $P_i^e = P_i^c - \rho_i g H_e$ (1), where P_i^c is the air pressure at the geometric centre of the zone, and H_e is the vertical distance from the zone centre. Pressure, temperature, and density observe the law of the ideal gas $\rho_i = P_i\, T_i / R_{air}$ is the gas constant). The airflow rate F_{ij} from zone i to neighbouring zone j is a function of pressure and density differences at the border and characteristics of the openings $F_{ij} = f[\Delta P_{ij}, \Delta\rho_{ij}, A_{ij}]$. Mass conservation is observed in each zone $V_i \frac{\partial \rho_i}{\partial t} + \sum_{j=1}^{J} F_{i,j} = 0$. Since massing changes caused by density difference is often negligible, we have $\sum_{j=1}^{J} F_{i,j} = 0$ (ASHRAE 2009). Airflow models calculating the F_{ij} and F_{ij} are provided in the authors' earlier work (Huang et al. 2015).

Energy conservation equation for the body of air within zone i is expressed in formula, which describes heat transfer from solid surfaces, airflows to and from neighbouring zones, thermal massing, and anthropogenic heat generation (vehicles & AC unites):

$$\frac{\partial T_i}{\partial t} C_p \rho_i V_i = \sum_{k=1}^{K} hA\left(T_k^{surf} - T_i\right) + \sum_{a=1}^{A} \lambda q_a^{gen} + \sum_{j=1}^{J} (C_P F_{ij} T_i - C_p F_{ji} T_i)$$

Equation 1

where K is the number of enclosing solid surfaces, each with the surface temperature of T_k^{surf}; h is the convective heat transfer coefficient between solid surfaces and air; T_k^{surf} is the temperature for each solid surface; A is the number of active heat sources within zone i, q_a^{gen} and λ are the power and operational coefficient of each heat source; F_{ij} and F_{ji} are the airflow rates between zone i and neighbouring zone j; J is the number of neighbouring zones; C_P and V_i are the specific heat capacity and volume of the zonal air.

2.3 Combination of UMM & BEM

We assume each individual building is treated as one or multiple indoor zones with predefined temperature/humidity conditions. Each indoor zone exchanges energy with those of outdoors via conductive and radiative heat transfer. Mass exchanges occur via HVAC systems and natural ventilation. For each building zone with n surfaces, the energy conservation equation is expressed in formula below

$$\frac{\rho_{air} C_p\, V_{room} \Delta T}{\Delta t} = Q_{other} + Q_{HVAC} + \sum_{k=0}^{n} U_k A_k \left(T^{internal} - T_k^{surf}\right)$$

Equation 2

in which Q_{other} is heat gains from internal lights, people, appliances, infiltration, etc. Q_{HVAC} is the rate of heat gains (+) or extraction (-) from building HVAC system. ρ_{air} is the air density; V_{room} is the zone volume; ΔT is the rate of temperature change of indoor zone; Δt is the time interval between each time step. U_k and A_k is the U-value and area of each wall k; $T^{internal}$ is the set temperature for each indoor zone; T_k^{surf} is the surface temperature for each building surface (walls or roof), which can be estimated by solving energy conservation at each surface expressed in formula below

$$\frac{\Delta T}{\Delta t} C_k M_k = (1 - Al_k) E_k + U_k (T^{internal} - T_k^{surf}) + \mathrm{h}(\mathrm{T}_i - T_k^{surf}) + \frac{1}{2} \varepsilon\sigma ({T_k^{mrt}}^4 - {T_k^{surf}}^4)$$

Equation 3

where Al_k is the albedo of the surface material; E_k is the incoming solar radiation intensity which is accurately calculated using backward ray-tracing methods, where a series of rays will be fired from the centre of the building surface, each returns the property of the obstacle reached, be it buildings, terrain, vegetation or sky dome; T_i is localized air temperature immediately outside of the wall; h is the convection heat transfer coefficient, a function of wind speed and horizontal/vertical position; ε and σ is the surface emissivity and Stephan-Boltzmann's constant; T_k^{mrt} is the mean radiant temperature at the building surface. $\frac{\Delta T}{\Delta t}$ is the surface temperature changes during each minuscule time-step; M_k and C_k is the mass and material specific heat capacity of the surface.

2.4 Field studies

To evaluate predicted localized air temperature and surface temperature of building facades, we conducted field experiments in Sai Ying Pun, a high-density neighbourhood in Hong Kong. Measurement was taken on December 9, 2014, a sunny winter day allowing us to avoid uncertainties associated with anthropogenic heat emission from window AC units. The study session lasted from 8:00 to 22:00.

Figure 4 describes the study location and site condition. Meso-scale prevailing wind speed was measured as 4.05 m/s from south west (225° from north) during the study day. Four measurement locations from A to D were chosen. Site A is on the sidewalk of Des Voeux Street, a main street with 4-lane vehicular traffic. Site B is at the road intersection between the Western Rd. and Queen's Rd. West; Site C is in Sai Yuen Lane, a narrow alleyway inside the residential block. Site D is at the end of Chung Ching Street. The street width, density and configurations vary among the 4 sites, allowing for considerable variable in microclimate attributes.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 4: The Sai Ying Pun area and 4 measurement locations (A, B, C, & D) source: Google Earth (300 by 160 meters)

Air temperature and wind speed were measured at the four locations at 1.5 meters above ground. An infrared camera (FLIR E40-NIST) was used to measure surrounding surface temperatures at hourly interval. Vehicular and pedestrian traffic were recorded at Site A and Site B to calculate the anthropogenic heat. A 3-min video were recorded at hourly interval. We counted the number of pedestrians and automobiles as well as the composition of vehicular fleet.

The weather input is obtained from the nearest weather station of Hong Kong Observatory weather station (HKO) network on 9 December, 2016 from 8:00 - 22:00 (Table 1). The wind speed of the simulation domain was adjusted from the weather station according to the exponential vertical profile.

Hour	8:00	9:00	10:00	11:00	12:00	13:00	14:00	15:00
Pressure(kPa)	102.39	102.35	102.29	102.20	102.09	101.99	101.93	101.94
Air Temp.(°C)	18.4	19.1	20	20.6	20.6	20.3	20.5	20.3
Wind speed (m/s)	2.3	2.1	1.5	1.5	2.0	2.2	1.4	1.2
Wind direction (°)	30	30	50	60	50	50	50	190
Hour	**16:00**	**17:00**	**18:00**	**19:00**	**20:00**	**21:00**	**22:00**	
Pressure(kPa)	101.97	102.02	102.05	102.10	102.14	102.14	101.97	
Air Temp.(°C)	19.7	19.7	19.5	19.8	19.8	19.7	19.6	
Wind speed (m/s)	2.6	2.9	3.1	3.2	3.4	3.5	3.8	
Wind direction (°)	50	50	50	60	60	50	50	

Table 1: Input hourly weather data measured from Hong Kong observatory weather station network on December 9, 2014. Air temperature and pressure are from Hong Kong observatory station (32 meter above sea level), wind speed and direction are measured by anemometer in green island (107 meter above sea level). Wind direction is degrees clockwise from north.

3. RESULTS

We modelled the Sai Ying Pun neighbourhood using the integrated model. The 3D building model domain consists of 71 external zones and 28 buildings. We divided the external zones in two vertical layers, allowing conditions to vary at near-ground (0 - 20m) and higher above (20 - 50m). Four measurement points related to those of the field studies were placed accordingly.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 5: Model domain, 3D building geometries and measurement locations

Model results included surface temperature, air temperature and wind speed at 4 locations. Figure 6 shows predicted air temperature at 4 locations. All curves show coherence of changing trend. The systematic offset is caused because of input environmental temperature. Weather station at Hong Kong Park is 30 meter higher in elevation and in rural area, which is almost 2°C lower than survey area. Figure 7 shows predicted result air temperature and wind direction. The temperature is significant lower in narrow areas than spacious one.

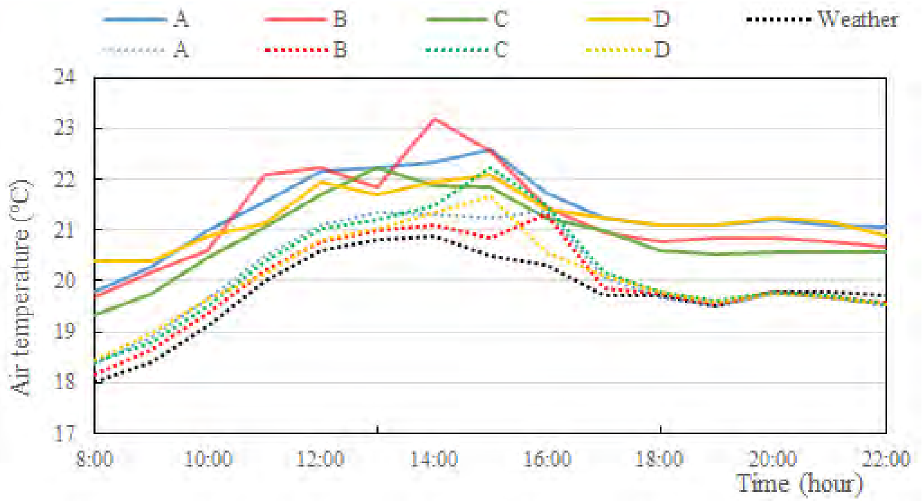

Figure 6: Predicted and measured air temperature at four measurement points. The solid lines are the measurement results, the dash lines are the simulation results of the model.

A visualization of predicted air temperature and wind flow are shown in Figure 7. Zones to the north were of higher temperature than those to the south due to the influence of solar heat gains from building walls.

Comparing Figures a and b, which are at 2 and 3 pm respectively, it is clear that changes of wind speed and direction produce dramatic fluctuation air temperature and flow.

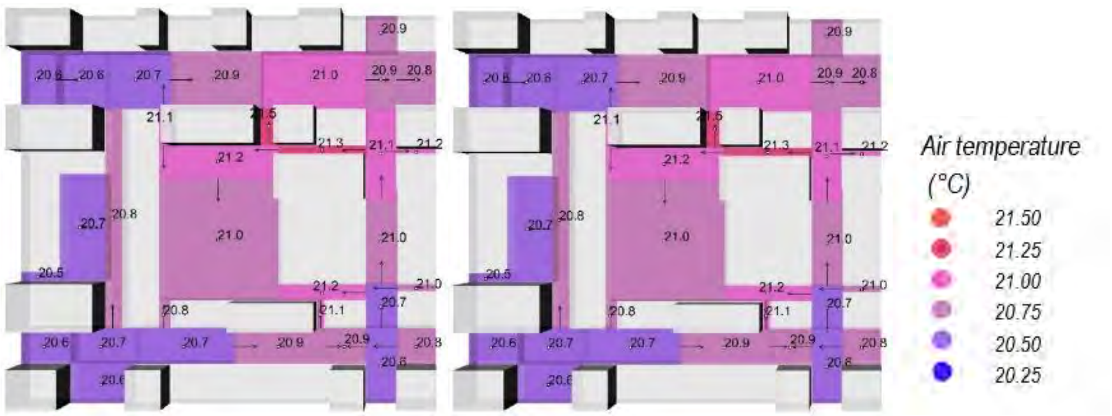

Figure 7: Predicted air temperature (in color) and airflow direction (in arrow) at on December 9, 2014. a) 2 am with wind speed at 1.4 m/s from south-west; b) 3 am with wind speed 1.2 m/s from north-east

Ideally, the system reach balance when amount of air flow in and out of reach zones are closed to each. Test shows that both overall system balance and maximum balance works. The simulation stops when maximum air flow quantity in both vertical and horizontal direction close to each other.

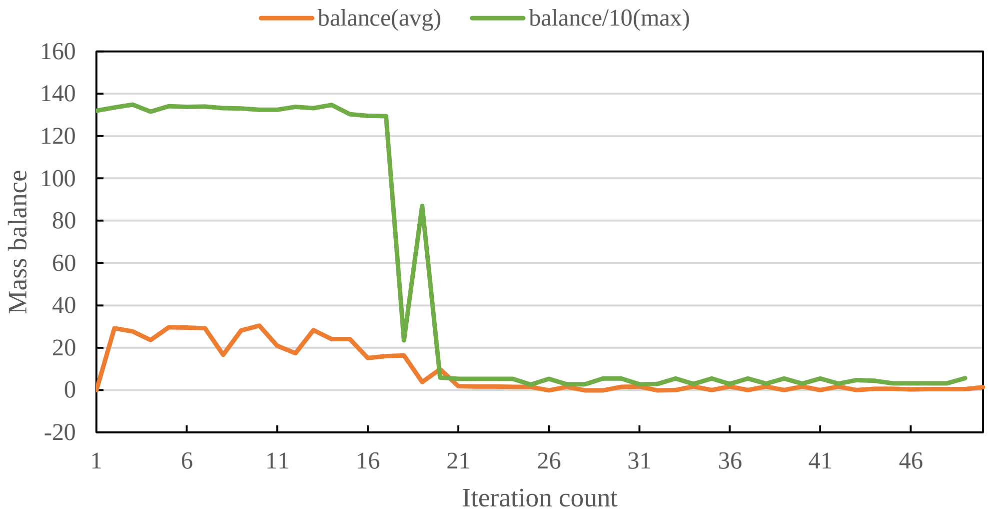

Figure 8: Model convergence criteria, heat balance of whole system

4. CONCLUSION

An integrated model for urban microclimate and building energy was developed. Field measurements were conducted in Hong Kong's high-density urban area to partially evaluate the model performance. Simulation results of the outdoor air and building façade temperatures within street canyons showed considerable variations among measurement spots. Although results have not reached satisfactory agreement with measurement data. We expect the reasons being complications from anthropogenic heat sources from traffic, restaurant that were unaccounted for in the model simulation at this stage. The next step is to address the limitations mentioned above and further evaluate the integrated model.

Re-Thinking Courtyard Housing: Development of Traditional Islamic Courthouses into Zero-Energy Buildings

Samer EL SAYARY [a], Osama Mohamed OMAR[b]

[a] *Beirut Arab University, Lebanon, s.sayary@bau.edu.lb*

ABSTRACT

Sustainable design is the philosophy of designing physical objects, building environments, and services that comply with the principles of social, economic and ecological sustainability (Lombard, L.P et al., 2008). The idea of courtyards as a method of plan configuration goes back to thousands of years to Neolithic settlements. In the beginning, the logic behind this configuration was mainly to provide a shelter against outside forces, such as invasions by humans and wild animals. Over time, it developed into a solid, logical configuration that not only maximizes the built-up area in the urban context but also allows controlling sunlight penetration, especially in regions where it is abundant. However, it soon became a generic typology in hot, arid, climatic landscapes and therefore formed the basis of the urban patterns of the Madina's in the Islamic World. Furthermore, the cultural relevance of this plan's typology is of high importance (P. Torcellini et al., 2006). A preliminary study output was performed prior to this research to analyze various physical elements of traditional courtyard houses located in a hot, arid region in Egypt. This paper presents a research project carried out to explore the potentials of traditional Islamic courthouses and to develop them into zero energy consumption houses that suits the Egyptian contemporary lifestyle. Wide and vast studies were conducted to investigate the passive aspects of the traditional Islamic houses in Egypt and to analyze their architectural vocabulary responsible for creating a passive contemporary sustainable house. Then by developing these elements, using environmental analysis of energy consumption calculations and CFD simulations, a contemporary prototype house was proposed as a development of the traditional Islamic houses that were built in middle Ages in Middle East.

Keywords: low-rise building, housing court house, zero energy house, CFD, sustainability

1. INTRODUCTION

Energy is one of the most important factors of development and production in most countries. The growing trend in building energy consumption will continue during the coming years due to the expansion of built area and associated energy needs, as long as resource and environmental exhaustion or economic recession allows it. Private initiative together with government intervention through the promotion of energy efficiency, new technologies for energy production, limiting energy consumption and raising social awareness on the rational use of energy will be essential to make possible a sustainable energy future as Lombart et al, 2008 indicated. In simple terms, a Net energy building is a very low energy building that balances its low annual energy consumption by the use of renewable energy on site.

To reach the Net-zero energy-building goal, we decided to conduct two important strategies at the design stage:

- To reduce demand using passive solutions and energy efficient systems.
- To generate sufficient electricity by renewable energy systems to achieve the desired energy balance.

Passive approaches play a crucial role in the design of Net ZEBs (Net Zero Energy Buildings) as they directly affect the heating, cooling, ventilation and lighting loads put on the building's mechanical and electrical systems, and indirectly reduce the sizing of the renewable energy systems that balance the consumption.

In 2005/2006, the Net zero buildings concept was still generic and in 2006 there was no harmonized understanding about what was really a Net Zero Energy Building (P. Torcellini et al., 2006). This was one of the principal motivations for an international collaborative research project that started in 2008 within the framework of the International Energy Agency "Towards Net Zero Solar Energy Buildings" (NZEBs, 2016). The objective of the current study is to suggest a sustainable, zero energy consumption, contemporary courtyard house design in

Alexandria city in Egypt as a development of the passive architectural vocabulary of the traditional Islamic courtyard houses and with the aid of recent computer Environmental analysis to act as a first prototype in such building.

Based on the climatic data of Alexandria downloaded from US department of Energy deduced from ZEH, 2016 and the features of traditional Islamic courtyard house the design has been established and then calculations were performed to compare the energy consumption in the traditional design and the new suggested design.

The courtyard as a volume inside the traditional Islamic courtyard house was re-defined and reshaped using previous environmental analysis to a new proposal to integrate the shade design with the cross ventilation design to eliminate the need of HVAC by achieving the thermal comfort inside the house.

1.1 Redefining zero energy house

The traditional ZEB definitions can be also divided according to the building type. In the prevailing literature there is almost no specific difference between the ZEB definition for neither a commercial building nor a residential building. Commonly in the publications three phrases are used: "zero energy building", "zero energy house" and "zero energy home". As the first term is the most comprehensive and includes both residential and commercial building, the two others typically are used for the residences (ZEBD, 2016).

With the ZEB concept gaining in popularity the literature on zero energy/emission buildings is also growing. Most of the publication focuses on documenting different ZEB demonstration projects without referring to the courtyard potentials ; however, a number of documents have significantly contributed to the discussion of understanding and re-defining new ZEB concept. One of those milestones is the report written by Torcellini, et al. in 2006. The authors point out that despite the exciting phrase of 'zero energy'. Torcellini, et al (2006) indicate that the definition of ZEB concept can be constructed in several ways, depending on the project goals, intentions of the investor, concern about the climate changes and greenhouse gas emissions or finally the energy costs.

2. POTENTIALS OF COURT HOUSES VOCABULARY FORMULATING THE CONTEMPORARY DESIGN

2.1. Relation between zero energy approach and courtyard

Many studies were conducted on courthouses due to its high climatic potentials either in cold whether or hot arid areas. Edwards et al (Edwards B., et al., 2006) studied their climatic impact in his book. Courtyard housing is one of the oldest forms of domestic development spanning from at least 5,000 years and occurring in distinctive form in many regions of the world. Traditionally associated with the Middle East where climate and culture have given shape to a particular type of courtyard housing; other examples exist in Latin America, China and in Europe where the model has been reinterpreted.

Besides having double facades, by courts, one inner and the other outer so increasing the perimeter of the exposed walls to daylight, the Inner facades are under shade most of the day, so providing indirect lighting and good thermal environment. Also, Leslie Martin and Lionel March carried out an extensive study of the environmental performance of courtyards at Cambridge University in the late 1960s. In a number of influential papers they addressed the question: 'What building forms make the best use of land?' The question of course implies a definition of 'best use'. Martin and March bound themselves to quantifiable parameters, such as 'built potential (the ratio of the floor area of the built form to the site area) and 'daylight availability' (Martin, L. and March, L. 1972).

They analyzed different archetypal built forms, such as pavilions, streets and courtyards. Their findings, based on mathematical analysis, showed that the courtyard was eventually the best performing urban type in terms of efficiency in site coverage: the court form is seen to place the same amount of floor space on the same site area with the same condition of building depth and in approximately one-third the height required by the pavilion form.

The ingenious solution of the courtyard house type in hot-arid climates, such as in Egypt, is the use of high thermal mass to store heat through the expansive external surface area during the day in order to benefit from it during the cooler nights.

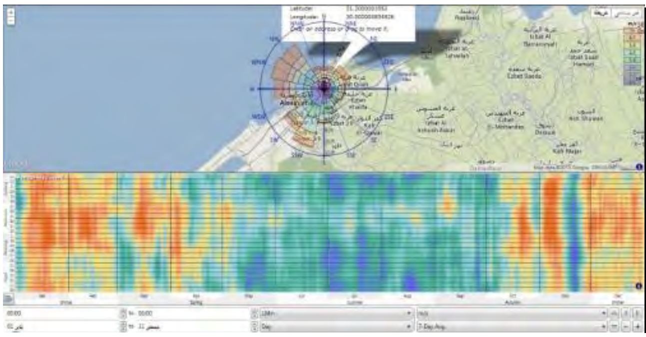

Figure 1: Wind rose of Alexandria

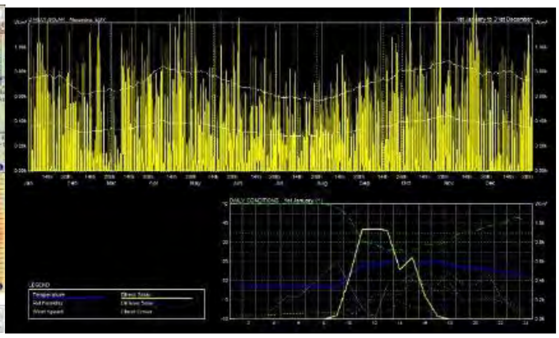

Figure 2: Alexandria average solar radiation

The proposed design, in the current study, addresses the following criteria in designing the new court:

- Increasing the surface to volume ratio to increase the perimeter of the inner façade, which results in a more indirect illumination of natural light.
- Increasing the shadow density based on the average data solar radiation (Figure 2) to create a thermal hot areas versus cold areas to help in breeze immigration from positive to negative pressure areas.
- Breaking down the one volume of the traditional court into multi-volumes to create cross ventilation from dominant wind patterns.
- Increasing sky view factor (SVF) to decrease the solar exposition to the open court aluminum shading louvers were introduced to the design. The function of these aluminum louvers is to reflect the indirect sun light into the court and derive the direct wind breeze into the court as well and to replace the traditional ancient Mashrabia in old courtyard Islamic houses.

The new court design has changed the introversion volume approach into broken down multi volumes mass to allow cross ventilation and was tested by Computational fluid dynamics (CFD) virtual wind tunnel simulation after processing the local digital file obtained from the US department of energy (ZEH, 2016) using the wind-Rose (Figure 1). The other parameter, LUX levels of natural light measurement, is based on detecting day lighting on the ground at hourly intervals on a piece of Alexandria city for a given day of the year (Figure 2). Then the average number of hours of shadows is calculated at each point. Steemers and Ratti (Steemers K. et al. 1999) used this parameter as an environmental indicator to inform bioclimatic urban design,

A thorough study were undergone by J. Climatol (Oke, T. 1981). When he indicate; the Sky View Factor was first introduced in heat transfer literature to model radiative exchange between surfaces, it also offers benefit in terms of urban climatology research. In fact, it represents a good measure of the openness of the urban texture to the sky and has been associated, among other indicators, to the increase in temperature in the urban context compared with the surrounding rural context-the so-called urban heat island phenomenon. The well-established relation between the Sky View Factor and the urban heat island consists of the observation that the smaller the Sky View Factor, the higher the temperature of cities (Oke, T. 1981).

By maximizing the surface to volume ratio, the courtyard acts as heat sink and therefore alleviates the extreme temperature stress: it reradiates this heat indoors as well as to the surrounding and to the sky during the cooler nights due to the time lag of the large thermal mass and the cooler air temperature.

Edwards B., et al., 2006 highlighted the suitability of courtyards for extreme climates due to their climatically buffering and filtering characteristics; he noted the prevalence of courtyard planning in hot-arid climates.

The sun concentrating character of cold areas courtyards is in fact due to the rather low height over width (H/W) ratio of the courtyard as observed by Mänty, which averages 0.6 in Scandinavian areas, compared to 1.3 in middle east as measured in the selected simplified prototype courtyard adopted for this study and more typical of hot-arid climates. It is in fact a matter of proportions that confers either the sun collecting or sun-protecting characteristic to the courtyard.

3. RESULTS AND DISCUSSION

In our proposed new design of the court, it was divided into multi small courts allowing the sun to enter simultaneously during the day hours. In addition to the design, other measures were taken to reduce the house energy consumption and achieve the target of ZEB: a) the substitution of traditional bulb lamps with LED lighting. b) The use of energy star appliances. c) The use of solar panels to provide required electricity. Figure 3 shows the plan of the designed house to be used in the power consumption calculation and its CFD model.

Energy consumption analysis of buildings is a difficult task because it requires considering detailed interactions among the building, HVAC system, and surroundings (weather) as well as obtaining mathematical/physical models that are effective in characterizing each of those items (University of Plymouth, Plymouth, UK, February 1999).

Although this difficulty we substituted the physical model using virtual simulations by Autodesk CFD simulation as a virtual wind tunnel simulation and Autodesk Ecotect 2011in electrical consumption calculations and Lux levels of daylight using DIAlux 4.

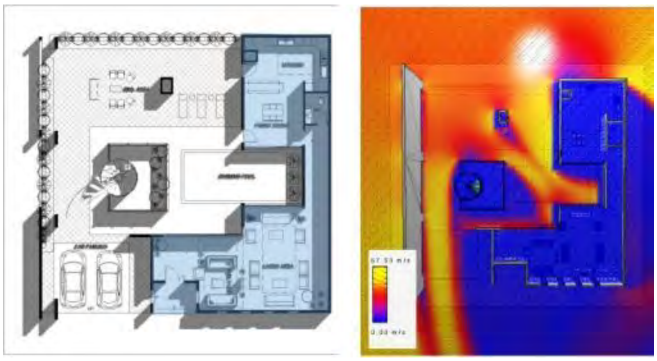

Figure 3a: Plan of the first floor of the suggested design and its CFD

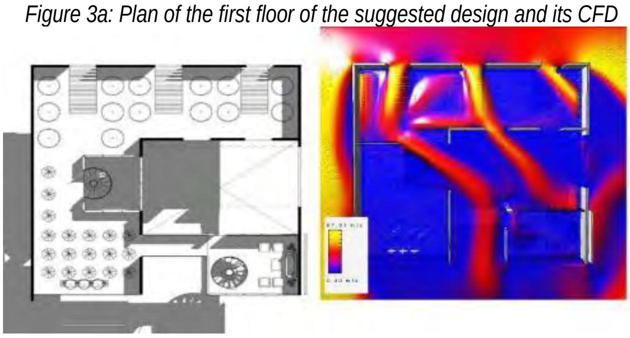

Figure 3b: Plan of the second floor of the suggested design and its CFD

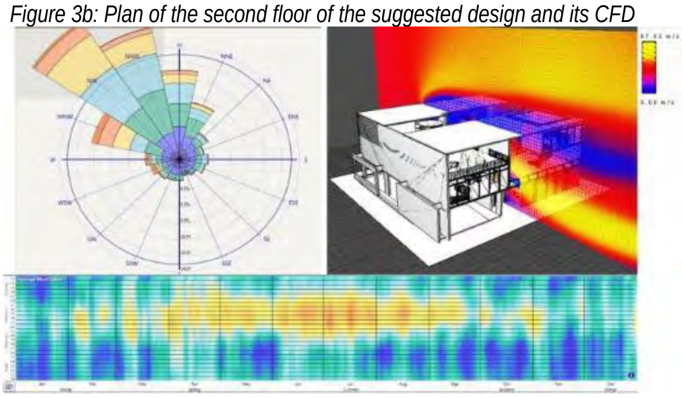

Figure 3c: CFD of the designed house

3.1 Hourly electricity use and energy consumption

By comparing the hourly electricity use before and after the energy conservation measures, it was found that an energy saving of about 60% was achieved as shown in (Figures 4 and 5). This can be attributed to the elimination of air conditioners need due to normal ventilation and the replacement of conventional appliances by energy efficient ones in addition to the increase in daylight factor.

3.2 Light measurement

The interplay between the divided volume of the courtyard surrounding the mass resulted in significance decrease in the need of artificial light as mentioned earlier. (Figure 6) shows the light measurement in Lux determining the sky view factor.

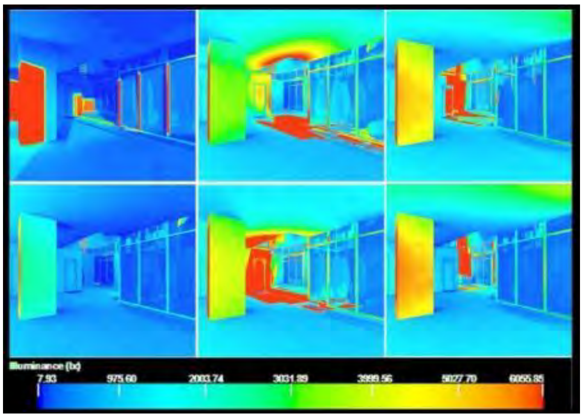

Figure 6: Light measurement in Lux

4. CONCLUSIONS

The overview and simulation of the blending of redefined courtyard and Net ZEBs carried out in the framework of this research has led to the identification of new ways of design for this type of ZEB courtyard house. The courtyard volume should be broken to multi-small courts scattered in the house mass in order to improve cross natural ventilation and daylighting. Its envelope should be multi-functional element to filter the outside environment to a set of free sources of energy such as wind, sun.

Session 4.8: Innovative Biophilic Design for Wellbeing

Systems Ecology as a Design Tool for Water Resources and its Environmental Education

DAY Yeong-tyi[a]

[a] *Chung Yuan Christian University, Taiwan, timday@cycu.edu.tw*

ABSTRACT

Planning water management of a sustainable campus needs to combine ecological, social, and economical aspects at the same time, which includes water volume control (Amount of input and output), water quality control (Organic and inorganic material recycling), energy management, and environmental education pertaining to water resources. About sustainable issues are traditionally designed separately by architects and/ or school managers, and are usually lack of connection among them. "Systems Ecology" is a discipline how ecologists describing natural systems with "energy systems language", which invented by ecologists, to interpret the energy flows among compartments of an ecological system. This article demonstrated a method to integrate those topics with different states clearly and effectively by using and modifying "Systems Ecology" as a designing tool, which provides a systematical thinking for the designer about water resource management on campus. An ideal model included 4 states (Water volume, materials, energy, and knowledge) was constructed as a reference. Also, an example was illustrated with a dormitory improvement design on the campus of the Chung Yuan Christian University, Chung-Li, Taiwan.

Keywords: sustainable development, campus sustainability, environmental education

2. INTRODUCTION

Sustainable development has become a universal conscience to achieve environmental, social, and economic goals simultaneously. The input/ output rule has been suggested that to keep waste within assimilative capacities, to harvest within generative capacities of renewable resources, and to deplete non-renewables at the rate at which renewable substitutes are developed. A sustainable campus is one that develops process or management systems that help create a vivacious campus economy and high quality of life while respecting the need to sustain natural resources and protect the environment. The policy of sustainable campus has been promoted in Taiwan since 2000, and environmental education emphasized particularly with improving both green infrastructure and buildings on campuses. However, I found it is difficult for architects and school managers to integrate all aspects of sustainability, and neither able to fulfil multiple and sustained usages of facilities in buildings and on campuses.

Therefore, this paper is to illustrate a systematic method to assist designers or school managers clarifying all possible components of improving campus sustainability.

3. METHOD

This study reviewed assessment discourses of sustainability for national, regional, campus, and building scales to extract issues related to water resources as the foundation of system compartments. The current status of water management on campus was comprehended with interviewing the principals of two elementary schools, and one managing staff of Chung Yuan Christian University. The processes of model developing included (1) defining boundary of real system (Literature review); (2) modifying Odum's energy language usable for states other than energy per se; (3) building modular models for each state; and (4) connecting modular models of different states. Graduate students and professors were organized separately into two special task teams (STT) and discussions held to validate the model's applicability and integrity. The model were then applied to a dormitory improvement projects of the Chung Yuan Christian University.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4. RESULTS AND DISCUSSION

Study focused on how to build and operate a water resources management hardware and software for a campus to achieve the goal of sustainability. Energy language of "Systems Ecology" was modified with new notations and objects interested rather than energy only. It is shown that the water resource management on campus can be made in complete analogy with the natural system. Modular model of different states can be validated to illustrate the conceptual system of both tangible facilities and intangible knowledge in the real world.

3.1 Sustainability issues pertaining to water resources management

In order to define the boundary of the system pertaining to water resources management and its environmental education on a sustainable campus, resubmission must provide the details of the work to readers. The issues related to water resources were extracted from assessment discourses of sustainability for national, regional, campus, and building scales. The contexts of the system were then determined, which includes water volume control (Amount of input and output), water quality control (Organic and inorganic material recycling), energy management, and environmental education. Water volume control plan reduces dependency on tap water and groundwater and increases usages and its efficiency. Water quality control plan retrieves organic and inorganic materials which are reusable and reduces pollution to its outbound. Energy management plan reduces dependency on national or urban electricity supply, and increase the use of renewable energy. Environmental education plan allows teachers, students, and neighbouring communities to create, teach, and learn associated knowledge. Integrity of the system improves holistic development of sustainability on campus.

3.2 Energy systems language to describe natural systems

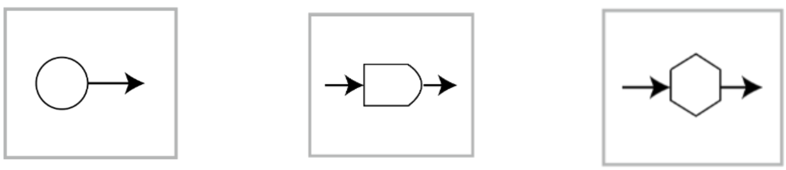
Ecologist Eugene P. Odum, called "the father of modern ecology," brought the word ecosystem into common phrase by making it the organizing concept in his 1953 "Fundamentals of Ecology". The structure and function of ecosystem were analysed and described with food chain/ web, where the energy flow thru producers, consumers, and decomposers. The energy systems language, also referred to as Energese, energy circuit language, or generic systems symbols, was developed by the ecologist Howard T. Odum and colleagues in the 1950s during studies of the tropical forests and are used to compose energy flow diagrams in the field of systems ecology.

I modified Odum's energy systems language to illustrate a multiple states system and applied it on sustainable campus design and management plans. Facilities, buildings, landscape elements, human, teaching activities, etc. are made in analogy with the structure of a natural system, as sun (source), green plants (producer), herbivores/ carnivores (consumer), and micro-organisms/ fungi (decomposer). Three other states of flow within the system were added beside of energy that are only concerned in energy systems language.

3.3 Notations

Compartments of system model are illustrated with notations for elements to interpret the direction and amount of energy or material flows. A system has three basic elements; that is, input, processing, and output. Elements are the smallest components to represent places, facilities, resources, human, functions, actions, and statuses on campus. Six types of element, which are source, producer, consumer, processes, and outbound, are developed to illustrate reality with a diagrammatic model. Outbound element represents inevitable lost states (Figure 1).

(A)Source element (B)Producer element (C)Consumer element



(D)Storage element (E)Processes (F)Outbound

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

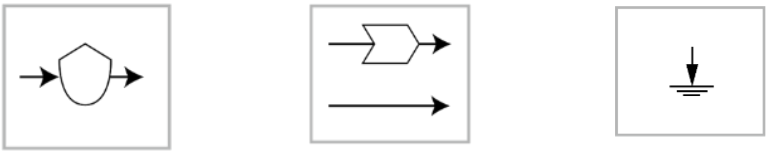


Figure 1: Notations of elements modified from energy language in Systems Ecology

3.4 Modules

Module is a model compartment which contain 2 and more than 2 elements with input and output terminals connecting other elements or modules. First order module connects only 2 elements, second order module connects 3 elements, and n order module connect n+1 elements in means of series connection. Parallel connections are also allowed. In real world, a module represents a repeatable items.

3.5 System of water resources and its environmental education on sustainable campus (SWREESC)

A system is a set of interacting or interdependent component parts forming a complex whole. System of water resources and its environmental education on campus (SWREESC) defines the boundary that enclose the hardware and software related to water resources management on campus sustainably. Utilizing above notation modified from energy systems language in Systems Ecology. SWREESC contains environmental, social, and economical issues of sustainability which should be practiced on the management of water resources on campus. Water volume, organic materials, energy, and knowledge of environmental education are states of systems model; therefore, are able to be organized and merged properly with engineering, interior design, building design, and landscape design, and teaching activities. One of the most important functions is the pathway of above states can be monitored, examined, and controlled. Furthermore, the Systems Model of Water Resources and its Environmental Education on Sustainable Campus (SMWEWWSC) is defined as a systems model that illustrates the paths and relations of each concerned state from source elements (input) to consumer elements and/ or outbound (output) holistically and completely for a SWREESC.

3.6 Four modules of the SWREESC

The source elements of water volume are tap water, ground water, runoff, and precipitation. Water may be retrieved from all stages of treatment which increases the total amount of usable water on campus; therefore, the producer elements are first, secondary, and tertiary wastewater treatment facilities. Storage elements are various, include all kinds of pools, ponds, tanks, and wetlands. Fourteen storage elements are recognized. Consumer elements are devises that use water, such as toilets, gardens, scenic ponds/ pools, kitchens, vanity, RO purifier, swimming pools, sanitary, air conditioning, livestock drinking and cleaning, fire fighting, etc. Interactions (processes) among elements are first, secondary, and tertiary treatments, and pumping. The sustainable principles of water management on campus are to reduce use amount of tap water, ground water, and runoff, and increase usage of rain. On the other hand, designer should increase the water recycling rate and utilization, by decreasing drainage and evaporation, and increasing infiltration and transpiration.

Organic material module includes three source elements, which are runoff, drainage, and black water from toilet drain. Producer elements are elements that increase the concentration of organic materials in the system, which include campus plantation and all devices of wastewater treatment. Storage elements are all sort of ponds for purification and filtration which will accumulate the organic materials in. Six consumer elements are recognized which are generators, fuels, building materials, landfill, composting, and soil improvement. To use nutrients retrieved from wastewater are barely practiced on campus in Taiwanese elementary schools actually. Interactions are mostly processes of wastewater treatment.

Energy module includes five kinds of renewable energy which able to be produced or utilized and is relevant to water resource management on campus. Source elements are solar, biogas, wind, hydraulic, and manpower. Producer elements are therefore solar panel, boiler, windmill, waterwheel, and rickshaw correspondently.

Generators are necessary for transform above energy into a common energy form. Batteries as a form of electrical storage facilities are regarded as storage elements. Consumer elements use at least one sort of energy forms to provide motion, temperature control, and driving fans, such as pumps, testing facilities, and machines. Interactions include heat, motion, electricity, and potential (hydraulic) energy.

Environmental education module includes all knowledge produced by the operation of water resource management on campus. Source element is the environmental knowledge which might be brought into the campus by teachers or NGO's member through lectures or workshops. Twelve producer elements are recognized by the environmental education theory, which include teaching methodologies through the learning of sensory organs, experiences, investigations, and researches. Four storage elements are "Environmental Education Classroom", campus buildings, and outside campus space, where provide space for teaching activities. Consumer elements are students, teachers, school staffs, parents, and people of nearby communities, who receive knowledge from the storage element. Interactions are awareness, knowledge, environmental ethics, skill of civil action, and experience of civil action. Therefore, an ideal systems model of environmental education with all possible knowledge transmitting pathways is able to be constructed.

3.7 Connecting models with different states

A final ideal model connected all four modular models of different states (i.e. water, energy, organic materials, and knowledge). The identical element in separate models provide an interface for transformation among states. For example, "Environmental Education Classroom" is an element to receive the relevant knowledge from outside (such as NGO's and school teachers), and produce (output) knowledge for pupils and publics. At the meantime, the facilities of collecting, filtrating, purifying, recycling, pumping, depositing, are the contents and teaching instruments of the "Environmental Education Classroom". Those sustainable facilities increasing ecological efficiency indeed (Positive to environmental and economical sustainability) are also observable for understanding its function and mechanism (Figure 2).

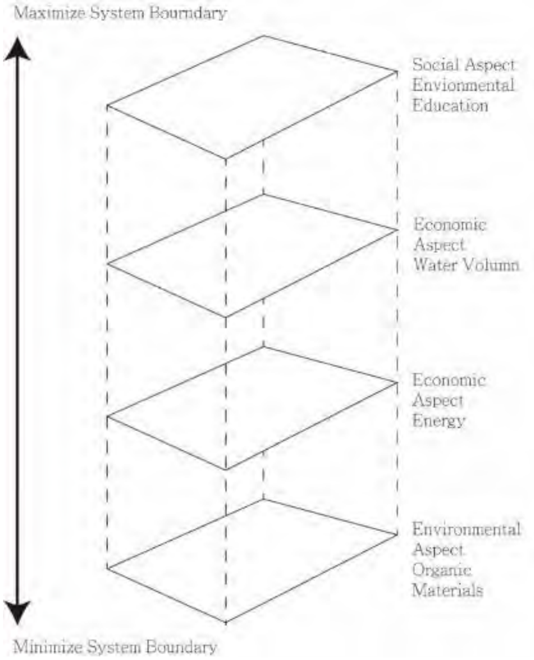

Figure 2: Four states of the water resources and environmental education systems model

3.8 Example: Dormitory design

An example was illustrated with a dormitory design on the campus of the Chung Yuan Christian University, Chung-Li, Taiwan (Figure 3). The hydrological usage was surveyed before modelling and was compared with the full model constructed previously which combined water, materials, energy, and knowledge. A system model therefore can be constructed to describe the current status of the water resource and environmental education for that particular dormitory. Tap water and ground water are two input sources. Tap water is stored in the ground, underground, and roof tanks, then provide to cleaning, drinking, and fire-fighting storage elements. The wastewater

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

output to the tertiary sewage treatment plant. Ground water needed pump to transport it to the secondary treatment devise to produce purified water to ground water storage elements. After cleaning and gardening, wastewater output to tertiary wastewater treatment plant. Black water form toilet flushing moved to septic tank, then to tertiary wastewater treatment plant. All purified water from the treatment plant leave the site before gardening usage.

The differences from the ideal model provide innovative foundation to increase the ecological efficiency of water resources. Five issues should be improved after comparison current usage with the ideal system model of water resources and environmental education. (1) Depending on ground water should be replaced with new source of water, such as rain. (2) Different pathways may be added before transporting to tertiary treatment plant. (3) If recycled water had other usage beside of toilet flushing. (4) New usages (elements) may be added between gardening and output. (5) Environmental education programs were absent. Therefore, five areas were designed based on above issues, which were (1) Roof rain-light garden: developed usage of solar energy and rain water; (2) Wind-light corridor: both solar and wind energy were induced; (3) Water purified and ecological corridor: living sewage was purified with aquatic water in a stream-like channel, and flow into a pond. (4) Flywheel exercise area: Transforming manpower to generate electricity. All equipment would be used for environmental education with posters and banners to illustrate the relevant sustainable knowledge.

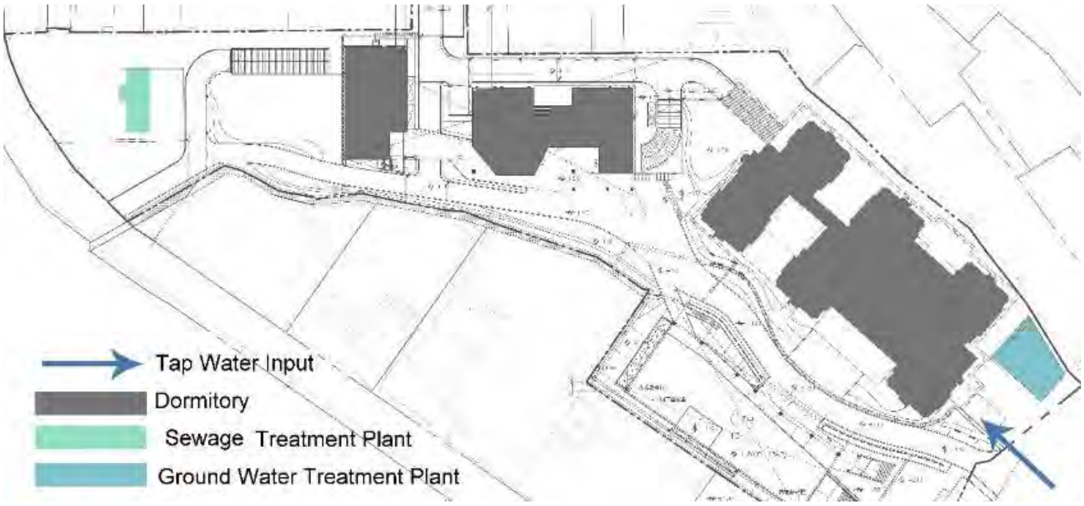

Figure 3: Current hydrological usage of the dormitory at Chung Yuan Christian University

5. CONCLUSION

One of the objectives of sustainable campus is to create a learning space for sustainability, which may adopt the design methodology of systems modelling to connect different model states and elements of a campus. It has used to be neglected usually or built separately without holistic thinking by engineers, architects and school managers. The systems modelling processes provide a chance to consider and discuss the possibility of connections of all needs and disconnection. Moreover, systems modelling may also apply on larger spatial scales, such as community and urban open space, by expanding its system boundary (Figure 4). Campus systems may interact with its surrounding community. The community may provide manpower and extra learning space for educational activities, such as farms, shops, factories which exhibit the production of the community. On the other hand, campus may provide its neighbouring community a space for public education and recreation. The most important connection is the physical infrastructure of water, materials, and energy, which may turn the campus and its surrounding area into a holistically managed system.

ABSTRACT

Shek Wu Hui Sewage Treatment Works (SWHSTW) with capacity of 93,000m3/day is currently operated by Drainage Services Department (DSD), the Government of the HKSAR. To cope with the growth of local community and nearby planned developments, SWHSTW will be expanded in phases to attain a treatment capacity of 190,000m3/day by year 2030, to serve a planned population of 600,000. With this largest regional tertiary STW to be built, DSD takes this opportunity to transform the conventionally functional driven SWHSTW to an "Environmental Campus linking with the Community", aiming at changing the community's perception of sewage treatment, and also blending the facility into the natural environment.

With the state-of-the-art treatment technologies adopted, SWHSTW will purify the wastewater to very high quality effluent before discharging into Ng Tung River, which finally flows into the ecologically sensitive Deep Bay. SWHSTW will also serve as the regional reclaimed water production hub for flushing and other non-potable uses. With dedicated energy efficient design, SWHSTW will strive to be a renewable energy recovery centre through potential sludge and food waste co-digestion. The integrated design of various sustainable "blue-green" features such as green roof, bioretention system and porous pavement with the plant's landscaping plan further make SWHSTW itself a "Living Outdoor Classroom", mimicking nature to cope with climate change challenges.

To connect this "Environmental Campus" with the community, various ideas including setting back site boundary to create a riverside promenade integrated with river beautification features, co-use of some STW facilities with the community and linking the treatment works with Sheung Shui Town, etc., will be developed to create an open and accessible SWHSTW for public enjoyment and enhancing the quality of life for the community.

Design innovation with Building Information Model is also adopted to facilitate the upgrading of a live STW, and paves the path of information management in future operation.

Keywords: sustainable neighbourhood, Shek Wu Hui sewage treatment works, environmental campus

1. INTRODUCTION

1.1. Climate change and the call for sustainability

The climate is always changing – but in recent years there has been a gradual and significant shift. The Intergovernmental Panel on Climate Change (IPCC) has projected the global temperature to rise between 0.3°C and 4.8°C by the end of the 21st century under various scenarios as shown in Figure 1 (IPCC, 2013). This will further increase the likelihood of severe and irreversible impacts for human and ecosystems. In fact, most of the warming that has occurred in the last 50 years is anthropogenic – attributable to human activities. With a growing human influence on our climate, an urgent global response is demanded to create options for a brighter and more sustainable future.

Notes:
RCP2.6: "peak-and-decline" scenario
RCP4.5: "stabilization" scenario
RCP6.0: "stabilization" scenario
RCP8.5: "high greenhouse gas concentration levels" scenario

Figure 1: Global average change in surface temperature (IPCC, 2013)

The term "sustainable neighbourhood" is emerging in recent years that advocates a liveable and enduring neighbourhood which does not compromise the well-being of future generations. It describes an area provided at the suburb scale that emphasizes the balance of social, cultural, economic and environmental aspects of the population, to provide opportunities for social interaction and achieve environmentally sustainable development.

1.2 Expansion of Shek Wu Hui sewage treatment works

Originally built in the 1980s, Shek Wu Hui Sewage Treatment Works (SWHSTW) has served Fanling and Sheung Shui areas for over 30 years, witnessing the rapid development of both towns from rural villages to a major population hub that it is today. With two upgrading works completed in the past, SWHSTW will embark on its third upgrade to become the largest tertiary STW in Hong Kong, aiming to double its capacity from 93,000m³/day to 190,000m³/day. The upgrading works is currently underway since mid-2015 and is anticipated to complete by year 2030. The proposed STW upgrade will enable future planned territory-wide developments to accommodate a potential population of 600,000, while increasing effluent quality to meet rising discharge standards.

DSD takes this opportunity to transform the conventionally functional driven SWHSTW to an "Environmental Campus", not only to adopt state-of-the-art tertiary treatment technologies, but also incorporate green design and community provisions to change traditionally unwanted "NIMBY (Not-in-my-backyard)" facilities into an integral asset in the local environment, thus highlighting the theme of "sustainable neighbourhood". Figure 2 shows the aerial photomontage of the future expanded SWHSTW.

Figure 2: Perspective of the expanded SWHSTW

2 GREEN TECHNOLOGIES/MEASURES

2.1 Taking a step further: Tertiary treated effluent reuse

Upon the further expansion of the SWHSTW, the effluent discharge standard will be tightened in order to achieve "no net increase in pollutant loads" to the ecologically sensitive Deep Bay Ramsar site, and also to honour the commitment of the revised Deep Bay (Shenzhen Bay) Water Pollution Control Joint Implementation Programme (JIP) under the Framework Agreement signed by the Chief Executive of Hong Kong and Governor of Guangdong in 2010. To achieve this, SWHSTW will be upgraded to a tertiary sewage treatment plant. Part of the treated effluent will be further polished as reclaimed water for toilet flushing and other non-potable uses in Sheung Shui and Fanling areas, and the planned developments in Kwu Tung North and Fanling North. Unlike other regions in Hong Kong, seawater flushing is not practiced in the North District due to its geographical distance to the sea. Therefore, reclaimed water reuse will ultimately save 21 million cubic meters of fresh water per year, equivalent to 8,400 Olympic size swimming pools (WSD, 2014). Reclaimed water will also be used in the SWHSTW for irrigation, flushing and cleansing, etc., which will reduce the fresh water consumption of the treatment works by 22%.

With the upgraded high quality effluent, DSD will also explore the opportunity to beautify Shek Sheung River by replenishing the concrete channel along with new landscaping works to further connect SWHSTW with the environment and the community. More details will be discussed in "Section 3: Sustainable Neighbourhood" below.

2.2 From waste to energy: Sludge treatment and renewable energy

One of the key initiatives is to harvest renewable energy from sewage sludge, an energy rich by-product generated from sewage treatment. Sewage sludge mainly composes of settled organic matters and surplus biomass growth in the treatment process, with high organic content and calorific value as high as 18,000 kJ/kg-ds (DSD, 2016). Conventional anaerobic digestion, which decomposes these organic materials in the absence of molecular oxygen, could transform the biosolids to biogas, which is rich in methane (about 60% by volume) (DSD, 2014). With the combined heat-and-power (CHP) system, biogas will be converted into heat energy and electricity for on-site plant operation such as powering equipment, temperature control as well as monitoring performance of sludge digestion process. To strive for innovative energy efficiency, the first-in-Hong-Kong thermal hydrolysis pre-treatment (THP) system will be adopted in SWHSTW to enhance biogas production by about 30%. This alternative "green" power will be fed back to the treatment plant and is estimated to generate about 20 million kWh per year, equivalent to the annual power consumption for 4,000 families (average household electricity consumption in Hong Kong is about 400kWh per month) (Environment Bureau, 2015). It will diversify the fuel mix of SWHSTW by offsetting approximately 10% of the total energy from conventional fossil fuels.

To fully utilize the energy recovery opportunity through this enhanced digestion system, DSD is also exploring the potential to turn the SWHSTW as one of the regional sludge treatment centre for other small scale sewage treatment facilities in the North District. We will also explore the feasibility to incorporate food waste co-digestion in the SWHSTW, not only to synergize the biogas thus energy recovery potential, but also to help lightening the demand pressure on landfills. Further studies will be carried out to confirm their feasibilities.

2.3 Sustainable by design: Green buildings

Building Environmental Assessment Method Plus (BEAM Plus) is a standard that provides building users with a single performance label to demonstrate the overall quality of a building. Considering the site area and its usage, the Administration Building and the adjacent landscape area in Zone A are targeted for undertaking the BEAM Plus Platinum Accreditation.

By partaking the BEAM Plus Accreditation, it will ensure the planning, design, construction and future operation stages of the new Administration Building and CHP Building to be "green" and sustainable, and to further support the overarching theme of "Environmental Campus" for SWHSTW.

BEAM Plus Accreditation focuses not only green elements, it covers the overall quality of the building including energy use and indoor environmental quality. Design initiatives including LED lighting, displacement ventilation and heat recovery for air conditioning systems, etc. will be implemented to reduce the annual energy consumption by up to 33%, while installation of solar panels atop the building will offset a portion of the energy consumption.

Innovative technologies and performance enhancements will be adopted to improve sustainable living, use energy efficiently, and thus reduce pollution.

2.4 **Pioneers in sustainability: "Blue**-Green Infrastructure**"**

Sustainable drainage system (SuDS) has been widely adopted in response to the extreme weather events induced by climate change, and DSD is one of the pioneers in Hong Kong striving to incorporate SuDS as part of our "Blue-Green Infrastructure" concept for alleviating flood risk, and also enhancing the runoff quality as well as promoting greening.

Rather than conventional collection and discharge, the SWHSTW will incorporate various SuDS in its landscape design for stormwater control and polishing, of which the "green" design can serve as an example to the public on tackling climate change and promoting water conservation through exhibition and plant tours. Examples of these SuDS elements, including green roof, bioretention system and porous pavement, proposed for the expanded SWHSTW are shown in Figure 3. In addition to reducing the peak runoff rate, bioretention and green roof could further purify the runoff quality by natural adsorption and microbe reaction through plant roots. Meanwhile, porous pavement, with multiple permeable layers of gradual gradation as shown in Figure 4, can remove between 60% and 95% of total suspended solids (i.e. silt) and 70% to 90% of hydrocarbons (CIRIA Reports C 697, C 609 and C 582). When subjected to low level oil drips, such as in car parks, the pavements can continue to biodegrade the hydrocarbons indefinitely (CIRIA 2007, 2004 and 2002).

Figure 3: Sustainable stormwater management systems in SWHSTW

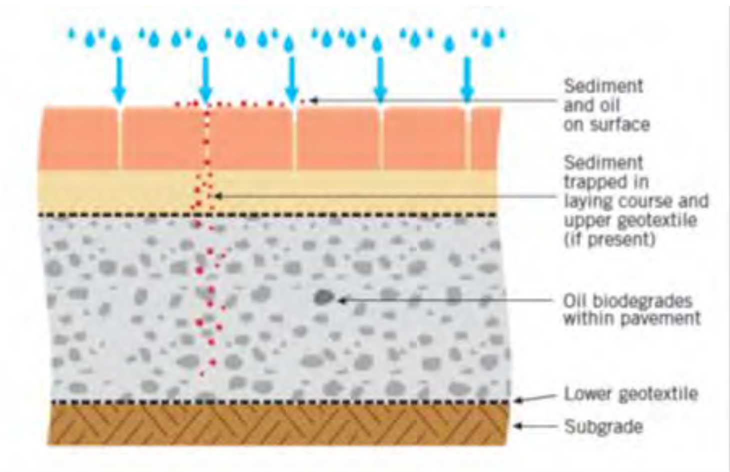

Figure 4: Trapping of sediment in porous pavement (Interpave, 2001)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.5 Putting it all together: Building information modelling

Design innovation with Building Information Model (BIM) is adopted to facilitate a piece-by-piece upgrade of the SWHSTW whilst in operation, through comprehensive construction planning using powerful time-based modelling and detailed crash analyses of pipelines. BIM also paves the path for information management for future operation and maintenance by identifying the configuration requirements for the model attribute fields to best suit the plant operators' needs. BIM technology will also be incorporated in the asset management system to provide a more reliable and secure sewage treatment service.

3 SUSTAINBLE NEIGHBOURHOOD

3.1 Learning by feeling: A living outdoor classroom

SWHSTW is located in a low rise industrial area surrounded by an expansive lowland. The surrounding areas are generally flat with agricultural fields and river channels, scattered villages connected by winding lanes and footpaths. Considering the aesthetics of the expanded SWHSTW, surrounding rustic environment and local community requirements, Environmental Campus linking with the Community is adopted as the design theme of SWHSTW.

The landscape theme will be designed for learning in a living outdoor classroom to echo the overarching theme of "Environmental Campus" in SWHSTW. The landscape design will aim to provide a pleasant outdoor learning environment on broad environmental initiatives where educational, environmental, professional, and research organizations can experience and appreciate the harmonious blend of advanced sewage treatment with natural landscape character and context. We strive to provide educational elements such that visitors or the general public can learn and be inspired by the revamped SWHSTW campus. For example, with the various SuDS incorporated in the landscape design, educational exhibits illustrating the functions of SWHSTW and associated climate change issues provided, visitors can easily understand real-life applications of textbook knowledge in the Campus. The landscape design also aims to provide a green and comfortable working environment to the operators by maximizing greening opportunities without compromising operational requirements. The site greenery coverage will be higher than 30%, giving the surrounding community a better and greener neighbourhood.

3.2 Learning by seeing: Educational plant tour

To enhance public awareness of sustainable development and strengthen their sense of belonging, guided educational tours will be organized to introduce the significance and operation of the expanded SWHSTW as well as the advanced treatment technologies adopted. Multimedia such as interactive models and educational exhibits will be placed along the visiting routes to different parts of the STW, fitting the theme of Environmental Campus.

With the use of BIM, a 3D model and virtual tours will be made available to the visitors for better understanding of the different treatment processes and technologies.

3.3 Giving back to the community: Riverside promenade

The expanded SWHSTW is surrounded by three rivers, namely Ng Tung River, Shek Sheung River and Sheung Yue River, offering a nice foreground view of the site from all sides. Riverside walkway, created by setting back the site boundary of the expanded SWHSTW, will be provided to create scenic spots and promenade areas for public enjoyment and leisure activities.

The proposed riverside walkway will connect to existing walkway and cycle path at Sheung Shui Town to enhance intra-district travel and strengthen connection of the expanded SWHSTW with the community. To provide a more pleasant environment and enhance the recreational value of the riverside walkway, landscape and water features will be introduced to complement the surrounding natural rivers. The perspective of the riverside walkway is shown in Figure 5.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 5: Perspective of the riverside promenade and walkway

3.4 Landscape integration: Shek Sheung River beautification

Part of the Shek Sheung River close to the SWHSTW is proposed to be beautified to further provide a linkage between SWHSTW and the community. High quality treated effluent from the expanded SWHSTW will be the water source of the beautified Shek Sheung River. The effluent will be discharged at Shek Sheung River after passing through the ultra-violet disinfection chamber to ensure a hygienic and safe water course. Figure 6 gives a perspective of the beautified Shek Sheung River and the proposed cascading water feature.

The beautification of Shek Sheung River will also aim to minimize the impact to the surrounding ecosystem. The existing two channels near Sheung Shui Heung will retain its natural course and merge with the replenished Shek Sheung River. Riparian vegetation will be planted on the embankment to segregate the effluent and the public, who may enjoy the scenery on the new timber deck platform adjacent to the river. In addition, fish ladder, animal passage, fish shelter and pools will also be provided for the connectivity and ecological enhancement of the local fauna. Figure 7 presents an impression of the enjoyable view of Shek Sheung River after beautification.

Figures 6 (Left) & 7 (Right): Perspective of Shek Sheung River beautification

3.5 Co-use of space: Public accessible facilities

To further connect the public with the expanded SWHSTW and attract users, co-use of some areas of the SWHSTW with the public is explored. Public accessible facilities will be provided for community enjoyment, including wetland garden, bio-retention lawn garden, seating area, viewing platform of the adjacent Long Valley wetland and multipurpose room in the Administration Building.

Wetland features with different wetland plant species including emerged, submerged and floating plants are proposed outside the Administration Building to welcome visitors to the SWHSTW, as shown in Figure 8. In addition to this public accessible wetland, a welcoming garden with multipurpose lawn is also proposed for public enjoyment.

Figure 8: Welcoming wetland to SWHSTW

SWHSTW sits near Long Valley. Having considered the enjoyable view to the future Long Valley Nature Park, the roof of Workshop Building in the SWHSTW will be designed as a viewing platform and will be open to public for viewing the farmland, birds and the stunning sunset scenery to the west. The pedestrian ramp reaching the viewing platform would also connect to a multipurpose room in the Administration Building. To enhance the integration of SWHSTW to the community, public can use this facility for meeting or other purposes by advance reservation. Furthermore, to allocate more space for public use, large multi-functional recreational platforms above rooftops of treatment buildings and ancillary buildings are currently under review.

4 SUMMARY

SWHSTW does not only provide sewage and sludge treatment. SWHSTW is developed to be a new generation of sewage treatment works as an "Environmental Campus linking with the Community". The proposed education tour in the SWHSTW aims to educate the visitors (especially students in Hong Kong) the importance of sewage treatment and its technologies adopted to minimize the unpleasant feeling of sewage treatment works, which is serving the function of "Campus". On the other hand, the landscape design aims to blend the sewage treatment works into the surrounding environment, fulfilling the theme of "Environmental". The beautification of Shek Sheung River can also enhance the integration of the treatment works into the environment.

As a sustainable neighbourhood, SWHSTW provides connection with the community. The scenic riverside walkway is proposed for an extensive network connecting the expanded SWHSTW and the Sheung Shui Town. It is aimed to enhance the recreational value of the site and provides an alternative choice for public leisure activities. Sustainable stormwater management system (including bioretention system, porous pavement system and green roof) will be implemented in SWHSTW to manage the quantity and quality of stormwater runoff.

A key lesson learnt in the planning of the SWHSTW expansion is that development of "NIMBY" facilities, especially with one in such close proximity to local communities, required extensive and comprehensive public engagement activities to ensure smooth progress. Transforming the community as well as the designers' mind set in viewing community infrastructure including the SWHSTW, from functional driven NIBMY facilities to be hidden, to integrated community asset to be shared and co-used as "sustainable neighbourhood" is another lesson we learnt. In considering local community's opinions on co-use of land and environmental concerns, we envisaged the Environmental Campus to be a perfect theme for the SWHSTW to seamlessly integrate into the surrounding environment and the community. Without compromising the capacity of the SWHSTW, the development paradigms are applied in a green, intelligent, cost effective, technically advanced and resilient manner, to provide a world-class wastewater treatment enabling the sustainable development of Hong Kong.

Biophilia and Nature-based Features to Support Stress Reduction in Knowledge Workers

Margaret Ann CALLAGHAN[a], Shauna MALLORY-HILL[b]

[a] *Conestoga College, Canada; Algonquin College, Canada, ann.callaghan@gmail.com*
[b] *University of Manitoba, Canada, s.mallory-hill@umanitoba.ca*

ABSTRACT

According to Duxbury and Higgins, 57% of full time office employees reported high levels of stress. Stress impacts the productivity, health and well-being of individuals, and the bottom line of employers. A growing body of research suggests that exposure to nature mitigates stress stimuli and therefore has restorative effects on memory and attention resulting in health, well-being and productivity benefits. This paper summarizes the findings of a 2015 MID thesis study that brings together information drawn from the neurosciences and environmental psychology including: attention restoration theory (ART), psycho-evolutionary theory, biophilic design, survival-advantageous characteristics, current case studies, and experience drawn from design practice. In this review, the authors highlight six key biophilic design strategies for stress reduction in office knowledge workers: locating in or near nature, movement in nature, maximizing daylight and views to nature, use of natural materials, plants and natural scents. These strategies focus particularly on providing workers with the most direct and indirect exposure to nature and, therefore, are likely to have the strongest impact on mitigating the stress response. Each strategy is shown in current applications in existing workplaces, where they are used in combination or independent of each other, depending on site conditions and opportunities.

Keywords: biophilia, stress, indoor environmental quality

1 INTRODUCTION

Stress is negatively impacting the productivity, the health and well-being of employees and the bottom line of employers. According to a Canadian study of 25,000 full-time employees 57% reported high levels of stress (Duxbury and Higgins, 2012). It is estimated Canadian employers lose $20 billion per year due to stress-related illness (Lem, 2013). Stress causes a loss of productivity and chronic stress can cause long term health issues (Posen, 2013).

A growing body of evidence suggests exposure to nature and nature-based or biophilic features may offer a solution to reducing stress in the workplace (Berman et al., 2008). This paper summarizes some of the findings from a 2015 thesis study (Callaghan, 2015) that includes a comprehensive literature review on the topic drawn from the neurosciences, environmental psychology, and examples in design practice. The purpose of the study was to determine strategies that would provide design practitioners with cost effective and straightforward ways of integrating nature-based features into workplace design to enhance well-being and reduce stress.

2 THE BRAIN AND THE NEUROSCIENCE OF STRESS

People are largely unaware of the stress stimuli they experience day to day, since the majority of sensory impulses are sorted in our sub-conscious. Neurosurgeon, Dr. Norman Hill describes that the brain, even during sleep, is constantly responding to sensory stimuli, endlessly coordinating all the chemical and electrical impulses, (N. Hill, personal communication, April 13, 2015 in (Callaghan, 2015) p. 7-9). The brain has evolved to place particular priority on sensory impulses to pass that are necessary to gain information about one's immediate environment to perform a specific task, typically related to survival.

Neuroscientist, Dr. Matt Hill, explains that, unfortunately, our response to stressors has not evolved to suit our modern-day workplace environment (Hill, 2013). Our response to life threatening and dangerous situations in the wild is physiologically similar to our emotional response to non-life threatening work pressures and physical characteristics of workplace environments (e.g. high stimulation). When external sensory stimuli trigger an alarm response in our brains, the neurotransmitter cortisol is released, producing a short term increased physiological function or what is commonly known as a flight or fight response.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

What was appropriate and effective metabolic response for survival when early humans where faced with a saber-tooth tiger, is very problematic when it is being reproduced by stimuli in modern workplace environments. This is because cortisol thins out dendrites that form the connections between our brain cells (Posen, 2013). Limiting the ability for one cell to speak to other cells effects short term memory. Memory is a key component in learning and cognition. It is theorized that these chemical and structural changes in the brain are the reason that individuals who are stressed experience memory loss and related mental and physical health problems. According to Posen, chronic stress can lead to depression. Others have identified stress as a risk factor for Alzheimer's (Le et al., 2016).

With advances in information technology, office workers are now working longer hours and spending more time indoors than workers did during the Industrial Revolution, which means they are being exposed to increasing levels of stress stimuli. Stress is a natural and useful biological response, but long-term stress can have dire consequences. While it is not possible, or even desirable, to attempt to block all of the billions of sensory stimuli received by the human body, designers may, according to environmental design theory and research, be able to mitigate worker stress by incorporating more natural, or biophilic, stimuli into workplace design.

3 ATTENTION RESTORATION THEORY AND BIOPHILIC DESIGN

If the human brain is not designed for the modern workplace, what is it designed for? According to acoustic ecologist Gordon Hempton, the ear, one of the brain's sensory receptors, is particularly attuned to better hear certain frequencies of sound (2-5 HZ) that communicate information about the natural environment and events in it relevant to survival (Hempton, 2015). Our vision system is similarly attuned to process daylight. E.0. Wilson's Biophilia Hypothesis suggests humans have a certain innate affiliation or love of other living things (Wilson, 1986), which makes sense given how easily we comprehend and communicate in it. Because humans are equipped with the perfectly designed biological receptors for processing relevant natural information means that we can do it effortlessly and without attention. In contrast, focused or directed attention towards something like a work-task or human-made environment requires a great deal of effort and can even overload our sensory receptors, causing mental fatigue and stress.

Thirty years ago, environmental psychologists Rachel and Stephen Kaplan developed Attention Restoration Theory or ART, suggesting that involuntary and effortless attention to nature rests the brain and thereby helps to restore memory and concentration (Kaplan and Kaplan, 1989; Kaplan, 1985). Kaplans' theory has been repeatedly tested and supported by numerous studies, with over 2046 citations currently in Google Scholar, including one in Li and Sullivan's recent 2016 study revealing the importance of views, over exposure to daylight alone, of school landscapes on recovery from stress in high school students (Li and Sullivan, 2016).

Roger Ulrich's (Ulrich,1993; Ulrich et al., 1991) own experiments suggest stress recovery during exposure to nature are derived from psycho-evolutionary theory related to positive emotional state and physiological changes, rather than involuntary attention, which Ulrich et al. was able to elicit with non-nature-based stimuli. Although Kaplans and Ulrich et al. provide us with different explanations of what happens during the restorative process, both (and many other researchers) found that views of nature, versus human made settings, account for cognitive recuperation and increased perceptual capacity (Hartig et al., 2008).

In 2008, social ecologist, Stephen Kellert began translating biophilia, ART, and psycho-evolutionary theory into a framework for biophilic design (Kellert, 2008). As a work in progress, Kellert's many different levels consisting of two dimensions, six elements and 70 attributes, can be difficult to follow and keep straight (Callaghan, 2015, p. 17). The attributes overlap and there are varying levels of detail within the elements. Architect and historian, Grant Hildebrand has proposed a similar nature-based design framework, but it is much smaller in organizational scale. Hildebrand's theoretical framework consists of five preferred architectural characteristics that emulate natural settings useful or advantageous to human survival. For example, Hildebrand references Jay Appleton's "prospect and refuge" (Appleton, 1996), a location offering a view of resources from a "protective place of concealment" (Hildebrand, 2000; Hildebrand, 2008). Although still mainly theoretical, both Kellert and Hildebrand's work to organize key ideas emerging from environmental design research has made it easier for designers to apply in actual design solutions.

In biophilic design, it is important to note that Kellert (2008) differentiates between three types of exposure to nature. The first is direct biophilic experience or self-sustaining features such as: plants, woods, gardens, daylight, views, landscapes and scents. Indirect biophilic experience is nature that requires on-going human intervention to survive, such as potted plants, which require watering and other maintenance. A third is symbolic represented in natural motifs such as leaves on column capitals or organic shapes on finish materials or images. Research by Kahn, et al., (2008) found that direct and indirect experiences with nature have greater potential for stress reduction. Interacting with images of nature, or technological nature, provides some, but not all, the enjoyments and benefits of interacting with actual nature (Kahn et al., 2009, p 41).

4 BIOPHILIC WORKPLACE DESIGN STRATEGIES IN PRACTICE

Biophilic workplace design is still relatively new, with relatively few examples, and of these, very little performance-based evaluation research has been done. While there are potentially many approaches to induce stress recovery through exposure to nature into workplace design, the following is a list of six practical design strategies drawn from a sample of seven biophilic workplace designs, along with additional related literature research. All six strategies focus on providing direct or indirect exposure to nature, or a combination of both.

4.1 Locating in or adjacent to nature

Locating work environments in natural areas provides opportunities for direct experience of nature immediately adjacent to, and usable as, a work environment. The Pond Studios, designed by Elva Rubio in a rural area near Lagrange, Georgia is a 15,000 ft^2 building extended over a large pond, providing a panoramic view of the surrounding nature. Several expansive decks encourage movement and use of outdoor spaces during office hours (David Oakley Designs, 1997).

In the case of SC3 Offices, the multidisciplinary design firm's building is located within an urban location (Winnipeg, MB) between two highways, a light industrial, and suburban residential neighbourhood (Canadian Architect, 2006) (see also Figure 1, Figure 2, Figure 3). Here the designers enhanced existing nature on the urban site, preserving and adding to a stand of spruce trees on the north side of the building and working with the local Municipal government to re-introduce a native prairie grassland along the south side of the site facing, and thereby mitigating sound from, the busy roadway. Walking paths, shared with the adjacent neighbourhood, are designed throughout. A broad, forest-sheltered exterior deck, fitted out with appropriate furnishings to minimize relocation time, extends the studio space into the new urban forest as a place for employees to unwind as well as undertake work tasks and meetings (see Figure 6).

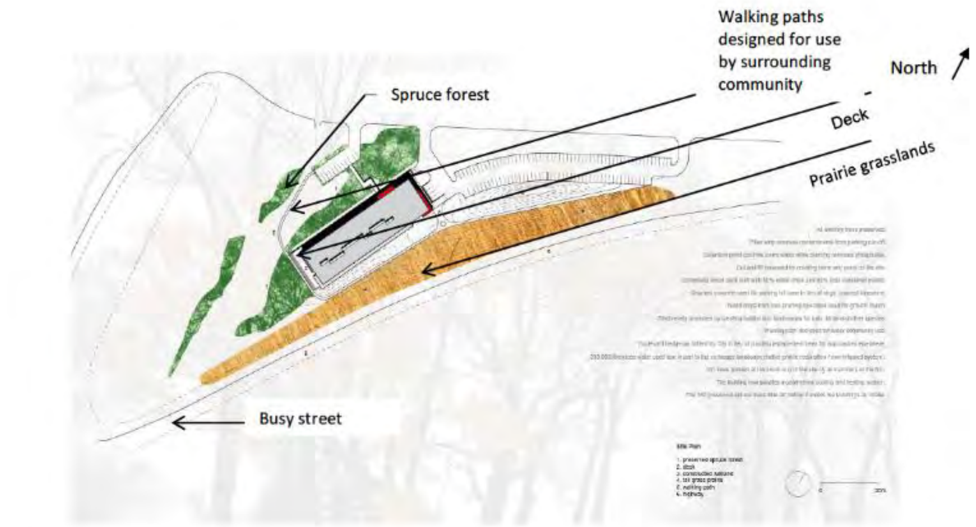

Figure 63: SC3 site plan (with permission Giles, 2014).

Figure 2: SC3 exterior. View of natural prairie grassland in the "front" yard view and tops of urban spruce forest in side and back area (with permission Giles, 2014).

Figure 3: SC3. View to urban spruce forest (with permission Giles, 2014).

4.2 Moving in nature

Several research studies (Berman et al., 2008; Nisbet et al., 2011) support the restorative benefits of not only viewing nature, but moving through it on vegetated paths and in urban parks and forests, compared to walking in urban settings without green infrastructure. Making nature both readily accessible, and possibly unavoidable, is a design strategy intended to build healthier workplaces. In the case of the proposed Google Campus in San Francisco Bay, California, designed by Architects NBBJ, a series of linked outdoor spaces and rooftops promote scooter-riding, jogging, biking, yoga classes all created from data on how employees work and relate in order to maximize "casual collisions of the workforce" (Radcliffe, 2013).

4.3 Daylight and views

Probably one of the most well-known and applied biophilic design strategies is the provision of natural daylight and view. As mentioned earlier in this paper, some research suggests that restorative benefits are more likely to be attributed to natural views, than to daylight, although both are important to human well-being and biological circadian function. Exterior glazing for daylight and view provides an additional opportunity to include operable windows for natural ventilation and improved indoor air quality and control.

The Selgas Cano architectural office provides its workers with an unusual ground level view of nature (Figure 4Figure 4). It is also an example of maximizing daylight and views by moving enclosed offices off glazed exterior walls and into the interior of the building floor plate, low (under 42 or 48") or no partitions and overhead storage units, and the incorporation of light colour furnishings and finishes to maximize day light penetration. SC3 uses similar strategies, including full floor to ceiling windows to optimize daylight and vegetated views (Figure 5). Glazed interior partitions and light shelves are also effective strategies for maximizing daylight and view.

Figure 4: Selgas Cano Architecture office set in suburban Madrid, Spain (with permission Cano, 2014).

Figure 64: SC3. View to nature from open workstations (with permission Giles, 2014).

4.4 Natural materials: wood

Tactile and visual stimulation provided by natural materials in indoor environments, and in particular, wood, has been shown to impact stress and relaxation responses. Researchers, Tsunetsugu et al., (2007) suggest that the ideal proportion of wood as an interior finish on walls and floors is between 30% to 45% of the combined surface area of a living space. Path, designed by Geremia Design in 2011, is a social networking application company's office located in a dense urban site in San Francisco. Path's office space cannot provide direct experience of nature, so the designers provide an indirect experience of nature through the use of well-placed plants, wood and other natural materials. Confronted with a similar dense urban location, Google's Tel Aviv's office designers' use spatial planning to create an interior park like setting with materials such: as wood benches, crates, flooring and natural tree trunks.

4.5 Plants

Another well-known and easily applied biophilic design strategy is the inclusion of plants in the workplace. Research studies by Raanaas et al. (2011) and Shibata and Suzuki (2004) suggest between one and five plants within the sight of the worker for stress reduction and improved health and well-being. On the ninth floor of its building in London, England, Goggle offers indirect nature in the form of gardening boxes on its decks and balconies, so popular there is a waiting list. Google Tel Aviv and Path's office areas also use the indirect nature of potted plants as discussed in 4.4 above.

4.6 Natural scents

Environmental psychologist, Sally Augustin suggests certain natural scents can reduce stress, promote relaxation (lavender) and can improve brain functions such as memory (rosemary), creativity (cinnamon-vanilla), and alertness (peppermint) (Augustin, 2009). The health benefits of the Japanese practice of shinrin yoku, or forest bathing, is supported by research that finds the scents, or essential oils, emitted by evergreen trees are associated with improvements to the immune system and production of natural killer cells (Tsunetsugu et al., 2010). SC3's location within a spruce wood forest provides an opportunity for workers to benefit from such essential oils, which also permeate into the indoor office space (Figure 6).

The introduction of scents inside buildings, sometimes referred to as environmental fragrancing, as in the Fredric's office building in Philadelphia, is intended to boost productivity of employees (Kadaba, 1994). Scents, especially ones from artificial or chemical sources, however, can be problematic for people with sensitivities. Moreover, the efficacy of scents is inconclusive. According to environmental psychologist, Susan Knasko, five out of eleven published studies, including her own, showed no effect of scents on task performance (Kadaba, 1994). Interestingly, congruency (how much an introduced scent matches its setting) has been shown to impact consumer behaviour in retail settings (Mitchell et al., 1995).

Figure 65: SC3 and surrounding deck area set in urban forest, natural spruce scent permeates indoor and outdoor spaces (with permission Giles, 2014).

5 CONCLUSION

Stress is a natural human response to dangerous or threatening situations, but according to neuroscience, the human biological response has not appropriately adapted to sources of stress stimuli found in today's work environments, contributing to the rise of chronic stress and its related health problems. A growing body of environmental design research suggests that the introduction of nature-based stimuli, or biophilic design, might help to recover from stress through restorative attention or by inducing positive emotional state.

The literature research from the MID thesis study summarized in this paper highlights how including nature and nature-based features in workplaces could potentially have a significant impact on worker health and well-being. An important finding drawn from the literature was that direct and indirect exposure to nature has the greatest impact over symbolic nature experiences. The implication of this finding is that designers should priorize strategies that provide direct contact. Four examples provided include locating workspaces adjacent to or in, nature, maximize movement in nature, exposure to scents in nature and optimize the provision of daylight and vegetated views. Where direct contact is not possible, exposure to indirect nature is recommended. Two strategies identified include the use of natural materials (wood), interior landscaping and potted plants. The case studies show how these various biophilic design strategies have been be applied in practice.

The authors note that biophilic workplace design is relatively new and that additional building performance evaluation research of buildings employing it is required to determine its impact on reducing worker stress. With a growing interest in promoting human health and wellness in buildings, biophilic design is now being integrated into green building rating systems such as Leadership in Energy and Environmental Design (LEED), Living Building Challenge (LBC) and the Well Building Standard, which likely will transform how future buildings are located and built. Rating systems, along with more multidisciplinary approaches to design delivery, will provide an excellent opportunity to integrate environmental design research with lessons-learned from measurement and monitoring of buildings employing biophilic design strategies.

Pioneering "Comprehensive Urban Landscape Technology" (CULT): An Integrated System Model for Urban Sustainability as Community Amenity in A Compact Urban Environment

Thomas CHUNG Wang-leung[a]

[a] *The Chinese University of Hong Kong, Hong Kong SAR, tchung@cuhk.edu.hk*

ABSTRACT

Floating Fields is at once an edible pond-scape and enjoyable public space. Conceived as a productive landscape for an architecture and urbanism exposition, the built project reinterprets the local cultural context and water-based agricultural traditions to create integrated sustainability. The 3,200m^2 project comprises a self-cleaning water cycle with floating farm plots, fish, duck, silkworm and microalgae cultivation, as well as filtering plants. Aspiring to an alternative, place-based bio-social urbanism, the project was awarded the Organizing Committee Grand Prize for the Shenzhen Hong Kong Bi-city Biennale of Urbanism\Architecture UABB (SZ) 2015-16. The project continues to act as a multi-disciplinary laboratory and research node on urban food production, sustainable design and green development.

Currently, Floating Fields is being transformed to demonstrate possibilities of comprehensive sustainability through calibrating an urban landscape system as innovative model for future community amenity. Eventually, the intention is to optimize the system to develop a prototype for other new urban developments.

Keywords: integrated sustainability, productive landscape, inclusive eco-design

1 INTRODUCTION: BACKGROUND AND CONTEXT

Floating Fields is a major architectural landscape commissioned for the Shenzhen Hong Kong Bi-city Biennale of Urbanism\Architecture UABB (SZ) 2016 at the Former Dacheng Flour Mill in Shekou. At once a productive edible pond-scape and enjoyable public space responding to the biennale theme of 'Re-Living The City', the 3,200m^2 project comprises a self-cleaning eco-water cycle of ponds with floating farm plots, fish, duck, silkworm and microalgae cultivation, as well as filtering plants. The project draws from the site contexts, inspired by the operation and tradition of oyster cultivation using floating bamboo plots in Deep bay, while also reviving the roots of the water-based polyculture ecology (multiple agri + aqua-cultures) that once defined the unique territorial landform of the Pearl River Delta in Southern China.

In the past, inhabitants of the low-lying, flood-prone, delta landscape fused agriculture including silkworm, mulberry leaves and fish cultivation with inventive eco-engineering to evolve the Mulberry-dyke Fish-pond, one of the most celebrated examples of intensive eco-agriculture of the region. It engendered a once flourishing water-based commerce that has now all but vanished leaving abandoned landscapes. The existing site, an obsolete flour factory, is a product of Shenzhen's rapid modernization, whose concrete construction was cracking up to allow the enduring resilience of nature to return as overgrown wild blossoms.

Figure.1: Left: Disused dormitory, middle: Traditional mulberry-dyke fishpond, Right: Deep Bay oyster rafts

2 CONCEPT AND DESIGN

The design operates on several levels to resuscitate the lifeless site. The presence of an existing covered waterway running diagonally through the site parallel and west of the oblong former factory dormitory spawned the idea to reintroduce the aquatic theme. The life-giving waterway is revitalized into a row of filtering ponds. The idea of a connected series of ponds holding various aquatic functions is extended around and outwards from the building. Their orientation, size and configuration derive from the structural bay rhythm and main entrances of the existing building, a linear block that has itself been converted during the biennale into a multi-use learning resource centre with exhibition, roundtable space, mezzanine library and a café restaurant.

Concrete ground east of the building is broken up to form larger ponds. Part of the rubble is crushed and recycled as gravel to fill pathways between ponds. The productive ponds are themselves formed from concrete bricks, and complemented with various pathways, platform and bridge with steps, benches and pavilions to create a walkable landscape combining food production and leisure.

3 ECO-WATER CYCLE AND FLOATING PLOTS

Figure 2: Eco-water cycle plan diagram showing complete cycle from 1 to 8.

A complete ecological pond-scape wraps around the old dormitory. The self-sustaining water cycle begins with nutrient-rich 'waste' water fed into the algae pavilion's ponds (7). Two types of colourful micro-algae are expertly cultivated in two ways to enhance the water purification. A specially designed three-step cultivation open pond sequence culminates in the harvest tank where the grown algae can be collected to ultimately produce organic fish feed, fertilizers and even biofuel.

Next comes a corridor of filtering ponds that purify the project's waste water using filtering gravel and filtering plants as the filtering medium (8). Volcanic rocks, broken tiles, and coarse river sand make up the gravel, while the plants include Umbrella Grass, Powdery Thalia, Iris, Alocasia plant, etc.. Water trickles through the medium successively in a zigzag fashion to elongate the filtering distance. The water-based plants are chosen for both their filtering capabilities and their visual qualities, and can be viewed along the elevated brick bridge.

The 'cleaned' water then flows into the prominently placed water lily pond (1), through the koi carp pond (2) and duck pond (3), into the big ponds where a contemporary version of the Mulberry dyke-Fishpond cultivation is combined with aquaponics (4 and 5). Carp stool, uneaten fish-feed and duck droppings nutrify the water. Edible fish ponds and floating plots are surrounded by mulberry beds that are grown to feed cocoon-spinning silkworms inside a silkworm pavilion (6).

The floating plots return oxygen to the water while partially absorbing nutrients in it, before it is fed back to start of the cycle to the algae pavilion. The floating plot, inspired by existing flotilla of bamboo rafts that is part of the oyster cultivating tradition of neighbouring Deep Bay, is tested out within the ponds as light-weight, mobile farming plots. This latter idea is tested on different horizons, on water-bodies, filling pavilion roofs or on top of the converted dormitory. Part of the cleaned water is also used for rooftop plot irrigation.

Floating Fields integrates multiple cycles, wherein each pond can have two-way nutrient provision, waste water recycling, crop production, water purification and landscape features, creating more flexibility than conventional systems. The connected pond-scape operates as a self-sustaining ecology to demonstrate a virtuous cycle of hybrid urban-agricultural environment that can also become at once a productive and leisure public space for the enjoyment of all.

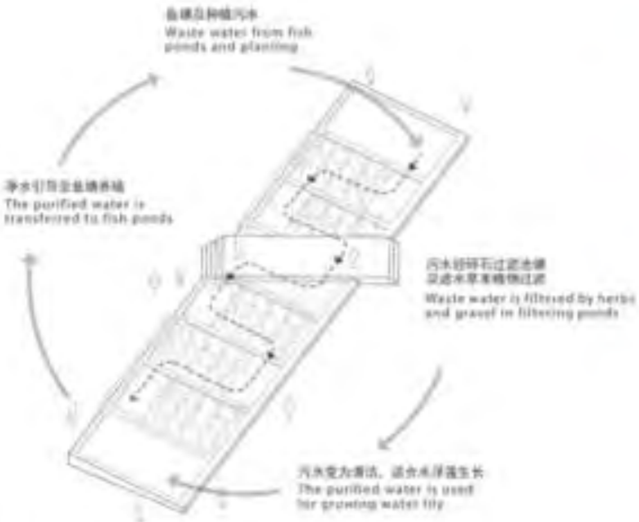

Figure 5: Filtering ponds diagram (Left), photo (Right)

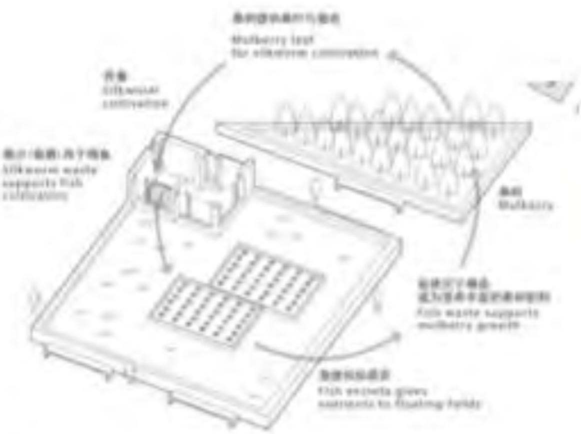

Figure 6: Floating plot aquaponics diagram (Left), photo (Right)

Figure 7: Floating fields as productive edible pond-scape and enjoyable public space

4 PUBLIC ENGAGEMENT AND RECOGNITION

Floating Fields generated events with great response and publicity from local community and media. At the Biennale 'Opening Forum', in the presence of all curators, international critics, architects and exhibitors, Floating Fields was a featured project in the discussion on notion of envisioning PRD 2.0. 'Planting Day' gave over 100 city kids and their families the chance to sow their own floating plots, catch fish and learn about duck, silkworm and algae life-cycles first hand. 'Tasting Festival' supported by local CSA (Community Supported Agriculture) groups offered participants fish soup and salad rolls (harvested on site) with talks on urban agriculture and the potential of microalgae in architecture and urban ecology. 'Harvest Parade' at the Biennale Closing successfully harvested the first crop of floating plots, presented algae cultivation results, and included a forum "Envisioning urban agriculture and ecology for Bio-social living". At the Biennale Closing, Floating Fields was awarded the UABB (SZ) 2016 Organizing Committee Grand Prize. Recently it has been shortlisted as the World Architecture Festival 2016 (WAF) Production Energy and Recycling Completed Building category Finalist.

5 CONTINUITY AND EXTENSION

Currently, Floating Fields is being transformed to demonstrate possibilities of comprehensive sustainability through calibrating an urban landscape system as innovative model for future community amenity. There are three main objectives:

- To demonstrate the key role architectural and landscape design play in integrating biodiversity and environment-related technologies to create sustainable public amenity.
- To test and optimize the constructed system as a dynamic, multi-functional facility that addresses: minimising carbon footprint, resource recycling, waste reuse, urban food production, waste water recycling in the water-carbon-food nexus.
- To combine productive, leisure and educational functions and operate as a live demonstration of urban sustainability within a real-life community.

General research themes include: low carbon energy production, turning waste into energy; cultivation of wide range of local species – from microorganisms (algae) to plant form (edible crops and filtering plant, fish and poultry); waste reduction and recycling – food waste for algae, fishfeed cultivation; and improving water treatment – water purification by algae, aquaponics – converting it into part of productive cycle.

With pertinent urban problems such as dwelling space shortage, urban food supply and production, carbon footprint, wise use of resources 3Rs (food and water waste), there is a great need in Hong Kong to educate and raise public awareness via demonstration projects that also function as community amenity public space. Separate studies of aforementioned research themes have been carried out, but an integrative comprehensive approach at a larger scale, using a real design on a living community has not been attempted.

Specific scope includes 1) optimising individual parts into the integrated system (data analysis); 2) evaluate architectural and landscape design of system; 3) refinement of integrated system and individual parts through periodical feedback loop (eg. review every 3-4 months); 4) develop comprehensive evaluation framework to coordinate system effectiveness and optimize production (perform the multi-objective optimization of the whole

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

system to achieve design goals with efficient resource allocation); 5) display and educational aspects evaluation through questionnaires; and 6) community participation, contribution of food waste, assistance with cultivation and monitoring, engagement through events and promotion. Eventually, the intention is to optimize the system to develop a prototype for other urban developments.

Figure 10: Innovative public space model of hybrid productive leisure architecture-landscape

6 CONCLUSION

To continue the project as a live experiment, it is hoped that Floating Fields will eventually become a multi-disciplinary laboratory and research node on sustainable design and green development. Using the site and Shekou as base and context, the intention is to engage in innovative research on topics such as bio-social design, architecture and urbanism; empirical research on water ecology and algae cultivation; and sustainable urban food production and its integration with the built environment.

Returning to fundamental urban re-living, disbanding excessive construction, and resuming a symbiotic space for nature, Floating Fields hopes to engender an innovative public space model that cultivates comforting nourishment and soothing experience amidst the restlessness of our buoyant city.

ABSTRACT

Humans are inherently interested in connecting with the natural environment. With the increasing urban constructions, they not only induced severely environmental impact, but also separated us from the nature. Despite the adoption of conventional green building technology can mitigate some of the adverse environmental impact, seldom can it help to re-establish the human-nature connection. To regain the missing link, Biophilic Design has become one of the strategic developments for AECOM Sustainability in the recent two years. Through a proper way to articulate the relationships between nature, science, and built environment so that we may experience the human benefits of biophilia in our design applications. Through a proper architectural design and the utilization of building physics, Biophilic Design can successfully integrate various natural elements within our working environment or habitat and positively influence our living style. Numerous research efforts have supported the benefits of adopting biophilic design in various development, which include helping hospital patients to recover within a shorter timeframe, increasing the students' learning motive and achievements, enhancing the working efficiency of employees and strengthen the communication within the community.

Currently, the lack of physical activity is being listed as one of the world's top ten major risk factors for death. The decline in the rate of physical activity is partly due to the limitation from our workplace and the sedentary living habit of modern society. To promote the concept of healthy living style through exercising amongst local community, the Community Active Design makes use of proper space planning and design to provoke the curiosity and interest of citizens to explore the nature of space around the neighbourhood, which can imperceptibility influence their living habits, enhancing their health and well-being and foster a healthy community.

Keywords: sustainable neighbourhood, biophilic design, active design

1 INTRODUCTION

This paper is mainly divided into two sections. In the first section, the guiding principles of biophilic design will be discussed. In addition, special interests are drawn to examine the applicability and feasibility of integration biophilic design concept into modern architecture development. In the latter section, focuses will be switched to discuss how Community Active Design positively influences citizen's living habits through appropriate community planning and design.

2 BIOPHILIC DESIGN

Biophilic Design is a dedicated effort to affiliate human affinity with natural systems. Although the concept has existed for many years, it has not yet been a common consideration factor in modern architectural design. With the growing quantified supports from researches, the positive impacts of biophilic design begin to gain increasing attentions (Kellert, 2005).

To develop a common ground for discussion and to better organize the diverse concept, Terrapin (2014) has issued a paper to identify 14 patterns of biophilic design, which are organized into three main categories namely – (i) Nature in the Space; (ii) Natural Analogues and; (iii) Nature of the Space. Table 1 outlines the overview of 14 biophilic design patterns under these three categories and their possible forms of expression.

Nature in the space: Incorporation of plants, water, and animals into the built environment, especially with movement	Natural analogues: One degree of separation away from true nature; patterns and materials that evoke nature	Nature of the space: The way humans respond psychologically and physiologically to different spatial configurations
1. Visual Connection with Nature – plants inside and out, green roofs, and living walls, water, nature artwork	8. Biomorphic Forms and Patterns – organic building forms, structural systems (savannah effect)	11. Prospect – views, balconies, 6m and above focal lengths, open floor plans
2. Non-Visual Connection with Nature – sun patches, textured materials, bird sounds, weather, nature scents	9. Material Connection with Nature – organic building forms, structural systems (savannah effect)	12. Refuge – protected spaces, overhead canopies or lowered ceilings, places providing concealment
3. Non-Rhythmic Sensory Stimuli – clouds, shadows, nature sounds, water reflections	10. Complexity and Order – fractal patterns, sky lines, plant selection, and variety, material textures, and colors	13. Mystery – winding paths, obscured features, flowing forms
4. Access to Thermal and Airflow Variability – shade, radiant heat, seasonal vegetation		14. Risk/ Peril – floor to ceiling windows, water walks, high walkways
5. Presence of Water – rivers, fountains, water walls, ponds, day lighted streams		
6. Dynamic and Diffuse Light – light from different angles, ambient diffuse, lighting, circadian lighting		
7. Connection with Natural Systems – seasonal patterning, wildlife habitats, diurnal patterns		

Table 1: Patterns of biophilic design

2.1 Nature in the space

Nature in the Spaces emphasizes on the direct, physical and ephemeral presence of nature in a space or place. Natural elements like the presence and diversity of plant lives, animal species and water features can be included within the built environment to strengthen the nature-human connection. There are mainly two strategies to bring nature into the interior space including integration or simulation.

The most common approach for integration is to include tangible or integrate visible green features within the built environment. Should there be sufficient space, designers can consider features like indoor-terrace-gardens and courtyards. For area with limited space, features like potted tree and small water features can be adopted. Designers should also use windows strategically to maximize the visual connection with natural landscape. Additional benefits can be realized if natural ventilation or lighting is integrated to the building design to provide

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

occupants with non-rhythmic sensory stimulation. While no specific criteria is laid down by the biophilic design guide in this area, references can be drawn to some of the internationally recognized standards like the ASHRAE 55 and ISO 7730 standard as design guide.

Besides integration, simulation is another useful technic to mimic the natural environmental for place where space or outdoor view are greatly limited. For examples, landscape representation (e.g. paintings) can be used as indoor decoration to enhance visual experience. Nevertheless, these simulated environments are steady with no variation across time. A more favourable alternative is to simulate the nature scenes through digital medium (e.g. video depicting nature scenes).

2.2 Natural analogues

Natural analogues focus more on evoking the indirection connection with the natural environment. The ultimate intention is to imitate the natural environment and articulate connections between aspects of the built and natural environments.

There are essentially two approaches to applying natural analogues concept, as either a cosmetic decorative component of a larger design, or as integral to the structural or functional design, characterizing mainly through four different forms: representational artwork, ornamentation, biomorphic forms, and the use of natural materials. For the former three forms, much emphasis is placed on using fractal patterns to create a visually nourishing environment that engenders a positive psychological or cognitive response (Salingaros, 2012). Extreme caution must be taken when using such strategy as over complex patterns are found to induce stress and visual perception problems (Hägerhäll et al.,2008). It is more preferable to apply this tactic to common area like corridors or pantries rather than normally-occupied space, which helps avoiding visual fatigue induced by prolonged exposure. For the use of natural materials, it is recommended to preserve the natural forms of the materials or undergo minimal processing. Terrapin (2014) pointed out that the type of material is important for perceived restorative quality and people usually preferred real materials over synthetic one. Hence, designers could consider adopting the natural materials such as natural stone and clay. Priorities should be given to those rapidly renewable materials which can replenish faster than traditional extraction demands, thereby reducing the adverse impact to the environment.

2.3 Nature of the space

Nature of the space pinpoints to the innate and learned desire of human to see beyond our immediate surroundings. The degree of perception of human in this aspect is greatly influenced by the spatial configurations of the space. Examples includes creating an unimpeded views over a distance or conversely, partially obscured views that inspire a sense of mystery.

The understanding in this category of biophilic design has long been demonstrated by a number of ancient and contemporary architectural examples. For illustration, the examples from JWT office in Atlanta and Hubspot's Headquarter in Cambridge will be used to demonstrate how this biophilic design category can be applied in modern office development to create a sense of prospect and refuge.

JWT Office – Prospect

The design is focused on creating a space which allows people to see from one space to another. This is based on the survival philosophy that it is the human instinct to be able to understand the environment and estimate any threats or opportunities. Hence, the JWT has applied a large number of windows both interiorly and exteriorly to provide users with a condition suitable for visually surveying. The exterior window façade also allows visual connection with nature which optimize the prospect experience with a quality view.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 1: JWT office in Atlanta

Hubsport's headquarter – Refuge

The design objective is to provide users a small portion of protective environment within a large space. The area should limit visual access into the refuge place and offer overhead and back protection. In particular, it can be seen from the Hubspot's example that entirely enclosure of the refuge place is not necessary; instead a proper opening can provide users visual or aural contact with the surrounding environment for surveillance.

Figure 2: Hubspot's headquarter in Cambridge

3 ACTIVE DESIGN

The Biophilic Design is usually applied at individual building level, which targeted at enhancing the psychological well-being and health of occupants through applying the 14 biophilic design patterns. Active design, on the other hand, is concerning the ways to form a healthy community through proper space planning and design. It focuses on inducing peoples' initiatives to explore and utilize their surrounding facilities; thus, promoting the physical health of the occupants. By applying these two design philosophies at both building and community level, it could maximize the health benefits to occupants both psychologically and physically.

3.1 Oversea and Chinese researches comparison

In recent years, active design and active community concept have becoming a more popular topic in the green building industry. Numbers of researches have been published discussing ways to promote healthy lifestyle. Noticeably, the research direction for oversea researchers and Chinese researches are distinctively difference.

The researches effort in China is mainly focus on application level, especially the difficulties in implementing active design concept in China. Researchers conclude that there are two primary reasons that limit the prevalence of active design community. First, there are inadequate connections between active facilities and communities. Some active facilities are exists independently rather than an integral part of the community. For example, fitness trails are often only available around stadium which located distance away from the resident blocks. Such inconvenience discourages people to use these facilities. Second, designers sometimes have failed to recognize the cultural differences in planning the construction of community facilities. For instance, people in China are comparatively less enthusiastic about basketball than European countries. As a result, the utilization rate of these facilities are not too satisfactory.

Overseas researches show different areas of focus. They are more interested in establishing the positive relationship between active design and health. The hypothesized Active Community Environments (ACES) model proposed by Scott Doyle (2007) illustrated the process of how active community environments improve the overall health status of occupant (refer to Figure 3). Scott also found that sense of safety and the walkability of community are parts of the influential factors – people living in a walkable community with low crime rates tend to be healthier.

Active Community Environments (Walkable and Safe) → Greater Physical Activity → Lower Obesity Rate → Fewer Weight-related Chronic Problems → Better Overall Health

Figure 3: Aces model proposed by Scott Doyle

Although Chinese and oversea researchers have explored various factors influencing the active design, limited attention was paid to investigate the importance of human perception on comfortability. In a survey conducted by Lay (2014), his result proved the relative importance of comfort to active community design. When answering the question 'Why you choose this outdoor space?', over 58% of the respondents replied the primary reason was due to comfort-related concerns including thermal comfort, air quality and acoustic environment. Figure 4 presents the overview of the survey's result.

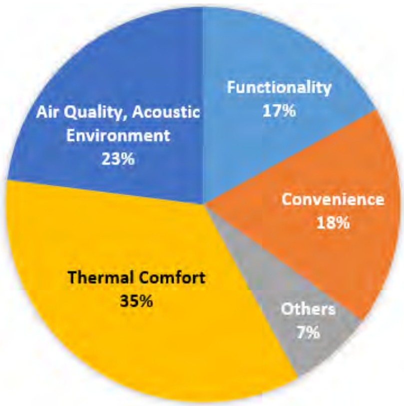

Figure 4: Aces model proposed by Scott Doyle

3.2 Consideration factors in active design

Despite the differences in researches focuses between Chinese and Oversea scholars, their ideologies are not contradictory but complementary to each other. To provide a more systematic approach and overall picture towards Active Design, the following matrix (Table 2) are proposed:

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

	Community Level	
Building Level	Safety: From a design perspective, it is mainly affected by the environmental design including the lighting level, access control (e.g. locks, guards), surveillance and etc.	Walkability: A measure of how friendly an area is to walking. Factors influencing walkability include the presence or absence and quality of footpaths, sidewalks and etc.
1. Building Facilities – promote physical activity and encourage healthy living style through provision of supporting facilities, e.g. indoor gardening area or bicycle parking facilities)	✓	✓
2. Open Space Design – provision of recreational facilities appropriate to local culture, e.g. For China → provision of Taichi and dance area)	✓	✓
3. Circulation – refers to appropriate design of indoor circulation path and provision of adequate signal to encourage physical activity within indoor environment, e.g. provision of office stair with appropriate length	✓	✓
4. Perception of Comfortability – can be addressed through proper consideration of site characteristics such as site wind availability, noise emitting source from proximity area and etc.	NA	NA

Table 2: Active design consideration matrix

The above table outlines the general design principles to be applied at both building and community level. It should be noted that these principles have to be considered as a whole in order to achieve a satisfactory active community design.

3.3 Active design in application – Foshan MEGAHALL MOMA project

To instil a sense of safety, the carriageway of this project was designed all along the exterior area of the community while all pedestrian areas were centralized in the middle of the project site. This effectively separated the pedestrian and vehicle movements and improved the residents' safety index. Moreover, the community reserved a large, concentrated and open spaces for recreational and leisure purposes of the all-age of occupants. Advanced sunlight analysis and wind environmental analysis were also conducted within the subject site to assist in the strategic planning of community. For instance, the activity spaces for children and seniors were deliberately placed at areas where abundant of sunshine was availability to ensure the maintenance of a comfortable environment.

Regarding the community facilities, a 600 meters long jogging lane was provided within the community site. Calories signs were marked on the lane every 150 meters to promote a healthy lifestyle. Apart from the provision of traditional lighting facilities, fluorescent coating was also painted along the lane. This special feature provided extra incentives or attraction for people to explore the lane and to exercise more frequently.

4 CONCLUSION

This paper presents the design principles in implementing the concept of biophilia and active community. It points out the associated psychological and physical health benefits to the occupants such as the enhancement of employees' working efficiency and the reduction of risk of having chronic-related health problems. In particular, based on literature reviews and precedent project experiences, the paper briefly discussed the difficulties in applying biophlic design and active design in real-project situation. To address/ eliminate these potential difficulties, the paper also proposes some practical approaches, through project examples, to provide design insight for optimizing the building and community design which can facilitate the development of a healthy and comfortable community environment.

ABSTRACT

Hong Kong, locating at a lower latitude area, is suitable for solar energy application, especially building-integrated solar photovoltaic (BIPV) application for power generation in urban environment. A BIPV system is highly dependent on available installation area of a building because usually the PV panels are placed on roofs or vertical facade of a building due to their broad and open surfaces for receiving more sunlight. However, the available roof and vertical facade area for PV installation in the proposed Green Deck is very limited due to green areas and other facilities. Therefore, in this study, the walkable solar PV panel is proposed for application in the pavements and cycling tracks, which receive a lot of sunshine and can be sued for power generation as well. This is a green and innovative solution to integrate sustainable energy technology into the Green Deck and it can help to achieve the target of low carbon city in Hong Kong. The major research activities are presented in this study, including literature review on available technologies, configuration design, prototype preparation, electrical, and thermal performance tests. Results show that the developed PV pavement panel has satisfactory performance in solar energy conversion efficiency and other performance.

Keywords: renewable energy, green deck, solar photovoltaic pavement

1. INTRODUCTION

Solar energy is considered as one of the potential feasible sources of wide-scale renewable energy application in Hong Kong, along with wind energy and waste-to-energy (EMSD, 2002). In urban environment, building integrated photovoltaics (BIPV) system is an attractive application of solar energy (Lo, 2005). BIPV refers to PV cells which can be integrated into the building envelope as part of the building structure, and therefore can replace conventional building materials (Henemann, 2008). BIPV applications in Hong Kong are truly sustainable with short energy payback time and greenhouse-gas emission payback time, around 2-3 years for roof-top type and 3-6 years for other vertical PV façade, both are much less than their lifespans of 30 years (Lu and Yang, 2010, Lu, 2011). A BIPV system is highly dependent on available installation area of a building because usually the PV panels are placed on roofs or vertical facades of a building due to their broad and open surfaces for receiving more sunlight.

Figure 1: The Green Deck project proposed by The Hong Kong Polytechnic University

The Hong Kong Polytechnic University proposed the construction of a Green Deck over the Cross Harbor Tunnel plaza to tackle the problems in the vicinity – poor air quality, overloaded footbridge, poor connectivity within the district and lack of open space (Figure 1). The Renewable Energy Research Group at the university, therefore, has conducted a previous study to investigate the feasibility of using BIPV system for power generation to achieve the zero carbon emission green deck. However, result demonstrates that the available roof and vertical facade area for PV installation is very limited due to green areas and other facilities on the Deck (Yang et al., 2014). To find more possible areas for solar power generation, this research project focuses on how to use the pavements and cycling tracks for installing PV panels so that most or all the electricity consumed by the Deck can be supplied by solar energy. Therefore, walkable solar PV-panelled pavement is proposed to replace traditional floor tiles for the pavements and cycling tracks, which receive a lot of sunshine every day.

This is a green and innovative solution to integrate sustainable energy technology into the deck and to achieve the target of zero energy consumption and zero greenhouse gas emissions of the Green Deck. Moreover, the appealing design of the solar pavement could offer a fantastic range of configuration possibilities in colour to enhance the aesthetic value. The major objectives of this study are as follows:

- To investigate the feasibility of this technology applied on the Green Deck;
- To develop new PV panels used for pavement, and
- To study the panels' electrical and thermal performance experimentally.

2. LITERATURE REVIEW ON AVAILABLE TECHNOLOGIES

Currently, there are several demonstration projects of solar road or pavement in the word. The Netherlands built the world's first solar road, which is an energy-harvesting bike path paved with glass-coated solar panel (Figure 2). After one-year's trial, the novel solar road has proved more successful than expected (Macdonald, 2015). It can generate about 70kWh/m2/year, indicating that the 70-metre test bike path is enough to power a small household. However, this cutting edge technology is under its infant development stage and still has some problems, for example, such solar panel is very heavy so it is very difficult to install it, and the anti-slip coating, which provides grip to the surface, has become delaminated due to long term sun exposure and temperature fluctuations.

Figure 2: Netherlands' solar road project

Another innovative technology is the walkable solar PV pavement developed by Spanish tech company Onyx Solar (Onyx, 2016). Such PV floor can comply with the anti-slip regulation and support 400 kg in point load tests. To demonstrate the capabilities of the technology, The George Washington University created what is claimed to be "the first walkable solar-panelled pathway in the world" (Figure 3). This micro power plant has a peak power output of 400 watts, which is enough to illuminate an array of 450 LEDs that light the pathway at night, shining up through the panels from beneath. However, this solar cell is based on amorphous silicon technology with relative low efficiency. Besides, the front glass is translucent so the received solar radiation is reduced. Therefore, the power output is very limited.

Figure 3: A walkable PV pavement system

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The third technology is the solar block or solar brick light (Figure 4), which are integrated with a self-contained illuminating device. They can add both day and night-time colour to walkways and other outdoor surfaces without additional wiring. The small PV tiles can generate electricity and store energy (even in rainy days), emitting a soft LED glow at night. This technology is popularly used in some parks and walkways. However, the major problem is that each PV tile can only generate several watts electricity for powering LED lights, not suitable for large scale power generation system.

Figure 4: Solar PV light emitting tiles

3. PROTOTYPE DEVELOPMENT

In this project, we developed a new type of solar PV pavement panel through collaboration with a local solar PV engineering company. Figure 66 shows the layout design of the PV floor configuration, which is sandwiched between anti-slip front tempered glass, EVA/PVB foils, solar cells, and rear support tempered glass. The total front size is 500×500mm, similar to the general pavement tiles. The thickness is about 20mm. In each floor tile, 9 monocrystalline silicon solar cells are connected in series, so that he expected power generation and efficiency are about 30-40Wp and 15%, respectively.

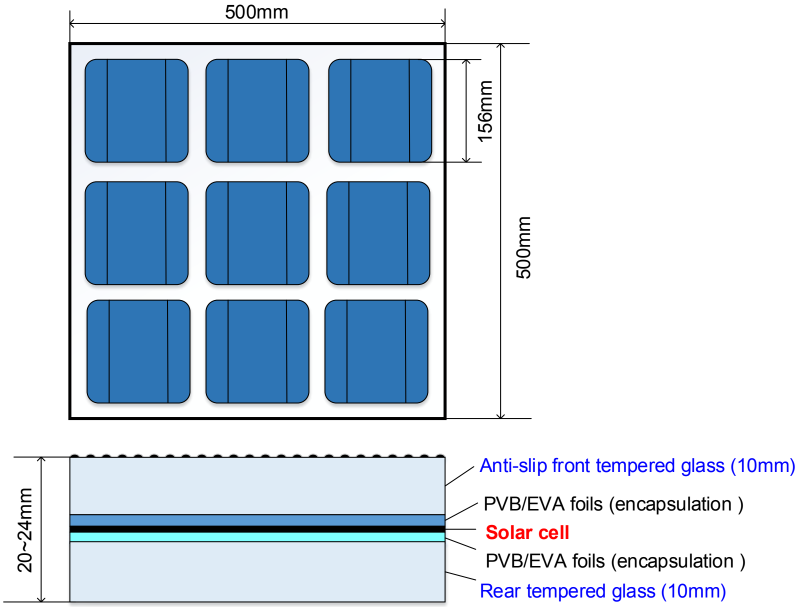

Figure 66: PV floor tile configuration

The raw materials including tempered glass and solar cells were purchased from manufacturers in mainland China,

Kong (Eco Engineering Limited).

Figure 67 shows the two developed prototypes of the PV floor tiles with different anti-slip surfaces, i.e. cross-line pattern and dot pattern. In general, the floor tile with cross-line layer has higher anti-slip performance but lower sunlight transmissivity.

Figure 67: PV floor tiles with different anti-slip surfaces

The major features of the developed solar PV floor tile are summarized in Table 12. The static coefficient of friction of the PV floor is 0.78 for dry surface and 0.54 for wet surface, indicating that it is absolutely anti-slip. It also has high transparency with solar light transmissivity of 90%. The heat-resistance temperature can be up to 288 ºC, so there is no need to worry about whether it will be broken under long time sun exposure. The energy efficiency of solar cell and module can be up to 18% and 15%, respectively.

Features	Parameters
Anti-slip	Static coefficient of friction (COF): 0.78 for dry surface 0.54 for wet surface
High efficiency	module: 15%
High transparency	transmissivity: 90%
High compressive strength	max load: 74 kpa
High heat-resistance temperature	up to 288 ºC

Table 12: Major features of the developed solar PV floor tile

4. PERFORMANCE EVALUATION

4.1. Indoor laboratory test

The test of the developed PV floor tile was first conducted in our solar simulator laboratory in the Hong Kong Polytechnic University. Figure 7 shows the test rig. The instrument EKO MP-11 is used to collect the I-V curve and power output every minute. The pyranometer is used to measure solar radiation intensity at the same level with the PV floor tile.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

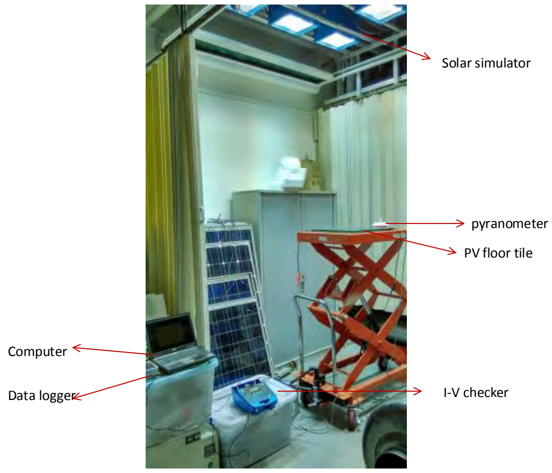

Figure 7: Test rig in PolyU laboratory (indoor test)

Figure 8 shows an example of the collected I-V curves and P-V curves. It can be observed that the maximum power output is 20.5W when solar radiation is 960W/m2, and the energy efficiency is 10%.

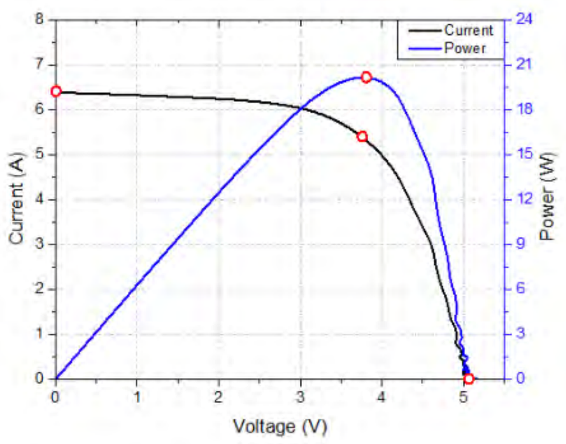

Figure 8: An example of the collected I-V curves and P-V curves

4.2. Outdoor field test

We also conducted outdoor tests on the solar PV floor on the 6th floor of Bock Z with an open and no shaded space (Figure 9). The electrical and thermal performance has been tested. Figure 10 illustrates the collected solar radiation and power output from 12:00 to 3:00 in the afternoon. It is obvious that the variation of power output has close relationship with solar radiation. Besides, the solar radiation on the day is not very good because the weather is cloudy, ranging from 200 to 800w/m2, therefore the power output of one PV floor tile is from 5 to 20W, and resultant efficiency is about 10%.

Figure 9: Outdoor test system in the 6th floor of Block Z

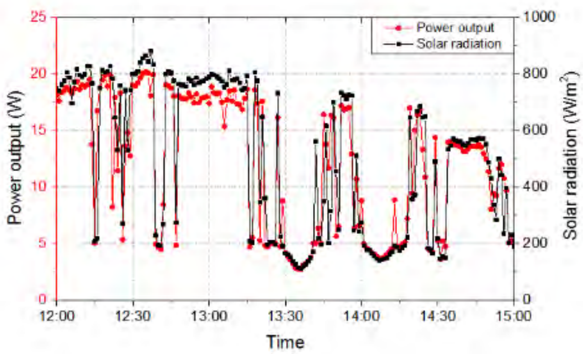

Figure 10: Collected solar radiation and power output

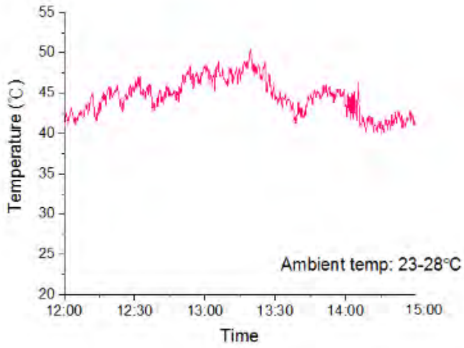

Figure 11: Thermal profile of the PV floor

The temperature of the PV floor tile under outdoor test was measured to evaluate its thermal performance. Figure 11 presents the temperature profile of the back side of PV floor tile. The module temperature is in the range of 40-50 ºC although the ambient temperature is about 25ºC on that day. Based on the specification of solar cell, the high temperature will have negative impact on power output by -0.5%/ºC, therefore, the temperature difference of 25~30ºC can result in about 13% (4W) decrease in power output.

The laboratory test and outdoor test results show that the power output are lower than the rated values because the transmissivity of the tempered glass is reduced by the additional anti-slip surface, which means that the received solar radiation on solar cells is decreased and the measured temperature of the PV floor is very high, which can reduce power generation by 10%-20%. Besides, the solar radiation on that day fluctuates greatly and does not reach the standard test condition of 1000W/m2.

5. CONCLUSIONS

In this study, the walkable solar PV panel is proposed for installation on pavements and cycling tracks for the Green Deck project. The feasibility and potential area of applying this innovative PV floor on the green deck was investigated. Two prototypes were developed and tested to evaluate its electrical and thermal performance. Results show that the developed PV pavement panel can achieve satisfactory performance in solar energy conversion efficiency, anti-slip, heat-resistance, durability and compressive strength, demonstrating that such panels can be used as a replacement of the pavements and cycling tracks in the Green Deck. This technology can combine active elements (power generation) with passive elements (waste material for back panel manufacture), providing an innovative and green solution to integrate sustainable energy technologies into the deck and help to achieve the target of zero carbon emission of the deck.

6. ACKNOWLEDGMENTS

The work described in this paper is supported by research funding provided by The Hong Kong Polytechnic University, for the Green Deck project.

ABSTRACT

Recently, the occurrence of extreme weather events has gradually increased in many areas due to climate change. Furthermore, human health problems are resulting from such dramatic climate changes, as noted in hospital emergency visits and attendance rates after the occurrence of extreme events. In general, previous studies have used outdoor climatic data from ambient stations to assess the human health risks caused by extreme events. However, elderly people are often more vulnerable to heat exposure and thus spend most of their time indoors. This study aims to propose a predictive model to determine the indoor climate from weather forecasts in order to reduce health risks through the development of a warning system for susceptible populations.

In the present study, we propose a predictive model based on building energy simulations (EnergyPlus) and then performed field measurements of residential buildings to gather one year of data for verification. We further applied the simulation model in order to study the influence of changing building construction/materials in relation to adjusting the climate. Finally, we examined improvements made to indoor environments and their effect on the health risk of the susceptible population. The results demonstrate that not only can the indoor environment be properly predicted by the building energy simulation model, but also that improving thermal insulation, ventilation, and vertical greenery can improve the indoor environment, thus resulting in reduced health risks of the susceptible population.

Keywords: susceptible population, health risk, EnergyPlus

1. INTRODUCTION

Due to the increased occurrence of extreme weather events around the world, many studies have focused on the subsequent related health risks. However, most temperature-mortality studies have been performed in European and North American cities but rarely in areas with a subtropical climate. Crossed by the Tropic of Cancer, Taiwan is an island located in the west of the Pacific Ocean. With extreme weather expected to intensify in the future, evaluating the health risks associated with hot and humid climates, such as that in Taiwan, is important.

According to estimates made by the United Nations, the total number of people aged 65 years and older was 506 million in 2008, which is expected to more than double to 1.3 billion by 2040. Bunker et al. (2016) found that elevated risks for the elderly were noticeable in the outcomes of temperature-induced chronic diseases. Such risks will likely increase with climate change and global ageing. As the elderly often spend most of their time indoors, adverse indoor environments may potentially influence the health status of the elderly and cannot be ignored. Quinn et al. (2014) found that most residences surpass the heat index threshold during extreme events, indicating that changes in indoor temperature and humidity during heat waves can threaten occupants' health.

Indoor air quality has recently become a more important research topic with regard to improving the indoor thermal comfort, health, and even work efficiency of the occupants. Thermal comfort is influenced by outdoor environment and a building's construction/materials, including air temperature, mean radiant temperature, relative humidity, and ventilation. Kitamura et al. (2016) indicate that dramatic temperature changes in winter lead to the increased morbidity of cardiovascular diseases. After installing insulation on the opening, the aforementioned study's results showed that simple thermal insulation can slightly improve the indoor thermal comfort of the residents even without heating equipment.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Besides insulation materials, external shading devices are the most effective way to improve thermal comfort by controlling the solar load on buildings. Stazi et al. (2014) compared the thermo-physical behavior of five kinds of external shading devices, and their simulation results demonstrated that shading devices can improve indoor thermal comfort by decreasing the solar heat gain.

With shading, evapotranspiration, and reduced wind velocity, vertical greenery designs have been recommended in cities throughout the world to improve thermal comfort. Sunakorn et al. (2011) studied the effect of temperature reduction by vertical greenery with cross ventilation in Thailand and found that vertical greenery had a significant influence on temperature reduction during the day and increased the temperature difference between indoor and outdoor when wind velocity is low.

In this study, we developed a simulated prediction model and verified it with field measurements. Furthermore, indoor thermal comfort is improved by enhancing thermal insulation and installing external shading devices and vertical greenery on balconies in order to adjust the climate and decrease the health risks to susceptible populations.

2. DEVELOPMENT OF THE PREDICTIVE MODEL

2.5 The object of measurement study

In Taiwan, the most common residential patterns were categorized into townhouse (5F or less), apartment (5F or less), and mansion (6F above); furthermore, 70.9% of residences are under five floors. For this study, we selected a three-story townhouse located in Tainan with a latitude of 22˚99′ north and longitude of 120˚20′ east for real-time monitoring, as shown in Figure 1.

We carried out real-time monitoring from October 1, 2012 to September 30, 2013. Indoor temperature and humidity sensors were installed in the study participants' main bedroom, where the occupants spent most of their time when inside the house. The sensors were attached to furniture under the ceiling, approximately 1 m away from windows and heating devices and out of direct sunlight. The sensors were programmed to record measurements every hour and remained in the residence for 3 months.

2.6 Development of the indoor temperature predictive model

In order to create a predictive model between outdoor and indoor temperatures, we performed monitoring and simulations. The results were used to evaluate indoor health risk.

EnergyPlus, software that analyses buildings' energy performance, was used to simulate the daily average temperature throughout the year. Local weather data using the TMY3 format was used for the simulation; Table 1 shows the parameters of the indoor boundary conditions. The discharge coefficient of windows with screens was set as 0.4 for the calculation of natural ventilation, and the inner heat source of two occupants, lighting, and a television were applied to the main bedroom. Furthermore, the set-point of air-conditioning was set to 27˚C between 19:00 and 24:00.

We studied the correlations between the measurements and the simulation to verify the simulation. Figure 2 shows that the temperature coefficient of determination (R2) is 0.97, indicating that the simulation model of this study has certain credibility.

Table 2: Temperature threshold in subtropical climate zones.

2 CASE STUDY AND EVALUATION

2.1 Definition of temperature extremes

Table 2 shows five recent reviews of subtropical climate zones that describe temperature's effect on people's health. Xu et al. (2013) compared apparent temperature (AT) to mortality outcome and found that an AT below 20.8˚C was related to an increase in mortality risk of all causes of cardiovascular and respiratory disease for every 1˚C decrease in AT over the following three days.

To assess the risk of emergency room visits for both cardiovascular diseases and respiratory diseases associated with ambient temperature, Wang et al. (2014) studied the related risk in Taipei and found that temperatures below 14˚C and above 32˚C were correlated with an increased rate of hospital emergency visits. Likewise, Wang et al. (2015) evaluated the association between environmental factors and health risks in Taiwan, determining that younger people had more outpatient visits for exposure to temperatures below 18˚C and that seniors more vulnerable to temperatures above 30˚C.

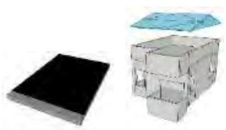
Since climate changes every year and the frequency of extreme events has gradually increased, a temperature index between 18˚C, which is at approximately 5th-20th percentiles of the average temperature, and 30˚C, which is at approximately 95th-97th percentiles of the average temperature in 2000-2008, was selected in this study to evaluate health risk with the recent weather data, as well as to discuss the health risks of the elderly in Taiwan.

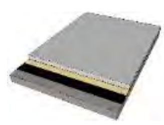
2.2 Strategies to reduce health risk

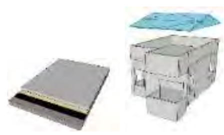
To determine potential townhouse reforms and improve indoor thermal comfort during extreme weather events, the aforementioned building was used as a prototype of a common townhouse in Taiwan with a balcony on one side of the building's long side. The studied room was on the top floor and on the west side to simulate the warmest situation. The parameters were the same as the predictive model, except that the HVAC was not set in this case study so that we could evaluate the true properties of the improvement projects.

As shown in Table 3, the six improvement projects mentioned in the study can be categorized into insulation (case 1-3), external shading devices (case 4-5), and vertical greening on the balcony (case 6). In order to decrease thermal heat transfer, improving insulation material is one kind of method to reduce indoor air temperature differences. Two methods common in Taiwan for improving roof insulation were studied, including installation of a metal canopy on top of the roof or an insulated layer of polyurethane and foam concrete.

We performed analytical simulations of two types of opaque external shading devices that were installed outside all of the windows in a dynamic regime, including external horizontal shading and an aluminium horizontal louver. The width of the horizontal shading was 0.5 m and the louver's slats vertical spacing and slats width maintain a unitary value of 0.085 m.

Case 0	Case 1	Case 2	Case 3
15 cm RC + Ruberoid	Case 0 + Metal canopy	Case 0 + Insulation layer	Case 0 + Metal canopy + Insulation layer
			






Case 4	Case 5	Case 6
Horizontal shading	Aluminium louvers	Vertical greenery
		
Slats width 0.50 m Slats thickness 0.05 m Slats length 1.40 m	Slats width 0.085m Slats thickness 0.008m Distance between slats 0.085m Distance slats-glass 0.090m Louver inclination 90˚	Discharge coefficient 0.48 Transmittance 0.144

Table 3: The studied cases.

In the EnergyPlus software, the vertical greenery system composite model was set up to simulate the activities of plants with two planes of shading and ventilation. We do not address the evapotranspiration effect in this study. Wild allamanda (Urechites lutea), a subtropical trailing plant, was used for the vertical greenery system located on the balcony. We conducted an experiment that included field measurements and properties experiment of plants. Transmittance was also measured to be used as a parameter in the simulation. With shading and ventilation effects in the simulation, the transmittance and discharge coefficient were set to 0.144 and 0.48, respectively.

2.3 Results and discussion

Figures 3 and 4 show the simulation results of temperatures lower than 18˚C and above 30˚C, respectively. We used the data of June 1–September 30 in the summer and November 1-February 28 in the winter to determine the effect of a building's adjusting strategies for reducing the accumulated hours that exceed the threshold. Regarding extreme heat, the effect of decreasing solar heat gain from windows (cases 4-6) was found to be much better than changes to the roof's insulation (cases 1-3) by at least 1.13%. Furthermore, the effect of installing a metal canopy is better at reducing the roof's temperature than changing the roof's insulation material due to the shading effect.

Compared to the horizontal external shading devices, an aluminium grille more effectively reduced the amount of solar heat gain from windows, indicating that a high temperature health risk can be reduced 0.31% more by an aluminium grille than by horizontal external shading devices. However, considering the lighting effect when the shading devices were used, an intensive aluminium grille may result in lighting problems. Therefore, with the effects of shading, evapotranspiration, and reduction of wind velocity, vertical greening on the balcony has the best results with regard to decreasing indoor air temperature by obstructing the majority of solar radiation at a low angle from the west, even if the accumulated risk hours in the summer are slightly worse than with the aluminium grille.

Furthermore, regarding extreme cold, our results demonstrated that installing a metal canopy (cases 1 & 3) can improve indoor temperatures in winter but also obstruct the solar heat gain (case 4-6), thus having the opposite effect.

The simulation results of vertical greening on the balcony are contradictory because they are the best in summer but worse in winter. The variability of the vertical greenery system, from which the plots can be removed in the winter, compared to the fixed external shading devices, is the project with the most potential to improve thermal comfort. Furthermore, therophyte, which has a life cycle of growing in the summer and withering in the winter, can be planted on the vertical greenery system to obstruct solar radiation in the summer and increase solar radiation transmittance in the winter.

3 CONCLUSIONS

In this study, we discussed the building's adaptability of thermal health risks in extreme weather events and proposed six strategies. According to the improvement projects' results, the fixed external shading device is not recommended to improve indoor thermal comfort in the winter. In contrast, installing a vertical greenery system on

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

the balcony, which can be removed in the winter, or planting some kind of therophyte is a better way to improve thermal comfort and reduce the health risk to susceptible populations.

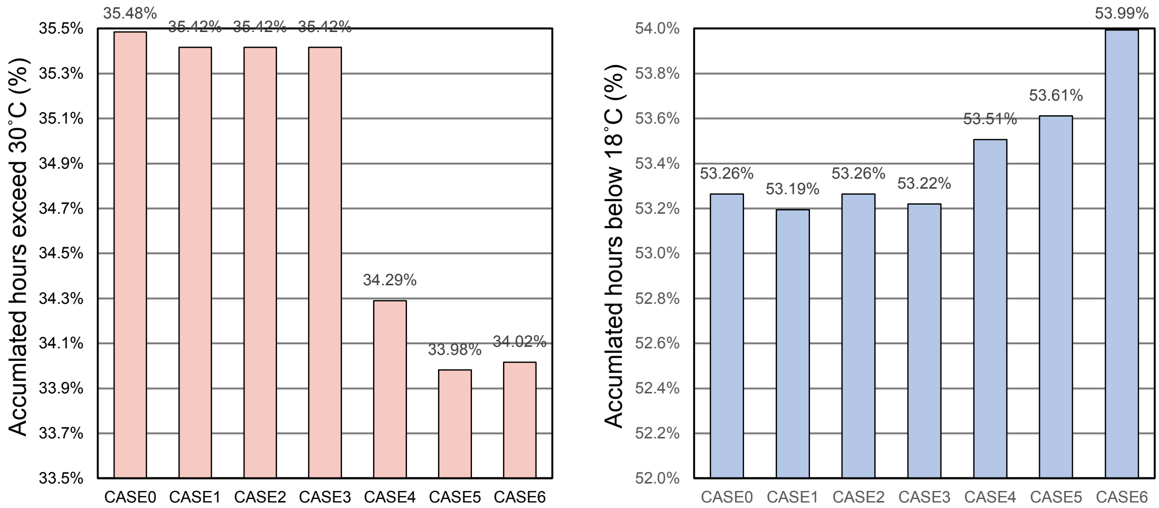


Figure 3: The simulation results of accumulated hours that are above 30˚c and below 18˚c

However, this study has some limitations. The attributable burden of risk to high and low indoor temperatures could not be quantified in this study due to the threshold of indoor air temperatures and the relative health risks not having been defined in Taiwan. Therefore, more research should be done to examine the relationships between various indoor temperatures and outpatient visits for temperature-related cardiovascular diseases and respiratory diseases.

Improvement Strategy of Urban Street Thermal Environment

WANG Wen-an[a]

[a] *Tamkang University, Taiwan, rumm0924@yahoo.com.tw*

ABSTRACT

Owing to the increase in building structures and road system, lack of sufficient green area in urban environment, imperviousness of ground surface and large amount of waste heat, a large heat retainer has been fabricated, which has resulted in the heat island effect. This research mainly focuses on the geographic feature of the urban buildings groups in its investigation of the outdoor thermal environment. This research used factors such as improving the reflectivity of the building materials, increasing the permeable rate of the paving material and planting arbours as shade trees as the design variables. Moreover, the research has employed the Computational Fluid Dynamics as the prediction and analysis tool to analyze the feasibility and efficiency in order to improve cooling through the design variables in the urban street canyons where there is only limited room for improvement. This research then proposes the guidelines which help in reducing the heat island effect based on the analysis results. Partly from the research results, the wind speed can improve the cooling effect of the variables. Compared with the preset reference temperature, it was observed that 5% discomfort zone can be improved through improving the reflectivity of the building materials, 13% through improving the permeable rate of the paving material and 40% through the shade from arbours, which is the maximum.

Keywords: micro-climate, temperature lowering, computational fluid dynamics

1. INTRODUCTION

Aggravating global warming problems have intensified extreme weathers, engendering an increase in the number and severity of natural disasters. The rapid growth in urban population also exerts a substantial impact on the environment, in which urban heat island effect is a primary factor influencing global warming. Excessive population density inevitably causes a considerable rise in the demand for living spaces, which leads to increased land use density, frequent construction of buildings and road systems, insufficient green land in urban areas, generation of impervious ground surfaces, and intense anthropogenic heat dissipation. Ultimately, these reactions form a massive heat-storing entity, thus creating a thermally uncomfortable street environment. Thermal environment in urban areas directly influence the quality of living and comfort level for humans. Therefore, improving the heat island effect in urban areas is a topic meriting immediate attention.

1.1 Research objectives and methods

Vegetation, green lands, and permeable pavements effectively absorb heat because of their large heat capacity. Furthermore, the evapotranspiration functions of these elements exert a cooling effect that facilitates regulating microclimates and stabilizing weather conditions (Sun et al., 2010; Lin et al., 2001). The present study was conducted to investigate the geographical characteristics of an outdoor thermal environment—building clusters in urban areas. By improving factors such as the reflectivity of outer walls of a building, permeability of ground pavements, and shades under plants and trees and using these factors as design variables, we analysed the effects of these design variables on cooling environment of urban spaces. Subsequently, computational fluid dynamics (CFD) was employed as a simulation tool to analyse the feasibility of using the design variables to reduce temperature for improving such limited space as urban street canyon. Finally, the analysis results were used as the basis for proposing plans to mitigate the heat island effect in urban environments.

1.2 Research scope

The research site of this study is a community in Neihu District in Taipei City. Prior to its renewal, the community was a five-storey apartment building. Following an urban renewal plan implemented by the government, the building was reconstructed into a dual 23-storey high-rise building. Because the building volume before and after reconstruction differed considerably (Figure 1), this study examined the effect of reconstruction on the thermal comfort in peripheral spaces.

Before: Five-storey old apartment building	After: High-rise building
	

Figure1: schematic diagram of research site

1.3 Data establishment and simulation setting

1.3.1. On-site measurements

Measurements were taken in pedestrian environments and areas around buildings (Figure 2) to collect information on wind speed, wind direction, temperature, humidity, and precipitation. Same numerical values were collected from different measuring points in areas around the buildings. The collected data were employed as the basis for verifying numerical simulations. The relationships among the collected data were evaluated to examine the effects of different pavement materials and plant types on the physical environment of a street.

Figure 2: Experimental measurement equipment configuration and meteorological station

1.3.2. Boundary condition setting

Taipei City is located near the 25th parallel north. Because it is on an island located between the East Asian continent and the Pacific Ocean, where the island is subjected to influence by the cold, dry Pacific high pressure and warm moist Mongolia interaction, Taipei City experiences subtropical monsoon climate, which is exposed to the effects of south-westerly airstream in summer. Therefore, we selected the summer season for our simulation, and configured the boundary conditions according to the highest insolation amount at noon. Table 1 presents the boundary parameters used in the simulation.

Summer Meteorological Parameters		
	Onsite Measurement	Bureau-Monitored Data
Temperature (℃)	35	27
Wind speed (m/s)	1.5	2.2
Humidity (%)	47	77.3
Direct insolation intensity /(W/m²)	-	617
Diffused insolation intensity/(W/m²)	-	175

Table 1: Meteorological parameters

1.3.3. Simulation of the current status of the research base

Urban heat island effect is strongly influenced by local climate factors, particularly temperature, cloud cover, and wind speed. The scope of this study comprised Tainan County and City, which are located in a subtropical zone where monsoons are prevalent. Therefore, Tainan is situated in monsoon climate zone. The meteorological factors closely related to urban heat island effect are described below.

Figure 3: Simulation analysis of the current situation and improve

Table 2: After the temperature distribution area and to improve the current situation

According to the simulation results, we analysed the effect of urban renewal (reconstructing a 5-storey building into a high-rise building) on the thermal environment of the surrounding area to investigate differences before and after improvements. Table 3 presents the simulation results of temperature distribution and area, which shows the effects of building volume after urban renewal on the surrounding environments. In particular, when measurements were taken at 1.5 m above the ground, areas measuring ≥36.0°C were reduced by 1.61%; areas measuring 33.0–35.0°C were reduced by 21.11% compared with the current condition; and areas measuring 31.0–33.0°C were reduced by 4.26%. By contrast, areas measuring ≤30.0°C increased by 27%. The simulation results revealed that the thermal comfort in relation to building volume after urban renewal improved. Although the areas measuring 33.0–35.0°C were reduced compared with the current condition.

2. NUMERICAL SIMULATION ANALYSIS

2.1 Formulation of improvement plans

In this study, simulation configuration involved three types of improvement plans (Figure 4). Plan 1 entails increasing the reflectivity of building material; Plan 2 involves improving the permeability of pavements; and Plan 3 was to increase the number of plants and trees. Subsequently, we examined the effectiveness of these three simulation plans on the heat island effect in the outdoor areas of the community building during summer.Tables 3 and 4 present the parameter settings.

2.2 Simulation analysis of outer building wall variable

In this simulation, we improved the reflectivity of the building material and pavement material to examine the difference in their effect before and after urban renewal. To configure the model, this analytical module was used as the setting for material reflectivity; therefore, the reflectivity coefficient was adjusted whereas the boundary condition settings remained unchanged. According to the simulation result of temperature distribution shown in Table 5, when measurements were taken 1.5 m above the ground, areas measuring ≥36.0°C increased by 0.41%; areas measuring 33.0–35.0°C increased by 3.43% compared with the current condition; and areas measuring 31.0–33.0°C increased by 23.28% compared with the current condition. By contrast, areas measuring ≤30.0°C were reduced by 6.46%. Moreover, regions where wind speed is low or leeward exhibited a rise in average temperature, whereas regions with wind speed of 1.5–2.5 m/s exhibited a reduced average temperature by approximately 1.0–2.0°C. Therefore, increasing material reflectivity is ineffective in areas with low wind speed, whereas such increase can effectively cool the temperature of regions with high wind speed.

	<30°C	31–33°C	33–35°C	>36°C

Simulation of Current Status	Increased Reflectivity

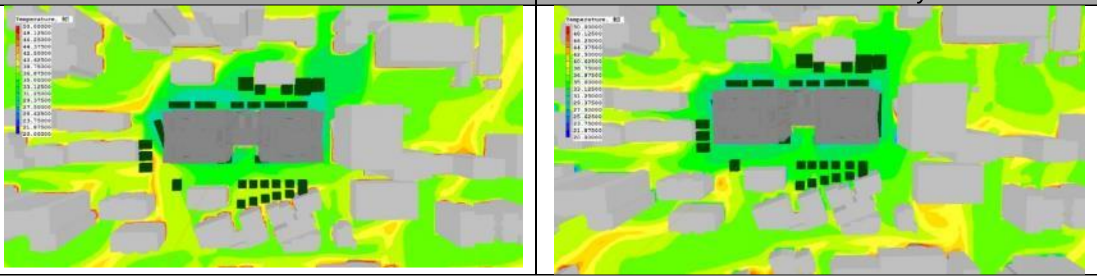

Figure 5: Simulation set up

2.3 Simulation analysis of permeable pavement variable

According to Table 6, which shows the temperature distribution results of a pavement material with improved permeability, areas measuring ≥36.0°C were reduced by 1.04% compared with the condition before improvement; areas measuring 33.0–35.0°C were also reduced by 4.13%; areas measuring 31.0–33.0°C increased by 3.96; and areas measuring ≤30.0°C increased by 1.72%. Increased ratios and decreased ratios were summed to calculate the overall cooling effect, and we determined that approximately 10.85% of the base area exhibited improved temperature-cooling effect. The average temperature in the region decreased by roughly 1.0–2.0°C. Figure 11 illustrates the pavement permeability simulation result, which indicates that the optimal cooling effect was observed in areas measuring 33.0–35.0°C after the permeability of pedestrian pavement in the research base was improved, and these areas registered wind speed of 1.5–2.5 m/s. By comparison, areas measuring ≤30.0°C demonstrated poor cooling effect compared with the current status because these areas are either leeward or lack concave-shaped building layouts to shield the area, causing poor cooling effect.

	<30°C	31–33°C	33–35°C	>36°C
After Renewal	914.17 m^2	457.25 m^2	411.06 m^2	78.52 m^2
Improved Pavement Permeability	946.2 m^2	531.08 m^2	334.12 m^2	59.11 m^2

Current Status	Reflectivity of 0.9	Temperature

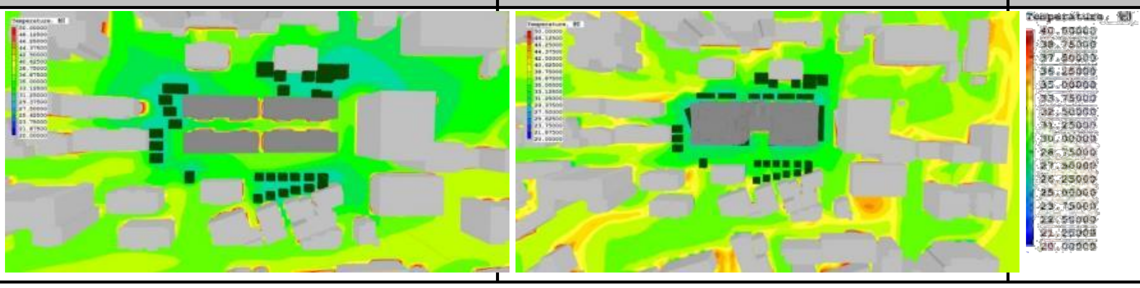

Figure 6: Simulation set up

2.4 Simulation analysis of plant variable

Wind field is a factor influencing environmental conditions. In addition to the cooling effects of plants, the influence of air flow on plant shading effect was also analysed. The simulation results shown in Table 7 indicate that when plant shading is used and wind speed is ranged at 0.5–1.5 m/s, areas measuring ≤30.0°C increased by 10.48% compared with the area distribution ratio of the current condition; areas measuring 31.0–33.0°C also increased by 7.23%; and areas measuring 33.0–35.0°C were reduced by 10.51% compared with the current condition in the same wind speed field; and areas measuring ≥36.0°C were also reduced by 2.36%. Increased ratios were used to calculate the overall cooling effect, and we determined that approximately 30.58% of the base area exhibited improved temperature-cooling effect.Therefore, compared with the aforementioned factors of permeability and reflectivity, planting presented better temperature-cooling effect.

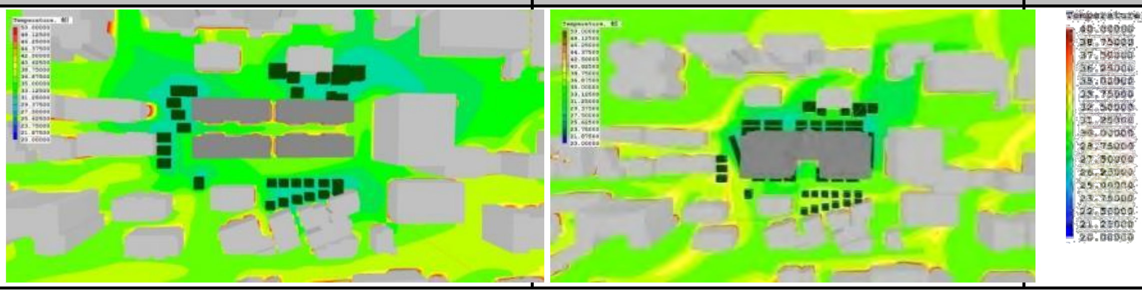

Figure 7: Simulation set up

3. CONCLUSION

This study obtained the following findings:

According to the experimental result, regions with wind speed of 1.5–2.5 m/s can reduce temperature by 0.5–1.0°C, whereas regions with wind speed of 0.5–1.5 m/s can reduce temperature by only 0.1–0.3°C. The temperature did not decrease substantially when wind speed is low or in regions with insufficient wind speed. In addition, regions where wind speed approximates 0 m/s exhibited slight increase in temperature.

According to the analysis result based on improved pavement permeability, the overall cooling effect manifested by the sum of increased ratios and decreased ratios showed that approximately 55.79% of the base area exhibited improved temperature-cooling effect. When the wind speed ranged between 1.5 and 2.5 m/s, optimal cooling effect of approximately 1.0–2.0°C on average was observed.

The overall cooling effect according to increased ratios showed that approximately 67.82% of the base area exhibited improved temperature-cooling effect. The optimal cooling effect of 3.0–4.0°C was observed; therefore, regions with a strong flow field such as shades under a tree exhibited optimal cooling effect. When air flow is insufficient, the shade still provided a cooling effect of 0.5–1.0°C. Therefore, compared with the aforementioned factors of permeability and reflectivity, planting presented better temperature-cooling effect.

ABSTRACT

This paper explored on the climate adaptive design of green rural houses in the south Shaanxi province through literature review, field investigation, analysis and summarization methods. Pattern language of architecture design which reflect climate adaptive features and regional architectural characteristics in existing local traditional rural houses were extracted and summarized. Influencing factors were analyzed, relevant design strategies and their tentative application in the researched region are proposed. Results of this work is expected to provide references for the green rural houses design in south Shaanxi province and other regions with similar climate features.

Keywords: green rural house, climate adaptive design, China

1 BACKGROUND

Observing that traditional rural houses mostly adapted very well to their regional natural environment and possess distinguished climate adaptive features, it is considered worthwhile to conduce exploration and studies on traditional rural houses in different regions. Base on this understanding, a preliminary exploration has been conducted targeting climate adaptive design of green rural houses and their contemporary application in the south Shaanxi province of China, which locates at the southern foot of Qinling mountain area.

2 CLIMATE ADAPTIVE LANGUAGE IN THE TRADITIONAL RURAL HOUSES

Taking traditional rural houses in Qiangning County Hanzhong City as the object of research and through practical observation and interview in Caochangba village and Jinjiaping village, with the analysis of a great number of documents, this paper conclude some architecture vocabulary which could reveal the climate adaptability and regional features of local traditional rural houses.

2.1 Plan and envelope system

Generally speaking, the traditional rural houses contain merely one floor with large height. Its planar formats are mainly linear or look like capital “L”. The main part of these houses include 3 or 4 bays, the width of each bays is about 4 to 6 meters and the depth is about 4 meters. The outer fence structure is 300-500mm rammed earth wall that possess excellent thermal storage ability and obvious heat preservation effect. As the rainfall is pretty large, the base is formed by stones and rocks, the middle part of the walls are rammed earth structure and the top of walls are applied Chuandou system with wooden structure. (Figure 1) In order to decrease heat loss in winter, the traditional windows in Ningqiang region are very small with 1, 5-meter width and 1.2-meter height. (Figure 2) The sills of the house are normally 1 to 1.2 meters high. The door of the house is generally 1.4 meters width and 2.3meters high and its threshold is about 0.2 meter. The window frame and doors are all made of wood.

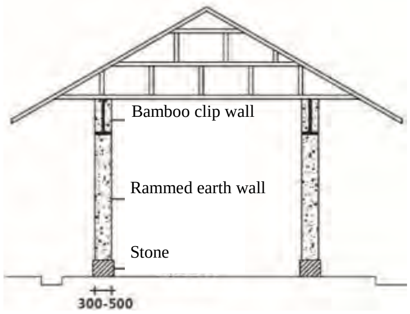

Figure 1: Wall structure

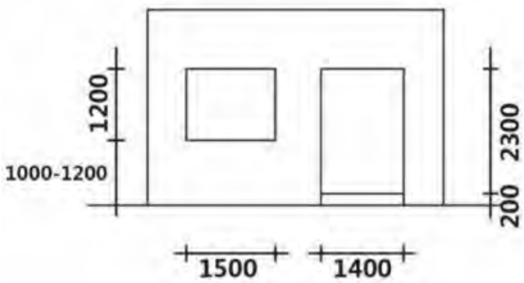

Figure 2: Window and door

2.2 Functional layout

The local traditional rural houses consist of yard, main architecture and attached rooms. The yard can be divided into five types, including backyard, front court, front yard, combined yard and courtyard. (Figure 3) Yard is mainly for sun drying, family activities and neighbor exchange. The main architecture is evolved from "one bright and two dark" building. The hall is at the center part of the entire house, located at north and facing south. The entire house is situated at the principal part of the symmetric axes of the building, which could link all rooms and is the center of family daily activities and guests' exchanges. The center of the space is hall, then the bedrooms are at left, right and back of the hall. Compared with hall, the space of bedrooms is smaller and connected with hall. Attached rooms contain kitchen, toilet, storage room and many other rooms which are for breeding and crop cultivating.

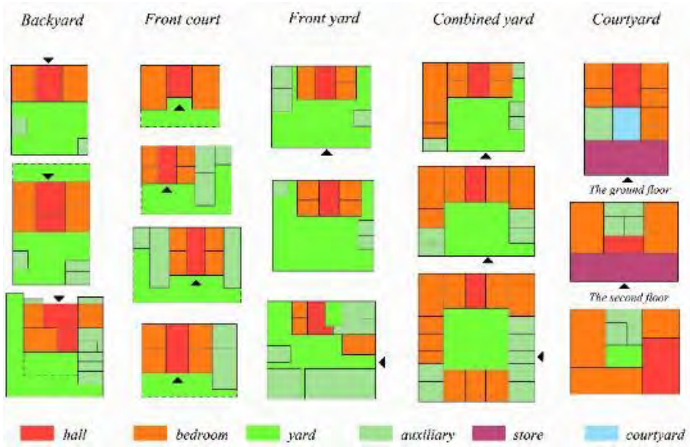

Figure3: Space layout

2.3 Eave

The summer in this region is sultry and eaves of houses spread a long distant from roof (nearly 2.5 meters), which could not only could shelter from sunshine and rain but also is a daily living place for chatting and dining. This eave is named cornice and it possesses a variety of types. (Figure 4) The forms and functions of the space beneath cornice vary. It could be an attic, Meirenkao for rest and observation or a platform for sun-drying or storage. (Figure 5)

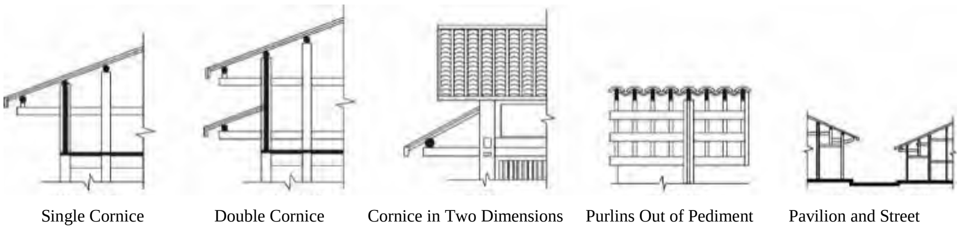

Figure 4: Types of cornice

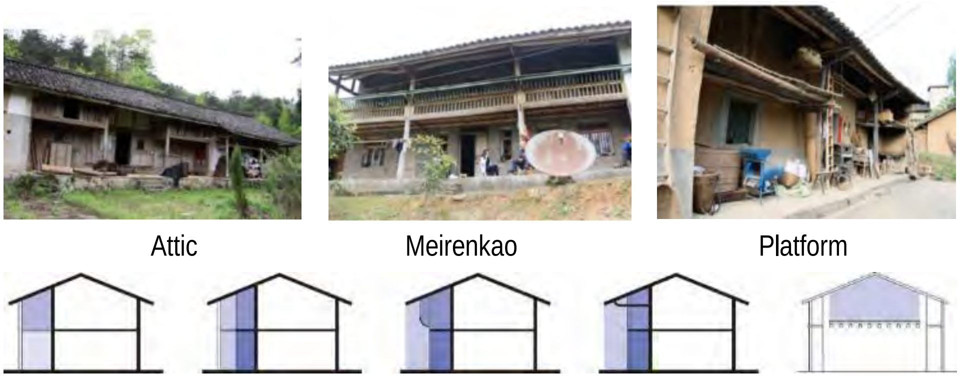

Figure 5: Space forms beneath cornice

2.4 Attic

Attic is a general type of architecture in traditional rural houses where we investigated. As the room for storage, it mainly connect beneath space with a ladder or fix stair. In addition, attic is also an air layer which could buffer thermal exchange between inside and outside air. With the opening on the top, the attic could keep warm in winter and reduce the temperature and humidity in summer. (Figure 6)

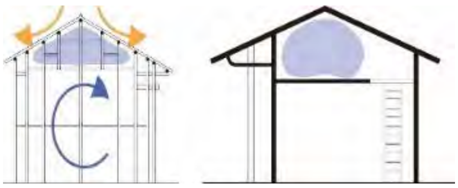

Figure 6: Attic

Figure 7: Opening

The opening on the top of attic are with different forms, such as “Swallow Grotto” and “the Cat Drilling”. “Swallow Grotto” is the opening on the wall and “the Cat Drilling” refers to a small opening on roof which is piled with tiles and the shape could merely pass a cat. (Figure 7)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.5 Entrance hall

A The entrance hall is also call “the room without walls” and refers to two big halls that connect with each other. Seeing from the Figure, the hall could nearly link up all rooms. It is comparatively small and without opening roof. In order to adapt to hot and sultry summer, the local entrance halls could be applied to ventilate rooms. (Figure 8)

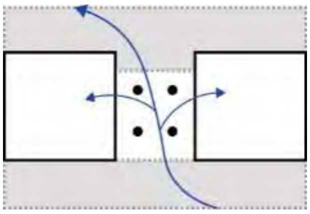

Figure 8: Entrance hall

2.6 Courtyard

The courtyard refers to an open narrow space which is surrounded by buildings. However, it is not very common in local region. Merely the old houses with three halls and five halls still contain courtyard. Generally, it is located at central part with two wings on the sides. Its width is the same as main room and its depth is equivalent to wings. The courtyard could change buildings with too big depth and could provide more sunshine demand and enhance ventilation function and heat dispersion and supply sharing space. (Figure 9)

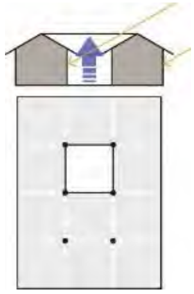

Figure 9: Courtyard

2.7 Huotang

Huotang is also called “Huokeng” 、 “Huopu” , which consist of Huotang scaffold 、fire stove 、base and wooden fence .Generally speaking, it is used for cooking, heating, lighting and sleeping on. At the same time, it also involved in many activities, including personal exchange, party, discussion and sacrificial activities. The investigation discovered that the majority of families are using Huotang and they even replace it with movable fire brazier. It possesses various forms and its location is flexible. Normally, it is located at lee of main hall, one side of living room or kitchen, even under eaves. It is applied to smoked meat, boiling, drying and cooking and in winter, it is an important heating producer.

3 THE FORMATION FEATURES OF MODERN NEW RURAL HOUSE

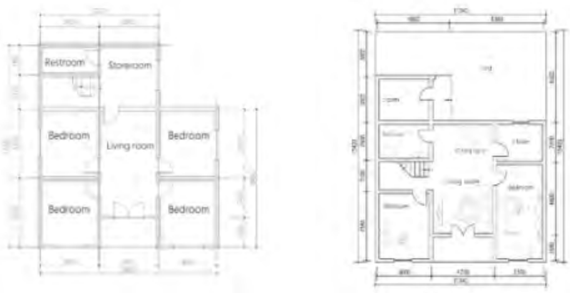

Figure 10: Modern rural houses plan

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The traditional rural houses possess excellent climate adaptability but there are few traditional rural houses at local area. The majority houses are commonly modern buildings. According to investigation, the new rural houses are normally brick-and-concrete composite building with one or two floors and planar or oblique roofs. One floor is about 3 to 3.3 meters and the second floor cold reach 2.8 to 3 meters with width 3 to 4. The width of main rooms is about 3.3 to 3.6 meters and its depth is about 4.5 to 5 meters. Its space structure is similar with traditional rural houses. The hall is located at the principal part of symmetric axes and connect with all rooms. Although the modern rural houses are improved in the aspects of layout and humidity reduction, it is hot in summer and cold in winter with less sunshine and storage space. The Figure3.1 above includes two plans of local rural houses. (Figure 10)

4 THE INTRODUCTION OF MODERN GREEN DESIGN STRATEGIES AND TECHNOLOGIES

Based on the extraction of local traditional architecture vocabularies, this paper analyzed that, according to local climate conditions, economic level and so on, the construction of sun room and rain collection these two types of modern green design strategies and technologies could be taken into consideration.

4.1 Attached sun room

Attached sun room is a kind of passive solar building, which consist of sun room, main room and warm protection walls. Compared with other methods, the attached sun room added heat-absorbing devices and it not only is a buffer between outside and inside but also reduced cold air infiltration and heat loss and extremely enhanced the comfort of rooms beside the sun room. Therefore, designer cold directly install a glass space on the main rooms toward south or corridor and the glass space is sun room. (Figure 11)

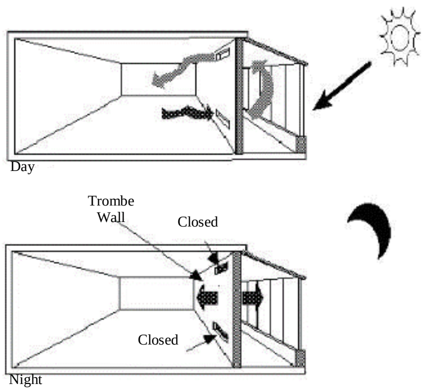

Figure 11: Working principle of attached sun room

4.2 Rain collection

Considering local realistic situation, the low technological rain collection system could be applied to this region, which include eave gutter, rain tank, rain pipe, filtering layer and water tank and without equipment devices, the cost of this system is low and its installation is convenient. There is a gutter above eaves .Through inside drainage system, the collected rain will be gathered to eave gutter, then rain funnel and rain pipe will conduct rain and water to the water tank on the second layer. There is a filtering layer inside water tank, which is formed by stone layer and sand layer. After filtration, a part of water will be transferred to storage tank on the ground. And the rest water can be used to flush toilet. (Figure 12)

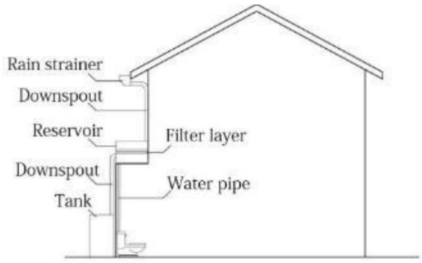

Figure 12: Rain collection system

5 REFERENCE PROJECT

Combined with background above, we could conduct the entire plan of green rural houses. The project covers 196.18 square meters and include three bedrooms and two halls, total two floors. The plane layout will be applied to modern rural houses. The living room is located at axis, connected with all rooms. Besides garage, the roofs are sloping and the eave nearly spread out 900 to 1800 mm, which could not only shelter summer sunshine but also can prevent the erosion of rain water, and the abundant space beneath the eave is also a type of benefit . The design could increase the space of storage room, garage and sunshine platform and garage could also be applied for storage. The rooms toward south and bedrooms will be attached with sun rooms and rain collection systems. The second floor will be installed a ladder toward attic. (Figure 13 to 15)

6 CONCLUSION

Based on bibliography and investigation on site, the climate adaptive language of traditional rural houses in Shanxi province has been extracted. The paper concluded the formation features of modern new rural houses. Combined with modern green design strategies and technologies, the paper proposed design advice and reference project of climate adaptive green rural houses in Shanxi province. As the limitation of time and ability, the paper has not fully discussed many contents about other perspectives and hope that the relevant results could be enhanced and perfected in the future research.

Socio-Environmental Framework for Integration of Lightweight Tensile Structure Windcatchers in Contemporary Hot-arid Urban Context of Tehran

Homeira MIRHOSSEINI[a], Shane Ida SMITH[b]

[a] *University of Arizona, United States of America, mirhosseinihomi@email.arizona.edu*
[b] *University of Arizona, United States of America, shaneida@u.arizona.edu*

ABSTRACT

A design framework for integrating windcatcher functions within the contemporary hot-arid urban Iranian context of Tehran responds to two major changes impacting their current utilization: 1) urban densification resulting in modified access to adequate airflows, and 2) sociocultural shifts towards dependencies on modern mechanical air-conditioning systems. Windcatchers are ubiquitous and integral to buildings throughout the hot-arid regions in the Middle East, and traditionally provide human comfort cooling functions through combinations of thermal mass, stack effect, and evaporation techniques. In historic context, the windcatcher is effective for passively moderating indoor temperatures by means of these natural ventilation cooling strategies. However, this passive technology is rarely used in recent decades due to emerging disadvantages such as maintenance difficulties, lack of urban air filtration methods, decline of cooling efficiency due to modified airflow patterns, habitable space utilization modifications, and the resulting dependencies on mechanical cooling systems.

Modular lightweight tensile structures are identified as a potential method for integrating windcatcher functions to reduce energy use and engage regional textile industry. The beneficial aspects of this design strategy emphasize adaptability through inhabitant control for localized modulation to airflow through potential integration in existing multi-story apartment buildings. In addition, the framework suggests advancements for environmental performance of lightweight textiles, such as particulate matter filtration, kinetic energy transformation, and photo-response for passive shading or natural daylighting strategies.

The specific objective presented in this study is to define the parameters required for improving natural ventilation cooling and inhabitant adaptability. Existing windcatcher dimensions, microclimate conditions, and urban morphology are identified to inform the Sangelaj neighborhood in Tehran to develop the heat transfer and airflow analysis theory alongside human interface metrics that will inform lightweight tensile structure designs. The comprehensive research project situates intersecting transformations between evolving urban fabric and sociocultural agency with environmental performance and local material industry.

Keywords: windcatcher, adaptable design, climate responsive architecture

1. INTRODUCTION

Windcatchers are utilized for natural ventilation of living spaces in buildings to provide passive cooling and achieve thermal comfort for many centuries and can be found in traditional Persian-influenced architecture throughout the Middle East in both hot-arid and hot-humid regions (Saadatian et al., 2012), (Elmualim, 2009), (Pearlmutter et al., 2008), (Hughes et al., 2012). Windcatchers play an effective role in moderating residential space temperatures for humans by means of natural ventilation (Mahmoudi, 2010), (Bahadori Nezhad and Dehghani, 2008). The windcatcher provides natural ventilation by taking advantage of stack effect, air buoyancy, thermal mass, cross ventilation, and evaporation techniques (Elmualim, 2009). While windcatchers are a passive cooling strategy that could widely benefit humans, they are rarely utilized in recent decades because of emerging drawbacks such as:

- High installation and maintenance costs (Hughes et al., 2012);
- Minimal ability to control of the volumetric flow rate to maintain a comfortable indoor climate (Hughes et al., 2012);
- Draughts through the tower may cause discomfort to occupants during the winter (Hughes et al., 2012);
- Small birds, insects and dust may enter the building (Hughes et al., 2012), (Dehghani et al., 2015);
- Lower wind speeds and higher temperatures due to the effects of the urban heat islands and increasing desertification due to climate change (Hughes et al., 2012);

- Enhanced noise and pollution in dense urban environments prohibits natural ventilation strategies (Hughes et al., 2012); and
- Increasing urban density resulting from population growth and immigration is limiting apartment building massing and floor plan layouts with access to adequate airflow (Hughes et al., 2012).

Increasing dependency on mechanical cooling systems is a result of modernization and these emerging disadvantages of windcatchers. However, the energy consumption for mechanical cooling systems in these climate zones is exceedingly high (Saadatian et al., 2012). Dependency on high-grade electricity for low-grade thermal comfort control is not sustainable for long-term environmental management. If some of the drawbacks of windcatchers can be addressed through contemporary integrative design techniques, then socially accepted practices for passive comfort cooling strategies in Iranian dwellings could be achieved.

Through a comparative analysis of existing vernacular windcatchers throughout Iran with the increasingly dense building typologies of contemporary Tehran, techniques for re-integration of original socio-cultural and comfort cooling functions of windcatchers are identified (Figure 1). We propose the integration of lightweight tensile structures with thermal mass components in the designs of new and existing multi-family apartment buildings to replace or assist mechanical ventilation systems in contemporary hot-arid, high-density urban contexts like Tehran.

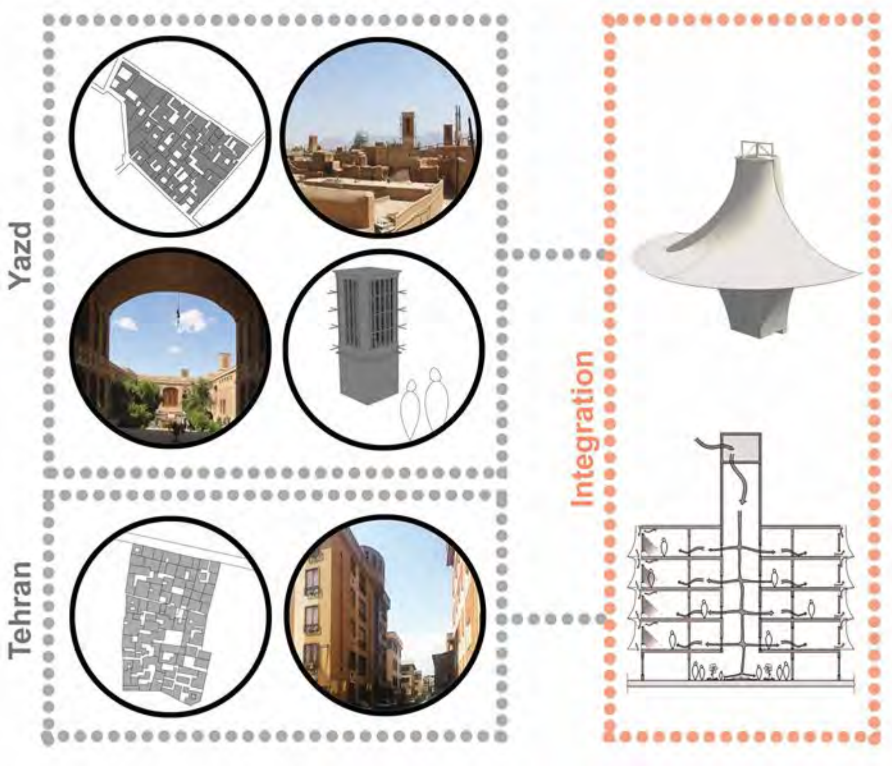

Figure 1: Framework diagram: Existing urban context and vernacular windcatchers of Yazd (upper left) compared with dense modern urban context of Tehran (bottom left) informing new strategies for integration of windcatcher concepts through tensile fabric techniques

2. BACKGROUND CONTEXT

2.1 Windcatcher characteristics

Windcatchers work on the principles of natural ventilation, employing both wind driven and stack effect ventilation (Moghaddam et al., 2011). The wind-induced forces will always be the main factor influencing natural ventilation (Hughes et al., 2012). In so doing, windcatchers need a driving force to operate where the first force is stack effect of air buoyancy, which occurs due to a difference in indoor-to-outdoor air density resulting from temperature differences. The stack effect is dominant through regions and periods with low wind speed or without prevailing wind (Koch et al., 2004) (Figure 2). The second force is external wind. Windcatchers are generally dependent on wind to operate; therefore, air velocity and volume of induced air circulation are important factors. Research

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

experiments indicate that windcatcher efficiency is altered by changes in outdoor air velocities, temperature differentials, wind angle orientation and number of openings (Saadatian et al., 2012), (Montazeri, 2011). Cross-section shapes of windcatchers (square, rectangle, hexagon, octagon, and circle) affect induced airflow rates and consequently their efficiency. A square shape windcatcher has the highest rate of induced airflow (Saadatian et al., 2012), (Pearlmutter et al., 2008), (Hughes et al., 2012) (Bahadori et al., 2014) (Figure 3).

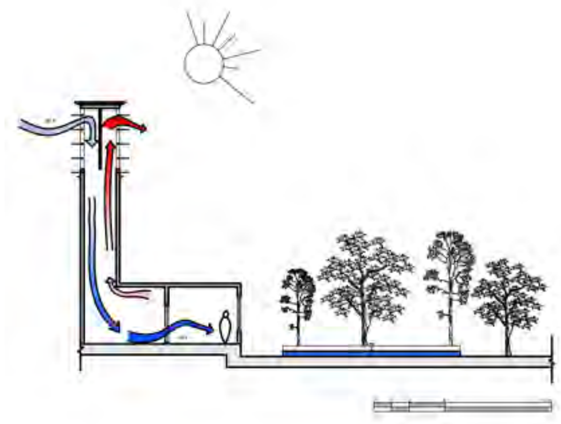

Figure 2: Typical vernacular windcatcher: Natural ventilation caused by stack effect

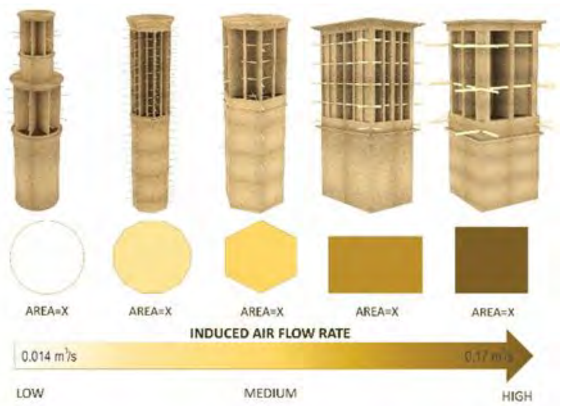

Figure 3: Effect of cross-section shape of windcatchers

2.2 Tensile structure characteristics

Tensile structures are light in weight because their structural stability results from pre-stressed shape rather than the mass of the materials used (Forster and Chilton, 2004), (Berger, 2005). Thus, despite being lighter than conventional building structures, they still offer high stability. The lightweight quality of tensile structures provides unique characteristics such as mobility, adaptability and convertibility. Tensile structures are the most convertible systems that are flexible in configuration and form for a variety of spatial arrangements in response to social and climatic variations (Forster and Chilton, 2004), (Schock, 1997).

The resistance of membranes to soiling is beneficial for their appearance and maintenance cost. Nanotechnology can provide high durability and self-cleaning chemistry for fabrics (Forster and Chilton, 2004), (Koch et al., 2004). One of the most important qualities of tensile structures is optional translucency to provide adequate daylight for inhabitants and reduce dependencies on electric lights. Also, when applied to the building roof, tensile fabric membranes provide radiant cooling effects (Forster and Chilton, 2004), (Scheuermann and Boxer, 1994) (Figure 4a).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

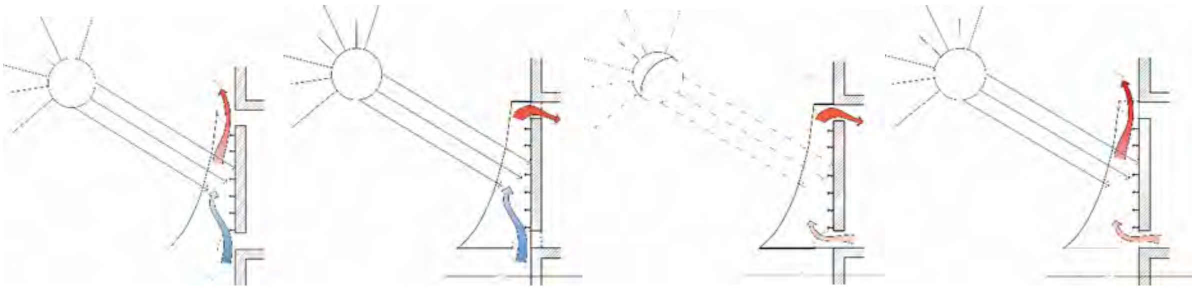

Figure 4: Lightweight tensile structures integrated with exterior building walls for convective functions: a) Heat removal; b) Preheating of fresh air; c) Reheating circulated air; d) Venting and flushing of exhaust air (Berger, 2005)

The effective shading capability of tensile structures due the membrane coating materials can reflect a high portion of solar radiation. Also, this shading capability provides a cooling effect, which then can be promoted by using natural ventilation, thermal mass and driven airflows inside or underneath the tensile structure. The variations in solar radiation during daytime and also radiation heat losses to the clear sky at night make the surface temperature of the membrane swing rapidly. The exposure of membrane skin to unequal solar radiation and sky temperature provides a vertical temperature satisfaction. The membrane surface temperature can swing rapidly because of variations in solar radiation during daytime as well as radiation heat losses to the clear sky at night. Vertical temperature stratification is derived from exposing the membrane to unequal solar radiation and sky temperature. (Forster and Chilton, 2004) (Figure 4a, 4b).

3. METHODS

The adaptive integration of thermal mass windcatcher functions through lightweight tensile structures in the contemporary hot-arid urban context of Tehran requires identification of specific parameters addressing natural ventilation cooling and inhabitant adaptability. The existing urban morphology and correlated airflow patterns (velocities and directions based on microclimate conditions) of the Sangelaj neighborhood in Tehran are documented in order to identify information on air speed potentials for windcatcher effectiveness. Existing building typologies are identified as multi-story apartments with double-loaded corridor configurations. Because of limitations of open space surrounding existing buildings in this context, integration of traditional thermal mass windcatcher forms as additions to these buildings is not possible. Therefore, concepts for achieving windcatcher thermodynamics through lightweight structures is addressed a mode of transforming the mechanical cooling functions towards passive mechanisms.

Multiple tools are used in the design development and performance analysis process. First, initial climate analysis is conducted with Ladybug plug-in for Grasshopper-Rhino. Second, Computational Fluid Dynamic (CFD) visualizations for wind velocity, pressure, and vectors are conducted through the OpenFoam platform for the existing urban context to determine realistic airflow patterns influencing potential windcatcher ventilation cooling techniques. Third, the design analysis tool for tensile structure morphology is implemented to develop viable fabric forms in response to documented wind pressures.

Physical models of the proposed tensile windcatcher forms are being developed for empirical analysis in a wind tunnel laboratory. These results will aid in corroboration of digital simulation techniques. Implementation of wind tunnel experiments by experimenting different types of physical models from vernacular thermal mass models to modern tensile structures and gathering information about the adaptation of these two to find the best possible adapted model of traditional windcatchers and tensile structures. Steps can be first, making a model of vernacular windcatcher using a material that behaves like thermal mass in order to measure the wind velocity and volume for inlet and outlet. Second, making a simple tensile model in order to test the behavior of tensile structures in the wind tunnel and to measure the identified parameters for inlet and outlet. Finally, making a simple adapted model of tensile structure integrated with thermal mass in order to compare measures of the wind velocity and volume of the new model with both the basic traditional thermal mass model and the basic tensile structure model. Development of the adaptive physical model will be based on some effective characteristics like height, form and location to find the efficient Integration.

4. ADAPTATION

The proposed adaptation is based on a typical existing apartment building in Sangelaj neighborhood in Tehran (Fig. 5a). A cool tower is introduced as a source of fresh air within the central core of the building. Hydro-equipped units are located at the top of the cool tower to provide cool air from evaporation water in a closed loop and gravity flow (Chalfoun, 1991). Hence, fresh cool air sinks through the tower and then enters the openings of each floor in order to provide required natural ventilation into the dwelling units. The exterior windows are replaced with Phase Change Material (PCM) glazing systems to provide thermal mass. PCMs are ideal products for thermal management solutions and they can be translucent (Simen and Jelle, 2015). Hence, by applying translucent fabric for tensile structures and translucent PCM windows for thermal mass within the windcatchers, diffuse natural daylight for each floor in multi-story buildings can be provided. This adaptation works seasonally:

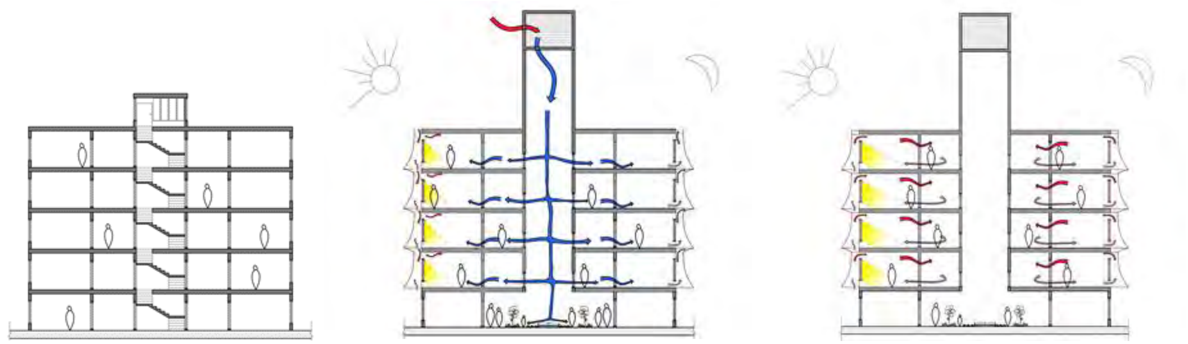

Figure 5: Integration of lightweight tensile structures to existing multi-story apartment buildings for windcatcher functions: a) Section of an existing building in Sangelaj neighborhood in Tehran (left); b) Function of thermal mass integrated tensile structures by using cool tower and adapting with section of existing apartment in Tehran in summer (center); c) Function of thermal mass integrated tensile structures by using cool tower and adapting with section of existing apartment in Tehran in winter (right)

Summer-Day: During day, sun heats up the thin fabric layer of tensile structures. Airflow absorbs heat from the fabric and rises through stack effect while aiding exhaust of warm air from inside the building (Figure 6a). This circulating air movement inside of the building cycles a replacement of the exhaust air with fresh air from the cool tower (Figure 6a). Also, the thermal mass absorbs the heat from the sunlight, which could be useful in the night as it re-radiates to warm the interior spaces (Figure 5b, 6a).

Summer-Night: During night, thermal mass releases back the stored heat to outside because of temperature differences between outside and inside of the building. Cool air from outside enters into the fabric area and absorbs the heat released from thermal mass and rises through stack effect while aiding exhaust of warm air from inside the building (Figure 6b). By this way, not only warm air of inside the building is exhausted, but also fresh cool air from the cool tower is pulled through the interiors of the building in order to replace the warm exhaust air (Figure 5b, 6b).

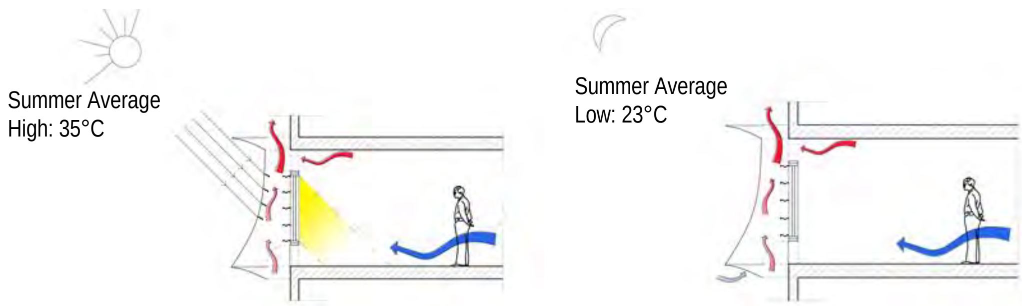

Figure 6: a) Adaptive wind-catcher concept for the summer day; b) Adaptive wind-catcher concept for the summer night

Winter day: Cold air coming from the bottom opening becomes warm as a result of contacting the heated fabric by sunlight and rise. Airflow after absorbing heat from fabric rises due to stack effect and captures warm air inside the building from the opening on top (Figure 7a). The warm air will flow inside and heat the interior spaces of the building. Also, the thermal mass absorbs heat from the sunlight, which is beneficial for re-radiating into the building at night (Figure 7a, 5c).

Winter Night: During the night, all external vent openings will remain closed. The thermal mass will release the absorbed heat back to the interior. The airflow coming from inside the building absorbs heat from the thermal mass and becomes warm (Figure 7b). The warm air rises to circulate back into the building again and completes the loop (Figure. 7b, 5c).

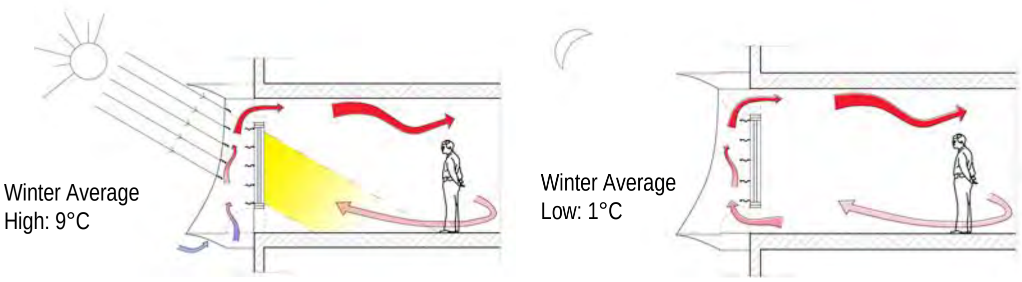

Figure 7: a) Adaptive wind-catcher concept for the winter day; b) Adaptive wind-catcher concept for the winter night.

Figure 8: The proposed adaptive wind-catcher concept in the existing urban context of Tehran

5. CONCLUSIONS and FUTURE WORK

This research establishes the framework for adaptation of traditional thermal mass windcatcher functions into contemporary dense urban contexts to maximize their passive cooling advantages and take measures towards solving its disadvantages. In so doing, the tensile structure is identified as an adaptive membrane that can potentially accommodate variant airflow patterns and thermal regulation for inhabitants' social needs through energy efficient means. Additionally, due to the increasing density of cities during recent centuries, the research considers the exterior integration of lightweight tensile structure windcatchers in multi-story buildings. The façade adaptation considers natural ventilation by stack effect and Bernoulli principle in the design of the lightweight tensile windcatchers in conjunction with other characteristics of the fabric and PCM glazing to assist natural daylighting to the building interiors. The work is being progressed through the physical modelling and CFD simulation analyses (Figure 9a, 9b).

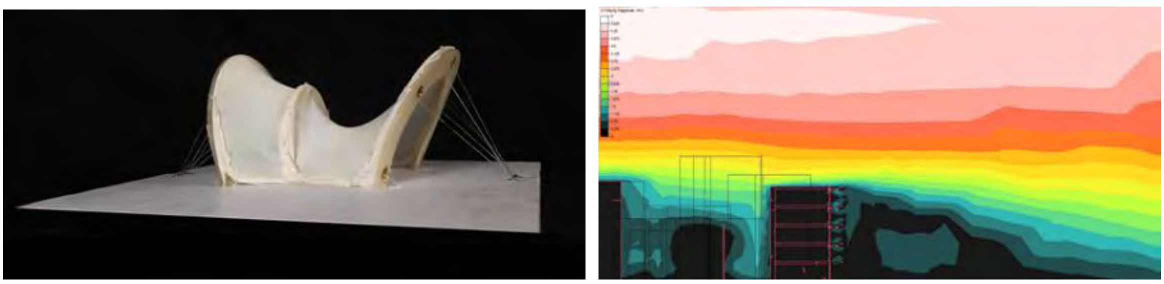

Figure 9. a) Photograph of physical model of one module; b) Image of CFD simulation (wind velocity) in urban context of the neighbourhood

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The next step in this research would be to find a relation between height, inlet, and outlet of vernacular windcatchers to be optimum, to work on form and aerodynamic of windcatchers based on airflow patterns, and to scale up for initial physical prototype construction and testing when simulation validations are complete. Additional research is also being conducted on the Iranian textile industry to consider how to adapt cultural heritage weaving techniques into modernized fabrication processes for the lightweight fabrics. Further work is also required with inhabitant interface and social interactions with the adaptive tensile windcatchers.

ABSTRACT

Organisations are increasingly expected by shareholders and the community at large to demonstrate corporate social responsibility in consideration of the environment, employees and the community. Leading organisations are demonstrating that corporate social responsibility starts at 'home', using their workplaces as practical exemplars of their commitment. This study investigated the key performance areas and priorities of a major international banking organisation in developing and incorporating sustainability criteria into the design and decision-making processes that govern the commercial workplace fit-outs. The sustainability guidelines established the performance indicators and benchmarks for the workplace environments consistent with the organisation's expectation for quality, value and sustainability for the accommodation and office environments.

A key issue in achieving sustainability in office fit-outs is to be informed of the options and their potential impacts and being able to make design decisions that will maintain the integrity of the design but have the smallest ecological footprint. The theoretical framework of life cycle thinking (LCT) is a vital part in understanding sustainability. The selection of the standards and criteria which form this guide drew on this principle and aims to promote holistic decision-making during the fit-out design process and implementation. The Sustainability Guidelines is based on the environmental principles, effective practices and concepts featured in the rating systems Green Star and NABERS (Australia), LEED (US), BREEAM (UK) and BCA Green Mark (Singapore). The guideline is applied to the fit-out of commercial workplace projects, including new facilities and changes to existing facilities. It provides a framework of considerations for reducing environmental impacts and contains information on opportunities and strategies to illustrate achievement of key performance benchmarks. It identified the mandatory minimum standards and facilitates the material specification for sustainable fit-out design and on-going ecologically sustainable development (ESD) solutions and initiatives outcomes for the bank's commercial workplace fit-outs.

Keywords: corporate social responsibility, sustainability guidelines, workplace fit-out

1. INTRODUCTION

Expectations on organisations to exercise social responsibility in their corporate performance have led to most to consider their commitment to the environment, employees and the community as a crucial aspect in gaining competitive advantage. These companies are increasingly operating in rapidly changing and more challenging global operations, where the shifting landscapes combined with significant changes in populations and demographics, urbanisation, resource utilisation, climate change, and employee and consumer attitudes have become the impetus to review corporate governance, social and environmental performance.

Leading organisations are demonstrating that corporate social responsibility starts at 'home', using their workplaces as practical exemplars of their commitment. This study investigated the key performance areas and priorities of a major international banking organisation in developing and incorporating sustainability criteria into the design and decision-making processes that govern the commercial workplace fit-outs. The sustainability guidelines established the performance indicators and benchmarks for the workplace environments consistent with the organisation's expectation for quality, value and sustainability for the accommodation and office environments. This paper reports on the process undertaken to formulate the bespoke sustainability guidelines for the office fit-out.

2. DEFINING SUSTAINABILITY IN ACCORDANCE WITH THE ORGANISATION'S ASPIRATIONS AND PRIORITIES

Setting common standards for sustainability initiatives for an organisation with an extensive and diverse property portfolio across different global regions poses a unique challenge. Multiple factors can render readily available prescriptive standards impractical or irrelevant due to project-specific constraints and opportunities. This study was guided by the main objective to develop and incorporate sustainability criteria into the design and decision making processes that govern commercial fit-outs across the operations of the organisation. It was highlighted that the criteria need to address the organisation's vision of environmental sustainability and must be interpreted by a global audience of operational units. The standards will leverage existing guidance available through best practice guidelines and relevant rating systems. Standards will adopt a form that is sufficiently detailed to guide the development of detailed, project specific, specifications, however retaining sufficient flexibility to enable deployment globally.

From the outset, the formulation of the guidelines reflected the fact that the banking organisation commitment to the four pillars of sustainability, namely economy in general, the industry, society and the environment. Sustainability understanding in the financial services industry was the underpinning guiding principle for the study. All organisations in this services industry sector will have some issues surrounding these sustainability pillars relative to each other. The approach taken for this study was not designed to be comprehensive nor prescriptive in judging was is good, good enough or bad practice. It was based on a consistent approach of analysing objective and quantitative measures which can be adjusted by the organisation as appropriate for incorporation.

Sustainability has been defined contextually in numerous ways. The popular and often quoted definition is from the 1987 Report of the World Commission on Environment and Development, "Our Common Future" [Brundtland Report]. Simply put, this defines sustainability as referring to human society being capable of continuing indefinitely. The development that will move society in that direction is sustainable development. However, the concept of sustainability become relevant only when the un-sustainability inherent in the current activities of society is understood. "Sustainability is a term that arises in response to a potential environmental and human disaster … and cannot be separated from that other great concept …globalisation".

Predominant models of sustainability include the 'triple bottom line" (TBL), coined by Elkington in which the environmental, social and financial outcomes are taken into account (Figure 1).

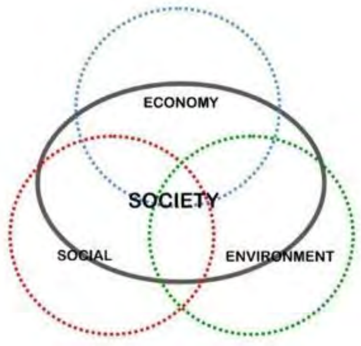

Figure 1: Triple bottom line framework for sustainability

Miller et al further contend that building sustainability knowledge requires a fundamentally different approach to the ways organisations coordinate capacity building and research and how it relate to society.

2.1 Sustainability knowledge as the guiding principle: Overarching sustainability principles

In the development of the set of generic environmental sustainability requirements relating to office fit-out which reflect the organisation's corporate sustainability vision, the research team, in collaboration with the bank's heads

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

of Sustainability and Property Advisory Services, drew on the bank's corporate responsibility framework and priorities (CRF). The organisation is committed to reducing the impact of its business activities and operations on the environment. The CRF guides and underpins this commitment to improve environmental performance which is integral to the bank making a sustainable contribution to society (Figure 2).

The bank has demonstrated this commitment by achieving a carbon neutral footprint across its portfolio globally. In its commitment to invest in the management of environmentally, socially and commercially sustainable banking operations, it has established targets for greenhouse gas (GHG) emissions, energy use, water use, paper use and waste to landfill to assist in the management of its environmental performance.

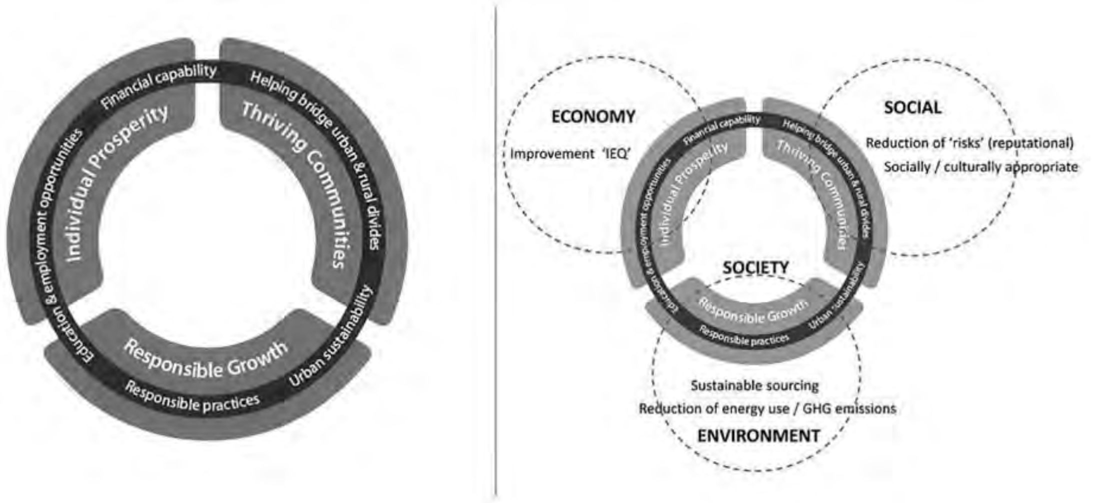

Figure 2: Translation of the corporate responsibility framework (CRF)

3. APPLICATION OF SUSTAINABILITY PRIORITIES: FRAMEWORK FOR THE SUSTAINABILITY GUIDELINES

The outcome of the study is a document that provides general standards for achieving sustainability outcomes in the bank's new commercial office fit-outs. The guidelines were presented within a framework that provided explanation and rationale. The objectives and scope for formulating the document allow its suitability for deployment as part of a generic design brief provided to fit-out designers and will be sufficient to enable detailed project specifications to be developed.

A key issue in achieving sustainability in office fit-outs is to be informed of the options and their potential impacts and being able to make design decisions that will maintain the integrity of the design but have the smallest ecological footprint. The theoretical framework of life cycle thinking (LCT) is a vital part in understanding sustainability. The selection of the standards which form this guide drew on this principle and aims to promote holistic decision-making during the fit-out design process and implementation.

3.1 Reference to green building rating systems

The standards outlined in guidelines define the attributes of a sustainable commercial workplace fit-out and provide definitive criteria for evaluation of its performance from a 'tenanted space' perspective. The Sustainability Guide is based on the environmental principles, effective practices and concepts featured in the rating systems Green Star and NABERS (Australia), LEED (US), BREEAM (UK) and BCA Green Mark (Singapore). It was recommended that these ratings systems as well as the locally appropriate assessment tools be referenced in relation to the performance goals and technical strategies contained in the guide.

3.2 Key performance areas and priorities

In close consultation with the bank, particularly the sustainability and corporate social responsibility teams, key principles from the five (5) reference green building rating systems were identified and formed as the standards to align with the four (4) overarching key performance areas and priorities of the bank (Figure 3): climate change and resource use (CRU), well-being and health (WH), socially and culturally appropriate (SC), and reduction of risks (RR).

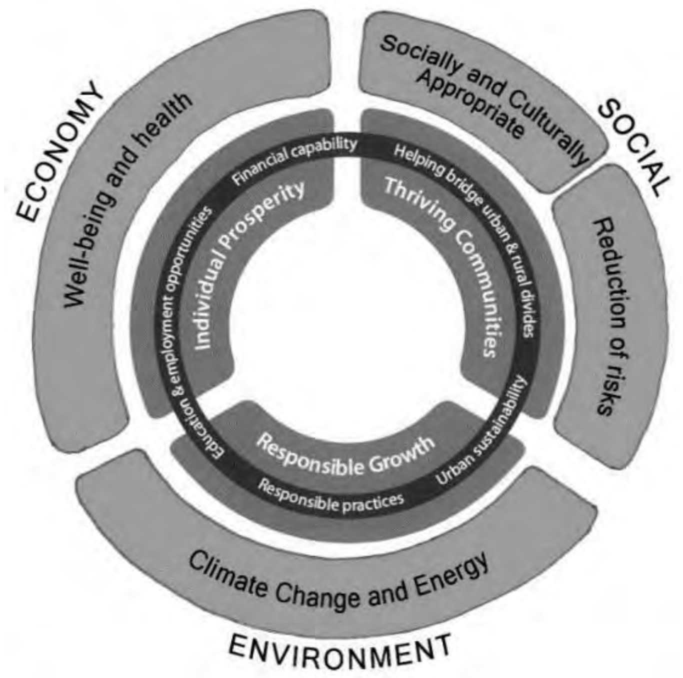

Figure 3: Application of sustainability priorities

Climate change and resource use (CRU)

- Energy management: Achieve benchmarks and performance targets in energy efficiency and minimising loads on energy supply infrastructure.
- Reduction in GHG emissions: Achieve performance targets in absolute emissions reductions.
- Water conservation: Achieve benchmarks and targets in water use reduction.

Well-being and health (WH)

- Indoor environmental quality (IEQ): Improve indoor environmental quality (IEQ) and achieve healthy internal building environments.

Socially and culturally appropriate (SC)

- Waste minimisation and Avoidance: Reduce waste generated by building occupants that is collected, hauled to and disposed of in landfills; material re-use.

Reduction of risks (RR)

- Materials: Minimise the environmental impacts materials used in the fit-out and works.
- Responsible sourcing: Supporting regional economies and reducing environmental impacts resulting from transportation and servicing.
- Management of risks and compliance issues: Minimising operation costs, potential compliance issues and reputation through recognition and management of risks related to the fit-out process and its implications for ongoing business performance.

3.3 Structure, interpretation and use of the guidelines

The Guidelines apply to the fit-out of office accommodation occupied by organisation, in Australia and its global operations. All up, 15 standards were identified and these provide a framework of considerations for reducing environmental impacts and contain information on strategies and opportunities relating to key performance benchmarks (Table 1).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Climate and Resource Use (CRU)		
	CRU 1-1	*Lighting power density*
	CRU 1-2	*Lighting zones and controls*
	CRU 1-3	*Energy efficiency (equipment and appliances)*
	CRU 1-4	*Energy monitoring (energy sub-metering)*
	CRU 1-5	*Water efficiency (fittings)*
Well-being and Heath (WH)		
	WH 2-1	*Visual comfort*
	WH 2-2	*Indoor air quality – low-emitting materials*
	WH 2-3	*Thermal comfort*
	WH 2-4	*External view and daylight*
	WH 2-5	*Internal noise levels*
	WH 2-6	*Water quality*
Socially / Culturally Appropriate (SC)		
	SC 3-1	*Reduction of waste*
Reduction of risks (RR)		
	RR 4-1	*Responsible sourcing*
	RR 4-2	*Regional materials*
	RR 4-3	*PVC Use*

Table 13: Structure of standards

The purpose of the guide is to direct and complement the structured fit-out planning, design and construction process provided by design professionals. It facilitates the material specification for sustainable fit-out design and on-going ecologically sustainable development (ESD) solutions and initiatives outcomes. Each of the standards follows a common format which outlines the Intent – a summary statement of the key performance principles or practices, the performance Target which indicates the requirements, the rationale and benchmark for the standard, and a range of Potential Technologies and Strategies to be used in achieving the requirements. A number of the standards also contain opportunities Beyond Compliance which outlines the potential performance targets beyond the mandatory requirements. Information on Reference Protocols with achievable scores as required by the selected building rating tools is provided for each of the standards.

As an illustration, the standards CRU 1-1: Lighting power density and CRU 1-2: Lighting zones and control are as follows:

Sustainability standard	**Target**	**Beyond compliance**
CRU 1-1: Lighting power density		
[a] Efficient light fitting, electronic ballasts [b] Low standby power not greater than 0.001 watts per watt of lighting power [c] Fixture uniformity – maintain uniform lumen levels through group relamping	9 W/m² LPD	7 W/m² LPD
CRU 1-2: Lighting zoning and controls		
[a] Maximum lighting zones [b] Individual lighting controls [c] Occupancy sensors [d] Daylight controls for daylit areas [e] Daylight controls for 50% of the lighting load	to be 100m² for 90% (min) of office space 75% (min) of the connected lighting load.	

4. REFLECTING SUSTAINABILITY REQUIREMENTS: SUSTAINABILITY GUIDELINES FOR COMMERCIAL WORKPLACE FIT-OUTS

The guide applies to the fit-out of all the bank's commercial workplace projects, including new facilities and changes to existing facilities. It provides a framework of considerations for reducing environmental impacts and contains information on opportunities and strategies to illustrate achievement of key performance benchmarks. The purpose of the guide was to direct and complement the structured fit-out planning, design and construction process of organisation's Workplace Environment provided by design professionals. Crucial and key to the formulation of the guidelines was the close collaboration with the bank's sustainability team, property services, environmental and services project design. Prior to finalisation, training workshop session and sign-off, the draft document was circulated to key personnel interstate and overseas groups for review and comments. Complimentary feedback received from the bank's sustainability team generally referred to the guide meeting the needs of the organisation in being comprehensive yet concise and easily able to be used by both staff and external contractors and consultants.

The office fit-out contributes significantly to efficiency and operational effectiveness. For example, an energy-efficient office fit-out design offers the possibility of significantly increased worker productivity. Healthier working environments include favourable lighting, acceptable acoustic levels, indoor air quality and indoor thermal comfort are affected by many energy-efficiency measures. An increasing number of case studies reported that healthy indoor environments can increase employee productivity. Because office workers are by far the largest expense for most organisations (typically for offices, salaries are 72 times higher than energy costs and account for 92% of the life cycle cost of a building), therefore increased employee productivity has a significant effect on overall profitability. An audit of the organisation's offices, on average, salaries are approximately 45 times higher than energy costs.

Office fit-outs designed for energy-efficient performance have very attractive economic returns. A case in point is an efficient lighting design and well-managed lighting system which can contribute to significant improvements in energy efficiency in office tenancies. Although it varies from office to office, as an example, lighting can typically account for 30% of a commercial office tenancy's power consumption. Case studies indicated that, depending on the installation and usage patterns, energy savings on lighting in the range of 20-70% can be achieved in a typical office with a 3 to 5 year-payback of investment.

ABSTRACT

Abuja F.C.T. is the Federal Capital Territory of Nigeria; with a population growth rate of about 25% - 45% annually and is projected to reach 10million by 2018. This has led to housing shortages and the need for many housing schemes. Many Residential housing developments do not reflect the desired housing needs of the end-users in terms of satisfaction and sustainability, despite a growing interest in green buildings among the various stake holders. Previous research efforts showed that the results are still uncertain and conflicting. Nonetheless, such studies have exposed the main variables especially the human factors affecting green building projects such as different success criteria, divergent success factors and lack of common or shared perspectives among the stake holders. Incorporating green building features are at the developer's disposal but should align with the potential end-users preferences as it affects the rentals and sales values of such developments. The aim of this paper is to explore the potentialities of using or adopting the End-users' preferences in green building features in estate development projects in Abuja, with a view of adopting green building features that satisfies the interest of both the developers and the end-users thereby promoting green building projects. Review of literatures helps identify and narrow the residential end-users satisfaction in various housing estates and their preferred green features. A 5-point Likert scale questionnaire survey was conducted on Estate Development Firms in Abuja; selected through random sampling method. The results showed that green building features such as: Energy Efficiency systems, Building Envelope, Water efficiency systems, Indoor Environmental Quality and Day-lighting systems were the features favoured by the End-users as they are also adoptable, affordable by the developers. Conclusively, they have the potential of providing a common ground to these stakeholders in adopting green features in residential housing developments in Abuja.

Keywords: end-users, estate developments, green building management, housing, stake holders, potentialities

1. INTRODUCTION

Abuja Federal Capital Territory (FCT) is the Capital of Nigeria the most populous African country located in western Africa; geographically located at the centre of Nigeria. Abuja under Köppen climate classification features a tropical wet and dry climate with three weather conditions namely; warm, humid rainy season and a blistering dry season; with a brief interlude of harmattan in between the two (WECSI 2014, demographia.com; Wikipedia.org and Dalibi et al., 2016). A good observation makes Abuja the largest construction site in Nigeria. It is considered among the fastest growing cities in the world, with a present population of about 4million; projected to reach 10million by 2018-20 (Muhammad 2013; Sundaram, 2012; demographia.com; Wikipedia.org). This explosive growth rate has created severe housing problems due to high demand resulting in problems such as overcrowding, inadequate electricity (power) and water supply, other degrading public infra

structure, deplorable urban environment especially the Built environment etc. Despite being a pre-planned city, Abuja is also affected by spontaneous and uncontrolled urbanization like any other city in a developing country and has led to growth of suburban city-like districts and springing up of many satellite towns around the city (Dalibi et al., 2016).

These housing conditions have continued to evoke considerable concern due to its effects on the built environment and also, the need for modern infrastructure that will serve the needs of the present and the future. This goes a long way in affirming the increase in global population growth accompanied by massive resource consumption and its negative impacts on the environment (Dalibi et al., 2016). The combination of these challenges gave birth to a

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

new concept in design, construction/ renovation, operation and maintenance of buildings in conformity with sustainable practices known as Green Buildings (Dalibi, 2014).

The relocation of various headquarters of Major corporations, banks, companies and businesses further compounded the housing challenges for the end-users with the need for high taste and or high-end housing Estate developments in Abuja FCT; specifically houses with features that add to user comfort ability and save running costs etc. such feature are common in green building projects.

1.1 Research problem

The problems of housing supply in meeting the ever increasing housing demand remains one of the most pressing problems facing Nigerian urban centres (Israel and Basiru, 2008).Although residential quality studies have gained increasing attention in recent times, the majority of such studies was foreign and focused mainly on factors affecting the quality and performance of construction, particularly in public or social housing programs within specific housing environment (Shinnick,1997; Djebarni and Al-Abed,1998, Saari and Tanskanen,2011). A few studies conducted locally have focused on the perception of residential quality in selected neighbour hoods (Ebong, 1983; Ibem, 2012); whereas others addressed the socio-cultural dimensions and patterns of housing quality (Akinola, 1998; Jiboye et al., 2005; Olayiwola et al.,2006; Jiboye 2010).

Over the years, many housing estates were developed by both the Public and the Private sectors or a partnership of both in the Abuja FCT. However, Such Housing estate developments were insufficient in terms of demands; do not reflect the desired housing needs of the end-users; in most cases affordable but not qualitative; do not possess green building features; affected by insufficient electricity (power) and water supply for residential consumption etc. (Dalibi et al., 2016). These outlined the need for housing estate development projects with features that can take into consideration the end-users preferences in such development projects.

Fenn et al., 1997; pointed out that incompatibility of interests amongst stakeholders caused conflicts and disputes in construction. Notwithstanding, Berke (2002) advocated the holistic inclusion of different interests from stakeholders and involving the public in planning. Incorporating the various interests of stakeholders should be extremely important for the preparation of green specifications, construction and maintenance.

Though, green building construction practice is a new trend (about two-three decades old) in construction with insufficient data about the costs and also the absence of measured building performance data from currently operating sustainably designed buildings (BD&C 2003; ENSAR 2003; Andreau et al., 2004). It is evident from some developers' attitudes, as they are not fully inclined towards constructing such projects due to lack of comprehensive data about the financial obligations with regards to Incorporating green features into renovation or proposed projects, Premiums, Marketability, Ratings, Cost of renting, Operating and Recurrent costs, Cost – benefit from envisage energy and water savings etc. (Dalibi et al., 2016).

Morris, 2007; argued that "The most common reasons cited in studies for not incorporating green elements into building designs is the increase in first cost"; the cost of incorporating sustainable designs elements depends on a wide range of factors which includes Building type, Location, Climate, Site conditions and the Project team. These factors may have relatively small or big but noticeable impact on green building developments especially in Abuja and cumulatively, they make a difference.

Sustainable design elements are gradually accepted in the mainstream of project design, in which building owners and tenants are beginning to demand and value those features. It is important to note, however, that advanced or innovative sustainable features can add significantly to the cost of a project and that these must be valued independently to ensure that they are cost and or environmentally effective (ibid). Incorporating green building features/ elements are basically at the developer's disposal and may have a significant impact on the total development cost which in turn affects end-users/ occupants in terms of Rental value, Sales value, Envisaged savings due to green elements, Future asset value of the green building etc. (Dalibi et al., 2016).

Thus, those elements must be checked with potential end-users in order to ensure they meet their housing needs, requirements and also their affordability which will also reflect on the developers' interests in terms of market value and faster sale of the Housing units.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

1.2 Research aim

The aim of this paper is to Explore the potentialities of end-users' preferences in adopting green building concepts in housing estate development projects in Abuja F.C.T., Nigeria. Review of literatures in the Eco/ green/ sustainable building field helps identify and narrow few environmentally sustainable passive and active elements in the particular context of Abuja.

1.3 Research hypotheses

The following hypotheses were formulated for this research; T-test statistical tool was used in testing these formulated hypotheses:

Null hypothesis (H_0); End-users preferences does not have any potential impact in adopting green building concepts in housing estate development projects in Abuja F.C.T., Nigeria

Alternative hypothesis (H_A); End-users preferences have potential impact in adopting green building concepts in housing estate development projects in Abuja F.C.T., Nigeria

2. LITERATURE REVIEW

2.1 The significance of stakeholder (end-users) engagement in green buildings (GB)

Stakeholder engagement is increasingly being recognised as more than just a defensive response to criticism or imminent conflicts but rather it contributes to organisational resilience and flexibility, to learning and innovation, to the identification of new opportunities, and ultimately to the improvement of sustainable performance (Partridge et al., 2005).

Any new building construction method or concept has its own peculiar challenges and green building is not an exception. For example, during the 1990s, green building measures were not been widely adopted, (Gottfried, 1996). Too few green building demonstration projects provide the industry with needed "how-to" information that reduces the perceived risk of "pioneering." Moreover, building owners and tenants are often aware of the connection between building-related environmental improvements and increased building economics and value, as well as increased occupant productivity (Ibid).

As such, incorporating the various interests of stakeholders is extremely important in green building projects from the preparation of green design, specifications, to green construction, operation and maintenance. This is done by acquiring all relevant information on green buildings, interpreting this information and effectively disseminating the information to persons who might need or involved in, and influenced by such projects. Communication is so important to project success that it has been referred to as the lifeblood of a project by many practitioners (Awati K., 2010).

The 5th edition of the project Management body of knowledge (PMBOK) published by the project management institute (PMI); outline Project Communications management and project stakeholder management as part the ten core knowledge areas. These two knowledge areas intersect first at the planning phase with one process each, namely; Plan Communications Management and Plan Stakeholder Management. This affirms the need for effective communications among the stake holders to enable success of projects especially green buildings.

Successful delivery of projects, their operations and management (including green building projects) is attributed to many factors of which stakeholders' perceptions, participation, roles and responsibility is among (Bourne, 2005 and Dalibi, 2014). Stakeholders' input, participation, roles and responsibility in Green buildings projects must be of high cognizance than conventional building projects because of the divergent stakeholders' interests (Dalibi et al., 2016). These warrants the need for exploring the potentialities of end-users' preferences in adopting green building concepts in housing estate development projects in Abuja F.C.T., Nigeria.

Several surveys, evaluations and research works were conducted at the post occupancy stages of various buildings to ascertain the level of satisfaction of the end-users and also to rate the intended performance of the buildings. Post Occupancy Evaluations were normally conducted in both residential and commercial buildings,

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

using various baselines and comparisons. Some studies focus on occupant satisfaction and/ or perception in green buildings (Armitage et al., 2011; Gou et al., 2012a; Wilkinson et al., 2013). Other studies emphasize the differences (if any) in the occupants' satisfaction in and/ or perception of green and conventional buildings (Abbaszadeh et al., 2006; Gou et al., 2012b; Paul and Taylor, 2008; Zalejska-Jonsson, 2012). Still others examine a move from a conventional building/ refurbishment of a conventional building to a green building (Agha-Hossein et al., 2013; Thatcher and Milner, 2012).

Comprehensive building performance evaluation and monitoring is an essential and no longer an optional way to check whether the actual building performance meets the design expectations and also to map the performance issues. It reveals the lessons of 'what works in practice and what doesn't' to be fed back to the construction industry (Bordass and Leaman, 2005 and Bordass 2011).

Occupant surveys are recognized to be a key component of any building performance evaluation study (Stevenson and Rijal, 2008). Recent research shows that different occupant lifestyle and behaviour may result in up to fourteen times difference in energy and water use for the same type of low carbon homes (Pilkington et al., 2011). Also, residents/ end-users provide a valuable source of information about the comfort conditions in a building and their level of satisfaction is an indicator of success or failure of the building performance (Nooraei, 2013)

2.2 Green buildings, end-**users' potentialities, preferences and impacts**

Green building (GB) sometimes called Green construction/ Eco-building/ High performance building/ Sustainable building is defined based on the features, components and perceived impacts. GB refers to a structure that uses all processes that are environmentally responsible and resource-efficient throughout a building's life-cycle (USEPA, 2009); sensitive to the environment, resource and energy consumption, impact on people, financial impact and the world at large (Greg Kats, 2003); environmentally friendly practices from building design to the landscaping choices by encompassing energy use, water use, storm-water and wastewater re-use (Zane et al, 2009); buildings designed, constructed to provide optimum performance of the building with positive impact to the occupants and the environment by combining energy, water efficiency systems, Day Lighting strategies, Indoor Environmental Quality (IEQ) systems and efficient Building Envelope systems (Dalibi, 2012).

The United States environmental protection agency as cited by Vatalisa et al., 2013; opine that "GBs are designed to reduce the overall impact of the built environment on human health and the natural environment through the goals of sustainable building such as Life cycle assessment (LCA), Energy Efficiency and Renewable Energy, Water Efficiency, Environmentally Preferable Building Materials and Specifications, Waste Reduction, Toxics Reduction, Indoor Air Quality, Smart Growth and Sustainable Development, Environmentally Innovative materials and services. While according to USGBC 2007; "GB is a holistic concept that starts with the understanding that the built environment can have profound effects, both positive and negative, on the natural environment, as well as the people who inhabit buildings every day. Green building is an effort to amplify the positive and mitigate the negative of these effects throughout the entire life cycle of a building".

Thus, the Green building elements and features considered in this work (based on US EPA 2009; Gregg Kats 2003; Zane et al, 2009, Dalibi, 2012; Vatalisa et al., 2013; greenbuildingsolutions.com; USGBC 2007) as cited by Dalibi et al., 2016 are limited to the following:

- Energy efficiency systems,
- Water efficiency systems,
- Day lighting systems,
- Indoor environmental quality (IEQ) systems,
- The building envelope systems.

3. METHODOLOGY

Secondary sources of data such as journals, conference/ seminar/ workshop papers, text books, newspapers, magazines and the internet etc. were used to review literatures in the green building field which helps identify and narrow few environmentally sustainable passive and active elements in the particular context of Abuja, Nigeria. Such GB elements/ features identified and limited in this work include Energy Efficiency systems, Water Efficiency

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

systems, Day Lighting systems, Indoor Environmental Quality (IEQ) systems and The Building Envelope systems. Moreover, other sub-elements/ sub-features under these systems were also considered; altogether, they formed the Backbone of the research questionnaire.

A random sampling questionnaire survey (as the primary source of data) was conducted to ascertain the end-users' preferences of green building features using a 5-point Likert scale (Highly preferable=5, Preferable=4, Neutral/ Undecided=3, Less Preferable=2, and not preferable at all=1). Frequency count tables, Mean item score and T-test statistics were used for data analyses.

4. PRESENTATION OF DATA AND ANALYSES

The Primary data for this research work was obtained through manually distributed questionnaires from five hundred Occupants/ End-users from twenty different housing estates and Twenty Estate Developing Firms in Abuja, Nigeria. The result collated was arranged and analysed in Table 1-4 below.

4.1 Results from the Administered Questionnaires

The table below shows the responses from the end-users' preferences and Residential estate developers in Abuja obtained from manually distributed.

Questionnaires	End-users		Developers	
	Frequency	*Percentage*	*Frequency*	*Percentage*
Returned & Usable	500	71.43%	20	71.43%
Non-Returned	192	27.43%	8	28.57%
In-complete	8	1.14%	0	0%
Total of Questionnaire Administered	700		28	

Table 1: The responses obtained from manually distributed questionnaires
Source: Authors' field survey 2016

The table above clearly shows that the total response rate for End-users was 508, out of which 8 were incomplete making the usable number to be 500 or 71.43% which was a very good response rate. Whereas, the response rate of developers was 71.43% which was also very good.

	GREEN BUILDING FEATURES	Mean Item Score for End-users	Mean Item Score for Developers	Remark
1	Energy Efficiency			
	Solar panels	4.79	5.00	*Adoptable*
	Wind turbines	3.09	1.00	*Not Adoptable*
	DC Inverters	4.82	4.10	*Adoptable*
	Solar-water-heaters	4.50	3.60	*Adoptable*
2	Water Efficiency			
	Grey and Black water systems	2.72	2.35	*Not Adoptable*
	Water saving appliances	4.98	4.80	*Adoptable*
	Rainwater harvest	4.85	4.25	*Adoptable*
3	Day light			
	Clerestories	4.16	4.40	*Adoptable*
	Spectral Glazing	3.12	2.90	*Not Adoptable*
	Solar-tubes	4.14	4.70	*Adoptable*
4	Indoor Environmental Quality			
	Indoor Air Quality	4.60	4.70	*Adoptable*
	Accoustics	4.73	4.85	*Adoptable*
	Adequate Lighting (Artificial-lighting+Nat Lighting)	4.33	4.50	*Adoptable*
5	Building Envelope	3.62	3.00	*can be Adoptable*

Table 2: Preferential responses of end-users and developers in Abuja, Nigeria
Source: Authors' field survey 2016

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The result of the various mean item scores for each green building feature as shown above were compared to ascertain the features that can be adoptable in GB development projects based on the 5-point Likert scale used (Highly preferable=5, Preferable=4, Neutral/ Undecided=3, Less Preferable=2, and not preferable at all=1). Any mean item score (weighted average) of 3.00 and above indicates that a green building feature can be adoptable.

4.2 Testing of hypotheses

The hypotheses formulated for this research work was tested using T-test statistics. The values for the mean item scores in Table 3 above were used as the data for the statistical computations as shown in the table below.

STAKE HOLDERS	MEAN	STANDARD DEVIATION	N	D F	Tcal	$Ttab_{0.05,\ 13}$	Decision
1. END-USERS	4.17	0.72	14	13	6.10	-1.77	Reject Ho, Accept H_A
2. DEVELOPERS	3.87	1.17	14	13	0.199	-1.77	Reject Ho, Accept H_A

Table 3: T- test statistical results
Source: Authors', 2016

With 13 degrees of freedom (DF) and 5% level of significance each, the T-test tabulated ($Ttab_{0.05,13}$= -1.77) is less than T-test calculated for both the end-users and the Developers; as such, the Alternative hypothesis was accepted; which states that "End-users preferences have potential impact in adopting green building concepts in housing estate development projects in Abuja F.C.T., Nigeria".

5. CONCLUSIONS

From the limited green building features used in this study (shown in Table 2), it can be observed that both the developers and the End-users Highly preferred, preferred, less preferred and remain neutral on certain green building features in terms of their Preferences and interests in estate development projects in Abuja. This affirms that both shared almost the same preferences regarding the features of green buildings; which is further attested by the T- statistical test by accepting the Alternative hypothesis. The following features as shown in Table 2 above can align the interests of both the stake holders since they were preferred by the end-users and are adoptable by the Developers:

- Solar panels, DC inverters and solar-water-heaters under energy efficiency systems.
- Water saving appliances and rainwater harvest under water efficiency systems
- Clerestories and the use of solar tubes under day-lighting strategies.
- Indoor air quality, acoustics and adequate lighting (artificial lighting + natural lighting) under Indoor environmental quality.
- The end users are in between "neutral/ undecided" and "agree" regarding building envelope whereas, the developers' are "neutral/ undecided". This indicates that building envelope can also be adoptable

6. RECOMMENDATION

Estate Developers in Abuja (including other cities in West Africa, the Whole African continent and the world at large) need to conduct or sponsor a lot of researches frequently on end-users requirements, preferences choices, operability, and additional needs in terms of qualitative or high end housing especially Green buildings. This will expose features that will enhance the market value of the housing estates. Other green building features/ components/ elements should also be considered and researched on, so as to expose many features that may align the interests of both stakeholders.

ABSTRACT

Green Business Parks (GBPs) as a way of achieving more sustainable industrial and business development are getting increasing interest from both public and private sectors. However, there have been few studies identifying the project management strategies for such projects. In light of this, the objectives of this study are to: (1) identify the critical success factors (CSFs) for GBPs; (2) investigate and assess the barriers hindering the adoption of GBPs; and (3) propose feasible solutions to overcome the barriers. To achieve the objectives, 30 CSFs, 15 barriers and 21 solutions were identified from a comprehensive literature review and then a questionnaire survey and post-survey interviews were conducted. The analysis results first reported that the top three CFSs were “strong top management support”, “strong financial capability” and “adequacy of design details and specifications”, while “perceived higher initial capital cost”, “uncertain trade-off between environmental and financial benefits” and “lack of government supports” were revealed as the top three barriers. The analysis also indicated that “better government funding” and “clients’ advocation of green management goals” were most feasible solutions to improve the potential adoption of GBPs. This study not only fills the gap in the knowledge area of the project management of GBPs but also points out the right directions for the practitioners to successfully adopt GBPs and ultimately achieve more sustainable developments.

Keywords: green business parks, critical success factors, barriers, solutions

1. INTRODUCTION

The sustainable development of the industrial and business sectors would lead to the great and efficient reduction of global greenhouse gas (GHG) emissions since industrial and energy sectors together are responsible for a major share of GHG emissions. According to Eurostat (2016), nearly half (45.4%) of all GHG emissions in the EU in 2013 were from the activities of electricity, gas, steam and air conditioning supply (26.6%) and the activities of manufacturing sector (18.8%). Together with the increasing developments of green buildings, Green Business Park (GBP), which is a way to create sustainable industrial and business development, has attracted a great attention from public and private sectors. GBP was defined as a hybrid concept between the agglomeration of conventional industry and green buildings (Stewart, 2007). Industrial ecology, eco-industrial park (EIP), industrial ecosystem and by-product exchange are complementary terms of GBP. Numerous Green Business Parks (GBPs) have been developed all over the world. For instance, until early 2001, at least 40 communities in the US initiated eco-industrial development projects (Lowe, 2001). Singapore and China have also launched the highly-specialized business parks such as CleanTech Park (CTP) (Green Business Singapore, 2013) and Sino-Singapore Tianjin Eco-City (SSTEC) (Flynn, 2012).

However, it is also true that the implementation of this concept is still at an early stage and encounters different kinds of difficulties (Gibbs, et al., 2005). Furthermore, the current research focuses just on definitions, benefits, drivers and limitations of GBPs through some case studies, and there have been very few studies focusing on the project management framework for GBPs. As a result, this study aims to: (1) identify the critical success factors (CSFs) for GBPs; (2) investigate and assess the barriers hindering the adoption of GBPs; and (3) propose feasible solutions to overcome the barriers. This study not only fills the gap in the project management knowledge area of GBPs but also points out the right directions for the practitioners to successfully adopt GBPs and ultimately achieve more sustainable developments.

2. BACKGROUND

Green Business Park has the root in industrial ecology or industrial ecosystem (Stewart, 2007). An industrial ecosystem was defined as a system in which "the consumption of energy and material is optimized, waste generation is minimized, and the effluents of the process serve as the raw material for another process" (Frosch and Gallopoulos, 1989). The early GBPs were called eco-industrial parks (EIPs) whose functioning was described as "applied industrial ecology" (Stewart, 2007). GBP is the hybrid of green buildings and EIPs (Stewart, 2007) and emphasizes the clustering of specialized industries by providing shared infrastructure and facilities (Tudor, et al., 2007).

The developments of GBPs attempt to achieve economic, social and environmental benefits, concurrently. First, GBPs have the potential to reduce operating costs, disposal costs and increase the income from the sale of by-products. For example, Mobil which is a park in the United State sold styrene to a recycler for 50 cents a gallon whereby previously it had to pay 1.00 USD per gallon for disposal (Stewart, 2007). Moreover, GBPs lead to a more rooted business, good jobs and a cleaner environment. GBPs are also designed to relieve the environmental pressure by promoting the closing of material cycles (Heeres, et al., 2004).

Critical success factors (CSFs) help to achieve predetermined goals and are indisputably necessary for the success of projects (Chan, et al., 2004). Through an intensive literature review on CSFs for the conventional business park, EIPs and green building projects, this study identified 30 CSFs (Table 1) which have the potential to influence the success of GBPs. Through the literature review, this study also identified 15 barriers (Table 2) having the potential to impede the development of GBPs.

3. DATA COLLECTION PRESENTATION

This study carried out a questionnaire survey to solicit opinions from experts. After developing a questionnaire based on a comprehensive literature review, this study conducted a pilot survey with three construction industry experts before finalizing the questionnaire. The first part of the questionnaire included the questions meant to profile the companies and respondents. Moreover, the questionnaire presented the 30 CSFs, 15 barriers and 21 proposed solutions. The respondents were subsequently asked to assess the criticalities of CSFs, significance of barriers and usefulness of solutions with a five-point scale. Taking the rating of CSFs as an example, "1" indicates "least critical" while "5" means "most critical". Finally, post-survey interviews were conducted with four experts who were either BCA certified Green Mark Managers (GMMs) or Green Mark Professional (GMPs) to validate the survey results. In post-survey interviews, the experts were provided with the analysis results and they all confirmed that the findings were reasonable and consistent with their expectations.

This study randomly sent out 124 sets of the questionnaire to professionals who are GMMs or GMPs, and 40 completed questionnaires were finally returned. The majority of the respondents (92.5%) had more than two years' experience in green building projects. Moreover, 85% and 57.5% of respondents had the working experience in commercial projects and industrial/business park, respectively. Furthermore, 65% and 32.5% of companies had the business background in green commercial/retail projects and industrial/business park, respectively.

4. ANALYSIS RESULTS AND DISCUSSIONS

4.1 Criticalities of CSFs of GBPs

This study first analysed the criticality of each CSF by adopting methods including descriptive means and one sample t-test (confidence level = 95%; p-value = 0.05). The criticality rankings and test results are summarized in Table 1.

"Strong top management commitment and support" (C06) was ranked first (mean = 4.75) due mostly to the importance of the upper management providing the necessary support and stipulating right policies. Moreover, without adequate and timely support from the top management, the project team will be less productive in completing their duties because of the inefficient access to organizational resources (Alexandrova and Ivanova, 2012). This is even more critical for GBPs because additional workloads are needed to achieve green requirements.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

"Strong financial capability" (C07) was ranked second (mean = 4.63). As a property development, a GBP should first meet the business and financial objectives. As a good example, in case of Kalundborg EIP, each business link in the system was negotiated as an independent business deal, and was established only if it was expected to be economically beneficial (Maxwell, et al., 2015). Moreover, as green developments tend to be discouraged by the perceived high initial capital costs (Houghton, et al., 2009), some financial initiatives, such as public private partnerships, can be also considered to maximize financial capability in such developments (Lowe, 2001). The strong financial capability was also emphasized by the post-survey interviewees as a key success factor for GBPs.

Factor Category	F-Code	List of Factors	Mean	p-value	Rank
External Factors	E01	Economic development strategy	4.38	0.00	12
	E02	Extensive government support (such as funding, schemes for workforce training)	4.50	0.00	7
	E03	Preferential policies, e.g. tax exemptions, technical training and standards setting	4.48	0.00	9
	E04	Strong demand from local and foreign companies and the existence of clustering companies	4.33	0.00	16
	E05	Planning guidelines for business parks to be mutually beneficial	4.23	0.00	20
Client Related Factors	C06	Strong top management commitment and support	4.75	0.00	1
	C07	Strong financial capability	4.63	0.00	2
	C08	Ability to convey project objectives and goals clearly	4.55	0.00	4
	C09	Realistic and well-planned project schedule and proper allocation of resources	4.45	0.00	10
	C10	Moderate variation orders during construction	3.68	0.00	28
	C11	Ability to arrange for autonomous management or private park ownership	3.68	0.00	29
Project Team Related Factors	PT12	Competency of project manager	4.53	0.00	6
	PT13	Ability to develop good relationship and continuous communications between teams and stakeholders	4.33	0.00	15
	PT14	Strong commitment and involvement of project team	4.38	0.00	13
	PT15	Technical competency, experience and knowledge of project teams in developments	4.48	0.00	8
	PT16	Effective risk management	4.03	0.00	24
	PT17	Pro-active management continuously evaluating park performance	4.13	0.00	23
	PT18	Competency of facilities management team's response to tenant issues during operations	4.28	0.00	19
Project Consultant Related Factors	CS19	Competency of project consultants	4.53	0.00	5
	CS20	Involvement of Green Mark Managers/Professionals	4.38	0.00	14
	CS21	Strong cooperation in solving problems	4.30	0.00	17
	CS22	Effective marketing of the business park	4.30	0.00	18
Project Contractor Related Factors	CT23	Adequacy of design details and specifications	4.60	0.00	3
	CT24	Emphasis on high-quality workmanship	4.40	0.00	11
	CT25	Skillful workers with adequate trainings in Green Projects	4.20	0.00	21
	CT26	Using advanced technology and automation for construction work	3.70	0.00	27
Project Related Factors	D27	Selection of prime location	3.75	0.00	25
	D28	Provision of enabling environment E.g. restaurants, leisure park and right infrastructure	3.55	0.01	30
	D29	Provision of park design with flexibility and allowance for future expansion	3.75	0.00	26
	D30	Design of buildings to fulfill standardization, simplicity and constructability	4.18	0.00	22

Table 1: Summary of criticality ranking of CSFs

"Adequacy of design details and specifications" (CT23) was ranked third (mean = 4.60). This result could be contributed by the requirements of additional green features and the compliance of green regulations or standards which can be achieved partially through the adequate design and specifications (Lam, et al., 2010). It is better for a contractor to have their own green design and construction team; otherwise, the cost and schedule of a green development would be affected (Samari, et al., 2013). Moreover, experts in the post-survey interviews also suggested that setting standardized design guidelines should be crucial to the success of GBPs. For instance, setting parcel design guidelines in the development of CleanTech Park in Singapore helped the owners to attain a minimum Green Mark Gold rating (Green Business Singapore, 2013).

4.2 Significance of barriers

This study analyzed the significance of the barriers by using methods explained previously, and the results are summarized in Table 2.

Barrier Category	B-Code	List of Barriers	Mean	p-value	Rank
External barriers	B01	Imperfect government regulations	3.80	0.00	4
	B02	Adjustment of functions and changing roles of parks	3.38	0.08	7
	B03	Lack of strategic location due to the scarcity of land	3.10	0.55	11
	B04	Lack of government supports such as funds and tax exemptions	3.83	0.00	3
Client related Barriers	B05	Perceived higher initial capital costs	4.40	0.00	1
	B06	Lack of potential clients' awareness and demand	3.80	0.00	5
	B07	More variance in project deliveries leading to a higher risk level	3.05	0.79	13
	B08	More variance in site practices leading to a higher risk level	2.95	0.76	14
	B09	Unequal distribution of advantages between developers and tenants	3.08	0.68	12
	B10	Uncertain trade-off between environmental and financial benefits	4.05	0.00	2
Project team barriers	B11	Lack of skilled labor in respect of green developments or GBPs	3.15	0.46	10
Consultants barriers	B12	Lack of marketing and promotion	3.20	0.34	8
Contractors barriers	B13	Lack of the effective coordination between key players	3.18	0.32	9
Project barriers	B14	Complexity in obtaining green certifications	2.70	0.08	15
	B15	Lack of proven benefits to entice potential investors	3.78	0.00	6

Table 2: Summary of significance ranking of barriers

Except "more variance in site practices leading to a higher risk level" (B08) and "complexity in obtaining green certifications" (B14), the means of the other barriers were all statistically greater than three. Among these barriers, "perceived high initial capital costs" (B05) was ranked first (mean = 4.40). Just like green building developments, the developments of GBPs were overwhelmingly discouraged by the perceived high capital costs (Hwang and Tan, 2012; Samari, et al., 2013). From a developer's perspective, sustainable developments require the city incentive and government support unless there is a sufficient demand for sustainable developments in the market (Maxwell, et al., 2015). All post-survey interviewees also agreed with this result.

"Uncertain trade-off between environmental and financial benefits" (B10) was ranked second (mean = 4.05). Currently, there are some difficulties to concretely demonstrate positive environment impacts and financial benefits. Gibbs, et al. (2005) disclosed one reason that there were relatively very few EIP sites which were engaged in measuring energy flows and exchanges. On the other hand, some intangible benefits, such as the increased productivity of staff working in green buildings, were difficult to measure and transfer to financial benefits (Reichardt, 2015). The interviewees in the post-survey highlighted that unbiased independent case studies which could clearly show the trade trade-off are urgently needed.

"Lack of government supports" (B04) received the third position (mean = 3.83). As GBPs are at the preliminary stage, governments play a vital role to promote such developments. Gibbs, et al. (2005) investigated 61 eco-industrial projects in USA and Europe and identified that over 40% of these projects had a lead partner who was local or municipal authority. Singapore has actually initiated some funding and several incentive schemes related to the energy efficiency and clean energy such as Energy Efficiency Improvement Assistance Scheme (EASe) and Grant for Energy Efficient Technologies (GREET) (Green Future Solutions, 2015). However, the industrial practitioners may not be familiar with these funding and incentive schemes since they still thought there was a lack of government supports.

4.3 Feasible solutions for overcoming barriers

This study also identified and provided a list of solutions to be able to overcome the barriers for the respondents to choose the best measures that can tackle the barriers. The frequencies (Freq.) and percentages (Per.) of the respondents who chose particular solutions for each of the barriers are tabulated in Table 3. For the sake of the length of the paper, solutions for barriers B08 and B14 were excluded because they were not statistically significant as discussed above. Moreover, except the solutions for the top three barriers (B05, B10 & B04), the solutions with Per. < 50% were also excluded from Table 3.

"Minimize variations order during construction to avoid delays by having efficient management" was suggested to overcome the high initial capital costs and the lack of potential clients' awareness and demand for GBPs (B05&B06). However, the low percentage (32.5%) indicated that it is not a useful solution. The interviewees in the post-survey commented that the high initial costs were mainly due to the difficulties in the establishment of interlink between companies, the requirements of additional green features and compliance of green regulations or standards. These could be properly maintained at the planning and design stage but not the construction stage.

As for the clients' perception of the uncertain trade-off between environmental and financial benefits (B10), 55% of respondents felt that the collaboration with research institutes and firms to study and highlight the long-term social and cost benefits can help to overcome the barrier. This solution aims to get more clients' advocation of green management goals. Furthermore, 80% of respondents felt that the government support, such as the increase in the scope of co-funding and the incentives for trainings and technologies were needed. Moreover, the government could also found some supporting structures like the training center or technology research center to educate the practitioners or the public.

Barriers	List of Solutions	Frequency	Percentage
B01	Policies and regulations for green industrial spaces to be structured in a supportive manner, such as flexible planning guidelines, tax exemptions and privileged permits with short time approval	30	75.0%
B03&B04	Government to increase the scope of co-funding and incentives for trainings and technologies	32	80.0%
B05&B06	Minimize variations orders during construction to avoid delays by having efficient management	13	32.5%
B09&B10	Relevant statutory boards to collaborate with research institutes and firms to study and highlight the long-term social & cost benefits in order to promote GBPs to the industrialists	22	55.0%
B11	Select qualified team members with specialized skill and provide proper trainings	25	62.5%
	To include at least one Green Mark Professional/ Green Mark Manager in the project	25	62.5%
	Encourage team to explore compliance requirement under specific standards together with other consultants during planning phase	27	67.5%
B12	Provide trainings for staff to understand such specialized facilities in order to manage them well during operation phase	24	60.0%
	Consultants should provide full cooperation to contractor/ client when their expertise are required	26	65.0%
	Strong communicate with the client promptly to avoid misinterpretation	25	62.5%

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

B13	Provide proper planning and scheduling during construction to ensure efficient allocation of resources and time to avoid cost overrun and disputes	20	50.0%
	Contractors who are specialized in green design and technologies can increase investors' interest by offering some form of indemnification for certain conditions	20	50.0%
B15	Permit authorities should work collaboratively with project teams to ensure specifications of project design are aligned with the criteria for certifications	22	55.0%

Table 3: Summary of suggested solutions for overcoming barriers

5. CONCLUSIONS AND RECOMMENDATIONS

This study aimed to identify project management strategies for Green Business Parks by investigating critical success factors, significant barriers and useful solutions. To achieve the objectives, 30 CSFs, 15 barriers and 21 solutions were identified from a comprehensive literature review. Having conducted a questionnaire survey, "strong top management support", "strong financial capability" and "adequacy of design details and specifications" were reported as the top three CSFs. Moreover, "perceived higher initial capital cost", "uncertain trade-off between environmental and financial benefits" and "lack of government regulations" were revealed as the top three barriers. The analysis also indicated that "better government funding" and "clients' advocation of green management goals" were most feasible solutions to improve the potential adoption of GBPs. This study not only fills the gap in the project management knowledge area of GBPs but also points out the right directions for the practitioners to successfully adopt GBPs and achieve more sustainable developments. Future studies could focus on the long-term social and cost benefits of GBPs increasing the clients' interest and demand of GBPs.

ABSTRACT

The desire by corporate occupants to be green, to be seen as green, and to shave costs is changing the way they manage their corporate real estate portfolios. Until now, there have been few 'greening' metrics for building occupants. Also it has been difficult to motivate occupants – particularly those in leased spaces – to change their behaviours. Consequently, despite green certifications for so-called 'trophy buildings', there has been virtually no broad market transformation.

In an age of fierce competition, the greatest driver of change in the workplace is the need to create an environment where ideas can flourish and be turned into business advantage. This means creating a workplace where a corporate culture finds its fullest expression, and where employees feel comfortable, inspired and connected. This paper describes a portfolio methodology that addresses sustainability with workplace comfort and productivity, and which is designed from the user-perspective. The paper touches on how smart building technologies are already accelerating the convergence between 'green' and 'productive'.

Keywords: corporate social responsibility, productivity, wellness

1. INTRODUCTION

This paper outlines some reasons that green assessments and certifications are not getting the broad penetration needed to transform corporate real estate; and describes an approach that is more likely to achieve that goal. Green + Productive Workplace, (G+P) is an assessment that targets a particularly challenging segment of the industry: corporate real estate occupants in leased and owner-occupied spaces.

The fact that buildings account for almost 20% of climate change emissions has given rise to certifications such as LEED, BREEAM, Living Building Challenge and many others. These have transformed our understanding of green building design and operations but they have not transformed the industry as a whole. Certified buildings account for less than 1% of building stock – and only about 2 out of ten thousand existing buildings. With a growing body of knowledge and increasingly sophisticated technologies, the certifications become more refined and generally more rigorous. Meanwhile, 99.98% of buildings do not undergo any environmental certification at all. Consequently, the bar gets higher and higher, but for few players. It is therefore time to rethink green assessments and address what we know to be the problems: cost, point-chasing, prescriptive requirements and prerequisites that often need 'interpretation', and complex submittals and certification protocols.

Reinventing Green Building [1]. by Jerry Yudelson recommends an approach that could be more effective in transforming the mainstream: simplicity without sacrificing rigor, and implementation that is designed from the user's perspective – affordable, strategic, focused on continuous improvement and the bottom line. Yudelson talks about one tool that does this: Green + Productive Workplace (G+P). As its name suggests, the objective of G+P is to green the workplace and make it healthy, comfortable and productive. It is for corporate portfolios of leased and owner-occupied facilities – which is one of the most challenging areas when it comes to sustainability in real estate.

2. OCCUPANTS MORE INTERESTED IN PRODUCTIVITY BUT REALIZE THAT THEY MUST ALSO BE GREEN

Office fit-outs and occupant behaviour have a significant impact on building performance, but there have been few metrics for building occupants. Also it is challenging to motivate occupants to adopt sustainability best practices because the value proposition of recycling or energy savings programs pale in comparison to the value proposition of adding features that will improve employee productivity and corporate branding.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Sixty eight percent of global Corporate Real Estate (CRE) executives have alluded to increasing business demand to enhance productivity and 65% have confirmed the need to transform the quality of the workplace – according to Jones Lang LaSalle's recent Global Corporate Real Estate (CRE) Trends report, based on a survey of over 630 global CRE executives [2]. The interest in workplace productivity is in response to the accelerated pace of innovation and marketplace flux, which are driving competition in every sector of the global economy. To address these business challenges, the workplace is changing: employees are more digitally connected and mobile; more are telecommuting; and a growing proportion of employees are short-term, contract workers. These factors make it difficult to predict head-count, which is part of the reason that the majority of businesses are adopting an open office environment, with hoteling work stations and an abundance of flexible, common space.

There is also a growing movement to implement features and management operations to support wellness in the workplace.

Meanwhile, there is a perception that a green office is by definition more comfortable and productive. Occupants are drawn to the concept of being in a green building as these tend to be high profile, interesting and attractive. However, one study of the greenest buildings in Australia showed that almost three quarters of occupants in green-certified buildings said that they did not feel any healthier or more productive [3]. One of the benefits of an open office concept is that it supports team collaboration – which is essential to bring new ideas to market. The reality though, is that not all tasks require collaboration, and there are certain features of an open office that many occupants find distracting. The survey of green Australian buildings showed that three things that occupants liked about a green office were: daylight, views and an open layout. The three things which many disliked were: noise, thermal discomfort and lack of personal privacy [4]. A plethora of studies, using many different productivity performance indicators all concur that taking corrective action where there are acoustic, thermal, lighting/daylighting, and air quality problems can have a significant impact on occupant productivity. The findings of many of these studies are summarized in the IFMA Foundation compendium called Applying what scientists know about where and how people work best. [5]

The reason to juxtapose sustainability and productivity is that many features in an office should be examined through both lenses. For example, daylighting can be a 'green' energy efficiency feature as well as being good for productivity. However, too much window is not green, and in some cases, can hinder productivity. Heating, cooling and ventilation have an important energy aspect. However, saving energy for HVAC can affect thermal comfort and indoor air quality. The premise of Green + Productive is that every workplace should strive to be both – green AND productive. The goal of G+P is to align criteria that either reinforce one another, or are in opposition, or must achieve a balance. This is consistent with the concept of a high performance building: one that is energy efficient and has a high rate of perceived indoor environment acceptability.

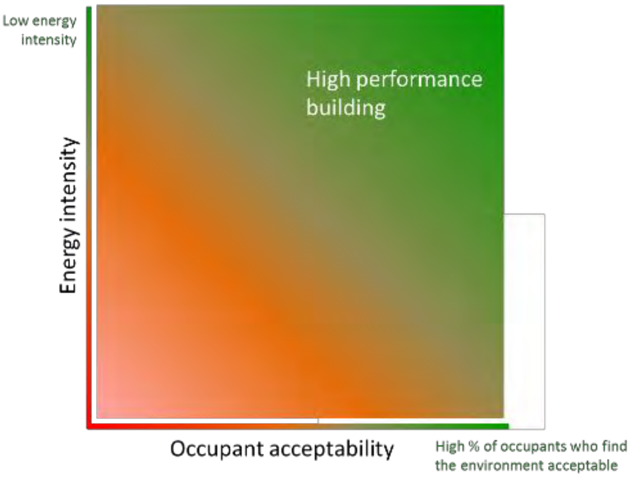

Figure 1: High performance building

Because corporate occupants know that they need to be green (and be seen as green) as part of their corporate social responsibility, the G+P strategy is to align greening of the workplace with the productivity agenda. As smart buildings transform the way occupants interact with buildings, there is now a stronger direct link between occupants

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

and operations. For example, smart building energy management systems can schedule lighting and air conditioning systems to turn on/off based on peak and off-peak occupancy periods and in response to occupant controls. In a building with multiple tenants, each organization's energy usage can be calculated precisely, in real time, and charged to the respective financial departments. This motivates tenants to examine how they are using energy, and better manage it, for example through a better allocation of space and scheduling. The convergence of 'green' and 'productive' aspects, which is accelerating thanks to smart building technologies, is driving the need to integrate the roles of corporate real estate management (CRE), IT, human resources, and communications to align decision-making with respect to: space planning and management, wellness, and sustainability.

Figure 2: Convergence between 'green' and 'productive'

3. G+P IS DESIGNED FROM THE USER PERSPECTIVE

To achieve a broad penetration, an assessment should be designed with the user experience in mind. An asset manager who wants to optimize their portfolio and make the best use of resources needs to be strategic. That's why G+P takes a portfolio approach, and addresses offices that are owner-occupied and/or leased, and/or contemplating a retrofit. Taking a strategic portfolio approach makes it possible to measure improvement from year to year, recognize and reward top performers, and focus resources where they are most needed. Some portfolios may consist of just one or two offices. Others may be large. For global portfolios, questions are regionally designed to address different standards and references for the Americas, Europe and Asia-Pacific.

Part of an effective portfolio approach is to document and clearly communicate certain portfolio-wide policies. Therefore, part of the G+P assessment is a section called Corporate Leadership. This section is short (less than 15 minutes) but it helps a portfolio manager to review how committed the organization is with respect to: portfolio-wide policies related to greening and wellness; public disclosure of energy, carbon water and waste; as well as directives and specific roles of various members of the organization: business unit managers, facility managers, green teams, employees, Human Resources and IT.

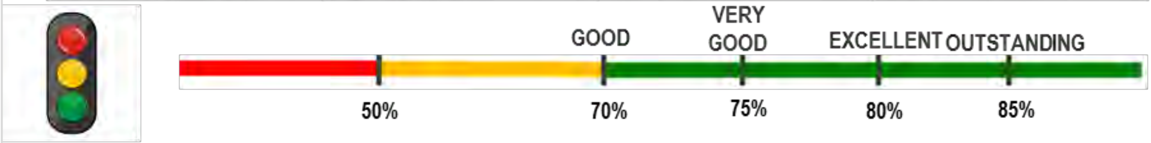
Once the Corporate Leadership section has been completed, the next step is to complete an assessment of each office in the portfolio. The assessment is designed to be done – not by consultants – but by the facility managers (FMs). Because they know more about the offices than anyone and are responsible for ongoing improvements, Facility Managers should therefore 'own' the process. However, there are concerns within the industry that FMs are facing an ever increasing workload. With this in mind, the G+P process is designed to be streamlined and simple: Each facility manager is given a login. Navigation of the site is self-explanatory; the G+P survey itself takes only 45 minutes; questions are clearly worded; responses are graduated; and pop-up tips define terms, explain concepts and describe the verification criteria.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The output is an individual report for each site and a portfolio report which includes an Executive Summary for the C-suite. The Executive Summary presents site scores, an industry comparison, and a thumbnail description of the 'red flag' issues for each site.

BENCHMARKING SCALE

Benchmark	Overall	Green	Productive
Good	70 -74%	70-100%	70-100%
Very Good	75 - 79%	70-100%	70-100%
Excellent	80- 84%	70-100%	70-100%
Outstanding	85 -100%	70-100%	70-100%



G+P Workplace uses a simple traffic light scoring scheme:
<50% Potential risk
50 – 70% Opportunity
> 70% Above average

YOUR BENCHMARKS

OFFICE	Overall	Green	Productive	Benchmark
Horsham	65%	58%	71%	-
San Diego	73%	71%	74%	GOOD
Lowell	60%	53%	65%	-
Santa Clara	75%	72%	78%	VERY GOOD
Lawrence	69%	66%	72%	-

Figure 3: G+P benchmarking for a portfolio

Taking the user perspective, costs are a huge consideration: the cost of the assessment, the cost of certification and the cost and benefits of taking measures to make a portfolio more green and productive. The pricing scheme of G+P is designed to be affordable for entire portfolios, so that time and resources may be focused on improving the portfolio rather than creating endless submittal documentation.

For offices that wish to obtain third party verification, the process consists of on-site measurements and a review on actual in-use documentation – versus documentation that has been prepared expressly for the purpose of a verification, and which then typically sits on a shelf gathering dust.

GREEN

Figure 4: Excerpt of a G+P portfolio report

Part of the strategic approach is to also to identify where to invest resources. G+P provides a high level financial estimate of wasted energy and lost productivity. These calculations are based on conservative assumptions and produce values that are not intended to be precise, but which give orders of magnitude. For asset managers, these can be red-flags, which indicate the need for some further investigation such as detailed measurements or occupant surveys to determine the exact nature and extent of problems and the corrective action needed.

G+P recognizes and rewards high performance using a benchmarking system with the main focus being on continuous improvement. It benchmarks performance by comparing offices, within a portfolio, and by providing an anonymous industry comparison, with all of the offices in the G+P data base. It also offers a comparison with past performance for the portfolio and for individual offices.

One of the challenges of assessments is to make them meaningful to the decision-makers – the ones who control the purse-strings, and who often don't see beyond the marketing value of green building certification. When a portfolio manager is able to show bottom line benefits of improved productivity, demonstrate that there is corporate leadership and a portfolio strategy for continuous improvement – then there is a greater chance of getting the attention and the needed resources.

Portfolio Report for MetroPlus

Green + Productive Workplace

FINANCIAL IMPACTS

The following values represent the order of magnitude of wasted energy and lost productivity due to current deficiencies. The estimates show the potential savings from taking corrective action. The savings factors are purposely on the low side to provide a credible case for action. Conservative estimates for energy savings are a maximum of 6% of annual electricity costs for a worst case of inefficient lighting and 5% for a worst case of inefficient plug load. Estimates for lost productivity are a maximum of 0.5% of annual payroll, which represents the equivalent of about 5 minutes per day of reduced quantity and/or quality of work output per employee for each worst case scenario of acoustic, thermal and visual discomfort, or indoor air quality.
Annual electricity costs are calculated as follows: (user-defined) **cost of electricity /SF x number of square feet**
Annual payroll cost is calculated as follows: (user-defined) **average hourly wage of employees x number of employees x 2080 hours/yr**.

For a comprehensive review of productivity studies, see IFMA Foundation publication "*Applying What Scientists Know About Where and How People Work Best*" http://www.ifma.org/marketplace/store/product-view/applying-what-scientists-know-about-where-and-how-people-work-best-(e-file). The purpose of these calculations is simply to flag credible (conservative) orders of magnitude for wasted energy and the significant financial impact when employees are distracted by noise, are too hot or too cold, are lethargic or unwell from poor air quality, head-achy from glare, unhappy from lack of daylight, and do not have the appropriate spaces for collaboration, concentration, confidential conversation and social cohesive networks.

Green Savings

	Square Feet	Lighting	Plug Load
Elliot	214,000	No Savings	$24,610
Tulsa	325,486	No Savings	$18,550
Dallas	465,211	No Savings	$30,240
LA	121,540	$9,240	$6,930
Tampa	400,000	No Savings	$20,000

Productivity Gains

	# of employees	Acoustics	IAQ	Thermal Comfort	Visual Comfort	Layout
Elliot	1,180	No Savings	No Savings	No Savings	$545,160	No Savings
Tulsa	1,515	No Savings	No Savings	No Savings	$799,920	No Savings
Dallas	1,896	No Savings	No Savings	No Savings	No Savings	No Savings
LA	435	$717,750	$215,330	No Savings	$215,330	No Savings
Tampa	1,418	$1,091,860	$327,560	No Savings	$327,560	$545,930

Figure 5: Excerpt from a G+P portfolio report (Executive Summary)

4. SIMPLE AND USER-FRIENDLY, YET RIGOROUS

Corporate real estate has a growing role in business enterprise for productivity, recruitment, retention, and branding. Smart technologies, employee mobility, the recognition of different workstyles and the importance of wellness – all are important aspects of the workplace of the future. Green + Productive Workplace is an online application for global real estate portfolios that aligns space planning and management, wellness and sustainability with IT, HR, and communications.

G+P illustrates that an assessment can be simple, user-friendly and non-punitive, without being simplistic. To date, some 6 million square feet have undergone G+P assessments. As G+P undergoes pilots by some the world's largest companies – it is becoming clear that the appetite for point-chasing, certification schemes is declining. This is being replaced with a hunger for streamlined, practical, affordable, strategic asset management and benchmarking platforms for portfolios. Large companies want more than just a certification of their trophy real estate assets. They want to address their entire portfolios in a strategic way that meets their needs: to be green, and to address productivity, CSR and sustainable growth.

Session 2.9: Practices & Methodologies for Green Building Management (2)

Green + Smart Buildings

Jiri SKOPEK[a]

[a] *JLL, Canada, jiri.skopek@am.jll.com*

ABSTRACT

'Green' is becoming increasingly synonymous with 'Smart.' There are several reasons for this including: the prevalence of IoT solutions, and the need to ensure that so-called green or high performance buildings will perform to the design or predicted performance once they are up and running. Proper transfer of design information into the operational environment, sophisticated, smart controls and monitoring, and properly trained operational workforce helps to maintain performance and achieve the desired carbon and energy savings.

This paper will examine the typical causes of t building performance slippage and remedies including deployment of ongoing commissioning enabled by big data analysis diagnostics, smart building solutions and appropriate staff training.

Keywords: smart building, green building management, high-performance building, post occupancy evaluation

1. HOW TO ADDRESS THE CARBON PROBLEM

It is well known that in order to combat climate change and keep the temperature rise below 2deg C, we need to cut our carbon emissions approximately by 50% for existing buildings and get to carbon neutrality for new construction by 2030. The various conservation efforts around the world show painfully modest reductions of 10 to 15%, often followed by regression due to the performance slippage. Net-zero buildings and certification schemes such as BREEAM, LEED or Green Globes are laudable; however their overall impact is miniscule. While these provide valuable insights into how buildings impact the environment, they are not effective enough to impact the vast majority of the building stock [1]. Something else needs to be done.

An effective approach to meet the carbon challenge can only come through a combination of measures, supported by technology. We need a robust solution on a large number of buildings, effective monitoring and analytics of building operations, advanced proactive maintenance, well trained building operators, and building owners and corporate Chief Executive Officers (CEOs) who are attuned to the ways that buildings impact both the environment and the productivity of the occupants. This would help them to make the right investment decisions on needed building improvements and ways to engage building occupants. With this, SMART will become synonymous with GREEN.

1.1 How to meet deep reduction targets and combat performance slippage

We are the first generation undergoing the transformation of paper based data into electronic bits - a similar revolution to Gutenberg - yet much of our energy data processing is still based on spreadsheets. Any data analyst will affirm that no data is perfect, but big data analysis can provide sufficient degree of granularity to identify likely trends. The mandatory reporting requirements in several jurisdictions are an example of utility metadata that will make it relatively easier to benchmark and establish reasonable targets.

A novel approach to data analysis, successfully tested in Cambridge, addresses districts (rather than individual buildings) and helps to uncover patterns in the data. Developed by the Department of Urban Studies and Planning jointly with Department of Civil and Environmental Engineering at the Massachusetts Institute of Technology (MIT), an algorithm evaluates buildings' energy consumption performance based on energy bills, building footprint and physical attributes of heat loss. The data then undergoes statistical analysis to establish, at the district scale, the energy consumption/carbon emissions and potential savings [2]. This can then be related to regional, and national goals.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Rather than using a shotgun approach, this results in a clearer understanding of what type and where specific energy and carbon reduction programs would be most effective. (See Figure 1-Representation of the energy saving potential of Cambridge buildings)

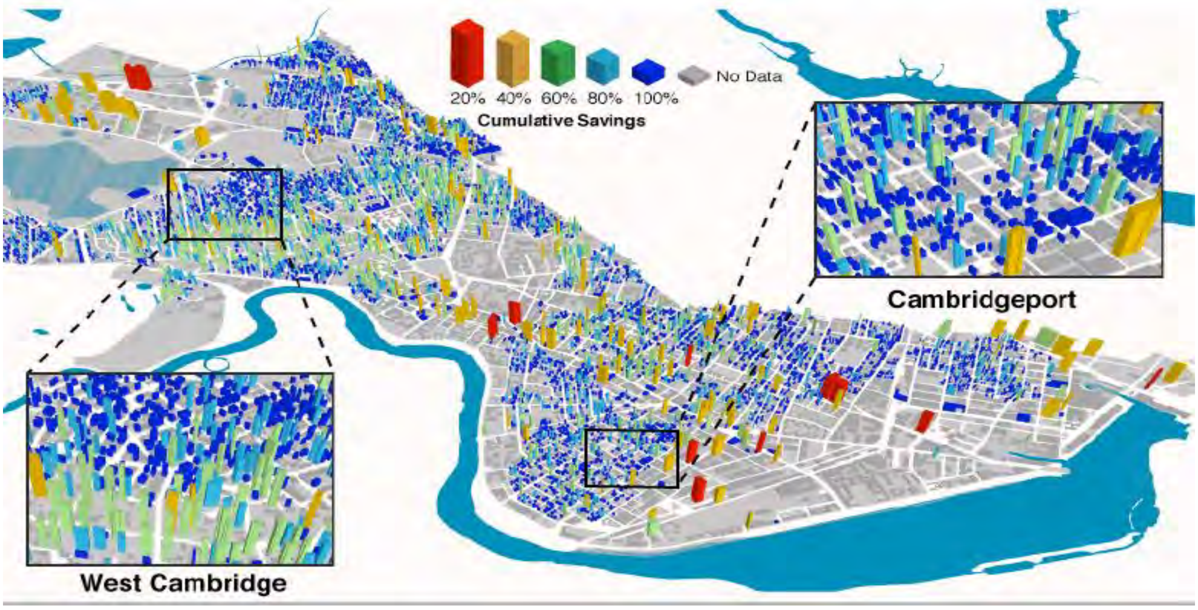

Figure 1: Representation of the energy saving potential of Cambridge buildings

Once areas or buildings with the highest energy improvement potential have been identified, it is much easier to contact the owners of those buildings and discuss with them, one-on-one, their business objectives for those properties. Thousands of energy audits are done each year, yet most of them end up on a shelf with no action taken because they do not fit the organization's business case or investment strategies.

Northwest Energy Efficiency Alliance (NEEA) [3] has identified the barriers to significant progress: First, a lack of understanding of the different drivers depending on whether the decision-maker is a large investor/owner, a Real Estate Investment Trust (REIT), a third party property manager or a smaller independent. Second is the excessive "noise" in the system from service providers, vendors and "helpful" organizations. A third barrier relates to scale. The energy savings gains of individual buildings are often too small to attract the attention of corporate real estate portfolio decision makers.

To achieve results, improvement strategies must be geared to the specific drivers for various types of organizations and decision makers. The building must have a certain business condition such as sufficient long lease with desirable tenants or long ownership pattern to be a good candidate for improvement investment.

1.2 Smart building solutions

Whether a building is new or existing, post occupancy studies [4] indicate what some of the reasons are that buildings are not performing as designed:

- Building occupancy is changing faster than anticipated.
- Building are designed with features that are beyond the capacity and training of the building operations management to use.
- Complex and innovative systems that may require several years to refine and understand.
- Lack of commissioning

Clearly there is a need for greater preparedness of the building operators as well as predictive maintenance or commissioning. Building operators training is of paramount importance. Training courses such as Building Operator Certification® (BOC) give operators the means to run their buildings more efficiently [5].

There are several studies which indicate that commissioning is cost-effective. For example Lawrence Berkeley's "Building Commissioning Golden Opportunity for Reducing Energy Costs and Greenhouse Gas" identifies a 16%

median whole-building energy savings in existing buildings and 13% in new construction, with payback time of 1.1 years and 4.2 years, respectively [6].

Typically issues addressed by commissioning are:

- Equipment running in excess of scheduled operations-overage
- Simultaneous Heating and Cooling
- Economizer Malfunction
- Leaky Valve
- Night Setback
- Morning warm-up
- Space temperature variations
- Optimum Start-up/Stop
- Duct Static Pressure Reset
- Chiller Analysis

The challenge of commissioning or retro commissioning is that it is time consuming and costly. Also, no sooner has retro-commissioning been completed, the building begins to slip out of calibration and savings achieved start to evaporate. Because today's buildings are so complex, even small problems or operational variances can escalate into large performance issues. A typical facility will become 3-5% less efficient every year without intervention. Also, as operations staff try to fix one problem at a time, soon they cannot see the forest for the trees.

This is where smart building solutions can help. Thanks to the diagnostic capabilities of smart buildings, performance optimisation is ongoing. Smart buildings also free the building operator staff from running around trying to catch up with problems, so that instead, they may proactively prepare themselves for the task ahead.

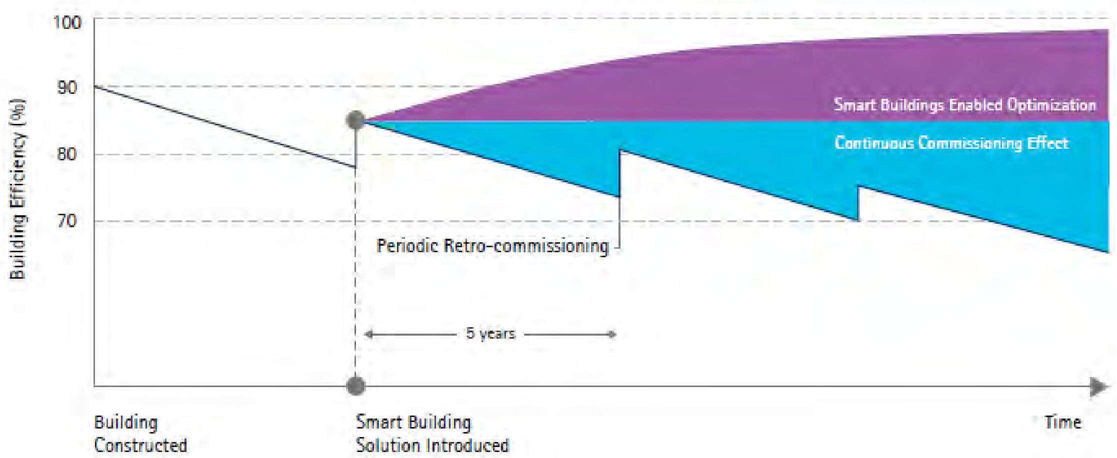

Figure 2: Ongoing, smart commissioning versus a traditional retro-commissioning approach

2. SMART + GREEN BUILDINGS

In one example of a more comprehensive smart building solution, data is collected from buildings of all types: retail, high rise office buildings, industrial or manufacturing, and critical environments such as hospitals or data centres. The extracted data captures the performance of the building systems such as HVAC and lighting, but can be also extend to other systems, such as elevators, security and life safety. The data are pulled from the site to the cloud, where they are analysed through a series of fault detection and diagnostic algorithms and rules engines. This automated analysis is further enhanced by subject matter experts operating 24/7 in a command centre.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

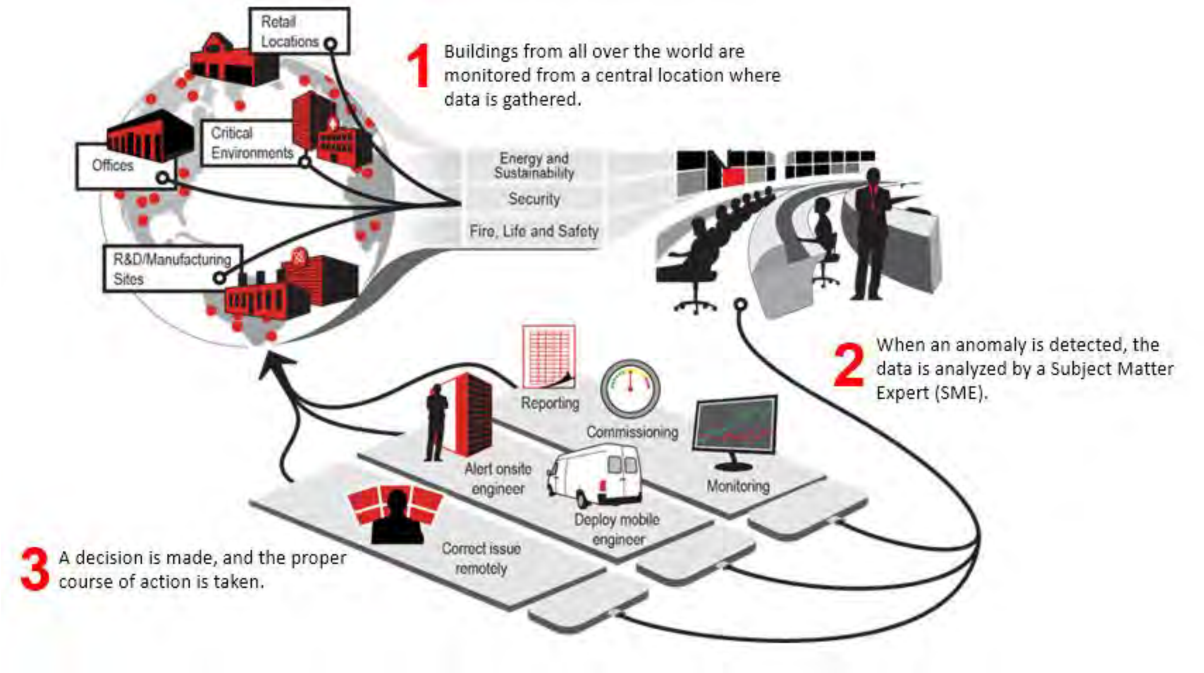

Figure 3: Smart building concept.

Issues and problems are identified and then corrective work orders are dispatched to building operating teams. This process provides building technicians with concrete, actionable intelligence that they can use to reduce energy costs, fix problems before they occur, and keep their properties running smoothly. Finally, these corrections within the building can be independently verified because all the data is available for review. Building engineers no longer need to wonder if they have fixed the problem.

Smart energy monitoring and ongoing commissioning systems already show a great promise. For example Procter & Gamble implemented such a system at four sites, comprising twelve buildings totalling 300, 000 m2 (3 million SF). The project produced combined savings of over $2.8 million in just 11 months (3 months overall ROI) more quickly and decisively than anticipated. Within a year, P&G reduced the facilities' energy costs by 8 to 13 percent, eliminating 4.4 million kWh of energy usage simply by optimizing building processes. In another example, in just three short months, a pharmaceutical company realized 3% reduction in utility cost at their corporate headquarters in New York, using this smart technology. Examples such as these now abound [7].

As mentioned, "smart" is now becoming synonymous with green. With a converged building services network, it is now possible to provide interoperable control systems which not only address the green aspects of the building (energy and water use, HVAC operation and lighting), but also the smart aspects such as connectivity, security and workplace productivity). These buildings are more efficient, easier to operate and maintain and provide a lower overall Total Operating Cost ("TOC").

Continental Automated Buildings Association (CABA) calls these "bright green" [8] - buildings that use both technology and processes to create facilities that are safe, healthy and comfortable, and enable productivity and well-being for occupants. The buildings self–report timely, integrated system information for owners so that they can make intelligent decisions regarding their operation and maintenance. They have an implicit logic that effectively evolves with changing user requirements and technology, ensuring continued and improved intelligent operation, maintenance and optimization. Bright green buildings are designed, constructed, and operated with minimum impact on the environment, and an emphasis on conserving resources, using energy efficiently and creating healthy occupied environments.

The collective impact of smart buildings will be much more noticeable at the district or portfolio scale and eventually at the smart city scale. Such undertakings will not be an easy task and will require an understanding of the business objectives of individual building owners to develop effective drivers, corresponding strategies, incentives and programs for a district.

3. CONCLUSION

To be effective, carbon reduction measures must be done on a larger scale, combining measures such as monitoring and analytics of the building operations, advanced proactive maintenance, well trained building operators, and buy-in from the building owners and corporate Chief Executive Officers (CEOs).

Smart building approach is especially helpful with operational improvements such as performance monitoring and ongoing commissioning. These technologies exist but have not been deployed to their full effect.

Smart and green building technology offers powerful, scalable e-market opportunities, especially in light of improved near-term and long-term trends in technology, finance, regulations and policy. The near-term business case is bolstered not only by the energy savings potential but even more so by workplace productivity gains from the strategic deployment of certain smart and green building features.

Longer-term market changes are already in play. The business environment is ripe for the arrival of consistent, widespread regulatory policies addressing energy efficiency and carbon reduction. Financing mechanisms already exist that can be scaled up for wider smart and green building technology for property owners seeking energy retrofits. Moreover, electricity markets and tenant expectations will continue to shift in favour of smart and green building deployment and ownership. Against a backdrop of energy efficiency and carbon reduction imperatives and emerging technologies, there is market evidence that the profound opportunities for savings will make smart and green buildings an agile and powerful asset class that is strategically aligned with shifting patterns of tenancy and use.

ABSTRACT

The newly established Kai Tak Development Area (KTDA) marks a new era of sustainable urban development in Hong Kong featured by its first-ever District Cooling System for air-conditioning of buildings in the district. The Trade and Industry Tower (TI Tower) is the first office building in this new exemplary district of sustainable urban planning and design. With its strategic location at the gateway to the KTDA, the design of the building is set for demonstration purpose using sustainability as the theme to showcase sustainable building design.

The office building is designed not only to meet the building occupants' needs in respect of comfort, security, safety and operational efficiency, but also to achieve an eco-friendly building following the assessment guidelines set out in the BEAM Plus for New Buildings and LEED for New Construction. The project was bestowed a Grand Award of Green Building Award 2014 by the Hong Kong Green Building Council and is certified to Platinum level under LEED® and provisional Platinum level under BEAM Plus.

This paper introduces the exemplary green building designs of the TI Tower, including extensive greening, passive architectural design and active energy efficient features for maximizing building energy performance, automatic refuse collection system, intelligent building control and monitoring systems, educational provisions for promoting sustainable building design to the public. Property management measures are put in place after completion to ensure that the building is managed, operated and maintained to meet the objectives of its green building designs.

In the course of realizing the green building concepts, the project met various challenges in terms of site constraints, technical feasibility as well as time and budgetary constraints. This paper attempts to sum up the invaluable experiences gained by overcoming the relevant challenges through the collaborative effort of all stakeholders involved in the project.

Keywords: green building, green building management, green construction technology

1. INTRODUCTION

The project is organized into a 20-storey Office Tower, in which all the government offices are located and a separate Community Hall, which accommodates the multi-purpose hall and ancillary facilities.

A conscious target is laid down at the outset to make the project "green" in both aesthetic and performance terms. In the design, soft landscaping is seen to meander from one corner of the site to the opposite, covering the roof of the Community Hall, spreading over to all four elevations of the Office Tower, reaching its roof to form a lush roof garden. The distinctive "Green Ribbon" forms the signature of the building and is clearly discernible from all directions. The aesthetic interest is enhanced by introducing an organic, aerodynamic form – the "White Ribbon" of the Community Hall to contrast the efficient and functional image of the Office Tower. The "Ribbons" combine to conjure up a concept of a "gift" of services from the government to the local community the building serves.

The completed building provides daily service and leisure to the general public, and therefore is an excellent showcase for various green features.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2. GREEN BUILDING CONCEPTS

2.1 Extensive greening

In keeping with the "Green City" concept in Kai Tak Development Area, emphasis of the project has been placed on greening.

An exemplary 42% greening ratio is achieved and over 120 trees are planted with over 40 of them on the office tower roof. Greening wraps around all surfaces of the development in the form of a "Green Ribbon", which symbolically and visually links and unifies spaces at all levels. The visual integration of landscape and greening with adjoining streetscapes is achieved by integrating bounding planting which compliment the selection and character of roadside planting outside the site boundary. A rich variety of open spaces, including at-grade spaces which are visually and physically connected to the ground level streetscapes, spaces at footbridge level with connecting staircase to ground level and break-out spaces on the roof of the office tower, provide a variety of passive recreation opportunities for visitors and users.

2.2 Sustainable building design

Sustainability is identified as one of the main themes of the project. Passive consideration of sustainability begins with the site planning and building layout and extends to the application of various features listed below:

2.2.1 Passive devices

- High performance facade material is selected with a Solar Coefficient (SC) value of 0.26. The glazing material is selected to maximize the amount of natural daylight provided to the building whilst reducing the solar heat gain.
- Solar shading is provided to all facades, providing shading from solar energy and from glare to the facade in the east and west under low angle sun conditions. Optimal application of solar shading also contributes to reduction of OTTV.
- Solar chimneys use solar energy to heat the air inside the 2 nos. of chimneys serving the Community Hall and basement car park, leading the air to become buoyant and driving an upward stack, entraining air in the low zones into the chimney to be extracted from the space. This allows the reduction in the amount of air conditioning and ventilation required to the Community Hall and car park respectively.

2.2.2 Active energy efficient features

- Connection to Kai Tak District Cooling System (DCS) provides the centralized air-conditioning system with a reliable supply of chilled water for building heat rejection. The DCS is over 20% more energy-efficient than a conventional air conditioning system using cooling towers. The connection with the DCS eliminates the building space required for accommodating the conventional heat rejection equipment such as cooling towers, thereby sparing more roof space for photovoltaic panel installation and roof garden. The elimination of evaporative cooling towers is also conducive to the saving of cooling tower make-up water, which is used for compensating for the evaporative water loss and regular water bleed-off. The DCS also eliminates the need of installing chillers in the office building, thereby reducing the total electricity demand as well as the space for accommodating power supply transformers.
- Free Cooling Design is adopted for the entire air-conditioning system so that the conditioned space is served by 100% untreated fresh air when the outside air meets the prescribed air intake conditions. During the free cooling mode of operation, the fresh air supply from PAU is shut off whilst the chilled water supply to the AHU cooling coils is also shut off for the sake of saving energy.
- Improved Specific Fan Powers for all Air Handling Units (AHUs) by reducing the external static pressure by paying careful attention to the pressure drop of ductwork.
- Condensate Recovery System is adopted for collecting the cooling coil condensate water from drip trays of CRAC units and AHUs of each floor to a thermally insulated condensate storage tank via a vertical riser. Condensate water is then pumped to a separate cooling coil of a designated PAU for reducing the DCS chilled water demand of the same PAU.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Heat Recovery Wheels are adopted for all 6 No. of PAUs. Each PAU is equipped with a heat recovery thermal wheel between the supply and return air streams for reclaiming the waste energy from exhaust air and pre-cooling or pre-heating the incoming fresh air.
- Demand Control of PAUs Based on the Indoor CO_2 Concentration Levels and Temperatures facilitate energy saving of the fresh air supply system, especially for indoor spaces with significant variations in the number of occupants. The PAU is equipped with a variable-speed drive for coping with the fluctuations in fresh air demand at different times.
- Active Harmonic Filters of the Electrical Distribution System minimize the electrical energy losses arising from harmonic currents that originate from electronic equipment or components (power switching devices, IT equipment etc.). The Active Harmonic Filters eliminate the undesirable harmonics by using power electronics, reducing the thermal stress induced by harmonic currents and enhancing the efficiency of electrical power distribution.
- Active Power Factor Correction Units of the Electrical Distribution System improve the overall system power factor by counteracting the undesirable effects of electric loads that create a power factor that is less than 1. Power factor improvement is achieved by reducing the reactive component of the supply current by adding capacitors in parallel with the connected inductive load circuits. The inductive effects of an electrical load are cancelled out by the current generated by the capacitors. The power factor improvement enhances the energy performance of electrical distribution system, including the improvement of cables' current-carrying capacities, reduction in electrical power losses as well as increase in the portion of useful electrical energy produced from the electrical energy sources.
- Heat Pump System is used to absorb heat from the return chilled water and pre-heat the hot water tank. This serves as a secondary heat source to the Solar Hot Water Supply System when the installed solar collectors cannot provide the required heat energy for pre-heating the incoming water of the water mains, therefore enhancing the overall energy performance of the Solar Hot Water System. At the same time, the chilled water demand of the air-conditioning system is also reduced.
- Service-on-demand Mode of Operation is adopted for the four escalators at G/F and M/F, whereby passenger proximity sensors are installed at the entrance of each escalator for controlling the ON/ OFF operation of the escalator, thereby contributing to a substantial saving of escalator running energy during the period when there is no passenger traffic.
- Demand Control of Mechanical Ventilation for Basement Carpark based on Indoor CO_2 Level and Temperature is an effective means of minimizing energy consumption of variable-speed exhaust air fans whilst keeping concentrations of indoor pollutants like CO and NO_2 below the ceiling levels by use of gas monitoring devices throughout the carpark.
- LED and T5 Fluorescent Lamps are adopted for the lighting system. Tubular LED lamps are installed at selected part of the office areas whilst LED downlights are provided for lift lobbies, lavatories, pantries and outdoor areas. High efficiency T5 fluorescent lamps are installed in office areas, corridors and plant rooms.
- Energy-efficient Fan and Pump Motors are selected to enhance the energy performance of mechanical, electrical and plumbing systems.
- Variables Speed Drives (VSD) are adopted for all chilled water pumps, AHU and PAU fan motors, lift motors, escalator motors and automatic refuse collection system. The extensive use of VSD boosts the energy performance of electric motors running under part-load conditions.
- Occupancy Sensor Control of VAV Boxes reduces the VAV air flow rate to a preset minimum level so as to minimize wastage of cooling energy when the air-conditioned space is unoccupied.
- Lift Regenerative Power Converters are installed to all of the 18 lifts serving the building. The regenerative energy can be reclaimed under light-load lift ascending and heavy-load lift descending operation modes. When a lift car moves down with a heavy car load or moves up with a light car load, the lift traction motor is driven by the lift car load or the lift system counterweight and, motor braking is necessary to prevent free fall of lift car. The energy generated under the motor braking mode is called the regenerative energy. To harvest such regenerative energy, the lift system is provided with a regenerative energy converter for diverting the regenerative energy to the building's electrical distribution system for use by other electrical loads.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.2.3 Renewable energy

- Photovoltaic (PV) system comprises 189 opaque PV panels at the roof top, 48 see-through thin-film PV (TFPV) panels at main entrance canopy and 96 TFPV panels at 1/F elevated walkway. The entire PV system has an installed capacity of 42kW, helping to offset the amount of electricity provided to the building from the local power grid. The orientation of PV panels is optimized by means of sun path analysis so as to maximize the annual collection of solar energy.
- Solar hot water supply system is equipped with evacuated tube solar collectors, which serve to pre-heat the incoming water for a shower room. This type of solar collectors is compact in size and can maintain a high level of solar energy absorption without the need of separate solar tracking device. The solar heating design can reduce the total energy demand of electrical heating energy when compared with the traditional electric water heating system.

2.2.4 Features reducing reliance of artificial lighting

- 27 nos. of Fixed Light Pipes, 3 nos. of Anidolic Sun Pipes and 6 nos. of Sun-tracking Optic Fibre Sun Pipes are installed to reduce the artificial lighting energy consumption. The locations provided with Light Pipes are mainly interior zones of the office tower and the community hall such as basement carpark, multi-purpose hall, dressing rooms and top floor toilets. Sun Pipes make use of its highly reflective internal surfaces for transmitting sunlight from one end to the other. The Sun-tracking Optic Fibre Light Pipes are designed for maximizing the collection of available sunlight by use of automatic solar tracking devices. Sunlight is transmitted to indoor spaces via optical fibres, which can be routed virtually in any direction to the indoor spaces. The Sun Pipes are connected with photo sensors for facilitating automatic dimming of indoor artificial lighting whenever sunlight is available.
- Adoption of task lighting in office areas also helps to reduce the energy consumption of background lighting, the design illumination level of which is generally reduced from 500 lux to 300 lux, resulting in a Lighting Power Density (LPD) of 8.5 W/m^2, which outperforms the LPD requirements of 15 W/m^2 stipulated in the Building Energy Codes of Hong Kong (2012 Edition).
- Occupancy sensors are used extensively for both inner zones and perimeter zones and daylight sensors for perimeter zones throughout all open plan offices and cellular offices contributes to the effective saving of lighting energy that is otherwise wasted in un-occupied office spaces and in those perimeter zones with adequate daylight above 300 lux.
- Light colour scheme is adopted for indoor furniture and architectural finishes (e.g. partition walls, carpets etc.) so as to improve the indoor light reflectance and indoor illumination level and hence, reducing the lighting energy consumption.
- Computerized Lighting Control System is utilized to control the On/ Off of the lightings according to the pre-determined time zones at working days, Sunday or holidays.

2.2.5 Automatic refuse collection system

The Automatic Refuse Collection System (ARCS) is designed to facilitate effective waste management for the building. In the refuse room on each floor, two refuse disposal outlets are provided at two vertical refuse chutes for transporting solid wastes, one for recyclable paper wastes and the other for general wastes, to two large waste storage bins at the basement. The ARCS facilitates collection of solid wastes in an efficient and hygienic manner. This system also reduces the traffic of service lifts and manpower for refuse collection when compared with the conventional solid waste collection system. Whenever the wastes collected at the bottom section of the vertical refuse chutes reach a certain volume or after a certain time interval, it will be sucked into the respective container for storage and the paper wastes will be collected regularly for recycling purpose.

The ARCS is connected with a vacuum air system for maintaining a negative pressure inside the refuse chutes. The exhaust air from refuse chute is pre-treated by a dust filter and a water scrubber before discharge to the ambient. The ARCS is equipped with a built-in alarm system, which shuts down the entire system automatically in the event of blockage inside vacuum chutes so as to allow subsequent manual clearing of chute blockage. All vacuum chutes are covered with a layer of fire resisting material for minimizing the risk of fire spread through the chutes.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

To achieve efficient operation as well as reduce power losses due to harmonic currents, variable speed drive supplemented with active harmonic filter is provided at the ARCS system local motor control panel.

3. CHALLENGES ENCOUNTERED IN IMPLEMENTATION

The recurring challenge during the design process is to achieve all the design objectives with due respect to the time and cost constraints. Products which are well-proven and commonly available in the market are preferred. Conscious effects were also made in sourcing materials from an 800-km radius from Hong Kong. This would help to reduce the carbon emission caused by transportation of the construction materials.

Selections among different manufacturers are exhausted. For instance, in the selection of the curtain wall glazing, products from no less than 8 glass manufacturers were gathered for on-site inspections before narrowing down to 3 for the full scale visual mock-up. Technical data and visual effects from both directions were thoroughly compared. Bespoke components are thoroughly detailed to ensure practicality in fabrication. In another instance, 6 plant species were kept on site for a full 12-month period to test their growth rate, resilience to weather and ease of maintenance before the optimal species is selected for the Green Ribbon planters.

With the concerted effort from all parties, the project was completed on time and within budget.

4. PROPERTY MANAGEMENT MEASURES

Effective building management measures should be put in place to ensure that the building is managed, operated and maintained to meet the green building design objectives. In this regard, the following objectives have been set in formulating appropriate building management measures:

- To ensure that the green features and facilities function properly;
- To facilitate sustainable development of green management; and
- To promote green features to users.

4.1 Proper functioning of green features and facilities

The building adopts an all-in-one computer software named Central Control Monitoring System (CCMS) for controlling, monitoring and managing all the building operation-related equipment such as lighting, ventilation, air-conditioning, security system, access control, fire services installation, lift and escalator, plumbing system and other engineering system, etc. This useful tool not only facilitates the management party to improve energy performance for a range of building electrical installations and technical services but also ensures proper functioning of green features equipped in the building.

Also, CCMS assists the management party to monitor and record the plant status, environmental condition and energy consumption. With CCMS in place, management party can grasp a comprehensive picture of how well each component is being operated. It also facilitates the fine-tuning and troubleshooting of performance problems. The data provides useful information for further analysis of energy saving plan and formulation of procurement strategy.

4.2 Facilitating sustainable development of green management

To facilitate sustainable development of green technology and management, various house-keeping measures are carried out, including standardising the specified average room temperature of 25.5°C during the summer months and the core air-conditioning hours with a view to maintaining the workplace as a comfortably air-conditioned environment. Other measures including adoption of task lighting, use of installed occupancy sensor and daylight sensor for lighting control, optimising the operating hours of lift services and public lighting, the use of installed timer setting of CCMS to switch off building services installations, etc. are also implemented. Each user department in the building has appointed a Green Manager and an Energy Warden to assist in implementing energy saving house-keeping measures. By means of CCMS, the building management is able to monitor energy consumption of each floor, and review the implementation of the measures and degree of energy saving.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

With respect to air quality, arrangements have been made in the building to achieve "Excellent" class for Indoor Air Quality in 2016. Waste reduction and recycling programmes and floor-to-floor waste separation are also implemented. Data on the quantities of recyclable wastes collected under each category are recorded and reported to the Environment Protection Department periodically.

User's awareness and engagement is also critical to the sustainable development of green management. In addition to distributing green tips and guidelines, management party invited user departments to express their views on the facilities/ installations of the building through Building Management Committee (BMC) which comprises representatives from the user departments in the Tower. BMC meetings are held regularly to discuss, among others, issues on green management and energy saving. Messages on green management and energy saving would also be disseminated to all users in the BMC meetings.

4.3 Promoting green features to users

In order to promote energy efficiency and renewable energy technology as well as public awareness of government's initiatives on greening development, an education path is set-up in the building. Along the path, exhibition panels and signage are placed next to the green features which are accessible by building users and visitors. An interactive display, forming part of the education path is located at 1/F of the Tower, provides a virtual tour of the green features in the aspects of energy, water, indoor environmental quality and material, etc. Guided tours are regularly organised for user departments and the public to introduce and promote green building designs in the building.

5. CONCLUSION

The building projects an image of efficiency, practicality and education. The project demonstrates an exemplary performance of energy efficiency, by aiming to reducing energy consumption by around 27%. The high level of greening combines with the green features would result in a saving of around 36% in carbon emission as compared against the Building Energy Code (BEC) 2007 Baseline model.

The theme of sustainability features prominently on the outside, displaying an iconic "green" image. The green building concepts in the project are conceived from Day 1 through to completion. This principle is used throughout the complicated design process, despite controls of time and budget. The building is also an education tool – for the occupants and the public. The performance goals cannot be met unless the users appreciate them and use the building responsibly. TI Tower is a building to look at, to work in, to be served in, to play in and to learn from.

ABSTRACT

Nigeria is a West African country with a climate classification of a tropical wet and dry climate with three weather conditions namely; warm, humid rainy season and a blistering dry season; with a brief interlude of harmattan in between the two. As such, Green building (GB) designs and constructions in Nigeria must be characterized by features that suit its weather and the environment. GB features include but not limited to the building envelope (BE), Energy efficiency, water Efficiency, Indoor environmental quality (IEQ), Day lighting systems etc. Such features/ components are integrated into the GB for various purposes and functions; as a whole they help solve sustainability issues within the built environment. The BE consists of structural materials and finishes that enclose space, separating inside from outside with a proportionate impact on other green features. The BE design is a specialised area of design and construction engineering practice that draws from many areas of building science and disciplines. With new trends emerging coupled with the shift toward timesaving standardization; this will necessitates mass customization of BE components. BE technology is important first in uniting the industry to overcome some of the factors and challenges that hinder innovation in buildings. The aim of this paper is to examine and assess the impacts of building envelope on other green building features with a view of ascertaining the impacts of the envelope on the GB concept as a whole. Reviewed literatures were used to identify, explore and examine the various green building features, the impact and the relationship of building envelope on such features within the context of Nigeria's built environment. The results showed that Building envelope have a significant impact on green building features such as Energy, Day lighting, Indoor environmental quality and water efficiency systems and strategies.

Keywords: indoor environmental quality, green building management, building envelope, built environment, green features, impacts, Nigeria

1. INTRODUCTION

Nigeria is the most populous African country located in western Africa; a former British colony till October, 1960 when it gained independence. Lagos (a coastal city) was then the capital city till December, 1991 before the seat of power was moved to Abuja within the Federal Capital Territory (FCT) in the same year. Geographically, Nigeria is located in West Africa with the southern part of the country having a long costal line with the Atlantic Ocean and the north with the Sahara Desert. Under Köppen climate classification, it features a tropical wet and dry climate with three weather conditions namely; warm, humid rainy season and a blistering dry season; with a brief interlude of harmattan in between the two (WECSI 2014, demographia.com; and Wikipedia.org). As such, Construction projects in Nigeria's built environment; be it Housing, Industrial engineering, Roads and other civil and infrastructural projects were affected by its weather, location and available construction materials. Like any other construction industry of a developing nation in the world, the industry in Nigeria also pollutes the environment.

These showcased the built environment impact (due to human activity) on resources, that is buildings have a significant impact on the environment, accounting for one-sixth of the world's freshwater withdrawals, one-quarter of its wood harvest, and two-fifths of its material (Eurostat, 2011); 40% primary energy consumption (Bauer et al., 2007). Structures also impact areas beyond their immediate location, affecting the watersheds, air quality, and transportation patterns of communities (Eurostat, 2011). The combination of these challenges gave birth to a new concept in design, construction/ renovation, operation and maintenance of buildings in conformity with sustainable practices known as sustainable/ eco/ high performance/ green buildings (Dalibi, 2014).

It is worthy to note that since the emergence of Sustainable/ eco/ high performance/ green buildings, there were so many attempts to clearly define it, with each Industry and discipline defining it from its own perspective. Below were some definitions:

- Green building (GB) refers to a structure that uses all processes that are environmentally responsible and resource-efficient throughout a building's life-cycle from Siting to Design, Construction, Operation, Maintenance, Renovation and Demolition. This practice expands and complements the classical building design concerns of economy, utility, durability, and comfort (USEPA, 2009).
- Sustainable/ green buildings are those sensitive to the environment, resource and energy consumption, impact on people, financial impact and the world at large. While Zane et al, 2009; referred to the term “Green Building” as environmentally friendly practices from building design to the landscaping choices. It also encompasses energy use, water use, storm-water and wastewater re-use (Greg Kats, 2003).
- According to Dalibi, 2012; Green buildings (GB) are buildings designed, constructed and operated to provide optimum performance of the building with positive impact to the occupants and the environment by combining energy, water efficiency systems, Day Lighting strategies, Indoor Environmental Quality (IEQ) systems and efficient Building Envelope systems.
- The United States environmental protection agency as cited by Vatalisa et al., 2013; opine that “Although new technologies are constantly being developed to complement current practices in creating more sustainable buildings, the common objective is that green buildings are designed to reduce the overall impact of the built environment on human health and the natural environment through the goals of sustainable building such as life cycle assessment (LCA), energy efficiency and renewable energy, water efficiency, environmentally preferable building materials and specifications, waste reduction, toxics reduction, indoor air quality, smart growth and sustainable development, environmentally innovative materials and services
- Another definition by green building (GB) solutions is that: green building design and construction provide an opportunity to use resources more efficiently, while creating healthier and more energy-efficient homes and commercial buildings.
- “Green building (GB) is a holistic concept that starts with the understanding that the built environment can have profound effects, both positive and negative, on the natural environment, as well as the people who inhabit buildings every day. Green building is an effort to amplify the positive and mitigate the negative of these effects throughout the entire life cycle of a building (USGBC 2007).

Thus, from the above definitions, an adequate building envelope system is one of the features of GB. A Building envelope (BE) is the physical separator between the conditioned and unconditioned environment of a building including the resistance to air, water, heat, light, and noise transfer (Cleveland and Morris, 2009 and Syed, 2012). The BE is all of the elements of the outer shell that maintain a dry, heated, or cooled indoor environment and facilitate its climate control. Building envelope design is a specialized area of architectural and engineering practice that draws from all areas of building science and indoor climate control (Syed, 2012).

According to Straube and Burnett (2005), the functions of the BE can be separated into three categories:

- Support (To resist and transfer structural loads),
- Control (The flow of matter and energy of all types),
- Finish (Meeting human desires on the inside and outside).

1.1 Research problem

Over the years, many housing estates were developed by both the Public and the Private sectors or a partnership of both in Nigeria. However, Such Housing estate developments were insufficient in terms of demands; do not reflect the desired housing needs of the end-users; in most cases affordable but not qualitative; do not possess green building features (Dalibi et al., 2016). Though, green building construction practice is a new trend with insufficient data about building performance from currently operating sustainably designed buildings (BD&C 2003; ENSAR 2003; Andreau et al., 2004). It is also evident from some developers'/ clients' attitudes, as they are not fully inclined towards such projects due to lack of comprehensive data about the financial obligations with regards to Incorporating green features into renovation or proposed projects (Dalibi et al., 2016).

Casado (1996) stressed the importance of studying the potential environmental impacts produced by the use of certain building materials with the need to highlight the impact represented by the combination of these materials when used in a certain constructive assembly. Morris (2007); Asserted that "the cost for incorporating sustainable design elements will depend greatly on a wide range of factors, including:

- Building type,
- Project location,
- Local climate,
- Site conditions, and
- The familiarity of the project team with sustainable design.

In most cases, these factors have a relatively small but still noticeable impact on the overall cost of sustainability. Cumulatively, however, they can make quite a difference.

Hence, the need to examine the impact of BE on other GB features based on building type, project location, local climate, site conditions, and the familiarity of the project team with sustainable design; which is further compounded by the perceived synergetic effect of GB features in ensuring sustainability within the construction industry.

1.2 Research aim

The aim of this paper is to review the perceptible impacts of BE on other GB features within the Nigerian and global context with the view of improving the existing literature. Review of literatures in the eco/ green/ sustainable building field helps identify and narrow few environmentally sustainable passive and active elements or features of which the impact of BE will be examined upon.

2. METHODOLOGY

The main sources of data were journals, conference/ seminar/ workshop papers, text books, newspapers, magazines and the internet etc. which were used to review literatures in the green building field which helps identify and narrow few environmentally sustainable passive and active elements within the Nigerian and Global context.

Huedo et al., (2016), opined that environmental assessment of the building assemblies used for the envelope requires a scientifically rigorous methodology such as environmental impact assessment. The life cycle analysis (LCA) is the most suitable because it is an analytical procedure focused on evaluating the whole life cycle. LCA, however, it is an exhaustive, very laborious and complex process that must be carried out by highly skilled professionals and the time needed to apply it is often incompatible with the time available for producing designs. As a result, few life cycle analyses of buildings have been carried out in some countries. In the international context, a wide variety of tools based on the LCA methodology have been developed with the specific aim of aiding the planner in the sustainable selection of building assemblies.

These tools hardly apply outside the countries where they were developed since the environmental impact level caused by building materials and assemblies varies from one territory to another, due to the geographic placement of raw materials extraction and transformation plants in relation to the building location as well as to the possible differences in construction techniques (Mateus and Bragança, 2011).

3. LITERATURE REVIEW

3.1 Building envelope

GB is an integrated building system that encompasses all the efficiency systems (into a single system) for the purpose of sustainability. Sustainable design elements are gradually accepted in the mainstream of GB project design, as the major stakeholders (clients and end-users) are beginning to demand and value those features. It is important to note that, the advanced or innovative sustainable features can add significantly to the cost of a project and that these must be valued independently to ensure that they are cost and or environmentally effective when integrated together. Such elements include energy efficiency systems, water efficiency systems, day lighting systems, indoor environmental quality (IEQ) systems and building envelope systems etc. through the use of sustainable building materials.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The building envelope, also called building enclosure, shell or fabric, is the boundary or physical separator between un-conditioned or conditioned interior of a building and the outdoor environment. Building envelope, consisting of external walls, roofs, ceilings, floors, windows, and doors, regulates the flow of energy between exterior and interior of the building and plays a crucial role of both protecting building occupants from external environment by providing them comfort and by enhancing their productivity. Building envelope also plays a critical role in determining the amount of energy a building will use during its operation. The energy costs associated with the production and transportation and overall environmental life-cycle impacts of different envelope materials vary greatly (IEA, 2013).

Thus, to increase the sustainability of construction it is necessary to consider reducing both the energy consumption and the CO_2 emissions of buildings by improving the building assemblies that make up the building envelope. This envelope has to guarantee the quality of the environment inside the building, since the exchange between the inner and outer environment takes place through it. It is also the point where illumination, ventilation or heat flows act as fundamental design parameters (Haapio and Viitaniemi, 2008).

The use of materials and construction technique in building envelope widely differs between developed countries like Europe, USA, and developing countries especially those within the tropics (IEA, 2013). In almost all parts of the world, buildings used to be constructed using local materials to maximize comfort considering local climate. In warm-humid areas larger openings were provided in the buildings for natural ventilation for cooling etc. But, due to modernization and faster urbanization rate, the force of market economy and electronic media along with a change in socio-cultural outlook have made people accepting the gradual change in the building design and construction materials even in remote rural and semi-urban places (Sarkar, 2015a).

Present day construction practices utilize modern standardized building materials and construction methods that dominate the market in the country (Sarkar, 2015a and Sarkar, 2015b). Local climate and function of the building are the two foremost important parameters affecting building envelope design. The thermal loads of residential buildings are primarily external (from sun). The efficiency of building envelope design is significantly affected by the building configuration and foot print also (ibid).

3.2 Envelope and other GB features

Green building elements and features considered in this work as cited by Dalibi (2016), and also based on US EPA 2009; Gregg Kats 2003; Zane et al, 2009, Dalibi, 2012; Vatalisa et al., 2013; greenbuildingsolutions.com; USGBC 2007; include (but not limited to) the following; energy efficiency systems, water efficiency systems, day lighting systems, indoor environmental quality (IEQ) systems and the building envelope systems.

As such, the perceptible impacts of building envelope (BE) in this work also will be based on the following features and their sub-components:

- Energy efficiency systems,
- Water efficiency systems,
- Day lighting systems,
- Indoor environmental quality (IEQ) systems,

3.3 Impact of BE on green building energy efficiency system

Buildings are responsible for more than one third of the total energy use and associated greenhouse gas emissions, both in developed and developing countries (UNEP, 2014). Buildings consume a lot of energy all around the world and are responsible for high environmental pollution. However, the main focus is also put on new construction technologies to assure low energy needs of new buildings (Chwieduk, 2016).

Nowadays building envelopes are designed and constructed according to energy saving measures, with high quality of thermal insulation and high thermal capacity of construction elements. Heat flow through opaque external walls has been reduced significantly, and it takes a minor part of the total energy transport between the outdoor and indoor environment. The influence of solar radiation passing through glazing on the heat balance of a building is especially evident in new low energy buildings with high thermal resistance envelopes (ibid).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

It is necessary to be able to establish relationships between these impacts and those produced throughout the lifespan of the building, due to both the actual materials used and the energy consumption linked to the building assemblies employed in the building envelope (Huedo et al., 2016). Residential and commercial buildings consume approximately 60% of the world's electricity (www.isi.fraunhofer.de; 2012) in Europe, the residential sector requires 27% of the total energy and it contributes proportionally to the emission of CO_2 (Nejat et al., 2015). Some studies show the impact of energy efficiency measures related to refrigerators, washing machines, air conditioners, televisions and heating and cooling service (Montejo and Pardo 2016; Arto et al., 2016).

Huang and Hwang (2015) studies of residential apartments in Taipei, have observed that cooling demand could increase of 31%, 59%, and 82% over current levels respectively for the 2020s, 2050s, and 2080s. Thus, they have underlined an urgent need to regulate the excessive use of cooling systems, also by remodelling existing buildings with passive design measures. Discussions and new solutions for energy efficiency in building sector are thus indisputable (Huang and Hwang 2015).

By using water piping system, the exterior to interior heat transmission can be reduced, which results in interior thermal comfort and reduced energy consumption by air conditioners. The heated water in the piping system is stored in an insulated water tank and is used for domestic hot water to save energy. Integrating a solar thermal plant with the building envelope reduces the high cost of electric grids, but also generates the electric power by buildings demand. (http://australia.energy.com, n.d.).

3.4 Impact of BE on green building water efficiency system

Demand in every area of water use in urban, industrial, and agricultural has increased, often because of mismanagement, overuse, and waste. This clearly indicates that mismanagement, overuse, and waste of water in buildings is a strong issue that needs proper and lasting solution in order to be water efficient (Gottfried, 1996).

In the average household, 68% of drinking water is used for washing and toilet flushing. Laundry and dishwashing actions account for another 19%. The remaining water volume is used for drinking and cooking and also for garden watering and cleaning (Bauer and Schwarz, 2007). As such, Water efficiency in green buildings can be achieved through the combination of the following: systematic rainwater utilization, water conserving appliances, grey water and black water systems

- Rain water use: Systematic rainwater utilization reduces drinking water consumption by about half. Rainwater can be used for flushing, washing and cleaning, as well as for watering the garden. This requires a rainwater tanks and additional piping system.
- Water conserving appliances and technologies: Effective ways to reduce water use include installing flow restrictors and/ or reduced flow aerators on lavatory, sink, and shower fixtures; installing and maintaining automatic faucet/ tap sensors and metering controls; installing low-consumption flush fixtures, such as high-efficiency water closets and urinals; installing non-water fixtures.
- Grey water and black water systems: Grey water is the waste water from households, stemming from shower, bathtub, bathroom sink and the washing machine and which, hence, is not contaminated with faeces or highly polluted kitchen waste water (black water). It only contains a moderate amount of soap residue and skin oil. The average household produces about 60 liters of grey water per day, per person. This type of water can be processed into usable water, which is safe from a hygienic point of view but does not have the same quality as drinking water. It can be used for toilet flushing, watering and cleaning purposes. This means, in effect, that drinking water is then being used twice.

3.5 Impact of BE on green building day lighting efficiency system

Day lighting is the practice of bringing light into a building interior and distributing it in a way that provides more desirable and better-quality illumination than artificial light sources, reduces electricity use and its associated costs and pollution and creates healthier and more stimulating work environments than artificial lighting systems and can increase productivity up to 15 Percent (Romm and Browning, 1994).

Day lighting significantly reduces energy consumption and operating costs. Energy used for lighting in buildings can account for 40 to 50 Percent of total energy consumption. In addition, the added space-cooling loads that

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

result from waste heat generated by lights can amount to three to five percent of total energy use. Properly designed and implemented day lighting strategies can save 50 to 80 percent of lighting energy. Greater use of day lighting can also provide advantages for the environment by reducing power demand and the related pollution and waste by-products from power production. The greatest savings from day lighting occur during periods when sunlight is most intense, which coincides with periods of peak demand for heating, ventilating, and air-conditioning (HVAC) and refrigeration loads. Therefore, wider use of day lighting would reduce both the need for new peak demand capacity and overall power demand (Andersen windows 1993; Romm and Browning, 1994; Gottfried and Simon, 1996).

Day lighting requires the correct placement of openings, or apertures, in the building envelope to allow light penetration while providing adequate distribution and diffusion of the light. A well-designed system avoids excessive thermal gains and excessive brightness resulting from direct sunlight, which can impair vision and cause discomfort. To control excessive brightness or contrast, windows are often equipped with additional elements such as shades, blinds, and light shelves. In most cases, the day lighting system should also include controls that dim or turn off lights when sufficient natural light is available to maintain desired lighting levels. It is also often desirable to integrate day lighting systems with the artificial lighting system to maintain required task or ambient illumination while maximizing the amount of lighting energy saved. Recent day lighting innovations offer a wide range of advanced, highly efficient, and, in some cases, highly engineered systems. In reviewing these options, the practitioner should recognize that higher efficiency and improved day lighting performance may entail additional costs. The benefits of day lighting include improved visual quality, better lighting-colour rendition, reduced solar heat gain, and improved visual performance and productivity. These benefits can make any increased engineering and installation which costs a worthwhile investment for the building owner or employer (ibid).

The following include some of the day lighting strategies:

- Side lighting (Clerestories in form of windows etc.)
- Top lighting (Saw tooth, stepped monitored etc.)
- Sky lights (Horizontal openings in roof etc.)

New glazing technologies are also in use in green buildings which include:

- Spectral glazing materials
- Switch-able glazing materials
    - Photo-chromic glass
    - Thermo-chromic glass
    - Electro-chromic glass
    - Liquid crystal (LCD)

3.6 Impact of BE on green building indoor environmental quality (IEQ) system

People spend up to 90% of their time indoors, increasing their chances of exposure to pollutants and other indoor environmental stressors including noise, glare and uncomfortable temperatures (USGBC, 2007; WHO 2013).

The process or act of making the link between potential sources of pollution or discomfort and actual health and performance effects are very challenging tasks, involving the interaction of a complex array of variables within the building indoor. First, indoor pollutants may arise from many sources, indoor or outdoor, and may have chemical, biological, gaseous and/ or particulate elements. Second, these pollutants interact with a range of indoor conditions including varying levels of temperature, humidity, ventilation and occupant behavior. Third, levels of occupant exposure to indoor pollutants or stressors will vary based on circumstances, and actual physical reactions will vary not only by pollutant and its level but also by characteristics of the occupant.

The concept of Indoor Environmental Quality (IEQ) in green buildings is broad and complex because it encompasses a lot of design and construction factors. Such factors include but not limited to:

- Indoor air quality
- Thermal comfort (Heating, cooling and ventilation etc.)

- Lighting (Both electric lighting and day lighting)
- Acoustics etc.

It also includes access to views of the outdoors and all other factors affecting the full range of human sensory conditions inside the buildings.

4. ANALYSES, SUMMARY AND CONCLUSION

From above literature reviewed, it can be observed that any GB is an integrated building system where all the elements/ features impact each other in terms of functionality, usability, fitting and or assemblage. However, among the major elements/ features of GB identified in this paper were energy efficiency systems, water efficiency systems, day lighting systems, indoor environmental quality (IEQ) systems, the building envelope (BE) systems. The main focus here is the impact of BE on other features because it serve as the enclosure/ shell/ barrier between the exterior and the interior of any GB.

Several studies conducted reveal the impact of BE on other GB features summarised as follows:

- Energy efficiency system: The BE help in retaining the conditioning inside the GB while also preventing the outside weather condition coming inside. It also allows integrating and fixing of renewable sources of energy within its system. e.g. solar panels etc.
- Water efficiency system: The BE can incorporate additional piping works for grey and black water systems, so also the any additional tank and pipe works required for effective utilization of rainwater.
- Day lighting: The type and positioning of clerestories and glazing choices within the BE system highlights the high impact of BE on the day lighting system and strategies.
- Indoor environmental quality (IEQ): This encompasses indoor air quality, thermal comfort (heating, cooling and ventilation etc.), lighting (both electric lighting and day lighting), acoustics etc. Without an adequate BE system all the four subcomponents of IEQ will not be achieved. The control function of BE improves the indoor air quality, thermal comfort, lighting (especially day lighting) and acoustics within a building.

At this juncture, it is worthy to note that adequate BE system impact other GB features due to: the use of materials and construction technique in building envelope, it is also the point where illumination, ventilation or heat flows while also enclosing and separating the un-conditioned or conditioned interior of a building and the outdoor environment.

5. RECOMMENDATION

There is need for an in depth further study of:

- BE on each GB element/ feature over a long span of time to ascertain the actual impact of BE.
- BE impact based on the perception of professionals and other stakeholders
- Other green building features/ components/ elements should also be considered and researched on, so as to expose how they interact with each other.

ABSTRACT

Green building construction sector has achieved a rapid development over the past two decades owing to an increasing global recognition for its environmental benefits. However, very limited research effort was made to investigate the safety performance in green building construction projects. This study aims to identify and assess the critical safety performance factors in green building construction projects in Singapore. To achieve these objectives, a comprehensive literature review and three preliminary interviews were carried out, followed by a questionnaire survey conducted with 30 Singapore-based construction companies. The survey results showed that the top five critical safety performance factors are "safe operation of construction equipment," "proper and effective two ways communication between the management and workers," "management commitment towards safety," "provision of personal protective equipment," and "establishing a comprehensive companywide safety policy." This study contributes to the body of knowledge by exploring the critical safety performance factors in green building construction projects. The findings from this study can also help develop more effective strategies to improve the safety performance in green building construction projects.

Keywords: critical safety performance factor, green building construction projects, Singapore

1. INTRODUCTION

Based on a worldwide recognition for its efficacy of saving energy and resources consumption, green buildings have gained a remarkable momentum in numerous countries recently, and one typical representative is Singapore (Hwang et al., 2015). Singapore is a densely populated city-state with limited areas and resources, making green building a necessity rather than an option for this country (Agarwal et al., 2016). In 2005, the Singapore Government embarked on the green building movement by launching the Building and Construction Authority (BCA) Green Mark scheme. Since then, this country has advanced three rounds of Green Building Masterplans successively (i.e., Masterplans of 2006, 2009, and 2014) to promote the development of green buildings (BCA, 2014). Motivated by this comprehensive suite of schemes and plans, green buildings in Singapore have achieved a rapid development recently, and the number of green buildings in Singapore grew exponentially, from 17 in 2005 to over 2100 in 2014, which was equivalent to 25 percent of the total built-up area in the country (BCA, 2014).

According to the Workplace Safety Health Council (WSHC, 2014), construction, marine, and manufacturing, have been assessed as the top three unsafe industries in Singapore. The numbers of workplace minor, major, and fatal injuries in the Singaporean construction industry increased significantly from 1718, 133, and 22 in 2011 to 2686, 202, and 27 in 2014, respectively (WSHC, 2012, 2013, 2014). Moreover, the local construction industry has been accounting for the largest proportion of workplace fatalities in this country continuously since 2006 (WSHC, 2014). All these statistics show that construction safety remains a significant concern to Singapore.

Given the grave situation of construction safety in Singapore, and the fact that numerous green building projects are under construction in this country, it could be inferable that the safety situation in the green building construction industry of Singapore should be stressful. Nonetheless, current literature reveals that few studies have addressed the safety issues in green building construction projects. Therefore, this study attempted to bridge this knowledge gap by identifying and assessing the critical safety performance factors in green building construction projects in Singapore. This study contributes to the body of knowledge by exploring the critical safety performance factors in green building construction projects. This study is also beneficial to the industry as its findings can help the practitioners develop more effective strategies to improve their safety performances.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2. BACKGROUND

2.1 Green buildings

Green buildings are a particular type of building designed for optimum energy efficiency and constructed with a preference for natural, reclaimed and recycled materials (Hwang & Ng, 2013). These buildings provide healthier, more comfortable and productive indoor environments for occupants by maximizing the efficient usage of resources like energy, water and raw materials (Hwang & Leong, 2013). The American Society of Testing and Material (ASTM, 2009) maintained that green buildings provided the specified building performance requirements while minimizing disturbance and improving the function of local, regional, and global ecosystems throughout its entire building life cycle. Burnett (2007) described that the ideal green building should have five major features: integration with local ecosystems; closed-loop material systems; maximum use of passive design and renewable energy; optimization of building hydrologic cycles; and full implementation of indoor environmental quality measures.

2.2 Safety concerns in green building construction projects

Compared to traditional building construction projects, green building construction projects seemed to have imposed a higher safety risk to the workers. Walter (2011) stated that construction projects that were built to achieve Leadership in Energy and Environmental Design (LEED) certification accounted for a higher recorded injury rate than non-LEED buildings. Dewlaney et al. (2011) found that, compared to those on non-LEED projects, workers on LEED projects were subject to a 36 percent increase in laceration, strains, and sprains from recycling construction materials; a 24 percent increase in falls to lower level during roof work because of the installation of on-site renewable energy (e.g., photovoltaic panels); and a 14 percent increase in exposure to harmful substances when installing innovative wastewater technologies. Fortunato et al. (2011) expressed the similar concerns because their cases studies also showed that workers on LEED construction projects were exposed to work at height, with electrical current, near unstable soils, and near heavy equipment for a greater period of time than workers on traditional projects. The grave safety situation above implies that more efforts should be put in tackling safety issues in green building construction projects to improve their safety performances.

3. METHODOLOGY AND DATA COLLECTION

Despite the grave situation of safety in green building construction projects, few studies have examined the critical safety performance factors in such projects. Fortunately, studies that investigated safety performance factors in traditional building construction projects were abundant, which could provide solid support for this study. Based on a comprehensive literature review (e.g., Sawacha et al., 1999; Jannadi & Bu-Khamsin, 2002; Siu et al., 2003; Choudhry et al., 2008; Ulubeyli et al., 2014; Zhou et al., 2015), 39 factors that affect the safety performances in traditional building construction projects were identified. However, these traditional project related factors might have an issue of compatibility with the context of green building construction projects in Singapore. Thus, this study conducted interviews with three experienced industry experts to refine these 39 identified factors within the context of green building construction projects in Singapore. Finally, a total of 35 safety performance factors were finalized, as listed in Table 1.

Based on the results of the interviews, a questionnaire was developed and then disseminated to 102 BCA certified companies in October and November 2014. The questionnaire included the questions meant to profile the companies and respondents, and the questions meant to evaluate the significance of each safety performance factor using a five-point rating scale (i.e., 1 = least important, 2 = somewhat important, 3 = neutral, 4 = important, and 5 = most important). The survey received valid responses from 30 companies, yielding a response rate of 29 percent, which was consistent with the norm of 20 to 30 percent with most questionnaire surveys in the construction industry (Akintoye, 2000). The collected replies were from various construction-related organizations including 20 contractors, four consultant firms, three private developers, and three quantity surveyors. As for the respondents, 57 percent of them had at least three years of experience in undertaking green building construction projects, and 63 percent of them were holding top-level management positions like project director and project manager. Thus, obviously the respondents had sufficient knowledge and experience to address the research questions of this study. In addition, two statistical methods, namely, the Cronbach's alpha and one sample t-test, were used to analyse the data collected from the questionnaire survey. The Cronbach's alpha was employed to measure the internal

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

consistency or reliability of the data, while the one sample t-test was used to check whether each safety performance factor has significant impact on safety performance in green building construction projects.

4. RESULTS AND DISCUSSIONS

Data collected from the questionnaire were input SPSS Statistics 17.0 to perform the analysis, and the evaluation results as well as the relevant statistical analysis results were presented in Table 1. In this study, the Cronbach's alpha value of safety performance factors was 0.806, which was higher than the minimum threshold of 0.7 (Nunnally et al., 1967). Thus, the collected data were reliable. In addition, the mean values of all safety performance factors were statistically greater than 3, which was the test value of the one sample t-test. Thus, all the safety performance factors had significant influence on the safety performances in green building construction projects. It could be noted from Table 1 that the top five critical safety performance factors were "safe operation of construction equipment," "proper and effective two ways communication between the management and workers," "management commitment towards safety," "provision of personal protective equipment (PPE)," and "establishing a comprehensive companywide safety policy."

No.	Safety performance factors	Mean	Rank	Std. Dev.	p-value
1	Safety uncertainty	4.43	7	0.57	0.00*
2	Employee commitment/ participation towards safety	4.40	8	0.50	0.00*
3	Provision of safety training & seminar	4.30	15	0.60	0.00*
4	Reckless human behaviour / operations	4.37	11	0.49	0.00*
5	Knowledge of safety system	4.37	12	0.49	0.00*
6	Self-esteem	3.87	32	0.63	0.00*

Table 1: Evaluation results of safety performance factors in green building construction projects

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

"Safe operation of construction equipment" was regarded as the top critical safety performance factor with the highest value of 4.60. Construction equipment are heavy machineries and vehicles that are used for executing construction operations. Construction equipment are also known as heavy machinery, which are used to perform construction tasks such as excavation, lifting, material handling, drilling, hauling, excavating, paving and grading. As for green building construction projects, there are numerous green featured construction tasks (e.g., constructing atria and installing green roofs, and photovoltaic panels) that must be completed with the assistance of construction equipment (Fortunato III et al. 2012). The improper operation of those construction equipment (e.g., cranes and loaders) can impose significant safety risks to the frontline workers and might incur serious injuries (e.g., caught-in injuries and struck-by or against injuries) to them. Thus, the respondents assessed the safe operation of construction equipment as the most critical safety performance factor in green building construction projects. Dewlaney et al. (2012) also emphasized that the proper operation of construction equipment was extremely important to improve the safety performance in those green building construction projects.

"Proper and effective two ways safety communications between the management and workers" was ranked second with a mean value of 4.57. Safety communication mainly refers to the extent, frequency, and effectiveness of the information exchanged on safety issues between the management and workers (Jiang et al., 2015), and effective and proper safety communication could increase the workers' safety awareness and knowledge and thus improve the project safety performance significantly. Safety communications are more crucial to green building construction projects than to traditional building construction projects. This is because green building construction projects always adopt innovative and complicated green construction methods that might bring in some special safety regulations. With the aid of the proper and effective two ways safety communications, the site supervisor can inform the workers all the special safety regulations that must be complied with; while the workers can also have proper channels to report to the management about those hazards omitted by the manuals but existing in reality.

"Management commitment towards safety" was assessed as the third most critical safety performance factor in green building construction projects. "Management commitment towards safety" mainly refers to a bunch of commitments made by the management, such as the promise of achieving a high standard of occupational safety and health management for the project implementation, providing adequate resources to implement the safety policies, and ensuring the understanding and execution of safety measures at all levels in the organization. Safety commitments play a vital role in improving safety performance of building construction projects (Demirkesen & Arditi, 2015; Shen et al., 2015), and they are even more crucial to green building construction projects than to traditional ones. This is because normally the management pay so much attention to the sustainability performance of green building construction projects that they may neglect the safety performance of in these projects, while the safety commitments from the management can increase the practitioners' awareness of construction safety, restrain them from conducting unsafe operations, and thus improve the safety performance in green building construction projects eventually.

"Provision of personal protective equipment (PPE)" was ranked fourth with a mean value of 4.53. Nowadays, the construction industry has developed an integrated set of PPE to protect the frontline workers from any potential safety hazard. These PPE includes wearing safety helmets, safety shoes, and safety gloves, wearing hearing protection in noisy environments, putting on goggles or eye protectors while doing welding, wearing respirators in dusty conditions, using breathing apparatus when working in confined spaces, putting on a safety harness when working at height, and wearing a reflective vest where good visibility was required (Choudhry, 2014). PPE is even more critical to workers those working on green building construction projects because they are exposed to the toxic substances, work at height, with electrical current, near unstable soils, and near heavy equipment for a greater period of time than those working on traditional projects (Fortunato et al., 2011). Currently, provision of proper PPE has been included into many green rating systems (e.g., Green Rating for Integrated Habitat Assessment, India)(Pearce & Kleiner, 2013), indicating that its importance has been widely recognized by the authority and the industry.

"Establishing a comprehensive companywide safety policy" was considered to be the fifth most critical safety performance factor in green building construction projects. A safety policy of a construction company is a recognized written statement that states the company's commitment to the protection of the health and safety of the employees. It shows the details of all occupational health and safety elements with the policy to protect the employees' life and health, and the relevant forms include the safety standard, safety regulations, safety procedures, and even the safety incentive programs (Choudhry et al., 2008). Establishing a comprehensive companywide safety policy is extremely important to those organizations working on green building construction projects. This is because can only a comprehensive safety policy cover all those special, hidden, and unexpected safety hazards brought by the green building construction projects. In addition, a comprehensive safety policy can raise the employees' awareness of safety and health and provide information and instructions to them on the relevant safety regulations and good work practices. Park and Tae (2016) also reached the similar conclusion that an integrated safety policy was crucial to the safety performance in green building construction projects.

5. CONCLUSIONS AND RECOMMENDATIONS

Owing to an increasing recognition for the environmental benefits brought by the green buildings, there has been a significant growth in green building construction worldwide over the recent years. Nevertheless, minimal research effort has been devoted to examine the safety issues in green building construction projects. This study attempted to make a preliminary investigation of safety performance factors in green building construction projects. Facilitated by a series of qualitative and quantitative research methods such as literature review, structured interviews, and questionnaire survey, this study identified and evaluated 35 safety performance factors in green building construction projects. Results showed that the top five critical safety performance factors were "safe operation of construction equipment," "proper and effective two ways communication between the management and workers," "management commitment towards safety," "provision of personal protective equipment," and "establishing a comprehensive companywide safety policy." The findings from this study have presented a general view on the critical factors that affect safety performance in green building projects, which can also help develop more effective strategies to improve the safety performance in such projects. Future studies could be conducted to investigate the interrelationships among these critical safety performance factors in green building construction projects. Also, it would be interesting to compare the safety performance factors between the green and traditional building construction projects.

ABSTRACT

Architectural Services Department (ArchSD) supports the Government's role to promote low carbon buildings in Hong Kong and at the same time to share the good practices in our green building projects with the building industry. A holistic integrated approach from design to construction and then maintenance is adopted.

To demonstrate the good practice of sustainable project delivery at interior space, this paper introduces two renovation projects in which sustainable and sensible solutions have been implemented. They are the renovation of 1/F Main Block of APB Centre and the renovation of the 10/F Government Logistics Centre (GLC) into an administration office as part of the relocation project of the Printing Workshop for the Government Logistics Department (GLD).

APB Centre is a government building and ArchSD is the premises user. The renovation project at APB Centre was to transform the storage area at 1/F into a green workplace to demonstrate the good practice in achieving low carbon, healthy and modern indoor environment. GLD's Printing Workshop relocation project involved the refurbishment and alteration works of 3 floors of the GLC at Chai Wan to accommodate the printing machineries and office accommodation. The renovation works at 10/F has transformed the existing space into an administration office of the Printing Workshop with green and pleasant environment for the staff. Sustainable design in both projects was achieved through energy efficient air-conditioning and lighting design, sustainable materials selection, excellent indoor environmental quality, etc. In APB Centre project, an innovative radiant cooling system was also employed for the open office areas. Both projects have achieved Platinum ratings under the BEAM Plus Interiors accreditation and, in particular, the renovated 1/F Main Block of APB Centre is the first government office in Hong Kong achieving the Platinum Rating under this assessment system launched in September 2013.

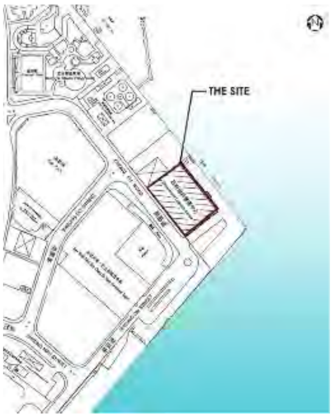
6. INTRODUCTION

This paper introduces two renovation projects, commissioned by Architectural Services Department (ArchSD), in which sustainable and green features and practices have been implemented. They are "the renovation of 1/F Main Block of APB Centre" and "the renovation of the 10/F Government Logistics Centre (GLC) into an administration office". Both projects have achieved the BEAM-Plus Interiors Version 1.0 Final Platinum.

Site Plan

Renovated office area

The new ArchSD office transformed from an existing store is located on 1/F Main Block, APB Centre, Hunghom. It has an internal floor area of around 800m² accommodating about 100 staff. The renovation was completed in March 2015 and successfully demonstrated the feasibility of practice of a sustainable office renovation.



Government Logistics Centre *Reception*

The refurbishment of the 10/F GLC is part of the relocation project of the Printing Workshop for Government Logistics Department (GLD). The refurbishment work has transformed the once unattractive space into a green and lively contemporary office for the Printing Division of GLD. The refurbished area is about 930 m^2 which mainly consists of open plan office, cellular offices, conference room, reception and balcony.

7. KEY FEATURES OF THE RENOVATION OF 1/F MAIN BLOCK OF APB CENTRE

The renovation project adopted a holistic approach on sustainable design, green construction, environmental friendly operation and maintenance to transform an existing office premises to a green workplace. Almost all furniture, partitions and electrical appliances in the new office were reused from the existing office to minimize purchasing of new items. Sustainable and innovative design strategies, such as radiant cooling system, indirect LED lighting, automatic control for building systems, water efficient fixtures, sustainable materials and flexible layout were integrated to create a low carbon, green, healthy and modern indoor environment to the office occupants.

The sustainable design features including interior space design, interior green wall, sustainable materials selection and energy efficiency features are described below:

3 Feature 1 – Sustainable materials

More than 97% of the furniture and partitions in the new office were relocated from the existing office and more than 80% of newly installed materials were from sustainable sources. The new office adopted bamboo for the wall covering (photo below refers) and skirting. Bamboo is a well-known rapidly renewable material having a harvest cycle of less than 10 years. The raised floor system (photo below refers) and carpet were made of recycled materials in the manufacturing process and the doors were made of sustainable timber.

Bamboo wall panel *Raised floor system and carpet were made of recycled materials*

The project also planned for the reuse of building materials at the end of life cycle of the office. All newly installed elements are in modular design and easily disassembled in the next renovation for potential reuse.

4 Feature 2 – Waste management from demolition to operation

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

In demolition stage, the demolished concrete was reused in another ArchSD site, as the filling materials. In construction stage, recyclables were sorted and stored properly in the designated area to facilitate recycling from time to time. Over 98% of the demolition and construction waste (C&D waste) from the renovation work was recycled. In operation stage, several types of recyclables, including Paper, Metal, Plastic, Glass and Rechargeable Batteries are provided.

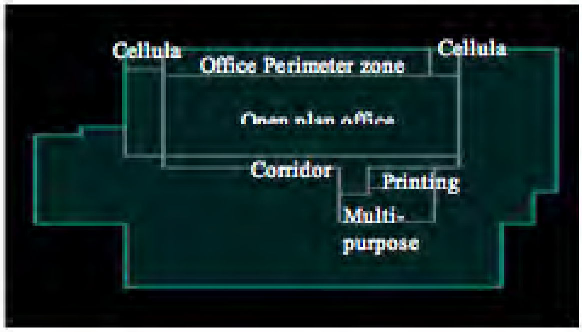
Demolished concrete was used in another site as filling materials

Recycle collection bins in the new office

5 Feature 3 – Energy

Energy Conservation Measures are applied in this project. The building automation control such as occupancy sensors are installed in the open plan office to turn off the lighting and air-conditioning system after office hours and daylight sensors are installed within 5 metres from the perimeter zones for dimming control, both helping reduce energy consumption in the office.

Occupancy sensors for lighting system

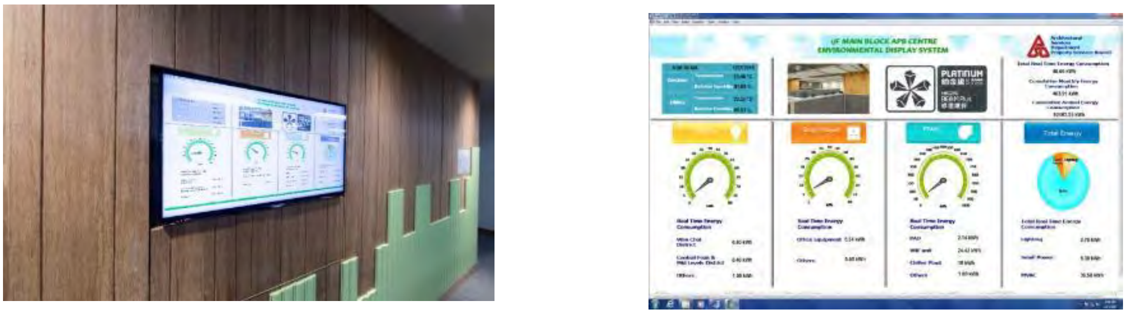


Energy model for the new office

Energy simulation for the baseline building was conducted by the software – eQUEST 3.64, which is a sophisticated building energy use analysis tool that provides professional results. eQUEST has all capabilities described in Appendix A – Building Energy Analysis of Code of Practice for Energy Efficiency of Building Services Installation 2012 Revision 1 (BEC 2012). The baseline building in this project's energy simulation runs used the assumptions and modelling methodology described in BEC 2012 with its addendum.

The predicted baseline annual energy consumption and carbon emissions of the office are 156.5 kWh/m^2 and 101.0 tonne CO_2 respectively.

The real time energy consumption of the office is monitored by the energy meters, temperature sensors and flow meters. The data are feedback to Building Management System (BMS). The real time consumption is transmitted to the environmental display system at the entrance of the office (photo below refers).



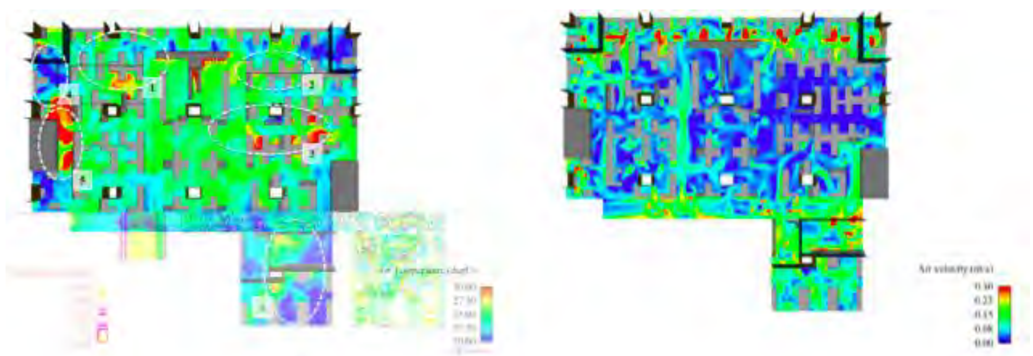
Real time environmental display system

The actual annual operating energy consumption and carbon emissions of the office in the previous year (Apr 2015 to Mar 2016) were 141.8 kWh/m^2 and 91.2 tonne CO_2 respectively. Therefore, the actual energy consumption is reduced by around 9% from the BEC2012 baseline.

Annual office energy consumption

6 Feature 4 – Indoor environmental quality (IEQ)

To analyse the distribution of indoor air temperature and air speed and evaluate the indoor thermal comfort, a three-dimensional Computational Fluid Dynamic (CFD) analysis has been conducted. The velocity distribution within the study area, which is affected by the office layout and the location of vent openings and mechanical fans, has been simulated under operating conditions. The thermal comfort simulation under steady-state full load conditions has also been carried out.



CFD models for air temperature and air velocity

A green wall serving as an air filter is installed in the main corridor of the office. Its combination with the air-conditioning system allows the return air from the office to pass through the green wall before recirculation. This helps refresh air supply to the office.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Bio-filtration green wall

Other key elements of IEQ of the office include – A task light for every workstation, CO_2 sensors to monitor the CO_2 concentration and an independent local exhaust system provided for the printing room.

7 Feature 5 – Green roof

As part of the renovation, the existing podium roof has been transformed into a green roof with around 60 m^2 vegetated area. The greening can help minimize the urban heat island effect.

New green roof

8 Feature 6 – Innovation

Apart from the innovation features of real time energy use display and LED office light fittings and radiant cooling, another innovation approach is adopting the Building Information Modelling (BIM) for Operation and Maintenance in the office on 1/F Main Block, APB Centre. The BIM Application forms an accurate sharable 3D design information database of both the existing building and the new design, and can improve internal evaluation of the cross-disciplinary workflow.

Virtual vs Reality

8. KEY FEATURES OF THE RENOVATION OF THE 10/F GOVERNMENT LOGISTICS CENTRE INTO AN ADMINISTRATION OFFICE

The refurbishment work has adopted a green approach by using various sustainable design features to provide a pleasant working environment for staff. Excellent class in Indoor Air Quality has been achieved and certified by the Hong Kong Environmental Protection Department. The sustainable design features including interior space design, interior green wall, sustainable materials selection and energy efficiency features are described below:

3.1 Feature 1 – Views to outside and daylighting

In order to enhance the liveliness of the office space, workstations are laid out so that at least 65% of them would have a view to the external. Special design is adopted that the upper part of the office cubicle partitions being glazed to facilitate viewing from works stations to outdoor. It also allows employees to enjoy the natural daylight, external scene and reduce the use of artificial lighting.

Office layout plan

Section

New design of office cubicle partitions

3.2 Feature 2 – Interior green wall

Interior green wall is designed as a signature feature to enliven the indoor environment of the new office. It is located at the transition corridor from reception to the interior office space which brings a strong image about this green and sustainable office.

Interior green wall at the corridor

3.3 Feature 3 – Amenity space

The once redundant balcony has been successfully transformed into a welcoming relaxing space for staff. It is a precious opportunity for an office in an urban area to have a breakout space. Planting are provided along the balcony to soften the edge of the building.

External view from balcony

New designed outdoor balcony

Original

3.4 Feature 4 – Green materials

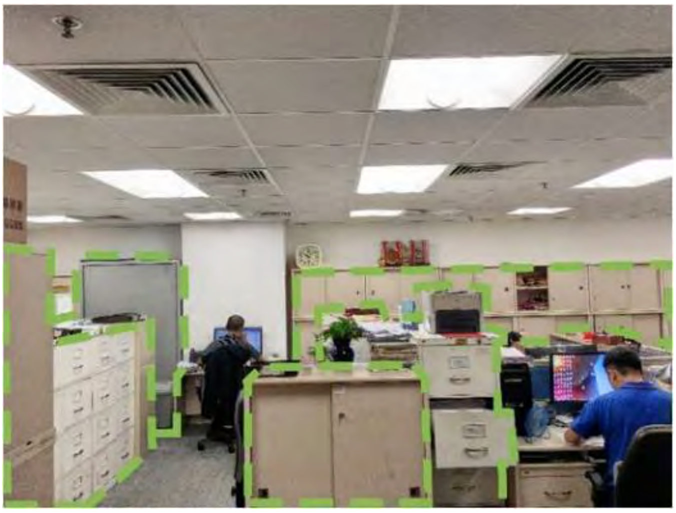
Materials with high recycled content, such as carpet and ceiling, are used in the refurbished office. Recycled timber decking is used at the balcony to match the images of outdoor environment. More than 50% of flooring, ceiling and door products are regionally manufactured materials.

Materials containing rapidly renewable materials such as wall panels manufactured from bamboo are used in the Conference Room. These bamboo panels are regionally manufactured.

Bamboo panels at the conference room

3.5 Feature 5 – Re-use furniture

As the project is a refurbishment project, a lot of existing furniture can be re-used in the new office. A majority of the furniture (over 70%) has been re-used in the new office. It helps to reduce a lot of wastage, transport and man-power for demolition.



Layout of re-used furniture in the new office

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

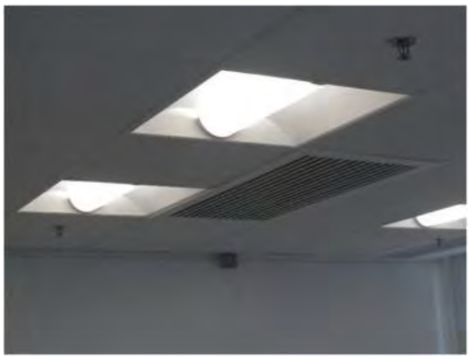
3.6 Feature 6 – Waste recycling facilities

Facilities are provided for recycling glass and small electrical appliance in addition to the standard provision for recycling metal, paper and plastic.

Waste recycling facilities

3.7 Feature 7 – Energy efficiency

Different energy efficiency features have been adopted to reduce power consumption. The new office provides task light for every workstation and high efficient fluorescent lighting for the open plan office. Daylight sensors and occupancy sensors are installed to control the lighting and fan coil units in the office.



High efficiency lighting at office area

9. CONCLUSION

Finally, both projects have achieved Platinum Rating under BEAM Plus Interiors Accreditation after the successful transformation. ArchSD being the works agent for government properties has implemented green design not only in new development but also in renovation of existing buildings. These two projects demonstrated the sustainable design in existing premises through architectural layout design, lighting design, sustainable materials selection and good indoor environmental quality.

Session 3.9: Practices & Methodologies for Green Building Management (3)

Life Story of the Repurposed Shipping Container

Alice L. F. YEUNG[a]

[a] *Architectural Services Department, Government of the HKSAR, Hong Kong SAR, yeunglf@archsd.gov.hk*

ABSTRACT

Hong Kong has always had a high level of construction activity. This is a sign of prosperity; the waste generated by the construction has always been a problem. Construction waste is anything generated as a result of construction and then abandoned, regardless of whether it has been processed. It comprises surplus materials from site clearance, excavation, construction, refurbishment, renovation, demolition and road works. Every day, Hong Kong generate over 3 500 tones of construction waste. What if we could use the old to create something new?

This paper tells the story of collecting construction wastes and repurposed shipping containers for construction. What makes the unappealing shipping containers such an attractive choice for forward-thinking architects? These all-but-forgotten boxes are almost boundless starting with the industrial strength a steel box that can carry up to 30 tons. The real challenge with the stigma of the containers is how to create architecture out of them without compromising design quality.

Shipping container architecture gets a lot of encouraging coverage in the design world as a green alternative to traditional building materials, a smart choice for eco-consciousness. The story reveals the challenges and opportunities of reusing construction wastes and shipping containers and shares the case studies of Energizing Kowloon East Office (EKEO), the pilot trial of green site office in Government projects and the community green stations in Shatin and Hong Kong East, Hong Kong.

EKEO examines the possibilities of revitalize unattractive land, using left-over spaces under flyovers, utilizing modular construction approach by using recycled shipping containers and other steel structures for construction. Use of recycled, re-used and renewable materials to reduce building's energy footprint through practical and innovative sustainable measures in terms of site planning rather than intrusive mechanical installations.

Adopted construction wastes for the construction of the green site office and collected old plastic bottles to create office greening provides an alternative to traditional building materials for site office. A courtyard is introduced between the site office blocks, to create a different form of cooperation between the site staff and the contractor. When the site office was to be removed, the re-used components and materials would be collected again, to re-erect them for the site office of the next project.

The Community Green Stations, located in Shatin and Hong Kong East Hong Kong were pilot projects to implement the Government's "reduction first" waste management strategy. The challenge is how to use shipping containers to create a recycling station in our neighbourhood that would have positive impact on the community and treated sustainable design not a technique but our local culture. The buildings are composed of modular containers, while modified to suit the need of different functions.

Lean construction methods and low embodied energy materials would be the way to develop Hong Kong into a green and sustainable city.

Keywords: construction waste, lean construction, community green station

6. INTRODUCTION

The consultancy report published by Construction Industry Council (CIC) in early 2016 and said that construction waste generated in Hong Kong is on the rise, which is a concern for the community. In 2014, the overall construction waste disposed of at landfills averaged about 3,942 tonnes per day, and amounted to 27 per cent of the total waste disposal.

Through four case studies - Energizing Kowloon East Office (EKEO), construction of temporary green site office and Community Green Stations in Shatin and Hong Kong East to present tangible ways in which we might begin to think, act and design differently. The building industry is beginning to approach the design of buildings in a fundamentally different ways by reusing construction wastes and repurposed shipping containers for construction and with the mind-set of using towards zero materials.

1.1 First ultra-low embodied carbon building: EKEO (Case study 1)

The EKEO is a champion of sustainability by using a raft of integrated green building technologies and features, lean construction method and low embodied energy materials to become Hong Kong's first ultra low embodied carbon temporary office and first BEAM Plus Platinum Government Building. The temporary office is located at a piece of unattractive land on a site under the Kwun Tong Bypass. The structure of Kwun Tong Bypass shades the roof of the building blocks of which it reduces solar heat gain and it provides lift-shelf effect to light up the courtyard inside the building. With passive design in mind at start to reduce the building energy footprint, building orientation is designed to align with the prevailing southeast wind to facilitate wind passage, planters and green wall are installed. Modular construction by using recycled freights containers and other steel structures, which can be easily dismantled and reused elsewhere in future are adopted in the design.

Recycled materials including paving blocks made from recycled aggregate, glass and fly ash from power plants. New highly efficient technologies/design such as air-cooled variable refrigerant volume air conditioners, T5 fluorescent tubes, daylight sensors to deliver savings in energy use and dual flush toilets, low flow taps and harvesting rainwater for irrigation to conserve water have been incorporated in the design.

Quantifiable features to demonstrate the building performance including projected annual operating energy consumption of about 88 kWh/m^2 and 32% reduction in energy consumption compared to design based on the requirement of EMSD Performance-based Building Energy Code (PBEC). About 52.2 tones CO_2-e per year and carbon reduction is 28.1tonnes CO_2-e per year which is equivalent to 1.211 number of trees are projected annual carbon emissions related to the operation. Indoor ventilation rate is increased by more than 30% compared with the basic requirement by ASHRAE 62.1 to enhance IAO. Windows are provided on opposite sides of office area to facilitate natural cross ventilation. The advanced energy simulation software eQUEST is used for energy analysis.

1.2 First new model of green site office (Case study 2)

Every day, we generate over 3,900 tonnes of construction waste in Hong Kong and that includes wastes from the demolition of site offices no longer to be used. Hong Kong Government is committed to reducing the generation of C&D wastes in public works. To this end, we have conducted research and explored the type of prefabricated components to allow reuse in future and reduce C&D wastes, the market readiness to reuse the recycle old construction materials to create green construction office. To enhance a sustainable future of the construction industry, a more environmental friendly site office helps to promote a positive image of the industry in attracting a sustainable workforce.

The concept was to use the old to create something new. The site office for the Kai Tak Schools was the pilot trial; we collected used materials and components to construct the site office. When this first site office was to be removed, we collected the re-used components and materials again, to adapt them for the next site office of Kwun Tong School and further for other future projects.

Apart from adopting sustainable construction, the green site office also worked towards enhancing the working environment of site offices. A courtyard was introduced between the site office blocks, to create a different form of cooperation. Long ribbon windows and screens were used to connect the spaces, the courtyards, the offices and the garden, creating harmonious environment. This aims at shaping a new model for site offices, to re-distribute wastes and materials, and to provide a harmonious environment for our site staffs and contractors.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Essential quantifiable features including actual annual operating energy consumption is 230kWh/m^2 and actual annual carbon emissions related to the operation is 160kg of CO_2/m^2. The offices were sited to enhance cross ventilation and maximize use of natural lighting through long ribbon windows and screens while taking advantage of shelter from excessive daylight by sun decks and adjacent existing buildings. Roof greening was also installed to reduce heat gain to the offices below. As such, the contractors have reported average reduction of 20% electricity consumption.

1.3 First community green station: Shatin (Case study 3)

Shatin Community Green Station (CGS) is one of the first CGS in the 18 districts of Hong Kong. It serves for education on recycling and serving as resource collection station. The site is divided into the garden courtyard and the backcourt to serve the function of exhibition and workshop respectively. The buildings are composed of modular containers, while modified to suit the need of different functions. The idea of garden courtyard is to embody a sense of community and a touch of oasis within the heart of an industrial area. It creates multiple layer of space from public to private, from open space, semi-open space to enclosed area, as an interpretation of pavilions in Chinese garden. These concepts of 'pavilion' and ''veranda' are expressed in the exhibition space and circulation area, with diffusion of daylight through the bamboo trellis.

As there will be no air-conditioning, the building envelope will open up to the courtyards to maximize cross ventilation together with the provision of large overhanging roof and vertical trellis/greening to shelter from the sun. Major components including the containers, bamboo and paving blocks are made of recycled or salvaged materials.

Although the building is temporary, it embodies permanent, cultural value, rediscover our roots and finds parallel with prevailing green features.

Essential quantifiable features including projected annual operating energy consumption is 147.5kWh/m^2 and actual annual carbon emissions related to the operation is 103.3kg of CO_2/m^2.

1.4 Community green station in an urban site: Hong Kong East (Case study 4)

The Hong Kong East Community Green Station (CGS) promoting green living and collection of recyclables at the community level in an urban setting. We do not want the Station to be a rubbish collection point, but a positive asset to the local area. The concept is to create a 'Street' through the site to connect the surrounding communities. Greenies of the nearby Park are extended to the old district through this urban intercourse. Through the use of green wall, bamboo trellis and courtyard garden, it creates an urban oasis within the city.

We reused the modular containers as the buildings yet modified to suit different functional needs. Various sustainable initiatives and adopted to put the green culture of "Use Less, Waste Less" into practice. The flyover above contributes to the passive cooling of the venues thus reducing solar heat gain. The provision of large overhanging roof and vertical greening can shelter the interior from the sun. Natural daylight is brought into the multi-purpose room by large Low-E glazing.

Employing the same technique we adopted in Shatin CGS, although the building also is temporary, we reinforced the cultural value and at the same time incorporate prevailing passive design and green features in the design.

Essential quantifiable features including projected annual operating energy consumption is 98.7kWh/m^2 and actual annual carbon emissions related to the operation is 70kg of CO_2/m^2.

7. CONCLUSION

In the pursuit of promoting material reuse and through the life story of reusing unappealing shipping containers, we have created interesting architecture, reinforce cultural value and at the same time find parallel with the prevailing green features to design building that gives back to the world as much as it takes. Now the next question is what more can we do to build a green and sustainable environment for our future.

[c] *University of Moratuwa, Sri Lanka, thanuja03@hotmail.com*

ABSTRACT

Sustainable Facilities Management (SFM) has gained attention due to challenges in todays built and natural environments. SFM is regarded as the delivery of sustainability in facilities Management (FM) practice and this offers several benefits such as; improved productivity, greater financial returns, reduced detrimental effects on the environment and increased reputation. Despite this, it is identified that only few FM professionals are able to embrace the sustainability concept into their operations. Because sustainability efforts are ambiguous, multi-dimensional and generally not easy to understand. On the other hand, research focusing on the soft issues such as humans capabilities, and skills are still lagging behind the efforts in developing knowledge portals, technical manuals and guidelines. Thus, this paper aims at developing a conceptual framework identifying the necessary human capabilities that are necessary to practice SFM.

Hence, this study is based upon reviewing the current literature in relation to SFM practices forming a basis to identify the potential paradigm for further research on identifying the required capabilities to practice SFM. The findings on literature review identified 49 human capability factors catagorised under five main criteria in which most of the factors (23 factors) were identified in interpersonal competence criteria. Among these factors holistic thinking in systems thinking criteria received 54% showcasing to be the most important factor while 13 factors received 8% and identified to be less important. Hence, this paper theoretically evaluates the human capabilities and leads towards developing a conceptual framework to practice SFM. Hence, this paper highlights the relationship among human capability to practice SFM for FM practitioners through the development of conceptual framework.

Keywords: facilities management (FM), capability, sustainability, conceptual framework

1. INTRODUCTION

Traditionally, Facilities Management (FM) was regarded as an old fashioned profession which operates in the field of repairs, maintenance, cleaning and care-taking (Atkin and Brooks, 2005). In general, it was considered to be more technical-oriented and reactive (Barrett, 2000). Since then, FM profession has evolved and witnessed a rapid development (Meng, 2014; BIFM, 2016). It has moved from being a non-core function towards delivering strategic decision making (Alexander, 1994). In todays environment sustainability is regarded as an enabler in delivering strategic support which helps a FM practitioner to achieve sustained competitive advantage (Chotipanich and Lertariyanun, 2011). This is emphasised by BIFM (2016) stating that embracing sustainability in FM practice is recognized as a strategic response. Improved productivity, greater financial returns, reduced detrimental effects on the environment and increased reputation are some benefits attained through integrating sustainability in FM practice (Shah, 2007).

Hodges (2005) lists a number of capabilities that FM profession should possess in order to carryout sustainable practices in a holistic integrated manner. However, it appears that only few FM professionals are able to embrace the sustainability criteria into their operations (Lai and Yik, 2006). This is due to facts such as lack of specialist knowledge, tools (Hodges, 2005; Elmualim et al., 2009), unavailability of supportive case study materials (Elmualim, et al., 2009), gap between capability and skills (Hodges, 2005; Shah, 2007), unwillingness of Facility Managers and organisations to adopt changes (Elmualim et al., 2010) are repeatedly emphasized.

Further, it is identified that researches on sustainability in FM have primarily focused on approaches, benefits, barriers and stakeholder commitment (Elmualim et al., 2010; Hodges, 2005; Shah, 2007; Wyatt, Sobotka and Rogalska, 2000) while FM personnels capabilities, skills and knowledge are yet to be researched (Elmualim et al.,

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2010). However, Sarpin, Yang and Xia (2016) have highlighted this gap and identified 23 critical human factors that are important to practice SFM. But yet, this study have considered all functional levels of FM namely strategic, tactic and operational level as equal and specified that it require same capabilities. But Kincaid (1994) argues that each of these functional levels require different capabilities and skills to perform their different expected tasks. Further, Sarpin, Yang and Xias study also limits its content to human capabilities without addressing the importance of organisational capabilities. Dosi, Faillo, & Marengo (2008) emphasis that organisational capabilities are firm specific and helps to address the key problems in an organisation. Adding to this Moustaghfir (2009) states organisational capabilities helps to enable a firm to attain distinctive competitive edge. Further, capabilities cannot be identified despite the consideration of key factors such as facility type, scale of organisation (small, medium and large), organisation characteristics, business sector, local context and culture (Chotipanich, 2004). However Sarpin, Yang and Xia (2016) neglects to consider these key factors in identifying human capabilities.

Considering the knowledge gap outlined above, this paper initially critically reviews the current literature and aims to develop a conceptual capability framework to practice SFM. The first part of this paper identifies and integrates the possible capabilities pertaining to sustainable FM practice. It then presents the developed conceptual framework to practice SFM effectively.

2. CAPABILITY AND SUSTAINABLE FM PRACTICE

FM practitioners need certain capabilities to practice SFM. These capabilities are defined by Oxford Dictionary (2016) as the power or ability to do something. This may comprise of competence, experience and expertise a person possess (Ulrich and Smallwood, 2004). However, both Elliot and Dweck, (2005) and Takala (2011) define competence as the specialized system of abilities, attributes, proficiencies or skills that enable an individual to perform in various complex situations.

Environmental management or sustainability is considered as a complex process identified as HR intensive, which requires support from the area of human resources and the development of people capabilities and skills in order to guarantee the success of its implementation (del Brío and Junquera, 2003). Barney (1991) and Wright, McMahan, & McWilliams, (1994) emphasis that human resources are an important potential resource in an organisation to attain sustainable competitive advantage. This is due to the fact that human resources are rare, non-imitable, and non-substitutable who differ in range of capabilities, abilities, attributes and skills etc (Saa-Perez & Garcla-Falcon, 2002).

Hence, this points out the necessity of FM professionals to be highly capable with knowledge, skills, abilities, attributes, experience and values etc to practice SFM. On the other hand, from an organisational perspective, the organisational capabilities refer to particular forms of organisational knowledge that enable an organisation to perform its core operations (Dosi, Nelson and Winter, 2002). These are the collective competence, knowledge, skills etc of its individuals (Ulrich and Smallwood, 2004; Zollo and Winter, 2002), which helps the organisation to be firm specific in dealing with organisational problems (Dosi, Nelson and Winter, 2002). These capabilities are rather constant or stable and do not change rapidly. As organisational capabilities are developed over a long period of time, this in turn can give an organisation a sustained competitive advantage (Schienstock, 2009). This emphasize the importance of both the individual and organisation capabilities are highlighted in practicing sustainability in FM.

Following from above discussions, capability factors are identified under two areas namely; human capabilities (individual perspective) and organizational capabilities (organisational perspective). However, due to space limitations, this paper only focuses on presenting the human capability factors and developing a conceptual framework highlighting human capability as the initial input to practice SFM.

2.1 Human capability criteria and factors

Human capabilities can be judged on infinite variety of factors. This study adapts the framework developed by Wiek, Withycombe, & Redman (2011) for sustainable competence in which the author lists five main competences (which will be referred as criteria from this point onwards) as follows:

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Systems-thinking competence (ST) - allows a professional to build up their ability on collectively analyse the complex systems across different domains namely; environmental, social and economic etc and among different scales such as; organisation, local and global etc.
- Anticipatory competence (A) - the ability to jointly investigate, evaluate, and articulate the future related sustainability issues and sustainability problem-solving
- Normative competence (N) - the ability of assessing the current issue and then the creating more sustainable vision for that issue.
- Strategic competence (S) - the ability to design, implement, intervene and transform strategies towards sustainability agenda.
- Interpersonal competence (I) - refers to the ability to motivate, enable, and facilitate collaborative and participatory sustainability research and problem solving.

Altogether, forty-nine (49) human capability factors to integrate sustainability in FM were identified under the aforementioned five criteria. Table 1 summarises the findings on human capability factors under each of these five criteria.

	Human capability factors	Percentage	Source
	System thinking capabilities (ST)		
ST1	Holistic thinking or seeing as a bigger picture	54%	[2] [4] [5] [6] [7] [12] [13]
ST2	Understand the social justice, equity and challenges of sustainable development (SD)	23%	[2] [12] [13]
ST3	Understand both the natural and human systems and their interactions for sustainable development	15%	[4] [6]
ST4	Understanding how the core business activities create opportunities for other actors in society and how the company can make a contribution to sustainability;	8%	[1]
ST5	Understanding the social and environmental risks and opportunities of the company and its industry sector;	8%	[1]
ST6	Understand the competence demand of different stakeholders related to sustainability	8%	[1]
	Anticipatory competence (A)		

A 1	Act for long-term benefit	23%	[1] [6] [12]
A 2	Recognise any short and long term consequences of any plan or decision	23%	[1] [7] [12]
A 3	Ability in foresighted thinking	23%	[4] [9] [13]
A 4	Able to show the degree of global consciousness as a consequence of present activities	23%	[4] [7] [13]
A 5	Ability to realise their part and limitation in harming the environment	15%	[1] [6]
A 6	Identify the consequences of any actions with regard to environmental, social and economic pillars	15%	[6] [12]
A 7	Able to categorise direct and indirect consequences to environment and eco system	15%	[6] [12]
A8	Ability to think of the future generations welfare	8%	[6]
A 9	Possess a bright vision for future	8%	[5]
	Normative competency (N)		
N 1	Competency in trans-cultural understanding and interdisciplinary work	31%	[4] [6] [9] [10]
N 2	Competency in distanced reflection on individual and cultural models	23%	[4] [6] [9]
N 3	Value diversity, the environment and social justice	15%	[1] [11]
N 4	Able to change thought processes and values to develop an ecologically sustainable culture	15%	[1] [7]
N 5	Understand a variety of perspectives, values and beliefs and their implications for sustainability	15%	[1] [13]
	Strategic competency (S)		

S 1	Taking a strategic view of the business environment and build strategies for change	23%	[1] [2] [11]
S 2	Does not focus exclusively on cost and budgets (Understand Whole life-cycle cost (WLCC) and total cost of ownership (TCO) techniques)	23%	[1] [2] [12]
S 3	Develop organisations sustainability strategies considering the following areas; Environment management, community management, disaster management, energy management, waste management, corporate social responsibility (CSR), health and safety and WLCC etc.	15%	[3] [12]
S 4	Recognising that business does have responsibilities to the broader society.	8%	[1]
S 5	Building capacity and external partnerships and creating strategic networks and alliances.	8%	[1]
S 6	Develop good relationship with the organisations top management	8%	[12]
	Interpersonal capabilities (IC)		
IC 1	Communicating with passion	38%	[1] [2] [4] [8] [12]
IC 2	Critical thinking;	31%	[1] [2] [4] [11]
IC 3	Appreciating and embracing diversity;	31%	[1] [2] [11] [12]
IC 4	Team player	31%	[1] [2] [9] [12]
IC 5	Respect for people, society and environment	31%	[1] [2] [4] [11]
IC 6	The capacity to think outside the box.	31%	[1] [6] [10] [12]
IC7	Managing stakeholder network relationships;	31%	[1] [4] [12] [13]

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

IC8	Problem solving and intellectual curiosity	23%	[1] [4] [11]
IC9	Ethical practice, persistence, and tolerance.	23%	[1] [4] [6]
IC10	Business acumen;	23%	[1] [2] [6]
IC11	Listening skills;	23%	[1] [2] [4]
IC12	Open-mindedness; Generosity	23%	[1] [6] [10]
IC13	Self-motivation, Self-management, Self-assessment	23%	[1] [9] [12]
IC14	well founded and balanced judgment and empathy	15%	[1] [9]
IC15	Creativity, innovation and original thinking;	15%	[1] [2]
IC16	Honesty and integrity	15%	[1] [2]
IC17	Conviction and courage for original thinking	15%	[1] [10]
IC18	The drive to contest resistance;	15%	[1] [6]

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

IC19	Emotional intelligence	8%	[1]
IC20	IT literacy	8%	[2]
IC21	Reflecting on experiences and Maturity	8%	[2]
IC22	Ability to work across disciplines	8%	[12]
IC23	Ability to plan and implement sustainability efforts	8%	[12]

Table 68: Human capabilities for SFM

Among these 49 factors, 6 factors were identified under the system thinking criteria. Out of these 6 factors holistic thinking or seeing as a bigger picture have the highest percentage of 54% and understand the social justice, equity and challenges of sustainable development (SD) received the second important factor receiving a percentage of 23%. However, out of these 6 factors in systems thinking criteria 3 factors were identified to be least important receiving a percentage of 8%.

Under anticipatory competence 9 factors were identified in which act for long-term benefit, recognise any short and long term consequences of any plan or decision, ability in foresighted thinking and able to show the degree of global consciousness as a consequence of present activities attained equal importance receiving 23%. However, ability to think of the future generations welfare and possess a bright vision for future are identified to be least important factors receiving percentage of 8% each.

Normative competency (N) recognized to have 5 factors in which competency in trans-cultural understanding and interdisciplinary work was identified to be the very important factor receiving 31%.

In strategic competency factors namely taking a strategic view of the business environment and build strategies for change and does not focus exclusively on cost and budgets were identified to be most important factors receiving 23%. This was subsequently followed by factors such as; develop organisations sustainability strategies, recognising that business does have responsibilities to the broader society building capacity and external partnerships and creating strategic networks and alliances and develop good relationship with the organisations top management in which the first received 15% and the rest considered to be least important factors with attaining equal importance of 8%.

Lastly among these 49 human capability factors most of the factors (23 factors) were categorized under interpersonal capabilities (IC). Here communicating with passion was identified to be the most important factor receiving 38% while 5 factors were identified to be the least important factor receiving a percentage of 8.

3. CONCEPTUAL FRAMEWORK FOR PRACTICING SFM – HUMAN CAPABILITIES

The conceptual framework for SFM was developed based upon the literature findings as shown in the Figure 1. This framework is categorized into four phases namely; FM input phase, FM process phase, FM output phase and impact phase. Each of these phases are elaborated as follows;

FM input phase - This is the initial step needed by a facilities practitioner to practice SFM. The framework suggests that human oriented capabilities (refer Table 1) are the basis input required to practice SFM.

FM process - The second step of the framework instructs how FM professionals need to do their work to achieve sustainability. For that purpose this phase holistically consider the components such as; life cycle, FM functions, people management practices and continual improvement as main area to consider. FM functions has been categorised under three broad functions; namely the strategic, tactical and operational functions (Alexander, 1996; Chotipanich, 2006; Patanapiradej, 2012). These each functions may have its own unique value adding criteria that collectively contribute to the value added facilities management function depending on the work carried out. Also these three FM functional levels require different capabilities and skills (Kincaid, 1994). Keeping this in mind this paper will propose capabilities required in terms of these each functional level. Further in this phase there are two more elements considered important to carryout FM process effectively which are;

- People management practice - This considered vital in an organisation because it influences employee skills, capability, knowledge and experience etc through the acquisition and development of an organisations human capital (Saa-Perez & GarcLa-FalcOn, 2002). This refer to functions such as communication systems, reward systems, socialization systems and training programmes, work design, culture, leadership etc to act in the interests of the organisation to attain its goal (Schuler & MacMillan, 1984). To attain sustainable competitive advantage both human capital pool (highly capable skilled work force) and people management practice are required (Dunford, Snell, & Wright, 2001).
- Continual improvement; Any organizational activity to be successful it is very important to have a continues improvement strategy to achieve organizational goal (IAEA, 2006). There are many continues improvement strategies are available but this paper adapts Environmental Management Systems (EMS) - specification with guidance for Use ISO 14001:2005 (ISO, 2017). This will address the following components;
  - Environmental Policy: Continuously review environment related policies for any updates and amendments.
  - Planning
  - Implementation and Operation
  - Checking
  - Management review

This continual improvement component of the framework establishes a process for responding to change, capturing data and implementing processes within an overall goal or set of objectives to attain SFM practices for facilities practitioners.

FM output phase - This phase illustrates that if FM practitioners adhere to the above two phases effectively, then simultaneously would be offering best services while supporting development and maintaining good relationship with stakeholders.

FM Impact phase – Effective practice on this framework expects to be positively impacting on the surrounding specially focusing on environment, economic and social as well as on the core businesses results in satisfaction,

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

cost reduction, adaptability, culture management and highly reliable which will ultimately expect to lead towards SFM.

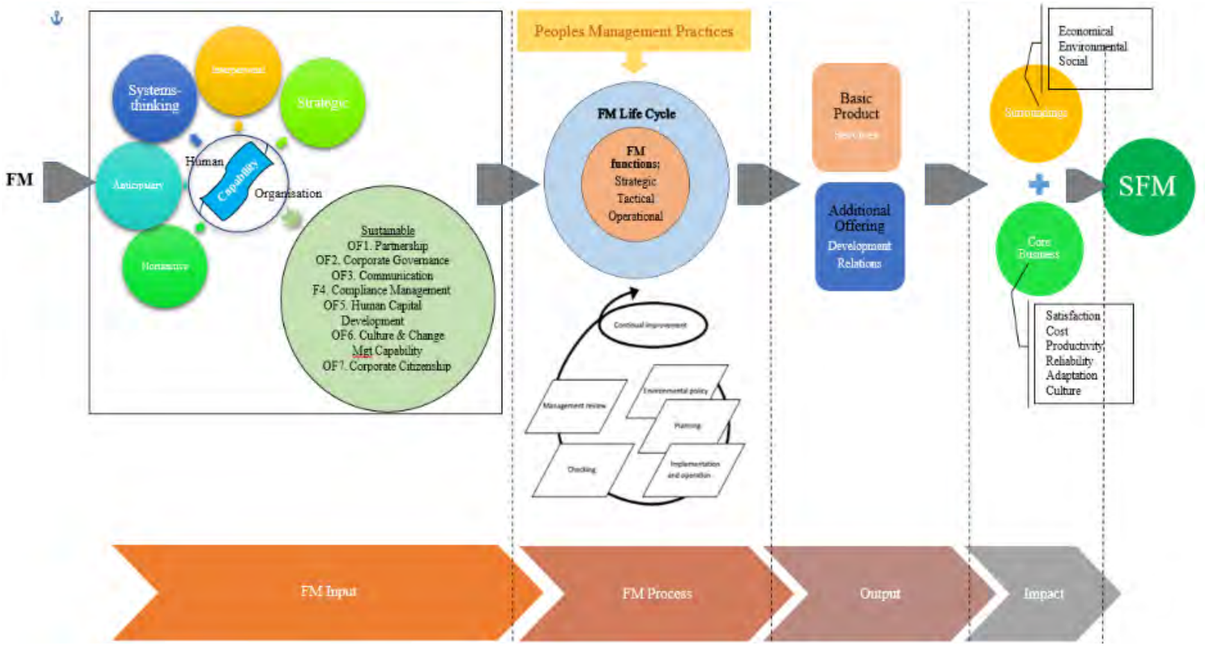

Figure 1

The conceptual capability framework as shown in the Figure 1 for SFM practice expects to provide strategic guidance to the facilities professionals (Facilities managers, property managers, maintenance managers, maintenance engineers, operational managers) who may be faced with the dilemma of practicing sustainability in FM.

4. CONCLUSION

Human capability is the enabler to practice SFM. The literature findings found 49 human capability factors categorized under 5 criteria as listed in Table 1. Among these factors holistic thinking or seeing as a bigger picture in systems thinking criteria received 54% showcasing to be the most important factor. However, 13 factors received 8% and identified to be less important. However, this findings are purely based upon the literature findings and the importance of factors will vary depending on key factors such as; facility type, scale of organisation (small, medium and large), organisation characteristics, business sector, local context and culture.

Further, this findings were carried forward to develop the conceptual framework to practice SFM. For that purpose this framework was organised in terms of four phases namely; FM input, FM process, FM output and impact phase. Among these four phases FM input phase emphasis human capability as the basic input to practice SFM and leads to other phases subsequently as shown in Figure 1. Also this framework will provide FM practitioners a new outlook on pinpointing on the required capabilities and how to master their skills to practice SFM.

5. FUTURE DIRECTIONS

Human and organisational capabilities are identified to be most important to practice SFM. However, this paper initially addresses on human capability perspective while future studies will be focused on addressing organisational capabilities.

Further, capabilities cannot be identified despite the consideration of key factors such as facility type, scale of organisation (small, medium and large), organisation characteristics, business sector, local context and culture where the FM practice takes place. Moreover, capabilities also cannot be determined in general for all FM scope and FM functional level namely strategic, tactic and operational. Keeping this in mind the future studies will intend to examine the capability requirements with the consideration of these factors.

Sustainable Construction: Quality of Life of Construction Workers in Private Sector: Case Study of L.P.N Development Public Co., Ltd.

Pimchanok SRIRUTTRAKUL[a]

[a] *Wisdom Consulting and Solution, Thailand, sriruttrakul.p@gmail.com*

ABSTRACT

Sustainable construction often refers as the processes that are environmentally responsible and resources-efficient. Most efforts for sustainable building focuses on the construction management and less to human resources management. As a vital part of construction process, contributing towards sustainable development the construction worker's welfare is something cannot be neglected.

One of the biggest real estate development company in Thailand, L.P.N. Development Public Co., Ltd., have made commitment to continuously enhance its long-standing dedication to Corporate Environment and Social Responsibility (CESR) is demonstrated, and promote and take part in corporate social and environmental responsibilities with in and after process in line with sustainable development principles. L.P.N. has developed a set of core values that emphasizes performance standards in sustainability for construction workers. By considering construction workers as one of the resources involves in the built environment, the workers' welfare must be sustained as well. The company has taken care of workers in all dimension from working condition, workplace safety, living quarter aim to enhancing and supporting workers' wellbeing.

Green Construction Workers camp practical guidance, developed by L.P.N., sets out new commitment to improve the workers' quality of life. The company aims build a healthy-hygiene durable and remote camp that feature accommodations, kitchen and facilities, recreation spaces to encourage workers to work efficiently while avoid negative environmental impact on neighborhoods.

Inside living quarter the company provides safe spaces for children of construction workers to learn and play. These spaces have been established at a number of L.P.N. construction sites. Children are given a safe environment assuring the on-site construction workers that their children are in a safe and sound environment. The company also foresee the importance of early childhood development, by providing caretakers to teach them a basic knowledge, thus they can have equal opportunities with other children in the society.

Keywords: corporate social responsibility, construction workers, construction camp

1. INTRODUCTION

The implementation of 'Sustainable Development' and green construction practice has become priority for many developer, many real estate companies are focusing on integrate environmentally responsible principles into real estate industry and build up new policy initiatives. The challenges of developing sustainable framework is how to shift the paradigm of the investors, proves that socially responsible or sustainable real estate development does more than turn a profit. The concept of "Triple Bottom Line; People, Planet and Profit" theory was adopted as a part of sustainable strategy to real estate investing aiming to achieve the result in long-term profitability, reduce negative environmental effects of development and contributing social responsibility.

L.P.N. Development Public Co.,Ltd. is the developer of residential condominiums for middle to low income group of customers at the affordable price in Thailand. The vision and mission of the company stresses the importance of all stakeholders. The Company does not only focus on financial aspect of the operation but the environmental and social responsibility one also. As the leader of residential condominium development under "Lumpini" brand, the Company is well aware of direct environmental and social impacts as a result of large-scale project development. It is thus ensured that all operational processes are strictly controlled and the organization is managed to enhance the sustainability of the business operation.

In order to develops integrated values in the operation in all departments to be delivered to the stakeholders, society and environment the Company strives to be a "Value Organization" that gives importance to the sustainability in all aspects according to "6 Green LPN" concept including; Green Enterprise, Green Financial Management, Green Marketing Management, Green Community Management, Green Design Concept, and Green Construction Process

2. L.P.N GREEN CONSTRUCTION

In early 2014 L.P.N. decided to standardised the company's construction process and set up the standard in L.P.N. way, and successfully implement in all construction project in 2015. It helps codified best practices and methods of how to construct sustainably, reduce construction project disturbances to neighbouring properties, rainwater systems and the site itself. Brainstorming workshop are usually held twice a year to develop construction process standard and construction pollution prevention plan as construction can cause a risk of producing pollution into the environment which can affect the neighbourhood and local ground. It is vital to control the impact of construction activities on human and environmental health.

L.P.N. Green Construction Process Standard concentrate on a construction manager's roles and responsibilities during the construction phase of a project not only to minimizing the impact of construction activities but also enhancing the quality of life of construction worker as well. Moreover, random checks and on-site visit by L.P.N. staffs are usually occurred once a month throughout the project duration to ensure that the standard practices are implemented on-site properly.

3. CONSTRUCTION WOKERS; QUALITY OF LIFE

Working in building construction sector related with building material and life-risking task, due to workplace surroundings. Adequate safety equipment must be provided in order to preventing harm in the workplace, keeping workers healthy and safety, and reducing the severity of accident that may occurred on construction site. All workers need to be trained to acknowledge basic first aid and to avoid any unsafe conditions Furthermore, safety meeting will be held every morning in order to remind them to work carefully and safe.

In order to ensure that working environment is harmless to the construction workers' health air and noise pollution are conducted once a month, since construction activities is the main cause annoyance and affect the health.

In terms of living conditions, construction labours are mostly migrating from different provinces or different countries into the city centre. They move from place to place, depended on the project they are working with their families and live in the place provided by the owner of the construction company or somewhere nearby, building temporary shelters. In order to achieve maximum mobility, most of the shelter are construct roughly by steel and wood structure, lack of safety inspection and vulnerable to weather conditions. The labours live there for the duration of the construction project which may last for years before move to other project, forcing them to live in an extreme condition.

Figure 1: Shelter for construction workers

L.P.N. has developed a set of core values that emphasizes performance standards in sustainability for construction workers. The standard has been set to improving housing condition for workers. By considering construction workers as one of the resources involves in the built environment, the workers' welfare must be sustained as well. The company has taken care of workers in all dimension from working condition, workplace safety, living quarter aim to enhancing and supporting workers' wellbeing.

3.1 Construction workers camp; practical guide

L.P.N. oversees housing for construction workers and set up standard regarding their living conditions, such as fire safety, living space and sanitary. The typical standard camp made entirely from steel structure and metal sheet. Provided appropriate protection against heat, rain and, in particular, insects. These are less vulnerable to weather condition, although metal sheet roof still lead to heating up the living quarters, the ventilation is good enough it can cool down the space quickly.

Furthermore, the company is ensure that the housing which is provided is not overcrowded, be in good condition and not pose a risk to the health and safety.

Figure 2: L.P.N. construction camp

In the camp, there is also recreational space and health facilities for workers to relax and exercise while they not at work, encouraging the worker's wellbeing.

Figure 3: Recreational space for construction workers

Instead of letting the workers cook inside the temporary house causing fire risk and being unclean, the company provided common kitchen area for workers. They will bring their own kitchenware and ingredients to cook together, influence people to interact with others.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 4: Common kitchen area in construction camp

For drinking water, washing clothes and bathing. The company arranged number of drinking water machine, washing machine for the construction workers. The toilet facilities are also conveniently accessible and clean. Sanitary inspections conducted at least once every 3 months to assure that all facilities are in a sanitary condition.

Figure 5: Basic amenities; drinking water machine, washing machine and toilet facilities

3.2 Children in construction site

The company provides safe spaces for children of construction workers to learn and play. These spaces have been established at a number of L.P.N. construction sites. It is a standard nursery room and playground area for children while their parents are working, instead of let them wandering around construction site and risk their life. The children in construction camp are given a safe environment assuring the on-site construction workers that their children are in a safe and sound environment.

Figure 6: Nursery room at L.P.N construction sites

The room are well manage, clean and organized. There are basic educational aid and toys provided for the children as the company also foresee the importance of early childhood development, by providing caretakers to teach them a basic knowledge and Thai language for alien children.

Day/ Time	9.00-10.00	10.00-11.00	11.00-11.30	12.00-13.00	13.00-14.00	14.00-15.00	15.00-16.30
Monday	Thai practice	Watching Cartoon	Lunchtime	Sleep	Drawing and Painting	Watching Cartoon	Playtime
Tuesday	English practice	Dancing	Lunchtime	Sleep	Playtime	Watching TV	Playtime
Wednesday	Basic Match	Watching TV (English Program)	Lunchtime	Sleep	Playtime	Watching Cartoon	Meditation
Thursday	Thai	Watching TV	Lunchtime	Sleep	Drawing	Watching Cartoon	Playtime
Friday	English	Watching	Lunchtime	Sleep	Drawing	Watching Cartoon	Meditation
Saturday	Basic Match	Watching TV	Lunchtime	Sleep	Playtime	Watching TV	Playtime
Sunday	Thai	Watching Cartoon	Lunchtime	Sleep	Playtime	Watching Cartoon	Meditation

Figure 7: Example of class schedule for children in construction camp

By organizing classes in the construction camp managed to give the children an experience of learning thus they can have equal opportunities with other children in the society.

4. CONCLUSION

By considering construction workers as one of vital resources of the company. L.P.N. has develop the standard regarding the quality of life of the labours, aiming to improve both on working condition and living condition. After 2 years of implementing the standard, it is clear that L.P.N. construction camps become a high quality camp site, ensuring good standard in living facilities, and enhance the quality of life.

By applying this standard the labours' welfare is raising up variously, benefit includes; less turnover rate in employment, reduce serious accident, minimizing negative environmental impacts on neighbouring area, improving a better living environment for children of construction workers, and helps them work more efficiently.

L.P.N. is one of Thai developers who step up and take serious responsibility in construction workers' health, safety and living condition. The company makes a public commitment by setting a standard, not just to be a policy or guidebook but to protect and promote the worker's rights in the construction industry. L.P.N. will continuingly manage the construction process to ensure the high standard of practice has been carried on, and to collaborate with other stakeholders, in order to support the company's vision and mission of sustainable strategies.

Mining for Resources: Problem-Oriented Building Information Management and Development of Agile Facility Management Methodologies Through Industry-University-Public Collaborations

Yu MORISHITA[a], Bumpei MAGORI[b], Tomonari YASHIRO[c]

[a] *The University of Tokyo, Japan, ymorishi@iis.u-tokyo.ac.jp*
[b] *The University of Tokyo, Japan, magori@iis.u-tokyo.ac.jp*
[c] *The University of Tokyo, Japan, yashiro@iis.u-tokyo.ac.jp*

ABSTRACT

Advanced information-embedded buildings are considered to bring opportunities for mining data for the purpose of revenue improvement and cost reduction, resources that will enable sustainable service provision and facilities management (FM). While the initial cost of informatization of buildings are still high, the onsite reality of existing facilities in operation alludes to necessity in development of problem-oriented information management methodologies, where it is hardly possible to obtain complete data of the whole of the building as in the case of new construction. The paper illustrates the development of agile facility management methodologies through the case of 3-year industry-university-public collaborations onto an existing facility complex. The exemplary case was Okinawa Convention Center, 29 years old, large-scale (55,000m^2) convention and cultural facilities complex in Japan, where the operational cost was overwhelming its annual revenue. A 3-year collaboration began with filling the gap of information that allowed for overarching, cross-stakeholder 'mining' of recourses out of the existing built environment. The development of the management methods focused on problem-oriented quantification that is operationally effective to the actuality of the building operation over the years. Mining of data thus targeted, 1: energy and environment monitoring toward an adequate billing system, 2: project monitoring toward the re-evaluation of maintenance budgeting, 3: monitoring of shift in demand in original design and renovation method re-evaluation and resource reorientation, and 4: maintenance record monitoring toward the identification of unexpected risk reduction. The result displays the outcome development of methodologies for agile FM through showcasing the quantified improvement through each instance of resource mining. The collaboration resulted in a set of communications where the shift from as-built maintenance to profit-oriented improvement of the existing environment was agreed.

Keywords: agile management, information management, facility management

1. INTRODUCTION

1.1 Background

Recent technological advancements in sensors, networks, as well as software has brought the building industry into a new paradigm of advanced information-embedded buildings. This concept embraces the utilization of building information to conduct better management of the facility as well as value production, which had previously been untouched. However, much of the discussions on technological applications are based around new construction. Since the proliferation of the concept of Facility Management (FM) in the1980's (Rondeau et al. 2006), the information management of the operational phase of the facilities have slowly become a norm for the building industry, yet there are many buildings and organizations that have not caught up on the actual operational level. Discussions on strategically aligning the FM often begin with an information inventory, where building the database determines its operational planning, then down to project planning (Rondeau et al. 2006). However, the realities of older buildings are an unavailability of information stock, which are either too obsolete or too incomplete to initiate the inventory processes necessary for strategic FM implementation. Such cases of information production require large investments, where the financial capability of the organization hinders the previously aligned priorities of financial plans for facility improvement on the hardware side, such as overhauling mechanical equipment. These info-less facilities need more agile and small-scale project-based information production methodologies to initiate their informatization processes, resulting in mid-range schematizations of their FM strategies.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

1.2 Previous studies

The data requirements or guidelines for each FM organization are diverse, where they are often prepared by each organization itself. It is an ad hoc combination of tools that is supporting different FM projects, where industry standards are yet to be established (Teicholz & IFMA Foundation 2013). In order to establish individuated yet workable management systems for each facility, FM stakeholders must necessarily undertake the management processes which best fit and are adaptable for their own organizations. To initiate such processes under uncertain, info-less situation, the agile management methodology suggests some potential in the “action first” mode of operation. Since the release of a statement in 2000, agile project management methodology (Beck et al. 2001) has seen a few cases of adaptation in the construction industry (Everts et al. 2011). Since the methodology itself has not yet become wide spread within the FM realm, there are few cases of actual project-based analysis of methodological applicability and evaluation of its effectiveness. While the field of business management shows applicability and potential hazard of agile process (Rigby et al. 2016), the FM realm also needs to establish better ways of bringing the info-less, unmanageable facilities into the state of manageability.

1.3 Purpose of the paper

This paper aims to give a concrete example of an agile FM process and its potential for existing facilities in the state of ill-structured information management. A case study showcases the project-based, problem-oriented agile information management processes applied to an existing FM process of a facility complex. The paper exhibits ways for currently info-less buildings to bring itself up to the strategic level with small degrees of upfront investment. This research finds the ideal process of information management and its structure-building from a learning-by-doing process as well as a learning-from-failure process (Edmondson 2011) that are akin to an agile management process. Compared to a waterfall process that places action as the last step of the management process (Figure 1: Left), the agile process defined within the paper places small scale, dispersed project planning and action as the first step (Figure 1: Right). The aim of this process was to enable the structurization of information for strategic planning. Through the case study, the analysis identified the types of informational operations that lead to quick and concrete output toward the strategic communication among the involved stakeholders.

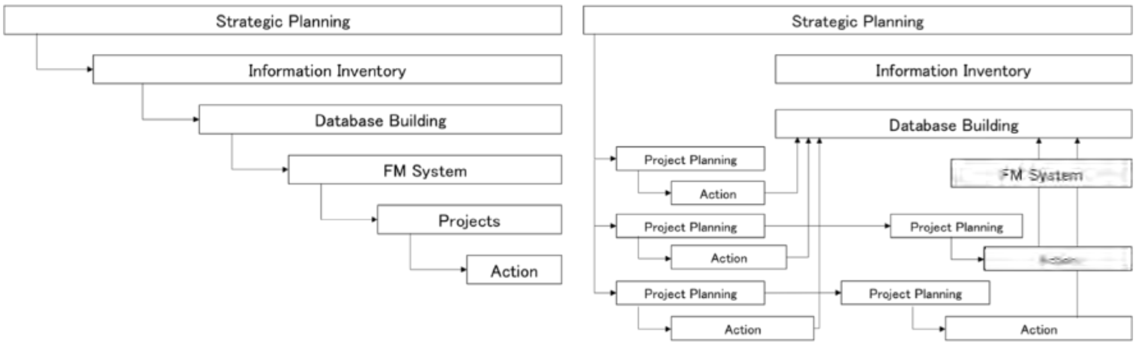

Figure 1: Left: FM decision system redrawn from Rondeau et al. 2006, pp.71, Right: Agile FM methodology

2. METHODOLOGY

2.1 The role of third party institution added to FM stakeholder relationship

The exemplary case followed industry-university-public collaborations, where the academic positioned itself as the third party institution to enable the process of FM structure renovation. After nearly 30 years of operation, a vertical organizational structure built by the prefecture, the operational staff, building management companies, and contractors has become a barrier for a necessary adaptation of the FM operation. In order to break the ice, a third party advisory position was established, aiming for a horizontal mode of communication among stakeholders. The goal was to enable an open discussion of the existing problem so as to reframe the problems into opportunities within existing capabilities and resources, shifting the organization away from structure-based processes toward communication-based processes. From the academic perspective, testing the effectiveness of rapid and partial implementation of advancing technologies such as BIM for FM, 3D scanning, or various sensors and monitoring systems was a paralleling goal, which is often a burden for the public-run existing organization to implement as a complete package of upfront investment.

2.2 Mining for resource-oriented information

The actual activity began with mining for information that can become a resource for value-creating processes within the existing facilities. This process was different from initiating the management process by acquiring a large amount of data. Rather, the process aimed to define the most problematic issues the facility and the operation team were facing. The set of meetings and walkthroughs with the operational team was intended to compare and criticize the initially planned operation of the facilities to the current operations and its problems, and was followed by the potential solutions. The major problems of the current operation were often tied to a lack of adaptation to social and cultural shifts in the demand of facility usage over the years. These apparent problems were then analyzed from the different facets of data mining that can be applied toward project implementation. These acts of mining were initiated through energy and environment monitoring, project monitoring, demand monitoring, or record monitoring (Figure 2).

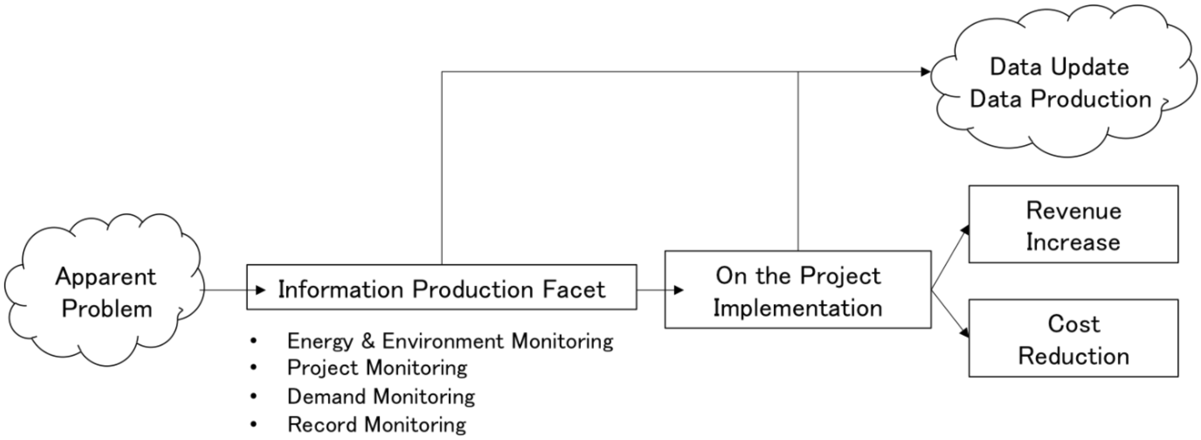

Figure 2: Problem-oriented information management

Analyzed information was grouped into two major outcomes, where the information helps the facility to increase its revenue, while the other reduces the cost. The former outcome took a design-based approach to questions of the basis of the problem, while the latter took an engineering approach to measure, report and verify. The focus was understanding the cost and time it takes to resolve the problem, while capturing the return of investment (ROI) from the resulting solution. The less time it took for the solution to come into effect with a larger ROI was the best fit for the methodology in discussion. As problem-solving projects get implemented, the assumed benefits of the small-scale investment manifest themselves as ROI. The outcome is not only a set of information but also a resource for further investment. Here, the management process assumed the delivery of three outputs: increase in revenue, reduction in cost, and data updates and production for information inventory.

3. CASE STUDY

3.1 Okinawa Convention Center

The paper showcases the Okinawa Convention Center (OCC) complex to exemplify the above given methodologies of mining resources. This public complex is 55,000m^2 and consists of the following fourteen facilities: theater, exhibition hall, two buildings with lecture rooms and smaller halls, open air spaces, administration wing and mechanical rooms. The first part of the complex was built in 1987, and has been in operation for 29 years. The major problem of the complex is the ill-structured balance of the cost of operation and the revenue, where the large-scale renovation both in building itself and mechanical equipment is on its way. OCC can be considered prototypical of many existing mid-aged, public, large-scale building complexes, where initial investment at the time of construction was high due to the economic boom (in Japan), the current operational demand for the facility is still high. In addition, the operational budget has shrunk, its lifecycle management problem is complex, while the human resources are limited. The overarching aim of the academic research is to establish a better-fit methodology to bring these info-less, management-lacking facility complex into the realm of well-structured management.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.2 Three years collaboration

In late 2013, the operational management company (private) and the university began a collaboration process, later involving the prefecture (public). The role of the university was to revaluate the current structure of FM and to provide engineering and technology advice to the existing stakeholder relationship. The collaboration has now reached its third year, where several results have manifested in figures. The initial survey suggested a potential for large-scale reduction in its overall maintenance/ operation cost, yet closer investigation showed the lack of up-to-date building documents and ledgers, leading to identify necessity for investment in large-scale information production processes. At this point, due to the budgetary constraints, traditional step-by-step FM methodology was not operationally viable for the team of collaborators, where a rather small amount of ad hoc information production and corresponding ROI were necessary to initiate the process of restructuring FM. The underlying goal to compile a strategic facility plan remained, yet the method for OCC was agile, where the result of distributed information production and corresponding opportunities were built-up to result in a set of information that leads to its strategic planning.

4. MININGS

The potential financial resources for FM organization can be, a) to increase operation, b) to reduce cost, c) to apply for subsidies, or d) to recruit for new funding opportunities. Since the option c) and d) were rather nominal and obligatory within the process of a) and b), the paper has focused on the first two processes to understand the existing built environment as a resource to mine. The following four sections show the actual agile information production methodologies applied at the OCC.

4.1 Energy and environment monitoring

The theatre and the exhibition hall of OCC are both large-volume open space with event-based, non-continuous operation schedules. The subtropical climate necessitates pre-cooling of the event space previous to the actual operation, where the cost of cooling was comparatively high in regards to similar scale nominal buildings. The building documents were not up to date to run a fast calculation, therefore it was necessary to produce as-built system diagram of the building, while implementing a partial CO_2 monitoring system with motorized dumpers.

- Identification: We identified the pre-cooling period to be the resource.
- Info production Method: CO_2 monitoring to reduce warm exterior air intake.
- Implementation: Instalment of motorized dumpers to automate the control.
- The result: 10% reductions in annual energy cost per year, after the initial investment on monitoring system.

4.2 Project monitoring

Some of the existing upcoming projects on the list had already been budgeted at the time of collaboration initiation. First, the revaluation of the renovation method and the extent of project were adjusted, while occupation rate-based synchronization of project priorities took place in order to reduce non-operational periods, as well as to find opportunities of resource sharing among multiple constructions such as scaffolding via separate ordering.

- Identification: We identified several on-the-horizon projects that can be included in the upcoming project by redefining the construction scope. Also, chances of synchronizing the construction period of multiple projects were found.
- Info production Method: project road mapping and operation-rate monitoring.
- Implementation: Revaluation of project scope and range.
- The result: Reduction in spending on base construction costs such as scaffolding. Cancellation of unnecessary projects. Reduction of non-operational days.

4.3 Demand monitoring

Throughout the years of operation, the initially planned and designed operational scheme has shifted. There were several planned spaces that have rarely been used over the years, yet all of them are maintained at occupational service level. Within the identified spaces, one has history of a major accident, while another has also been a cause of small accidents and maintenance over time. Through monitoring the life cycle occupation rate of each of

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

these spaces and the revenues they have created, it was possible to identify the life cycle usability of these spaces and their potential alternative uses, turning them into rentable space thorough minimum grounds keeping, or relatively large-scale demolition if the return of investment can be met.

- Identification: We identified the unused spaces to be the resource.
- Info production method: Life cycle occupation rate and accumulative maintenance costs were compared to the occupational redesigning cost and its operational cost. To calculate the soil removal volume, 3D scanning was utilized.
- Implementation: Demolition of unused landscape features, reclamation of unused open space for a parking extension/ event space, and drawing a plan for the demolition of water feature that caused fatal accident.
- The result: 23% of the aimed parking addition to be completed in the first year (9% increase). Putting hold onto ordering of structural renovation project for water feature that can then be removed and turned into rentable event space. Reduction in accident-based and non-operational maintenance fees.

4.4 Record monitoring

Through a close look at previous maintenance records and a rapid walk-through, it was possible to identify several targets of resource mining, where an unnecessary large amount of maintenance has been executed repeatedly and frequently. In the case of OCC, some were material-prone, with continuous use of original materials, such as steel drainpipes and steel handrails for exterior locations. Others suggested were operation-prone, such as overgrown vegetation, and some were based on the original design problem. Even though the maintenance for these identified risks was frequent, the aging was also rapid, where a complete removal/ renewal of these risk-prone elements enabled not only LCC reduction by number but also better safety assurance and better serviceability towards the tenants. As for the removed vegetation, it has created better parking circulation as well as additional parking lots, which can be counted within the overarching scheme to increase the total number of parking lots for revenue increase.

- Identification: We identified repeatedly maintained failures to be the resource.
- Info production method: Reorganization of a record in timeline and a building walk-through to tag the potential reductions onto the documentation. Updating the landscape planning.
- Implementation: Updating the material specification, plotting and tagging the vegetation with risk-based priorities and removal, removal of risk-prone high-maintenance building details.
- The result: Reduction in LCC, reduction both in everyday and post-disaster (typhoon) landscape maintenance fees, reduction of disaster-based risks.

5. FINDINGS

Considering the role of these agile, fast-tracked, project-first operations as the foundation for larger budget operations through stakeholder communication, different facets of resource mining have distilled the points of communication betterment.

- Small-scale technology implementation with concrete results could draw incentives toward full-scale renewal of existing building operation systems.
- Timeline coordination was effective in synchronizing and communicating operational (revenue-based) data onto building maintenance (cost-based) data.
- Awareness toward shifting demand enabled the baseline mindset to shift from as-is conservation to profit-oriented preservation.
- Numerable expressions of the risks previously hidden in the record clarified the need for risk management and prioritization initiatives, assisting the decision making process for risk-based, bold interventions.

6. CONCLUSION

Through various trials of problem-oriented information management within the given budget of listed projects, we have seen that even within a tight budgeted organization, it was possible to begin the process of mining for chances of information production. Through reorienting the existing FM schemes to more tenant-oriented, clear and concrete result-based operations, the process of information production was accompanied by on-site results that were more effective in communicating with prefectural staff and other off-site stakeholders. Compared to the upfront planning of strategic schemes and the requesting of a large preparatory budget for information production, it was easier for the off-site financial decision making stakeholders to grasp the visualized information of concrete results and figures that were achieved through the on-site learning-by-doing processes.

Technically, it was difficult to assess whether the subsidy-based, initial large-budgeted information production project may have resulted in a better financial outcome. However, the study provided insight to a more concrete methodology for stakeholder communication, where existing facilities are diverse and need different sets of investment toward its information production. Agile FM as communication-based strategy could be one of the ways to address the needs for strategic FM planning and as an incentive for larger-scale investment in information production.

The developed methodology was more likely to be applicable to information-less and ill-structured facilities with many unsolved problems to start their first steps in defining their sustainable management methods. It may be less applicable to facilities with plenty of as-built information, or where the management has been systematized and the stakeholder relationship well structured.

ABSTRACT

The JKR-UNDP's Building Sector Energy Efficiency Project (BSEEP) in Malaysia is aimed at reducing the growth rate of GHG emission of the building industry in Malaysia. Component 4 task in BSEEP in 2015 was to develop a document allowing the Malaysian building industry to compare energy efficiency of different buildings in a fair manner. The MERIT is one of the output by this project.

MERIT is a proposed methodology for gathering, interpreting and the use of data for the purpose of obtaining an accredited Malaysian Energy Efficiency Rating of Building for Offices (MERIT for Offices) for existing buildings using 12 months of actual data. MERIT is based on the computed Building Energy Intensity (BEI) in kWh/(m².year); an index that is commonly used in South East Asia.

During the development of MERIT, a study was made on the linear normalization of operational hours of office building that is commonly practised by the building industry in South East Asian region. It was found in this study that a linear normalization significantly misrepresents the BEI of an office building operating 24 hours daily versus a building that is operating only 8 hours a day from Monday to Friday.

A linear normalization was unable to capture the effects of building thermal mass and base-load effects of buildings with different operating hours. Further studies establish that a logarithmic fit is more appropriate method for normalizing operational hours of building's BEI.

This will be the 1st tool in South East Asia that will use a logarithmic normalization methodology to allow better representation of the BEI due to different operating hours in buildings.

Keywords: *energy use, building energy rating tool, normalization factor*

1. INTRODUCTION

A recent study made by Exergy Sdn Bhd verified the proposed MERIT logarithmic normalization of different operational hours for buildings in Malaysia. Since there is a second verification party that conducted the study using different methodology, building conditions and software; and arriving at the same result; it is hereby proposed to use the proposed MERIT logarithmic normalization method to compute MERIT's BEI. The proposed changes to the BEI computation is shown as Equation 1-1 below, incorporating the logarithmic "normalization factor (NF)".

$$BEI = \frac{Total\ Building\ Energy\ Consumption}{Rated\ Areas\ x\ Rated\ Hours}\ x\ 52\frac{hours}{week}\ x\ NF$$

Equation 1-1

Where NF is defined as:

Rated Hours per Week (x)	NF
40	0.89
45	0.94
50	0.99
52	1.00
60	1.02
85	1.15
105	1.21
168	1.35

$Where, NF = 0.3113\ln(x) - 0.2381$, R^2 = 99.45

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The linear BEI formula that is commonly in use in South East Asia today is as shown as Equation 1-2:

$$BEI = \frac{Total\ Building\ Energy\ Consumption}{Rated\ Areas\ x\ Rated\ Hours}\ x\ 52\,\frac{hours}{week}$$

Equation 1-2

The MERIT logarithmic normalization is a proposed method that accounts for the effect of base building load during unoccupied hours and the thermal mass effect of the building in the computation of BEI.

The development of this "normalization factor" is similar to the development of the constants in OTTV (Overall Thermal Transmission Value) equation used in Malaysian Standard 1525 since early 1990s; that is based on approximately 60 building energy simulation results.

A total of 72 simulation studies was conducted with different base loads and operating hours to derive the normalization fit for MERIT's BEI.

Finally, it should also be highlighted that the American's EUI (energy usage intensity) also employed a logarithmic fit to normalise buildings with different operational hours of use. The derivation of the logarithmic fit for building operational hours in US was based on thousands of actual performance data collected from existing buildings.

2. BASE LOAD EFFECT

Consider two identical building with the same occupancy density, same air-conditioning system, same lighting system and same plug load. One is being operated 10 hours per day from Monday to Friday and the other one being operated 24 hours a day, 7 days a week. The BEI computed for the 10 hours building and 24 hours building should be the same because the default BEI is normalised to 52 hours per week (via a linear normalization). However, the linear normalization method does provide the same BEI number and one of the reason for this error is due to the base load effect as presented in Figures 2-1, 2-2 and 2-3.

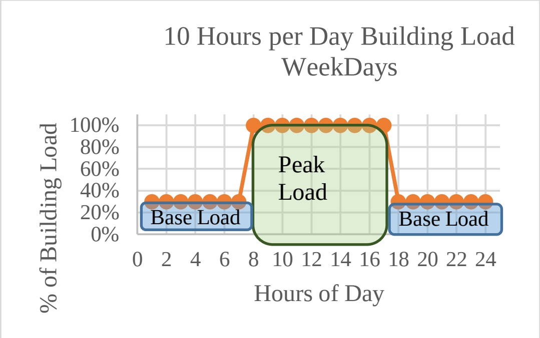

Figure 2-1: Building energy load scenario with 10 hours per day during weekdays

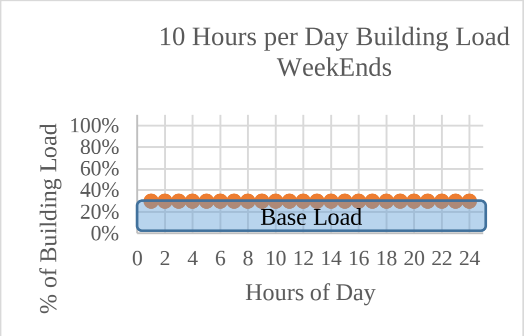

Figure 2-2: Building energy load scenario with 10 hours per day during weekends

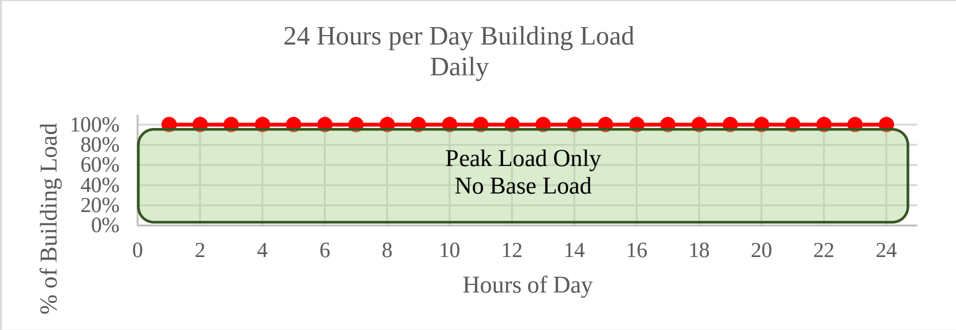

Figure 2-3: Building energy load scenario that operates 24 hours a day

To illustrate the base load effect (ignoring the thermal mass effect for now), a set of BEI computation are provided for 3 scenarios of operating hours: 50, 85 and 168 hours per week following the charts provided. The following assumptions were used on all 3 scenarios modelling a building that is exactly the same, with the only exception of different operating hours; thereby different base load hours:

- Building Size: 1,000 m²
- Peak Load Power: 21.65 kW
- Base Load Power: 6.5 kW

Operating Hours per Week	50 (Base)	85	168
Default Linear BEI, kWh/(m².year)	100	76	58
Error from Base	0%	-24%	-42%

Table 2-1: Computed BEI based on linear normalization

Operating Hours per Week	50 (Base)	85	168
Logarithmic BEI, kWh/(m².year)	99	87	78
Error from Base	0%	-11%	-21%

Table 2-2: Computed BEI based on logarithmic normalization

The computed BEI with Linear Normalization is shown in Table 2-1 and it showed an error up to 42% for building operating 24 hours daily. Table 2-2 showed the computed BEI with Logarithmic Normalization Factor used and it reduces the maximum error down to 21% for the same building operated 24 hours daily.

However, this set of calculation ignored the effect of thermal mass that is also occurring on the building due to the differences of building operational hours. Therefore, the error computed here, by the Proposed Logarithmic Normalization Factor, seems to be large at 21%.

3. THERMAL MASS EFFECT

The thermal mass of a building caused peak cooling load to be different due to the different operational hours. In a building that operate 5 days a week, the building mass will absorb heat during the weekends and cause a peak cooling load to occur on Monday morning. However, in a building that operates 24 hours daily, this thermal mass effect is not relevant anymore as it does not have any hours where the building mass is allowed to heat up.

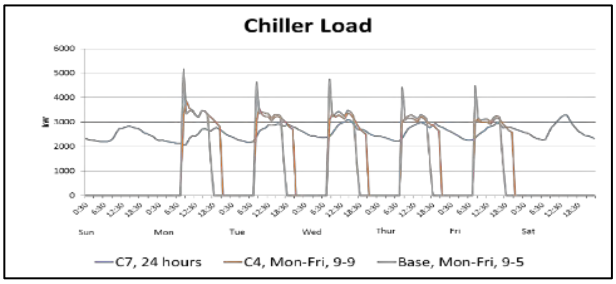

Figure 3-1: Chiller load due to different operating hours

Fundamentally, the longer the operating hours of the air-conditioning system, the less hours the building mass is exposed to heat gain, reducing the relevancy of thermal mass effect on the peak cooling load.

Building energy simulation studies were conducted to capture the effect of building thermal mass effect on the BEI computation. A range of simulation studies were made to calibrate the BEI to account for the base load effect and thermal mass effect at the same time, for buildings with different operational hours.

The dampening of cooling load effect due to longer operational hours of a building is shown in Figure 3-1 above.

4. DERIVATION OF THE MERIT LOGARITHMIC NORMALIZATION FACTOR

The logarithmic normalization factor was derived from a set of 72 cases of simulation study of a typical office building of 17 floors with these conditions:

Different energy use intensity

Three basic building scenarios were created to model the influence of operating hours on the BEI computation. These three building scenarios represents the followings:

- Low Energy Building: This is a model of a building that is reasonably well optimized for energy efficiency. It has good building fabric, low lighting power density, low small power density and efficient air-conditioning equipment. This building is modelled with variable air volume system and variable chill water flow.
- Medium Energy Building: This is a model of a building that has standard efficiency. It has moderate building fabric, medium level of lighting power density, medium level of small power density and average efficiency air-conditioning equipment. This building is modelled with variable air volume system and variable chill water flow.
- High Energy Building: This is a model of a building that has poor energy efficiency. It has poor building fabric, high lighting power density, high small power density and poor efficiency air-conditioning equipment. This building is modelled with constant air volume system and constant chilled water flow.

The lighting and air-conditioning equipment in these three buildings remain exactly the same for all the simulation cases based on the building scenario. The objective of this study is to model the same building with same equipment and occupant density. The only difference that made to the building is the operational hours which impacts the hours of occupancy, hours of small power use, hours of lighting power use and air-conditioning hours.

Different base loads

In addition to the above, three different base loads were simulated for each building scenario. These three base loads were selected to study the influence of different base load on BEI and operational hours of the building. The following assumption on base load were made:

- Small Power base load of 10%
- Small Power base load of 35%
- Small Power base load of 50% (65% for High Energy Building).

Different operating hours

Finally, eight cases of different operating hours of a building were made. These cases modelled building with operating hours of 2080 to 8760 per year. The details of the operating hours are as shown in Table 4-1 below:

Cases	Operating hours (Mon-Fri)	Operating Hours (Sat)	Operating Hours (Sun)	Weekly Operating Hours
Base Case	9am to 5pm	Off	off	40
Case 1	9am to 6pm	Off	off	45
Case 2	8am to 6pm	Off	off	50
Case 3	8am to 6pm	8am to 1pm	off	55
Case 4	9am to 9pm	Off	off	60
Case 5	9am to 9pm	9am to 9pm	9am to 9pm	85

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Case 6	9am to 12 midnight	9am to 12 midnight	9am to 12 midnight	105
Case 7	24 hours	24 hours	24 hours	168

Table 4-1: List of operating hours simulated

The simulation studies were conducted using IES<VE> building simulation software, with full modelling of the air-conditioning system. Conventional building material and power consumption was obtained from the building industry professional through stakeholder's engagement; via the Building Sector Energy Efficiency Project in Malaysia to represent the common building industry practise.

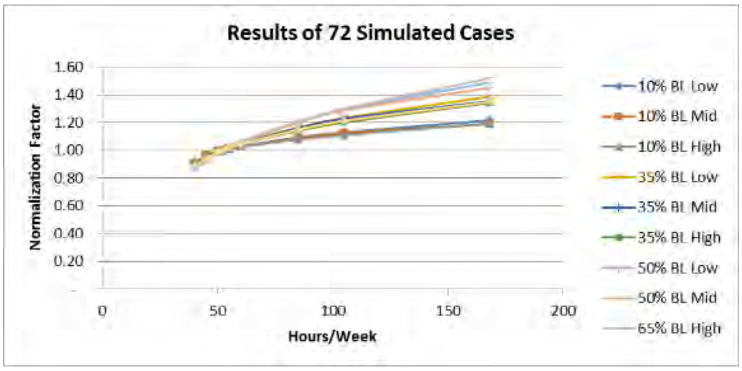

Figure 4-1: Results of 72 simulated cases

Hours/week	Average Normalization Factor	Potential Error of Computed BEI (±) Confidence Interval		
		80%	95%	99%
40	0.89	1.1%	1.7%	2.2%
45	0.94	0.6%	0.9%	1.2%
50	0.99	0.2%	0.2%	0.3%
52	1.00	0.0%	0.0%	0.0%
55	1.02	0.2%	0.4%	0.5%
60	1.04	0.6%	1.0%	1.3%
85	1.15	1.9%	2.9%	3.8%
105	1.21	2.7%	4.1%	5.3%
168	1.35	4.0%	6.1%	8.0%

Table 4-2: Confidence interval of proposed normalization factor

The result of the simulation studies indicated that the proposed calibration factors are very accurate for weekly operational hours between 45 to 60 hours per week, as it is within 99% confidence interval that the computed BEI will have a maximum error of less than 2.2%. Longer operating hours have higher uncertainties due to the ambiguity of the actual base load during non-occupancy hours. The uncertainty of the base load also impacts the building thermal mass, causing further uncertainty.

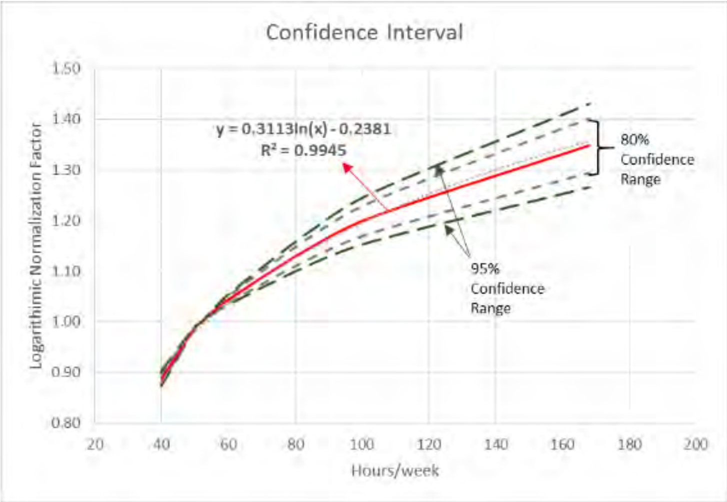

Figure 4-2: Confidence interval of proposed logarithmic normalization factor

Although there are uncertainties, the results from this simulation study showed that the proposed normalization factor will provide a maximum of ±6% error, within a 95% confidence interval in the worst case scenario. This result is deemed accurate enough for such tool to be used by the building industry.

5. VALIDATION BY EXERGY SDN BHD

Exergy Sdn Bhd has completed a verification study on the proposed MERIT logarithmic normalization factor by conducting building energy simulation studies using a different software (EnergyPlus) on four (4) of their actual office building projects. These buildings have BEI ranging from 135 to 180 kWh/(m².year) at 52 hours/week operational hours and has different Gross Floor Area (GFA), different air-conditioned space ratio to GFA, different building orientation, different building heights and different windows to wall ratio for each of the project. The results of Exergy studies are as summarized in the tables below:

Bldg 1	Hr/wk	Act BEI *	Def. BEI**	BEI @ 52 Hr/wk	NF for Bldg 1	MERIT NF	Diff (%)
C1	40	127	164	146	0.89	0.89	**0.0%**
C2	45	135	156	146	0.93	0.94	**-1.1%**
C3	50	143	149	146	0.98	0.99	**-1.0%**
C4	55	152	143	146	1.02	1.02	**0.0%**

Table 5-5: Summary comparison of 4 buildings normalization factor (NF)

The results from Exergy studies verified that the proposed MERIT logarithmic normalization factor provided a good calibration of the BEI due to the differences of operational hours on four of their building projects. The average differences of BEI computation by Exergy to the MERIT proposed logarithmic normalization factor range from a low of -1% to +1%, suggesting a very good fit.

A maximum difference of 4.4% is shown to occur for a building running 24 hours daily. This result corresponded well to the statistical analysis of the proposed MERIT logarithmic normalization factor which showed that the confidence interval gets larger with longer hours of building use.

6. SUMMARY

The proposed logarithmic normalization factor for BEI computation is shown to provide a more correct comparison of energy consumption of buildings with different operational hours of use.

A table providing normalization factor was proposed as a mean of offering the building industry a simple tool for it to be adopted easily. The normalization factor proposed provided a confidence interval of 95% that the computed BEI falls within a margin of error of ±6% even on the worst case scenario.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

It is therefore, proposed for Malaysia building industry to adopt this methodology to normalize BEI of buildings with different operational hours.

ABSTRACT

In Europe, the DIRECTIVE 2010/31/EU requires increasing the number of nearly zero energy buildings. The existing building stock needs to be included in order to achieve the 2020 EU environmental targets. The main barriers of energy neutral refurbishment of existing non-residential buildings appear to be financial rather than technical, next to a number of other extrinsic factors that do not stimulate such an investment. While a business case for new energy neutral buildings is believed to exist, controversial opinions can be found with respect to refurbishment of existing large buildings. Let properties, in particular, have a harder-to-justify business case because of contractual agreements between landlord and tenant: the former is usually accountable for renovation and the latter for energy bills.

The present study aims at providing an overview of the barriers and benefits of energy neutral refurbishment according to relevant stakeholders. Through interviews with real estate investors, energy service companies and tenants, the main interests and risks encountered today to undertake deep energy retrofit as well as technical constraints were investigated. Subsequently, a roundtable discussion was organized with the interviewed real-estate investors. During the roundtable, the investment needed to refurbish an existing office building, meeting the zero energy target was presented and different strategies to improve the financial attractiveness of energy retrofitting were discussed.

The study has shown that combining different benefits in the renovation is fundamental to convince investors. When the design provides additional benefits, such as increasing the rent, or allocating an energy budget to the tenant, the refurbishment can become feasible. Ultimately, a screening-checklist is proposed for a qualitative estimation of the potentials offered by a given building for a feasible energy neutral refurbishment.

Keywords: energy neutral, deep building renovation, stakeholders

1. INTRODUCTION

Of all the large building stock in Europe, only about 1.2% is renovated and about 0.1% demolished in any given year (Energy Performance of Building Directive, 2013). Approximately 1% of new constructions are added to the existing stock and since buildings are long-term assets, designed to function for at least 50 years, it is foreseen that 75-90% of those standing today will remain in use in 2050. Given the fact that energy use in buildings represents about 40% of Europe's total energy consumption and CO_2 emission (European Commission, 2008), deep energy retrofit should increase strongly, aiming at a rate of at least 2% yearly and with no less than 60% of energy savings (European Commission, 2015). Both the quality and the speed of refurbishment need to improve. This is why this study addresses the zero energy refurbishment, as a way to analyse a high, but soon required, energy goal. Here the term zero energy refers to a building with zero net energy consumption, meaning that total amount of energy used by the building on an annual basis, is roughly equal to the amount of renewable energy created onsite (Torcellini et al., 2006).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Contrary to the case of refurbishment, the business case existence for new buildings to achieve the zero energy target is not subject of discussion. This is not only because of the return of investment new buildings can offer, but mainly because energy neutrality will be a compulsory practice for all new buildings from the year 2020 (European Commission, 2010). A rather complex business case concerns let properties. Rented properties in The Netherlands host 32% of Dutch residents (EUROSTAT, 2016) and 63% of office buildings (Rijksdienst voor het cultureel erfgoed, 2013). The contractual agreement for these properties usually considers the building owner accountable for renovation costs while the tenants for energy bills.

Under this condition, the present study analyses barriers and opportunities of the energy neutral refurbishment according to relevant stakeholders. Knowing the perspective of actors involved in the decision-making and design processes, as well as the one of the users, can help policy makers and designers achieving the zero energy target. First, the main interests and risks encountered today to undertake deep energy retrofit as well as technical constrains, were investigated, through interviews with real estate investors, energy service companies and tenants. Subsequently, a roundtable discussion was organized with the interviewed real-estate investors. Finally, a screening-checklist is proposed for a qualitative estimation of the opportunities of a given building for a feasible zero energy refurbishment.

2. METHODS

The method to discuss the viewpoint of some relevant stakeholders on the zero energy refurbishment of let properties, included two phases: first a set of interviews were conducted, to identify barriers and opportunities; then a roundtable discussion with different real-estate investors was organized, to evaluate the proposed business cases.

2.1 Interviews

For the scope of this research, a general interview guide approach (Turner, 2010) was chosen. A list of questions was prepared but only used as outline to assure covering the intended topics. A total of 9 interviews were conducted covering the following topics:

- Personal knowledge of energy neutral concepts applied to existing buildings;
- Drivers for refurbishment and drivers for zero energy refurbishment;
- Opportunities (business/ market/ design/ innovation related) of zero energy refurbishment;
- Barriers for zero energy refurbishment.

The interviewed stakeholder were investors, designers, real estate experts, energy service companies (ESCOs), tenants.

2.2 Roundtable discussion

At the roundtable discussion the following was presented to investors:

- A case study design, aiming at determining the interventions and the costs needed to refurbish an existing office building, meeting the zero energy target;
- A set of strategies studied using Monte Carlo simulations for risk and sensitivity analysis;

The methods for the zero energy design and the Monte Carlo simulations, can be found in Greco et al. (2016).

The roundtable discussion was structured as follows:

- Introduction/brainstorming session on barriers for the zero energy refurbishment of commercial buildings;
- Presentation of the case study, model and strategies;
- Model inputs change, using participants' suggestions;
- Running of the improved Monte Carlo simulations;
- Discussion of new results;
- Wrap-up expressing participants' vision on the future of zero energy refurbishment.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.2.1 Case study design

The case study presented to investors consisted of a single-tenant Office building from 1980, occupying a gross floor area of approximately 35,000 m^2. For this, it was initially estimated a price of about 12 mln € to upgrade from energy label G to zero-energy, with a payback time of 18 years and a NPV equal to 3.27 mln €.

2.2.2 Strategies

The deterministic analysis that brought to the results above mentioned was carrying a certain degree of uncertainties, related to volatility of the variables used as inputs. Therefore, a stochastic model was made, in order to take into account such uncertainties, allowing for a more objective discussion with investors.

The following strategies were proposed (further explanation follows below):

- Base Case
- Budget Allocation
- Increase of surface
- Combination

All the strategies describe a renovation consisting of the minimum interventions needed to reach zero energy with a rent within the market range for that specific location. The base case represents today's common practice, where the owner pays for the renovation and the tenant for the energy bills. In the budget allocation strategy the tenant pays a quota that is equal or smaller than the previous energy bill, which is added to the competitive market rent. The owner officially pays for energy, but with zero energy buildings the only energy to be paid is for backup system (lack of renewable energy supply) and grid connection. Should the tenant demand too much energy, he would need to pay for it. Such a measure seems to offer a win-win situation for tenant and owner solving the typical user-behavior problem of all-inclusive contracts and allowing the owner benefiting from renovation. The increase of surface strategy aims at increasing the rentable space with the renovation, allowing increasing the rent within market range. The combination strategy couples the two strategies above mentioned. Table 1 summarizes the assumptions made for each strategy, together with the probability for each strategy to provide a positive NPV and a payback period shorter than 15 years. Note that a 5% discount rate is used in the NPV calculation. It can be seen that the probability for the NPV to be positive goes from 32% with the base case strategy to 91% with the combination strategy.

	Increase of floor area	Owner does not pay for energy	Owner pays for energy	Probability NPV>0 (%)	Probability payback t < 15 years (%)
Base Case		✓		32	6
Budget allocation			✓	70	31
Increase of surface	✓	✓		65	28
Combination	✓		✓	91	61

Table 1: Description of the Four Strategies and the Related Probability

3. RESULTS

3.1 Subtitle

3.1.1 Investors

According to all the investors interviewed, one of the main drivers for any type of refurbishment is location. In real-estate evaluation, location is considered to be the most relevant factor. The minimum and maximum rental prices are related to location. The limit of rental increase given by location can be therefore determinant for the decision making of energy retrofitting.

The second top driver is considered to be the tenant. In particular: the number of tenants per building and the tenants' prestige.

In case of a single tenant who is asking for a building renovation, the owner is in a weak position when it comes to decision-making. If the tenant leaves, it would be more difficult to find a different tenant that suits the building

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

dimension. Changing tenant has also the risk of having to undertake the renovation again if required, under certain market conditions. On the other hand, multiple tenants are more difficult to manage and the owner would rather agree on renovating than losing a single tenant for a large building. When the tenant is prestigious, corporate image could be an important factor, as being located in sustainable buildings is more desirable. In addition, when the tenant is prestigious, it is more likely to have the financial possibility of moving to a different building, in case the current one does not satisfy his requirements.

Moving to the barriers, the most relevant is that the energy efficiency does not (yet) directly reflect in a pre-definable increased building value or revenue. A general remark is that investors are hesitant about the technical feasibility of zero energy renovation.

3.1.2 Designers

Designers follow their clients' requests concerning energy efficiency. Only when making an offer to the client, they might suggest different energy targets. Concerning energy efficiency, their primary role consists in providing clients with solutions for energy saving and an estimation of the actual savings they can "guarantee" when a certain measure is applied.

Designers see more challenges in refurbishment than in new buildings, independently of the energy target. However, for high standards of energy efficiency, the interventions are objectively more risky and complex.

3.1.3 Real estate experts

With real estate experts, the barriers and drivers identified were similar to the ones mentioned by the investors. Location, property value increase and vacancy rate are the most important drivers. The return of investment and the revenue coming from a renovation are expected to be the decision-making parameters for a building owner.

3.1.4 ESCOs

Energy Service Companies are concerned about the "de-centralization" of energy that follows from the application of renewable sources. In other terms energy production is coming from different sources (e.g. from a rooftop with solar panels) and not anymore from few dominant energy providers. ESCOs are trying to get a managing role in this new market. They are also starting to invest in energy renovation for commercial or public buildings, while they do not do it for houses (this is to invest on buildings that can provide a more safe return of investment). As far as zero energy is concerned, the general impression is that many technological and economical limitations do not allow for an actual implementation of high-energy efficiency measures. High initial costs with a too long payback periods are to be considered the main barrier in this context.

3.1.5 Tenants

The tenant interviewed affirmed that zero energy is not a target he would consider for his building. He also doubts whether a zero energy renovation would actually be possible. The tenant does care about energy savings and corporate image. The office is the working place for employees and meeting points with clients, what is therefore considered important is a degree of sustainability that can be seen and felt by clients and personnel working in the building.

3.2 Roundtable discussion

According to the investors invited to the roundtable discussion, the most important barriers for an attractive business case for the zero energy refurbishment are the capital investment required and the way such interventions are reflected in the final value of the refurbished building. Another problem already mentioned that brings doubts among investors is the difficulty to guarantee that a certain building performs as zero energy, taking the user behavior and the availability of renewable energy supply into account. The investors confirmed the hypothesis that the most important parameters to affect the zero energy refurbishment of commercial buildings are location and age of the building.

Figure 1: Roundtable discussion

When the location is central and the building needs to be renovated for additional reasons (e.g. it is old and needs upgrade or needs to be adapted to a different function), it is easier to create the business case. Changing the building function could help creating the business case depending on location. The more convenient building age for a zero energy renovation is 25-30 years old. This is a time when the building needs renovation anyway and it is therefore a good moment to add zero-energy as a goal of the renovation plan.

Generally, the investors found the model representative and considered that the strategies made are realistic and helping building the business case for the zero energy refurbishment. It was also suggested that risk and sensitivity analysis, are an excellent approach to evaluate business case opportunities.

4. DISCUSSION

Including the zero energy target as objective of a refurbishment is considered a time and resource consuming process by both investors and designers. To support this process, a screening checklist is proposed (see Figure 2). The checklist was based on the barriers identified and highlights the parameters that were considered important for the business case. Thus, it can speed up the decision making process and help predicting if the zero energy target can bring financial benefit, suggesting to explore this option with a preliminary design. If all the conditions stated in both a) and b) subsist (the ones in the darker area, excluding additional benefits), then meeting the zero energy target will most likely bring financial benefits to the owner who invests in the refurbishment and rents out the building. The conditions under “additional benefits” are indeed extra and can only improve the business case; alone, they are not sufficient to create it.

Business case screening checklist for zero energy refurbishment	
a) Building description	
The building is located in an area that is considered a good location for its specific function	☐
The building is in need of major refurbishment because of one or more of the following reasons: • It is between 25-30 years old and never had a major refurbishment • More than 25 years have passed since the last major refurbishment • The current tenant strictly demands deep energy retrofit • A new function has already been planned, which implies major architectural transformations • Other	☐
Additional benefits if:	
The renovation gives opportunity for rentable floor area extension	☐
Replacing of the building envelope gives opportunity for on-site energy production (e.g. PV panels installation on the façades)	☐
b) Commercial conditions after renovation	
The building has an occupancy rate of at least 50%	☐
It is possible to increase the total rent* (e.g. tenant changes; same tenant is willing to pay more; market, regulations and location allow it)	☐
The building value increases	☐
Additional benefits if:	
Contractual agreements allow allocating an energy budget to the tenant	☐
*Total rent: surface x rent x occupancy rate	

Figure 2: Screening check list to support the evaluation of the financial attractiveness of energy neutral refurbishment

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

5. CONCLUSION

Zero energy refurbishment does not belong to regular practice, particularly in the commercial sector. The stakeholders interviewed agreed that zero energy refurbishment of let properties lack of financial attractiveness. This represents a great barrier for the so needed large-scale implementation of the energy neutral refurbishment. It can be concluded that the most important parameters that play a role in determining the business case are location, building characteristics and tenants' requirements.

Therefore, different strategies where proposed to a group of relevant real-estate investors to discuss the opportunities to improve the financial attractiveness of those interventions. Strategies such as increasing the building surface with the renovation and allocating an energy budget to the tenant, proved to improve the business case and were appreciated by investors. Increasing the rentable surface however, is neither always possible nor at all times convenient. Different is the case of the energy budget allocation strategy, which would provide a zero-cost solution for improving the business case. Further action by governmental entities would be needed to regulate and support such and similar strategies. This study shows that there are opportunities to improve the financial attractiveness of zero energy refurbishment. Stakeholders' awareness about the opportunities of undertaking deep energy retrofit meeting the net-zero energy target, should increase strongly. It is also crucial to consider the weight that real-estate investors give to certifications showing the need of warranty for zero-energy performance. The latter suggests that zero-energy will become more common as improved certification system will be introduced and a surplus value will be given to the energy performance of buildings in real-estate evaluation.

How a Changing Socioeconomic Context Affects the Demand for High-performance Buildings

Clinton ANDREWS[a]

[a] *Rutgers University, United States of America, cja1@rutgers.edu*

ABSTRACT

Technological and design innovations are important drivers of change in the built environment, but they do not work alone. This paper examines a parallel set of demographic and economic trends that will shape future demand for high-performance buildings. It considers historical and projected human populations, since more people means more buildings. It examines changing age distributions, noting that people are living and working longer, older people are becoming a macroeconomic burden, and fewer children are entering the demographic pipeline. The paper also examines economic changes that are resulting in fewer hours worked and more leisure time, albeit with great disparities across countries and occupations, as well as increasing income inequality. It also investigates the role of urbanization which can generate benefits due to propinquity and mobility, as well as costs such as segregation and congestion. Finally, the paper considers the emergence of transhumanism, exemplified by the shift from an office in a building to a smartphone in your pocket, and eventually to implants under your skin. Each of these factors will influence the amount and qualities of shelter we will require, the home/workplace split, the functions required of future buildings, and the energy and environmental footprints of buildings. It relies on the latest historical data and projections by the United Nations, OECD, and other statistical agencies to quantify each of these trends and their implications for the high-performance building community.

Keywords: high-performance building, urban regeneration, green economics

1. INTRODUCTION

When researchers think about the future of high-performance buildings, many use a supply-side perspective that emphasizes emerging technological opportunities and policy objectives, such as smarter systems and carbon neutrality, respectively. This paper instead uses a demand-side perspective to ask how social and economic forces will shape the built environment. It discusses implications of several well established demographic trends as well as a set of more contingent social and economic trends that will affect the demand for high-performance buildings.

2. TRENDS

Several powerful forces will affect the demand for future high-performance buildings, but the trajectories vary from highly likely to highly speculative. This section introduces the most relevant of these trends. See Table 1 for details.

2.1 Established demographic trends

The human population is highly likely to continue growing in every region of the world, with the largest absolute and relative growth occurring in Asia, Africa, and to a lesser extent, Latin America and the Caribbean. The population growth rate represents a lower-bound estimate of the growth rate of demand for new buildings. Replacement of obsolete buildings will further add to demand, and may dominate in Europe, Northern America, and Oceania.

Variable	Year	World	Africa	Asia	Europe	Latin America & Carribean	Northern America
Population (billions)	1950	2.53	0.23	1.39	0.55	0.17	0.17
	2000	6.13	0.81	3.71	0.73	0.53	0.31
	2050	9.73	2.48	5.27	0.71	0.78	0.43
Median Age (years)	1950	24	19	22	29	20	30
	2000	26	18	26	38	24	35
	2050	36	25	40	46	41	42
Urban Population (%)	1950	30	14	18	52	41	64
	2000	47	34	37	71	75	79
	2050	66	56	64	82	86	87

Table 1: Selected demographic variables by region: historical and projected

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

More interesting for the high-performance building sector is the expected aging of the human population. Median ages will increase in every region of the world, both because people are living longer and because they are having proportionally fewer children. The common measure of whether the aged population is becoming an economic burden is the old age dependency ratio (retired dependents/ working-age population), and it is expected to reach levels not experienced in the prior 50 years. This implies that many older people are likely to continue working past previously common retirement ages. They will demand affordances at home and at work to compensate for diminishing mobility, eyesight, hearing, and cognitive function. User-friendliness will gain importance as a metric for high-performance buildings.

Urbanization is a third relentless driver of demand for buildings. Every region of the world will experience an increase in the percentage of its population that lives in urban areas. The rural-to-urban migration that fuels urbanization implies, simultaneously, that there will chronic urban housing shortages and underutilized rural housing.

The proportion of the urban population living in large cities will also increase all around the world. However, it is inappropriate to assume that this will lead to widespread adoption of Hong Kong-style, high-rise building designs. Instead it is important to note that the land areas of most major cities are growing faster than their populations, so that urban densities are diminishing. High-rise building will be a stylistic choice rather than a demographic necessity, and high-performance buildings will continue to come in varied shaped and sizes.

2.2 Plausible economic trends

Positive growth in aggregate and per capita income is likely in all regions of the world, although rates of growth may vary substantially. Differences between high- and low-growth scenarios will be due to the extent of economic openness, inter-country convergence, and growth in productivity. Annual growth in Gross Domestic Product (GDP) per capita globally is likely to be the range of 1% to 5% by 2030 and to diminish to 0% to 3% by 2050. GDP growth and building construction show strong correlations historically, so the construction industry may follow a similar trajectory.

Income inequality has also been increasing worldwide due to economic globalization, uneven education and skill levels across workers, principal-agent problems that allow some leaders to reap outsized financial rewards, and tax policies that concentrate wealth. If this trend continues, it will exacerbate the problem of unaffordable housing in high-growth locations, while continuing to fuel investment in luxury buildings in those same locations. High-performance building frequently targets luxury segments of local real estate markets, so it benefits from the income inequality trend. However, the greater human need will lie with innovative, affordable housing.

The number of hours worked per year by a typical worker has declined in many countries around the world due to improved total factor productivity, changing social norms, and labor-friendly public policies. However, the average trend masks three diverging patterns: (1) High earners are working more hours, (2) Lower earners are often working part time, and (3) More females are working. Residential buildings are therefore likely to enjoy continued intensive use, and commercial buildings will need to offer more flexibility regarding work activities, schedules, and gender affordances.

Advances in information and communication technology (ICT) are helping some workers become untethered from their desks because they can now work anywhere, making cafes and airports new foci for high-performance building. Many more workers, however, will remain tied to specific locations because they need to serve the public, use capital equipment, or engage in face-to-face collaborations.

Two aspects of the ongoing ICT revolution may be of greater interest. First, the human-building interface is changing, as sensor networks become available to monitor local environmental conditions and occupant activities. This movement toward smarter buildings has great potential to improve energy and water efficiency, as long as the systems accommodate the reasonable range of real occupant behaviors. Smart buildings need good user interfaces.

The second ICT trend depends on the relentless force of Moore's Law which has led to exponentially increasing computing capacity, exponentially decreasing computing costs, and dramatic miniaturization of equipment. If the previous decade supported a shift from an office (with a desk, telephone, and personal computer) to a mobile

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

phone that performs multiple functions anywhere, the next decade could see a shift to miniaturized, perhaps subdermal forms of human augmentation by technology. Buildings will have to adapt continually to serve the information infrastructure needs of these transhumans. Information flows may become as much of a design consideration as energy flows.

3. CONCLUSION

Longstanding demographic forces and less certain economic trends both will shape the demand for high-performance buildings. A growing population will support a growing demand for buildings, especially in Africa and Asia. An aging population will demand more user-friendly buildings with affordances. An urbanizing population will require more affordable housing and convenient workplaces, but not necessarily more high-rise buildings. Continued GDP growth will spur continued building construction, but income inequality may exacerbate affordable housing shortages in growing cities even as concentrated wealth supports high-performance building innovations. Working life may continue to change, with some working fewer hours and others more hours, with some workers becoming increasingly mobile even as others stay in place to provide service, use capital-intensive equipment, or perform in-person collaborations. Advances in ICT seem likely to change both buildings and their occupants, bringing high-performance aspirations to building systems and the technologically-augmented humans who use them. User-friendly interfaces, distributed sensor networks and computing power, and seamless information flows are likely to play more central roles in defining which structures are considered to be high performance buildings.

Green Lease Insight – Integrated Approach

Tim SHEN[a]

[a] *RICS, Hong Kong SAR, tim.shen@cbre.com*

ABSTRACT

This paper uses three case studies to illustrate green lease program development best practices for the Hong Kong commercial market. In addressing common barriers to the adoption of green leases, it is hoped that green clauses can rapidly become an industry norm.

Keywords: green lease, climate change, industry insights

1. INTRODUCTION

Climate change is the most pressing long term environmental issue of our time. It's widely regarded that the real estate industry is responsible for around 40% of Greenhouse Gas ('GHG') emissions from end-use energy consumption, and in some markets such as Hong Kong, that number can be as high as 90%. In the commercial sector, the amount of energy used is a combination of tenant and landlord activities. Tenants can be responsible for up to 50% of energy consumption. Through the considered incorporation of green provisions in the lease process, tenants and landlords can work together to reduce energy consumption and associated GHG emissions and other negative environmental impacts, paving a path to mutual realisation of multiple business benefits.

Various publications have been released around the world to educate the real estate industry on the concepts behind green leases, outlining the potential benefits, and providing examples of clauses that landlords and tenants can consider implementing. These include the UK Better Buildings Partnership Green Lease Toolkit, Council of Australian Government's Green Lease Handbook, Singapore Building and Construction Authority's Office Green Schedule, and Hong Kong Green Building Council's Green Tenancy Driver for Office Buildings. However, despite these valuable resources, we have yet to see the mainstream adoption of green leases in most Asia markets, and are still far from it becoming business as usual.

This Insight Paper seeks to build on the existing body of green lease literature by looking directly at some practical issues that present an ongoing barrier to widespread adoption and seeing how industry leaders have overcome these. The aim of this document is to provide a flexible model for the creation and implementation of effective green lease clauses for a variety of asset classes, and by both landlords and tenants. To that end, the paper provides perspectives from both landlords and tenants, and practical advice for, different stakeholder groups including peers, their brokerage agents, legal representatives and property managers.

The Insight Paper will show how an integrated approach to engaging all stakeholders in the lease negotiation and transaction process can lead to more effective uptake of green lease clauses, and lead to tangible positive outcomes for landlord and tenant alike. The authors have endeavoured not to duplicate existing work, and have provided references to some of the excellent work already carried out in the industry to date, which readers are encouraged to explore.

2. GREEN LEASES IN THEORY

Although 'Green Lease' is now a common industry term, it is perhaps more useful to refer to 'green clauses' that are typically incorporated into an otherwise standard commercial lease document as being what most industry stakeholders would recognise as a green lease. There are a few examples of lease agreements which are more radical in nature, with commercial conditions being built from the ground up with environmental performance in mind, but these are very much still the exception, rather than the norm. These, so called, 'Dark Green Leases' include provisions to facilitate extreme levels of green building performance, such as committing tenants to a strict energy budget to ensure a building can meet its net-zero energy goals.

Green lease clauses can be introduced by both landlords and tenants, but usually in either case, organisations will start out developing 'Light Green Leases' which seek to address environmental issues in basic terms, and usually

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

allowing flexibility with regards to these are treated in the negotiation process. Often, environmental requirements are not directly embedded in the lease document itself, either because one or both parties have a valid reason for not wanting to make them legally binding, or because requirements may change during the tenancy and are better placed in a separate Memorandum of Understanding ('MOU'), Service Level Agreement ('SLA'), or some other kind of addenda that can be more readily reviewed and revised by the parties. Compliance with the green performance requirements in the addenda is then referenced in the lease. Light Green Leases will usually not include any form of penalty for defaulting on a green lease clause – the focus being on the landlord and tenant fostering a relationship of ongoing communication and collaboration, where transparency and teamwork help both sides achieve greater value from the tenancy. This is a key concept – a good green lease will benefit both signatories.

The types of issues typically covered by green lease clauses include dialogue, sharing of data, and actual performance on energy and water efficiency, and waste management. Often, green building issues will be addressed, such as landlord requirements for tenant green fit-outs, or tenant requirements for base building specifications, future upgrades, and property management practices to support green certified fit-outs and other programs such as certified Environmental Management Systems (e.g. ISO 14001). Most green lease clauses are focused on performance outcomes and are therefore ongoing in nature, needing to be translated into processes and procedures for property, facility, and office management personnel.

3. COMMON CHALLENGES TO ADOPTION

While the fundamentals of green lease clauses are relatively straight forward in principle, there are numerous practical challenges that prevent mainstream adoption. Some of these challenges relate to common real estate practices, such as the often-cited issue of split incentives between the parties, which can present very real obstacles during negotiations. Even quite pragmatic issues such as these can be overcome if a green lease program is established with the right foundation. Doing so also helps to address other roadblocks to green lease adoption, including:

- Lack of understanding or misunderstanding about what green leases are, and what they require.
- A perception that green lease clauses present an unnecessary risk – This can vary between stakeholders. To the tenant or landlord, it may be an obligatory risk or the concern over increased cost of fit-out, or operations, whereas to brokers, the issue may be that negotiating additional requirements that aren't considered essential, could present a risk to a deal getting signed.
- The sheer diversity within the real estate industry, when overlaid with the range of issues that green lease clauses could potentially cover, can be overwhelming – Leading to a lack of focus and trying to address too much in specific terms. The greater the scope, the more stakeholder issues are likely to come to bear.
- A lack of executive ownership, stakeholder accountability, and incentive for stakeholders to actively pursue green lease negotiation.

4. TOWARDS A PRACTICAL FRAMEWORK FOR GREEN LEASE ADOPTION

In reviewing common practices adopted by companies that have created successful green lease programs to date, several best practices are evident, that are strongly recommended for anyone wishing to start creating a green lease program.

- Before reviewing industry publications that advise on green lease concepts, first gather a group of stakeholders to discuss and agree why green lease clauses are needed, and what the performance goals for a green lease program should be.
- Review common clauses and work with legal advisors to adapt clauses that facilitate the achievement of the identified, but only develop clauses that are deemed necessary, and can clearly be explained to the other party in terms of necessity (e.g. achieving corporate goals, or supporting green building certification).
- Identify key stakeholders in the lease negotiation process and ensure they are well-versed on the green clauses, why they are important, the required outcomes, and how best to introduce and discuss them with the other party. Consider incentivising stakeholders though Key Performance Indicators.
- Integrate the green lease clauses into the real estate process – Particularly ensuring that teams involved in ongoing operations are involved in discussions early.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Periodically review and revise clauses and their supporting strategies.

4.1 Case study – A landlord green lease

The management team of one prominent Hong Kong landlord wanted to explore how green leases could enhance the environmental performance of its portfolio to the benefit of tenants and the communities they support, but at the same time recognised that being a relatively new concept in Hong Kong, and determined that it would be more effective not to try to unilaterally develop a program.

Therefore, in order to better understand where the market was positioned with respect to considering green lease clauses, they convened a stakeholder workshop with other landlords in Hong Kong and a representative selection of tenants – including those that have a demonstrated commitment to green real estate, for example, having green building certified fit-outs of premises in Hong Kong. The purpose of the workshop was to learn from other stakeholders' experiences and foster alignment to identify the most effective ways to move forward, and enable the landlord to create a green lease program that also actively supported green tenants.

The team reviewed best practice from other countries, such as the UK, Australia, and Singapore, and distilled the best from each that fitted within the context of the Hong Kong market. Differences in how tenants are billed for utilities or how waste is managed were critical factors for adaption. The landlord focused on energy, water, and waste because of their universal nature and ease of discussion with tenants.

From their stakeholder engagement program, it became clear that for most tenants, there was a need to do much more work as an industry to raise awareness before green clauses could be formally adopted within legal documents.

The team is holding back from switching straight to a legally binding green contract. Instead, they have opted to take a phased approach to implementing green leases, starting with the incorporation of green aspects into their standard tenant handbook. This is now referenced in all formal lease agreement and all new tenants are thus now required to abide by the green requirements in the handbook. As leases are renewed through their natural cycles, actual green clauses will be gradually introduced throughout the portfolio.

In addition, as green clauses are directly incorporated into leases, the landlord plans to adopt a graduated approach with foundational, primary, intermediate, and advanced clauses being introduced. This is an acknowledgement of the reality that, while everyone has a general sense of environmental challenges that Hong Kong faces, as a landlord, the landlord has a very diverse tenant base, some of whom will want to negotiate very progressive environmental requirements into their lease, and some of whom will be more comfortable with basic elements.

Foundational clauses acknowledge fundamental issues such as energy, water, and waste and provide a platform for collaboration between landlord and tenants. Primary clause will advance this to an agreement to report on performance annually, whereas Intermediate clauses require monthly reporting. Advanced clauses are designed for tenants with their own green commitments - in addition to requiring intensity reporting, there will be a requirement to follow the Hong Kong Green Building Council guidelines such as BEAM Plus Interiors certification. Each level of green lease clause is designed to progressively build on the previous one, rather than represent a huge leap forward.

The program itself has presented challenges for the landlord too, such as how to standardise Greenhouse Gas emissions reporting with tenants. In preparation for this, the team has conducted a thorough review of their own sustainability policies and practices in preparation for the development of formal green lease clauses. The team has also started to organise green lease information sharing workshops through its Tenant Academy to gradually educate tenants and raise awareness of environmental challenges, and the benefits of green occupancy strategies and lease clauses.

The landlord's longer term goals are to see if a platform can be developed that creates a community between itself, green lease tenants, their employees, visitors and people who live around the portfolio. Ideally this would include collaboration with other Hong Kong landlords to ultimately develop standard green lease terms for the Hong Kong market.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4.2 Case study – A tenant green lease

Standard Chartered Bank ('SCB') has been running a tenant green lease program covering their entire global real estate portfolio for several years. Given that their corporate strategy is focused on providing banking services in emerging markets, this has required the development of a green lease platform that can successfully integrate clauses in markets where it will be a completely new concept to most landlords, and even green buildings are at a nascent stage of development. This has become a successful program, introducing green leases to many countries for the first time.

The development of the SCB green lease program has followed the best-practice approach outlined in this paper. Initially the bank's corporate real estate team recognised that green lease clauses would be essential to meeting the company's aggressive operational energy and water intensity performance targets . In many emerging markets there is an institutional lack of transparency for a tenant over their actual energy use, so simply having a clause to provide consumption data would be hugely enabling.

The team started by reviewing the sort of green lease advisory documents mentioned in the introduction, and focused down on those provisions that seemed most likely to help meet their corporate goals for energy and water across the portfolio. Through discussion between asset managers and facility managers, a list of six clauses was finally agreed upon.

Importantly, in drafting these clauses, the team took care to present obligations as being mutual, with the Bank and its landlord agreeing to share and collaborate where applicable. This makes a big difference in how green lease clauses are initially perceived by the other party, and facilitates consideration and increases the chance of adoption.

A negotiation strategy was created and disseminated through the asset managers to leasing advisors. While ideally, the Bank wanted all six leases to be incorporated into every lease document, the corporate real estate team recognised that this wasn't going to be feasible from day one – particularly in emerging markets. Therefore, while leasing agents were asked to present and negotiate all six clauses for each lease opportunity, they provided some flexibility with regard to adoption. The exception to this was the first clause, which was made mandatory for any space greater than 10,000 square feet.

When they outsourced their global asset and transaction management advisory in 2015, the Bank made a review and enhancement of the green lease program a priority for their service provider, attaching overall account Key Performance Indicators including an absolute increase in the rate of green lease clause adoption year-on-year. In addition, the appointed service provider was tasked with working with a competitor organisation providing outsourced facility management services to develop a plan to convert successfully negotiated green lease clauses into performance outcomes during the tenancy, where landlord cooperation could be tracked.

The service provider developed an enhanced green lease strategy for the bank, which integrated the FM provider, whereby they would be informed of which clauses were included in each new lease so they could follow up with the landlord during fit-out and occupancy. The facility managers are also invited to provide feedback to the leasing team on how the clauses actually perform to enable the whole program to be periodically reviewed and enhanced. Another key component of the new strategy was a comprehensive training program that was developed for the service provider's account staff and leasing brokers to introduce them to the concept of green leases, the Bank's objectives, and advise on how to effectively introduce and discuss clauses with landlords, as well as properly track outcomes. After the implementation of this program, the global green lease adoption rate increased by 68% in the first year. Significantly, now that they have far greater visibility on actual consumption data, they are in a much better position to start managing for performance to achieve their efficiency targets.

4.3 Case study –Working with tenant green leases

Increasingly, tenants have their own green requirements presented in lease clauses to landlords. If the landlord already has green lease clauses, this often makes the process easier for both parties to negotiate because they are approaching the discussion from a position where stakeholders are already familiar with the issues and common clauses. However, this can present a challenge if the landlord does not have experience with green leases, as was the case for one major Hong Kong landlord when it was leasing a new commercial property to two new major tenants. Each tenant had different requirements and approaches to discussing green lease requirements.

The first started in a traditional way, with discussions around standard commercial terms. At the time, the building was still under construction, so the tenant wanted to look at potential base building features that could be adapted to meet their green building requirements, particularly with respect to optimising the performance of future operations. Because of the uncertainty surrounding what those operational needs would be, both parties realised that they could not be hardwired into the lease document itself because it would not be practical to repeatedly go back to the lease to update it as requirements evolved. Therefore it was agreed that the lease would reference a separate document that covered all operational issues, including environmental performance, which could be regularly updated.

A second tenant introduced their green requirements to the landlord prior to the discussions of commercial terms. They had an established green building program and rigorous performance targets, shared case studies and even invited the landlord to visit their green offices in other countries to better understand their expectations from a regional headquarters. They needed assurance from the landlord that they were willing and able to be flexible to accommodate their green needs even before commercial terms were considered. A detailed landlord selection Q&A session on operations planning was held, and the tenant gave active feedback on their expected standards for energy performance, water treatment, and waste management. The landlord's agreement to meeting fundamental environmental commitments became a prerequisite to moving on to discuss numbers and starting the traditional lease negotiation process. Because of the focus on performance, it was agreed between the parties to develop a Service Level Agreement that was formally incorporated into the lease, and includes the provision for not just an annual review, but also an improvement plan.

The leases for both tenants reference the agreement to setup and share a comprehensive environmental management plan that, in addition to covering the sharing of energy, water, and waste performance data, also commits the landlord to maintaining indoor air quality to international standards, and reducing environmental impact to community and society. The leases also oblige the landlord to support the tenant's green fit-out certification goals.

The experience with these tenants turned out to be the start of a valuable sustainability journey for the landlord. In seeking ongoing performance improvements, they have had to review standard property management practices at a very detailed level and evaluate how changes to standard protocols, such as raising common area temperature set points from 23.5°C to 25°C would be best managed – requiring asset managers to actively work on education and change management with their stakeholders, including staff and tenant, ensuring context and benefits were effectively communicated.

A critical difference promoted by the green lease process in this building, was the development of an unprecedented level of transparency and ongoing communication and collaboration between the landlord and its tenants. This not only included sharing landlord data on building energy use, but also pricing. The results of occupancy patterns and behaviours (such as elevator usage) are recorded and shared with the tenants so they can be disseminated with their employees. This has helped tenants to review their workplace strategies to drive ever greater efficiencies, particularly with respect to after-hours working arrangements.

In this case, the key to successfully meeting the green lease requirements of two large multinational tenants was for the landlord leasing team to engage with their property management colleagues and bring them into the discussions from the beginning. Having obtained their feedback and approval, the leasing team had the confidence to negotiate and agree to the tenant's green lease requests.

Both parties regularly follow up on the green lease program and the performance it was designed to facilitate. While most of that work is now done by the landlord's property management team, the leasing team is still indirectly involved through management level tenant relationship discussions. The team's work has developed a market-leading reputation for the building, and the landlord, in terms of green performance, has shown that a carefully considered approach to environmental performance in the leasing process translates to real business benefits and has encouraged the landlord to actively consider its own program.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

5. CONCLUSION

The industry still has a long way to go before green lease clauses can be considered. Industry leaders with experience have already discovered that there are numerous benefits to investing time and resources to create a green lease platform and educate stakeholders to facilitate the change management process. Hong Kong is setting aggressive GHG intensity reduction targets to meet obligations under the United Nations' COP 21 agreement signed by China. Not making green leases, the new business as usual for the commercial real estate industry is missing a relatively easy and cost effective way to identify efficiencies and foster ever stronger relationships between tenants, landlords, agents and the community in general.

ABSTRACT

Urban sustainability strategies – increasing transit connectivity across geographical scales, enhancing jobs accessibility, density, mixed-use, creating high urban quality – create density and accessibility dividends that increase land and property values. It is of interest for developers and long-term investors to adopt sustainable urban development strategies. Building on the 3Values Framework developed by the World Bank, on Value Capture Finance mechanisms, on case studies such as King's Cross in London, and Hudson Yards in New York, the paper presents sustainable planning and design principles, and innovative finance mechanisms. Property value is created by connectivity and urban quality. Their dynamic interplay has been conceptualized in the World Bank 3V Framework for TOD based on Node, Place and Market Values.

Node value is created by public investment in connectivity/accessibility: 3.6 billion US$ public investment have been spent in King's Cross in London, the first European interchange for international high speed, national, and local travel, and 2.87 billion US$ to enhance connectivity in New York's Hudson Yards.

Place value is created by sustainable planning with dense street patterns and small blocks, and by design qualities – such as place making, enclosure, human scale, layering of space, complexity, coherence, legibility, and linkage: three major New York parks converge in Hudson Yards with a total public investment of 660 US$ million. Community socio-economic qualities - quality and proximity of education, health, culture, parks and other social amenities, and jobs opportunities - also contribute to place value.

Once node and place values are created by public investment, private sector investment realizes market value. Private and public sector may then capture value and recycle part of it in further connectivity and place improvement, thus initiating a positive feedback loop of Value Capture Finance increasing both real estate property values and sustainability.

Keywords: planning, transit-oriented development, real estate value

1. INTRODUCTION

This paper addresses the following question: what is the impact of sustainable planning and design such as Transit-Oriented Development on real estate market potential and market prices? Transit-Oriented Development (TOD) refers to an urban environment with high densities, mixed land uses, and quality public space within easy walking distance of a transit stop (Calthorpe 1993). Empirical studies have proven that TOD can effectively increase walking and biking, boost transit ridership, reduce car dependence, lower travel emissions, and enhance accessibility (Arrington and Cervero 2008, Transportation Research Board 2012, Ewing and Hamidi 2014).

Understanding the impact of TOD on real estate markets presents a strong interest for stakeholders. First, when high levels of value are created and realized, local governments can finance infrastructure provision, as well as social housing and social amenities, with value capture finance. These value increases along urban transit stations and corridors, are partially recaptured in cities like London, New York, Hong Kong, Tokyo, for financing further enhancements of infrastructures and of the public realm. This creates a positive feedback loop of development bringing money to governments and developers for financing urban growth. For example, Hong Kong Rail plus Property model allowed Hong Kong government to derive about HK$140 billion gain (1980-2005) while unlocking land for 600,000 public housing units (Salat and Ollivier 2016). Second, understanding where and when high value potential is created, enables developers to make the right investment decisions on where and at which level to invest in anticipation of increases in transit connectivity, and to develop the right planning and design strategies to maximize economic value around transit stations.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

In the first section, based on a literature review, we demonstrate the positive impact of TOD policies on real estate market. In the second section, we present an innovative framework for maximizing economic returns around transit stations developed by the World Bank with the Urban Morphology and Complex Systems Institute, the 3V Framework (Salat and Ollivier 2016). In the third section, we present case studies in London and New York illustrating how value is created and realized through the interplay of the 3 values.

2. THE POSITIVE IMPACT OF TRANSIT ORIENTED DEVELOPMENT ON REAL ESTATE VALUES

2.1 Pedestrian-and transit-friendly design features are capitalized in the purchase or rental price

The positive relationship between TOD characteristics and property value is well established in an international context. Empirical studies have proven that the market values pedestrian- and transit-oriented design, and that this valuation is reflected in the price people are willing to pay to live in well-designed places. In the words of the economist, pedestrian- and transit-friendly design features are capitalized in the purchase or rental price (Landis, Guhathakurta, Huang & Zhang 1995). Characteristics such as land use mix (Cao and Cory 1981, Song and Knaap 2004), street pattern (Guttery 2002), municipal amenities (Shultz and King 2001, Benson et al 1998), proximity to transit stations and commercial centers (Bowes and Ihlanfeldt 2001, Song and Knaap 2004), etc. have been shown to affect the value of residential properties located nearby.

In a very detailed review of the literature, Wardrip (2001) shows that there is a general consensus that accessibility to transit outweighs transit nuisance, and induces a premium on property prices and rental value. However, there is no clear agreement on the magnitude of the impact of transit accessibility on land value, as it also depends on a number of exogenous factors. For instance, the magnitude of this impact is likely to be greater in cities where transit provides clear benefits in terms of accessibility to economic opportunities, as for instance highly congested cities, or cities with very reliable and frequent transit systems (Agarwal 2011). The following table presents several case studies quantifying the impact of transit accessibility on land value.

Goetz et al. (2010)	Hiawatha Line in Minneapolis	$5,229 premium for single-family homes within half mile radius catchment areas (4% premium in average). $15,755 for multifamily properties (10% in average)
McMillen and McDonald (2004)	Midway transit line in Chicago	10% premium on single family homes on the long term
Knaap, Ding, and Hopkins (2001)	Portland light rail line	31% premium within half mile radius catchment areas, 10% within one mile radius catchment areas
Immergluck (2009)	Atlanta Beltline	15 to 30% increase in single family homes prices within 1 quarter mile of transit, compared to similar homes more than 2 miles from transit.
Dubé, Des Rosiers, and Thériault (2012).	Commuter Rail Transit in Montreal	1% to 1.5% for houses located less than 1.5 km from the station.

Table 1: Impact of transit accessibility on land value in four US cities and one Canadian city

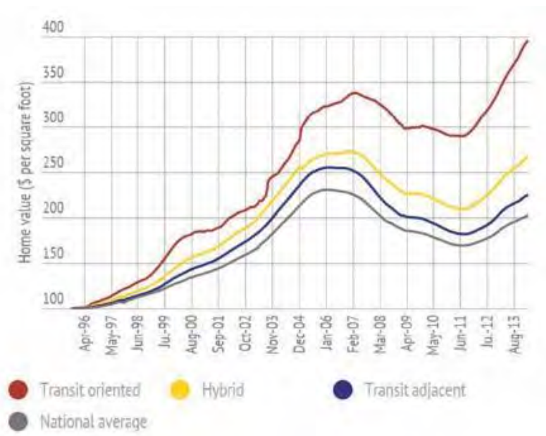
2.2 The TOD index in the United States

The TOD index study (Renne 2014) in the United States has calculated the differences in property values between TODs and TADs. Transit-Oriented Developments (TODs) are defined as walkable, mixed- use and dense communities within a half-mile of a train station while Transit-Adjacent Developments (TADs) refer to station areas that are characterized by low-density, auto-oriented land uses. Research indicates that gross housing densities should be at least 4,000 households within an area radiating a half-mile from a train station) in order to support transit ridership. Walkscore.com rates communities with a 70 or greater (out of a possible 100 score) as Very Walkable or a Walker's Paradise (above 90). The TOD Index provides a new benchmark to track both home and rental values in train station areas across the United States. The TOD Index includes stations categorized as TODs,

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Hybrids and TADs. Each category is also benchmarked against the national Zillow Home Value Index (ZHVI) or the national Zillow Rent Index (ZRI). The study has analyzed 4000 passenger train stations across the United States, among which 1441 have been found to meet TOD criteria of density AND walkscore. 1180 have been categorized as hybrids meeting the criteria of density OR walkscore but not both. 1,775 stations across the US are categorized as TAD stations, which do not meet either criteria for a TOD or Hybrid.

The following charts show the combined impact of density, walkability of the public realm and proximity to urban amenities on the growth of property values. For two similar homes priced 100 in 1996, the home located in a TOD district is worth 400 in 2013, to be compared to 225 for a home located in a TAD district. This impact on rental value is also very significant. For two similar homes rented 100 in 2012, the increase in the rental value of the one located in a TOD district is of 18%, to be compared to 11% only for TAD districts.



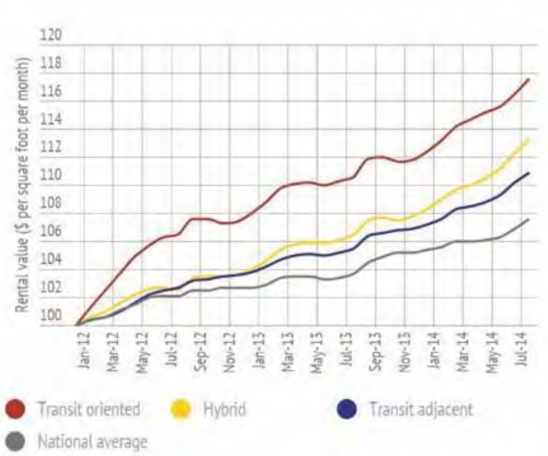


Figure 1: Left: Average home value in the United States in transit oriented, hybrid and transit adjacent areas, and national average, since 1996. Base 100 in April 1996. Source: Urban Morphology Institute. Data: Zillow and TOD index.
Figure 2: Right: Average rental value in the United States in transit oriented, hybrid and transit adjacent areas, and national average, since 1996. Base 100 in April 1996. Source: Urban Morphology Institute. Data: Zillow and TOD index.

2.3 Impact of TOD on housing prices in the Chinese context

These results have been confirmed in the Chinese context. Jiang 2016 has built a TOD score based on density (population density, job density, development compactness), diversity (land use mix, job housing imbalance), design (street network density, highway density, ground-floor retail density, number of parking facilities) and accessibility (distance to transport hub, distance to services, number of bus lines, number of bus stops). He found a positive correlation in Shanghai between the TOD index and housing prices.

Figure 4: Right: Station TOD Score vs. Housing Prices in Shanghai. On the x axis, TOD Index, on the Y axis, Housing price (RMB/sq.m). Source: Jiang 2016.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.4 The synergy of TOD characteristics

TOD characteristics reinforce each other in a synergistic manner. According to Bartholomew and Ewing (2011), the combination of TOD features contributes to higher property value. Neighborhoods showing at the same time higher than average densities, mixed use, public and open space and interconnected street networks benefit from a higher willingness to pay from residents. According to Song and Knaap (2003), this premium is of US$24,000 in the Portland Area.

2.5 TOD has different impacts on commercial and residential values

The impact of TOD is however different for residential and commercial land. The impact of stations on residential land values can generally be seen across a relatively wide geographic area with a radius of up to 2 to 4 km from transit station (Steer Davies Gleave 2011). On the other hand, the impact on commercial and business property value is more limited in space, with a radius of 500m to 1km (Steer Davies Gleave 2011). This difference in land value patterns around transit stations is shown in the following figures.

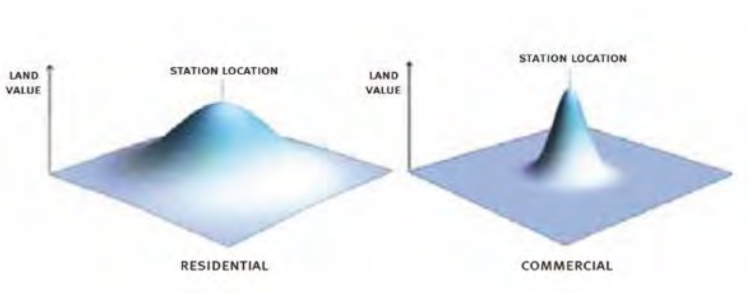

Figure 5: Residential and commercial land value patterns around transit stations (Steer Davies Gleave 2011)

3. HOW TO IDENTIFY “AREAS OF OPPORTUNITY”? THE 3 V FRAMEWORK

3.1 Understanding where, when, and how economic value can be created requires a typology

Understanding where, when, and how potential value can be created requires tools that help differentiate the opportunities offered by the diverse stations in a mass transit network. A TOD typology differentiates transit station areas according to their suitability to accommodate urban and economic growth. A TOD typology aims at creating an aspirational vision of future land uses, prioritizing stations for investment, providing guidelines and actions for implementation, and measuring performance on a range of metrics. The methodology called the “3 Value Framework”, or “3V Framework”, has been elaborated by the World Bank to that end (Salat and Ollivier 2016).

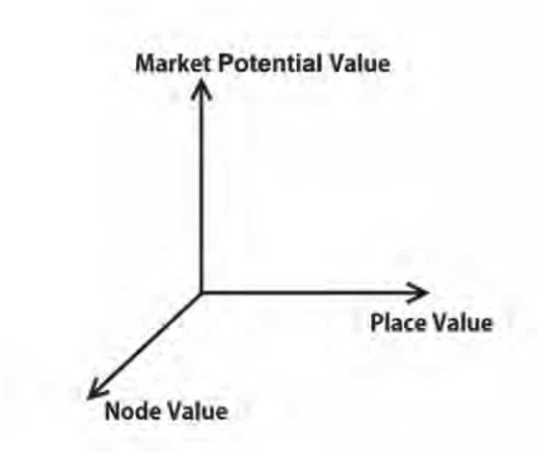
3.2 Maximizing economic opportunities through the interplay of 3 values

The 3V Framework generalizes previous international approaches based either on node/place model first introduced by Luca Bertolini (1999) or on a market/place model (typologies implemented in Portland and Baltimore) by identifying the three different values that can characterize a transit station: “node value”, “place value”, and “market potential value”.

- “Node value” describes the importance of a station in the public transport network derived from its passenger traffic volume, inter-modality, and centrality within the network.
- “Place value” describes the urban quality of a place and its attractiveness to residents in terms of amenities, schools, and healthcare, of type of urban development, of local accessibility to daily needs by walking and biking, of quality of the urban fabric around the station, in particular its pedestrian accessibility, the small sizing of urban blocks, and the fine mesh of connected streets that create vibrant neighborhoods, and the mixed pattern of land use that creates diversity.
- “Market potential value” refers to the unrealized market value of station areas, derived through the practice of real estate market analysis. Real estate market analysis is the identification and study of demand and supply and it examines the market potential. Market potential value considers major drivers of demand including current and future human densities (that is resident + job densities), current and future number of

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

jobs accessible within 30 minutes by transit, and major drivers of supply including amount of developable land, potential changes in zoning, such as increasing FARs, and market vibrancy. The approach looks forward rather than being only static or looking backward.



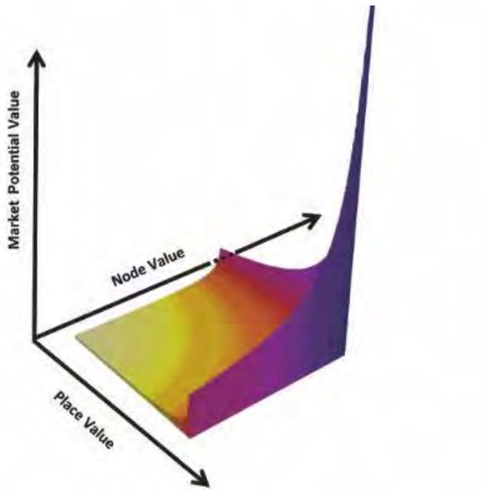


Figure 6: Left: 3V Framework.
Figure 7: Right: Synchronization of high peaks of node value (major connecting hubs) with high quality place making creates spikes of market potential value. An example is King's Cross in London or Hudson Yards in NYC. Source: Salat and Ollivier 2016.

The 3V Framework provides an analytical method to classify transit stations according to their potential to foster economic concentration and land value increases. It presents two main interests for policy makers:

- Building a typology of stations, which classifies the tens or hundreds of stations in a mass transit network into sub-groups for applying different development strategies.
- Determining the imbalances between connectivity, accessibility, place quality, and market potential values in a given station. Addressing these imbalances creates a high potential for economic value creation such as creating place value around an important connective node or bringing additional connectivity to a booming area.

Several levers increase node, place, and market potential value:

Node Value	Place Value	Market Potential Value
Increase number of hubs and number of lines/modes they connect to	Increase compactness (proximity to existing urban activity and short travel time to main destinations)	Increase residential density
Interlink neighboring stations into clusters	Increase diversity of uses	Increase job density
Increase accessibility within the network for all	Increase concentration of commercial, cultural and education amenities	Increase human density
	Design neighborhood that promote walking and biking	Increase diversity of land parcels to create a vibrant land market
	Create a vibrant public realm	Increase social diversity
		Allow for vertical separation of development rights
		Increase FARs

Table 2: Levers for increasing the 3 values. Source: Salat and Ollivier 2016.

4. HOW TO REALIZE MARKET VALUE?

Once areas of opportunities identified with the 3 values framework, this section explains how to create and realize market value. The 3V Framework typology allows identifying imbalances in local development and underutilized assets (either because an increase in connectivity linked to public investment in infrastructure calls for a redevelopment; or because high place value calls for investment in connectivity to create a positive feedback loop for market growth). The framework allows fine tuning public investment to market response potential in order to initiate these positive value capture feedback loops addressing the challenges of financing the infrastructure of fast-growing cities.

4.1 Value creation

Value creation strategies involve increases of the three values, each one supporting the others. In King's Cross in London and in Hudson Yards in New York, potential asset values have been created by public sector intervention increasing node value and place value. Public investment in area parks, mass transit and infrastructure will ensure these places become the most livable areas of their cities. Higher node value was supported in both cases through transport infrastructure provision. In King's Cross, it took the form of major investments in local transport infrastructure (up to now, £2.5 billion) turning King's Cross/St Pancras into the most significant interchange for local, national and international travel in London. Similarly, in Hudson Yards, it includes the extension of the No. 7 Subway west and south from its old terminus at Times Square adding a new station at West 34th Street and 11th Avenue as well as the renovation of Moynihan station (total subway extension estimated at US$3 billion).

Higher place value was supported through environmental and social improvement and investments to enhance urban quality and image of those sites. King's Cross development combined physical regeneration (e.g. developing sites, refurbishing buildings) with community regeneration (e.g. providing skills, training, community facilities). In the Hudson Yards area, the public sector undertook the renovation of the Javits Center for US$465 million. In both King's Cross and in Hudson Yards, a lot of attention has been given to the provision of high quality public space and iconic architecture. Three major New York parks (the third section of the High Line, Hudson River Park, and Hudson Park & Boulevard) converge in Hudson Yards supported by major public investment in the public space and parks (US$630 million).

Higher market potential value was supported by allowing population increase and through land use changes using planning and regulatory tools. In both Hudson Yards and King's Cross, major increases in human density are planned for jobs and for residential purpose creating very dense mixed-use communities with human densities (people + jobs) of around 1,750 per ha. Land use changes have taken the form of rezoning at higher values. Zoning is the planning instrument of the physical city. It aims to promote an orderly pattern of development. The Zoning Resolution is a legal instrument to regulate and establish limits on the use of land and building size, shape, height, and setback. Rezoning FARs (Floor Area Ratio, that is the amount of permissible built floor space divided by the land area) at higher values is a planning intervention that creates market potential value in well-connected areas, centrally located, when there is a high demand at city scale. Margins of flexibility between base FAR and maximum FAR allow capturing part of this value creation.

4.2 Value realization

Potential increased asset values are realized by private sector investment. Asset values are tangibly increased and unlocked by private sector involvement and investment through direct investments, comprehensive master planning, and area promotion. For example, growth in New York New West Side can be attributed to the success of the High Line, which has spurred $2 billion of private investment, 12,000 new jobs and 29 development projects since opening in June 2009. In both Hudson Yards and King's Cross, innovative master plans, with high quality public space and local connectivity, have been designed by developers with, in London, high level of public participation, and in both cases dialogue between public and private actors. Finally, area promotion through enhanced destination branding and marketing enable new areas to emerge. King's Cross and the area surrounding Hudson Yards are in a process of transformation from derelict industrial rail yards' areas into beacons for creative professionals, a hub for fashion, design, communications and the arts. Both areas are in the process of becoming the home of Google and other fast-growing technology and digital media firms.

5 CONCLUSION

Some cities have created and captured higher land values through strategic mechanisms coupled with supportive regulatory changes for sustainable urban finance and development. Hong Kong SAR, China, Tokyo, New York, and London have generated funds for their transit systems and promoted sustainable urban development. Once node and place values are created by public investment, private sector investment realizes market value. Private and public sector may then capture value and recycle part of it in further connectivity and place improvement, thus initiating a positive feedback loop of Value Capture Finance increasing both real estate property values and sustainability. The approach is not limited to developed cities and can be applied to fast growing cities. Nanchang, Delhi, and Hyderabad are adapting such an approach for their metro construction.

Responsible Investing in Green Buildings and Portfolios

Ruben Langbroek[a]

[a] *Head of Asia Pacific, GRESB, Singapore, r.langbroek@gresb.com*

Responsible Investing is getting more and more attention, while an increasing amount of investors are incorporating its principles into their investment process. But what exactly is Responsible Investing? According to the UN Principles for Responsible Investment (PRI), it is an investment approach that explicitly acknowledges the relevance to the investor of environmental, social and governance (ESG) factors, and the long-term health and stability of the market as a whole. The approach recognizes that the generation of long-term sustainable returns, depends on stable, well-functioning (and well governed) social, environmental and economic systems.

We (and the buildings we work and live in) consume natural resources faster than they can be replenished. While doing so, the emissions that are responsible for climate change just keep increasing. And besides these issues, there are other, unprecedented environmental and social issues such as food, water and energy security, air pollution, waste streams, urbanization, human rights, supply chain labour standards, etc. These are clearly major concerns, but why should institutional investors care about them? Because it is core to their (fiduciary) duty. Which is to act in the best interest of their clients and beneficiaries. Responsible Investing requires investors to take a wider view, acknowledging the full spectrum of the risks that are facing the society as a whole. By incorporating sustainability performance outcomes into their investment process, institutional investors can allocate capital in a manner that is aligned with the interests of their clients.

The aforementioned issues are not just environmental or social concerns. They are material, economic issues, and that makes them relevant to investment risk and return. Investors' main concern is that sustainability-related risks, as well as the policies that are put in place by governments around the world to avert those risks, will damage the companies and portfolios they invest in. Shareholder value is at stake.

And so, the question arises: can you invest in green portfolios and achieve stable financial returns? The short but clear answer to that question is: yes. A number of studies have shown that listed REITs and private property funds that performed well on sustainability have outperformed their peers in terms of financial returns. And even though the findings do not prove that these portfolios provided higher returns because of the fact that they are sustainable, it does illustrate that sustainability is compatible with good returns.

Further, an increasing amount of evidence, including research performed in Asian markets, shows that green buildings not only provide general benefits such as regulatory compliance, reduced environmental impact, and improved occupant health, well-being, and productivity. But importantly, they also provide financial benefits, including lower operating costs, higher rental level potential, lower vacancy levels, higher capital values, and increased asset liquidity. In short: green buildings provide clear green dividends for investors.

Moreover, green buildings do not have to cost more. We already have the knowledge and experience to develop net-zero buildings that are cheaper to light, heat and cool. Buildings that have reduced environmental impact, and that are resilient to climate change. And buildings that support improved occupant health and well-being.

However, in order to allocate their capital responsibly, investors need to know which property companies and fund managers are focusing on green buildings and portfolios. Further, those that want to go green, need to know where they stand (in absolute terms and relative to their peers), and how to improve their sustainability performance. As Lord Kelvin already stated over a century ago: "If you can't measure it, you cannot improve it". So, more insight into green performance (and green economics) of buildings and portfolios is needed in order to transform the built environment into an energy-efficient, low-carbon and climate-resilient one.

To conclude, today more than ever, green is the colour of money. Investors that are willing to invest responsibly, are key to driving change in sustainability approaches in the real estate sector. That change will be crucial, because in the end, more than just shareholder value is at stake.

Economic and Sensitivity Analysis of Net Zero Energy Refurbishment of Terraced Houses

Angela GRECO[a], Tim JONATHAN[b], Andy VAN DEN DOBBELSTEEN[c]

ABSTRACT

Post-war terraced houses, built en masse for the European middle-class, remain a major consumer of energy, significantly affecting the performance and quality of the residential stock. Prêt-à-Loger is a net zero energy refurbishment (NZER) concept addressing 1.4 million post-war Dutch terraced houses and possibly some other 30.6 million spread throughout North-Western Europe. By applying an integrated external renovation system (called “the skin”), the house becomes energy neutral while at the same time the living quality and the durability of the house are improved, and extra space is added. This non-invasive renovation project competed at the Solar Decathlon Europe 2014, winning five prizes, among which the first in sustainability. Despite the easy and fast applicability, the financial aspect still presents a serious barrier for large-scale implementation of this and other energy neutral renovation concepts.

The research summarised in this paper firstly identifies the economic factors that can boost the investment in energy neutral refurbishments, on the basis of interactions with public and local authorities, private companies, research institutes and end-users. Secondly, it studies the economic potential of the NZER and the relative importance of the identified factors with Monte Carlo simulations. Different cases are considered to address the situation of single homeowners as well as housing associations needing to refurbish multiple dwellings.

The increase of total rent after renovation for the housing association case and the energy prices for the homeowner case are the most influential factors together with the capital expenditures; the maintenance cost and increase of property value are also relevant elements that can be affected by the right design choices. For the Prêt-à-Loger solution, for instance, a higher increase of property value is registered in comparison to other energy neutral renovation concepts. These findings provide an important support and inspiration for designers and decision makers operating in the field of deep energy retrofit.

Keywords: net zero energy refurbishment, green economics, Monte Carlo simulations

1. INTRODUCTION

Energy use in buildings represents about 40% of Europe’s total energy consumption and CO2 emission (European Commission, 2008). About 70% of buildings are over 30 years old and about 35% are more than 50 years old (Poel et al., 2007), while less than 1% of new constructions is added in any given year. Given the fact that buildings are long-term assets, designed to function for at least 50 years, we can foresee that 75 - 90% of those standing today will remain in use in 2050. These same buildings will form the means to achieve the required 80% reduced energy consumption compared to the 2008 levels (European Commission, 2010). Aiming at high standards of energy efficiency is essential for residential buildings, since they account for 70% of the building floor space (Itard et al., 2008). Within the residential typologies, the post-war terraced houses remain a major consumer of energy, significantly affecting the performance and quality of the residential stock. Around a quarter of Dutch housing consists of terraced houses built between 1946 and 1975. They have a poor energy performance, experience moist and mould problems and offer too little living space by modern-day standards (van den Dobbelsteen et al., 2015).

Prêt-à-Loger is a net zero energy refurbishment (NZER) concept addressing 1.4 million post-war Dutch terraced houses and possibly some other 30.6 million spread throughout North-Western Europe (Bogers et al., 2014). By applying an integrated external renovation system (called “the skin”), the house becomes energy neutral while at the same time the living quality and the durability of the house are improved, and extra space is added. This non-invasive renovation project competed at the Solar Decathlon Europe 2014, winning five prizes, among which the first in sustainability. Despite the easy and fast applicability, the financial aspect still presents a serious barrier for large-scale implementation of this and others energy neutral renovation concepts.

Over the past few years, the government in The Netherlands has stimulated the development of so-called "Nul-op-de-meter" ("zero-on-the-meter", i.e. net zero energy) renovation concepts for terraced houses. The organisation coordinating this initiative, the Stroomversnelling, proposed a target price for these renovations of €45,000 for the private sector, based on savings of energy costs. Because of subsidies related to this fixed target-price, cost benefits on energy savings are often taken as a main criterion by builders to decide which renovation measures will be taken. However, based on current construction methods, builders are still unable to create a renovation achieving both the energy reduction as well as the target price.

In this paper, all financial factors for energy neutral refurbishment of terraced houses are explored. The economic potentials of the NZER and the relative importance of the identified financial factors are then analysed with Monte Carlo simulations (MCS). These allow for a sensitivity analysis of the considered variables, showing the relative impact they have on the value of the refurbishment. Awareness of the relevance of the economic factors can support decision-making and the design phase, which will help create feasible renovations.

2. METHODOLOGY

This section summarises firstly the renovation type considered, then the approach used to identify the financial factors, and lastly, the methodology adopted to perform the MCS.

2.1 Renovation type

For this analysis, the Prêt-à-Loger solution is considered. This is because such a renovation differs from other concepts present on the market, which are not believed to be financially attractive yet. Prêt-à-Loger achieves a higher increase in post-renovation property value, key factor to determine the business case. The issues addressed by the Prêt-à-Loger solution are high energy bills, moisture problems and lack of living space. To preserve the original house, the renovation is designed as a non-invasive construction. An outer skin allows the inhabitants to live in the house during the renovation (hence the name Prêt-à-Loger: ready to inhabit). The skin integrates a number of measures to make the house energy neutral: roof, cavity wall and crawlspace insulation, mechanical ventilation system with heat recovery and phase changing materials (PCMs) in combination with a greenhouse.

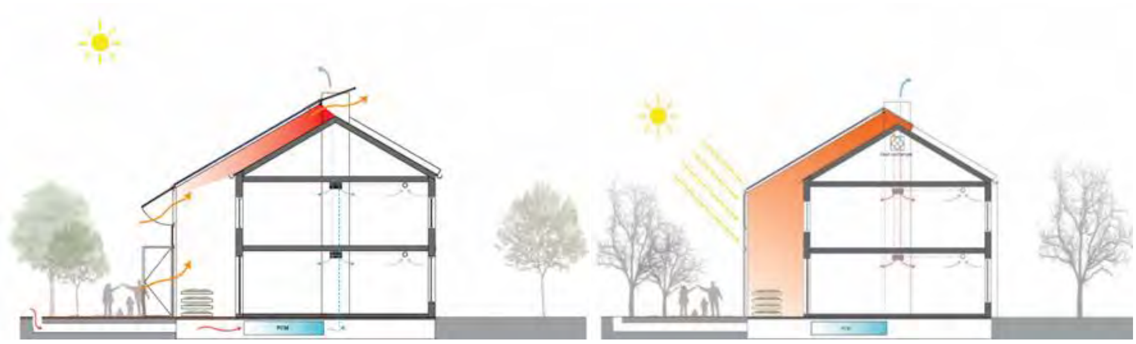

Figure 1: Prêt-à-Loger climate design functioning in summer (left) and winter (right)

A smart domotic system controls all installations in the house and provides information about its performance to inhabitants. The insulation, heat recovery and green roof are meant to reduce energy losses through the skin, while the greenhouse harvests the energy from the sun, producing electricity, hot water, and warm air, while also collecting rainwater, and producing food. In spring and autumn the greenhouse can be used as living space, during winter as a rough-climate winter garden buffer zone, and in summer it becomes an open covered terrace connecting the garden and the living room.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.2 Financial factors

The financial factors were identified by means of interaction with public and local authorities, private companies, research institutes and end-users. The conditions created today by local subsidies and regulations for investments to take place were also considered.

2.3 Monte Carlo simulation

Monte Carlo simulation is a method to solve complex problems by varying parameters within statistical constraints. Each variable is assigned a range rather than a specific value, which allows carrying out analyses when variables bear a certain degree of uncertainty. The Excel application called Oracle Crystal Ball was used to perform the simulations. By defining variable inputs in terms of realistic range of possible values, Crystal Ball performs thousands of calculations, each time using a different randomly selected value based on a specific probability distribution function. In this case, a beta-PERT distribution was chosen as it allows giving a minimum, a most likely and a maximum value. The input variables and the related ranges are given in Table 1 and described in section 3.1. The Net Present Value (NPV) is chosen as output variable, being the most commonly used discriminator for the business attractiveness of a project. A sensitivity analysis on the NPV was performed to study the weight of the variables used as inputs in the model.

2.3.1 Cases

For the simulations, four energy neutral renovation cases are considered:

- Privately owned house with and without greenhouse addition;
- Rented house with and without greenhouse addition.

For each case, two sets of simulations were performed: one assuming realistic variable inputs as shown in Table 1, the other altering the mid value by plus 5% (maximum value) and minus 5% (minimum value) to test the effective influence of each variable independently from its actual uncertainty. All variables shared across the two cases, such as renovation costs or maintenance costs, were kept constant. This is a conservative assumption because when a housing association decides to renovate or maintain part of their buildings, it is likely to do it in bulk, achieving lower renovation costs per housing unit with respect to a single homeowner.

To avoid repetition in the methodology and results sections, the most relevant input variables are explained in section 3.1.

3. RESULTS

3.1 Financial factors

The relevant financial factors identified in the first part of the research are explained in this section as input variables. These are part of the result but also of the methodology adopted for the MCS.

Renovation costs: The reference minimum value for the renovation costs is related to the one suggested by the Stroomversnelling, which takes into account an average Dutch energy expense of €175 per month, expressed in a mortgage that adds up to €45,000 over a 30-year period. Construction companies are striving to get close to this target, but still cannot achieve it. A price of €80,000 was chosen as mid value for the renovation with greenhouse (€ 60,000 for the case without greenhouse) as this is the closest price for energy neutral renovation of terraced houses that construction companies have achieved so far. This price, however, is still hardly available for private homeowners, while it can be accessible to housing corporations refurbishing more dwellings simultaneously. €100,000 is about the price any (terraced house) household can find on the market, but it is considered not attractive enough.

Property value: The appraised value depends on the type of renovation and the specific location of the house and is normally estimated using previous evaluations or by comparing it to similar interventions. Various aspects, such as floor area and aesthetics, drive this increase of value. For NZER the value increase will also originate in part from the energy savings and changed maintenance requirements, although incorporating any kind of energy

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

intervention in real estate evaluation is a practice still in its infancy. The increase of property value can potentially contribute to the initial capital to finance the renovation. Dutch banks are allowed to provide a loan to value (LTV) of 106% for NZER opposed to a 102% LTV for normal mortgages. A real-estate evaluation of the Prêt-à-Loger renovation done by ten different brokers estimated an increase in property value of €37,000 approximately (mainly because of the greenhouse in the backyard – circa 15 m^2 of additional surface), against the €5,000-10,000 estimated for the average energy neutral renovations that can be found on the market.

Mortgage: As mentioned before, banks can provide a mortgage with a loan to value up to 106% when the property undergoes a deep energy retrofit. Furthermore, Dutch legislation allows banks to provide an additional sum in the form of a mortgage potentially up to €27,000 for energy retrofit, on top of the loan to income. Finally, the Dutch government provides a partial refund on interest paid on housing mortgages (Belastingdienst, 2016).

Loan interest rate and duration: At present, Dutch banks require an interest rate of circa 2% for a fixed mortgage plan (Trading Economics, 2016). The values for the loan duration are chosen considering usual practice for loans (amount and years packages offered by banks) as well as the life span of installations needed for the NZER. The Dutch government refunds part of the interest paid on the mortgage for the first 30 years, and therefore a loan longer than 30 years would not be considered attractive for a house renovation. Thus this value is used as upper bound in the simulations.

Energy performance compensation: Under certain conditions, housing associations are allowed to charge residents with the so-called Energie Prestatie Vergoeding (EPV) (Energylinq, 2016). This energy performance compensation is a monthly fee that may be charged by the landlord to the tenant if the property meets certain energy efficiency standards. The EPV is the (new) part charged in addition to the rent and service charges. For this analysis the three possible EPV values of 1.0, 1.2 and 1.4 €/m^2/month are applied (Coen and Stutvoet, 2015).

Rent increase: Similarly to the property value, the rent could also be increased within market and legislation limits. It should be noted however that with regards to affordability of social housing a rental increase for housing corporations might not be applicable. If the EPV is applied, energy performance cannot influence the increase of rent (Coen and Stutvoet, 2015). The pre-renovation rent value is taken from AEDES (2016).

Maintenance difference: New installations like PV panels, heat exchangers and heat pumps will introduce new maintenance costs. Over the course of a 30-year mortgage, these installations have to be replaced at least once. On the other hand, the renovation itself makes up for overdue maintenance. Furthermore, a smart design in combination with the right choice of materials could potentially reduce the cost of general maintenance. Maintenance costs are taken from AEDES (2016).

Future value: For simplicity, the future value of the variables used in the simulations is calculated using an average inflation rate (EUROSTAT, 2016b). The discount rate is assumed to be zero because investments from homeowners and housing associations are more for savings and energy performance than for economic returns.

Tax implications: The property tax in the Netherlands oscillates approximately between 0.075% and 0.250% of the market value of the property itself (Cijfer Nieuws, 2015). An increase in property value implies an increase in the property tax.

Energy bills: The calculation of the energy cost is a combination of the average consumption rate (Milieucentraal, 2016) and the average energy prices (EUROSTAT, 2016a).

3.2 Sensitivities

Table 1 shows the range used as input for the MCS, while Figure 2 and 3 show the NPV sensitivities for each case. The sensitivity analysis for the NPV is shown from Figures 2 and 3 for the housing association and homeowner cases, respectively. For almost all cases, the biggest impact on the NPV (43 to 65%) is given by the renovation cost. The revenue sources of increase of total rent (including the EPV, which is de facto an increase of rent) for the housing associations (17 to 30%) and energy bills for the homeowners (17 to 53%) also play an important role. Other variables such as the increase of property value (1 to 12%), the increase of maintenance (2 to 11%) and the loan interest rate (1 to 6%) have limited but non-negligible influence on the NPV of the renovation.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Variable	Low	Mid	High	Unit
Renovation cost w/o greenhouse	40,000.00	60,000.00	80,000.00	€
Renovation cost w/ greenhouse	50,000.00	80,000.00	110,000.00	€
Loan interest rate	2.0	2.7	3.5	%/year
Loan duration	15	25	30	Year
Increase of m2 (only w/ greenhouse)	0	7	20	m^2
Increase of property value w/o greenhouse	0.00	7,000.00	14,000.00	€
Increase of property value w/ greenhouse	15,000.00	27,000.00	40,000.00	€
Increase of maintenance	200.00	500.00	800.00	€
Increase of rent	2.00	5.00	8.00	€/m^2/year
EPV	12.00	14.40	16.80	€/m^2/year
Electricity cost	500.00	800.00	1,200.00	€/year
Gas cost	800.00	1300.00	1,800.00	€/year
Tax refund on mortgage		50		%
Discount rate		0		%
Inflation rate		2		%
Improvement in occupancy rate		1		%
House m2		100		m^2
Property tax (*WOZ-warde*)		0.150		%
Initial rent per m2		60		€/m^2/year

Table 1: Variables and related ranges used for the Monte Carlo simulations.

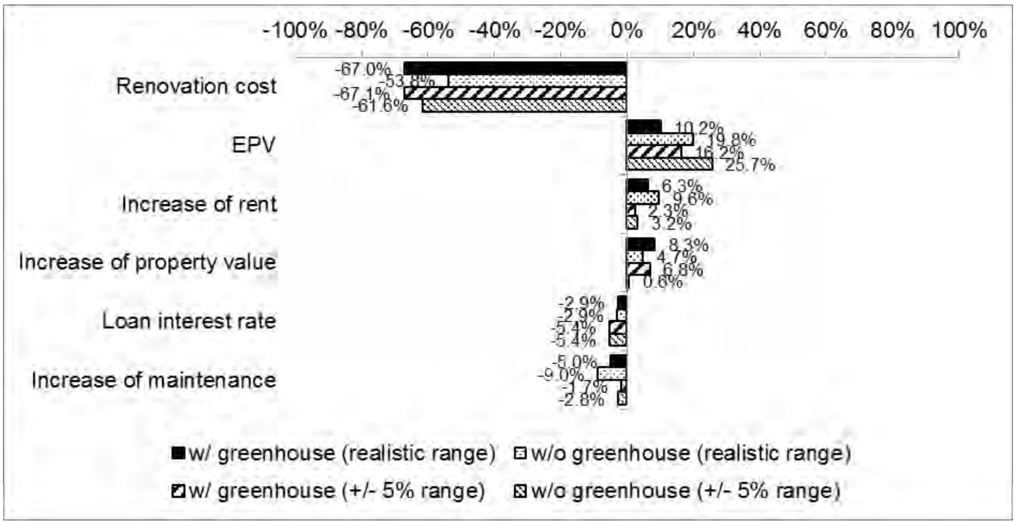

Figure 2: NPV sensitivity for the housing association case.

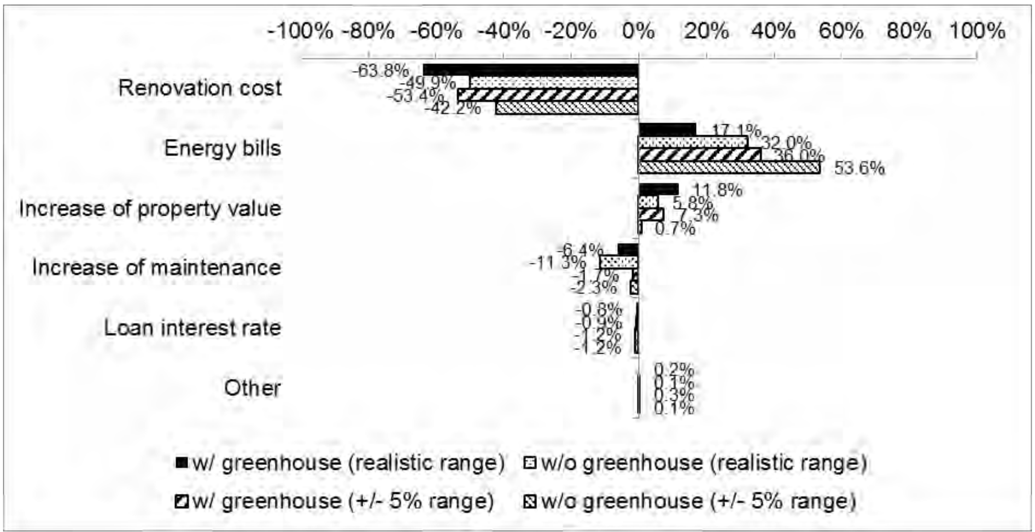

Figure 3: NPV sensitivity for the homeowner case.

4. CONCLUSION

Reducing the cost for energy neutral refurbishment is a relevant and well-understood problem among the involved parties. The sensitivity analyses performed in this study indeed suggest that the initial investment is the financial factor that influences the business case the most. Housing associations have higher chances of improving their business case by accessing to lower prices when refurbishing a large number of dwellings. Increase of rent for the housing associations and reduced energy bills for the homeowners are the most influential sources of revenue when evaluating the feasibility of the NZER. For private homeowners, it is also beneficial to address aspects such as increase of property value, reduced financial risk, and improved living quality.

The Prêt-à-Loger concept has resulted in a higher increase of post-renovation building value, which makes the renovation attractive and more feasible (e.g. due to the higher loan to value). Energy cost abatements and fluctuations in the energy prices strongly influence the return of investment. It follows that improving the living comfort, which affects the increase of property value, becomes even more important when performing energy related upgrades, as this could reduce the dependence of the renovation on the energy market.

Finding the Value in Deep Energy Retrofits

James Scott BREW[a]

[a] Nikken Sekkei, Japan, brew.james@nikken.jp

ABSTRACT

Using stories from two iconic international projects located in Germany and North America, this session will first outline why deep energy retrofits make financial sense to building owners and investors followed by how to approach them and achieve measurable results.

Globally, many Real Estate Investment Trusts, building owners and investors understand the value of "green" buildings. And they also know that simply being green is not enough. They understand that true value of deep energy retrofits lies not in the energy or carbon cost savings, which remain important, but in the asset value and human performance value post-retrofit.

Using pre- and post-occupancy data from real estate valuation, actual energy and water consumption, and human comfort surveys facilitates setting aggressive goals, validating designs using risk mitigation, and measuring performance against prior benchmarks. Applying the right steps in the right order, using a whole-systems or integrative approach, will be covered to demonstrate the important role these play in achieving super-efficiency.

Results from featured buildings and other case studies will show that deep energy retrofits can often save 30 to 50 percent or more in energy cost and carbon and much more in water and waste while improving human health, comfort and productivity.

The real economics of "future proofing" real estate assets in a carbon constrained world lie in the human performance value of our building occupants. Introduction to unlocking this potential will be discussed to encourage more research, application and results.

Keywords: deep building renovation, design process, green economics

1. INTRODUCTION

Around the world, the green building market is maturing. As it does, the strategies and approaches to achieving higher levels of sustainability have improved and become easier to achieve. For example, the number of projects achieving LEED certification at the certified (entry) level is declining while higher levels of certification, Gold and Platinum are increasing. The Gold certification level passed Silver in 2006. See Figure 1.

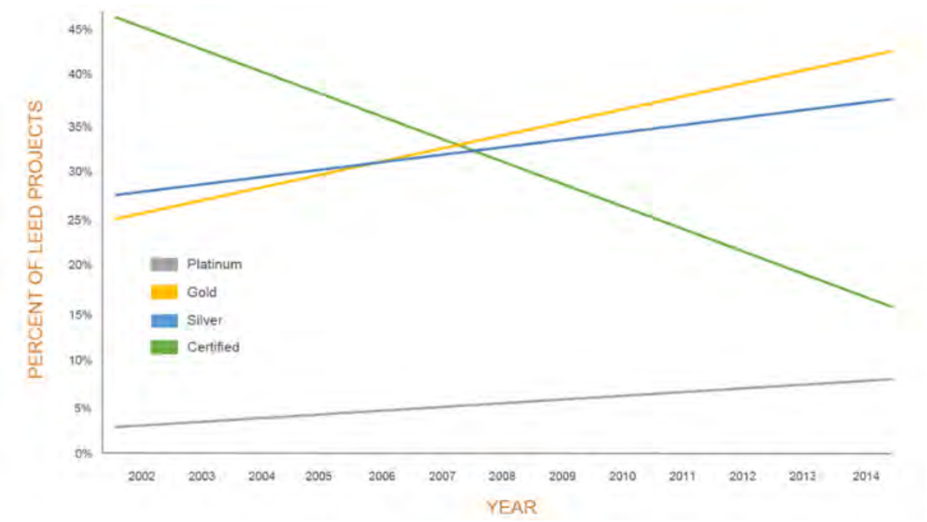

Figure 1: LEED certification trends (USGBC)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

But one emerging area that is rapidly evolving is asset valuation. In the past, the value of “green” was determined by simply calculating the Return on Investment (ROI) for individual or collective strategies being applied to a building using either simple or Net Present Value (NPV) energy payback calculations. Today, the investors are more engaged and they are not interested in windows, insulation, or air conditioning systems. They are looking for real financial value.

1.1 What is the value of green?

For investors, the value of green is beyond energy savings and green building certification. It is all about the real estate asset value. This is not only projected earnings and Net Operating Income (NOI) but begins to apply increased tenant absorption and retention rates by using research comparing conventional buildings to green buildings in mature markets.

Today, Real Estate Investment Trusts (REITS) are required to have a strategy related to Corporate Sustainability Reporting (CSR) and the pressure to perform on the strategy is increasing. Whether they are driven by the urgency of climate change or fear of a carbon tax or simply “future-proofing” their investments — their engagement in the value of green will likely continue.

For building owners and occupants, whether in leased or owned space, the value of green is different. There is increasing evidence that human performance is not only affected by building design decisions, but that worker engagement, health and productivity can be improved by design.

A new standard, the WELL Building Standard®, is the first such green building related standard to focus exclusively on human health and wellness. WELL is administered by the International WELL Building Institute™ and certification is overseen by Green Business Certification Inc., which administers LEED certification and credentialing for the U.S. Green Building Council (USGBC).

This focus on human performance is likely to grow and become more sophisticated in the near-term as owners and researchers look for improved metrics and techniques to optimize human factors.

1.2 Two deep retrofit examples

The value for the investments in the deep energy retrofit of both the Empire State Building (New York City, USA) and Deutsche Bank Headquarters (Frankfurt, Germany) were largely based on energy and carbon savings. However, the value created and realized post-retrofit involved more than just energy.

The Empire State Building Company, LLC began their whole-building retrofit with energy and carbon savings as important, but certainly secondary to interior upgrades to finishes and furnishings to regain a Class A office building status. Original estimates of energy savings as compared to then current consumption were 17 percent. After expanding the design and construction team to include Rocky Mountain Institute, whole building energy simulation was utilized to optimize proposed strategies, and to bundle such strategies into packages of potential savings.

The end result was greater than 40 percent energy savings and a less than two-year simple payback. But the real asset value came from the attraction and retention of satisfied tenants post-retrofit. Figure 2 shows the primary strategies and avoided costs (from original investment intent).

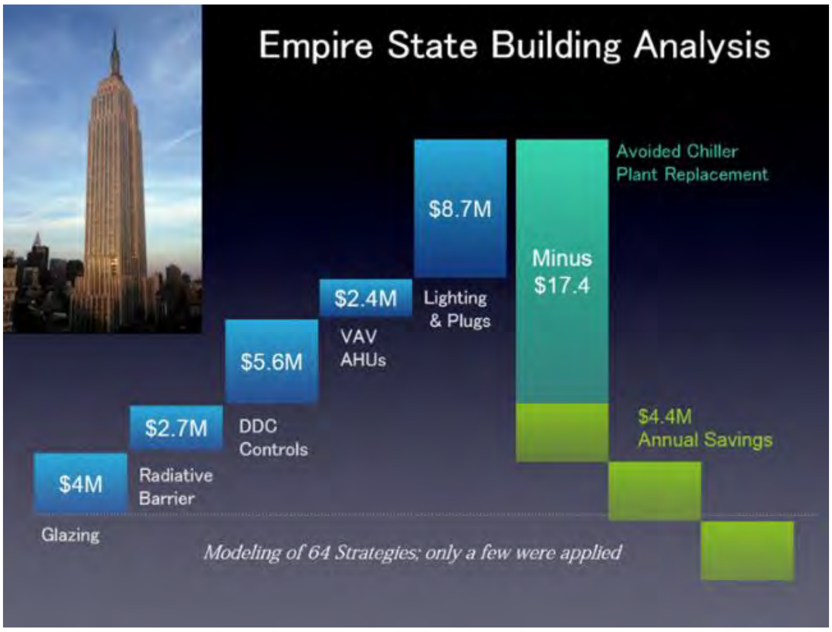

Figure 2: Empire state building savings

Deutsche Bank began their retrofit as a requirement due to a failed fire suppression system. With the building vacated for safety, the opportunity for a whole-building approach became apparent. The existing twin towers were stripped to their original 1970's concrete shell both inside and outside and rebuilt using integrative design, whole-building simulation, super-efficient Heating, Ventilating and Air Conditioning (HVAC) systems, operable windows. Figure 3 shows the actual investment cost (which was slightly above median for the scale and scope of the retrofit) in 2011 USD and JPY.

Figure 3: Deutsche Bank energy reductions and investment cost

However, the real value for Deutsche Bank came as a result of good architectural design. Because daylighting and operable windows were key design strategies, the architect removed the offices from the perimeter of the building on all floors, in each tower and moved them inward, using glass on at least one wall to harvest daylight. This allowed a more efficient office layout resulting in approximately 300 additional people being accommodated in each tower. The financial value of this strategy alone more than paid for the investment in green building and energy efficiency almost immediately.

2. APPROACH: MEASUREMENT MATTERS

If there is one word that sums up the optimal approach to deep energy retrofits, it's comprehensive. Said another way, an approach that uses whole-systems or an integrative design process will yield the best results. In any case, when dealing with an existing building asset, benchmarking is essential to developing a comprehensive strategy.

Benchmarking the historical energy, water and carbon use is relatively straight forward for most asset and facility managers. In North America, it is quite common to use Energy Star's Portfolio Manager to understand how an assets performance compares to similar assets, nationally (adjusted for climate, size and occupancy). Figure 4 shows an example comparing individual assets using Portfolio Manager.

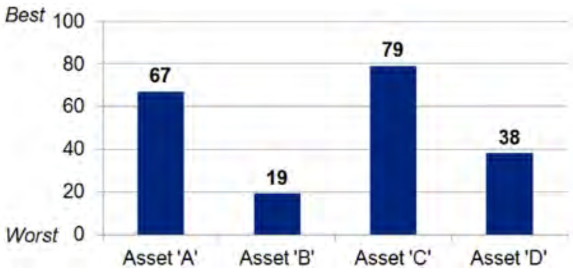

Figure 4: Benchmarking with Portfolio Manager

Benchmarking human performance is typically more subjective. While post-occupancy evaluations are routinely performed by engaged facilities professionals, PRE-occupancy or PRE-retrofit surveys are not common. Easily obtained measurable items include temperature (indoor/ outdoor), relative humidity, CO2 levels (indoor/ outdoor), lighting levels, ventilation rate (measured or calculated) and VOC levels. But the real value to such surveys is in the human perceptions. How people feel is generally closely related to their actual performance, engagement and wellness. In other words — perception is reality. Elements to be surveyed should include thermal, acoustic, and visual comfort, perceived productivity, satisfaction with various elements of the space (such as color, wayfinding, furnishings, etc.), and perceptions of air quality and other factors relevant to the property.

If there is some occupant dissatisfaction with specific elements of a building, prior to retrofit, these might be targeted or prioritized for investment and elements of high satisfaction might seek to be maintained or improved to meet new standards (such as ventilation rates or lighting levels).

3. RESULTS: YOUR MILEAGE MAY VARY

Calculating the real estate value of green appears to be more of an art than a science. While it is always about location and the specific market context, the assumptions used in determining that value are usually an investor or sellers professional opinion.

One way to visualize this value is using the following generic chart, developed by the author. See Figure 5. The 10 - 26 percent savings shown in Figure 5 comes from a comprehensive report by the World Green Building Council.

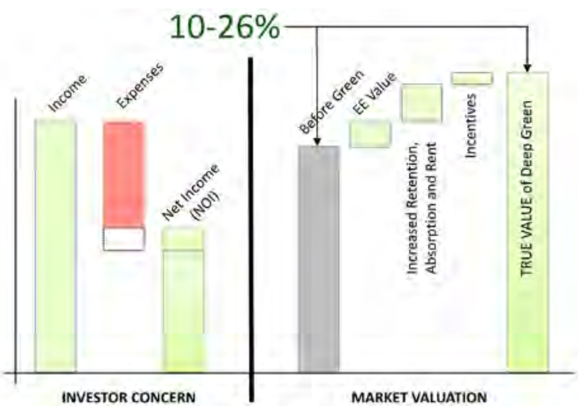

Figure 5: Relative value increase from green investment

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

In a detailed analysis by the author for a confidential new corporate office headquarters located in Tokyo, Japan, the value beyond energy savings was estimated using research, post-occupancy surveys and relevant studies on absenteeism, presenteeism and turnover rates from the Japanese market. The investment cost and energy savings, all shown to scale, are from actual figures. See Figure 6.

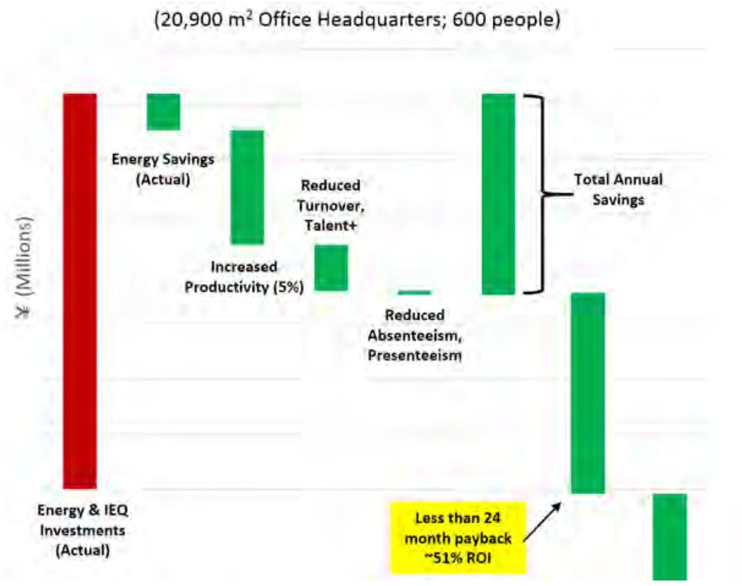

Figure 6: Value beyond energy savings

4. FUTURE-PROOFING: BEYOND THE BUILDING

The real value of deep energy retrofits lies far beyond the energy and carbon savings alone. Uncovering and measuring this value is not only important, but necessary for meeting the challenges we are facing in regards to climate change and facilitating the transition off fossil fuel to a renewable energy supply.

The business case for added financial value in real estate valuation exists in some markets. It is likely to continue to grow and spread to new markets with maturity.

The human value in health, wellness and productivity has been demonstrated to exist in several recent studies where cognitive function is used as a proxy for increased productivity and where specific controlled studies with repetitive tasks are utilized. Because a company's salary cost is 50 - 100 times that of energy and water utility costs even a small percentage increase in productivity or reduction in absenteeism can more than pay the energy cost for an entire year.

Productive Green Roofs

Matthew PRYOR [a]

[a] *The University of Hong Kong, Hong Kong SAR, matthew.pryor@hku.hk*

ABSTRACT

Although interest in productive gardening, as part of a healthy, high density city lifestyle, is growing rapidly, severe spatial constraints limit opportunities for ground-level community gardens and urban farms. Over the last ten years, community groups in cities around the world have begun to activate under-utilized building roof spaces for use as community-based urban rooftop farms (URF). These spontaneous projects offer valuable opportunities to address this situation by creating city-based venues for food production, social interaction, and active recreation, and have generated a sense of stewardship for the built environment. Additionally, URFs can have environmental and sustainable building benefits, such as improved building thermal performance, reduced urban heat island effect, increased sound insulation, and urban greening, similar to those of traditional green roofs systems.

This paper reports on an on-going research study to determine the potential for URFs in Hong Kong. All existing URF projects within the Territory were surveyed, to determine the building, environmental, operational and community conditions under which they occur. Analysis of building and land use across all urban districts revealed that some 594ha of existing roof space may be suitable for farming. Assessment of participation rates in open-to-public farms indicate that URFs could provide opportunities for active participation to more than 18,000 people. Given that existing farms are entirely community driven and receive no policy, technical or financial support from Government, potential participation could be much higher. This suggests considerable positive environmental and social benefits could be achieved at the city-scale if URFs were actively promoted and formally incorporated into urban land use planning and city decision making processes.

Keywords: urban rooftop gardening, community empowerment, healthy urban lifestyle.

1. INTRODUCTION

Increasing spatial congestion in high density cities have led to concerns over impoverished environments, unhealthy lifestyles, and low levels of physical activity and community interaction. Opportunities for productive gardening, in particular, are very limited. In Hong Kong, less than 0.1% of the population has access to a private garden and, to date, only 22 ground level (government operated) 'community farms' have been established at the urban edges, offering just 1,140 places for would-be gardeners.

In response, some high density urban communities have started to utilize their building roof decks for productive purposes. Since 2009, some 60 urban rooftop farms (URF) have been established on residential, commercial, industrial, and institutional buildings across the city (images 1 and 2). These are run either: by a specific interest community group e.g. a residential, corporate or educational community where participants are drawn from within the building or campus (restricted-access); by a community enterprise which rents roof space to members of the public (open-to-pubic); or (c) privately, as an entirely closed operation (private),. Although the farms are distributed widely, there are notable concentrations within districts such as Kwun Tong, Central and Wanchai.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 1: Urban rooftop farms in Hong Kong in 2014, (Pryor 2016)

Figure 2: Aerial photo of the rooftop farm on 38/f of Hysan Place, from Causeway Bay

URFs can be distinguished from ground level farms by their greater spatial limitations and operational complexities (Hui 2011; Thomaier 2015). They emphasise participation rather than production, i.e. involving many participants motivated by personal interest (Pourias et al 2014; da Silva 2016), but working within very small planted areas to produce small quantities of a wide variety of crops. Community benefits such as active stewardship of the urban landscape (Proksch 2014; Pryor 2015) and positive community engagement through place-making (Noori et al. 2016) have been identified as key motivations.

Studies have reported that, in impoverished urban environments, URF's can have similar benefits to green roof installations, e.g. lower solar heat gain and better insulation (Cerón-Palma et al. 2012); improved energy conservation, thermal performance and sound insulation; reduced urban heat island effect (Kitaya et al. 2009); improved air quality (Tong et al 2015); and increased urban biodiversity and positive contribution to urban greening (Borysiak et al. 2016). Specht et al. (2014) also highlighted community benefits of URFs, including higher levels of active recreation, healthier urban life-styles, and greater social interaction amongst participants.

To date, rooftop farming has not been successfully commercialized, but there is growing interest in the potential for large-sale food production on city rooftops (Donald, 2011), to address urban food security issues. Schemes demonstrating commercial potential have been established in Singapore (The Staits Times 2015), and Guangxi (China Daily, 2014), and researchers are now exploring the use of rooftop glasshouses (Cerón-Palma et al. 2012; Sanyé-Mengual et al. 2015); aquaponic and hydroponic systems (Taylor et al. 2012); and vertical growing structures (Banerjee and Adenaeuer 2013), to increase production. Technical and economic aspects of commercial rooftop farming are being tested, such as: suitable crop species, growing media, growth performance and production capacity of different farming modes (Pfeiffer et al. 2015; Orsini et al. 2014); sustainability of food production and the influence of climate on potential production; and infrastructural requirements and building restrictions in different cities (Specht et al. 2014).

City authorities are actively looking to farming to make a positive contribution to the urban environment (Colding & Barthel 2013; Martin et al. 2014). The potential for URFs at the city-scale, however, has not been examined. A lack of clear definition or performance criteria have made it difficult for URFs to be formalized within urban land use planning and decision making processes. For example, in Hong Kong, they are not recognized as 'green roofs' under Sustainable Building Design Guidelines (Buildings Department 2011), so do not count towards green building coverage.

The objective of this research study has been to make a systematic evaluation of the potential for URFs within Hong Kong, quantifying both the total physical roof space that could be activated for farming, and the possible levels of civic participation in the farms, if established.

2. SURVEY OF EXISTING URBAN ROOF FARMS

The research team conducted a detailed survey of all existing urban rooftop farms and farming operations across the territory, recording the range of building, environmental and community conditions under which they occur. These limits were then mapped against existing land use, building records and census data to give an indication of the possible number of buildings that could be utilized for URF operations, as well as the total area of farmable roof space, and the maximum number of participants that they could support.

Farms were identified from published articles, websites, and aerial photographs, together with reports from managers and participants of known farms. The research team visited each of them over a 4-month period in early 2016, to document the extent and material condition of the roof and the nature of the farm operations. The survey comprised a detailed physical inspection of the building and farm, interviews with farm managers / owners and survey questionnaires of farm participants. City-wide building and population data was compiled from HKSAR Government building records (Building Department), lands use plans (Lands Department) and census data (Census &Statistics Department).

Those that were private or had been in operation for less than two years were excluded. Amongst the remaining 48 farms, 6 (12.5%) were located on residential buildings (built between 1983-00), 11 (22.9%) on institutional buildings (1983-13), 18 (37.5%) on industrial Buildings (1970-03), and 13 (27.15%) being on commercial buildings (1978-13). There were 19 'Open' farms (ave. 42 farmers, total farm area 7,315 m^2) and 29 'Restricted' farms (ave. 22 farmers, total farm area 5,270 m^2).

In addition to building type and age, data collected to determine the environmental and building limits for URF operations, included: farm location (rooftop / podium deck); rooftop height; means of access (by stairs or lift); roof size and farmed area; other roof uses (e.g. emergency refuge); structural capacity of the roof deck; parapet edge conditions; services / structures; roof drainage; water proofing; water supply; and sunlight / wind exposure. Examples of farms on industrial buildings are shown in images 3 and 4.

Figure 3: Aerial Photo of Hong Kong's Oldest Rooftop Farm, in Quarry Bay

Figure 4: Aerial Photo of the Newly Established City Farm, in Tsuen Wan

During each visit the farm manager / owner was interviewed to understand the history of the farm; building and farm ownership; the funding model and operational structure; the number of participants in the farm and their origin (specific community group or the general public); planter type and typical crop species; soil material and estimated weight; and related activities (instruction sessions, crafts etc.). Managers / owners were further invited to share their experience of the operating limits of rooftop farming.

A questionnaire was distributed through the farm managers to farm participants to generate data on their age and gender; employment status; motivation for participation; frequency and timing of visits; time spent per visit; point of origin (home or work); distance travelled; and level of farming experience.

3. ASSESSMENT OF POTENTIAL FOR URBAN ROOFTOP FARMING IN HONG KONG

Two approaches were adopted to generate a preliminary indication of the potential for URF within Hong Kong, (a) an estimate of physical capacity i.e. the total roof area of all existing buildings capable of supporting URFs, and (b) an estimate of the participatory capacity i.e. applying rates of participation in existing farms (number of participants with respect to their catchment populations), at a city scale.

There are some 41,600 buildings within the territory, comprising residential / composite buildings (80.8% of total building stock); institutional buildings, (6.8%); office/ commercial buildings (6.2%); industrial buildings (4.2%) and others (5.0%). An assessment of the number of buildings on which URFs would be possible was made based on limiting factors.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Structural capacity of the roof deck was the primary limiting condition. All existing URFs are on buildings with flat concrete roof decks. With reference to the existing green roof constructions in Hong Kong, it was determined that only those roof decks that had been designed for emergency fire refuge should be included in the assessment, as these were the only ones that had sufficient structural capacity to support the farm, were accessible directly from the roof level or floor immediately below, and could be used safely. Buildings with long span, lightweight structure roofs (e.g. sports halls), and those with pitched roofs were not included. Buildings with secured uses, sensitive rooftop features or property rights issues that would preclude public access, were not included.

Environmental conditions on the roof were not found to be a limiting factor (as had been anticipated). All farm managers reported that growing conditions (sunlight, rain, shelter from winds, presence of insect pollinators) were favourable, due to the screening effects of parapet walls. As the two highest existing URFs were on 38/f and 39/f level, a cut off building height of 39 floors (approximated to +150m) was adopted in the assessment.

Planted area as a percentage of space covered by the farm was measured at between 14% for larger farms and 32% for the smallest, to an average of 24%. The minimum operable area required to sustain a community-based URF was estimated by farm managers at approx. 40 m^2 (with an equivalent planted area of 12.0 m^2). This effectively excluded all individual, low rise residential buildings.

Farmable roof area was calculated by deducting the space required for rooftop infrastructure (elevator housings, AC units, water tanks etc.) and operational requirements (access to parapet edge for cleaning and inspection, emergency evacuation etc.), from the total building footprint area (measured from building and land survey plans). The typical building footprint area and proportions of roof space taken up by infrastructure and operational requirements was estimated (by building type and height), from building records and land survey plans, for all buildings within two sample urban sub-districts (one in a newer and one in an older urban area). These were cross-checked against aerial photographs.

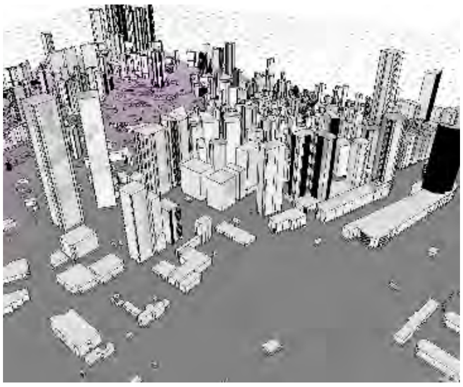

Figure 5: 3D Modelling of Buildings in Hong Kong based on Footprints and Heights, Used in the Estimation of Potential Farmable Roof Spaces

All existing buildings within urban areas were assessed against these building and operable area limits (image 5), to identify those that could be used for rooftop farming, and estimate the potential farmable space on them, (Table 1). This should be considered as only an estimate, based on measurements of two sub-districts. Going forward, the research team will systematically identify and measure each building.

Building type	Building height *Low (0-4/floors)* *Medium (5-12/f)* *High rise (13-39/f)*	No. useable buildings in HK *(estimate no.)*	Typical building footprint (m^2) *(estimate no.)*	Percentage of building footprint farmable (typical %)	Estimated Farmable area (m^2)
Residential	Low rise	0			0
	Medium rise	2,160	1,250	10%	270,000
	High rise	5,390	1,070	35%	2,018,555
Institutional	Low rise	320	1,820	65%	378,560
	Medium rise	1,220	1,480	50%	902,800
	High rise	80	920	45%	33,120

Commercial	Low rise	60	2,470	20%	29,640
	Medium rise	110	2,200	50%	121,000
	High rise	1,430	2,070	25%	740,025
Industrial	Low rise	540	1,510	75%	611,550
	Medium rise	930	1,360	65%	822,120
	High rise	60	940	45%	25,380
Total		12,300			5,952,750

Table 1: Preliminary estimate of total farmable rooftop space in Hong Kong

The second measure looked at the potential public demand for rooftop farming across the territory. Owners of open-to-public farms reported that the only limitation on their current operation was physical space. Uncertainty over legitimacy of rooftop farming as a permitted land use and the Government not yet having recognized URFs as countable green building coverage, were seen as principle capacitors on expansion. Owners noted that their farms were heavily oversubscribed and they had to restrict both membership and the extent of farm area worked by individual participants. This is corroborated by the multiple year waiting lists for similar ground level productive garden plots within community gardens (LCSD 2016).

In interviews, farm managers identified participants as either ‘regular farmers’, typically visiting the farm four or more times a week for a total of more than 3.5 hours, or ‘occasional farmers’ who visited only once or twice per week for less than 1.5 hours in total. There were many more occasional farmers then regular farmers in each farm, but farm operations were sustained in the long-term by the regular farms, of whom, they felt, there needed to be at least three.

In open-to-public farms, regular farmers rented 2.0-2.4m^2 of planter space, but occasional farmers usually rented only some 0.5m^2. In restricted farms, space was usually less constrained and was not always subject to subscription. Dedicated regular farmers in these operations could manage planted areas of up to 10.0m^2, with occasional farmers managing 0.9-1.8m^2 planted area, on average. These figures are comparable to the standard plot size in ground level community gardens of 2.25m^2 (LCSD 2016), but small in comparison to individual plot sizes of 9.25m^2 rented out by weekend farms in the New Territories (outside the city) (Fedvmcs 2016), and very considerably below typical rented garden allotment sizes in Europe, of approx. 50m2 (Bell et al 2016).

Questionnaire responses indicated that the key demographic groups amongst farmers were young professionals (18-25), middle age workers (35-55), and the recently retired (55-75). The elderly (65-85) were widely viewed as a group likely to become much more involved in future (as the density of farms in the city increased), due to their greater free time and interest in health issues.

Nearly all occasional farmers reported their level of experience as ‘very little’ or ‘none’, but regular farmers (who saw themselves as enthusiastic amateurs) reported their experience as ‘somewhat competent’ to ‘competent’. Farm mangers did not consider expertise to be a limiting factor in the development of rooftop farming as instruction and support was readily available, and because the key outcome for most participants was social rather than productive. Farmers reported their key motivations as: learning new things; pleasure in growing things; social interaction; and opportunity for outdoor recreation.

For open-to-public farms, questionnaire responses indicated that more than 64% of participants travelled less than 400m to the farm (<10 minutes) from their point of origin (home or work), with 96% having journeys of 800m (20 minutes) or less. 800m was taken to indicate the likely maximum distance a participant might be prepared to travel to get access to a farm. Based on census data for different urban districts in Hong Kong, the likely population within an 800m radius catchment area around of a given location in the city would be between 31,000 and 54,000 people (C&SD 2016).

Participation rates in existing open-to-public farms, i.e. percentage of the population within the 800m of the location of the farm that was involved with the farm, was estimated at between 0.19% and 0.32%. This is similar to the current participation rates for government run community gardens. Restricted URFs drew participants from much smaller catchments (450-27,500 persons), and had participation rates of between 0.38% and 4.4% of that

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

population. Participants in this type of farm travelled shorter distances (commonly less than 200m) from point of origin (i.e. within the institution or work place).

4. DISCUSSION

Urban rooftop farms have developed spontaneously in many urban districts across Hong Kong over the last few years, without any technical assistance or policy support, suggesting a broad based interest in the activity within the community. This is underpinned by questionnaire responses from existing farmers who cite their motivations for participation as being the desire for healthier lifestyles, social engagement and opportunities to participate in active, nature based recreation, rather than food production. Further, URFs have been established on very different types of building, indicating potential both in terms of the range of spaces that might be available for farms, and the nature of the communities that would be willing to support them.

The survey of current URF operations in Hong Kong, highlighted that the physical restrictions on the use of roof decks for farming were less than anticipated. Since 1970 most building roof decks in the city had been designed for some form of emergency fire escape, giving them the structural capacity to support the weight of rooftop farms, as well as providing suitable safety features and means of access. Only buildings with lightweight or complex roof construction, such as sports halls, did not have the physical capacity.

Aside from small low rise residences (mostly village houses), the roof decks of most buildings were large enough to support a community based farm. Commercial buildings (of all heights) appear to offer the greatest potential area for developing rooftop farms (ave. <2,000 m^2), although low or medium rise industrial buildings had the greatest percentage of useable area (65-75%) due to their having least amount of rooftop installations and operational requirements.

The preliminary estimation of 595ha of farmable roof space on buildings in urban Hong Kong needs detailed verification, but when compared with the total area of existing URFs measured in the survey (1.25ha), suggests considerable potential for expansion of rooftop farming activities, if current capacitors can be addressed.

Further, considering that the area of land used for vegetable, flower, field crop, production in rural farms across the whole of Hong Kong was only 420ha at the end of 2015 (AFCD 2015) and is in steady decline due to continued urbanisation, farmable rooftop space offers a potentially valuable resource, if farming practices can be commercialised.

The number of rooftop farmers engaged in the surveyed URFs (total, 1,435), was similar to the number engaged in the government's community farms, with both being restricted by available farms and farming space. Farm managers' response to the long waiting lists of limiting plot sizes, has helped to maximize the number of participants within the space available, but with rooftop plot sizes much smaller than those for weekend farms in Hong Kong and only a small fraction of average overseas allotment garden plots, there could be strong demand for greater farm space just from current farmers.

Participants of open-to-public farms were drawn from the resident population immediately around the farm. Easy access to farms was reported by farmers as a key consideration in their participation, with the majority travelling less than 10 minutes to the farm. Participation rate in open-to-public farms, based on the population within a notional 800m catchment of a typical urban district, was estimated to be around 0.25%. Simply applying this to the total urban population suggests that territory wide participation in rooftop farming could exceed 18,000 people. With participation rates up to 4.4% in restricted farms, it is possible that total participation could be higher, particularly as more farms became available and travel distances were reduced, and if the initiative was supported by government and promoted centrally.

The study has indicated that there is already a strong demand and a sizeable potential for the development of urban rooftop farming in Hong Kong. Although not yet a component of the Government's New Agricultural Policy (FHB 2016), urban rooftop farms offer a better prospect than traditional urban farms because of the potentially greater farmable area on the city's rooftops, and closer proximity to participant populations. Rooftop farming also aligns directly with policies promoting healthier urban lifestyles; community engagement, and aging in place.

ABSTRACT

Large parts of the real estate sector have realised that the consideration of the sustainability-related performance of single buildings as well as integration of sustainability aspects into the further development of building stocks are preconditions for the viability and future-proof development of housing and real estate companies. In this context, it can be observed that formerly purely image-driven approaches and corporate strategies with isolated assessments of sustainability aspects are now complemented and/or replaced by more integrated approaches; i.e. real estate sector organisations increasingly attempt to embed sustainability considerations into business routines. However, embedding sustainable development principles within decision making processes requires an integration of sustainability aspects into the methods and tools of such organisations; this includes, for examples, portfolio management, risk analyses, property valuations and economic efficiency calculations. In order to achieve such an integration, these methods and tools do not need to be replaced but specifically further developed. This specific further development of real estate sector business methods and tools is the subject of the present paper. By taking the Discounted Cash Flow (DCF) method as an example, the paper explains which information and data on sustainability-related characteristics and attributes of buildings can be directly and indirectly "translated" into cash flows and how this impacts on DCF-results. The paper will propose subtle adjustments to the traditional DCF method which are likely to result in both, increased transparency and an improved understanding of the various economic advantages of sustainable building features as a basis for decision making.

The paper also argues that any attempt to integrate sustainability considerations into the business routines also requires adjustments and extensions to traditional building descriptions and specifications; which in return, leads to new requirements for the design and planning stages as well as for the documentation of buildings and the facility management process.

Keywords: green economics, real estate companies, business case

1. INTRODUCTION

Within the current scientific debate concerning the description, assessment and interpretation of the economic performance of buildings two approaches can be distinguished: On the one hand, the consideration of the economic dimension is inseparably linked to any assessment of buildings contribution to sustainable development (see also: ISO [1]). In this regard, goals are the minimisation of life cycle costs as well as the preservation of economic capital. The core list of assessment indicators published by ISO [2] contains a reference to life cycle costs. The authors of this paper have already contributed to the development of proposals for an assessment of value and value stability within European standardisation activities (see: [3]). Currently, there is a need for the development of appropriate calculation rules for these economic indicators.

On the other hand, there is growing awareness within the construction, housing and real estate industry for the need to consider sustainability aspects right from the beginning of project developments and within investment decision making processes (see: [4]). Within many different working groups at European and international level, the implications for investment calculations and property valuations have been discussed. Notably for the integration of sustainability aspects into valuation theory and practice respective guidelines and basics for the further education of real estate professionals have already been developed.

Within this context, the possibility of taking sustainability considerations into account within discounted cash flow (DCF) analyses deserves particular attention since the DCF method combines aspects of life cycle costing with an assessment of a building's future economic value at the end of the holding period.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The DCF method and the approach of discounting have been and still are subjects of ongoing discussions. Particularly within the sustainable development discourse the argument is often made that by using the standard DCF approach with constant exponential discount rates to evaluate real estate investment decisions the longer-term implications (both benefits and adverse impacts) are simply discounted away. In order to overcome this problem, the application of declining discount rates would represent an alternative. However, while the underlying logic of declining discount rates appears convincing, from a real estate valuation perspective, this would not be a feasible option because within the context of market valuations, the applied discount rate needs to be market derived and the discounting approach needs to reflect the prevailing market conventions.

Therefore, this paper does not discuss possibilities for altering the DCF approach through alternative forms of discounting (since this would most likely not be taken into account by market participants and professional valuers) but focuses on subtle adjustments to the traditional DCF approach as it is currently widely applied in the real estate investment and valuation context.

2. DISCOUNTED CASH FLOW – A COMMON METHOD

The Discounted Cash Flow (DCF) method is among the most widely used property valuation approaches as well as a commonly accepted method for comparing/analysing competing investment alternatives. Within the scope of this paper the focus is placed on the DCF-method as a tool for estimating the value of single buildings only.

In principle, the DCF method can be used to estimate present value of a real estate asset or to extract a rate of return from comparable sale. In typical valuation work, the valuation professional begins by developing detailed spreadsheets containing itemized incomes, expenses and cash flows year by year (or occasionally month by month) over the presumed period of ownership (holding period) or any other study period. The cash flows – including the projected sale price (terminal value) – are then discounted at a particular rate (discount rate) to derive an indication of present value (see Figure 1). The selected rates shall reflect all the risks (and chances) associated with the subject property. For a more detailed explanation of the DCF method, see [7].

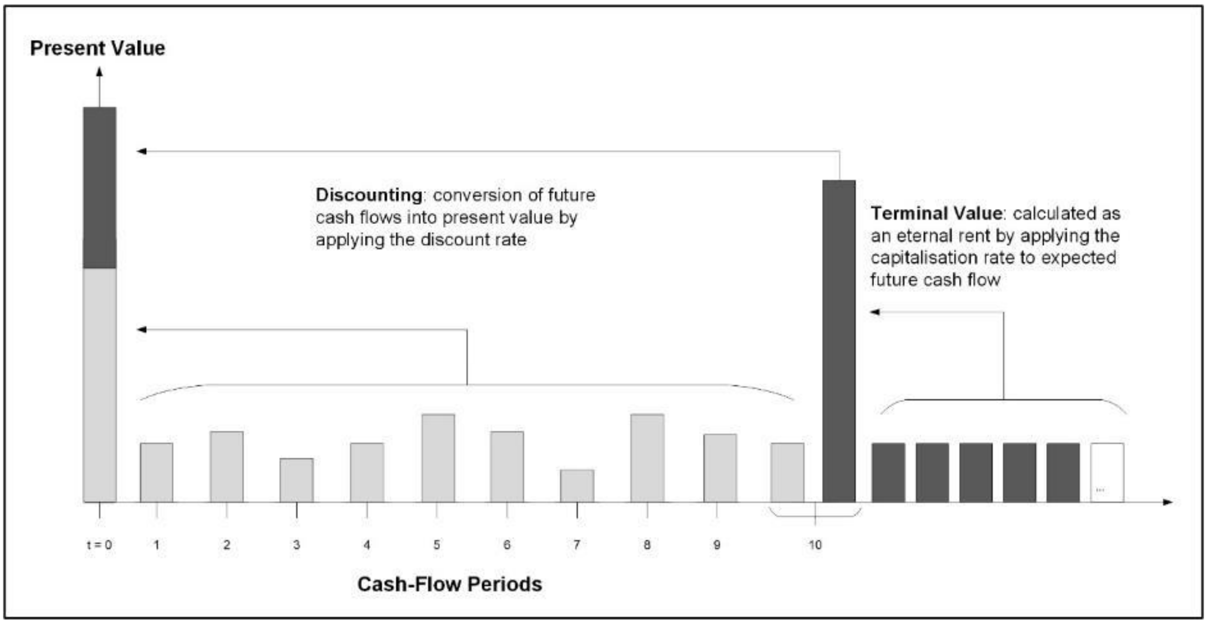

Figure 1: DCF scheme

The figure makes clear that:

- In theory, the DCF method can be very explicit/transparent during the study period since it requires for detailed cash flow projections. This is particularly true whenever the valuer's/analyst's assumptions are not "hidden" within the applied discount rate but made explicit through the modelling of the individual cash flows.
- The terminal value at the end of the holding period usually significantly impacts the DCF result. However, estimating this terminal value is associated with considerable uncertainties that need to be taken into account. In addition, longer-term aspects (like recyclability of the building, etc.) need to be taken into

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

account within the terminal value estimation. For both of these reasons, particular attention has to be paid when determining the capitalisation rate.

- There is a tension between the usually short-term oriented decision-making horizon of investors and longer-term impacts of sustainability-related qualities/performance aspects of the building.

Against this background the following section contains some critical reflections on the traditional DCF approach as it is currently widely applied in practice.

3. REFLECTIONS ON THE TRADITIONAL DCF APPROACH

From the authors point of view, the major criticism of the traditional DCF approach applied to real estate is its lack of transparency. This lack of transparency is mainly due to two circumstances:

First, within the real estate industry there is currently no uniform / generally accepted structure or format for DCF calculations and documentations. This means that varying structures of DCF calculations can be found in practice and benefits and risks associated with real estate assets are accounted for through different input parameters of the DCF calculation. For example, an above-average energy performance can feed into the DCF calculation either through a higher rental growth estimate or through a lower discount rate or through a combination of both.

Second, when applying and determining discount rates, real estate professionals do take into account a whole range of issues implicitly and often even do not make an attempt to explain what has been accounted for and why. Both circumstances hinder real estate market participants in understanding the analysts or valuers thought process and how he or she derives at an estimate of a building's economic value and how sustainability related considerations might (or might not) have actually played a role and have affected this estimate of value.

In addition, further problems arise from the current application of DCF calculations: On the one hand, market participants and property professionals typically apply a rather short holding/study period. In most of the cases, the holding/study period is between 5 and 10 years only. This contradicts with the desired consideration of the full building life cycle (e.g. within the scope of a life cycle cost analysis) and leads to the question how future impacts of certain building characteristics and attributes (such as flexibility and adaptability, recyclability, design for deconstruction, etc.) can be appropriately reflected and taken into account within the DCF calculation. On the other hand, there are currently only few published approaches on where and how to appropriately feed sustainability-related considerations into the traditional DCF approach.

In order to increase transparency of the traditional DCF approach it is therefore necessary to identify the typical information needed to determine the input parameters for performing a DCF calculation and to discuss how sustainability related considerations potentially impact on these parameters. This will be done next.

4. RECOMMENDATIONS FOR FURTHER DEVELOPING THE TRADITIONAL DCF APPROACH

4.1 Increasing the transparency of cash flow projections

As it was explained above, the starting point within the DCF approach is the determination/projection of expected cash flows. However, within the traditional DCF approach, usually only those cash flows are represented/covered which directly relate to the perspective of the decision-maker (i.e. in most cases investors). But this also means that some information will get lost.

For this reason, it is recommended to take the complete cash flow along the building life cycle as a basis and to present (or at least mention) all potential incomes and expenses. This should be contained in the DCF calculation as an additional information – comparable to a complete finance/budget plan – accompanying the actual DCF result.

Within the presentation of all incomes and expenses (usually in the form of a spreadsheet) this would result in two additional columns indicating which incomes and expenses have actually been considered for the calculation and which ones are presented as additional information only (see Table 1 for an example). This additional information can then serve as foundation for certain assumption within the actual DCF calculation. For example, low energy

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

costs (additional information/data) can justify the assumption of a higher rental income or rental growth rate (valuation-relevant information/data).

Incomes	**DCF-calculation**	**Additional information**
Rents	X	
Incomes from advertising, mobile communications antenna, etc.	X

Table 1: Example of an extended DCF spreadsheet

4.2 Allocation and integration of sustainability-related aspects

The authors take the view that an integration of sustainability-related aspects into property valuation and business case analysis does not require the development of new methods but a fine-tuning / further development of existing approaches. This view is shared in the literature (see, for example, [8], [9] and [10]). In this regard, the authors have contributed to a guideline for Austria, Germany and Switzerland on integrating sustainability aspects into property valuation practices (see [11]). As a result of a research initiative of the Green Building Alliance, recommendations for integrating sustainability aspects into DCF calculations are now also available. The following tables 2 and 3 represent some of these results which have been produced with the authors substantial participation.

Rental space information	Building management information	Market assumptions	Terminal value assumptions
For each lease: - Type of lease - Rental level - Area - Utilities payments (energy, water and waste bills) - % of utilities payment charged back to tenants	- Operation expenses and repairs - Capital expenses (modernisation and replacement)	- Market rent - Inflation - Discount rate - Capitalisation rate - Duration to let - Letting fee	- Market rent at exit date - Maintenance costs at exit date - Capitalisation rate at exit date - Utilities payments at exit date - % of utilities payment charged back to tenants at exit date

Table 2: Proposal of format for a generic DCF framework presentation to ensure accounting of sustainability related-information (see [12])

The most important variables which are influenced by sustainability issues and which influence the risk premium and the composition and modelling of a property's cash-flow, are the risk of losing the tenant(s), growth potential for rent and value, occupier costs, tenant retention and fluctuation, duration and costs of letting, and depreciation as well as refurbishment and maintenance costs. While these variables are considered implicitly to a large extent when using the standard investment valuation method where the property's net income is capitalised as an eternal rent, they can be made explicit when using the discounted cash-flow (DCF) method. For this reason, Muldavin and others have argued that the application of the DCF method is the only meaningful option for practitioners, as it

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

allows consideration of the full spectrum of sustainability-related revenues, chances and risks within the valuation process in a comprehensible and understandable manner.

For both the DCF and standard investment method, the applied discount and/or capitalisation rates are used to transform future net income into the property's present monetary value. In doing so, the applied rates indicate the risk associated with the future income stream: the higher the risk, the higher the discount and/or capitalisation rate and the lower the assigned monetary value of the property. When using the DCF method, a constant discount rate is generally applied for the entire period under consideration (usually five to ten years). However, this constant rate is essentially the average of an exponentially increasing rate because income streams at points further in the future are more risky (the same applies for the capitalisation rate when using the investment method, where a constant rate is applied in calculating the present value of an eternal rent). This explains why sustainability issues must be considered today whenever discount or capitalisation rates are determined for valuation purposes. Future risks can be considered lower for sustainable buildings, whereas the future income stream of conventional buildings is assigned a higher risk.

DCF Input Parameters	Key sustainability-related quality and performance characteristics
Market rent	- Comfort level - Building related services: serviceability - Aesthetic and cultural quality - Presence of certification schemes/labels (and associated brand image) - Energy performance level (based on EPC or other assessments) - Mandatory requirements and market standards as regards sustainability performance - Space efficiency - Accessibility
Current utilities	- Level of utilities costs attributable to the tenants and the owner - Source of energy (presence of renewable sources) - Energy costs trends
Operation expenses and repairs	- Durability and maintainability of components - Ease of cleaning (part of maintenance) - Cost of repairs - Reliability of technical installation (failure per hours of running time)
Capital expenses	- Modernisation expenses (energy efficiency retrofit, improvement of functionality, resources consumption, etc.) - Costs for adaptation to climate change and user needs - Dismantling, landfill and /or recycling of components
Duration to let	- Aesthetic and cultural quality - Flexibility and adaptability (easy to move in), - Compliance with ESG regulation of tenants - Presence of certification schemes/labels (and associated brand image) - Space efficiency - Accessibility
Discount rate	- Risk assessment of impact of climate change - Resilience against natural and climate hazard (e.g. flooding, etc.) - Structural safety
Capitalisation rate	- Durability and recyclability of the building - Future-proofness and degree of resistance against various forms of obsolescence - Compliance with foreseen regulations - Long-term aesthetic quality

Table 3: Proposal for the allocation of sustainability-related quality and performance characteristics into DCF input parameters (see [12])

At the minimum, it is recommended that within a DCF calculation a supporting document or explanation is being produced revealing which sustainability-related aspects have been taken into account through which input parameter. In addition, the respective source of information (e.g. planning documentation, building passport, consumption values) should also be disclosed.

5. CONCLUSION

The recommended adjustments to the traditional DCF approach can contribute to an improved transparency and traceability of DCF results. They can also provide a basis for the development of a standardised/generic format and approach for DCF calculations and resulting documentations. In addition, they improve the ability of decision-makers to better fulfil their responsibilities towards the environment and society. Also, the consideration of sustainability-related aspect within the scope the estimating the terminal value of a building at the end of the holding period contributes to resolving the conflict between investors short-term oriented decision-making horizon and longer-term implications of certain sustainability-related performance aspects of a building. However, it needs to be acknowledged that the topic of terminal value estimation – particularly the issue of treating uncertainties – deserves further work and scientific debate.

Business for Sustainability: Market Incentives for the Better

Thomas SCHLUCK[a], Robert BÜHLER[b], Sabine SULZER[c], Matthias SULZER[d]

[d] *Hochschule Luzern, Switzerland, matthias.sulzer@hslu.ch*

ABSTRACT

An important cornerstone to reach the goals of the Swiss energy turnaround is the consecutive addition of renewable power sources. The integration of these sources into the existing electricity grid bears new challenges and requires an increased flexibility of the electrical grid since the power generation tends to be more decentralized and volatile in nature.

This development implies shifts in the daily power production and in consequence needs an adaption in load-management. A further aggravation is the planned liberalization of the Swiss electrical power market, which will force utilities and providers to search for new business models, which will cope with all of these developments.

Such a new business model is "Change38", which focuses on renewable energy sources and establishes a common market for local producers and consumers. Its goal is to distribute the produced electricity among its participators in real-time and to set local incentives to drive and accelerate the further addition of power supply and storage systems.

The business models approach addresses the questions of load-management, dissemination of renewable energy sources and monetarization of further sources by a self-regulatory approach. It gives merely the necessary framework to produce and consume on the right, most valuable time.

The developed business model addresses the socio-economic trend of a share-economy as well as the socio-technical trend of industry 4.0.

In previous works a simulation framework was presented, which allowed calculating all monetary flows and physical balances for each participant based time-series for power production and power demand.

Here we will compare our findings with the first available live-data sets and present the latest developments and adaptions of the business model.

Keywords: distributed energy system, energy measurement and verification, renewable energy

1. INTRODUCTION

With the realignment of the Swiss energy policy in 2007 (Bundesamt für Energie, 2015) (Pito, 2014) (Bundesamt für Energie, 2016) it was decided that decentralized renewable energy sources (DES) shall become a major pillar of the Swiss energy supply. Since then the question how to integrate DES into the existing power grid stimulated research in this field (Farhangi, 2010). For the dissemination of a technology federal subsidies are an effective, but short term solution. For a sustainable realization and long-term preservation a technology must be profitable. This is a more and more crucial point such that new and effective business models (Tanaka 2011) (Facchinetti et al., 2016) (Facchinetti and Sulzer, 2016) are in need, which do not rely on any subsidies at all.

Business models following the socio-economical trend of sharing and the socio-technical trend of the industry 4.0 (Lasi et al., 2014) by matching demand and production (Palensky and Dietrich, 2011) are now emerging. An instance of such a new model is the "Brooklyn microgrid" (Orsini, 2016), which intends to establish peer-to-peer trading based on the blockchain-technology (Swan, 2015). Another instance is the Swiss start-up company "Change38" (Bühler, 2016) which provides a self-developed platform for sharing that brings participants together and establishes incentives to produce and consume energy when it is needed, respectively available. In contrast to Brooklyn Microgrid Change38 is not only connecting providers with consumers, but it is part of the system. A

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

detailed description of the underlying business model can be found in (Schluck et al., 2016). In this work the parameter space of the Change38-model was explored based on Monte-Carlo simulations such that the system had been characterized in terms of its profitability and physical behaviour. Since then the model has undergone some slight modifications, which will be mentioned and presented here later on. However, the fundamental relations between the participants did not change and the findings in regard to the physical performance indicators like the self-sufficiency, self-consumption, and the ratio of production and consumption of pooled participants still holds true.

In addition for about a year a pilot project is running in the village "Gachnang" to establish a better understand of this economic-physical system and among others develop the necessary hardware. The collected data helped to clarify some critical parameters and supports the findings of the before mentioned Monte-Carlos simulations. Here we will present some implications and give some illustrations of the collected data.

1.1 Working principle

The basis of Change38 is to cluster local producers and consumers and set incentives for matching their production and consumption within their cluster. The idea is that in the long term this should lead to participants trying to fill the supply gaps. To make this work all production and consumption must be monitored. Thus the participants will get an update to their standard electricity meter with a real-time measuring device. The data is then saved online and for each point in time the matching of production and consumption is calculated.

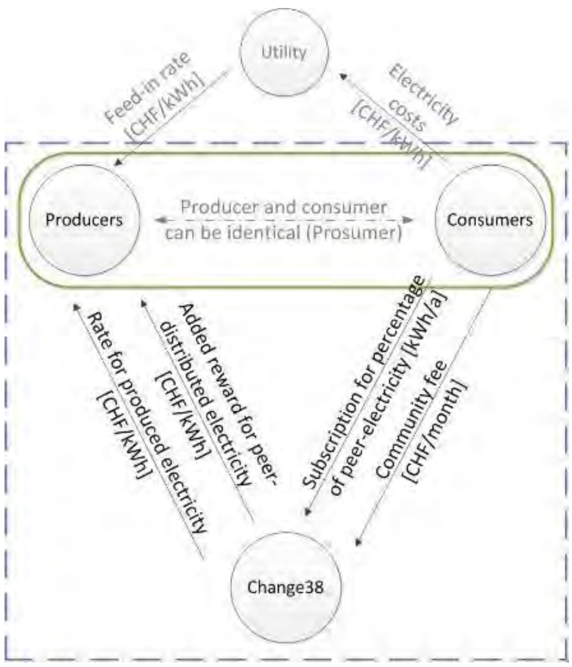

Figure 69: The actual business model of Change38. In the previous model the consumer was charged for the consumption of non-peer-electricity. Now the consumer subscribes for a guaranteed amount of peer-electricity.

2. THE MODEL AND ITS LATEST MODIFICATIONS

The system developed by Change38 can be separated into two aspects – namely the economic and the physical. Economically three kinds of participants are interacting: Change38, producers and consumers. For the producers and Change38 this venture should be profitable and consumers must get some added value to a reasonable price. Physically only two types of participants interact: the producer and the consumer. Among others their constellation, their technical equipment and their behaviour determine how their cluster performs, e.g. in regard to self-consumption, self-sufficiency (autarchy), or the production-to-consumption ratio.

Business Model: Figure 1 shows the business model in principle. Unchanged are the incentives given to participating producers. They will get two rates for their production: A base rate for each kilowatt-hour produced and a bonus rate for each produced kilowatt-hour that is consumed by peers. However the relation to consumers has been changed. In the previous model a consumer was charged for each kilowatt-hour he did not receive from the pool and thereby giving him an incentive to a behavioural change. In the actual model a consumer now subscribes for a guaranteed percentage of delivered peer-electricity per year. This change was considered necessary due to higher consumer's acceptance and acceptable due to the assessment that this costumer's incentive would have only shown a small impact. As a consequence Change38 must manage cluster configurations to a certain degree.

Clustering and Pooling: Figure 2 shows the evolvement in the clustering process. In the previous system's set-up participants are clustered as outlined in 2A) and plainly taken together. The actual approach as shown in Figure 2B) is more centred on the consumer's view, which is now perceived as a costumer. The consumer can now not only decide whether or not he will join a cluster, but he can choose to a certain extend what producer shall provide him with electricity. This additional service for the consumer comes on the cost of simplicity. Consumers now see different constellations than producers do. The possibility of aggregation is therefore much lower compared to the previous model. In addition, it becomes necessary to draw a distinction between pools, which are the sum of all producers a consumer has booked (As shown in Figure 2B)) and clusters, which are now the aggregation of all consumers that a specific producer provides to.

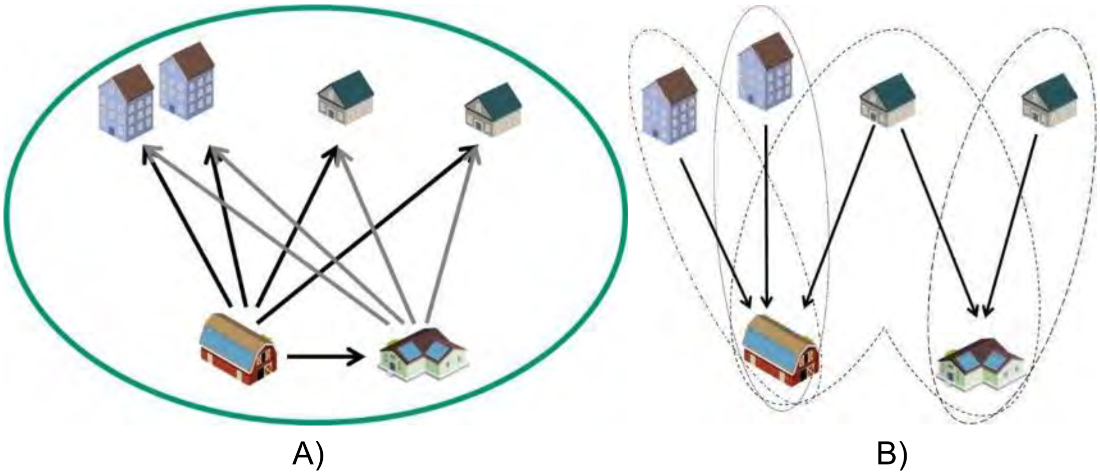

Figure 70: Clustering and pooling mechanisms. A) The clustering mechanism as it has been used in the previous model. Consumers and producers were aggregated in local clusters for matching their production and demand. B) In the latest mechanism the consumer books different producers and thereby creates his individual pool (Consumer's view), which in turn leads to clusters of one producer with his inscribed consumers.

Distribution: Matching production and demand and establish a mechanism for the distribution of the electricity is at the core of the model and did also change slightly. Previously producers have been granted a privileged allocation based on their seniority. The main idea was to reward early adaptors and risk-takers and give incentives to the latecomers to concentrate on the mismatching in a cluster. This funded on the precondition that a cluster contains several producers that must share the peer-electricity. Due to the more sophisticated clustering and pooling approach this concept was rendered unsubstantial, such that production and demand is now distributed evenly within a cluster.

Introducing options based on a more costumer centric view refined the model without abandoning its basic mechanics, which is in particular the cluster. While previously a cluster would normally contain more than one producer, a cluster will now be rendered by one producer alone. However, a cluster will still be assessed based on the same principles and performance indicators, which are:

- The percentage of self-consumption, i.e. what share of peer-electricity is consumed in the cluster.
- The percentage of self-sufficiency or autarchy, i.e. what share of the totally consumed electricity is covered by peer-electricity.
- The ratio of production to consumption.

These indicators were already used successfully to characterize and assess clusters that were simulated based on a Monte-Carlo approach (Schluck et al., 2016).

3. LIVE DATA FROM THE PILOT REGION

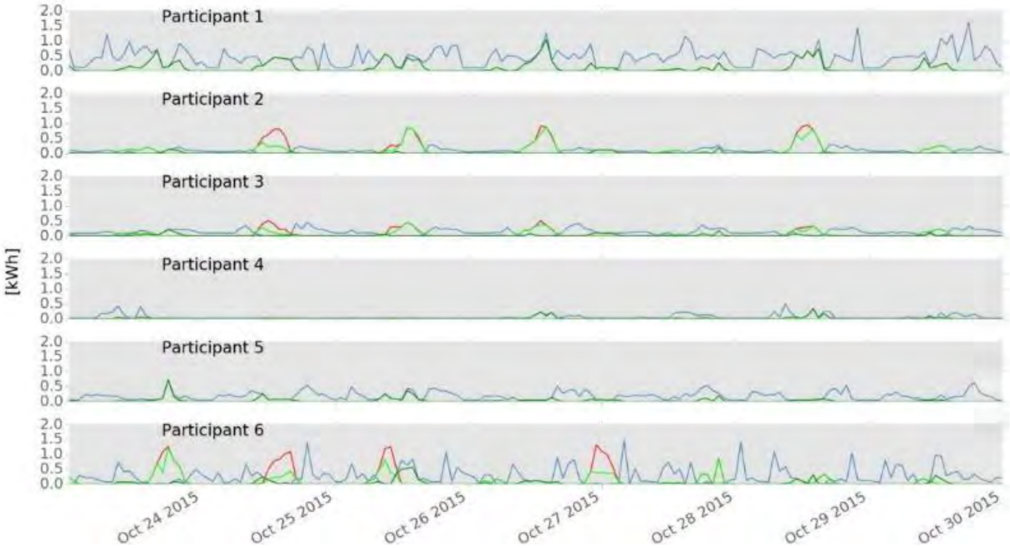

Figure 3: A week clipped from the live data set gathered in Gachnang. participant 1, 4 and 5 are pure consumers while 2, 3 and 6 are prosumers. In red each prosumers production is given, in steel-blue each participants consumption. A prosumer's production distributed among its peers is shown separately and coloured in lime, while consumption that is covered by peer-electricity is depicted by a green line.

Figure 3 shows the consumption and production of the participants during a week. The production that is consumed by the peers of a prosumer and the consumption that is covered by peer-electricity is separately shown. The constituents of this pilot project were three prosumers and three consumers in the village Gachnang. All production came from photovoltaic plants. The goals of this small pilot were to develop and test the necessary infrastructure, run a proof-of-concept for the clustering approach and determine some performance indicators of the cluster. The economics however have not been implemented at this stage.

So far the hard- and software has been developed and the clustering of the participants rendered successfully. To characterize the cluster based on the collected data the before mentioned performance indicators were evaluated. Although the underlying data set was carefully processed and aligned some data was missing due to the failure of some premature monitoring devices. Therefore the indicators were established for the entire time frame of one year and a single, but complete week. The results are shown in Table 1, which gives all indicators for the pilot region and from the latest Monte-Carlo simulations in comparison.

			Simulations		
			Self-cons	Self-suff	Prod-cons-ratio
Live data whole year	Self-cons	40.4	-	24.5±2	60±2
	Self-suff	14.1	76.5±2	-	18±2
	Prod-cons-ratio	34.9	57.5±2	19.5±2	-
Live data one week	Self-cons	72.0	-	15±2	21±2
	Self-suff	16.8	69.5±2	-	25±2
	Prod-cons-ratio	24.2	68.5±2	16.5±2	-

Table 1: Performance indicators for the cluster of the pilot project in comparison to the computed indicators evaluated using Monte-Carlo simulations (Schluck et al., 2016). For better comparison (based on the production-consumption-ratio) the indicators of the live data and the corresponding indicators from the simulations are highlighted. (self-cons: self-consumption, self-suff: self-sufficiency; prod-cons-ratio: ratio of production to consumption; values in [%])

3.1 Comparison and implications

In (Schluck et al., 2016) cluster constellations were simulated based on the assumption that all production was covered by photovoltaic plants . For these cluster types a hyperbolic relation between the production-to-

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

consumption-ratio and the self-consumption (correlation of -0.84) was found, as well as between the production-to-consumption-ratio and the self-sufficiency (correlation of 0.87).

Comparing the indicator values found in Gachnang with the by simulation evaluated indicators a general correspondence can be determined. All indicators lie within the same order of magnitude although. The indicators for the clipped data of one week can be arguably considered coherent with the computed indicators while the indicators of the whole year fells back in comparison.

As mentioned before the pilot was also conducted to test and develop the infrastructure in a sandbox like environment, such that a failure in data acquirement did occur frequently. This has certainly introduced a bias that led to the observed incoherence.

4. ANALYSIS OF CURRENT STATUS AND PROPOSED IMPROVEMENTS

Over the course of the last months Change38 refined and sharpened its model and introduced some further options for consumers. As a consequence, most consumers will become members of several clusters due to their booking (compare to Figure 2B)). This raises the issue of how to handle the distribution of energy between clusters. The simplest, but not most efficient, approach is the distribution by a previously defined, fixed rate. Other solutions make use of more sophisticated algorithms, but have not been developed yet.

A further question also associated with this issue is how many consumers effectively can be connected to a producer as this was identified to be an essential factor. The production-to-consumption-ratio is the corresponding performance indicator and was shown to be highly related to the profitability of Change38. Although this correlation was explored on the previous and less sophisticated model this should still hold true as the liable system's mechanics are still in place. The production-to-consumption-ratio is thus an important operative indicator. It is of special significance that it is highly correlated to the self-consumption and self-sufficiency, which are important indicators for a cluster's efficiency, independence and ecological footprint. These interrelations give an impression of the business model's systemic character.

The hitherto collected and analysed data supports these findings and backs up the latest simulations and thus the underlying modeling framework.

5. CONCLUSION

This work presents the latest developments of Change38 – a start-up that created a platform and business model for locally matching and distributing electricity. Here, the latest modifications of the business model are featured and their implications discussed. Furthermore, live-data from the cluster of the pilot project in Gachnang is presented, which is running since mid of 2015. To characterize the pilot's cluster the performance indicators "self-consumption", "self-sufficiency" and "production-to-consumption-ratio" have been calculated and drawn in comparison to the findings of a previous work. In this work clusters were simulated at random in a Monte-Carlo approach and characterized by the same indicators. The comparison of the indicators of the computed clusters with the indicators of the pilot supports the simulation approach and underlying modelling framework.

Next steps will be the further exploration of the latest business model by means of simulation and further in-depth analysis of existing and additional data.

ACKNOWLEDGMENTS

We would like to thank the Swiss Commission for Technology and Innovation (CTI) that partially funded this work within the research framework of the SCCER FEEB&D. Our gratitude also goes to Change38 for the inspiring and thriving cooperation.

Private Public Partnership Energy Efficiency Assessment Program at Hong Kong Aircraft Engineering Company, Xiamen facility, China

Samuel KWONG[a], Matthew TANG[b]

[a] *John Swire & Sons HK Ltd, Hong Kong SAR, samuelkwong@jsshk.com*
[b] *Hong Kong Aircraft Engineering Company, matthewt@haeco.com*

ABSTRACT

Hong Kong Aircraft Engineering Company (HAECO) invited a group of students from Tsinghua University Beijing to conduct an energy assessment of one of its facilities in Xiamen in July 2015. The study was done on two of the 6 maintenance hangers and has identified a total of RMB 2M per year of savings with zero to low capital expenditure investment. This amounts to approximately 10% of the annual electricity consumption of the whole facility. Most of the findings can be applied to the other hangars resulting in a higher potential savings. There are also further savings if improvements with longer payback are taken into account for example replacing air-cooled chiller system with water-cooled model. Some of the key sources of inefficiency identified are: oversized design and improper operating control; improper design & installation usually resulting in pressure drop; blockage and malfunction especially on piping and valves; and mismatch of supply and demand. The study team comprised of undergraduates and research students and was led by two professors.

The study is a part of the summer programme for Tsinghua University. It allows students of building services and facility management studies to apply and compare what they have learnt in studies to real situations and at the same time identifying energy saving opportunities for the host company. During the exercise, new topics for further researching and investigation may also be generated for the university. Further to the success of this study, the holding company of HAECO, Swire Pacific, has reinforced the partnership with Tsinghua University by offering up to RMB 4M per annum for 2015-2018 in funding for building energy efficiency and sustainability researches for the private sector. Subsequently, several energy efficiency studies have been conducted. The possibility of applying the learning from the initial study model is being explored in other business operations and new development under the company.

Keywords: energy efficiency, private public partnership, energy assessment

1. PRIVATE PUBLIC PARTNERSHIP

The partnership was between HAECO Xiamen and Tsinghua University. Students from the Faculty of Architecture Building Environment and Services, Building Energy Research Centre (BERC) were invited to carry out an energy assessment at the aircraft maintenance facilities in HAECO Xiamen during July and August 2015. The main objectives are to identify the energy management opportunities at HAECO Xiamen and to provide training ground for students to practise their studies in real situations. The Tsinghua team was led by two professors and comprised of three research students and six undergraduates.

Tsinghua has been providing the energy assessment summer projects to private and public sectors since 1995. It has been widely welcomed by students, the university and hosting organisations. This was the first time that such project was carried out on an industry facility focusing on aircraft engineering.

1.1 HAECO Xiamen

HAECO, established in Hong Kong in 1950, is one of the world's leading independent aircraft engineering and maintenance groups. It is one of the largest maintenance, repair and overhaul service providers in terms of capacity. HAECO offers a full spectrum of services including airframe services, line services, component services, engine services, inventory technical management, fleet technical management, cabin solutions, private jet solutions, freighter conversion, parts manufacturing and technical training through its 19 subsidiaries and joint venture companies around the world.

HAECO Xiamen is one of the subsidiaries of HAECO located at the Xiamen Gaoqi International Airport. With six double-bay maintenance hangars capable of accommodating ten fully docked wide-bodied aircraft, HAECO Xiamen is one of the world's largest airframe maintenance facilities. Supporting its overhaul services are a wide range of in-house backshops and fabrication facilities, as well as testing and calibration laboratories.

1.2 Tsinghua University Building Energy Efficiency Research Centre

Tsinghua University has 14 schools and 56 departments with faculties in science, engineering, humanities, law, medicine, history, philosophy, economics, management, education and art. The University has now over 25,900 students, including 13,100 undergraduates and 12,800 graduate students. As one of China's most renowned universities, Tsinghua has become an important institution for fostering talent and scientific research.

Tsinghua University's BERC is a leader in the field of building energy conservation in China, and has a responsibility to promote energy saving and emission reduction in the architecture field. BERC's main work includes: national conditions and development strategy research of building energy conservation; building energy efficiency technology research; policy, regulation and standards making; engineering consultancy for major projects; propagandizing and popularizing the research achievements, and cultivation of professional talents, etc.

2. ENERGY ASSESSMENT FINDINGS

2.1 Energy consumption analysis

HAECO Xiamen has six maintenance hangers in which the majority of operations are conducted and energy is consumed. The hangers comprise of two main components: bay area and annex building. Both have separate air conditioning system, lighting and electricity supply.

The average annual energy consumption of HAECO Xiamen was 20M kWh between 2012 and 2014, of which approximately 66% was used in the annex buildings and 34% was used in the bay areas. Energy used in air conditioning comprised 38% of the total energy consumption (10% for bay area; 28% for annex building) and 23% for lighting (13% for bay area and 10% for annex building).

Based on the total energy consumptions and energy intensities of the hangers, Hanger 3 and Hanger 6 were selected for detailed assessments because of the high consumption and potential for improvement.

2.2 Air conditioning– bay area

Air conditioning in the bay area is provided by chilled air delivered to the aircraft and work areas by flexible tubes. Chilled air is generated by fixed central air conditioning units and mobile air conditioning vehicles. The measured coefficients of performance (COP) of the fixed and mobile units were 2.9-3.2 and 5.3, respectively. The monitoring results showed that only 30-40% of chilled air was effectively delivered. Much was wasted during delivery due to pipe leakage and uncontrolled outlets. The efficiency of chilled air delivery fan units was low and the delivery power was larger than demand resulting in localised temperature discomfort.

The suggested improvements include increasing the proportion of mobile air conditioning supply because of the higher COP, retrofitting the fan units with variable speed model or several small fans, strengthening wind tube valve control and switching off chiller units when not in use. The suggested control measures are expected to save 1.08 million kWh of electricity per year with zero to very low capital investment cost.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 2.2a: Chilled air supply at Bay area

Figure 2.2b: Mobile air conditioning vehicle

2.3 Air conditioning – Annex building

Air conditioning is provided by water cooled system to the Annex Buildings being studied (i.e. Hanger 3 and Hanger 6). Each has four chilling units and two sets of five cooling water and chilling water pumps. At the time of the measurement, two chilling units were running at COPs of 3.58 and 4.54, significantly lower than the designed COP rating of 5.45. The efficiencies of four of the running pumps were measured. They were all running at lower efficiencies (46-60%) than the designed one at 79%. This suggests that both the chilling units and the pumps are oversized and not properly operated.

The water pressure along the cooling water system was measured. A significant pressure drop of approximately 25m was found at one section of the pipeline located on the roof top, suggesting a potential air stuck in the pipeline and the condenser, resulting in high energy consumption and low heat transfer capacity.

At the time of the measurement, only three of a set of four connected cooling towers was running. The switched off tower created an air flow shortcut wasting 25% of the total air flow through the towers.

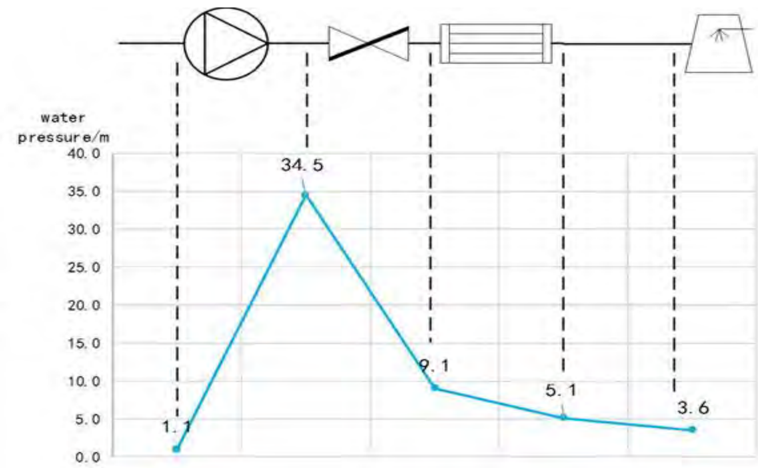

Figure 2.3a: Cooling water pressure measurement

Some preliminary improvements were made onsite including: shutting down one set of chiller and pump unit to increase the loading capacity to 90%; installing vent valves at local high points and allowing air trapped inside the system to be released; and switching all fan units in the cooling towers on. Both system COP and the energy efficiency have improved significantly after the improvements. It is estimated that approximately 154,000 kWh of electricity per year can be saved (27% increase in energy efficiency).

Further improvements could be made by installing variable speed drives at the cooling towers, lowering the chilled water set point (e.g. to 7oC), and changing the oversized pumps with the appropriate capacities. With these additional improvements, it is estimated that the energy efficiency of the system could be improved by approximately 34%, saving 200,000 kWh of electricity per year.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 2.3b: Vent valves installed

	Before Improvement	After Improvement
Chiller COP	4.11	4.82
Cooling Water Efficiency	54%	72%
Chilled Water Efficiency	51%	57%
WTF Load	20.0	35.5
WTF Source	19.1	29.6
Total Power (kW)	338.7	246.9
Energy Efficiency Ratio	2.76	3.37

Table 2.3: Performance before and after improvements

2.4 Lighting

Lighting amounts to 23% of the overall energy consumption of HAECO Xiamen, of which 75% (i.e. 1.3M kWh/year) is for high bay and 25% for general use. Lighting intensity at the bay area was found to be in compliance with the China Civil Aviation Standard MH3145.86-2001 of 500 Lux at daytime when the door of the bay was opened. Some areas would require illumination when the door was closed. It is therefore suggested that natural lighting be improved and sensors be installed for the highbay lighting at the bay areas. The saving from this improvement is estimated to be approximately 816,000 kWh/year.

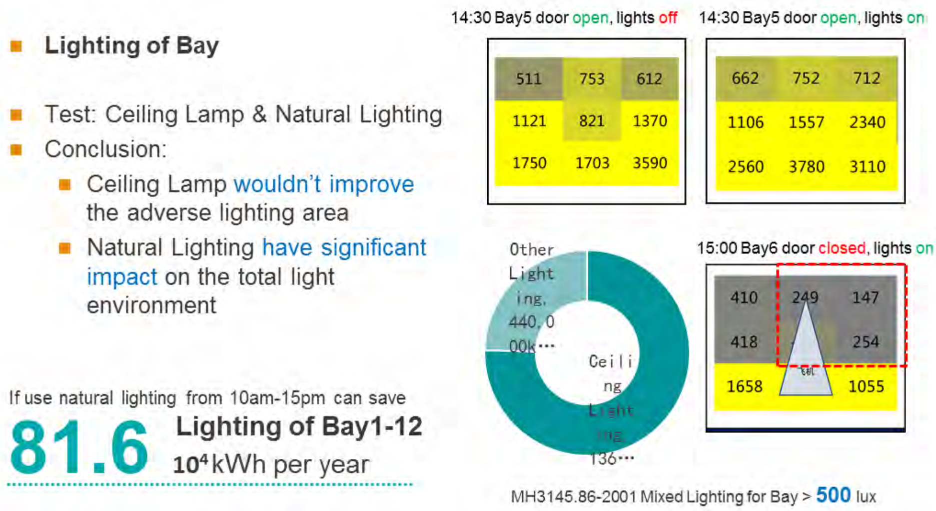

Figure 2.4: Lighting intensity measurement at bay area

2.5 Ventilation - Central warehouse

The central warehouse uses 200,000 kWh of electricity per month i.e. 12% of the total consumption of the HAECO Xiamen, of which the majority (~76%) is from air conditioning. Occupancy by the operators and warehouse staff is concentrated but fresh air is provided to the whole space via the central air conditioning system with ventilation at the ceiling of the warehouse approximately 10m aboveground. Installing specific air conditioning for the office areas, adjusting the fresh air return and switching off the highbay lights when not in use could result in an estimated saving of 280,000 kWh/year with nominal to zero investment cost.

Figure 2.5: Central Warehouse Layout

3. NEXT STEP FORWARD

The partnership provided an opportunity for students to apply what they have learnt in real situations and for the University to identify new topics for further researching and investigation. The host company was benefited from the technical advices from Tsinghua and getting access to the latest technologies and management approaches on energy efficiency.

Further to the success of this pilot, the holding company of HAECO, Swire Pacific, has reinforced the partnership with Tsinghua University by offering up to RMB 4M per annum for 2015-2018 in funding for building energy efficiency and sustainability researches for the private sector. Subsequently, several energy efficiency studies have been conducted. The possibility of applying the learning from the initial study model is being explored in other business operations and new developments under the company.

Leveraging the Power of Story to Achieve Greater Sustainability

James Scott BREW[a]

[a] *Nikken Sekkei, Japan, brew.james@nikken.jp*

ABSTRACT

If you google "storytelling for business" you will quickly learn that this is not a fad. And Chief Storyteller is not just a creative title for cool companies. Storytelling has always inspired humans to think differently, act on change or just make more informed decisions. This paper will focus on how and why storytelling works — using research from psychology and brain science, introduce story types and structures, and conclude with a true story from a large scale project for a major multi-national corporation.

Scientists, academia, and even research journals are only now discovering the power of storytelling in getting their message to be not only better understood, but also remembered. We have learned more about the human brain in the past 10-15 years than in all of human history before. Using sophisticated brain wave and brain chemical reactions, we are now able to measure the impact and memory triggers of a carefully structured story as compared to the same information, presented as mere data or facts.

To maximize impact, it is important to understand story structure and story types as well as how to develop story and logic models. This "process" helps frame a compelling story into one that will be understood and remembered.

Keywords: education and training, green economics, storytelling

1. INTRODUCTION

Too often, on climate change and sustainability fronts, we are challenged in making convincing arguments for greater investment or why needed change is urgent. There is a tool that we use every day, and it is more powerful than a life cycle cost assessment or a simple payback calculation — it is called storytelling. Storytelling can also be thought of as presentation. And great presentations, with or without PowerPoint, are commonly designed and presented in the form of a story.

While we all tell stories quite often — daily for most people, the way in which we tell them can be very effective or not effective at all. The more we understand about story purpose, story types, story structure, and story logic — the better our storytelling becomes.

Storytelling usually requires an audience — a listener or listeners. And while story listening is also an important skill, knowing your audience is the first step to effective storytelling. The more you know about them, the more likely your story will be structured and framed to resonate with them.

Before you embark on writing or telling a story, it is also good advice to understand your story's purpose. What is it you want from your audience? A decision? Are you trying to inform them of something they need to know? Perhaps you are hoping to persuade them to believe something they might not believe at the beginning of your talk. In any case, it is a good idea to know what it is you want from your audience before you write or tell an important story.

2. WHY STORIES WORK

There are many scientific and psychological reasons that stories work for humans. But the most basic of these reasons is primal. We are hard-wired for story — in fact, storytelling is how we survived as a species. An example often used is this:

Imagine you are a caveman or woman — living in a subtropical climate, ten thousand years ago. And one day as dusk approaches, you watch as three of your fellow cavemen walk away from the cave into the distance to hunt for food. Later, only one of your friends returns. What happened, you wonder. When your surviving friend tells everyone how a large toothed cat hunted them and how it killed their two friends as they tried to fight it off, you listen very intently--because you don't want to die like that. It's that simple. And the same was true for injury, disease, or death from water, fire, weather, shelter, and so on.

2.1 Story types and structure

There are a variety of story types in the world. Most of us have heard of at least some of them: comedy, tragedy, the hero's journey, and so on. We are not limited in the types of stories we might tell in our professional work, it is very situation dependent. The hero's journey is used in over half of all Hollywood movies and nearly all of the most watched TED talks.

In the sustainability world, we may often be telling vision stories (of a future where we overcame climate change) or a values or teaching or learning story, where there is a lesson such as if we do 'this', then 'that' will happen. Another story type that might apply to fighting climate change is battling and beating the monster or dragon. Becoming familiar with some of these types is useful in understanding and becoming a better storyteller.

Story structure is generally quite straight forward. While there are variations and simplifications, most stories follow a fairly common structure, as shown in Figure 1.

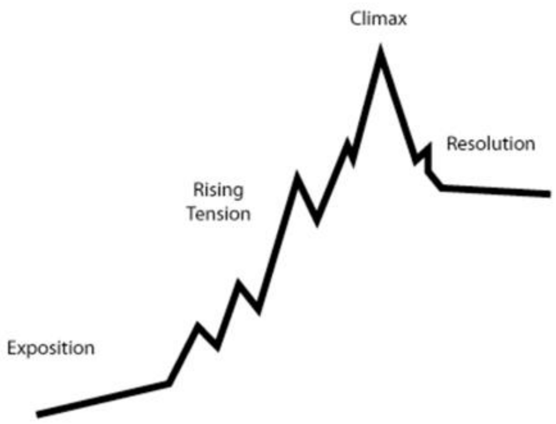

Figure 1: Story structure

The exposition can be thought of as the context or "where are we?" as the story begins. Rising tension is the presence of a problem or challenge that the character(s) must overcome. Research has shown that this rising tension is critical to maintaining an audience's attention and gaining their empathy. The climax can also be thought of as the turning point. Finally, the resolution is the conclusion. It is very often preceded by tension in the form of a small setback or potential failure.

A much simpler way to think of story structure is in three basic parts. 1. A Trigger: The problem or challenge to be overcome; 2. Transformation: The turning point or climax; and 3. Life Lesson: What the character or listener has learned from the experience or story.

Storytelling is not just for oral delivery. This structure or logic flow of narrative can be used for business communications, marketing and even dropped into reports to help reinforce more complicated information.

2.2 Story Science

Many sustainability and business professionals understand the compelling nature of stories. Recent scientific research is able to more clearly identify how stories can change our attitudes, beliefs and behaviours.

Humans rely on other humans for survival and happiness. When we show kindness to others — even basic kindness to strangers, the neurochemical oxytocin is produced. Oxytocin is like the body's natural "empathy drug". Empathy is important for humans so that we can predict how we might react to similar situations and for getting along with others — for example co-workers or customers.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Stories with character-driven content and emotional content not only build empathy and attention — they are also remembered longer than those without it. Sometimes our presentation or speech is about something emotionless like a technology or piece of mechanical equipment. In these cases, the author uses the opening of the presentation as an opportunity to tell a "related" story (no matter how distant) that perhaps brings home a simple point like making the right decision or right-timing or lost opportunity.

The human brain is designed to recognize patterns. This is useful so that we can predict what might happen next. But it is not just visual patterns, like the face of someone you met before, but also oral patterns. And this is one of the reasons the brain loves stories — we recognized them. Narrative structure is the most elegant form that has been honed over thousands of years to help us learn, remember and change.

There are two main areas of our brain that light up when we are presented with information or data—Wernicke's and Broca's [see Figure 2]. These two areas process language and speech. And given that many sustainability professionals speak using technical terms, acronyms, and engineering language — the brain can easily be overwhelmed.

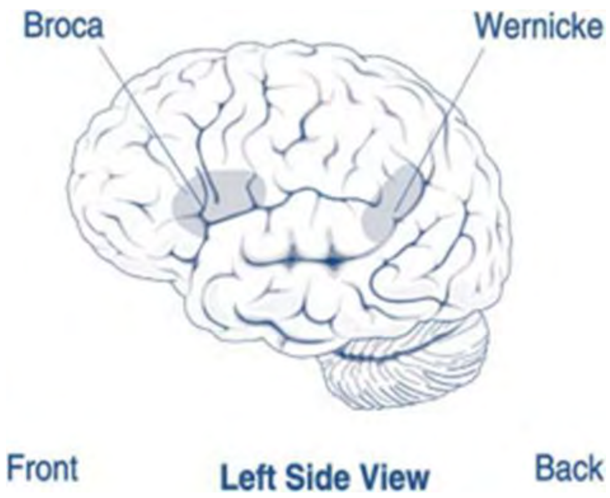

Figure 2: Wernicke's and Broca's brain areas

When we are presented with a narrative that includes sensory descriptions — even if it's about the information or data, multiple brain regions are activated. Here's a very simplified example:

Informational: The office air conditioning system uses radiant cooling panels with small fans delivering air flow at the rate of 0.2 to 0.3 m/s.

Narrative: The office cooling system is designed to give you the same feeling you get when you enjoy a slight breeze while sitting beneath the shade of a tree on a hot day.

We are a sceptical species. When we are presented information in the form of statistics, percentages and facts, we switch to an analytical mode and immediately question or even doubt the data we are hearing. Research by Jennifer Edson Escales, Marketing Researcher at Vanderbilt University, found that a test audience had more positive reactions to advertisements that were told as narratives than those which simply used facts and arguments. Compelling facts are best delivered in story form with sensory or human elements that bring them to life.

Other research has demonstrated how, when someone tells you an engaging story of something that happened to them, the very same chemicals are triggered in your brain as were triggered in the storytellers brain, when it happened to them. This is further evidence to support why story's capture our hearts and quite literally, our minds.

3. A TRUE STORY

The following story is a real example of leveraging story to achieve greater sustainability — but it starts with better listening. It ends with a powerful framing of the opportunity, which essentially set the project up for success when it appeared to be doomed. See if you can recognize all of the elements of story structure as you read it.

3.1 Is sustainability expensive?

About 6 years ago, the non-profit sustainability consulting firm I worked for, was retained by a global mining corporation in Australia to help them design 500 new, super-efficient homes for their workers--essentially a new small town.

At the time, their existing town housing was using about seven times more energy per square meter than a typical Australian home. They were also experiencing problems with mold in some of their housing units. As we embarked on the research and design solutions for climate responsive, super-efficient housing, it seemed quite apparent that this project was, to put it simply, a low-energy housing design exercise similar to those we had done before, except this one was at a larger scale. Or so we thought.

A few days into our work on the ground in Australia, we attended a mining workshop mostly just to understand the mining business and to meet some of the senior managers. It was on the first day of that two-day workshop that we learned that an entire town's energy use--even at the very high current levels, was but a mere fraction of the mining operations energy use and therefore we suddenly realized that our sustainability efforts may not get senior management support. This is because every project has a budget and we were going to certainly be asking for increased investment in the housing (for things such as more and better insulation, double glazed windows, healthy building materials, etc.). We felt defeated that day.

One evening, my colleagues and I were at our client’s home for a BBQ with some of the client team when the discussion turned to their company and some of the challenges their industry is facing. They mentioned the high turnover rate in the mining industry and how disconnected mining workers and their families feel living in the remote Australian regions. We also learned later that week about how worker fatigue contributes to safety failures (critical injuries--even death) costing the corporation millions (USD) annually.

By listening carefully to the real issues affecting the company, a story and logic model was developed around how healthy housing can contribute to reducing worker fatigue, improving safety, and how creating better community-focused neighborhood designs could contribute to improving worker retention, and how more efficient housing can reduced infrastructure, maintenance and peak energy loads that, in total, with relatively modest attribution rates, could potentially save the company nearly $1B USD annually. We now had a powerful story that would resonate with senior management. And it had very little to do with energy, climate change or sustainability as the lead story.

4. CONCLUSION

Storytelling works. Science has proven this. In facing and overcoming the challenges we are dealing with around climate change and natural resource constraints, we need more storytellers. Great communicators understand that business is about emotion and emotion revealed in the form of story can inspire their customers and employees. We all have stories. And many of our stories can be used to support a more technical presentation or speech where you might be asking for an important decision related to achieving greater sustainability. It’s all in the telling.

Embedding Sustainability in Higher Education Course Content: An Industry and Education Perspective

Lloyd Martin SCOTT[a], Sushismita BHATTACHARJEE[b]

[a] *Dublin Institute of Technology, Ireland, lloyd.scott@dit.ie*
[b] *University of Oklahoma, United States of America, suchi@ou.edu*

ABSTRACT

Large amount of environmental resources are utilized towards the construction, renovation, operation and maintenance of buildings. Though buildings enhance the standard of living, it accounts for a large portion of non-renewable energy depletion, greenhouse gas emissions, raw materials use, waste generation, and freshwater consumption. Sustainable design and construction practices can substantially reduce or eliminate negative environmental impacts through high-performance design, construction, and operations practices. With most of the top design and construction firms in the globe implementing sustainable design and construction practices, there is a huge responsibility on Architecture, Engineering and Construction (AEC) professionals to be knowledgeable in sustainable design and construction practices. Although many higher education institutions have begun to provide sustainability related courses, there is a lack of consensus on what constitute the body of knowledge on sustainability and knowledge expectations from the recent graduates when they join the workforce. The purpose of the research study is to identify the industry expectations of sustainability knowledge of recent graduates and how that is delivered through course curricula.

The research methods adopted for the study will be three folds, starting with an initial literature review on sustainability and how it is addressed by AEC as well as non-AEC course curricula, followed by a survey of AEC industry professionals (listed in Engineering News Record's top 100 list) to identify the sustainability knowledge expected from recent graduates. Further, using content analysis, the AEC educators' interview data and the course descriptions will be analyzed to identify how well the industry expectations are delivered through the course curriculum.

The findings of the study will provide important feedback for AEC educators to revise and evaluate their course curricula to address the important sustainability knowledge identified by the industry professionals.

Keywords: green construction technology, sustainable neighbourhood, design process

1. INTRODUCTION

There is a growing consensus that appropriate strategies and actions are needed to develop sustainable built environments and construction activity and the role and the role of education in this pursuit so the future leaders of the Architecture, Engineering and Construction (AEC) sector will need to be technically advanced, highly adaptable, collaborative, good communicators and lifelong learners (Scott, 2015). Progress toward sustainable built environment and construction activity must build on robust knowledge about the interaction between, and consequences of, the built environment and construction activity and the natural environment. This need is recognized, and "... environmental issues are now becoming a critical edge in construction research" (reference to be added)

Sustainability in the context of sustainable development is defined by the World Commission on Environment and Development (1987) as 'forms of progress that meet the needs of the present without compromising the ability of future generations to meet their needs'. This broad definition emphasises the aspect of future orientation as a basic element of sustainability. This care for the future implies, among other things, a wise use of natural resources and other aspects regarding the environmental footprint. The 'green' aspect of sustainability is recognised in many other definitions of sustainability.

The International Institute for Sustainable Development (2010) elaborates on the generic definitions in a definition more focused on sustainable management of organisations: 'Adopting business strategies and activities that meet the needs of the enterprise and its stakeholders today while protecting, sustaining and enhancing the human and natural resources that will be needed in the future.' Important in this definition is the mentioning of the 'needs of the enterprise and its stakeholders today'. Construction has been accused of causing environmental problems ranging from excessive consumption of global resources both in terms of construction and building operation to the pollution of the surrounding environment, and research on green building design and using building materials to minimize environmental impact is already underway.

The widespread acceptance of sustainability was initiated by the report published by the Brundtland Commission in 1987 titled "Our Common Future". In that report, sustainable development was defined as "development that meets the needs of the current generation without undermining the ability of future generations to meet their own needs." The report emphasized the importance of sustainable development at a level more than its intrinsic value to ensure there is enough resources to meet the requirement of the future generations. A plethora of attempts have been made to define sustainability since then emphasizing its importance. Today, sustainability is most popularly defined in terms of the three associated dimensions: social, economic, and environmental (Robert, Parris, & Leiserowitz, 2005; Tracey & Anne, 2008). This concept of the three dimensions of sustainability is embodied in the definition of sustainability adopted under United Nation's "Agenda for Development" which states "Development is a multidimensional undertaking to achieve a higher quality of life for all people. Economic development, social development, and environmental protection are interdependent and mutually reinforcing components of sustainable development" (UN, 2007). The popular means of conceptualizing sustainability in terms of social, economic, and environmental dimensions originated from Elkington's (1994) Triple Bottom Line concept. Opoku and Ahmed have advance the concept of sustainability, particularly in the context of AEC and offer the following definition "the adjustment of human behavior to address the needs of the present, without compromising the ability of future generations to meet their own needs" (2013:141). There are many researchers who advocate imminent actions to change the way in which young people become educated in matters about the environment (Cotgrove and Kokkarinen, 2013).

2. SUSTAINABILITY IN HIGHER EDUCATION

The concerns about sustainability indicate that the current way of producing, organising, consuming, living, etc. may have many negative effects on the future. In short, the current way of 'doing things' is not very sustainable. Therefore, some 'matters' have to change. Because of change in organisations, whether it is a new production plant, a new product, a new business process or a new resource, is in many cases organised as projects (Silvius and Batenburg 2009), it can be deduced that a (more) sustainable society requires projects. In fact, this connection between sustainability and projects was already established by the World Commission on Environment and Development (1987).

When discussing the implications of sustainability for AEC professionals, it is of eminent importance to have a clear understanding of the elements of sustainability outlined above. This may be a challenging exercise as the elements are conceptual, rather than practical (Moneva et al. 2006; Pope et al. 2004) is how and to what extend they are included in the education of the AEC professional. The concept of sustainability is understood intuitively, but is not easily expressed in concrete operational terms (Briassoulis 2001). The relationship between sustainability and and it position in the AEC sector is still an emerging field of study.

Sustainable and environmental education in built environment needs to be provided to students to imbue them with the concepts of environmental stewardship, sustainable design and application. More importantly, it is their responsibility to ensure that their decisions and actions are taken in the interest of environmental preservation. The demands of various interested parties need to be met, including those of traders concerned with the design of a cost-effective and superior solution; consumers who need an easy, comfortable and safe solution; and the government, which requires economic, social and advanced technologies without a negative impact on the environment.

3. RESEARCH METHODOLGY AND METHODS

The methodology applied was determined on the basis of relevance to the focus of this research enquiry but also on the basis of pragmatic positioning. This was the case as a different methodological stance would not have allowed the research to be completed within the constraints applicable. Creswell (2009) stated that research methodology is the systemic approach that a research adopts to accomplish the research's aim and with that in mind an explorative interpretivist position has been adopted. In relation to the purpose of the research: it is concluded that the theoretical argument developed for the enquiry has the potential, by using an explorative perspective, to reveal new insights and a better understanding of stakeholder perceptions and awareness of sustainability and whether there is some alignment of those positions.

3.1 Research aim and objectives

The aim of the study was to compare industry expectations about essential sustainability knowledge with academics' perceptions of requisite knowledge about sustainability to work efficiently in the AEC industry. The specific objectives were as follows:

- To determine the expectations of the AEC firms regarding essential knowledge on sustainability of recent graduates entering the workforce.
- To determine the perceptions of the academics in design and construction programs regarding the required sustainability knowledge necessary to work efficiently in the industry.
- To compare the industry's expectations and the academics' perceptions.

The objectives were achieved by conducting surveys among the design and construction firms as well as academics teaching on construction programs. The survey questionnaire for the construction firms was divided into three sub-sections to accomplish the main objectives, which included: (1) Capturing the background information of each firm; (2) Understanding the sustainability practices adopted by the firms and their perceptions; and (3) Examining the essential sustainability knowledge expected from recent graduates. Similarly, the survey questionnaire for the academics was divided into three sub-sections including: (1) Understanding the background of individual respondents; (2) Examining the importance of sustainability practices as perceived by the respondents; and (3) Examining the essential sustainability knowledge required to work efficiently in the industry as perceived by the respondent.

The overall research process of the study involved the following steps:

- Selecting sample firms working in the design and construction industry and academics teaching on AEC programs;
- Developing the survey instruments;
- Performing cognitive interviews for instrument validation;
- Distributing the survey questionnaire to selected samples;
- Collecting data to examine the industry's expectations and academics' perceptions; and
- Analyzing the collected data.

3.2 Survey instrument development

The individual survey questionnaires were composed of two types of questions: (1) Close-ended questions with ordered choices; and (2) Five point Likert-type scale questions. The survey instrument development process is summarized in figure 1 and described in this section.

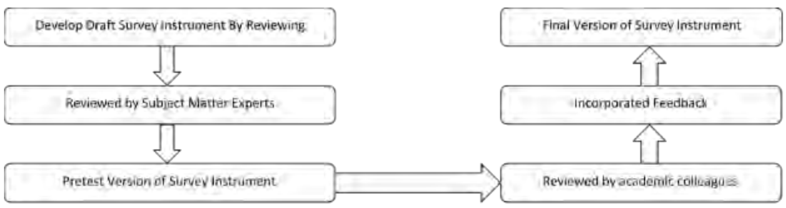

Figure 1: Survey instrument development process

4 DATA ANALYSIS

As mentioned previously, the survey questionnaires were divided into three sub-sections. The first section in the questionnaires was meant to understand the background of educational programs. The second section contained items to determine the perceptions about sustainable design practices. The third section contained items to determine the topics that were included in the sustainability courses in the education program.

Survey data were analyzed using Simple Relative Index (RI) and Spearman Rank Correlation Coefficient (SRCC) techniques to identify the level of importance and degree of association between the responses of the firms and the educators. An ordinal scale was used for the measurement of each survey item, each respondent being asked to assign a level of importance from 1 to 5, where 1 = most important and 5 = least important. From this, the magnitude of the RI for each item was calculated. All the numerical scores of each item on the questionnaire were transformed to relative indices to decide the rank orders. The RI was calculated using the following formula:

$$\frac{\sum w}{Wn}, \ (0 \leq \text{RI} \leq 1)$$

Equation 1

Where,

w = Weighing given to each item by the respondents ranging from minimum of 1 (denoting least important item) to a maximum of 5 (denoting most important item);

W = The maximum weighting (which was 5 in the study);

n = Total number of respondents.

This was followed by rank ordering of the items based on the RI, where the highest RI = highest rank and vice versa. For items with equal RI, they were ranked in accordance with the percentage of respondents assigning 5 to the item. The ranked variables gave insight as to the essential sustainability knowledge expected by the industry and sustainability knowledge provided to the students to work efficiently and effectively in the industry.

4.1 Background information on the program or institution of responding educators

All the respondents (N = 54) were educators of construction program. For accurate analysis only the perspective of the construction firms was used to compare the essential sustainability knowledge with the actual topics covered through sustainability courses. 67% of the total respondents were from US, followed by 13% from EU, 11% from the continent of Africa, 5 from Australia and 2 from Hong Kong and Turkey respectively. The number of students in the program of the responding educators were used to identify the size of the program. The number of students ranged from less than 50 students per program to greater than 400 students in a program. Though there was a fair distribution of program size among the respondents, yet the major respondent group with respect to program size was 100 – 200 and 200 – 300 students per program as shown in Figure 3 below. It has been noted that the average program sizes in EU and Australia are larger than in US.

Respondents indicated that sustainability is taught both as standalone course and integrated with other courses. Results indicate a wide variation in the number of courses where different topics related to sustainability are addressed. The distribution of the number of courses addressing sustainability among the different construction programs across the globe were captured. It has been noticed that programs in Australia and Ireland has more number of courses addressing sustainability than average program in US or UK. Further the results indicate that sustainability is being addressed at all levels during the course of the study. As shown in Figure 2 only 12.77% of the programs indicated that they have specific courses addressing sustainability in their graduate program. Maximum number of institutions indicated that sustainability is being addressed at the Year 3.

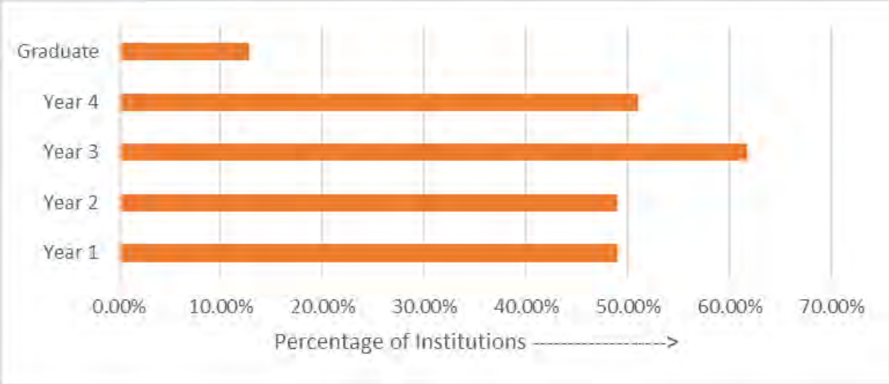

Figure 2: Total number of courses per institution addressing sustainability

4.2 Respondents perception about importance of sustainability knowledge

When asked about the importance of sustainable knowledge and practices for students, approximately 69% of the respondents indicated it to be important. This is very much in congruence with the response received from the design and construction firms, where 66.1% of the responding firms indicated that their firm has implemented sustainable design or construction practices in the past of which 2% of the firms have sustainable components integrated with all their design or construction projects (Figure 3). Further, 42.4% of the responding firms indicated that they either encourage or require their employees to attend trainings or workshops on sustainable design and construction practices.

When asked about the importance of knowledge about team building and goal setting for green building design and construction for professional success, approximately 70% of both group of respondents (industry practitioners and educators) indicated it as extremely or very important.

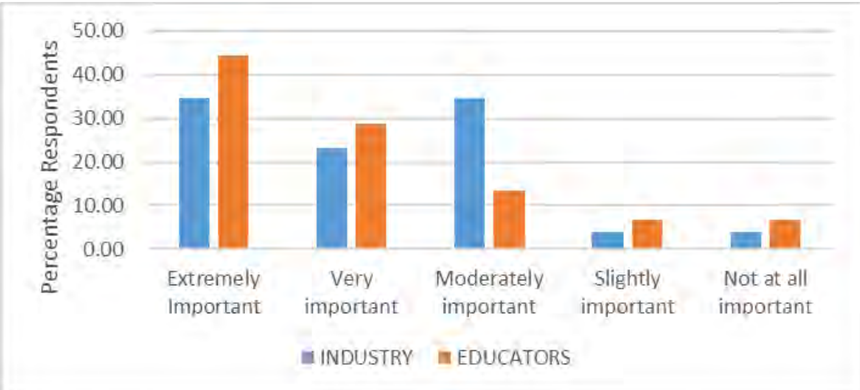

Figure 71: Comparison of industry perception versus educators about the importance of team building and goal setting knowledge for green building design and construction

In order to compare the industry expectations about essential sustainability knowledge with the actual topics covered in sustainability education, educators were asked to indicate the level of inclusion of nine specific topics related to sustainable design and construction as identified from literature. The educators' responses were compared with the responses of the industry practitioners.

Based on the two sets of response from the educators and industry practitioners, the RIs for each of the items were calculated followed by rank ordering of the survey items. A summary of the derived RIs and ranks for all the topics are given in Table 1. In the next step, SRCC test was performed on the pair of ranks. Negative correlation between the ranks of the various sustainability knowledge items was found amongst the educator and the industry practitioners ($r = -0.28$, $p > 0.05$ [two tailed], $df = 7$). In other words, there is absolutely no agreement between the expectation of the industry practitioners about the required sustainability knowledge to work efficiently in the industry and the actual topics covered as part of sustainability education. One such example was the topic of 'Biomimicry' which is barely introduced to the students through sustainability courses, but the industry practitioners have listed that as a required knowledge for student success.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Essential Sustainability Knowledge	Industry Expectations		Actual Inclusion in Education		Diff. in Ranks
	RI	Rank	RI	Rank	
Biomimicry	0.569	1	0.934	9	8
Green building construction means and methods	0.624	2	0.568	4	1
Climate change	0.635	3	0.8	8	5
Green buildings products and materials	0.635	4*	0.55	3	1
Life cycle cost analysis of green buildings	0.647	5	0.645	5	0
Principles of green building construction	0.651	6	0.514	1	5
Green building rating systems	0.667	7	0.526	2	5
Building codes related to green technology	0.671	8	0.696	7	1
Green building design process	0.671	9*	0.65	6	3
* Equal RI; ranked in accordance with the percentage of respondents assigning 5 to the item					
Spearman's Rank Correlation Coefficient, r = -0.28 p>0.05 (two tailed), df = 7					

Table 1: Summary of derived rIsk of essential sustainability knowledge

A summary of the derived RIs and ranks for all the rating systems are given in Table 2. Upon performing SRCC test on the pair of ranks, significant positive correlation was found amongst the responses of the educators and industry practitioners (r = 0.73, p > 0.05 [two tailed], df = 7). In other words, significant agreement was identified between the required knowledge of rating system as indicated by the industry practitioners and actual information about rating systems included in sustainability education. Similar to before the rating systems were rank order based on the importance as indicated by the industry practitioners and implemented in current sustainability education. LEED and BREEAM has been rated as by far the most important rating system adopted in US and UK respectively. This could be due to the significant importance given to the rating systems in the text books as well as in literature coming out of professional organizations.

Rating Systems	Industry Feedback		Actual Implementation in Education		Diff. in Ranks
	Freq.	Rank	Freq.	Rank	
LEED	70%	1	88%	1	0
BREEAM	31%	2	30%	3	1
Green Globes	2%	3	13%	4	1
Living Building Challenge	2%	3	10%	5	2

CASBEE	<1%	4	2.5%	6	2
Spearman's Rank Correlation Coefficient, r = 0.73 p>0.05 (two tailed), df = 7					

Table 2: Comparison of knowledge requirement about rating system and assessment tools

5. CONCLUSION AND FUTURE RESEARCH

This study developed an understanding of the current status of sustainable design and construction knowledge perceptions and requirements among academics and industry practitioners. The study had access to a random pool of respondents and reflected on the perception of the broad diverse population sample of design and construction industry practitioner and academics around the globe. From the findings, it can be concluded that though there continues to be a gap between what academics and industry practitioners consider and reflect about their perception on the essential sustainability knowledge, yet there is significant agreement between them about the importance of the need to expose the future professionals and leaders of the AEC to the principles and knowledge areas with respect to sustainability.

There is a depth of agreement in the need for the graduate professionals to have a sound and well developed understanding of the current knowledge and best practices that are required within the AEC to embed sustainability as a matter of routine practice. The students perceive that they must embrace them and include sustainable approaches in the daily protocols of built environment processes. The industry practitioners believe and have confirmed that graduates need be fully equipped with the knowledge and competences of sustainable strategies so that their futures employers can be informed by and benefit from their knowledge. Langford (2008) refers to embracing and encouraging the new construction professional on graduation as, while they lack experience, they will bring the innovation and creativity that those who are more established will lack. Looking to this research the construction professionals survey indicated that sentiment and the importance of the AEC industry being open to the supporting those new recruits.

As the AEC industry strives forward in the modern technological world it is the current student AEC body that will be the leaders in the next 10 to 15 years and their current educators have a responsibility to challenge and equip them to take on this role. Being sustainable will be part of that as recognized by those who have researched in the area but also those who have had an input into this research enquiry. Their message is clear, create significant learning opportunities that embed the necessary competences, understanding, skills and knowledge of sustainability so that society will be enhanced and sustainable. The potential to explore further research in this important area are boundless and this research group propose to achieve a deeper understanding through more interpretive qualitative methods of the participants.

It is clear from analyses in the paper that there is still much to do to improve the embedding of sustainability focused AEC curricula for the undergraduate. Key to the success of this process is taking students [and academics] deliberately out of the institutionalized frameworks that bind them - frameworks that often, ironically, hinder innovation and success. To succeed in an inter-professional, intercultural collaboration requires improvisation, both in mind-set and in design technique, and requires a willingness to operate with uncertainty whilst embracing risk, and risking failure.

The study confirms that AEC enterprises have the opportunity to offer powerful jobs in the industry. However, there is a lack of connection in order to increase and fully impact on real development as there is little commitment to invest in the education of the AEC future professionals. There is a huge gap between education and industry in terms of a commitment to investing in the future needs of the industry. There is as one respondent put it" a boom to bust attitude in the industry and so companies are reluctant to invest in education. This is one of the largest inhibitors to moving forward on the education front.

Sustainability and knowledge of our evolving technological driven society, are key skills in a world of rapid change and unpredictable unknowns. The professional roles in the built environment sector are rapidly evolving, and new formats of processes and transactions developing at an unprecedented rate. Successfully navigating this environment requires graduates with essential inter - professional skills, effectively acquired through collaborative inter-disciplinary projects that embed the principles of sustainability. Going forward this study propose that sustainability be embedded in as many forms of collaborative professional education as possible.

Importance of Built Heritage for World Sustainable Built Environment

Shahid Ahmad RAJPUT[a]

[a] *COMSATS Institute of Information Technology (CIIT), Pakistan, sarajput@comsats.edu.pk*

ABSTRACT

It is observed that our young generation of architects is solely dependent and inclined to take inspiration from shiny and tall buildings of the west to satisfy their quest in the field of architecture.

Some Professors including this author at the Department Architecture have been propagating over the years to seek inspiration from their own society and environment where there are plenty of examples of sustainable built architecture in form of Heritage. The plan of heritage buildings, selection of site, the design and the material used in respective heritage buildings has plenty to offer for ideas on sustainability of the built environment.

The main proposed of this paper is to highlight the features associated with the sustainable built architecture created by our ancestors, which is available in the neighbourhood to take inspiration from. This presentation will include slides of the project of heritage building made of locally available building materials and its impact on the sustainable built environment. It is hoped that my presentation will open new avenues for the young architects interested in the sustainable built environment.

Keywords: energy saving, heritage, sustainable neighbourhood

1. INTRODUCTION

For support of this belief and argument we have several examples of heritage buildings but this presentation will confine to one examples only.

The building chosen for this paper is a 16th Century Mughal Garden which is well known to the author from his early childhood and later in collaboration with the Dept. of Archaeology and Museums, Government of Pakistan he undertook a project for completing its architectural and hydraulic studies. The project was completed in two years 1993 and 1994. Based upon the discovery of its hydraulic system and first hand knowledge of the engineering involved in the construction of the building of this garden and developing the hydraulic system for running the fountains as well as water supply both hot and cold to the hammam (Turkish bath) two solid examples are worth quoting for the sustainable architecture found in this heritage building. We shall see all pictures and drawings in the presentation.

2. HISTORY

About two kilometres east of Hassan Abdal is a 16th century Mughal garden initially called Bagh-i-Hassan Abdal now popularly known as Wah Garden. Due to its historical and architectural importance, Wah Garden was acquired by the Government and was handed over to the Department of Pakistan Archaeology for its excavation, restorations and maintenance. (Figure 1)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 1: Wah gardens as it stands today

This paper deals exclusively with the examples found during the excavation relating to the world's sustainable built environment. Wah Garden was not pre-planned; it evolved over a number of years, growing according to the instructions of the Emperor who used it at different occasions.

The excavations began in March 1993 with the initial purpose to study the architectural and hydraulic features of the gardens. A number of important discoveries were made, e.g. a large water tank on the eastern end of Wah Garden, three water channels running parallel with the length of the garden and fifteen fountains in the central water channel with water inlets situated in the upper terrace. There is also a Hammam attached to the southern wing of the *Baradari* (Pavilion). The excavation report was published in a monograph by the Smithsonian Institution Washington DC in 1996. The main focus of this paper, however, is relating to the world's sustainable built environment that has never been published before.

The area where the Garden is located was given the name "Hassan Abdal" after Hassan, a famous saint of Qandahar, as he is in Pakistan. Abda was his title. He died and was buried in Qandahar. It is written on his tombstone that Mirza Shah Rukh (1406-1447) met him in Qandahar with due respect in 1417 AD. The Saint died during the life of Mirza Shah Rukh, between 1417 and 1447.

Near Hassan Abdal, even before the time of Akbar, there was a pond in the middle of which Raja Man Singh built a small building (pavilion), as recorded by Jahangir in 1607 during his first visit to Hassan Abdal . In 1581, when Akbar laid the foundation stone of Attock Fort, he appointed Raja Man Singh to protect the frontiers. Raja Man Singh stayed in Hassan Abdal from 1581 to 1586, during which time he might have built that small building. Emperor Jahangir visited Hassan Abdal six times between 1607 and 1626. On his first visit in 1607 he stayed here for three days and busied himself catching fish.

Four years later an English traveller, William Finch, although he never went to Hassan Abdal, repeated this story and attributed the anecdote to Akbar .

Subsequent writers (the European travellers) confused the historic chronology, however, later in October of the same year, i.e. 1607, on his way back from Kabul, Jahangir stayed at Hassan Abdal to hunt. Jahangir took an interest in the development of Hassan Abdal. Thus he sent large amount of money for the construction of a building in Hassan Abdal .

The Shahjahani historians, visited Hassan Abdal with Shahjahan in April 1639, and recorded Hassan Abdal as the most beautiful and gratifying garden between Delhi and Kabul. According to these chroniclers Shahjahan visited Hassan Abdal nine times during his reign, between 1639 and 1652. During his third visit, on his way back from Kabul in Oct.1646, the stay of Shahjahan in Hassan Abdal is recorded to have been in a garden called "Bagh-i-Bahisht "Ain" or Heavenly garden. Two years later, in 1649, when Kanboh came to Hassan Abdal with Shahjahan, he recorded Hassan Abdal as "Gulistan-i-Irum" or Paradise garden.

Finally Aurangzeb Alamgir stayed here for one and a half years between July 6, 1674 and January 2, 1676. His historians refer to this place as Bagh-i-Hassan Abdal.

2.1 Origin of name

The name "Wah" does not occur in any of the historical references. How then did this garden of Hassan Abdal acquire the name of Wah Garden? There is a gap in the history of Hassan Abdal after Aurangzeb, till 1815 when Elphinstone came to Hassan Abdal as a traveller and recorded his observations and the name of the garden as Hassan Abdal .

Then another English traveller, Moorcroft in 1823, visited the garden. In his travelogue he recorded a false anecdote that Akbar admired this garden and said "Wah Bagh" (what a beautiful garden!). Hence the garden was so named and it is known as Wah Garden to this day.

mechanical violence, the coloring has lost little of its original luster. Although possessing nothing majestic or imposing, the bath of Wah bagh must have been both commodious and elegant. The water, which was supplied from the reservoirs first noticed, is clear and in great abundance. It comes from several copious springs at the base of some limestone hills in the neighborhood and, after feeding the tanks and canals of the garden, runs off with the Dhamrai River that skirts the plain on the north and West". Later travellers do not add to this significantly.

The Illustrated London News, Saturday, April 20, 1850, published an article about Wah Garden with an engraving after a sketch by G.T. Vigne[21] in 1836 (Fig.5). This sketch was also published by F.S. Aijazuddin in his book The Historical Images of Pakistan,

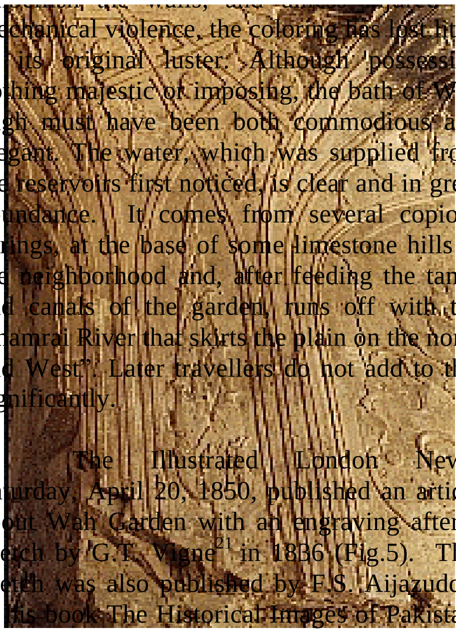

Figure 2: Stucco tracery on the inside of baradari.

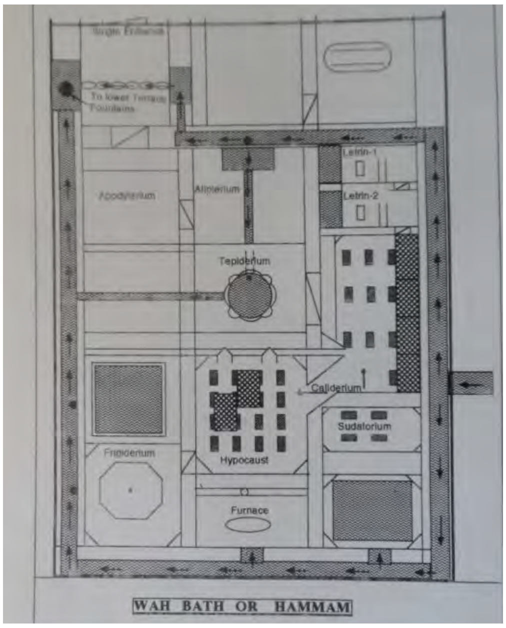

Figure 3: plan of the Hammam or turkish bath at Wah gardens

The description of Moorcroft about the gardens, however, is worth reading: "Advancing across the low ridge of the hills, we came to a plain in which stood the village of Wah, and an extensive garden, constructed by the order of Emperor Akbar, the beauty of which drew from the monarch the exclamation of "Wah!" whence the name of the new pleasure-ground originated. It covers a space about a quarter of a mile in length and half that in breadth, enclosed by walls partly in ruins. The gateways and turrets that were constructed along the boundary wall are also mostly in a ruinous condition. The eastern extremity is occupied by two large stonewalled tanks; the western by parterres, and they are divided by a building which served as a pleasure-house to the Emperor and his household. ….. The interior of the whole is stuccoed, and in the smaller apartments the walls are decorated with flowers, foliage, vases, and inscriptions in which, notwithstanding the neglected state of the building and its antiquity, the lines of the stuccoed work are as fresh as if they had but just been completed, indicating a very superior quality in the stucco of the East over the West (Figure 2). The chambers in the southern front of the western wing, and other continued beyond it, constitute a suite of baths, including cold, hot, and medicated baths and apartments for servants, for dressing, and reposing, heating rooms and reservoirs (Figure 3) the floors of the whole have been paved with a yellow breccia, and each chamber is surmounted by a low dome with a central sky-light.

3. THE SUSTAIBALE BUILT ENVIRONMENT AT WAH GARDEN

The following lines will describe the sustainable built environment and the Hydraulic Engineering of the garden and then shall be summarised in the conclusion:

a) Hydraulic System, and b) Hammam (Turkish Bath)

3.1 The hydraulic system

Our excavations have discovered a large water tank on its eastern end, fifteen fountains in the central water channel and their water inlets, three water channels, a Paien Bagh/Zanana, (garden for ladies) a few architectural ornamental objects in stone, and the Hammam or Turkish Bath. Our excavations confirm much of Moorcroft's descriptions of Wah Gardens. Our discussion shall be limited to the following two examples only for sake of limiting our discussion to the sustainable architecture:

3.1.1 Central channel

From the middle of the western wall of the main tank in the upper terrace, starts the main or the central channel which is 10'.4" wide & 11.3" deep. This channel passes through the Baradari down in the lower terrace, making a cascade. Water follows into the central channel when the main tank is filled to the height of 5'.6". There is a stone bridge on this channel at the distance of 91' from the main tank. Hitherto, only four fountains were known between this bridge and the main tank, but during our present project eight more fountains were discovered in the same area at regular intervals i.e, 7'.6"each. These fountains are connected by a terracotta pipe embedded in thick masonry, which is 40" deep. The drawing in (Figure 4) depicts the depth and width of the central channel and the details of how the fountains were connected with terracotta pipe and how the water was supplied to these fountains. This is the best example of sustainability for the architects to take inspiration from.

3.1.2 The Hammam or Tukish bath

Adjacent to the southern end of the Baradari there is a Hammam (Figure 4). Here an independent aqueduct running beside the eastern wall of the main water tank supplied the water. This aqueduct supplying water to is nine inches wide and one foot deep. Fortunately the Hammam is still in a good state of preservation, showing almost all the necessary architectural features in situ of which we can identify the water supply, the heating room, the hypocaust and latrines. Some important and interesting aspects of this bath are: it has a single entrance through the western wing of the Baradari; it has a complex arrangement of rooms and halls as was seen and recorded by Moorcroft ; its walls are extra-thick (40-55 cm) to maintain the inside temperature; it has hollow pavements and the provision for a hypocaust, for circulating hot air and steam in the Hammam and for boiling water for a hot bath, there is a furnace which is connected with the hypocaust. The furnace has an entrance from the out side of the Hammam; there is also an excellent arrangement of running water and the provision of pools for hot, cold and medicated water; it has an effective drainage system still in operation; initially it had special ventilators in the ceiling of the rooms and its walls on the inside were once embellished with cut plaster painting and floors with mosaic as recorded and published by Moorcroft in 1823. Traces of painting on the wall and mosaic in the floor are still to be seen intact. Moorcroft saw and recorded in his descriptions that all the chambers of the bath were surmounted by low domes with central skylight. But when this Hammam was excavated not only its low domed ceiling but also its walls were badly damaged and the whole suite of baths was buried under a mound of earth. Some functional and more important architectural features or elements of this Hammam are as follows: Apodyterium- where the bather undressed and left his clothes, measuring 7.4X7.8 feet; Alipterium- where oil was anointed, measuring 12X12 feet; Calidarium- hot room, it has two wings, measuring 14X14 feet and 14.10X9.4 feet; Sudatorium- steam room, measuring 12X10 feet; Tepidarium- warm room, measuring 14X14 feet. Tepidarium generally is a large hall with a beautiful pool in the middle, such as found at Wah Garden, and it was used as a special meeting room; Frigidarium- cold bath, measuring 12.10X10.6 feet. It has an octagonal pool, measuring 4.4X4.4 feet, with a fountain in the middle. These are the most important features of all the known Mughal Hammams or Turkish Baths. All these features provide beautiful examples of sustainability for the architects to copy in their present day architecture right in their neighbourhood rather than copying the western world which is alien for the local community.

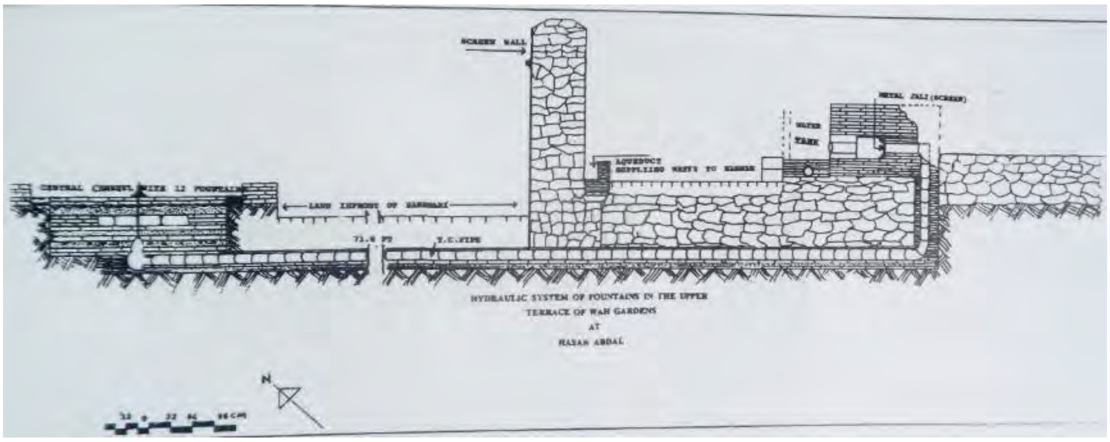

Figure 4: Cross section drawing of the hydraulic engineering / water supply to the fountains at Wah garden. Discovered and drawn by the author

4. CONCLUSION

This is the only garden in which a complete hydraulic system of Mughal period is discovered which represents a marvel of Hydraulic engineering of the 16th Century. The hydraulic engineering involved in this garden is based on the gravity and thus very simple but amazingly perfect and continuously running fountains were connected by Terra-Cotta pipe to a supplying reservoir whose base was approximately four feet higher than the fountain heads. This height through gravity kept the fountains running round the clock. The main purpose of paper is to draw the attention of the young architects to understand this simple but sustainable hydraulic system of the unique garden and to replicate it in today's architecture. There is no rocket science involved in it according to the original plan. It is very simple, main thing here is of understanding or get help from those who understand it and are willing to contribute for its authentic and original or near original replication elsewhere. This paper also provides a platform to benefit from and the author shall be available for consultation in case the young team requires assistance in understanding the hydraulic system. The author has first hand knowledge of all the architectural and archaeological features of these gardens and his excavation report was published in 1996. Since the excavation of Wah Gardens in 1993-94, the author has been involved in the research and teaching of Art and Architecture. He has been delivering the lectures on international forums and on Islamic Art and Architecture and has published number of papers and books on the subject. His recent published works such as a) History of Islamic Art; b) Significance of al-Mansurah ; c) Origin of Blue and white ; and d) Hydraulic Engineering of Wah Gardens; e) Principal source of Arabic Calligraphy are few examples of his commitment on the subject.

This heritage building has the best features of sustainable built environment for the students of architecture to take inspiration from. We hope and look forward to restore the garden once again according to the original pattern for the benefit of posterity interested in the sustainable built environment.

Developing a Conceptual Framework for Integrating Project Risk Management and Sustainability Objectives

Georgia Dodge GOSSE[a], Cheryl Julia Kiran DESHA[b], Timothy ROSE[c]

[a] *Queensland University of Technology, Australia, georgia.gosse@hdr.qut.edu.au*

ABSTRACT

It has been more than thirty years following the 1987 Brundtland report on sustainable development and professional project management standards have not fully integrated sustainability performance requirements. Acknowledging that while sustainable development is a critical topic area in the built environment sector, industry accepted project management processes still do not explicitly state how to embed sustainability throughout the life of a project. While some work has been done to determine how to integrate sustainability into some project management processes, the use of risk management to achieve sustainability outcomes is still absent. The challenge for both sustainability and risk management is the need to predict the future – either the future potential consequences of a risk or for sustainability the needs of the future generation.

Recognising this deficit, the authors draw on existing literature and precedents internationally to propose an innovative sustainability risk framework based on knowledge management to provide more intelligence to predict future impacts and needs and integrate within the risk management processes to transform project sustainability performance outcomes. The sustainability risk framework draws on a desk-based study that will subsequently be confirmed through interview and survey methods.

Risk management plays a critical role in project delivery and there are opportunities to harness existing knowledge management application to transform the risk management process to deliver on project sustainability objectives. The implications for industry are significant, providing a potential cost-saving mechanism for managing built environment projects, through process innovation and providing project managers with the power to influence and achieve sustainability outcomes on projects.

Keywords: project sustainability, project risk management, education and training

1. INTRODUCTION

Projects play a fundamental role in achieving the strategic sustainable development agenda for any country and it is imperative that projects include objectives that address sustainability. All 17 sustainable development goals set by the UN require projects at local, regional and national levels to achieve the ambitious targets (UN, 2016). In Australia, rating tools such as the Infrastructure Sustainability (IS) rating scheme and the Green Star rating system have been developed to help projects and their activities achieve sustainability. Although both the Infrastructure Sustainability Council of Australia (ISCA) and The Green Building Council of Australia (GBCA), recognise the influence of project sustainability objectives on the achievement of local, regional and national strategic sustainability objectives, sustainability is still predominately seen as a separate project management consideration outside time, cost and quality objectives and is usually only considered if the project sponsor has clearly articulated sustainability objectives. Even though there is clear evidence as describe above, that projects significantly contribute to the local, regional and nation achievement of sustainability objectives, the conceptual base of models and methodologies for project management has remained fairly static (Svejvig and Andersen, 2015).

In this paper, the authors review a typical project management framework, discussing its ability to support the achievement of sustainability objectives *and* manage associated risks. While there may seem to be conflict between traditional risk considerations/ objectives (time, cost and quality) and sustainability objectives they are inherently linked through their common objective to minimise negative project impacts to future generations (Krysiak, 2009). With this in mind, this paper focuses on the relationship between risk management and sustainability and reviews how risk and sustainability knowledge can move risk management from a compliance

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

exercise to a decision support tool that promotes the establishment and achievement of sustainable objectives on projects.

1.1 Definitions

Both project risk management and sustainability can be interpreted in a variety of different ways, depending on context. Project risk management is a proactive management process designed to exploit opportunities and treat risks to secure a project's agreed, defined and disseminated objectives (Chapman, 2013). This widely accepted best practice definition connects both risk and opportunities to project objectives.

The most globally accepted definition of sustainability was established by the World Commission on Environment and Development (WCED, 1987) which defined sustainable development as: 'development that meets the needs of the present without compromising the ability of future generations to meet their own needs, integrating social, economic and environmental goals to mutually reinforce each other'.

These definitions form the basis of this review.

1.2 Aim and objectives

The questions remains, *'how can project management be adapted to ensure that sustainability objectives are achieved on projects*?' Project sustainability objectives, where articulated, impact project management processes and so demands an evolution of the traditional project management approach to address these impacts.

Risk management is critical to the success of a project and whether actively or not, all project managers manage risks. However, it is the empowering of a project manager with the tools and knowledge to achieve sustainability objectives, using risk management that is the aim of this paper. As such, this paper will focus on the relationship between risk management and sustainability and review how the process and culture of active risk management can support and promote the establishment and achievement of sustainable objectives on projects.

2. METHODOLOGY

Peer reviewed, academic journal articles published 2000 onwards were retrieved from the following databases and search engines; Google scholar, Science Direct, Web of Science, and Emerald. The following three strings of key words were used in the search: sustainability and project management, risk management and project management and risk management and sustainability, which returned 514 results.

The breadth of both the fields of sustainability and risk management resulted in the need for a manual high level assessment to be undertaken to set boundaries and focus the research. Following a topic search, content analysis was used to ensure that the articles addressed the central research topics.

In order to make the final selection, articles had to have a 'Quartile 1 Q1' score from Scimago or be considered reputable conference proceedings (i.e. published proceedings with a formal peer-review process). Five books by reputable authors were also included, where the authors were well-referenced researchers in the field. As this paper focuses on the relationship between sustainability and risk management, articles specific to risk modelling, risk software, enterprise risk management or corporate sustainability were subsequently excluded. Based on these parameters 79 papers were considered relevant to the research aim and were used for the subsequent detailed review.

Other includes Q3/ Q4 publications and books

The next section presents a review of key articles defined by the initial literature categorisation, followed by the presentation of a conceptual framework demonstrating the relationships between sustainability and risk management as established from the review.

3. CRITICAL REVIEW OF PREVIOUS STUDIES

Substantial work has been conducted on defining sustainable projects and assessing sustainability risks at project level, along with defining sustainability broadly and in the context of infrastructure is acknowledge, as is the use of risk modelling techniques to priories and weight sustainability indicators. However, there is an acknowledged need to move from the high level objective level down to a delivery level which provides project managers with an avenue to address sustainability, throughout the life of a project, using methods they are already familiar with.

3.1 Sustainability and project management

Much work has been done to define sustainability from different perspectives and make it more tangible (Miah et al., 2014, Bell and Morse, 1999). Additionally, work has been undertaken on how to assess whether a project is sustainable, or not, at a planning and decision making level which addresses the initial question of whether or not the project is an inherently 'sustainable project' (Haavaldsen et al., 2014), through the use of 'sustainability indicators'. Some literature alludes to the potential increase in up-front costs associated with delivering a more sustainable project, such as additional design costs for 'eco-design', or the development of a cradle to cradle waste management plan, or even a more inclusive stakeholder process (Ugwu et al., 2006) and while many organisations can see the benefits of establishing and achieving sustainability objectives and outcomes, the largest barrier is measuring investment returns (Yang et al., 2015), which means research has tried to demonstrate that pursuing sustainability objectives can lead to better projects with minimal or no additional construction cost or effort (Anderson, 2012).

Further, significant work has been conducted to incorporate sustainability considerations into project management methodologies and provide high level guidance on what project management processes should consider in terms of sustainability (Silvius et al., 2012). In addition, there is a growing recognition that 'further development of the project management profession requires project managers to take responsibility for sustainability' (McKinlay, 2008), though the question of how it can be effectively incorporated remains unanswered?

3.2 Risk management and project management

Much of the project management literature recognises the role proactive risk management plays in the success of projects (de Wit, 1988, Cooke-Davies, 2002, Sanchez et al., 2009). However, many risk management methodologies primarily focus on the process of risk management and analysing risks against quantifiable criteria such as time, quality and cost (Taroun, 2014, Zhang, 2011). Recognising that projects are increasing in complexity and uncertainty, recent literature acknowledges the limits of traditional methods of prediction and planning and stresses the need to have multiple ways to anticipate and adjust to changes and disruptions caused by known and unknown risks (Shiroyama et al., 2012). An additional theme identified in the literature is the cultural and behavioural aspects of risk management and the recognition that to manage risk successfully it needs to be seen as more than a process, but a cultural mindset to seeing risk management as a tool for decision making and addressing knowledge gaps (Regev et al., 2006). There is potential to move away from the application of a risk management process and generic standards towards an informed and dynamic practice that empowers project management to make decisions.

3.3 Sustainability and risk management on projects

There is a growing body of literature focusing on the importance of identifying, mitigating and managing sustainability risks (Pojasek, 2011, Lenssen et al., 2014, Giannakis and Papadopoulos, 2015), predominantly at a corporate level that usually defined risks with environmental and social impacts. It is clear from the literature available, that assessing project risks against sustainability objectives has generally not been part of the process.

Project risk management is a very well-known and accepted area of practice, in which the risk management process is vital and fundamentally influences the likelihood of success for any project (Stackpole, 2013). Sustainability in terms of risk management needs more than identifying sustainability risks and needs to consider against all project objectives as well as the different viewpoints of all project stakeholders (Silvius and Schipper, 2014). Currently the literature lacks sufficient research on assessing risk impact on qualitative project objectives (Taroun, 2014) and while recent studies have focused on providing project managers with adaptations to current project management processes to address sustainability risks, there is little information available for assessing risks in terms of impacts to sustainability objectives (Maltzman and Shirley, 2011, Silvius et al., 2012). Such information would provide project managers the opportunity to look at project risks through a sustainability lens in addition to standard, time, cost, quality objectives and people/ resources lenses as advocated by the Prince2 methodology (Bentley, 2009) or PMBOK methodology (Project Management, 2013).

4. DISCUSSION

There is conflict between traditional risk considerations/ objectives (time, cost and quality) and sustainability objectives and risk management is a tool to more effectively establish and achieve sustainability objectives. Sustainability and risk management are inherently linked; firstly at the core of the sustainability definition is the desire to meet the needs of the future generations, while risk management assesses the consequences of a risk that might eventuate in the future. Predicting the needs of future generations creates uncertainty and a propensity for change, and risk management can be the tool to manage the future consequences of this uncertainty and change. Secondly, both sustainability and risk are ambiguous terms and mean different things to different people, projects and organisations based on personal values, perceptions and experiences. This means on a project that views, interests and preconceived concepts need to be coordinated and aligned to achieve common objectives. Finally, sustainability objectives seek to promote a set of outcomes on a project which are robust and able to still deliver their intended outcome even with the unpredictability of future situations and risk management is a tool which can be used to develop effective mitigation strategies for future situation. (Gray and Wiedemann, 1999).

The above discussion suggests that decision makers and contributors to the risk management process need to have more tailored information regarding future scenarios and risk consequences to make informed choices. Knowledge management can help address both future planning and any ambiguity challenges of sustainability and risk management as knowledge management is a systematic approach in which information is turned into actionable knowledge and made available in a usable form to the people who can apply it (Dalkir, 2005). With greater knowledge regarding both risks from previous projects and future scenarios, the risk management process becomes a dynamic and iterative activity that provides valuable information to decision makers and proactively addressed risks that could impact the establishment and achievement of any project's sustainability objectives.

A new approach for project sustainability and risk management could address the complexities and ambiguity associated with both defining and measuring sustainability and risk. A move away from the traditional risk management process towards a knowledge based project risk management framework is the proposed approach. It differs from traditional project risk management which is based on a process and introduces the analysis of previous project knowledge and experience regarding risks and the impacts risks have had on project outcomes to develop a culture that continually reviews risks considering the sustainability objectives and the potential impact of the project on future generations.

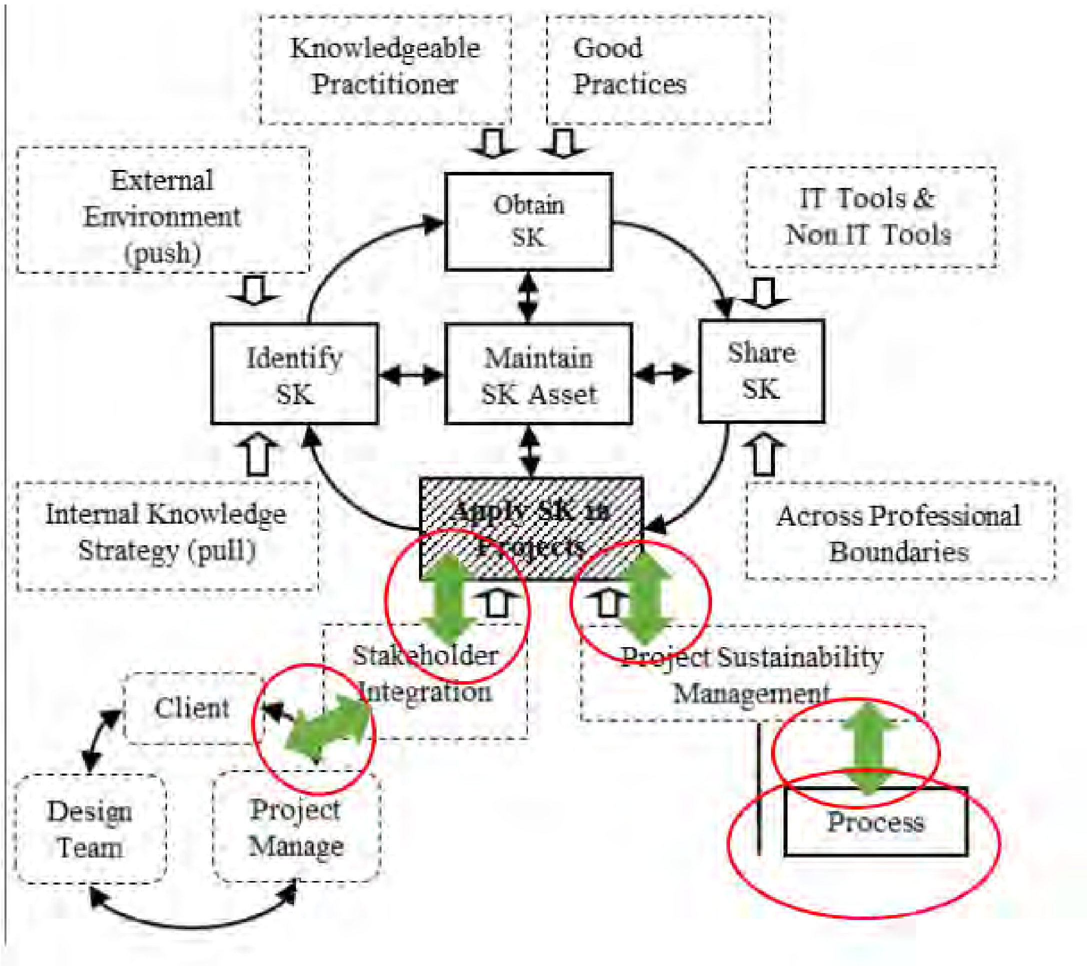
The conceptual knowledge management framework in



From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 72 (Yang et al., 2015) has been adapted to reflect the interconnectivity of the stakeholder integration, and project sustainability management with the rest of the diagram.

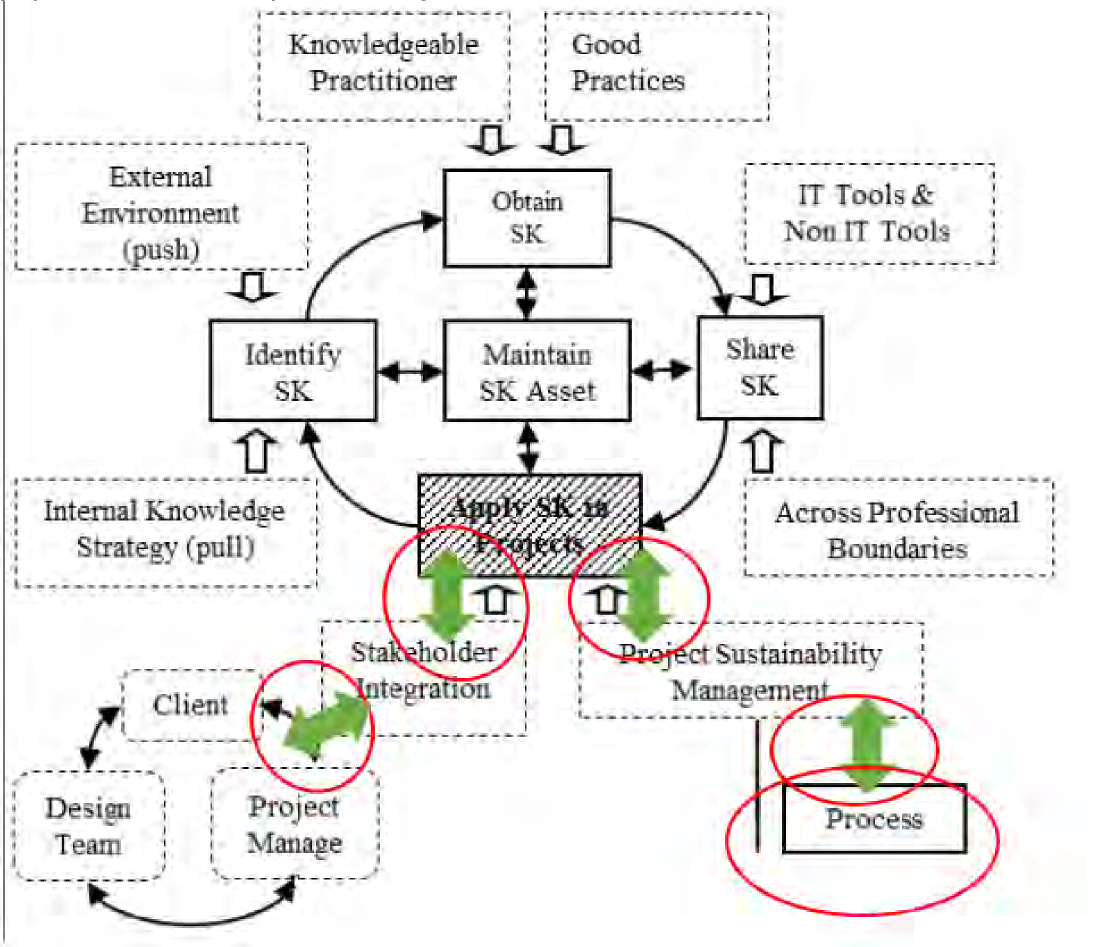


Figure 72 now recognises the need for a reiterative process as there needs to be a flow of information both downwards and upwards. Both stakeholder integration and project sustainability management contribute to sustainability knowledge (SK) on a project but sustainability knowledge from previous projects and project team members needs to contribute to the development of the stakeholder integration process and the project sustainability management process.

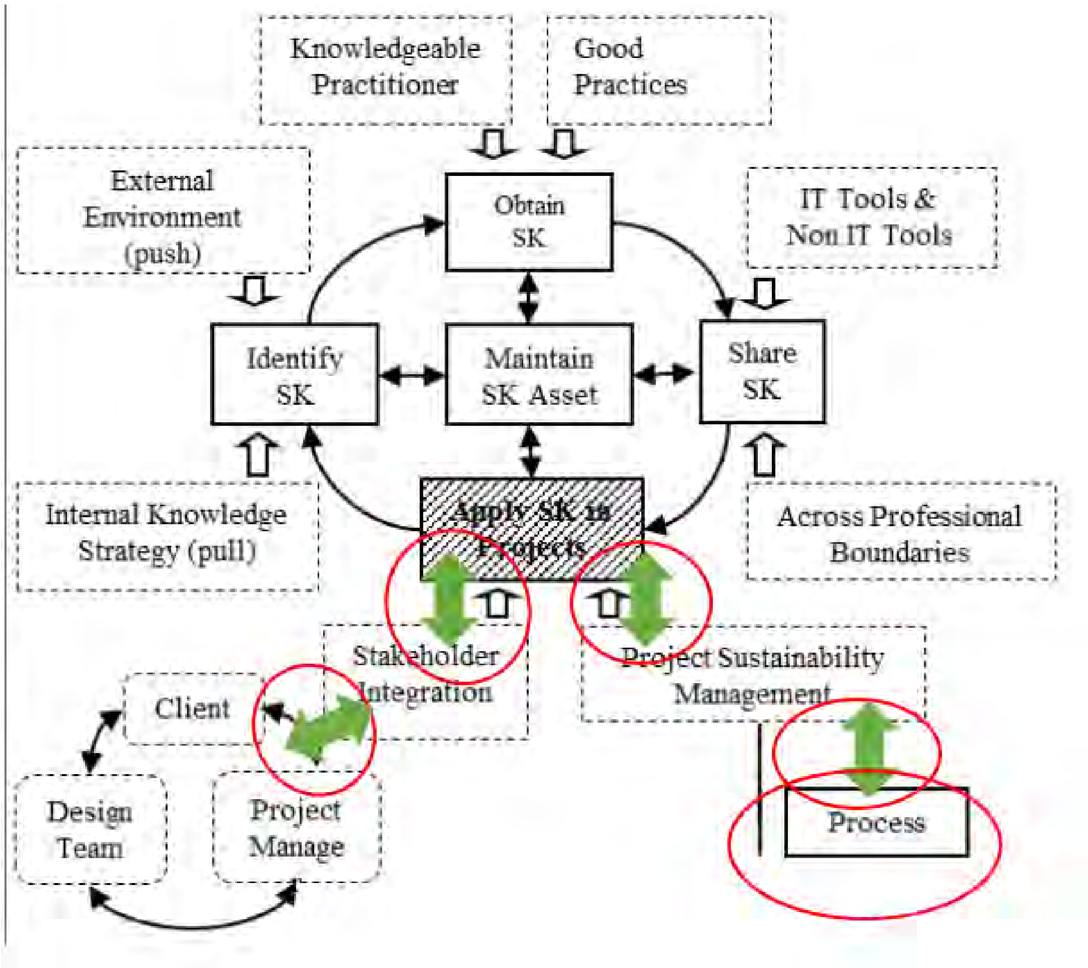

Figure 72: A conceptual KM framework (Yang et al., 2015)

Figure 73 further develops the project sustainability management and process aspects of the KM framework. The adaption reflects that the project sustainability management is missing an opportunity to be enriched if sustainability knowledge from previous projects and team members is not used. Using pre-existing knowledge can improve project outcomes as the decisions that project managers make will be supported by practical and factual information. This is important as it provides the project managers with a greater level of confidence in their ability to make the right decisions and justify these decisions based on existing knowledge, not instinct or pre-conceived biases.

In addition previous project knowledge initiates conversations regarding innovation, risk management, and lessons learnt. The project risk management process is greatly improved by the addition of previous project sustainability knowledge. Risks are better defined, where the assessment of the risk is grounded in actuals instead of predictions and the mitigation actions are informed by actions that have been both successful and unsuccessful in the past. In addition it provides critical information for more accurately quantifying risks which contribute to the budget contingency. This creates a risk management process that provides the project manager with greater confidence that risks on the project are applicable, comprehensive, and manageable and that the contingency applied to the project is realistic.

Figure 73: Sustainability and risk management conceptual framework

5. CONCLUSION

The link between sustainability and risk management is important. The recognition that assessing risks based on possible future scenarios and previous project knowledge means project managers are addressing sustainability, whether or not the project sponsor has clearly defined sustainability objectives. This means a shift away from project sponsor mandated sustainability objectives and towards a best practice embedded approach to establishing and achieving sustainability objectives on projects. Capitalising on previous project sustainability knowledge and using information as the new baseline for a similar project, forces continual sustainable improvement on projects. In addition, enriching the risk management process with sustainability knowledge increases the transparency and confidence regarding associated costs and improves strategic decision making, using evidence based on considerations of past incidents and actual issues addressed. Providing a framework for project managers to access and implement sustainability knowledge on a project will strengthen the delivery capability of project managers and drive the successful achievement of sustainability objectives on projects.

Session 7.9: Transforming Green Market – Supply Chain

New Visitors? Small European Companies Entering the Chinese Sustainable Building Market

Christian KOCH[a], LI Haixi[b], ZHAO Yimin[c], Anders LUTTEMAN[d]

[a] *Chalmers University of Technology, Sweden, kochch@chalmers.se*
[b] *Chalmers University of Technology, Sweden, haixi@student.chalmers.se*

ABSTRACT

The market for sustainable buildings in China is steadily growing. Also small and mediumsized European companies are able to internationalise and enter this market. Internationalisation is often initiated through participation in or even initiation of building projects. In particular Swedish building companies have a potential competitive advantage in the booming market for sustainable building, energy efficiency and energy renovation.

The main aim is to study how cultural aspect influence in a selected energy efficiency building project involving Swedish and Chinese partners.

The framework of understanding draws on small international business, supply chain and organization theory but focus especially on organizational culture.

The method rely on two case studies of Chinese sustainable building projects where a small Swedish consultancy company participate. Interviews was carried out with representatives from Swedish and Chinese companies active in two Chinese projects. One project is selected to study it is a green hotel project. Both projects obtains an EU green building certificate. The projects follow each other in time and can be seen as steps towards a niche for the Swedish company in China. Thus transforming them from visitors to permanent contributors to sustainable buildings in China.

The results in particular highlight that cultural differences in the Chinese supply chain of companies are more important than national distinctions Sweden-China. The cultural pattern is thus more of a multiple configuration than a dual culture. Nation, region, company and sector cultures interact and certain culturally based interpretations by the participants serves to confirm existing understanding of sustainable building projects. Small companies in particular are dependent of their cultural resources due to limited other resources. Through their network opportunities and dependencies they continually have to decide and act upon situational judgment informed by their cultures.

Keywords: energy efficiency, china, culture

1. INTRODUCTION

Sustainable buildings is a global trend due to a number of dynamics; building material suppliers globalise, methods and technologies do etc. Also the Chinese market for sustainable buildings are part of this development (Dodge 2016). Prognoses for China anticipates considerable growth in the sectors of new commercial and high-rise residential (Dodge 2016). Clearly this market will be occupied, penetrated by large players. However the growth, fragmentation and differentiations of the market also implies that there are large opportunities for smaller players (EU SME Centre 2013). Small companies are to an increasing degree internationalising, yet it is a prevalent concern that they might run into many of the same barriers large multinationals have previously experienced. One important is cultural differences (Lewis 2006).

The main aim is to therefore to study how cultural aspects influence in a selected energy efficiency building projects involving Swedish and Chinese partners?

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

It is important to study small companies contribution to sustainable building. Small companies can be agile carriers of innovative transformation in direction of more climate accountable solutions. When they operate small companies in particular are dependent of their cultural resources due to limited other resources. Through their network opportunities and dependencies they continually have to decide and act upon situational judgment informed by their cultures. And this naturally impact on their ability to create sustainable buildings.

The paper is structured in a traditional way. Starting with the method, followed by the theoretical understanding of culture. Then the case description and analysis.

2. METHOD

The paper built on research carried out by (author references). This research included several aspect of two energy renovation project in china involving a Chinese Swedish collaboration. For this paper we selected the cultural aspect for a more focused scrutiny.

The framework of understanding initially drew on small international business, supply chain and organization theory of culture. In this paper the focus is on cultures in multinational construction project and the theoretical framework combines several culture conceptualisation (Coffey 2010, Gesteland 2013, Lewis 2006) tied together by Alvesson (2003) multiple constellations of culture framework.

For the empirical material we selected one of two cases studied in (author reference), because the cultural aspect of this case was particularly interesting. We use the other case as background and contribution to our analytical framing, although we do posit that the case is a single qualitative insight in a particular constellation of cultures (Alvesson 2003).

Data collection was carried out by two of the authors. Initially pre-research and interviews was carried out to make the research question more accurate. Further, different relevant scientific data are used in the research as fundamental literature resources to support the empirical research. Interviews were designed based on the project materials and the literature resource to conduct better understanding of the project process. However, it was not possible to interview all the people involved in the project due to the time limit and other reasons, but the main actors from both Swedish and Chinese side are interviewed. The interviews are made in face to face and other possible ways. The case analysis is based on literature review, study of the case project material and the interviews. Discussion and Conclusion are built upon the previous research process.

3. THEORETICAL FRAMEWORK

In a construction section a number of culture producers are prevalent. The projects. Companies, sectors, regions and nations are some of them (Alvesson 2002, Coffey 2010).

Alvesson argue that cultures can be analysed in a integration, differentiation and ambiguity perspectives (Alvesson 2002)

Focusing in on cultural differences, they are often referred to as the most common issue in the current international projects (Zhang & Liu 2006). It impact on how people behave in their work and also many other parts of the international projects. Thus, it is important to notice and understand the culture difference enable to work together well. According to Gesteland (2013), there exists five divides of people's common behaving all over the world depending on the place they come from.

- Deal-focused vs. Relationship-focused
- Direct (low-context) vs. Indirect (high-context) Communication
- Informal (egalitarian) vs. formal (hierarchical) Business behaviour
- Rigid-Time (monochromic) vs. Fluid-Time (polychromic)
- Emotionally Expressive vs. Emotionally Reserved Business behaviour

The following part will explain what they are and what need to consider when cooperate the people that from these areas. However, culture is complex it includes too many thing that need to take into consideration. The aim of this part is to provide the readers a general guide of the culture difference and awareness.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The *deal-focused* culture built on believing in that trading unites people, whereas *relationship-focused* people are the people who often avoiding doing business with strangers, they prefer to choose the people from their personal network of contacts to get things done, such as Latin America, Asia/ The pacific region, most of Africa and the Arab world. Deal–focused people are the people who found the cooperators based on the competences, and is a natural thing to work with strangers. Including Europe, North America, Australia and New Zealand. The problem regarding to this categorization is how to make initial contact with the business partner. The formal introduction is not needed in a deal-focused country, while usually started with "cold calls". However, in relationship-focused countries, introduction is usually necessary. Gesteland (2013) also advised to apply an indirect approach to build up the relationship of business in the relationship-focused countries. The indirect approach refers to finding a third party to work as a recommender between the two business potential partners, preferably a high-status person. After the introduction part in relationship-focused countries, it is necessary to spend time establishing the business relationship. This is the reason that why it usually takes a longer time for the negotiations in relationship-focused countries than it in deal-focused countries. Except that, the face-to-face meeting is recommended in the communication with relationship-focused countries, since they always feel it is not polite to discuss important issues in writing or phone calls (Gesteland, 2013).

The direct versus indirect communication part is discussed the different communication manners of the relationship-focused and deal-focused people. It is one of the greatest causes of the misunderstandings. Deal-focused people usually say what they mean without any implicit meaning, while the relationship-focused people always have some implicit meaning by using the word "maybe" or "perhaps". Therefore, it should be carefully when two people coming from two different kinds of countries (Gesteland, 2013).

With other words the *informal vs. formal business behaviour* distinction is the distinction between hierarchical and egalitarian cultures. Hierarchical countries take most part of the world. In these countries, showing respects and addressing people formality is significant important, such as some Europe countries, Asia, Arab World and Latin America. By contrary, the egalitarian countries including Nordic countries, Australia, New Zealand, USA, Canada and The Netherlands. Therefore, when egalitarian countries need to have business with hierarchical countries and aware of this phenomenon is necessary.

In the two kinds of cultures, *rigid-time vs. fluid-time* they have different awareness about time. The schedules are usually fixed and highly valued punctuality in rigid-time cultures. Germany, Northern Europe, North America, Czech Republic, Hungary and Japan are included. On the other side, it is much less strict on schedule and time in fluid-time cultures, such as Africa, the Arab World, Latin America, South and Southeast Asia. Besides, there also exist some countries that belong to the part that between the rigid-time and fluid-time cultures, which are Australia, New Zealand, China, and Russia, most of East-Central Europe, Southern Europe, Singapore and South Korea.

Emotionally expressive vs. emotionally reserved cultures are expressed verbal paraverbal and nonverbal. Apart from verbal language, body language also plays a crucial role in how people communicate. Paraverbal is relates to how loud the talking and the meaning of silence. The paraverbal and nonverbal part are often have large distinctions in two kinds of cultures. There exists a possible problem when an expressive businessman communicating with a reserved non-expressive cultural person. In the latter person's perspective, the attitude of expressive may be seen as a hostile attitude. Therefore, the negotiations in reserved cultures usually spend a longer time since they are not in the same context of attitude with the emotionally cultures, and the negotiators may take turns in talking. It is only a little connection with verbal language, but have much more responses to paraverbal and nonverbal parts. Further, there are four elements that need to consider when talking about the nonverbal language, which are personal distances, touch behavior, eye contact and gestures. Overall, when a negotiation or a project communication occurs in an international project, it is not enough to just concern what the words that going to say, or if the counterparts could understand. It is also crucial to think about something that out of words, such as paraverbal and nonverbal parts. It is significant to ensure that all of the people involved in the project team are satisfied.

3.1 Lewis model: cultures in conflict

Lewis (2006) assumes that cultural conflicts are the main challenge for international management. According to Lewis (2006)'s conceptualisaition, there exist three types of cultures globally, which are Linear-active, Multi-active and Reactive. He categorized the culture in order to avoid the unnecessary offend caused by cultural distinction and also to predict different people's behaviors.

3.2 Alvesson model: multiple cultures in constellation

Alvesson proposes a multiple configuration as concept for this copresense of cultures. He argues that cultural similaries, differences and ambiguities exists in complex patterns, and that these are contextually specific, thus departing from Lewis (2006) preconditioning of cultural conflict. We therefore use the combined understanding of these culture scholars to inspire the case work in a relative open manner ex ante and even through revisiting the culture theory after having done a first round of analysis.

4. CASE: HANG XING PROJECT PLAYERS

DELTAte is a small Swedish consultancy company. BCKJ is a small architectural design firm in China. DELTAte was participating in a Chinese energy efficiency building project to provide the indoor climate system design solution with BCKJ. This energy efficiency building project is called Hangxing Technology Center. Hangxing Technology Center is defined as a new office building, and the owner of Hangxing Technology Center is Hangxing Machinery Manufacturing Company. BCKJ is responsible for the building's architectural and HAVC system design. Hang Xing Technology Center located in Beijing which has a surface of 33.500 m2 is the first project to obtain an EU green building certificate in China.

The project organization consists of project Management(Sweden) 2 persons (Swedish). Consultants three persons, one Chinese. Project Manager(China) one chinese- and a chinese HVAC engineer.

Players in Sweden:

- DELTAte (service provider)

Players in China:

- Hangxing Machinery Manufacturing Company (client)
- BCKJ (service provider)
- Construction Contractor (contractor)
- Construction Site Workers
- HVAC Engineers (supplier)
- Nokia (building user)
- IBM (building user)
- Beijing Planning and Construction Bureau (regulation agency)
- Beijing Architect Design Institute (regulation agency)

Other Players:

- European green building council (regulation agency)

5. HANG XING TECHNOLOGY CENTER PROJECT PROCESS

Below the overall process is first presented in three steps before going more in detail: The first step was a design and construction phase. Here suppliers applied for European Green Building certification to European Commission and related consulting works for this building. BCKJ is in charge of the primary material preparation and explanation. DELTAte is in charge of Hangxing office building's application, translation, and related consulting works. The second step was an adjustment phase on the completed building. Here consulting provided services on energy controlling, adjustment and optimizing ventilation, heating and cooling systems of Hangxing Technology Center. The third step is an operation phase. Here power management by remote controlling of ventilation, heating, and cooling systems. DELTAte specified solutions to particular problems of Hangxing Technology Center. More in detail Hangxing project started with a workshop for about one week in Sweden, Dongmei (the China project manager), a colleague of her, and two HVAC engineers came to Sweden for a study visit trip. They discussed the climate and how to design the natural ventilation system and also fan ventilation system for Hangxing Technology

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Center. Because the Swedish consultancy did not know the Chinese regulation, Dongmei as the design manager with HVAC engineers came from China were responsible for translate the design fit the Chinese quality standard. After the workshop, they were working separately in Sweden and China each their part of the project. Most of the project communication is through emails between the two sides of the project team from Sweden and China. There is one Chinese consultant named Liu who can speak both Chinese and Swedish, that worked in the Swedish team and was responsible for help with the communication in between. Sometimes online meetings and phone calls were also used as the communication tool. Based on the interviews, the communication through email works well and as intended. But both teams did not have a possibility for communicating with the site workers which is a significant issue since the Chinese site workers are not able to read the drawing and they made some mistakes during the building. Not much culture differences between Swedish and Chinese partners appeared during the project. Further, the one major challenge was to maintain and qualify the design to comply with Chinese regulation. Dongmei as the design manager for the Chinese side took most of the responsibility to work with this issue and explained the design for the related administration department since Hangxing at the time was the first building to apply the European green building certification. However, the biggest challenge for the Hangxing project was to negotiate with the building's user because of the insufficient communication between the building owner and its future user(s). The end user of the building refused to accept the indoor climate system designed for the building. They did not trust the system and wanted to change back to the old indoor climate system. In the end, the designer refused to change anything that was designed previously, a position which made the building owner unsatisfied with this action. After the construction, the building owner refused to do the project follow up work. Thus, the design team cannot do the project follow up even if the building has been successfully certified with the European green building certification.

6. DISCUSSION

This section contains three parts, which will show what are the similar, different and ambigious cultural characteristics and behaviours between Swedish and Chinese. By analyzing the case and interviews with two project managers, the cultural characteristics of players, Chinese and Swedish, could be concluded and categorized based on Alvesson (2002), Lewis model (2006) and Gesteland (2013).

6.1 Similar cultural behaviors

In an integration perspective one can note that the consultants, engineers and architects appear to draw on shared meaning on a common building design collaboration. This culture cuts across the national differences, Moreover although Swedish and Chinese are from different continents, they still have some similar cultural practices, based on the feedbacks from case and interviews. Nowadays, when either Chinese or Swedish seeking for the co-operators, both of them are focusing on two sides, which are the relationship and working abilities. Therefore, on this aspects, they have similar features.

6.2 Different cultural behaviors

In a differentiation perspective one can first, refer to the table of the cultural behaviors comparison between two national cultures shown below.

Chinese culture	Swedish culture
Relationship-focused & Deal-focused	Deal-focused & Relationship-focused
Indirect communication	Direct communication
Formal business behavior	Informal business behavior
Rigid-time	Rigid-time
Emotionally reserved	Emotionally reserved & expressive

Figure 1: Comparison between Chinese cultural and Swedish cultural behaviors in Lewis dimensions

As people of different nations, there exist some differentiations on personal characteristics between Chinese and Swedish. According to Lewis model (2006), Chinese belong to the reactive culture, which means that Chinese people have the features like quiet, introvert, patient and respectful. However, as Swedish are more tend to be the linear-active culture, which has the characteristics like strictly and having flatter organization. On the view of cultural behaviors aspect. Chinese are used to use implicit words or direct communication during the conversation, while

Swedish prefer to communicate in a direct way. Further, as hierarchical cultural people, Chinese people regard using formal business behaviors as important during the cooperation, while Swedish prefer informal business behaviors since they belong to a flatter culture. What proved to be a larger cultural challenges was the differences between the various chines players involved in the project. Collaboration between client and his end-user, with construction workers and more showed some typical fragmented culture elements for Chinese construction (Gao and Low 2014) and even comparable to other countries cultural fragmentation (Coffey 2010).

6.3 Ambiguous cultural behaviors

Except for the similar parts and different parts that discussed before, there also was some cultural behaviours or personal characteristics that were ambiguous and hard to be clearly categorized. On the attitude about the time, Swedish are significant more strict in this project context. Chinese also have a rigid time attitude. But unlike Swedish, there can exist some flexible changes on their schedule, which can hardly accepted by the Swedish in this project. This contradict however how Swedes in other building project might operate considerable time flexibility. In the project both parties experienced difficulties expressing direct refusing proposals. Saying no was difficult, yet for different reasons Furthermore, Chinese usually hide their emotions during the communication, while most Swedish like to show their feelings and emotions. However, based on the interview feedback, interviewees mentioned that Swedish also start to hide their feelings in the meeting. So it is such ambiguity to define if they are different or not.

7. CONCLUSION

The main aim of this paper was to study how cultural aspects influence in a selected energy efficiency building project involving Swedish and Chinese partners in the Beijing region. The theoretical framework juxtaposed several culture conceptualisation using a notion of multiple constellation of cultures as umbrella. The results in particular highlight that cultural differences in the Chinese supply chain of companies are more important than national distinctions Sweden-China. The cultural pattern is thus more of a multiple configuration than a dual culture. Nation, region, company and sector cultures interact and certain culturally based interpretations by the participants serves to confirm existing understanding of sustainable building projects. Small companies in particular are dependent of their cultural resurces due to limited resources. Through their network opportunities and dependencies they continually have to decide and act upon situational judgment informed by their cultures. The small Swedish company emerge into more projects in China. The authors studied two of them. The two green projects followed each other in time and can be seen as steps towards a niche for the Swedish company in China. Thus transforming them from visitors to permanent contributors to sustainable buildings in China. As this paper have shown they can draw on their understanding of fragmentation in construction even in China.

ABSTRACT

By a resolution of the Legislative Council in accordance with the Trading Funds Ordinance (Cap. 430), the Electrical and Mechanical Services Trading Fund (EMSTF) is established under the Electrical and Mechanical Services Department (EMSD) in 1996, with a view to improving the quality and cost-effectiveness of its engineering services through the pressure from quasi-commercial operation and market competition. Besides maintaining the government's vehicle fleets, EMSTF also provides operation, maintenance, project management, and technical consultancy services in relation to electrical, mechanical, electronic and building services systems and equipment at public facilities. Since its establishment, EMSTF has been growing steadily. In 2015/16, EMSTF recorded a business revenue of HK$5,764M and a rate of return on revenue at 4.8%.

To demonstrate the commitment to delivering sustainable and quality services for clients, EMSTF has been making extensive efforts in enhancing its management systems. EMSTF is the first government department to obtain corporate certification in ISO-9001 Quality Management System and ISO-14001 Environmental Management System during the turn of the century. In 2002, EMSTF became the first government department to obtain corporate certification for its Integrated Management System in quality, environment, and occupational health and safety. Moreover, EMSTF was also the first government department to receive the Total Quality Management Gold Award presented by the Hong Kong Management Association in 2006. Other certifications acquired included ISO 27001 Information Security System and ISO 50001 Energy Management System. Furthermore, to inspire by example, the EMSD Headquarters in Kowloon Bay is the first existing government building awarded a Platinum Rating in BEAM Plus assessment scheme run by the Hong Kong Green Building Council.

With the corporate goal of "creating public value for the community betterment through partnership with our clients", EMSTF set up its first Five-Year Strategic Plan (the Plan) in 2013. The Plan consists of five corporate strategies, namely 1) deliver excellent service, 2) become a trade model, 3) build capacity and caring culture, 4) enhance knowledge management and 5) sustain green operation. With our strategic plan translates into actions, EMSTF will advance in multiple fronts such as enhance customer services; apply new technologies to enhance reliability, performance and serviceability of E&M assets; build up staff competence and capability and sustain green operation with smart and low carbon solutions.

Keywords: E&M services, 5-year strategic plan, urban regeneration

1. INTRODUCTION

The Electrical and Mechanical Services Department (EMSD) is a works department under the Development Bureau (DEVB) of the HKSAR Government. The Department consists of two arms, namely the Regulatory Services and the Trading Services, to provide electrical and mechanical (E&M) services for enhancing the safety and quality of life of Hong Kong. By a resolution of the Legislative Council in accordance with the Trading Funds Ordinance (Cap. 430), the Electrical and Mechanical Services Trading Fund (EMSTF) is established under the Electrical and Mechanical Services Department (EMSD) in 1996. EMSTF was obliged to provide more flexible, cost-effective and customer-oriented services under a self-financed trading fund business model for enhancing the quality of living of the general public through services to a wide range of public facilities.

In the 20 years of journey, EMSTF achieved productivity enhancement, doubled its business volume and joined hands with clients to make substantial achievements in Hong Kong such as enhance engineering service to fight against SARS in 2003; provide specialist IT support to the World Trade Organization Meeting in Hong Kong in 2005; provide various engineering service for 2008 Olympic Equestrian Event; and 2009 East Asian Game. In addition, EMSTF has been investing substantially in the applications of new IT and E&M technologies to enhance the engineering performance of public facilities as well as the services quality to clients.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The corporate goal of EMSTF is “Create Public Value for the Community Betterment through Partnership with our Clients”. To achieve the corporate goal, a Five-year Strategic Plan (2012/13 to 2017/18) (the Plan) including five corporate strategies and eighteen initiatives was devised in 2013. The Plan aims to deliver the best engineering services to the public in Hong Kong, through implementation of innovative and integrative E&M works in the public facilities, advancement of engineering practices and effective management of knowledge. The five corporate strategies are: delivering excellent service, becoming a trade model, building capacity and caring culture, enhancing knowledge management, and sustaining green operation.

2. DEVELOPMENT OF ELECTRICAL AND MECHANICAL TRADING FUND

In 1996 the Electrical and Mechanical Trading Fund (EMSTF) was established to respond to the Public Sector Reform initiatives. The trading fund concept was introduced in Hong Kong with the intention that an institutional change would provide the appropriate means and nurture a new working culture to improve services in terms of quality and cost-effectiveness.

Since its inauguration in 1996, EMSTF commits to becoming a responsive, customer-focused organization, providing better value-for-money services for the clients which cover more than one hundred Government Bureaux/ Departments and public organizations. In addition, EMSTF undertakes different business development initiatives to enhance its competitive edges, such as implementation of reorganisation and regionalisation (R&R) of operations, development of complaints management system and corporate computer system (CCS). EMSTF also overhauls E&M engineering services delivery to the general public and re-shapes the mind-set and work culture of the Department.

In pursuit of quality services to the clients, EMSTF was the first Government department to obtain the ISO-9001 Quality Management System, ISO-14001 Environmental Management System and OHSAS-18001 Occupational Health and Safety System certifications in 1999, 2000 and 2001 respectively. EMSTF was also the first public body to win the Hong Kong Management Association’s Total Quality Management Gold Award in 2006. In addition, EMSTF continues to excel its quality of services in different areas such as information security management and energy management. EMSTF obtained ISO27001 Information Security Management System and ISO 50001 Energy Management System in 2011 and 2015 respectively.

Under the leadership of the Executive Board and the management team of EMSTF, it operates in a well financial position. In 2015/16, the return on revenue (ROR) was 4.8% with total revenue of HK$5,764 M. In view of the community demand on public services and the limited public resources of the clients, EMSTF commits to operating in a slim-profit model so that the clients can have more resources to better serve the community.

3. PUBLIC VALUE

EMSTF is a caring organization whereby people are the top priority. EMSTF cares about its clients, staff, and community. EMSTF always keeps in mind that the very reason for everything it does is to give people safe and pleasant experiences that contribute to high quality of life. This is “creating public value”.

To implement our public value, EMSTF and its staff work wholeheartedly to translate the service values into actions in fulfilling public expectations on the reliability and safety provisions of E&M facilities in public services such as hospitals, museums, and law enforcement operations etc. EMSTF also commits to safeguard the public E&M assets in supporting the high quality of living and prosperity of Hong Kong.

4. PARTNERSHIP WITH CLIENTS

EMSTF always welcomes clients’ comments and invites them to participate in EMSD’s activities e.g. seminars, knowledge sharing forums, new technologies briefings, etc. EMSTF endeavours to operate and maintain clients’ electrical and mechanical assets at its optimized conditions.

EMSTF has been conducting biennially Customer Opinion Survey (COS) since 1996. The COS aims to measure clients’ satisfaction on EMSTF’s services and more importantly to identify the area for improvement to strike for services excellence. To ensure impartiality of the survey, EMSTF commissions Consultants to conduct independently the COS as to measure customer feedback on EMSTF’s services and to identify areas for

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

improvement. The results of the Customer Satisfaction Index (CSI) calculated from the COS (1996 to 2016) show continuous uplift in score from 60% in 1996 to 80% in 2016. Also, the CSI is significantly higher in the years from 2012 to 2016 than that in the years before 2012. The rising CSI indicates that the five strategies of the Five-Year Strategic Plan are on the right direction to create the public value for the community betterment through partnership with clients.

5. THE FIVE-YEAR STRATEGIC PLAN

The Plan consists of five corporate strategies and eighteen innovative strategic initiatives as follows:

5.1 Delivering excellent service

Under this strategy, there are five strategic initiatives: enhancing customer service; applying new technologies; strengthening asset management; enhancing outsourcing with contract management; and enhancing quality management.

To enhance customer services, EMSTF has been carrying out different client focused initiatives since its establishment in 1996 such as reorganization and regionalization (R&R) of the operations, development of central complaint registry system and implementation of client opinion survey etc.. In order to further enhance its customer services, EMSTF is going to implement a Customer Centric e-Platform (CCeP) system by phases to enhance its customer services that integrating new IT technologies and innovation E&M systems and to set up a new Customer Services Centre (CSC). The first phase of CCeP implementation focuses on maintenance job management to provide integrated real-time job related information for sharing with stakeholders using mobile devices while the new CSC will be operated with the support by CCeP and various new systems such as the Geographic Information System (GIS) and Integrated Building Management System (IBMS), etc.. The CSC and CCeP will be put in operation in 2017/18.

The business portfolio of EMSTF covers about 8,000 government buildings and facilities being serviced in Hong Kong. Some of these buildings and facilities have been commissioned to serve the community since 1970s. EMSTF has been taking actions to apply new technologies and innovation ideas to the buildings and facilities for optimising the reliability, serviceability and energy performance of E&M plants. Taking the airfield ground lighting (AGL) system in the Hong Kong International Airport as an example, in order to effectively and efficiently test and calibrate the lighting power supply equipment, EMSTF and Airport Authority have designed a testing platform to facilitate the maintenance works in indoor environment such that the working time on the busy runway and taxiways can be minimized. With its innovative, creative and practical nature, this testing platform has been patented in November 2013.

In pursuit of higher operating efficiency and optimized service conditions of E&M plant, a number of new technologies have been identified and implementing in selected venues, for example: optimization control of building cooling system; electronically commutated fans; electromagnetic induction descaling devices; and maintenance practices for aspiration smoke detection system and automatic fire suppression system etc.

In serving our clients with care and innovation, EMSTF adopts a self-developed IT application using mobile devices to monitor work progress of outsourced maintenance works contracts i.e. “Performance Monitoring System for Maintenance Contract (PMSMC)”. The PMSMC has become a contract requirement since 2013. With the adoption of PMSMC, corrective maintenance notifications can be disseminated to contractors in real time for timely follow-up actions. Latest job status is updated via mobile devices. EMSTF supervisors can monitor the corrective and preventative maintenance jobs performed by contractors, with supporting documents and photographs taken on the premises. PMSMC is considered a cornerstone for improving the quality of records and monitoring of work progress.

Decreased operating efficiency and increased risk of breakdown frequency are common phenomenon of aging equipment which brings undesirable interruption to E&M services. To prioritize the actions on aging plant/ equipment, EMSTF customizes an asset database and obtained the ISO 55001 Asset Management System certificates for a number of major E&M equipment such as airfield ground lighting system in the Hong Kong International Airport and Ambulance Fleet of Fire Services Department, etc. In the coming years, EMSTF will continue to upkeep the asset database and to maintain the asset management.

5.2 Becoming a trade model

Under this strategy, there are three strategic initiatives: developing best practices; enhancing safety; and promoting E&M trade.

To enhance service standard and to deliver reliable E&M engineering services to the community, EMSTF works jointly with all practitioners to set up a framework of recognized works practices to handle a vast variety of E&M installations. Also, EMSTF is developing general specifications for operation and maintenance of major E&M engineering service in consultation with trade associations.

EMSTF has completed the consultation with trade associations on the revamp of the safety manual about E&M engineering works. This enables both EMSTFs staff and contractors to carry out E&M works following the same practices stipulated in the manual.

With concerted efforts with trade associations and Vocational Training Council, EMSTF participates in the Hong Kong E&M Trade Promotion Working Group to promote the image of E&M trade for attracting new bloods to the E&M trade. By attracting more young people to join the trade, EMSTF contributes to the provision of new bloods to meet the needs of the local profession and poses as a trade model to the industry.

In addition, to sustain the labour resources of the E&M trade in facing aging workforce, EMSTF also invests substantially in technician trainee training programme to attract new bloods to join E&M trade. From 2016 onwards for five years, EMSTF will invest over $600 Million on training to meet its business needs as well as the local E&M trade needs for the long term development in Hong Kong.

5.3 Building capacity and caring culture

Under this strategy, there are four strategic initiatives: building up staff competence; attracting young talent; establishing “centre of excellence”; and strengthening caring culture.

With technology advancement and high E&M engineering service demand, EMSTF has strong commitment to strengthen the knowledge and capacity of the workforce for building up staff competence to tackle the challenges ahead. In addition, EMSTF has been actively supporting the tertiary institutions funding application to Innovation and Technology Fund and study on new technologies.

EMSTF puts efforts on attracting more young people to pursue their career in E&M engineering through promotion activities. In the past three years (i.e. 2012/13 – 2015/16), the applications for our 3-year technician trainee training scheme and 2-year engineering graduate training scheme were increased for 14% and 65% respectively. In light of the increasing number of younger generation participation in the E&M trade through various training schemes, EMSTF will continue support the revitalization on E&M trade.

Selected EMSTF’s venues have been set up as the centre of excellence (CoE) to enrich staff knowledge through practices and various training. In 2015, a total of forty-seven CoE were established to showcase the competitive edges of EMSTF on its application of new technology and innovation practices in delivering of E&M services.

Under EMSTF’s caring culture, staff opinions are always taken into consideration in formulating policies. All tiers of workforce i.e. frontline, middle management and top management are invited to participate in management activities e.g. annual workshop for developing the strategic initiatives, annual communication forum. In addition, self-operated engineering programmes with Qualification Framework (QF) recognition are offering to EMSTF’s technician trainees and the workforce. Staff can develop their skills in a systematic way which aligned with the industry standard.

5.4 Building capacity and caring culture

Under this strategy, there are three strategic initiatives: enhancing knowledge communities; enhancing knowledge management-platform; and updating policy manual.

It is necessary to develop learning and knowledge sharing culture. EMSTF is committed to sharing knowledge with trades and clients through seminars, conferences and meetings. Knowledge transfer will enrich knowledge management of stakeholders which will eventually enhance the E&M engineering service providing to the community. In 2016/17, EMSTF arranged 14 knowledge sharing events and forums under different engineering themes, attracted over 2,000 attendees. The various knowledge management interest groups also planned to conduct about 50 sharing sessions with an estimated turn up rate of 1,000 attendees.

Knowledge management system supporting knowledge capture, retention, sharing and re-use is important for improving productivity, efficiency and cost effectiveness of E&M services. These strategic initiatives involve the cultural change on managing knowledge and the behaviour change on sharing expert knowledge within EMSD. We also integrated knowledge management activities in our critical business processes and reference document e.g. policy manual, enabling staff to acquire the needed knowledge in a more effective and efficient way than before thus shortening the time to competency.

Knowledge management is vital to capacity building as well as quality and productivity improvements. It also helps us document and share knowledge, enabling us to make the right decisions and stay at the forefront of the fields of engineering and management. EMSTF shall continue to improve and promote various knowledge management tools. In addition, EMSTF shares new and emerging technology with trade practitioners through technical seminars, forums and meetings so that the E&M trade as a whole will benefits from the actions on knowledge transfer.

5.5 Sustaining green operation

Under this strategy, there are three strategic initiatives: adopting green measure; promoting good practices; and supporting green building.

To combat climate change, EMSTF focuses on developing Hong Kong to become a smart and low carbon city. Energy savings through green measures is the priority of EMSTF. Control of energy consumption by buildings, optimizing E&M plant operation and adopting energy saving technologies are core elements for the smart and low carbon city development.

In collaboration with universities and the E&M trades, EMSTF has carried out pilot projects on green engineering measures such as adopting retro-commissioning practices, and developing control algorithms on the operation of major E&M plants of selected government buildings to optimize energy performance. The skills and engineering practices learnt from the pilot projects have developed good practices on green operation for sustainable development of the community.

Taking the lead by example, EMSTF supports the sustainable operation and maintenance of existing buildings. To strive for sustainable development, EMSTF adopts various green technologies in EMSD Headquarters, which was the first Government building awarded the Platinum Rating of the HK BEAM Plus on “Existing Building” and “Neighbourhood” presented by the Green Building Council in 2016. The EMSD Headquarters demonstrated the potential contributions of existing buildings in Hong Kong towards the development of low carbon and sustainable city such as energy saving, water saving and waste reduction.

6. CONCLUSION

EMSTF has been growing steadily and serving the clients with care and innovation. The five year strategic plan set out in 2013 provides a high level directive to strive for service excellence to clients with care and innovation.

With the vision of “Create Public Value for the Community Betterment through Partnership with our Clients”, EMSTF works collaboratively with E&M trades and universities in implementing the Five-year Strategic Plan, including the five corporate strategies and the eighteen strategic initiatives.

The results of the customer opinion surveys conducted from 1996 to 2016 shows that the clients are satisfied with EMSTF services with increasing trend of score with the highest score in 2016. It indicates that the five corporate strategies are on the right direction to deliver excellent services to the clients.

With the implementation of various strategic initiatives, EMSTF will become more customer focused, advancement in adoption of new technology and innovation practices and capable to combat climate change in supporting the low carbon and smart city development.

APPENDIX

Project Manager's Role in Sustainable Building Projects: A Case Study in Canada

Ricardo Ferreira LEOTO[a], Gonzalo LIZARRALDE[b]

[a] *Faculté de l'Aménagement, Université de Montréal, Canada, ricardo.ferreira.leoto@umontreal.ca*
[b] *Faculté de l'Aménagement, Université de Montréal, Canada, gonzalo.lizarralde@umontreal.ca*

ABSTRACT

It is estimated that the building sector, and its significantly fragmented industry, is responsible for 25% of waste generation, 40% of energy consumption, and 30% of greenhouse gas emissions. Not surprisingly, increasing attention toward sustainability and the reduction of fragmentation has led building sector stakeholders to implement alternative design methods and tools such as Integrated Design (ID). There remains, however, a disconnect between the often-ambitious objectives identified in the early phase of sustainable projects and the actual results achieved in the operation phase. This paper explores the role of project managers in ensuring that project and process fragmentation are reduced and that the sustainability goals set by the design team are effectively achieved.

The case study of a Canadian project (certified LEED-Platinum) helps us examine the success factors, optimization potentials, and shortcomings of project managers' role in the sustainable building process. The empirical data, which includes extensive documentation of the design, build and operation phases, LCA analyses and interviews, help us analyze the processes and stakeholders' interest and expectations. The results show that adopting ID in the design phase alone is not able to reduce fragmentation in following phases (notably without changes in the role of the project manager). From a theoretical point of view, these results highlight the importance of project management practices in integrating stakeholders, information, and knowledge in the age of sustainable development. From a practical point of view, they reveal opportunities to strengthening project managers' role in sustainable projects.

Keywords: green building management, integrated design process, sustainable buildings.

1. INTRODUCTION

The importance, socially and economically, of the construction industry in Canada, is significant: it represents 6% of Canada's gross domestic product (GDP) and 7.3% of employment. By contrast, environmentally, the sector is responsible for 25% of waste generation, 40% of energy consumption, and 30% greenhouse gas (GHG) emissions (StatCan, 2013). Both theory and practice show us that the traditional silo-type, linear, and fragmented design process are a significant barrier to the implementation of improvements in the built environment (Leoto et al., 2014; Magent, 2005).

However, the increasing focus on sustainable development leads clients and construction industry professionals to find new modes of operation to answer the new society's aspirations (Bonham, 2013). Green building certifications emerged in the 1990's as a methodological framework to diminish the negative impacts of the built environment on nature and human health (Ding, 2008; Berardi, 2012).These certifications propose, for example, alternative design methods such as Integrated Design (ID) to improve the environmental performance of buildings.

There remains, however, significant gaps between the sustainable building expectations at the design stage and the actual, subsequent performance. Regarding energy consumption, research shows that almost 90% are not able to reach the goals, and among them, 35% use more energy than their conventional counterparts (Newsham et al., 2009). The gap can also be verified in aspects such as comfort, overheating, cold spots, high levels of air movement, acoustics, material durability, indoor air quality and water consumption (Bartlett et al., 2014; Goodhew, 2016).

The objective of this paper is to explore the role of project managers in ensuring that project and process fragmentation are reduced and that the sustainability goals set by the design team are effectively achieved. The main challenges, as well as important opportunities for improvement in sustainable projects, are identified. A review of the literature on the fragmented nature of the construction industry and Integrated Design (ID) are presented in the first section. In the second section, the case study is presented by highlighting the qualitative results obtained from the analysis of documents and interviews. Finally, the discussion section presents the practical and theoretical implications of the findings, their transferability, and their limits.

1.1 Fragmented nature of the construction industry

The process of designing, constructing, and managing buildings is fragmented. The construction industry still applies the "over-the-wall" approach (Evbuomwan and Anumba, 1998) involving many participants interacting in complex ways over a prolonged period of time (Kalay et al., 1998). This process leads to a conflict between the expected and the actual project quality, which then results in buildings that operate below their optimum potential (Jayasena and Senevirathna, 2012).

In the design phase, for example, sequential communication among the participants is the norm: structural design does not begin until completion of architectural drawings with both needing to be completed before mechanical systems design begin, and subsequently for the other professionals (Kalay et al., 1998). In this context, meetings can occur but, in fact, they are only for coordinating purposes (Cole et al., 2008). The design deliverables of each specialty are separately prepared by each professional or firm and assembled at an advanced stage of the process.

In the following project phases, members of the project teams often change, thus increasing fragmentation in the process. Four different types of fragmentation occur during the construction process: (i) design project fragmentation; (ii) procurement fragmentation, (iii) construction industry fragmentation, and (iv) labour fragmentation at construction sites (see Table 1).

Design project fragmentation	The disjointed and sequential character of traditional design practice as well as the increasing specialization of roles lead to sub-optimal solutions, poor constructability, and operability. (Huovila et al., 1997).
Procurement fragmentation	Conventional procurement methods and contracts create adversarial relationships between parties reinforcing socio-cognitive barriers that hinder team efficiency and collective search for new ideas (Forgues and Koskela, 2008; Mossman et al., 2010).
Construction industry (CI) fragmentation	Construction industry is largely composed of a vast number of small and medium enterprises that work together for only short periods of time (Mossman et al., 2010). Also, we can verify strong division of labour, poor coordination among project participants, and significant amounts of subcontracted work (Van Nederveen et al., 2010; Gottlieb and Haugbølle, 2013).
Labor fragmentation at construction site	Accreditation for workers in construction (Canada since 1969) has fragmented the workforce by trade, sector, and geographic area. High-specialized labour with growing numbers of trades (152 different required skills in total) delay the process and increase the price of construction (Globe-Advisors, 2013; Lizarralde, 2008). In Quebec, 23 trades are recognized and regulated.

Table 1. Forms of fragmentation in the construction sector.

1.1 Integrated design (ID)

ID emerges in the 2000's as an alternative to design high performance buildings (Roundtable, 2007). ID proposes a simultaneous participatory process that brings together interdisciplinary experts and stakeholders (professionals, builders, experts, users, and owners) through intensive work sessions (dubbed design "charrettes") during the early phases of project design (Ghassemi and Becerik-Gerber, 2011). Green building certifications foster ID adoption in believing that decisions taken collectively can reduce fragmentation and enhance industry efficiency to deliver sustainable projects (Forgues and Koskela, 2009).

ID involves a holistic approach that relies upon every member of the project team working collaboratively to implement sustainability goals. The team is called to consider, for example, the whole life cycle of the building, not just the initial capital investment in construction (Rekola et al., 2012). By developing and sharing new knowledge, all stakeholders generate added value in the process and to the final product (Jayasena and Senevirathna, 2012).

1.2 Project management challenges in sustainable building

The adoption of sustainable goals and ID process increasingly challenges project managers (PM). Firstly, they now join the team since the early stages of the project and not only in the pre-construction phase (as per the norm)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

when the design project is already defined (see Table 2). Secondly, the PM's role is enhanced, called to collaborate in the integration of design and construction, thus helping to improve constructability and the implementation of sustainable goals (Tatum, 1987). Whereas previously PM goals focused on cost, schedule, and quality, sustainable design introduces low energy consumption, users' health, waste and pollution reduction, and environmental protection among other objectives (Vanegas et al., 1995; Bonham, 2013).

The PM in a sustainable project is now invited to participate in all "charrettes", being not only responsible for defining goals with the team but also insuring that targets will be met, for example, by selecting materials and systems according to the performance criteria by insuring that the final building design has lower impacts than a reference building. Besides that, certifications normally focus on rating systems and green targets, obliging PM to pay more attention to technically related issues during the construction phase to reach the green goals that include energy efficiency, site management, waste management and using environmentally friendly materials (Delnavaz, 2012; PMI, 2004; Herazo and Lizarralde, 2015).

Key work stages	Planning		Design			Procurement			Construction			Operation
Traditional project management						↔						
Detailed work stages	Appraisal	Design Brief	Concept	Design Development	Technical Design	Contractual documents	Tender Documentation	Tender Action	Site preparation	Construction to completion	Documentation commissioning	Post-practical completion and operation
Project management in sustainable buildings	↔											
Key phases in sustainable building	Sustainable building design					(Integrated Design)			Sustainable construction			Sustainable Building operation

Table 2: Comparing project management role in a building process (adapted from Delnavaz (2012)).

2. RESEARCH METHODS

We adopted a qualitative research approach, more specifically a case study approach "that investigates a contemporary phenomenon within its real-life context" as suggested by Yin (2003, p. 13). The case study of the Centre for Sustainable Development (CSD) was chosen because it fulfils the requirements previously identified: a) adoption of a green building certification (LEED®), b) a project that aims at being a social and environmental innovation hub, c) a project that adopted ID, LCA, and BIM,and d) full access to data, reports, and stakeholders.

We collected and analyzed primary data, including 13 integrated design reports, 23 emails, two contractual documents, construction schedules, photos, the web page of the CSD, two conference videos, LCA reports, energy simulations, and six press releases. The second step included more than ten visits to the project site during its construction and operation phases as well as nine semi-structured interviews with professionals, clients, and stakeholders involved in all project phases of ID.

3. RESEARCH RESULTS

Stakeholders' collective engagement with common values: The ID process needs a "champion" to coordinate efforts to successfully explore innovation potentials (Nam and Tatum, 1997; Lizarralde et al., 2012). In this project, the "green champion" chosen was one of the client's representatives who also acted as a facilitator during the project "charrettes". The champion's legitimacy, however, was not recognised by other stakeholders. Given increased tensions, the client decided to fire him. It is only at this moment, and after the sixth meeting, that the client finally decided to hire a PM to join the team and to ensure the role of facilitator in ID charrettes. In practice, documents show it was actually the architects who took the facilitating role instead of the PM, and meetings became rather conventional.

Increase in task complexity: CSD involved all stakeholders in ID “charrettes” since the early phases of the project, including the design team, contractor, PM, experts, client and users. Green certifications imply an increase of task for all professionals, including PM. All decisions now need not only be decided based on cost but its impact on the environment and energy consumption. Some tools used in CSD project to support designer’s decisions are: (i) ATHENA® Impact Estimator for Buildings v5.10102 for materials impacts, and (ii) EE4v1.7-2 for energy consumption calculation. We notice that, because the client was an environmental NGO organisation, decision making was even more complex due to the fact that its goal was not just to obtain green certification but to “do the right thing”, that is to give an example for others.

Increase in time required in the designing phase: in 2006, when this ID process took place, no consensus existed on how to operationalize “charrettes”. The stakeholders participated to 14 charrettes, where only seven were planned in the initial schedule. In fact, documents show, and the interviews confirm, that waste in the design process hid both innovation and collaboration. One architect contends that “the meetings were too long (some lasted more than 8 hours), and without a break between them to give us time to work on the data”. The client reveals a possible reason for this problem: “[even though] the level of participation was significant, the preparation and organization of meetings and work during the session’s ID could be pushed a little further”.

The operation is a key phase: In green buildings, the documentation and the commissioning phase are vital for optimizing the building's overall energy performance and to ensure that the building is operating as designed. Normally the PM’s and the design team collaborate in the commissioning process, one requirement to obtain green certifications. However, actual data from building and operation problems show that design teams fail to transfer their knowledge to the building’s new stewards (owner, occupants, and operation staff). Because the goal of green buildings is to reduce construction impact over their entire life cycle, this study compares targets defined during ID charrettes with actual data measured over four years’.

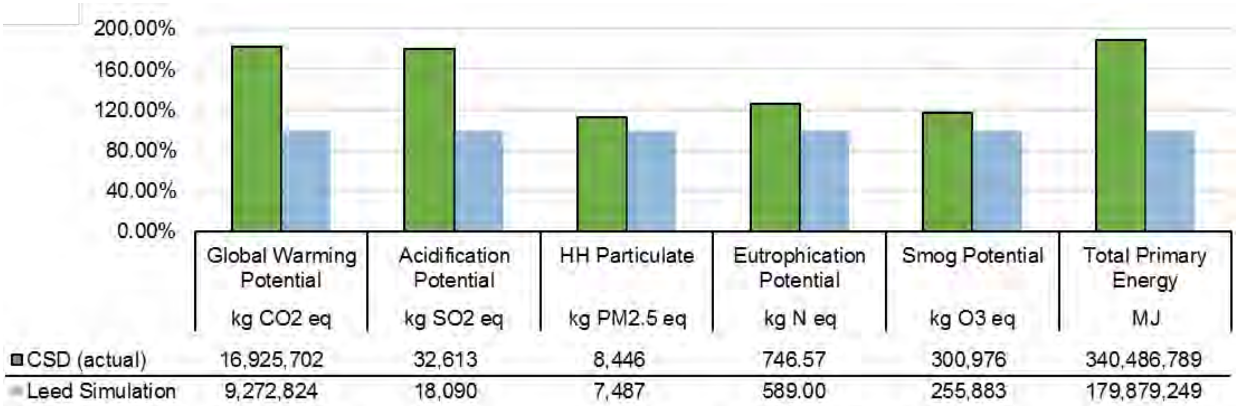

Figure 74: impact scores for LEED simulation and actual consumption in CSD

The LCA tool called ATHENA® Impact Estimator for Buildings was used to compare CSD actual consumption (electricity and gas), between estimated values defined during the design phase and LEED energy simulation document (see Figure 1). Results indicate that CSD has a bigger impact on the environment than expected. Moreover, Table 3 shows that even if CSD used less energy (four years’ measurements) compared to Reference Building, it never achieved the project goal defined in the LEED energy simulation document.

		Reference Building	LEED simulation	2012	2013	2014	2015
Electricity	(Kwh)	1,121,928	721,954	1,390,333	1,391,386	1,512,092	1,323,251
Gas	(m3)	113,645	4,206	10,644	29,046	25,223	3,084

Table 3. Comparative between LEED Energy simulation and real consumption in the last four years.

4. DISCUSSION AND CONCLUSIONS

This paper explored the role of project managers in sustainable buildings and summarized a comprehensive case study in Canada. ID, commonly used in sustainable projects, promises to reduce fragmentation in the design and consecutives phases. While this paper identified several project manager's challenges and opportunities in sustainable buildings, we recognize that other factors can also be relevant and deserve to be thoroughly studied. Further research can explore how new tools can assist the PM, for example, building energy simulation, BIM, and communications software.

Results show that, even if fragmentation in the design phase is reduced, it still occurs during the construction process and the operation phase. Nevertheless, this case study identified main challenges, as well as significant opportunities, for PM's to reduce fragmentation and to improve the sustainable performance in buildings. Firstly, the PM and the key members of the project team need to be hired early in the project's feasibility stage. The PM has the responsibility for building teamwork by the same values. The early development of a sense of common goal can increase the willingness of the parties to collaborate and achieve sustainability goals. Being the first professional to be hired and the last to leave the project gives the PM an opportunity to build links between phases and professionals.

Secondly, the PM needs to assist the client by organizing project design "charrettes" and the proper use of new tools and techniques related to sustainable goals. New tools include, for example, Life Cycle Analysis (LCA) to measure the impacts of design approaches, technical solutions, and materials. To better guide his/ her decisions, the PM needs to be better prepared to the new challenges and complexity facing sustainable buildings projects. Furthermore, improving ID design "charrettes" can improve the design process and diminish the team members' impression that they were "wasting their time."

Finally, the project team led by PM needs to follow the operation phase of the building. This case study indicates that, even if all the team participated in the documentation and the commissioning phases, it was not enabled to successfully transfer project knowledge, or either unable to anticipate future issues. In this case, the PM can collaborate in overcoming this weakness by extending its participation in the project during the operation of the building (see Table 2) during at least the first four years. In this sense, the PM cannot only ensure transfer knowledge but can also support new stewards with possible issues or optimizations. By reducing the four levels of fragmentation identified above, construction projects can have a more positive impact on society and the environment. This is a major task for the construction sector, in which project managers can play a significant role that goes beyond the implementation of technical solutions, and which requires social and "soft" skills.

ABSTRACT

China is faced with a heavy pollution issue while industrialization process. Millions of manufacture factories had been built every year discharging waste water, exhaust gas and useless solid material. Construction industry as one major polluted source was focused by China government more and more. Green building solution was encouraged to use for all types of building in last five years. But finally only 1% manufacture plant had been built following green label standard due to less of incentive policy and self-motivation. Most plant owners who are facing severe competition and survive pressure in China market do not willing to spend money and time for environment protection.

This paper summarizes a case study on an industrial project in China. Buildings in this project obtained both China 3 stars Green Building Label and US LEED Platinum (office) & Gold (factory) Certificate. The author involved in whole practice wishes to share experience from planning, design, construction, commissioning to operation process. Base on characteristics of factory building, an appropriate green building developed strategy is evidently helpful for green practice to balance performance, investment and payback period.

Keywords: integrative process, portfolio, commissioning

1. PROJECT INTRODUCTION

China now becomes a real world manufacture centre with huge capacity on multiple products. Year by year, millions of manufacture factories had been built all around country (550M SQM factory was built in 2015). Meanwhile, the pollution during the production process heavily influenced human living environment and sustainable development of the industry. Since 2015, the green development had been affirmed as one of five main strategies by China government and construction industry as one major polluted source was quite focused. The green building concept had been adopted broadly and the number of projects rapidly increased in the last 5 years. By the end of year 2016, 4221 projects got Green Label certificate but only 44 of them were industrial projects. The reason is not only because less of incentive policy but also complicate production environment in different industrial sectors.

Located in Xi'an High-tech Industry Development Zone (XHTZ) with a total construction area of 50,000 square meters occupying 190 Mu of land, BlueScope Buildings (Xi'an) Co. Ltd. consist of Admin office, manufacture plant, ancillary office, and raw material warehouse that all were built of steel structure was under construction from May 2012 to June 2013 then fully operated since July in the year. The project was successfully achieved all construction targets especially on green feature. It achieved LEED Platinum certification for Admin office and LEED Gold certification for the workshop. Meanwhile it became first 3 stars green design label in China and green demonstration project by Ministry of House and Urban-Rural Development of the People's Republic of China (MOHURD). Furthermore the project certified as Green Construction demonstration project in 2013 and Green innovation award in 2015 by MOHURD again.

The project has very outstanding feature to realize entire green process which can rarely find among most green projects. It needs set a green target in pre-design stage, executed through design and construction, enhance commissioning by third party, operated with data collection and monitor system. With around RMB 10M incremental green cost, more than twenty green techniques selecting by owner, consultant and design institute was implemented. As calculation, the incremental investment can be returned back within six years. The below content in this article will give you full penetration of this project case.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

1.1 Economic target

As a manufacture company, it is priority to control the investment tightly to achieve lower cost base for future factory operation. Even consider to achieving higher green level, the project team chose every technique carefully above bottom line which its return period should be less than eight years. Meanwhile one "Cost and Benefits" model was used to help on decision making, e.g. see Figure 1. It identifies right sequence from bottom to top visually which should use passive technology as priority, then active technology. And the renewable energy should be used rarely because big investment and relative small return. For instance, improving building envelope performance which belongs to passive technology only cost little money but can get quite huge improvement on energy saving.

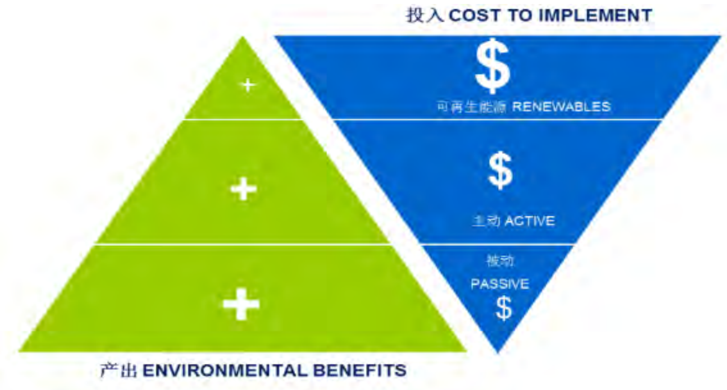

Figure 1: Environmental benefit vs. Cost to implement

1.2 Environmental protection

Minimum environment influence from production process is a basic requirement for green plant. The project team needs to identify any small pollution possibility caused by solid waste, water discharge, and exhaust gas emission. In this case, the solid waste such as steel scrap was stored in a special shed which far from production area and sold to third party for recycle purpose. The waste water only comes from worker's shower room was collected, filtrated and disinfection in a set of containers. The recycle rate was calculated as 42% yearly. The exhaust gas causing by welding and painting process was gathered and burnt in a special container to achieve national gas discharge standard. Any environment incident will be reported monthly to senior leader team of the company.

1.3 Social commitment

To realize sustainable development, corporate social responsibility will be final measured by social community. A big residential community just locates cross the road of this project. The equipment noise could heavily influence people's life as well. So the project team had to identified the noise source and put it as far as possible from inhabitant at schematic design stage. Then the master plan can be laid out properly even the gate of factory can't face to residential building. Internally, the noise can also hurt the hearing ability of the workers in the long period. Certain noise reduction action had been taken such as perforated panel on the ceiling and rubber padding block under the equipment.

2. INTEGRATIVE PROCESS

Integrative planning involves group people who expert in different aspects can maximum opportunity for cost effective adoption of green design and construction strategy, emphasizing human health as a fundamental evaluative criterion. Conclusion from this practice, any project should identify the main resource consumption in production activity and the local characteristics include weather condition, local plant and material resource, etc. The diversity of the team members did support to discover more synergy strategies and review carefully on trade-off strategies. Thus the negative impact was eliminated from whole green portfolio. For instance, good day lighting design will cause more indoor heat and glare.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.1 Water efficiency

Rain water collection and bath water recycle techniques are both used in this project. Rain water is free and clean resource can generate from factory's roof which is large enough normally. The bath water is more stable source relatively to fill in the tank. In the design, two kinds of water are collected separately but come together used for irrigation and some cleaning purpose. As synergy strategy, rain water collection can help to reduce runoff volume and make water balance on site. The water collected from bathroom need be purified with recycle facility cost little but reducing the waste water discharge to environment. Meanwhile all water used for landscape, irrigation, and cleaning purpose can contribute on cost saving, more important to save precious natural water. The whole water collection system in the factory with recycle concept can be described as below picture, e.g. see Figure 2.

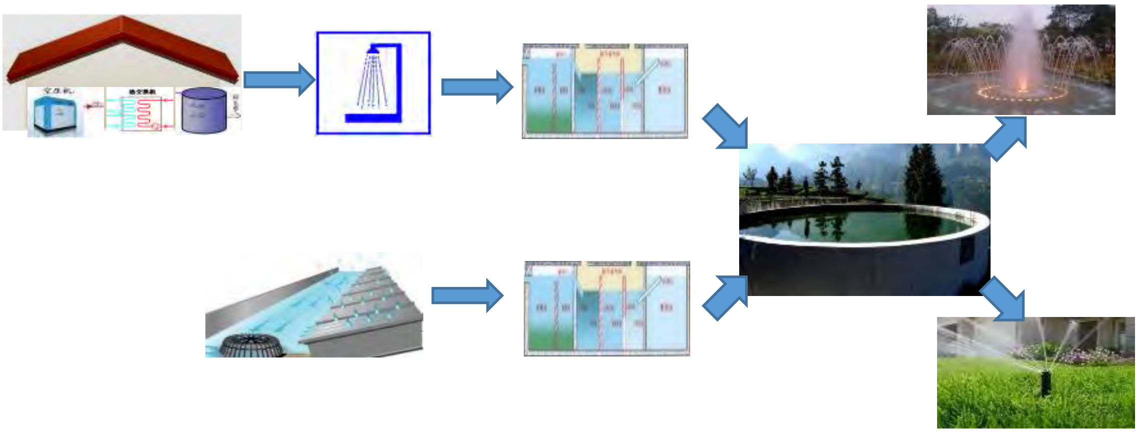

Figure 2: Water recycle process

The Figure also shows the shower water is heated by waste heat generated from equipment during the manufacture process. There is a good synergy to reduce both energy consumption on heating and heat emission to the atmosphere at same time.

2.2 Air-condition system

Ground source heat pump system had been selected based on good test result of the site soil. The struggle issue is what kind of air-condition system should be fitted for admin office around 6000 SQM. Variable Air Volume system was suggested by consultant company as new popular solution for energy saving. VAV system could adjust the supply air volume automatically according to the indoor heating and cooling load that can save AHU power consumption during partial load time and to control the temperature of each zone separately. The main weakness is also very obviously for this system include system noise, less of fresh air and bigger initial investment on equipment. Fan Coil Unit is another choice as traditional way design for office which can be controlled by occupant with different comfortable sensation. The problem is higher maintenance cost on complicate FCU system and condensation at air outlet. The expert group, owner and design institute had strong debate on these two systems. Finally FCU plus fresh air system was chosen consider the office is an open space without big heating or cooling load variation at working time since office staff usually start and end working at same time. Furthermore FCU system can save initial investment tremendously, easy to find maintain resource in a manufacture factory and condensation can be avoided if package the insulation well on the pipe system.

2.3 Energy saving portfolio

Air condition optimization is main part in energy saving pie in most projects. The other energy saving strategy, however, should not be neglected in green building design. Up to 40% energy saving target was made in this project, thus the project team needs define contribution from building envelope, glass of windows, exterior and interior lighting, day light control, variable frequency drive pump, heat recovery and solar water heating system. Some strategy even only counts less than 1% but still used to accumulate to big proportion, e.g. see Figure 3. The energy simulation model was built in Designbuilder software indicating the separate saving percentage of heating, cooling, lighting, and power system. In practice, the designer and consultant always prefer to choose new technology, product and material. The owner especially for manufacture industry, need balance on additional cost with the real benefit output.

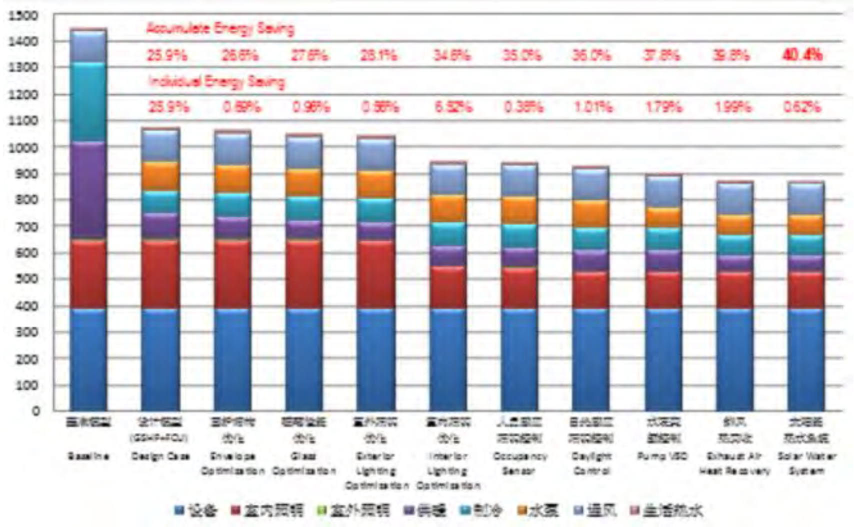

Figure 3: Energy saving contribution by green strategy

3 CONSTRCTION AND COMMISSIONING

Construction to realize all design intent is not easy especially for green technique. That's why only around 5% projects will get green operation label award after got design certification. Generally it is many and miscellaneous trifles job and could lead to even schedule delay. In this case, a small green construction office had been established on site to focus on daily green job. Most construction supervisors were trained several times on relative green knowledge before construction commenced.

Commissioning classified as fundamental and enhanced commissioning stages. Normally the fundamental commissioning will be done right after construction but enhanced commissioning need invite third party to complete by experienced people. An enhanced commissioning contract was signed which covered air-condition, electricity, pipe system, pump, envelope, training, etc. It allows the commissioning authority can involve in design and construction stage to deep understood project requirement.

3.1 Environmental site assessment

Many construction sites may contain contaminants that could harm the health and well-being of future occupants. It even will damage company reputation and devaluate the land when the factory needs to be sold to others with unexplained contaminants issues. The soil and underground water was sampled and sent to certified laboratory in Shanghai for testing. Unfortunately the hexavalent chromium was detected at that time in the underground water at South-west corner of project land. Meanwhile approximately 6 m^2 oil stain area was found at North-east portion. Then the phase Ⅱ environmental assessment needs to be implemented with 12 wells to pick more soil and water sample in different portion of the land. The purpose is to identify the distribution map of heavy metal.

The treatment process last about 3 months to fill clean water through the wells to dilute the concentration of the contaminant. The monitor data shows the chromium concentration was dropped but rebound again after stop water filling. The project team decide to leave this corner out of the boundary and keep monitor well for future action. The oil contaminated soil around 4 meters deep was evacuated and treated by a licensed hazardous waste treatment vendor.

3.2 Construction management

The construction activity not only produces light pollution and noise to neighbouring property but also make soil erosion, waterway sedimentation and airborne dust on site itself. The green construction plan has been made in advance by green construction office and many new initiatives were created during brainstorming meeting among owners, construction team, design institute and consultant. For example, the site discharge pipe system used to be laid down at last. Now it becomes first step of construction to ensure it can used for site rainwater and domestic sewage management during construction period; the temporary landscape and waterway can better control raising dust, e.g. see Figure 4; the waste material was gather by different category, e.g. see Figure 5; the proper boundary

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

wall and buffer zone were set up to control the mud fluid. Especially the construction road was built as same standard as formal factory road without surface course. The road surface will be final paved after most construction activity completed. The new method reduces solid waste when the temporary construction road is demolished as traditional way. With same methodology, the temporary construction office right locates on storage yard of the factory. The ground of the office had been built according to heavy load storage standard at beginning to avoid reconstruction. Moreover the construction team can save cost both on abolish temporary road and waste material recycle.

Figure 4: Temporary plant and waterway

Figure 5: Waste material collection

4. OPERATION MANAGEMENT

At operation stage equipments need to be well maintained to keep running well to generate return to owner. A small green facility group is responsible for observing parameter and recording the daily data in this project. They can monitor any problem happen tracking by a data collection system covering every meter which can transfer data automatically. On the other hand, occupants training for behaviour change will become headache and long term job by this group. In real case, people open the windows as while as using the air-condition system; use electrical lighting when it is sunshine. So the actual performance results of green building maybe far behind the design objective if don't focus on daily operation management in detail.

4.1 Indoor environment

Like most factory air-condition was not installed in the manufacture workshop. To avoid high temperature in summer and too cold in winter, the envelope design becomes very important part. The project team use reflection painting on the roof to reflect sunlight and also use 150mm thick fibreglass insulation to reduce heat penetration at day time. Hard thermal block was used at everywhere when insulation was compressed due to fixing on structural components. The windows and a small piece of curtain wall was tested to meet coefficient of heat transfer lower than 1.8. Actually natural lighting skylight on the roof was used for interior day lighting instead of setting more windows on sidewall.

Two temperature meters were installed both inside and outside factory to measure the actual temperature difference. The statistic shows the highest indoor temperature was 32.5 degree while outdoor is above 42.7 degree in summer, e.g. see Figure 6. It's quite successful result since 33 degree is critical point that people will be sweaty and influences their working efficiency as while. To provide comfortable indoor working environment was another basic task for green industrial building.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

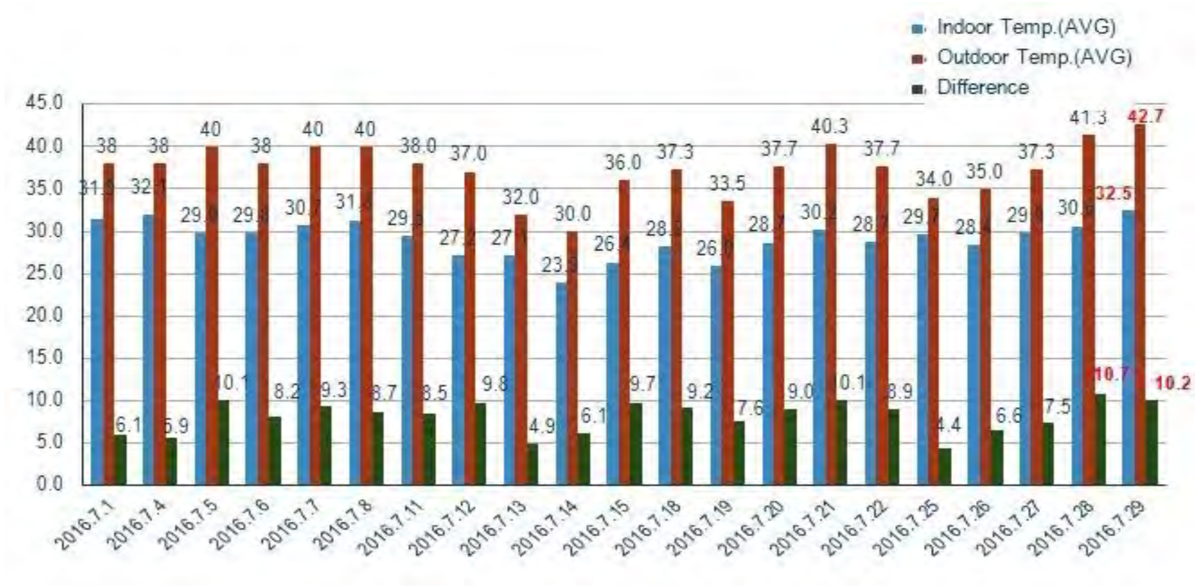

Figure 6: Indoor and outdoor temperature difference

4.2 Data collection and analysis

Both building-level and system-level metering system was constructed and working continuously to collect operation data in this project. All data was sent to specified computers and synchronously show on monitor screen. The system can also generate daily, monthly and annual report as required. Any leakage or damage issues will be identified quickly by facility maintenance team base on abnormal data. It also provides possibility for the team to find system bottleneck and opportunity to improve performance continuously. For instance, the team member found the difference in temperature of supply and return water of air-condition is not as big as design. It lead to indoor temperature can't drop quickly in hot weather. Then the issue was delivered to maintenance team and supplier to figure out solution.

5. CONCLUSION

Life cycle concept of green building runs through design, construction, commissioning, operation, and demolish stage. This project case introduced here had experienced entire journey to realize high standard green industry factory sample in China. The initial building investment increase around 9% but owner will get quick return and tremendous potential benefits during the building life cycle such as people with good feeling of working environment will be more innovative and efficient on their job. Meanwhile it can sufficiently prove the corporate social responsibility and support for sustainable development in near future.

Green building practice is not difficult but need consider in every detail. The success for this project is mainly by two reasons: The project team set green target at very beginning and interactive each other to choose suitable strategy and technology to approach cost-effective and better performance green building; green vision and strong executive ability of project members is another engine that make all conception in design drawing comes true.

ABSTRACT

The main policy in a city to deal with climate change is to promote energy saving, the reduction of carbon emission, and the construction of green building, which is also a kind of governance mechanism within the legal city planning and construction management system. However, in some areas, a lot of local governments and urban construction enterprises are still misunderstanding the concept of green building, especially in the application of low carbon technologies which may make some impact on the economic cost. At present, in this field, the discussion of the policy making is mainly aiming at the problem of technology application. As a decision maker or investor, it is essential to know the real meaning of green building and its economic efficiency. This paper makes an analysis on the current policy of green buildings and establishes the cost-benefit analysis method of green building based on the theory of property rights from a macro perspective, then points out that it is necessary to design a set of operational analysis tools in the project level, and should put the benefits of green building construction in a macro economy level. Green building with incremental costs will bring additional incremental investment, which will lead an additional increase in industrial output during the economic system, and thus will have a macro impact on the overall economy in turn.

Keywords: green economics, cost-benefit analysis, green building policy

1. INTRODUCTION

Climate change is the biggest and most controversial environmental issue of our times. For its profound impact on the existence and development of mankind and as a major challenge faced by all countries, the world now mostly agrees that something needs to be done about global warming and climate change. On 12, December, 2015, Le Bourget, Paris, the historic Paris agreement on climate change is finally adopted with no objection at the COP21. After signed the Paris Agreement, China is energetically exploring for low-carbon development pathways. The main policy in a city to deal with climate change is to promote energy saving, the reduction of carbon emission, and the construction of green building, which is also a kind of governance mechanism within the legal city planning and construction management system. In building industry, how to promote green building has become a central issue (Yudelson J., 2009, Miller N, 2009).

With the promotion of building energy-saving and the establishment of certification system in green building standards, the extra cost and benefits in the process of green building design and construction has been concerned with (YIP Stanley et al., 2011, Morris P. et al., 2007). An analysis of 33 buildings in California's green building economic indicators pioneered the trend of analysing the United States of green building cost (Kats et al., 2003). After that, the United States Federal General Services Administration (GSA, 2009) conducted a survey and made an analysis about the additional cost needed to be paid if the newly built or rebuilt project could achieve LEED certification (Steven Winter Associate, 2004, Miller N et al., 2008, Urban Green Council, 2009). Green Building Council of Australia firstly published the economic analysis of green building, which made a comprehensive description about business model of green building and market considerations (GBCA, 2006). In 2010, they suggested that the government should establish a perfect financial incentive and all the commercial buildings should offer their energy consumption efficiency (GBCA, 2010). For the government of United Kingdom, green building cost analysis of market impact is main policy basis of continuous promotion of standards of green buildings (DGLC, 2011). In China, the economic evaluation method of construction project was mainly divided into "financial evaluation" method and "economic evaluation" method (YANG Yan et al., 2007), which does not highlight the characteristics of cost and benefit of green building. Some researches put forward the principle of increment cost of green building (LI Ju et al., 2008) and also cited the concept of green GDP (ZHUANG Yunhua et al., 2010), which put forward the use of the method of difference comparison to evaluate the index which was divided into the

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

cost incremental index and benefit incremental index, thereby reducing the cost of green building and promoting the implementation of green buildings.

From the above researches, we can see the development and some achievements on the economic efficiency of green building construction policies and relevant technical standards. However, the existing research still has some weaknesses: they are mainly concerned with the content of the specific economic data analysis, focusing on the technical level of discussion, but are lack of economic efficiency from the basic economic theory to understand the green building policy. Green building policy is a part of low-carbon urban planning and construction system, so we need to analyse how to understand the efficiency of the policy from the perspective of economic theory. Moreover, as a decision maker or investor, it is essential to know the real meaning of low-carbon green building and its economic efficiency.

2. **THE ANALYSIS OF CURRENT CHINA'S ENERGY CONSERVATION POLICY ON GREEN** BUILDING

2.1 The government restriction policy system of China's building energy conservation

The government restriction method intervenes directly in the allocation of market resources or changes indirectly the supply-demand relationship between producer and consumer through law and administrative regulation. At national level, there are five gradation of legal system, including law, administration regulation, ministry rules, policy oriented document, standard specification and technical directives, which is to develop a legal basement for related policies and strategies. At present, the technical content included in regulation has been arranged widely and contains almost all kinds of techniques for energy conservation and renewable resource generation. However, the related economic bodies have no choice but to engage in specific service to achieve the government's stated goals, otherwise, it will be subject to legal or administrative sanctions.

In order to make the implement effectively, regulation must follow these three principles: the provision of energy conservation content should be clear, which will allow the influenced economic bodies understand the concrete demand; for energy conservation on green building, it is important to composite the macro goal into definite technical specifications for industry and implementation; the efficiency supervisory control method should be developed, for example, promoting related laws and strategies on energy consumption standards of green building.

2.2 **The economic policy system of China's** building energy conservation

The economic policy method no matter whether it belongs to punishment or incentive is the governmental intervening method based on the theory of classical economics and welfare economics in order to change the marginal cost of benefit subject (DAI Xuezhi, 2007). In China, the economic policy system includes main three parts, economic incentive policy, energy price, and energy conservation label and green building label certification.

In the first part of economic incentive, it contains four main methods: financial subsidy, revenue from tax, lending money to the enterprise and reward. All of those make a few contribution to the five subjects: consumer, which includes the terminal consumer both of individual and company who are all concentrated on the downstream of green building construction; capital construction organization, such as the first class developer who is responsible for preparation of land; development organization, such as the second class developer, owner, estate investor; equipment producer; government.

While in the use of financial subsidy and tax revenue, most of the policy is offered for the development organization, consumers obtain less who would receive more compensation in the second part of economic incentive of energy price policy, especially in the area of renovation of heat metering in north China. However, the conflict between the different economic subjects and the unclear setting of energy price ratio make it urgent to establish a more marketable and efficiency resource allocation.

So in this condition, in order to meet the demand of energy conservation of buildings in the new economy environment, the government in China has developed energy label certification institution to measure the energy usage efficiency of building and offer energy efficiency information for the market, which now not only contains the energy conservation label certification but green building evaluation standard. What's more, another important complement in the guiding policy is the Voluntary Emission Reduction Plan.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.3 The comment of China's energy conservation policy from the aspect of economic efficiency

According to the above analysis, the current China's building energy conservation policies is summarized as following Figure 1, and a further analysis from the aspect of economic efficiency will be made in the next.

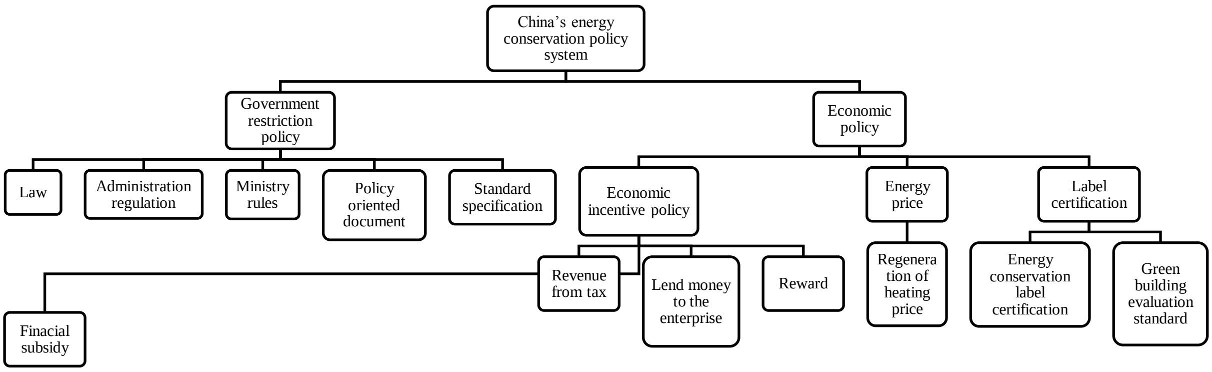

Figure 1: The framework of current China's building energy conservation policy system

2.3.1 The government restriction policy

Theoretically speaking, "order and control" method (government restriction policy) can control carbon dioxide emission of building by a clear and specific standard. While in reality, the standards and related regulations of energy saving may not be assessed by social and economic efficiency, so a suitable emission reduction level of building for the overall social benefit is difficult to be determined. Meanwhile, different developers have different production costs and in the same market there is also concentrating different producing bodies with different marginal costs of energy saving, so "order and control" method which asks for the same level of energy saving measures is not the preferred plan for the whole social economy efficiency.

2.3.2 The economy incentives policy

All the economy incentives in China are equal to a subsidy which transfers the public resource to private part in order to reduce the social influence of externalities. The beneficial parties will give up their originally owned economic property which in fact is the pollution right for producer in the current market mechanism, and in the area of green building construction which is the right of carbon dioxide emission of buildings. Whether the usage of social resource under economy incentives is optimized, it depends on cost of payment by the government (the cost of economy incentives). If the government wants to make use of the economy methods to encourage the property reallocation to reach the destination of mitigation of carbon emission of building, it should take the cost and benefit of the implement of policy and regulation into consideration, which will be discussed in the following part.

3. THE ANALYSIS OF COST-BENEFIT METHOD OF GREEN BUILDING

3.1 The concept of cost-benefit method of green building

Benefit means the increase of human welfare and cost means the decrease of human welfare. So focusing on a policy of green building, it means that the social benefit should be higher than the social cost. There are three basic concepts to further explain the cost-benefit method of green building:

- The impact of environmental damage and pollution caused by the construction of ordinary buildings can be assessed by economic loss and be calculated by economic price;
- In order to avoid the environmental damage and pollution, society will take measures on green building construction which will increase more incremental cost both in the technological application, trading cost, policy cost and all kinds of cost of capital and asset investment;

- The main theory of cost-benefit method is to solve the problem of externality, which is to try to measure the performance of all the costs and benefits by economic price. From the point of view of economy, the value of the cost- benefit method shows the preference of economic subjects, and also shows their willingness to pay.
- Cost-benefit method can give the policy maker a reference on what affects that different subjects impact on the environment and can be easily used in the comparison of policy option on different policy objectives;
- Cost-benefit method brings in the concept of time using the rate of discount to avoid the effect of different cost and benefit level in different time.

As it mentioned before, in order to solve the problem of policy efficiency, it is essential to develop a method to make an analysis on the cost and benefit brought by the policy, which should make the general concept of property theory as its basement and follow the principle of micro economic analysis combining the particularities of problems to establish a full set of operational, suitable and effective principles of property right allocation as concrete means to implement macro goals, which means to apply the cost-benefit analysis method of micro economics to the policy system analysis of the construction of green building and then offer a more objective policy assessment tool.

3.2 The theoretical basis of using cost-benefit method for analysis on economic efficiency of green building policy

Cost-benefit method is widely used in theoretical and practical analysis for climate change and environmental problems based on the following reasons:

- The basic principle of cost-benefit method guides the allocation of resources by measuring the economic benefit, which has wide applicability for policy in current environment with scarce resources;
- The process of cost-benefit method requires all participants outline their cost factor and benefit outcome, which can be formed as a list for reference of policy;
- Cost-benefit method combines the environmental impact with economic and financial effect as a unified way (economic price) to make comparison on every direct and indirect factor;

3.3 The basic model of cost-benefit method of green building

3.3.1 Economic model

Based on the cost-benefit analysis, this part will build a basic calculation model for green building following the three principles: marginal cost and benefit, Present Value and Net Present Value, decision rules.

- Marginal cost and benefit

Under the requirement of economic optimization, it needs to make the marginal cost equal to the marginal benefit, which can lead to an optimized equilibrium point of carbon emission of green building. While in reality government cannot find this point easily due to the policy cost and related particularity of using this method which will be explained in the following part.

- Present Value and Net Present Value

In order to calculate different green building construction means and the same green building construction mean in their different points of a whole life cycle, this part will use Present Value (PV) and Net Present Value (NPV) to calculate different periods of cost-benefit of green building.

The basic Present Value calculation equation is

$$PVc = \sum_{t=1}^{n} \frac{C_t}{(1+r)^t}$$

Equation 1

$$PV_B = \sum_{t=1}^{n} \frac{B_t}{(1+r)^t}$$

Equation 2

Where PV_C= Present Value of total cost of green building, PV_B=Present Value of total benefit of green building, C_t= the cost for the number t years, B_t=the benefit for number t years, r=discount rate, and t=time (year).

The basic net present value calculation equation is

$$NPV=\sum_t^n (B_{jt} - C_{jt} + B_{et} - C_{et})(1+r)^{-t}$$

Where NPV=Net Present Value of low-carbon green building, B_{jt}= basic building benefit for the number t years, C_{jt}= basic building cost for the number t years, Bet= basic green building benefit for the number t years, C_{et}= basic green building cost for the number t years, r=discount rate, and t=time (year).

Equation 3

- Decision rules

There are three decision rules for evaluating cost and benefit of green building:

- o Present value of total benefit should be higher than present value of total cost：

$$PV_B > PV_C$$

Equation 4

$$\backslash NPV > 0$$

Equation 5

$$NPV= PV_B – PV_C$$

Equation 6

- o Benefit-cost ratio：

$$PV_B / PV_C>1$$

Equation 7

- o Internal Rate of Return (IRR) can be used to make an analysis on economic returns of different economic bodies and to make an assessment on an overall cost-benefit returns influenced of different economic bodies on a policy. Calculate net present value of all kinds of cost and benefit and compare IRR of different policies or projects under the condition of NPV=0, and then choose the policy or project with higher IRR. The equation is:

$$B_0-C_0+\frac{B_1-C_1}{(1+i)}+\frac{B_2-C_2}{(1+r)^2}+\ldots+\frac{B_t-C_t}{(1+r)^t}=0$$

Where B_t= the benefit of carbon reduction in number t years, C_t= the cost of carbon reduction in number t years, t=time (year), i= Internal Rate of Return (IRR) of low-carbon green building policy

Equation 8

3.3.2 The cost and benefit factors of policy construction of green building

Under the green building construction policy, the economic bodies should undertake extra cost for carbon reduction caused by non-statutory requirements such as incentives, promotion, education, on the basis of statutory regulatory requirements. Meanwhile, all kinds of bodies can obtain corresponding policy benefit. The concrete cost and benefit that each group (the government, which stands for the overall society; organization, developer and investor including the first and second class developer; consumer and user) are facing under extra cost and corresponding benefit are listed on the Table 1:

	Cost	Benefit
Government	Promotion cost of green building construction	Investment reduction of conventional energy resources
	Management cost of policy implementation	Incremental GDP caused by construction of green buildings
	Financial inventive cost	Incremental job opportunities by construction of green buildings
	Subsidy of new energy of industry	
Organization/ Developer/ Investor	Low-carbon technologies and facilities	Government financial incentives by adopting low-carbon development model
	Green building design, certification and examination	Rise in selling price and renting price
		Company brand value
Consumer/ User	Maintenance and operation management of new energy facilities	Reduction of energy usage
	Extra cost of buying low-carbon green building	Government financial incentives
	Government financial method (the price of heat supply and power supply)	

Table1: The cost and benefit factors for each economic body

3.3.3 The particularity of cost-benefit method of green building

When making a cost-benefit analysis, regulation producer should offer a minimum baseline protection as a rigidity index to guarantee the carbon emission of buildings that is under a safety level to prevent all kinds of groups from irreversibility and maintain basic survival and social interest level. In the analysis of cost-benefit of green building construction, it is necessary to bring in the rigidity index and define the relevant rigid emission index as a constant, and then calculate the highest economic cost of this indicator. In recent international researches, all kinds of Integrated Assessment Model (IAM) are used in cost calculation of carbon emission, by which a pathway of change of optimized carbon emission can be simulated in marginal cost and benefit analysis. These can help policy makers know about the highest level of carbon reduction cost when a policy implement is according to a quantitative carbon reduction index and promote optimization of social resource allocation.

4. CONCLUSION

The current system environment in our country is transforming from the planned economy system to the market economy system, and the function of the market economy is increasingly perfect in the allocation of social resources. The economic means to promote public policy, especially in the face of "public goods" problem of the building energy conservation will be an important direction. The future development of the policy system should follow the dynamic market mechanism and optimize policy system, which must be established on the overall cost-benefit economic efficiency framework. It is necessary to take trading cost of governmental regulation into consideration scientifically and promote the economic incentives to consumer terminal, leading the terminal market demand driven supply.

Meanwhile, it is essential to design a set of operational analysis tools in the project level, and should put the benefits of low-carbon green building construction in a macro economy level from different aspects of economic bodies. More or less, there is an urgent need to establish unified marginal cost (carbon reduction benefit) data guidelines and methods for green building construction policy in China to make the cost-benefit method as the basic policy evaluation method, promote the assessment work of policy means, and develop a basis for estimating social cost of building carbon emissions for the local government. What’s more, green building with incremental costs will bring additional incremental investment, which will lead an additional increase in industrial output during the economic system, and thus will have a macro impact on the overall economy in turn.

Study on Consumers' Willingness to Pay for Products with a Green Building Material Label in Taiwan

TSAY Yaw-shyan[a], CHANG Yi-hsuan[b]

[a] *National Cheng-Kung University, Taiwan, tsayys@mail.ncku.edu.tw*
[b] *National Cheng-Kung University, Taiwan, sunny811104@yahoo.com.tw*

ABSTRACT

Taiwan's government implemented the Green Building Material (GBM) Labelling policy in 2004, and1,448 labels of 10,114 products had already been certified by December 2015. Since 2010, the building code has enforced the mandatory usage of 45% GBM products in the interiors and 10% in the exteriors of public buildings. The reputation of GBML products has been improving recently, and many consumers are requesting the use of GBM products in private buildings as well. Although some industrial investigation studies have been carried out to determine the economic effect of green business in relation to GBM policy, few studies have focused on the value of GBM for consumers.

In this study, we used the contingent valuation method (CVM) to perform a survey of consumers, in which the willingness to pay (WTP) and willingness to accept (WTA) of GBM were calculated. According to the results, the WTP for building material products with GBM was 13.6%, products of a famous brand was 12.2%, and products with both GBM and a famous brand was 15.9%, suggesting that the value of GBM is superior to that of a famous brand and that the label is highly regarded by consumers. On the other hand, the WTA of products without a GBM was 18.5%, without a famous brand was 18.8%, and products without either was 22.8%, thus indicating a positive tendency toward green consumption.

Finally, we performed Spearman's correlation analysis and found that the WTP of GBM was correlated to consumers' education and residence ($p \le 0.05$), while the WTP of famous brands was positively correlated to household income ($p \le 0.01$). A correlation between the WTA of famous brand and education was also found ($p \le 0.05$) in this study. These results can serve as a reference for building material industries that participate in green business.

Keywords: green economics, contingent valuation method, famous brand

1. INTRODUCTION

1.1. Taiwan's green building material labelling system

Before the promotion of green building evaluation and labelling, Taiwan's Architecture and Building Research Institute (ABRI) proposed the Green Building Material (GBM) Labelling system in 2003 and officially launched it in 2004. The goal of the system was to promote a sustainable built environment for the earth and a healthier quality of life for human beings. Taiwan's GBM evaluation system systematically comprises four categories, including health, ecology, recycling, and high-performance, as shown in Table 1. Its assessment generally adopts the life cycle assessment approach to cover the four stages of a building's life cycle: resource exploitation, production, usage, and disposal and recycling (Ho et al., 2008).

According to the Building Technical Regulations, since 2006, GBM must be used for interior furnishings and flooring of a public building and must constitute at least 5% of all decorating materials. In 2009, the utilization percentage was increased to 30%. Since 2010, the building code has enforced the mandatory usage of 45% GBM products in the interiors and 10% in the exteriors of public buildings (Tsay et al., 2015). Thanks to the leading of the policy, despite the economic downturn of recent years, GBM certification has increased significantly over the past ten years, as shown in Figure 1. As of the end of December 2015, 1,448 labels of 10,114 products had been certified.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

1.2. The value of GBM for consumers

The reputation of GBM products has been improving recently, and many consumers are requesting that GBM products be used in private buildings as well. While previous industrial investigation studies have aimed to determine the economic effect of green business in relation to the GBM policy, few studies have addressed the value of GBM for consumers.

Category	Definition
Healthy	A GBM is not harmful for human health and features such characteristics as low emission, low-pollution, low odor, and low physical harm
Recycling	A GBM focuses on the regeneration of recyclable building materials through proper remanufacturing processes to achieve the goal of Reduce, Reuse, and Recycle (3R).
Ecological	A GBM is a natural material that requires less processing and energy consumption, can be easily decomposed, and grows rapidly. Conforming to the local industry is also considered.
High-Performance	Regarding sound insulation, a GBM can effectively prevent noise. Regarding permeability, a GBM can promote water infiltration and retention through its high permeability.

Table 1: GBM categories in Taiwan

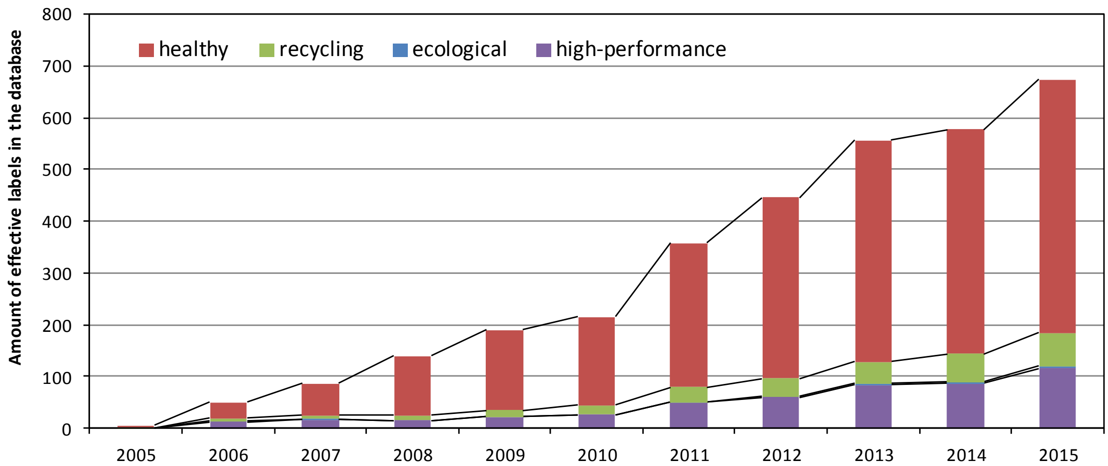

Figure 1: Amount of effective labels in the database

2. CONTINGENT VALUATION SURVEYS

In this study, we used the contingent valuation method (CVM) to survey consumers, in which the willingness to pay (WTP) and willingness to accept (WTA) GBM were calculated. In economics, WTA is the minimum amount of money that a person is willing to accept to abandon a good or to put up with something negative, such as pollution. On the other hand, WTP is the maximum amount an individual is willing to sacrifice in order to procure a good or avoid something undesirable. The price of any goods transaction will thus be any point between a buyer's willingness to pay and a seller's willingness to accept. The net difference between WTP and WTA is the social surplus created by the trading of goods.

WTP is frequently used as a measurement for environmental protection to evaluate natural resource valuations (Kopp & Smith, 2013). Many studies have also used CVM to evaluate the value of products with safety or sustainability certification. Basu and Hicks (2008) studied the WTP of Fair Trade coffee and identified the threshold property of performance-based labels. Furthermore Enneking (2004) performed a CVM survey for the WTP of the Q&S label in Germany and compared it with German premium brands for evaluation.

A CVM survey can be categorized into several methods, including the open-ended method, sequential bids method, dichotomous choice method, and payment card method. To start our empirical research on green building materials, the sequential bids method was applied in this study, using the WTP question "How much percentage extra are you willing to pay for this product?"

The survey was carried out at the 2015 Taipei International Building, Construction & Decoration Exhibition, which is Taiwan's largest exhibition of building materials. We passed out 104 questionnaires and received 102 effective questionnaires for analysis. The questionnaire was divided into two parts, including demographic information and WTP/WTA for GBM products, famous brand products, and both.

The price range of building materials is extremely large so we selected the following seven range options: 0-5%, 6~10%, 11~15%, 16~20%, 21~25%, 26~30% and above 31%. SPSS 2.0 was used for statistical analysis, including descriptive statistics, T-test, and Spearman's correlation coefficient.

3. RESULTS AND DISCUSSION

The results of the survey are shown in Figure 2 and Table2. Of the respondents, 55.9% are female, and 44.1% are male; the majority are under the age of 30, followed by the 31~40 age group; 57.8 % of respondents had a college education, and 30.4% have a master's or PhD; a household income below 0.5 million NTD/year and 0.5~1 million NTD/year are each 33.3% in the survey. Most respondents choose the WTP (extra cost) of 6~10%, 11~15%, and 16~20%, and mostly selected the WTA exceeding 11%.

WTP/WTA (%)	WTP_{GBM}		WTP_{FB}		WTP_{both}		WTA_{GBM}		WTA_{FB}		WTA_{both}	
	N	P(%)	N	P(%)	N	P(%)	N	P(%)	N	P(%)	N	P(%)
0-5	11	10.8	23	22.5	6	5.9	8	7.8	6	5.9	6	5.9

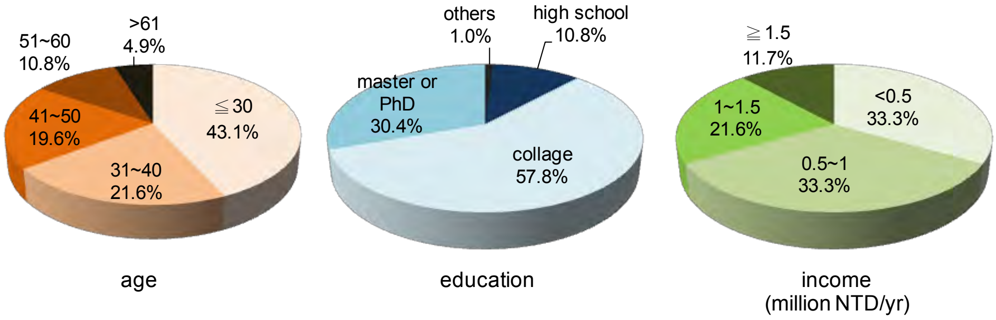

Figure 2: Demographic information of the survey

Figure 3 shows the average WTP and WTA. According to the results, the WTP of building material products with GBM was 13.6%, products of a famous brand was 12.2%, and products with both GBM and a famous brand was 15.9%, indicating that the value of GBM is superior to that of a famous brand, as well as that consumers highly

regard the label. On the other hand, the WTA of products without a GBM was 18.5%, without a famous brand was 18.8%, and products without either was 22.8%, suggesting a positive tendency toward green consumption.

Finally, we performed Spearman's correlation analysis, the results of which are shown in Table 3. In the survey, the WTP of GBM was correlated to consumers' education and residence ($p \leq 0.05$), while the WTP of famous brands was positively correlated to household income ($p \leq 0.01$). A correlation between the WTA of famous brand and education was also found ($p \leq 0.05$) in this study.

Furthermore, the WTA/WTP ratios of 1.36, 1.54, and 1.43 for GBM, FB, and both, respectively, are found in the survey, thus demonstrating that the respondents are conservative (rational) consumers. Note that a higher WTA/WTP ratio shows that the product's characteristics are less likely to compensate. These results can serve as a reference for building material industries that participate in green business.

	Sex	CHD	EDU	Age	Job	Income	Living Area	Know GBM	Ever buy
WTP_{GBM}	.022	-.122	-.199*	.146	-.081	.060	-.221*	-.103	-.100
WTP_{FB}	-.089	-.021	-.159	-.027	-.093	.271**	-.151	-.038	-.145

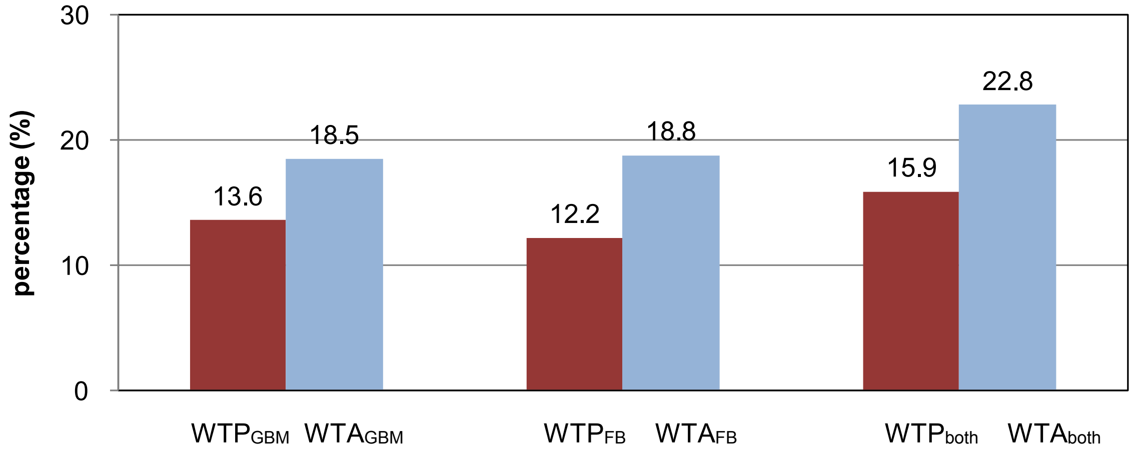

Figure 3: Results of average WTP/WTA

4. CONCLUSIONS

In this study, we carried out a survey based on CVM and calculated the WTP and WTA of building material products with GBM, famous brand, and both in order to evaluate the effect of GBM policy on the market and consumers. The results show that the WTP of GBM is 13.6% (extra pay), which is superior to famous brand products. The WTA values range from 18.5~22.8%, which are higher than the WTP in all categories.

In the survey, the results demonstrate a positive tendency toward green consumption and can be used as a reference for building material industries that participate in green business.

ABSTRACT

For more than 10 years, Taiwan has promoted environmental education in its schools and has even incorporated it into the curriculum guidelines for compulsory education of grades 1-9. Previous studies on the theory of education have suggested that by treating school campuses as a three-dimensional textbook, architects' designs can potentially provide many benefits for environmental education activities. The education provided in elementary schools is crucial for developing both children's personalities and their physical bodies. Teachers can use a variety of methods to provide environmental education and can even integrate the campus facilities/ space to improve the effectiveness of children's learning, thus influencing the practice of environmental education. Therefore, determining how to implement environmental education concepts in campus design is vital for architects.

In this study, we propose an assessment framework for elementary schools based on a reference review, which includes green campus design principles, children's learning development, and Taiwan's eco-school reform project indicators. We then used the resulting framework to assess the facilities/ space of 13 exiting campuses designed by famous architects or that had received funding from eco-school projects. The results showed that the architects' design strategies for eco-schools may not be appropriate for environmental education, and this study's proposed framework can provide a better thought process for relevant architects.

Keywords: assessment framework, design principles, field investigation

1. INTRODUCTION

In 1972, the United Nations published the Belgrade Charter, which defines the implications of environmental education in both formal and non-formal settings. Elementary and secondary education are undoubtedly the basis of formal education, so Taiwan began promoting environmental education in schools 10 years ago and, in 2008, even incorporated it into the grade 1-9 curriculum guidelines for compulsory education. Furthermore, in order to follow the "green campus" trend that has been promoted for years, Taiwan's Ministry of Education has established the "Sustainable School Project," which not only embodies the concepts of sustainable development but is also imbued with meaning for Environmental Education.

A school building is a teaching field established to achieve educational goals. Higgs and McMillan (2006) proposed that campus architecture as a "three-dimensional teaching material" can aid both teaching and learning. Many scholars have aimed to connect architecture and EE by designing physical environments as a Three-Dimensional (3-D) Textbook (Orr, 1993; Taylor and Enggass, 2009). Therefore, all on-campus facilities are part of overall campus planning, and the designers should consider education significance and determine the possibility of using it as a teaching aid.

The environment is an essential element of human living. In particular, the environment around children can significantly influence their development. Campus space facilities are a part of campus planning and are related to children's physical and mental development. Working on children's environments, Clare Cooper Marcus (cited in Loebach, 2004) explains that "children are more deeply affected by the environment than any other age group". Furthermore, according to Havighurst's (1972) theory, the learning development task of children between the ages of 6 and 12 years old can be divided into five major categories, which are physical development, cognitive development, moral development, social development, and emotional development.

Kong, Rao, Abdul-Rahman, and Wang (2014) focused on Bali's Green School as their research object to determine the relationship between campus and environmental education. After collecting data and interviewing experts and scholars, they proposed four attractive spatial characteristics for children, which are transparency, nature, creativity and imagination, and active learning. In this study, according to the results of our analysis, we determined the key characteristics and expanded them into a broader framework as a reference for campus architects.

These studies have shown that an elementary school has the opportunity to become a 3-D Textbook campus. If the architects that design schools incorporate EE, learning, and child development from the beginning, schools have the chance to become better learning fields. In this study, we proposed an assessment framework that we hope will help both architects and teachers.

2. METHODS AND PROCESS

2.1 Creating the assessment framework

This study aims to propose evaluation indicators to serve as references for architects. After a review of the literature, the study verified indicators, comparisons among indicators, and confirmation of actual cases. Then, according to these indicators, we proposed a design program. Based on the results of the literature review and our analyses, we developed a school building and space with environmental education concepts that not only meet the spatial needs of the campus but also have broader connotations of both complying with environmental education conceptual principles (Kong et al., 2014) and child learning and development (Toronto District School Board, 2013). Among the learning and development of children, the contents of both affective development and cognitive development are similar and can be integrated with nature-inspired and activated facilities; furthermore, we added the two indicators of science and technology and health and safety to this study, as shown in Table 1.

Main perspective	Secondary perspective	Evaluation factors
Design principles of sustainable environmental education	Obvious cue	a1. Exposure of natural building materials
		a2. Exposure of green construction equipment
		a3. Explorable ecology or procedures
	Nature-inspired (affective development)	b1. Indoor and outdoor natural relationships
		b2. Learning in an outdoor natural environment
		b3. Local characteristics of natural resources
	Innovative problem solving	c1. Aesthetic and creative facilities
		c2. Creative reuse of recycled wastes
		c3. Operating spaces for experiments
	Activated facility (cognitive development)	d1. Operable buildings and facilities
		d2. Open multipurpose spaces
		d3. Thematic space (such as animal farms or tree houses)
	Science and technology	e. An application of electronic equipment for transformation into easier concepts for perception.
	Health and safety	f. Focus on safety, health, and hygiene
A learning and development framework for children	Social development	g. Facilities as outdoor learning classrooms for two to three groups of children to undergo static or dynamic activities
	Physical development	h. Facilities that allow children to partake in physical activities

Table 1: Assessment framework for the environmental education functions of campus facilities

2.2 Comparison of indicators for a sustainable campus

One of the purposes of a sustainable campus is to develop a learner-friendly community environmental education center. Chen (2007) proposed the essence of environmental assessment indicators for sustainable campuses in elementary schools. We compare the assessment indicators proposed by Chen (2007) with the environmental education indicators for campus facilities found in this study with the goal of determining differences in order to explain the insufficient and improvable indicators for a sustainable campus in this study. Figure 1 shows the results of analyses after comparison.

From our comparison, we first found that the indicators for sustainable campus lack the spirit of children's development and learning. In children's growth stage, the essential activity space for playing games and conducting social activities is not mentioned. Second, children in this stage need a variety of functional spaces to inspire their creativity as one kind of learning, but the sustainable campus indicators do not mention such an item. Third, the indicators for sustainable campus do not reflect the needs of elementary school students. From a "campus as three-dimensional teaching materials" perspective, if the design of a campus cannot vary with students of different ages, it would not effectively be in line with the educational spirit of implementing different teaching methods for students of different ages. Therefore, environmental education indicators in campus facilities have to cover two perspectives: the sustainable campus and the learning and development of children. Children's learning and development can reflect the learning needs of children in this stage, which could better reflect the design spirit of an elementary school campus.

2.3 Field study for verification

This step is to verify the indicators proposed in this study in an actual environment. Using the facilities in elementary school campuses as objects, this study covers the following three types of schools: the supporting targets of a sustainable campus, the 921 new school movement, and excellent design cases. These three types have individual reference values. Using regional distribution, we selected 13 elementary school campuses to serve as the preliminary research objects. With prevalent investigations (observations, photo taking, and interviews), we carried out evaluations according to the constructions (Table 1) previously proposed to research the relevance between facilities in campus spaces and environmental education.

3. RESULTS AND DISCUSSION

In this study, we divided common outdoor facilities on campus into the following four categories: games facilities, green building machinery, ecological facilities, and independent functional facilities. Table 2 shows the verifications of these four categories of outdoor facilities according to the corresponding evaluation indicators. We selected three cases in this study to determine the feasibility of the optimized designs, which are shown in Table 3 ~ Table 5.

After evaluation using the case-by-case evaluation indicators, we summarized our results into the four items described below. First, Table 3 shows the common ecological facilities. For these facilities, relevant people need to pay more attention to whether they are in line with environmental issues from an ethical perspective. If local ecological characteristics can be shown on the edge of campus, school students have the opportunity to observe them when they go to and leave school, which allows the campus to highlight the idea of sustainable development in a community environmental education center. Second, the natural environment is the best playground. Integrating games facilities with the natural environment encourages children to combine games with cognitive development, which is more closely in line with the concepts of learning from games, as shown in Table 4. Third, some campus facilities do not meet the requirements of environmental education indicators. For example, the green building machinery (Table 5) in DaFu Elementary School (no.7) applied grills that obstructed the outer spaces, which is not in line with the design principle of obvious cues and creates disadvantages when teaching. Instead, the school could remove the grills to make it more convenient to observe the teaching situation. Furthermore, the school could improve the construction of facilities to enhance quantification and visualization (Kasai & Araki, 2015), which will help teachers provide lessons related to environmental education or natural science (materials). Fourth, the independent functional facilities on campus should consider how to combine the characteristics of spaces with the surrounding environment. For example, the integration of the natural landscape (nature-inspired) or other facilities (such as leaves for composting) makes the space a work zone for mutual learning (social development).

Table 2: Classification and evaluation of spaces and facilities of campus

School no.5: Ecological corridors for crabs		
	→Field Observation: Since crabs live in the neighboring waterfront near campus, the ecological restoration corridor was established. However, information obtained from an interview indicated that fry in a nearby fish farm would fall prey to the crabs. Therefore, this corridor has already been abolished in response to protests from fishermen. →Matched item: None (not in line with the application according to local conditions from the perspective of nature-inspired principles)	
Direction of optimal designs：■Nature-inspired		
■Nature-inspired： _ Learning in an outdoor natural environment(b2) _ Local characteristics of natural resources(b3) Explanation: In addition to ecological ethical considerations, ecological corridors could be established alongside the paths that students]walk by on the way to school or on the way home every day. By doing so, path learning concepts are in line with the idea of learning in the natural environment.	 Portland Green Street	 NTUT ecological fences

Table 3: Ecological facilities on campus (Eco-design suggestions)

School no.3: Games facilities in atrium	
	→Field Observation: Games facilities with soft cushion on the ground are uncommon in elementary schools, but they allow the facilities to be incorporated with the natural environment and elevate affective development, as well as enhance the shading effects. →Matched items: ■Physical development ■Health and safety
Direction of optimal designs: ■Nature-inspired ■Innovative problem solving	

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Direction 1; ■Nature-inspired _ Learning in an outdoor natural environment (b2) Explanation: Alter the relationship with nature and work with nature to incorporate the natural environment into the playground. 	Direction 2; ■Innovative problem solving _ Aesthetic and creative facilities (c1) Explanation: Alter the relationship and combine with small trees and glass houses to turn the games facilities into castles. 	Direction 3： ■Innovative problem solving _ Aesthetic and creative facilities(c1) Explanation: Alter the structure and use natural elements. 

Table 4: Games facilities in the atrium (Suggestion of eco-designs)

School no 5: Recycle facilities for rainwater		
	→Field Observation: The recycling facilities for rainwater in DaFu Elementary School (no.7) are surrounded by rainwater recycling bins, which makes students less likely to take the initiative to observe and contact them. →Matched item: None (already better than those that are completely sheltered)	
Direction of optimal designs：■Obvious cue ■Innovative problem solving		
Direction 1: ■Obvious cue: _ Exposure of green construction equipment(a2) Explanation: Removing the grills to expose building facilities, which makes it easier for teachers to teach and students to contact and learn. 	Direction 2: ■Obvious cue: _ Exposure of green construction equipment(a2) Explanation: Explanation: Combined with the building, the transparent floor makes the graduations on it visible, thus making it convenient for students to learn. 	Direction 3: ■Innovative problem solving _ Aesthetic and creative facilities(c1) Explanation: Alter the materials to make them transparent and quantifiable, thus allowing the students to more easily contact the information related to the measurements. 

Table 5: Recycling facilities for rainwater (Eco-design suggestions)

Category	Space name	Priority of evaluation indicators for review	Implications of incorporating environmental education
Games facilities on campus	Games facilities in the atrium, games facilities under trees, tree houses, platforms, and bunker	•Innovative problem solving (can incorporate waste reuse into their life) •Nature-inspired (Use local natural materials in manufacturing) •Physical development •Health and safety	This category of facilities is functional and emphasizes the physical development of children. Furthermore, using local natural materials in manufacturing can reduce the carbon emissions, thus complying with the spirit of sustainable development. Combining the planting of flowers and grass with different games, the facilities can better reflect the idea of learning through games.
(Green) Building machinery on campus	Rainwater recycling facilities, energy revealing facilities, and integrated wind and lighting pumping system	•Obvious cue (Expose construction equipment)	This category of facilities focuses on obvious and exposed cues. The designer should pay more attention to visualization and quantification perspectives, which allow for connections with teachers' instruction and allow students to observe and record naturally.

Ecological facilities on campus	Waterwheel in paddy, ecological corridors, natural farm, flower garden next to the classroom	•Nature-inspired (In line with application according to local conditions and natural characteristics/ learning in the natural environment)	This category of facilities emphasizes applications according to local conditions. Each base should take proper advantage of natural resources and take notice of location characteristics while designing. The locations should clearly arouse the spontaneous exploration and learning of children and thus provide better benefits.
Functional space facilities on campus	Recycling area, Semi-outdoor workshop , outdoor ladder theater	•Activated facility (Allows students to alter, take care of, and operate) •Nature-inspired (Near nature) •Social development (Form a working zone)	This category of facilities has independent functions. When combined with other facilities with similar characteristics, a working zone can be created to increase the opportunities for communications and learning among children, and teachers can design organizational environmental education lessons (such as resource flow cycle).

Table 6: Results of evaluation

4. CONCLUSION AND DISSCUSSION

This study is a preliminary investigation for campus building and environmental education. We selected 13 elementary schools to evaluate and verify. As shown in Table 6, the operational procedures of space facilities in campus design are initially qualitative and quantitative developing processes and cannot provide standard answers. This study has summarized the theories about environmental education from previous articles and carried out confirmation in order to provide architects with a set of referable indicators during their design procedures. Architects should maintain the core values of innovative inspiration in their building designs. However, with these verified standards and software teaching materials, they can better implement environmental education in campuses.

ABSTRACT

Green building is an essential component of sustainable development, but the benefits of and barriers to green building implementation in Hong Kong are unclear. A literature review and in-depth interviews were conducted to address this gap in our knowledge. The literature review results suggest that green building implementation leads to a reduction in lifecycle costs, occupant health and efficiency improvements, greater energy savings and efficiency, fewer environmental effects, and tax and market benefits. The barriers to such implementation include high initial costs, a lack of awareness and knowledge, a lack of financial incentives and government support, stakeholder conflicts, uncertainty and risks, and possible project delays. To address the impediments and promote green building implementation in Hong Kong, four interviews with green building specialists in Hong Kong were conducted, with attention paid to the distinct characteristics. The results suggest that the joint efforts of the Hong Kong Green Building Council and the government have led to some green building achievements in Hong Kong, although significant barriers remain, including high initial costs, insufficient market transformation, knowledge gaps, a lack of incentives for existing buildings and the public, and uncertainties and risks. Solutions to these urgent problems are proposed from the perspective of practitioners in green building. Market transformation can be driven based on the establishment of related policies and regulations by the government. The public mind-set and behaviours can be changed through education initiatives. More incentives should be issued to promote developers to turn traditional buildings into green ones. Besides, communication platform among stakeholders should be developed including project-specific platform and industry-wide one. It is also recommended that future research may focus on how to make existing buildings more efficient or on the development of business models for effective upgrades to such buildings.

Keywords: green building management, benefits and barriers, Hong Kong

1. INTRODUCTION

As part of the larger concept of sustainable building, green building is specifically defined as “the implementation of a sustainable design” (Montoya, 2010; Sillah, 2011). The design and construction of green buildings are based on the principle of sustainable development. To implement green building is to incorporate energy-saving features, water conservation, waste minimisation, pollution prevention, resource efficiency and indoor environmental quality enhancement in the building lifecycle, from siting to design, construction, operation, maintenance, renovation and deconstruction (Tam et al., 2012; Barnes, 2012). Most green building studies focus on the site, water, energy, material and indoor environment perspectives (Montoya, 2010). Sillah (2011) pointed out that in site layout and use for green construction, one goal is to reduce disturbance to the site to protect the surrounding habitat and environment. With regard to construction waste management, the employment of a waste management company and on-site waste sorting are effective ways to minimise construction waste (Glavinich, 2008). During the green building operation and maintenance phase, a post-occupancy evaluation can be made to test indoor air quality and energy use (Newsham et al., 2013). Zuo et al. (2014) conducted case study which shows that although green buildings have higher initial costs, residents’ long-term energy bills are significantly reduced. Kim et al. (2014) built a linear regression model to predict the lifecycle energy-saving trends of green buildings. Their lifecycle cost analysis demonstrated that the initial investment is recouped, with a profit earned over the entire lifecycle.

Hong Kong, one of the world’s most recognisable cities, is characterised by a high-rise, high-density urban environment, which makes energy reduction more of a challenge than in many European and North American cities. At the same time, space and natural resource limitations mean that waste recycling and reuse are matters of urgency. According to a recent Hong Kong report published by Construction Industry Council and Hong Kong Green Building Council in 2014, almost 90 per cent of electricity in Hong Kong is consumed by buildings, which also account for 60 per cent of greenhouse gas emissions. Green building implementation is thus important to balance development and environmental concerns. However, there is a lack of quantitative and comprehensive research focusing on the advantages of and obstacles to green building development in Hong Kong. Identifying the hurdles that are impeding such development is an urgent objective in the construction industry.

The aim of this paper is to elucidate the benefits of and obstacles to green building implementation in Hong Kong and to promote corresponding solutions. Content analysis and face-to-face interviews were used in the study reported herein to investigate the current green building development situation, laying the foundation for a further study on green building construction.

2. LITERATURE REVIEW

2.1 Benefits of green building

Green building is an environmentally friendly practice that is also conducive to social values (Tam et al., 2012). Its advantages are thus economic, social and environmental. The literature review identified several of the benefits of green building, which are listed as follows.

- Reduction in lifecycle cost. Yudelson (2008) pointed out that although the initial cost of a green building is 1 or 2 per cent higher than that of a non-green building, it offers long-term savings and a shorter payback period. Investment in green materials and technologies and the advance identification of potential problems with building operation make it easier to operate and maintain green buildings (Mathieson et al., 2008).
- Improving the health and efficiency of occupants. As Sillah (2011) and Ajilian (2014) state, green buildings offer a better indoor environment, including better indoor air quality, thermal comfort, clean water, effective lighting and a comfortable noise level, which brings health benefits to those who live and work in them. Working and living in a comfortable environment also promotes greater efficiency.
- Greater energy savings and efficiency. Studies suggest that many green buildings are designed to use 30-50 per cent less energy than traditional buildings, leading to significant energy efficiency improvements (Yudelson, 2008). Moreover, the energy-saving strategies adopted in green building design, such as green roof systems, active walls, Low-E glass, efficient HVAC and cooling systems, and light-emitting diodes, not only meet the requirements of users, but also save on limited energy resources (Kubba, 2010; Sillah, 2011).
- Lower environmental impact and preservation of ecosystem. As green buildings are designed and constructed in an environmentally friendly manner, a balance between building and ecosystem is sought throughout the building lifecycle. Such green strategies as renewable energy use and waste management can reduce energy consumption and the exhaust gas emitted into the environment, thereby protecting the ecosystem (Mathieson et al., 2008; Ajilian, 2014).
- Tax benefits and incentives. To create enthusiasm for green building development, many governments offer tax benefits and incentives in the form of cheaper land prices and green materials (Kubba, 2010; Zhang et al., 2011). Yudelson (2008) reported that, in the US state of Nevada, green buildings that achieve Leadership in Energy and Environmental Design (LEED) silver certification are eligible for tax abatement, and the state government also provides a sales tax rebate on green materials used in LEED silver-certified buildings.
- Market benefits. Many private and public developers and owners gain marketing benefits from constructing LEED-certified green buildings (Yudelson, 2008). For instance, green buildings promote product differentiation in the construction market and garner positive free press coverage (Sillah, 2011).

2.2 Barriers to green building

Although green building offers the numerous benefits outlined above, there are still obstacles to its implementation, such as higher transport, material and design costs relative to conventional buildings (Tam et al., 2012). The major barriers collected from the comprehensive literature review are listed as follows.

- Higher initial investments and costs. The initial cost of a green building is higher than that of a traditional building because of green requirements. Tam et al. (2012) pointed out that the larger initial investment needed results from the adoption of green and new technologies and the top-down construction method. Green building practices also need more time for implementation, which also increases costs (Richardson and Lynes, 2007; Sillah, 2011).

- Lack of public awareness and knowledge of green principles and technology. Although the number of green buildings has grown steadily in the past few years, green building remains a relatively new field, and green knowledge and technologies are still in the early stages of development (Sillah, 2011). Insufficient professional knowledge of and expertise in green technologies and methods lead to a vague understanding of the green building concept and a lack of awareness of the green tools and materials available, which hinders the implementation of green strategies.
- Lack of financial incentives and government support. The lukewarm attitude towards green building exhibited by the senior management of many development firms may directly or indirectly reduce the efficiency of green building practices (Lam et al., 2009). This lack of management support further deprives contractors of incentives to achieve green building goals. At the same time, insufficient government support often hinders green developers from accessing low-risk and affordable financial resources (Samari et al., 2013).
- Interest conflicts amongst stakeholders. As the initial cost of green buildings is higher than that of traditional buildings, the initial investment required of developers is also higher, whilst the benefits, e.g. a better indoor environment and reduced energy consumption, accrue primarily to tenants, resulting in an unequal distribution of benefits (Williams and Dair, 2007; Zhang et al., 2011; Hwang and Tan, 2012).
- Uncertainty and risks in investment and materials. Uncertainty and risks are greater in green buildings than in conventional buildings because they involve different contract types, methods of project delivery, and on-site practices and behaviour. Furthermore, when green buildings are completed, there is the risk of not obtaining green building certification (Glavinich, 2008).
- Lack of credible research and case studies on green building performance. There is inadequate information on green products and sustainable building systems to inform green building implementation (Hwang and Tan, 2012), as well as an insufficient number of case studies showing that green buildings have lower operating costs and greater environmental efficiency. Hence, the mainstream market does not realise the superior performance that green buildings offer (Sillah, 2011).
- Possible delays due to green requirements. As there are green material and green technology requirements in green construction, green buildings take longer to realise (Lam et al., 2009). In addition, unfamiliarity with green technologies can also result in delays in green design and construction (Zhang et al., 2011).
- Insufficient technologies strategies and time to drive green building. If there is not enough time and funding to support green building implementation, designers and constructors also have limited time to apply new green building technologies and strategies.

3. RESEARCH METHODOLOGY

The literature review carried out for this research identified six benefits of and eight barriers to green building implementation. To explore those benefits and barriers in the context of Hong Kong green building practices, four specialists in the green building construction sector were invited to participate in face-to-face interviews. They are all experienced BEAM professionals involved in Hong Kong green building development. Target specialists were contacted to determine whether they would be willing to be interviewed, and an interview guide introducing the research and giving details of the proposed interview was also provided for their reference. Each interview lasted about 30 minutes, and the questions focused on the current status of green building development in Hong Kong and the performance-related issues and barriers encountered in green building implementation.

According to the research conducted by Zuo et al., (2014), content analysis is a common approach for qualitative data analysis in built environment-related studies. In this research, qualitative content analysis was used to analyse the interview data. For qualitative content analysis, the emphasis is to determine the meaning of the data. So words or phrases which have similar meanings were noted in the analysis.

Coding is a process of segmenting and labelling text to form descriptions and board themes in the data. Coding was also conducted in this research to analyse the interview data. To conduct coding conveniently, the authors designed three columns one page, the interview record was shown in the middle column, codes that describing the text segment were written in the left column, and corresponding themes were in the right one.

4. RESEARCH FINDINGS AND DISCUSSIONS

4.3 Benefits of green building development in Hong Kong

Reducing energy consumption. Hong Kong has limited space and few natural resources, and green building developments, plans and actions have been formulated to reduce energy use. Examples include the establishment of the Buildings Energy Efficiency Ordinance and the Energy Audit Code.

Improving environment protection. Green building is an effective way of resolving pressing environmental issues such as global warming and climate change. By using green materials, technologies and strategies such as passive design, rainwater recycle systems, green roofs and green walls, buildings can reduce their impact on the environment and ecosystem.

Strengthening waste management. Hong Kong also has limited landfill space, and three-quarters of its land area is undeveloped or designated as country parkland. A recent Hong Kong report showed the city's daily per capita domestic waste generation to be higher than that of other Asian cities, with construction waste accounting for nearly 25% of solid waste. Waste management can be improved through green building development and the wider application of "reduce, reuse, recycle" principles.

Improving building liveability and occupant health. Green buildings improve the well-being of their occupants. When developing a green building, a green built environment is also involved, and when public space is designed in accordance with green standards, the entire district benefits.

Financial and market benefits. As noted, the government implemented a policy to promote green building development in 2011, i.e. the offering of GFA concessions to buildings that participate in BEAM PLUS, which has boosted the number of such buildings significantly. Developers that wish to participate in the system must undergo a BEAM PLUS assessment if they want to gain the concession.

4.4 Barriers to green building development in Hong Kong

Higher initial costs. The greatest obstacle to green building development in Hong Kong is the high initial cost. Developers must invest more in buildings that incorporate certain green features. Although green buildings may produce cost-savings over the entire building lifecycle, developers involved in speculative building are generally more interested in obtaining a quick return on their investment.

Insufficient market transformation. When looking to buy a property in Hong Kong, most members of the public are more interested in the proximity of public transport options, building materials and the appearance of the building than with green features, which are not seen as directly related to health and well-being. Hence, a green building market transformation needs to take place before green building implementation will become widespread.

Knowledge gaps. There are still a number of knowledge gaps concerning green building in the construction industry. Even when industry participants pursue the concept, they may be unaware of the best way to manage green building design, development or construction. Furthermore, the public does not yet value green features, which directly discourages developers from developing green buildings.

Lack of incentives for existing buildings. Unlike the GFA concessions available for new buildings, there are no direct incentives to implement green features in existing buildings in Hong Kong. Hence, few owners of existing buildings are willing to participate in assessments to obtain a green building rating. In fact, fewer than 10 existing buildings participate in BEAM PLUS.

Lack of incentives for the public. As electricity and water remain relatively cheap in Hong Kong, the general public has few incentives to pursue energy or water-saving measures. In addition, few people in Hong Kong relate global warming to their own lives or understand the effects it is likely to have on them or their children, and thus do not treat green features as an important factor in choosing a building in which to live.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Uncertainties and risks. Those applying for a green rating are often unsure about the rating they will attain, as there are numerous green projects and assessors with different assessment criteria. Moreover, it takes a considerable amount of time to obtain a very high rating, which can delay projects and increase costs.

4.5 Suggestions for green building development in Hong Kong

As there are many problems to be solved in Hong Kong, different parties have different priorities for resolving them. According to the interviewees, the most urgent challenges preventing more widespread green building implementation are the need for market transformation, a mind-set change and more promotion from the government.

Driving market transformation. Hong Kong enjoys a high level of technological advancement, which should make it easier to drive market change. One of the interviewees' key suggestions for promoting green building in Hong Kong is to drive market transformation by supporting the government's establishment of related policies and regulations.

Changing the public mind-set and behaviour. Key to changing the public mind-set is for the government to set a benchmark for general facilities. The government should also develop a way for owners to submit building data. If certain features fall below a certain standard, the government can then require that renovations be carried out. Tenants' behaviour can be changed through education initiatives than convince them that green behaviour and green building practices are beneficial to their quality of life and reducing costs.

More government incentives. The government and related organisations need to invest in more green promotion efforts targeting developers and the general public. The HKGBC has launched a number of marketing promotions, but more needs to be done. Existing buildings in particular are in urgent need of incentives for green feature implementation. Finding a way to incentivise developers to turn traditional buildings into green ones remains a challenge, although the HKGBC is currently in talks with the government to develop incentives for existing buildings.

Developing a platform for feedback. Developing an effective platform for feedback between end-users and the government or industry participants requires effective communication amongst those parties. It is very important to build both project-specific platforms and an industry-wide platform. For the former, post-occupancy evaluations are essential, as they allow the identification and notification of weaknesses. For the industry-wide platform, it is important that green building rating tools be improved to upgrade the assessment system.

5. CONCLUSIONS

Green building is an effective way of building a sustainable built environment. In the research reported herein, semi-structured interviews were conducted in Hong Kong to review the green building development process and related benefits, problems and solutions in conjunction with a review of the literature. The research findings suggest that the major problems with green building practice include higher initial costs than traditional buildings, insufficient market transformation, knowledge gaps, a lack of incentives for existing buildings and the general public, and uncertainties and risks (Lam et al., 2009; Zhang et al., 2011; Samari et al., 2013). To resolve these problems, the practitioners interviewed suggested that it is important to drive market transformation, change the mind-set and behaviour of the general public, implement more government incentives or regulations, and develop project- and industry-level platforms for communication. The interviewees further indicated that existing buildings constitute a major area for improvement to further green building development in Hong Kong. It is recommended that future research focus on how to make existing buildings more efficient or on the development of business models for effective upgrades to such buildings.

[b] *Kogakuin University, Japan, yusuke@cc.kogakuin.ac.jp*

ABSTRACT

In late years the introduction of the environment-conscious technologies such as photovoltaic power generation is increasing in school facilities. Environment-conscious technologies are demanded to be used by environmental education. However, it is the present conditions that the mechanism of the environment-conscious technologies is out of teacher domain, so these technologies aren't used for environmental education.

In a previous study, development of "the environment-conscious technologies guidebook" and its environmental learning contents were carried out. However, for the lack of the method of teaching and correspondence with a unit list, it was difficult for teachers to use it.

In this study, "the environment-conscious technologies guide" which incorporates an annual unit list of textbooks compliant with the environment-conscious technologies and example method of teaching was developed. The example method of teaching has time schedule and main point of teaching with some photographs and illustrations. Therefore, teachers are easy to understand the flow of the class. Using this example method of teaching, teachers can perform environmental study class by their own effort. As the result of trial classes using the guide, it was found that teachers could make documents for classes and explain them by their own effort.

Keywords: education and training, environment-conscious technologies, schools

1. INTRODUCTION

In school architecture in recent years, environment-conscious technologies such as photovoltaic power generation have been increasingly adopted not only at environment-conscious schools built to achieve building energy conservation and promote environmental education, but also at ordinary elementary schools. Since environment-conscious technologies are located in the student's immediate environment, there are expectations this will improve awareness of environmental problems, and thus there is a need to use these technologies in environmental education. However, for teachers, knowledge of the mechanisms of environment-conscious technologies is outside their specialization, and therefore at present even the environment-conscious technologies at environment-conscious schools are not adequately used for environmental education.

In past research, a proposal has been made to teach classes by producing an "environment-conscious technologies guidebook" to help teachers giving the class. However, it was found that the approach was inadequate to allow classes to be given by teachers alone because the explanations in the guidebook were still too difficult, and there was no correspondence with units.

Thus the purpose of this study was to develop a guide for environmental study classes incorporating an annual list of units bringing environment-conscious technologies into correspondence with the units in actually used textbooks, and a detailed example of how to proceed with the class.

2. ACTUAL SITUATION OF ENVIRONMENT-CONSCIOUS SCHOOLS AND ENVIRONMENTAL STUDY CLASSES ACCORDING TO PREVIOUS RESEARCH

Many environmental study classes in recent years have used social problems as a theme, and as part that, class formats are frequently based on observation, field trips and experiences in the area of coexistence with nature and garbage problems. However, with regard to global warming and energy conservation, classes do not often have an experience-based format using the environment-conscious technologies adopted in elementary schools.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

On the other hand, in certifying environment-conscious schools, the Ministry of Education, Culture, Sports, Science and Technology asks each certified school to conduct environmental study classes using adopted environment-conscious technologies. A questionnaire survey regarding environment-conscious technologies and environmental study classes was administered to environment-conscious schools by our laboratory in 2013. According to this survey, current conditions are such that schools which actually hold classes are extremely few in number, about 70% of the schools for which questionnaires were returned. As problems, respondents frequently mentioned struggling with how to use environment-conscious technologies in class, i.e., “It is difficult to think of class content,” and “I don't know how to make use of adopted technologies.” For this reason, there is thought to be a strong need for a guidebook on environment-conscious technologies.

3. NVIRONMENT-CONSCIOUS TECHNOLOGIES GUIDEBOOK, PROPOSAL AND ISSUES

In drafting an environment-conscious technologies guidebook, existing instructional materials for environmental study from all over Japan were investigated, with a focus on determining whether they include material on environment-conscious technologies and energy problems. In the results, there were almost no instructional materials or guidebooks with content relating to environment-conscious technologies or energy problems.

Therefore in 2014, our laboratory drafted an environment-conscious technologies guidebook, and environmental study classes for elementary school students were conducted based on the environment-conscious technologies guidebook. In addition, an interview survey was conducted with teachers who used the environment-conscious technologies guidebook. The teachers’ opinions included: “environment-conscious technologies are difficult because that content is not in the textbook,” “I don’t know which is the corresponding unit in the textbook,” and “it is easier to devise the structure of the class if there is guidance plan or something similar.”

The above results indicate a need to draft materials so that the environment-conscious technologies guidebook includes an annual unit list for each school year, showing the correspondence with environment-conscious technologies, and a guidance plan matched to the structure of the environmental study class. In addition, teachers have only limited time to prepare the structure of an environmental study class, and thus there will likely be a need to make the materials easy to understand, by simplifying explanation of environment-conscious technologies, and adding illustrations and text.

4. DEVELOPMENT OF GUIDE FOR ENVIRONMENTAL STUDY CLASSES

5.1 Composition of the guide for environmental study classes and composition of each technology

In this study, it was decided to use the name “guide for environmental study classes” (indicated as the “class guide” below) for materials incorporating an annual unit list brought into correspondence with environment-conscious technologies for each school year, and a guidance plan suited to the structure of environmental study classes, into the previous environment-conscious technologies guidebook. This class guide was then developed.

Figure 1 shows the composition of the class guide. “Chapter 1: Introduction” incorporates the background behind preparation of the guide for environmental study classes, and an annual unit list corresponding to environment-conscious technologies. “Chapter 2: Environmental problems (Global warming)” describes the environmental problems which serve as the lead-in in environmental study classes, and the reserve-production ratios for fossil fuels. “Chapter 3: Environment-conscious technologies adopted in schools and their use in classes” describes examples of use for each technology to serve as a reference for environmental study classes. “Chapter 4: Conclusion” provides requests for the class guide user and a questionnaire to be filled out after use. In addition, the “Materials section” includes PowerPoint files for classes at schools which actually assisted with preparation of the guide, and worksheets that can be used as is in class.

Figure 2 shows a conceptual illustration of an environmental study class using the guide for environmental study classes. Having teachers conduct classes using the class guide improves awareness of environmental problems among teachers, children and parents/guardians, and may also be effective for conserving energy at school and home due to implementation of energy conservation activities.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

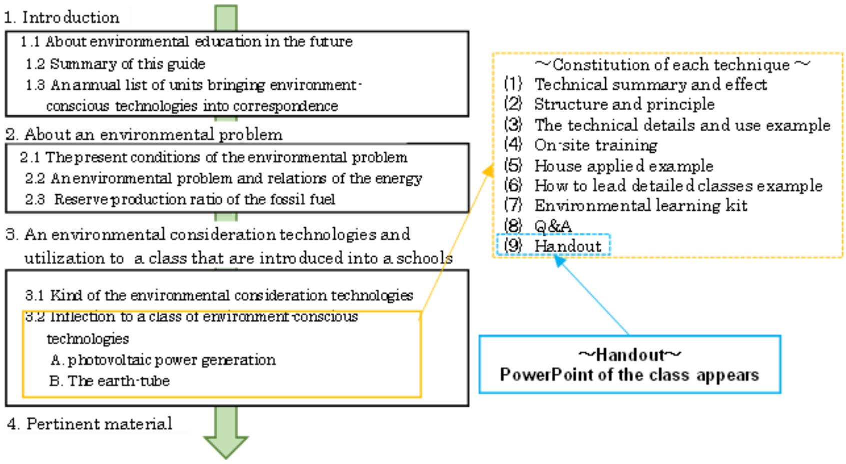

Figure 1: The composition of the class guide

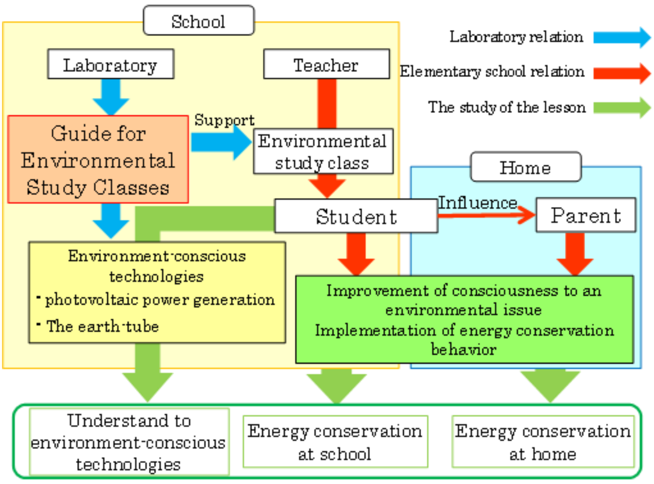

Figure 2: A conceptual illustration of an environmental study class using the guide for environmental study classes.

5.2 Selection of the types of environment-conscious technologies

Table 1 shows project types, nature of technology, and number of schools with renewable energy equipment installed (systems installed at 10 or more schools). There are many cases where photovoltaic power generation has been adopted, and thus this study examines this type of photovoltaic technology.

	The kind	Evaluation (The number of installation)
①	Photovoltaic power generation type	Photovoltaic power generation (7371)
②	The solar heat use type	Solar water heater (144)
③	Other new energy types	Wind power generation (610) Biomass generation of electricity (122) Earth thermal use (61) etc.
④	The wood use type	Use of an area wood
⑤	Energy saving and the resource-saving type	Drainage recycling etc.
⑥	The resource saving recycling type	Recycling building material Garbage disposer
⑦	The natural symbiosis type	Roof planting trees Building planting trees
⑧	Other	Natural lighting Natural ventilation

Table 1: Project types, nature of technology, and number of schools

5.3 Guidance plan on environment-conscious technologies (Example class)

Figure 3 shows an example of photovoltaic power generation for the "Composition of each technology '(6) Example of how to proceed with the class'" in Figure 1. Efforts were made to ensure that teachers can conducts classes easily by following the materials. This was achieved by simplifying the explanatory text, using plenty of illustrations and photos, and indicating guidelines for time allocation.

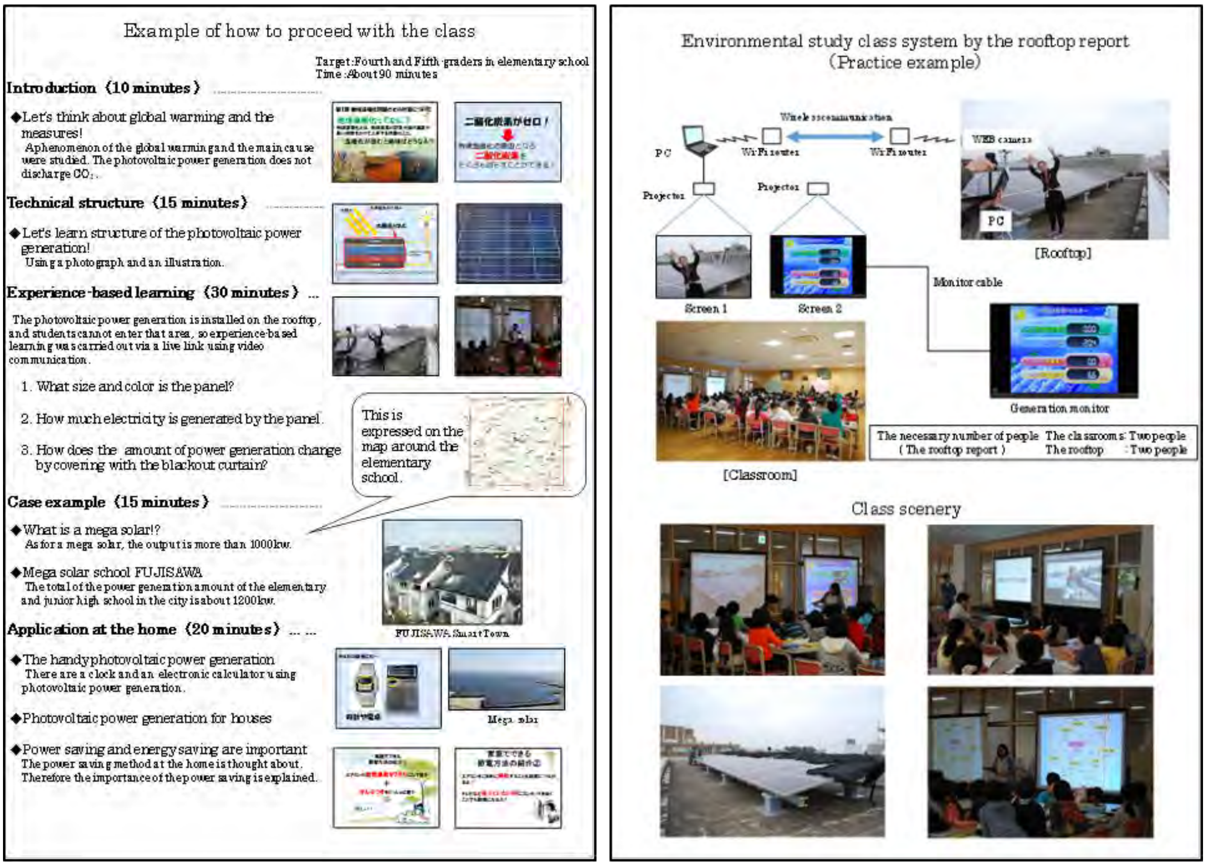

Figure 3: An example of photovoltaic power generation

5.4 Correspondence with curriculum and unit list in existing textbook

In bringing environment-conscious technologies into correspondence with the unit list in the textbook, the subjects were narrowed down to science, which can be easily brought into correspondence with environment-conscious technologies, and a publishing company was selected. The number of publishers established by the Ministry of Education, Culture, Sports, Science and Technology is 6 companies for elementary schools, and five companies for junior high schools.

In this study, as shown in Figure 4, three companies were selected which are frequently used in both elementary schools and junior high schools, and a correspondence was established with the unit list. Also, the content of environment-conscious technologies is difficult for students in the early years of elementary school. Thus it is likely best to provide this class for fourth-graders and above.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

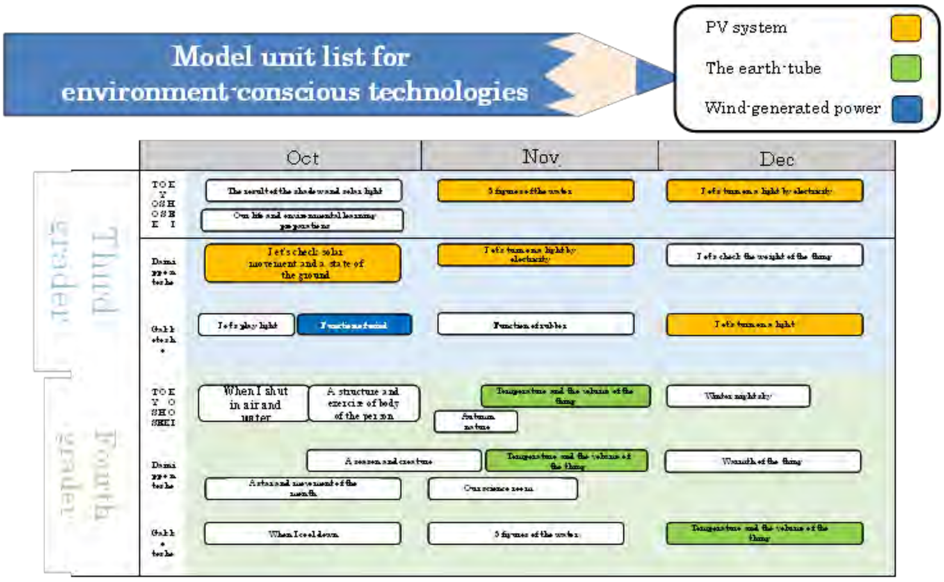

Figure 4: An example of an annual list of units

5. CONDUCTING CLASSES USING THE GUIDE FOR ENVIRONMENTAL STUDY CLASSES

5.1 Environmental study class using photovoltaic power generation

An environmental study class was held at elementary school A in Shinagawa Ward. The class was for fourth-graders in elementary school. Photovoltaic power generation was used as the content.

Figure 4 shows an example of a class using photovoltaic power generation. Four teachers were asked to carry out everything from preparation to actual classes by using class examples. Our laboratory provided support such as preparing equipment. Also, photovoltaic power generation is installed on the rooftop, and students cannot enter that area, so experience-based learning was carried out via a live link using video communication. In some cases, classes by teachers proceeded in accordance with “the example of how to proceed with the class” in the class guide. They were able to conduct classes without any major problems, and student reaction and degree of understanding were good.

5.2 Questionnaire for students after environmental study class

A questionnaire survey was administered to students after the environmental study class. Figures 5–8 show the survey results.

Figure 5 shows the items which generated the most interest in the class. The responses included: “Learning about the mechanism of solar power generation,” and “Putting a cloth (blackout curtain) on the solar panel.” It is evident that students have an interest in the mechanisms used to realize environment-conscious technologies.

Figure 6 shows responses regarding the ease of understanding a photovoltaic panel via a live link. Most students responded that they “understood” or “understood a little.” This shows they likely gained an adequate knowledge of the type of environment-conscious technologies installed at their own school.

Figure 7 shows the question of whether the students would like to know in more detail about the mechanism of photovoltaic power generation. Of the answers, 90% were “I would like to” or “I would like to a little.” This was a class which used environment-conscious technologies not appearing in ordinary classes, and thus it can be said that students showed strong interest/concern.

Figure 8 shows the question of whether the students would like to take an environmental study class again, led by the supervising teacher. Over 90% of the students responded: “I would like to” or “I would like to a little.”

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Based on these results, it seems that teachers in charge were capable of providing adequately effective environmental classes.

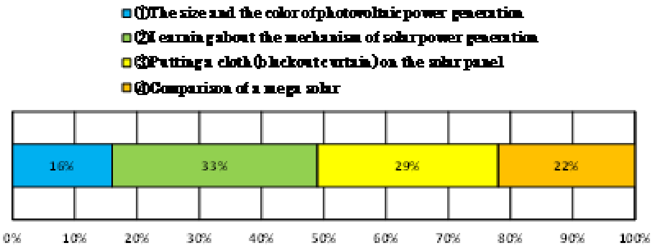

Figure 5: The items which generated the most interest in the class.

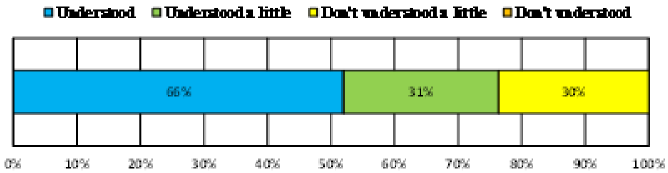

Figure 6: Responses regarding the ease of understanding a photovoltaic panel via a live link

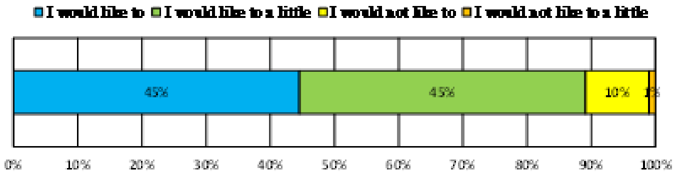

Figure 7: The question of whether the students would like to know in more detail about the mechanism of photovoltaic power generation.

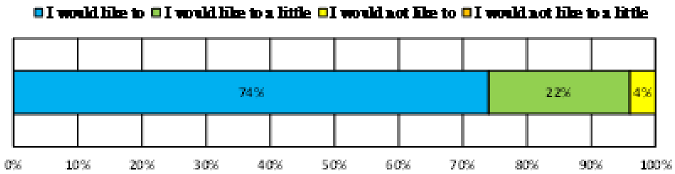

Figure 8: The question of whether the students would like to take an environmental study class again.

5.3 Questionnaire for teachers and consideration of plans for improving class guide

Elementary school teachers are in charge of many subjects, and thus the opinion was that it would be easier to prepare a class plan if there were a list of units corresponding to environment-conscious technologies. The view was also expressed, regarding the unit list and class example, that the layout and design are easy to understand.

For the PowerPoint presentation used in the class, on the other hand, materials were prepared comparing power consumption with other schools in the same ward in order to generate interest among the students. However, it is very difficult for teachers themselves to inquire with government offices and receive data. Therefore, the opinion was expressed that if data can be easily downloaded from a source such as the Internet, it will be possible for teachers to create class materials on their own.

6. CONCLUSION

In this study, class materials were prepared using the class example in the guide for environmental study classes, classes were conducted. By interviewing teachers, it was confirmed that teachers working alone are capable of preparing class materials and explaining the material to students by using the guide for environmental study classes.

As issues for the future, it will likely be necessary to create class plans which can be conducted by teachers in charge working on their own, and propose experience-based learning and experimental learning plans using only

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

the equipment available at schools. Also, when conducting environmental study classes on photovoltaic power generation, it will likely be necessary to call on the local government because it will be easier to conduct environmental study classes if communication equipment for live links is installed.

ABSTRACT

Drainage Services Department (DSD) and the Consultant collaborated on the conceptual design and implementation for beautifying Stonecutters Island Sewage Treatment Works (SCISTW) and demonstrated various sustainable features under Harbour Area Treatment Scheme (HATS) Stage 2A project. Such designs echo the policy initiatives in promoting sustainable built environments for Government facilities.

Upgrading works in expanding the treatment capacity at SCISTW include architectural and aesthetic designs of buildings and treatment facilities, both for existing and new ones. These include building facade with elevational treatment, grasscrete and porous paving, green roofs, as well as boundary and landscape planting. Beautification features specifically for future visitors at SCISTW include:

- Careful planning of visitor path with landscape enhancement works to balance visitor safety and experience in showcasing the basics of SCISTW operation, while minimising operation disturbance;
- Greeting visitors by water wall at sedimentation tank area, facing the main entrance. The water is replenished with recycled rainwater, a real-life application of rainwater harvesting; and
- Adopting sustainable materials including recycled glass-paving blocks and grasscretes at the new Main Pumping Station (MPS2) building.

Sustainable features include sustainable urban drainage systems (SUDS), for which multiple locations have been studied for pilot-testing. These include vegetated bioswales, permeable pavements, rain gardens, bioretention planters and rainwater harvesting. These SUDS will be evaluated with reference to overseas (USA and Singapore) SUDS experiences and manuals. Permeable pavers, one bioswale and one rain garden are currently undergoing test trial at the SCISTW and Chamber 15 sites. Localised design performance in reducing stormwater peak flow, runoff volume and pollutant loading will be evaluated through these installations.

Project-specific beautification design and detailed evaluation methodology and on-site performances of these sustainable designs in HATS Stage 2A project, and recommendations on their possible implementation in other similar built environments, will be presented in the full paper.

Keywords: green infrastructure, water management

1. INTRODUCTION

Since 2004, Drainage Services Department (DSD) of the Government of the Hong Kong Special Administrative Region has incorporated “integrating sustainability considerations into the design, construction and operation of our facilities” into their environmental policy. (Drainage Services Department of the Government of the Hong Kong Special Administrative Region, 2004). In the Hong Kong Climate Change Report 2015, the Government further prioritized the exploration for blue-green infrastructures as a major mitigation measure to climate change. In a congested city like Hong Kong, however, implementing such sustainable features has always been a challenge, and such challenge becomes more prominent when the development is not a greenfield site. In consideration of the beautification and sustainable designs at the Stonecutters Island Sewage Treatment Works (SCISTW) under the Harbour Area Treatment Scheme (HATS) Stage 2A project, a good balance has been strived among the user convenience, site constraints and sustainability.

2. CONCEPT DESIGN CONSIDERATIONS

2.1 Planning principles

The introduction of beautification and sustainable urban drainage systems (SUDS) to HATS was first inspired by the Active, Beautiful, Clean Waters Programme implemented in Singapore starting from 2006, which aims to seamlessly integrate the environment, water bodies, as well as the community to create new community spaces and to encourage lifestyle activities to flourish in and around the waters (Public Utilities Board, Singapore, 2014). As the climate in Singapore is different from that in Hong Kong, localisation of the experience was crucial to the success. Three fundamental principles were derived to assess the design options for HATS, namely:

- During the construction stage, sustainable materials shall be selected to minimise the carbon footprint;
- During the operation stage, water and energy saving shall be achieved to enhance operation efficiency; and
- The sustainable features shall be hospitable towards visitors so as to establish a case to promote sustainability.

With these principles in mind, as well as the knowledge for the best practice both locally and internationally, the concept for water feature wall, landscaping visitor route, and SUDS to HATS has been proposed.

2.2 Design concept of water feature wall

To echo the client's identity and to grab the visitor's attention on arrival, a water wall of recycled rainwater will be positioned outside the chemically enhanced primary treatment (CEPT) tank facing the site entrance. Renewable energy installations such as solar panels and wind turbines would also be explored, in order to enhance the eco-friendliness of the water wall as well as to reduce the operation cost. As the first feature to greet the visitors, the running water and the sustainable thoughts behind it shall inspire the visitor's thoughts about the use of recycled water.

Figure 1: Water feature wall (Photomontage)

Figure 2: Flow-through planter (Photomontage)

2.3 Design concept of landscaping visitor route

The visitor route is designed such that the interference of visitors with daily operations of the plant is minimised while the places of interests can be seen along the designated visitor route. This arrangement provides a safe route for visitors. Exhibition boards could also be displayed alongside the route to fulfil the needs of visitors who may have interests for more technical information. Along the route, the use of sustainable materials will also be demonstrated, such as the recycled glass-paving blocks and grasscretes at the new Main Pumping Station (MPS2) building. Sub-routes are also developed to cater for visitors with different backgrounds, appealing to both the general public and professionals.

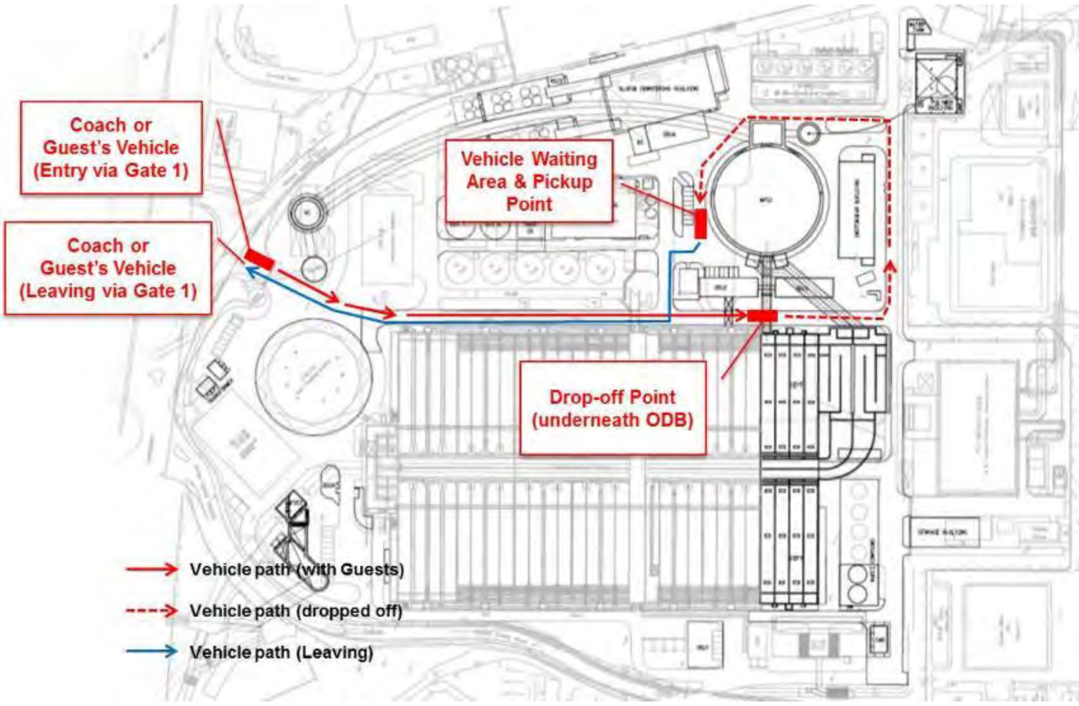

Figure 3: Visitor route for HATS: Vehicle circulation

2.4 Design concept of SUDS

SUDS refers to any stormwater greening technique, measure or device designed to retain and treat stormwater near the source of rainfall, thereby reducing the rate and volume of runoff discharged from the site and preventing pollutants from entering the drainage network and downstream water bodies. The reduced runoff could be further harvested to offset demands on the potable grid. Common SUDS measures include:

- Bioswale: A bioswale is a vegetated open channel used to treat and convey stormwater flows. Treatment action occurs along the surface of the swale by filtration through dense vegetation as well as by infiltration through the soil matrix and into the native soil.
- Rain garden: A rain garden is a shallow vegetated impoundment used to store and infiltrate stormwater runoff. Treatment occurs by infiltration through the soil matrix where pollutants are filtered out. Treated stormwater would infiltrate into the native soil or discharged via perforated subdrain.
- Flow-through planter: A flow-through planter is similar to rain gardens except it is contained within a walled container either as a raised planter box or in the ground. As with rain gardens, runoff is directed into an impoundment within the planter, stored and slowly infiltrated through the soil.
- Permeable pavement: Permeable pavement is a load-bearing surface used to allow infiltration of runoff through the pavement surface and into the soil below. Permeable pavements come in many forms including permeable "block" pavers, porous asphalt, porous concrete and grasscrete.

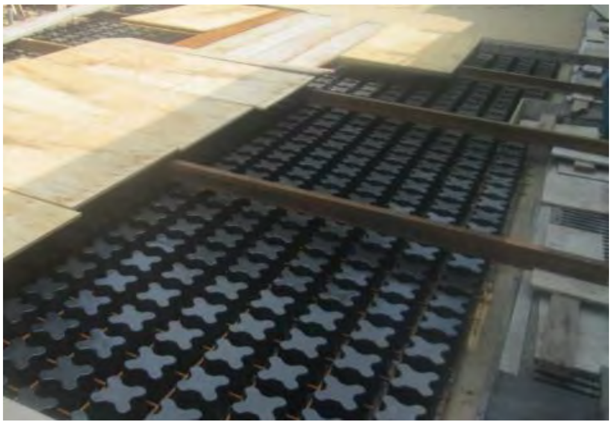

Figure 4: Grasscrete under Construction (1)

Figure 5: Grasscrete under Construction (2)

- Rain harvesting: Rain harvesting is a stormwater management technique that diverts stormwater from relatively clean surfaces such as roof and pedestrian paved areas into a temporary storage tank for reuse.

These options have been evaluated against several criteria as detailed in Table 1. It was concluded that the rain garden and the bioswale are most suitable for HATS, as they generally carry smaller footprints, have lower installation and maintenance costs, and are expected to improve the local biodiversity with the appropriate selection of plants.

SUDS Measures	Aesthetic Value	Maintenance Requirement	Installation Cost	Required Footprint	Ability to Improve Biodiversity	Qualitative Score (Max 45)
Priority Weighting	5	4	3	2	1	
Rain Garden	3	1	3	1	3	33
Bioswale	3	1	3	1	3	33
Flow-Through Planter	3	1	2	2	2	31
Rainwater Harvesting	1	2	1	1	0	18
Permeable Pavements	2	0	0	3	0	16

Performance Indicators:	Aesthetic Value	Maintenance Requirement	Installation Cost	Required Footprint	Ability to Improve Biodiversity	Score
	OK	Significant	Significant	Significant	Minimal	0
	Good	Moderate	Moderate	Moderate	Good	1
	Better	Minimal	Minimal	Minimal	Better	2
	Best	No Impact	No Impact	No Impact	Best	3

Table 1: Qualitative evaluation of SUDS options

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. DESIGN WITH SITE CONSTRAINTS AND NEW CONCEPTS

As HATS is not a greenfield development and the operation efficiency of the sewage treatment cannot be compromised, the implementation of the designed features faced challenges from unknown ground utilities, congested on-site traffic and the need for by-stage constructions to accommodate the critical construction activities. For SUDS, in particular, challenges also arose as there had been no previous use of such measures in Hong Kong. It therefore calls for by-stage constructions for better localisation of the SUDS design. Details of individual challenges are elaborated as below and illustrated how they are factored into the concept design.

3.1 Unknown ground utilities

Underground utilities are always key constraints to works at an existing development. Apart from the common utilities, such as stormwater drainage, sewerage, power cables and water supply system, there are numerous utilities that are specific for sewage treatment process, such as the centrate system, sewage culvert, signal cables, chemical pipe, etc.

Such constraints would impact on the design of the water feature wall, as its grey water recycling system needed to fit with the existing utilities. Surface runoff and roof drainage would be diverted to an underground grey water storage tank for screening and disinfection. The tentative alignment of the connection pipeworks has to avoid the conflicts with the existing utilities.

3.2 Congested on-site traffic

SCISTW is a centralised sewage treatment works for the CEPT treatment of the sewage generated from 17 preliminary treatment works. The frequency of the operational vehicles, such as chemical dosing trucks, sludge container trucks and other maintenance vehicles, are particular high. Coordination with the plant operator was required to obtain a thorough understanding of the logistics. Such understanding is necessary to avoid intrusion into the operating space and ensure that the maintenance requirement can be reasonably satisfied.

For example, one of the options for the visitor route proposed at an early stage was to make use of the road between sludge tanks with additional pot planters at the sides. Having learnt that the road would need to be cleared for occasional major maintenance, it was concluded that pot planters would be inconvenient during those occasions and the routing was reconsidered.

3.3 Need for by-stage construction

As a number of contracts were concurrently carried out at the SCISTW for achieving the full operation of the facilities of HATS Stage 2A, the construction of the planned beautification and SUDS works shall not affect the progress of the main works. To minimise the interface required, the construction of beautification works would be scheduled towards the end of the project, together with other landscaping works. SUDS was agreed to be implemented by stages, starting from a site trial at a nearby ancillary site called Chamber 15A. The by-stage construction also helped accrue knowledge and experience on the construction and performance of SUDS, as it is their first application in Hong Kong.

Since the rain garden and bioswale have been considered most suitable for the HATS project, they were selected to be the first ones for the site trial and were scheduled for construction in late 2016. It is anticipated that testing results will be published in early 2018 after the 12-month monitoring phase. The success of the site trial relied on the following aspects:

- Suitability of the selected location: The ideal locations of the site trial should not only minimise their impacts to the main works, but also be able to receive sufficient runoffs for meaningful test results. Careful studies on the contractor programme, site topography and utilities alignments were needed before deciding on the locations.
- Ease of sample taking: As water samples need to be collected over months, easy access to the samples should be planned at the design stage. Inspection manholes have been added to both inlets and outlets of the proposed rain garden and bioswale to facilitate the sample taking.

- Reliability of the test results: A detailed testing monitoring manual was issued to the Contractor to ensure the quality of sampling works. The manual has specified the requirement for regular maintenance, frequency of the sampling works, lists of equipment needed and the standard procedures. The pollutants proposed for testing included pH, temperature, conductivity, total dissolved solids, total suspended solids, nitrates/ nitrites, phosphorous, biological oxygen demand, chemical oxygen demand, copper, lead, zinc, oil/ grease, and faecal coliform.

4. VISION FOR FUTURE SUSTAINABLE DESIGNS

The experience gained from the design process would be beneficial to future sustainable designs in Hong Kong, as it represented the common challenges in most of the Hong Kong projects.

For the application of SUDS, in particular, the test results from the site trial would provide quantitative information for future cost-benefit analysis of similar facilities. At this moment without those test results, it is natural for clients and the public to view SUDS as white elephants since they are apparently considered more expensive with the need for frequent maintenance. In the case of the rain garden and bioswale, for example, monthly inspection and maintenance shall be carried out to clear the debris, prune and weed the vegetation, ensure the functioning of irrigation system, as well as to eliminate areas of stagnant water. However, the benefits of these facilities to the reduction of peak flows and pollutants into the municipal drainage systems are not intuitive. The site trials of SUDS carried out in HATS would bridge this gap for the clients and the public, allowing them to make more informed decisions for adopting sustainable designs in the future.

5. CONCLUSIONS

The design and implementation of beautification and sustainable initiatives in the HATS Stage 2A project face challenges common to most of the other Hong Kong projects. They would not have been solved without advanced knowledge of design requirements, thorough understanding of site constraints, and sufficient communications among stakeholders. The scientific data from the SUDS site trials as well as the project management experience would be beneficial to future sustainable developments in Hong Kong.

Building Water Resilience in Sustainable Neighbourhoods: A Progressive Shift in Hong Kong

Edmond WF LIU[a]

[a] Water Supplies Department, Government of the HKSAR, Hong Kong SAR, edmond_wf_liu@wsd.gov.hk

ABSTRACT

Hong Kong lacks fresh water resources. In the past, the government coped with the increasing water demand due to population and economic growth by a 3-pronged water supply, viz. local yield, seawater for flushing and imported raw water from Dongjiang in Mainland China. In the face of climate change challenges in the city and Pearl River Delta region in southern Mainland China, a progressive shift on the water resources management has been underway in the city since the promulgation of Total Water Management Strategy for Hong Kong in 2008. A number of initiatives are being implemented at both the city and neighbourhood scales to strike an optimal balance between the demand and supply of water resources.

This paper introduces the holistic approach and adaptive actions taken in Hong Kong in driving for sustainable use of water resources against the vulnerabilities under the climate change. The paper focuses on the inter-connected initiatives and opportunities at the neighbourhood level in Hong Kong which help strengthen resilience by transforming the water-related infrastructures into beneficial assets for sustainable built environment and a better living. Examples on water reclamation, greywater recycling and the smart water supplies network management system at a district level will be discussed with highlights on their roles, synergies and co-benefits towards sustainable neighbourhoods. The paper indicates that the water management measures at the neighbourhood level will continue to be crucial elements for integration into the overall water management strategy in building towards resilience to accommodate the densely populated metropolitan city as a sustainable habitat for generations to come.

Keywords: sustainable neighbourhood, climate change, total water management strategy, water reuse, water loss management

1. INTRODUCTION

Hong Kong is one of the world's metropolis, with a total area of about 1,100 km^2 and over 7 million population.

Providing an adequate water supply for Hong Kong has always been a challenge because there are no natural lakes, rivers or substantial groundwater resources. Our rainfall is abundant with an average of about 2,400 mm each year but it fluctuates from heavy rainfall up to 400 mm per month during the summer to minimal rainfall during the dry winter months. Although about one-third of Hong Kong's land has been gazetted as water gathering grounds where surface runoff is collected for potable use, local yield is insufficient to meet the increasing demand of potable water to support the economic and population growth, which amounts to 973 million m^3 (mcm) in 2015. Besides, the yield is unstable varying from 103 to 336 mcm/ year in the past 20 years.

Despite the inadequate natural water resources, Hong Kong has been enjoying reliable round-the-clock supply in the last thirty years. Over the years, Hong Kong has attained water security through innovative solutions including, (i) using seawater for flushing since 1957, (ii) importing freshwater from Dongjiang (DJ) in Guangdong province since 1965, and (iii) building impounding reservoirs including the two reservoirs built in the sea namely the Plover Cove and High Island Reservoirs in the 1960s and 1970s. At present, DJ water caters for 70 to 80% of the freshwater consumption in Hong Kong. There has been no water rationing since 1982. Yet, Hong Kong is facing challenges in the years ahead.

2. TOTAL WATER MANAGEMENT STRATEGY

Uncertainties due to climate change increase the risk of drought, not only in Hong Kong but also the Pearl River Delta (PRD) region. Although Hong Kong has adequate supply of DJ water even in drought condition, as a good partner to other PRD municipalities, we play a part in tackling this global challenge, and have developed and

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

implemented the Total Water Management (TWM) strategy for sustainable use of water resources since 2008. The strategy was initially formulated up to 2030 and is currently under review for period beyond 2030 in adapting to climate changes impacts.

The TWM strategy adopts a holistic and forward looking approach at both the city and neighbourhood scales emphasizing on an optimal balance by curbing water demand growth through conservation while strengthening water supplies management. On the demand side, the multi-pronged, community-wide water conservation measures in collaboration with stakeholders and the public and territory-wide water loss management programmes are being implemented. As for supply management, Hong Kong has been expanding its seawater flushing system and has increased its coverage from 80% to 85% of the population to save freshwater. Apart from the existing 3 water sources, viz. local yield, seawater for flushing and imported DJ water, Hong Kong has been actively exploiting 3 additional sources, viz. reclaimed water, recycled grey water/ rainwater harvesting and desalinated water, thus enhancing the supply from 3 to 6 prongs in the 2020s. Further, the TWM strategy achieves water conservation via multi-faceted soft and hard measures by encouraging active participation, commitment and cross-sectoral collaboration from government, stakeholders and the public. These include establishment of a “Water Resources Education Centre”, launching of the “Cherish Water Campus” for primary school students, and “Let’s Save 10L Water” campaign as well as a 5-day Water Conservation Week held in November 2016 where government, green groups, schools, trades and the public join hands to promote water conservation.

3. BUILDING WATER RESILIENCE AT NEIGHBOURHOOD LEVEL

Under the TWM strategy, opportunities have been identified from the demand and supply perspectives for implementation of inter-connected initiatives at the neighbourhood level for the quest of sustainable use of water resources in Hong Kong. It is achieved by the transformation of water-related infrastructures into beneficial assets to build and strengthen water resilience for sustainable built environment and a better living. The success of the transformation requires the timely planning and implementation of the relevant schemes under the respective initiatives, viz. (a) water reclamation in north-eastern part of the New Territories (NENT), (b) pilot scheme for greywater recycling at Anderson Quarry Development (AQR) development, and (c) smart water supplies network.

3.1. Water reclamation in north-eastern part of New Territories

In Hong Kong, the use of seawater for flushing has been a cost-effective solution to save precious fresh water resources. However, for those areas that are far from the sea, such as North-eastern part of the New Territories including Sheung Shui and Fanling (SSF), the cost of installing seawater supply networks for toilet flushing is high. With a view to supporting the development of NENT New Development areas (NDA), the government needs to expand Shek Wu Hui Sewage Treatment Works and upgrade its treatment technology to tertiary level to ensure that the additional effluent from the sewage treatment works will not increase the loading to the Deep Bay.

The government makes use of this opportunity to produce reclaimed water that could be used for toilet flushing and other non-potable uses as appropriate by further upgrading the quality of the tertiary treated effluent from the Shek Wu Hui Sewage Treatment Works to an acceptable water quality standard. The upgrading of the water quality could be achieved by an additional simple process of chlorination with sodium hypochlorite solution. The reclaimed water would then be pumped to the reclaimed water service reservoir for distribution to customers.

The use of reclaimed water in NENT, for the replacement of freshwater for toilet flushing and other non-potable uses, can save precious freshwater resources and alleviate the loading of existing water treatment works and fresh water supplies system. It also helps minimize the discharge of treated sewage effluent, and the associated stress and impact to the environment. It can also save the substantial capital investment for the infrastructures for sewage effluent discharge.

The government is currently taking forward the initiative to supply reclaimed water for toilet flushing and other non-potable use in NENT starting with SSF in phases from 2022 onwards. Planning and design of the different phases of the associated infrastructures are in progress and the construction works will commence in stages from 2017. In addition, the study on the financial and legal framework for supply of reclaimed water is also being undertaken.

At the ultimate stage, the reclaimed water supply will serve about half a million of population in the NENT, and by then the seawater and reclaimed water networks in the city will altogether provide flushing water to about 90% of

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

the population. The use of reclaimed water in the neighbourhood level in NENT will save a corresponding amount of fresh water consumption. The government will continue to study the feasibility of supplying reclaimed water in other areas without seawater for flushing at neighbourhood scale.

All in all, the water reclamation initiative at the neighbourhood level brings synergies and environmental benefits, in terms of reduced water pollution loading as well as achieving water conservation. It enhances the overall water security and hence the adaptation to the challenge of climate change.

3.2. Pilot scheme of greywater recycling at Anderson Road Quarry project

The exploration of grey water recycling (and rainwater harvesting) as an alternative water resource is another initiative under TWM. The government has begun planning a pilot scheme to supply recycled grey water for flushing purposes in the Anderson Road Quarry (ARQ) development project. The 40-hectare ARQ site used to be a quarry for the supply of aggregate, asphalt and concrete in supporting the construction works in Hong Kong since 1950s, and has been planned for residential development with 25,000 target population.

The grey water recycling facilities to be operated by the government centrally in the development, alongside with other planned smart water initiatives such as an artificial flood attenuation lake cum park, an underground stormwater storage tank, rainwater harvesting system, bioretention system, and porous pavement, are being explored and proposed in the ARQ development site. These green initiatives aim to facilitate sustainable use of water resources, and alleviate flooding with benefits of creating a healthy and harmonious environment in the ARQ development which also have beneficial effects to the revitalisation of Tsui Ping River downstream and its neighbour areas.

The geographical location of ARQ at the elevated platform of approximately +200mPD provides an invaluable opportunity to launch the pilot scheme of the public grey water recycling system for toilet flushing as an alternative to the conventional flushing supply of seawater. Grey water from wash basins, baths, showers, dishwashers, laundry machines and kitchen sinks etc. in blocks of residential buildings at the neighbourhood scale, in the ARQ development, would be collected via a separate collection pipework system for treatment in the grey water recycling plant in the development. Membrane BioReactors (MBRs) plus disinfection could be adopted for treatment of the collected grey water for flushing purpose. The recycled grey water, will be pumped to the recycled grey water service reservoir before distributing to the customers for toilet flushing in the ARQ development.

The grey water recycling system helps manage the water entering and leaving the AQR development at the neighbourhood level. It provides an efficient short circuit between disposal of the greywater and supply of flushing water via interflows which would otherwise need to be dealt with in the water loop at the territory level. Such territory-wide water loop would entail (i) the transport of the concerned grey water with other sewage via the sewerage system to the Stonecutters Island Sewage Treatment Works, at more than 10 km from the AQR development site, for further treatment before disposing of to the sea, and (ii) the intake of seawater via a pumping system for the provision of flushing water to the ARQ development which is about 3 km from the sea.

The grey water recycling does not only save the pumping energy required to lift the seawater for flushing to the elevated platform at 200m height but also reduces the overall lengths and hence the maintenance/ repair costs of the flushing water supply lines as well as the social disruption and complaints that may arise from leaks and bursts of the watermains operating at high pressure. Last but not least, the grey water recycling system reduces the impacts to the water quality of the receiving water body through reduction of effluent discharge.

The government will continue to work on the scheme layout for the grey water recycling system in the AQR development and will take it forward to the investigation and detailed design stage as well as resolving issues related to the grey water recycling such as amendment of existing legislation, incorporation of new land lease conditions and implementation of separate grey water collection systems both within the buildings and in the development.

Separately, the government is also taking the lead in implementing grey water reuse and rainwater harvesting in government projects through the promulgation of the joint technical circular of the Development Bureau and Environment Bureau. The government has been working with the Hong Kong Green Building Council to promote wider adoption of water recycling in private buildings through the Building Environmental Assessment Method

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

(BEAM) Plus scheme. Water recycling proposals adopted in the design of a building will be eligible for credits under BEAM. In so doing private developers are encouraged to implement water recycling systems both in new developments and renovation projects as well as in existing buildings.

3.3. Smart water supplies network for water loss management

With the substantial completion of the 15-year territory-wide replacement and rehabilitation programme of about 3,000km of aged water mains in end 2015, the condition of the water distribution network in Hong Kong has been returned to a healthy state. Both the number of bursts and leakage rate have been significantly improved.

Water loss management has been one of the key elements under the TWM. With the significant improvement in the healthiness of the water supplies network, the government switches the strategy from large-scale replacement and rehabilitation programme to a smart network management for maintaining the healthiness of the network in a cost effective way. Riding on the development of the advanced technology and with reference to overseas experience, the government plans to establish progressively the Water Intelligence Network (WIN), through the division of the water distribution network in the territory into some 2,000 District Metering Areas (DMAs)/ pressure Management Areas (PMAs) at the neighbourhood scale.

The DMA is defined as a discrete area of water distribution network established by the closure of boundary valve(s), and the water supply into the area is metered and monitored. The DMA can also be established as PMA to reduce the excessive pressure in the watermains within the area whilst adequate supply pressure to customers is maintained. DMAs and PMAs are equipped with monitoring and sensing equipment to collect network operation data, such as time-series flow into the area in particular the night flow, pressure data and other associated network data, for analysis of the water loss of the area.

The set-up of DMAs/ PMAs in a water distribution network at the neighbourhood level for water loss management, has a number of advantages. It has been very difficult to locate problematic locations in a large distribution network. Active leakage control as well as detection of unauthorized consumption in the smaller DMAs are more efficient, and leaks in the underground watermains could be identified by means of minimum night flow monitoring. Furthermore, pressure optimization can be implemented in the DMA to make it a PMA as well.

The set-up of DMAs under WIN at neighbourhood/ district levels help monitor the conditions of the water supply networks in individual DMAs continuously. Real-time monitoring can also be carried out when necessary. WIN will enable the determination of the most cost-effective network management measures or a combination of measures for the individual DMAs from the 4 pillars of actions, viz. (i) active leakage detection and control, (ii) pressure management, (iii) speedy and quality repair, and (iv) asset management by rehabilitation/ replacement of aged watermains which are beyond economic repair. In gist, it will enable timely preventive actions to be taken to ensure network healthiness, and thereby minimises water main bursts, leakage and inconvenience to the public and associated complaints in individual neighbourhoods. WIN can also prioritise the DMAs for action.

WIN strengthens the water loss management of the water distribution network at the neighbourhood level and enhances the water demand management contributing to the water resilience of the city.

4. CONCLUSION

The government has been planning for implementing various total water management initiatives at the neighbourhood level, including water reclamation at NENT, pilot scheme for grey water recycling at AQR development and smart water supplies network for water loss management. These initiatives are crucial elements for the individual neighbourhoods and also for integration into the overall TWM strategy. They will contribute and showcase the creation of efficient, integrated and resilient neighbourhood water infrastructures. The water resilience built by these infrastructures is of paramount importance to the growth of this metropolitan city.

It is expected that more sustainable water management developments would be continuously planned and built at both the neighbourhood and city scales to make Hong Kong a sustainable habitat for generations to come.

ABSTRACT

The Planning and Engineering Study for Housing Sites in Yuen Long South (YLS) has addressed critical issues relating to flood risk, water supply and wastewater treatment by adopting a Smart Green Resilient approach and integrating water management cycle at the heart of the sustainable planning, design and delivery process.

Throughout the planning and design to optimise the development potential of the degraded brownfield land in YLS for accommodating about 85,000 population, "water" has been used as a powerful "integrator" that delivers multiple benefits in supporting the development needs.

Examples of "water" strategies formulated in the YLS development include:

- Smart use of existing combined 3.5km long of concrete-lined drainage channel dissecting various parts of the YLS development for enhancing pedestrian connectivity and traffic safety by partially decking parts of the channels whilst creating scenic open space for enjoyment by local and future residents by revitalising the channels through various hard and soft landscaping treatment.
- Green and sustainable use of treated sewage effluent (TSE) produced by the proposed on-site tertiary sewage treatment works for non-potable water supply including toilet flushing and irrigation. Further polishing of the TSE will be provided in a created reedbed, for environmental enhancement and public enjoyment.
- Resilience built in through introduction of stormwater retention facilities that encompass a 1km long hillside river and provision of a retention lake to attenuate the increase in runoff from YLS in order to mitigate the drainage impacts to the downstream drainage system in the urban area of Yuen Long New Town. Footpaths and cycle tracks will be incorporated into the design of the hillside river and the retention lake to integrate functional facilities.

Keywords: smart, green, resilient

1. INTRODUCTION

1.1. Project background

The Yuen Long South (YLS) area has suffered from proliferated spread of open storage yards, warehouses and industrial workshops, resulting in degradation of its originally rural environment and setting. With growing pressure on land for housing supply and public aspiration of better use of degraded brownfield land for development, the Planning Department and the Civil Engineering and Development Department of the Government of the Hong Kong Special Administrative Region (HKSAR Government) have jointly commissioned the Planning and Engineering Study for Housing Sites in Yuen Long South (the Study), to examine the future land use, optimise the development potential, and ascertain the feasibility for public and private housing developments in the YLS area.

Taking into account territorial development needs as well as local characters and community aspirations, the Study has developed a vision of creating a sustainable, green and liveable community in YLS through provision of essential infrastructure to cater for the future development needs and improving the existing rural environment. The planning and urban design principles for YLS are outlined below:

- Creating an urban to rural experience

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The YLS development will integrate with its settings by designating higher density developments in the north near Yuen Long New Town transitioning to medium and low-density development in the south to blend in with the rural setting and the Tai Lam Country Park. A network of bicycle paths, including a scenic cycle track along the hillside river corridor will be provided and active agricultural land retained, to connect urban neighbourhood and the surrounding rural area.

- View corridors and breezeways

The gradation of development intensity and stepping building heights allow developments to optimise views to the mountainous backdrop of the Tai Lam Country Park, which also help wind deflection and avoid air stagnation.

- Creating open space and green network

Open space of various scale and functions together with the preserved active agricultural land, secondary woodland, natural streams as well as revitalised nullahs will form a comprehensive open space and landscape network to meet leisure and recreational needs while creating identity and character for YLS.

- Providing major focal points and key activity spine

A key activity node with public transport interchange will be provided at each residential community providing commercial, community, recreational and public transport facilities with comprehensive pedestrian and cycling network connection. Walkable communities with good provision of public transport will be created in YLS.

- Revitalisation of Nullahs

The existing nullahs in YLS are valued as key assets. They will be revitalised to reach their full potential as an attractive public realm, and functions as part of the sustainable drainage system for YLS to cope with climate change. The revitalised nullahs will provide a natural feel in the urban context and act as key north-south connectivity corridors. In line with the advocate of integrated blue-green infrastructure system and aspiration to improve aesthetics and ecological value of the land, a green and eco-hydraulics approach will be applied to improve aesthetic whilst maintain and compensate for the hydraulic performance of the channel.

In order to promote public ownership of the outcome and build community consensus for the YLS development, the Study has gone through a comprehensive and well-designed community engagement programme to present and seek views from the public on its plans and proposals.

1.2. Study area

The YLS area is located in proximity to Yuen Long, Tuen Mun and Tin Shui Wai New Towns, and the proposed new development area in Hung Shui Kiu. It is also surrounded by and integrated with various valuable landscape and ecologically important features, including woodland, Tai Lam Country Park, streams discharging to the existing nullahs, an abandoned egretry at Tai Tong and an active egretry at Pak Sha Tsuen.

The area is generally rural in character but occupied by a mixture of brownfield uses, including open storage yards, warehouses, workshops, industrial operations, with villages and residential settlements, agricultural land and unused land scattered in between.

The YLS development on completion can be broadly defined into five planning areas, consisting of three distinct residential communities, a Green Zone and an Employment Belt as illustrated in Figure 1.

The Study Area encompasses a combined 3.5km long of concrete-lined drainage channel dissecting various parts of the YLS development. Opportunity to transform these grey concrete nullahs into potentially attractive blue-green infrastructure system to improve its aesthetic and the environment is a key part of the Study objectives.

Figure 1: Proposed Yuen Long south development

1.3. Key challenges on water management

This Study will formulate stormwater drainage; sewerage conveyance, treatment and disposal; and water supply strategies and infrastructure proposals to support the housing development in YLS. The integrated water management planning and design needs to overcome the following key challenges:

- Conflicting traffic and flood protection requirements

There are existing drainage channels that run through the Study Area. Whilst they serve the important function of providing land drainage and flood protection for the immediate and upstream catchments, their alignment dissect the local community and affect the traffic circulation. Their concrete-lined surfaces are not appealing to the public as illustrated by the photos in Figure 2. There have been strong requests from some public to deck the drainage channels to provide space for improving the existing road network.

Figure 2: Photos of existing Yuen Long Nullah

- Potential adverse drainage impacts

The 183 ha of development area will increase paved surface and runoff discharge to the downstream existing drainage system in Yuen Long and Tin Shui Wai town centre, which has limited conveyance capacity to handle additional flows. The impact will be exacerbated with climate change with higher rainfalls and sea levels are anticipated in the future. The associated drainage impact needs to be mitigated to avoid increase in flood risk to the existing Yuen Long town centre.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Inadequate existing sewerage infrastructure

The proposed development will generate some additional 23,000m3 per day of sewage flows. Although some of the existing sewerage conveyance, treatment and disposal infrastructure are being upgraded currently to support the rapid development of the existing sewage catchment, their expanded capacities are still inadequate to serve the increase in sewage flows. Further extensive upgrading works or new on-site sewage treatment facilities will be required.

- Requirement of Sewage Effluent Discharge to Receiving Water Body

The treated sewage effluent (TSE) from the proposed development will discharge to Deep Bay, which is a "stressed" water body in terms of water quality. To protect the water quality in Deep Bay, there is a stringent requirement that there should be no "net increase" in pollution loading due to the proposed development, meaning that the TSE still cannot be discharged to the downstream Deep Bay. Either effluent reuse or export scheme will be needed for the development.

2. SMART GREEN RESILIENT APPROACH TO WATER MANAGEMENT

2.1 General approach

The 2015 Policy Address proposed to adopt the concept of revitalising water bodies in the planning of drainage networks for new development areas of Hong Kong to build a better environment for the public (HKSAR Government, 2015). It aims to integrate environmental and ecological considerations in the design of drainage infrastructure to create a better living place. The HKSAR Government is also promoting the application of "blue-green infrastructure" to improve the sustainability and resilience of Hong Kong's drainage system to meet the contemporary public aspiration in respect of the natural environment and protection of the local culture and rural lifestyle (Drainage Services Department, 2015).

The Study has fully adopted these intentions into the heart of its planning and design principles. In addressing critical issues relating to flood risk, water supply and wastewater treatment, the Study has used an integrated water management approach by adopting a Smart Green Resilient concept (Lau et. al., 2016) and integrating holistic water cycle management into the sustainable planning, design and delivery process. The proposed strategies will achieve wider benefits beyond their primary functions, as defined in Figure 3.

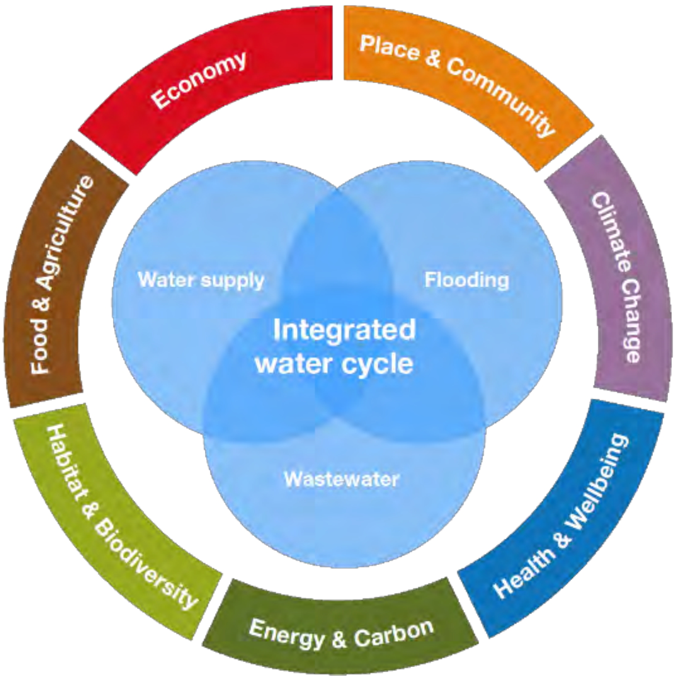

Figure 3: Placing an integrated water cycle at the centre of design to deliver multiple wider benefits (Arup, 2013)

Below are some examples of integrated water management strategies that have been applied to YLS, to deliver multiple benefits to the development based on a smart green resilient approach.

2.2 Smart use of existing combined 3.5km long concrete-lined nullah

To address current road safety concerns and meet future traffic needs after YLS development, decking of the existing Yuen Long Nullah will be required to create space along some sections of the Kung Um Road and Kiu Hing Road for road improvement works. Instead of investing in otherwise traditional large underground concrete structure for drainage with tarmac on top for road, we have adopted a partial decking design and proposed to revitalise the existing concrete-lined trapezoidal Yuen Long Nullah to form an aesthetically pleasant viewing corridor with integrated soft and hard landscaping themes. To compensate for the reduction in the hydraulic capacity due to the partial decking and revitalisation of the existing nullah, new box culverts are proposed that will run parallel with the existing nullah to increase its conveyance capacity.

There have been many successful international examples of regeneration of urban drainage channels, e.g. Cheonggyecheon in Seoul. Various hard and soft landscaping treatments and features will be applied to improve aesthetics, e.g. softscaped treatment of the bottom and the sides of the nullah to allow enhancement of biodiversity and visual integration, involving the use of low-maintenance planting at various levels.

To enhance pedestrian connectivity both internally and externally, it is also proposed to create the pedestrian spine along the sides of the revitalised Yuen Long Nullah. The pedestrian corridor with decent landscaping, comprising those planned along the proposed roads and improvements to existing ones, are highly visible and will link up major destinations. In terms of external connectivity, it is intended for the pedestrian network to tie in with the existing footpath in Yuen Long New Town. A cycle track is also proposed along the southern part of Yuen Long Nullah for public enjoyment and more importantly, for connecting the scenic cycle track to the woodland, natural stream as well as the proposed hillside corridor and reedbed, forming part of the recreational network for visitors and residents to enjoy the ambience of the green environment.

The partial decking design would also provide the opportunity to widen and upgrade the existing roads leading to Yuen Long New Town to facilitate traffic flow and improve the existing congested traffic condition.

Key Activity Nodes which serve the residents by providing living necessities, retail and leisure opportunities will be located along side the revitalised Yuen Long Nullah. The integration of multi-functional facilities through smart and adaptive design creates a synergetic and sustainable environment for the benefit of the community, and serves as a focal point of the YLS development.

Figure 4: Photomontage of the revitalised Yuen Long Nullah

2.3 Green and Sustainable Use of TSE from on-site Tertiary Sewage Treatment Works for Non-potable Water Supply

The existing sewerage infrastructure and its expansion has no spare capacity to convey, treat and dispose the sewage flow generated from YLS development. It is proposed to provide a designated new sewerage system to serve YLS development together with the adjacent village developments. The new sewerage system will comprise sewers, sewage pumping stations, rising mains and a sewage treatment works (STW).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The new STW will be designed to provide tertiary sewage treatment to produce high quality TSE that is suitable for reuse as non-potable water supply. As an alternative water supply source, the TSE is being considered to be reused locally for toilet flushing, landscape irrigation and make-up for water features within YLS development. A new TSE supply system, including TSE pumping station, service reservoir, transmission and distribution network will be provided for YLS development. This is an important green and sustainable measure to make use of "wastewater" as a valuable source of water supply and will help to preserve fresh water for potable consumption only.

The provision of tertiary sewage treatment and recycling of the TSE as non-potable water supply will also support the compliance of the stringent requirement of no "net increase" in pollutant loading for Deep Bay. The YLS development is expected to consume some of the total TSE generated from the STW. To ensure no TSE is discharged to the Deep Bay, opportunities will be explored to export the remaining or surplus TSE to other new development areas or existing urban areas in the vicinity for similar non-potable uses.

To further enhance the quality of the TSE, it is proposed to develop the 3.8 hectare site adjoining the STW into a reedbed wetland to further enhance the quality of the TSE for reuse. The TSE will discharge first to the reedbed wetland, where the residual pollutants will be further uptake by the plants therefore reducing the TSE residual pollution loading. The design of the reedbed wetland will also incorporate facilities for the public such as, walkway, cycle tracks and sitting out areas for public enjoyment.

2.4 Building Resilience with Storm Water Retention Facilities including Hillside River and Retention Lake

The existing Yuen Long Nullah and Tin Shui Wai Main Drainage Channel systems downstream of YLS has no spare capacity to accommodate the additional flow discharges from YLS development. Flood retention facilities are proposed for attenuation of the increase in peak runoff, such that there will be no increase in the 50 year peak flow discharge after YLS development to the downstream existing drainage systems in Yuen Long and Tin Shui Wai. Stormwater runoff will discharge into the retention facilities for temporary storage. The retention facilities will be provided with control outlets that limit discharges to pre-development level.

The proposed retention facilities will encompass of a 1km long hillside river and a 0.6 hectare of retention lake. The hillside river is located in between the mountain backdrop and the new developments of YLS development. The hillside river forms a protective barrier for the future developments downstream, collecting stormwater runoff from the slopes while providing an attractive leisure environment. Nearby, a created reedbed is proposed for further water polishing of the TSE, whilst providing an attractive wetland area, allows an enhanced ecological footprint and in combination with the adjacent recreational grounds a large scale natural area in biodiversity.

To build better resilience for climate change impacts, the design of the hillside river and retention lake has also considered impacts of increased rainfall intensities, which will generate additional surface runoff from YLS development and the existing drainage catchment. Areas have therefore been reserved adjacent to the retention lake. In the future, the retention lake can be further enlarged to provide additional storage volume.

Figure 5: Photomontage of the riverside channel and retention lake

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. CONCLUSION

The planning of YLS development aims to create a sustainable, green and liveable community for accommodating about 85,000 population. It will provide infrastructure to cater for the future development whilst improving the existing rural environment. The blue-green infrastructure system comprising the enlivened and new watercourses/ the preserved natural streams, the Green Zone and hillside landscape enrich the character of YLS development and promote urban, rural and nature integration attracting both residents and visitors.

The concept of revitalising water bodies in the planning of drainage network has been fully considered and applied in the development area by the smart use of the existing concrete-lined channel. Coupling with the provision of cycle track and pedestrian walkway network, it promotes walkability and sustainability which are essential for new development for the future generation. With the stringent requirements on no net increase in pollution loading for Deep Bay, a great challenge has to be overcome and the beneficial use of the treated sewage effluence would be explored for various non-potable uses.

ABSTRACT

Hong Kong Housing Authority is responsible for producing and managing one of the world's largest public rental housing programmes, helping low-income families gain access to adequate and affordable quality housing. Over the decades, we have been planning, designing and building to drive and deliver a long term green and sustainable development for public housing in Hong Kong.

To drive innovations for green infrastructure components, we focused our research effort on maximizing greening opportunities and water conservation in landscape irrigation. This Paper focuses on the following research topics:

- Sustainable planting system for roof greening
- Cost effective vertical greening system
- Rain water harvesting system with bio-retention mechanism
- Root zone irrigation system for ground cover and shrubs
- Zero irrigation system (ZIS) for ground cover, shrubs and small trees

We have put on trial the above research topics in some pilot projects with encouraging results, particularly for ZIS, which is a self-sustained and passive design to deliver water to the vegetation and minimize topsoil evaporation through capillary action. It aims at harvesting the rainwater directly underneath the planting areas for irrigating purpose. It also provides a sustainable urban drainage system by reducing and deferring the volume of storm water entering the sewer system and to restore the natural hydrologic cycle. ZIS is also found more efficient in water conservation and less mechanical part for maintenance when compared with Rainwater Harvesting System or Root Zone Irrigation System. In the trial project, the water consumption of planter with ZIS was monitored over 24 months and no potable manual watering was required.

With the fruitful and promising research result in hand, our ultimate goal is to share the knowledge for the benefit of the society so as to achieve a sustainable green infrastructure, improve living environment, enhance human comfort and contribute to management of natural resources.

Keywords: water conservation, zero irrigation system, affordable quality housing

1. INTRODUCTION

Hong Kong Housing Authority aims at providing affordable quality housing in a proactive and caring manner, by using public resources effectively. Over the decades, we have been planning, designing and building to drive and deliver a long term green and sustainable development for public housing in Hong Kong.

To drive innovations for green infrastructure components (Greening, Landscape & Tree Management Section, Development Bureau, 2016), we pioneer in conducting studies on “Green Infrastructure Components” since 2008. We have been working on different greening studies to achieve a more sustainable and cost effective ways for maintenance of green roofs and vertical greening systems.

Besides our greening efforts, as fresh and clean water is a limited and precious resource in the world, we also launched initiatives for water conservation by reusing or recycling water where possible. In recent years, we focused our research effort on water conservation in landscape irrigation. These include rainwater harvest system, root zone irrigation system and Zero Irrigation System (ZIS).

Researches conducting for various green infrastructure components include the followings (Yim, 2015):

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Sustainable planting system for roof greening
- Cost effective vertical greening system
- Rain water harvesting system with bio-retention mechanism
- Root zone irrigation system for ground cover and shrubs
- Zero irrigation system (ZIS) for ground cover, shrubs and small trees

2. SUSTAINABLE PLANTING SYSTEM FOR ROOF GREENING

Research was carried out to study the performance of different plants species on green roof in order to establish a low maintenance green roof. We aim to compare the growth performance of two commonly used plant species (Sedum mexicanum and Arachis pintoi) and to test the performance of the system.

The results showed that the growth performance of Arachis pintoi is better than Sedum mexicanum. Arachis pintoi is a fast growing species which is able to provide greening impact quickly. It also has higher Nitrogen-fixing capability and is relatively free from pests and diseases. Therefore, it is easier to maintain. Moreover, it is observed to have a better heat reduction impact compared to Sedum mexicanum (Figure 1). (Hong Kong Housing Authority and C.Y. JIM, 2013)

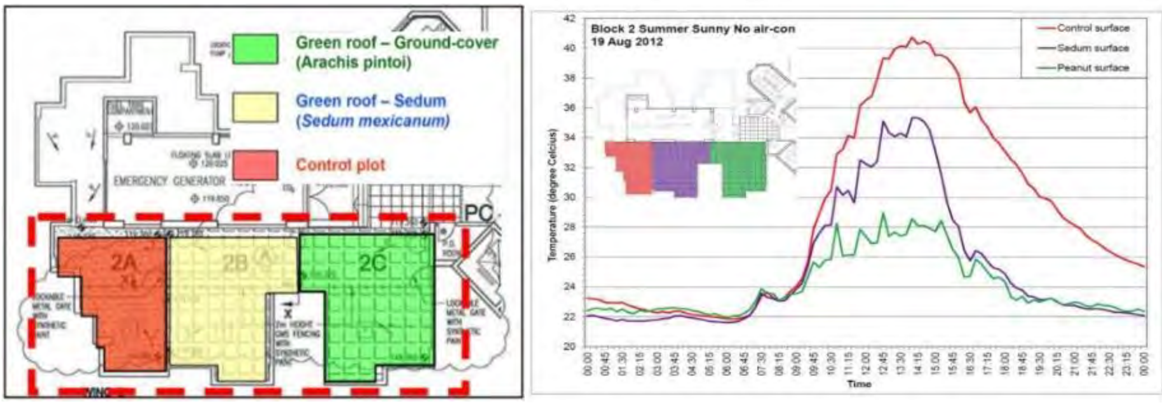

Figure 1: Roof temperature graph

3. COST EFFECTIVE VERTICAL GREENING SYSTEM

In 2010, we carried out a research on heat reduction capacity of vertical greening system and a cost effective way to maintain vertical greening system. The vertical greening system applied in the study is a green panel system. A maximum of 16°C temperature reduction was recorded for a vegetated wall surface.

Research results indicated that the substrate moisture content should be maintained at between 25% to 35% and liquid fertilizers should be applied regularly for duration of six weeks each year, preferably at spring time. From the research, we also found that seven out of nine species tested are suitable for vertical planting. They include Zoysia japonica, Alternanthera versicolor, Axonopus compressus, Cynodon dactylon, Arachis duranensis and Sansevieria trifasciata .

4. RAINWATER HARVESTING SYSTEM WITH BIO-RETENTION MECHANISM

We also studied various landscape irrigation systems for reduction in water consumption. The rainwater harvesting system is developed to collect rainwater and treat rainwater to an acceptable quality for landscape irrigation. Bio-retention treatment measures were selected for water treatment. Bio-retention acts as a self-sufficient system which provides both physical (sedimentation and filtration) and biological (pollutant degradation) treatment. The illustration of bio-retention treatment pond is at Figure 2.

A study was carried out at public housing estate at Shui Cheun O. Five species of plants, namely Pennisetum alopecuroldes, Cyperus papyrus, Miscanthus sinenesis, Tradescantia albiflora and Pteris ensiformis were identified to be suitable for bio-retention. (AECOM, 2014)

Rainwater collected passing through the bio-filtration and physical filtration. The quality of filtered rainwater generally complied with the standard stipulated by the Hong Kong Water Services Department (WSD) except the results on turbidity and colour. The results in the mock up (Figure 3) also indicated that E.coli removal rate was above 97%. Further study would be pursued.

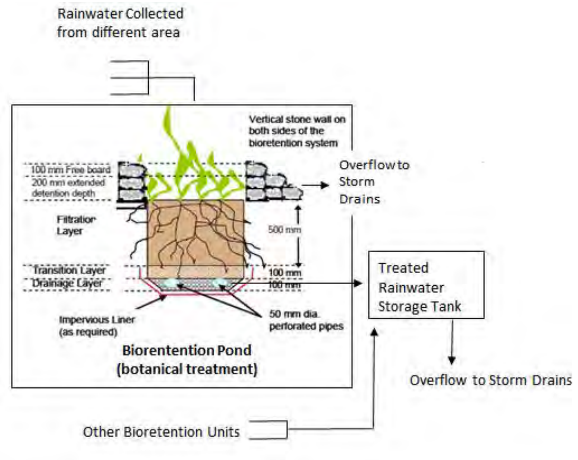

Figure 2: Bio-retention pond *Figure 3: The mock up system*

5. ROOT ZONE IRRIGATION SYSTEM FOR GROUND COVER AND SHRUBS

Root zone irrigation system is one of the water conservation irrigation methods we studied recently. Based the pilot scheme of a public housing project in Kai Tak area, this system is able to achieve water saving up to 38% .

The root zone irrigation system consists of polyethylene dripping tubes wrapped with specially designed fleece, which is sewed into two further layers of non-woven fabric to form the Root Zone Irrigation Mat.

The function of the mat is to secure an even distribution of water as well as to prevent sand and other materials from clogging the drip pipes. Irrigation is then performed by the water saturation effect of the mat and resulting capillary action, guiding the water towards the drier part of the soil. The roots of most plants can grow through the mats without changing the irrigation performance of the mat. The irrigation mats are usually installed about 100 to 200 mm below soil surface and can irrigate lawn areas, flower beds and small shrubs.

5.1 The trial study at public housing estate at Kai Tak

A trial system was set up at Kai Tak public housing site to compare the performance of conventional irrigation method (sprinkler system) with that of the root zone irrigation system in terms of water consumption and the growth performance of the plants in 2011.

Two planters of similar sizes were constructed. Six types of vegetation which were commonly adopted in HA's projects were planted. The conditions of the two planters at around the beginning and end of the study are shown in Figure 4 respectively. Planter no. 1 (on left side) was irrigated by the root zone system while planter no. 2 (on right side) served as the control was irrigated manually via a sprinkler system.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 4: Photo of mock up planters taken on 2 Feb 2011 and 5 Jun 2012

Water consumption of the two irrigation methods were logged on a weekly basis from March 2011 to March 2012. The health condition of the plant species was also checked on monthly basis by comparing the conditions of the root growth of the plants in the two planters.

5.2 Findings

5.2.1 Performance of plants growth

A comparison of water consumption and the performance of the plant species were recorded as in Figure 5. No significant difference is observed regarding the performance of the plant species in both planters.

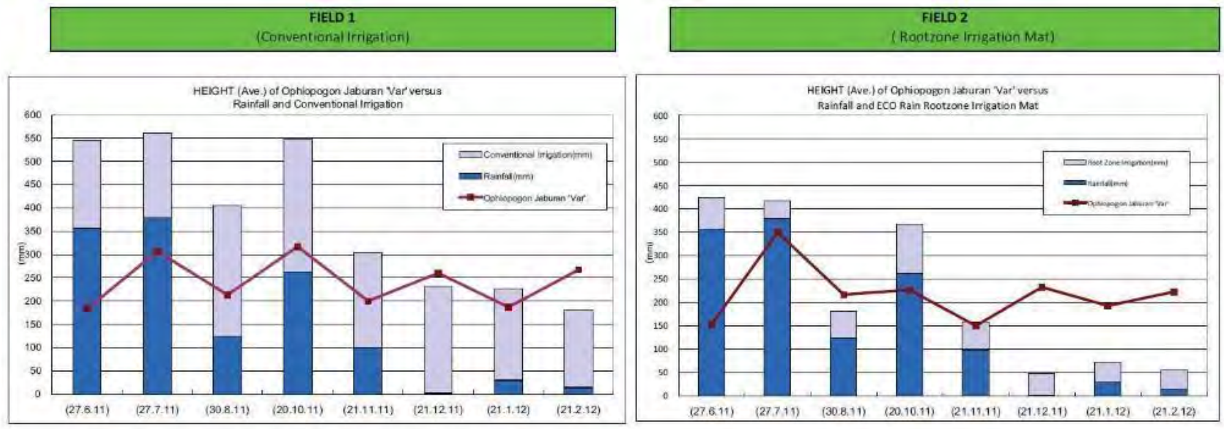

Figure 5: Plant growth monitoring graph

5.2.2 Irrigation water consumption

The average water consumption rates of the planters from 12 May 2011 to 31 March 2012 were 1.54 and 5.7 litre/m²/day respectively. By comparing with HKHA's latest standard manual irrigation rate of 2.5 litre/m²/day, root zone irrigation system can maintain the plant growth to the same extent with a water saving potential of approximately 38%.

6. ZERO IRRIGATION SYSTEM (ZIS) FOR GROUND COVER, SHRUBS AND SMALL TREES

Another pioneering study on sub-irrigation method is the Zero Irrigation System (ZIS). There are two design objectives of ZIS. First, it aims to harvest the rainwater directly underneath the planting areas for irrigating purpose so as to minimize the manual irrigation operation and maintenance cost. Second, as it uptakes the storm water, it reduces the storm water run-off and groundwater recharge.

The ultimate goal of ZIS is to achieve zero portable water consumption for irrigation. ZIS offers great potentials for water conservation in landscape irrigation. We have therefore conducted pioneering studies on ZIS with a view to fully realizing such potentials in our new public housing estates. The pioneering studies comprise two separate trials on ZIS, conducted at the public housing estates at Tuen Mun Area 18 in 2013 and Homantin site in 2014 respectively.

6.1 Components of zero irrigation system (ZIS)

ZIS is a sub-irrigation method that water is delivered to the plant root zone from below the soil surface and absorbed upwards through capillary action.

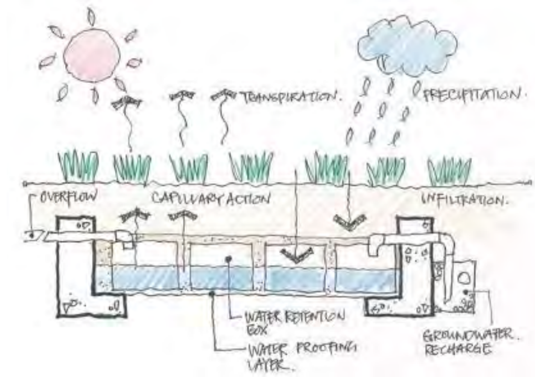

Figure 6: Illustration of zero irrigation system (ZIS)

Figure 7: Construction of ZIS at trial planter

The illustration in Figure 6 indicates how ZIS functions in practice. After rain falls, water is then absorbed into the soil; any excess is collected in special retention boxes under the ground. When the soil above becomes dry, capillary action draws up water from the retention boxes to irrigate the plants in a self-sustaining cycle. In general, as ZIS has less mechanical parts, it operates at lower capital and management costs than other sub-irrigation systems, and can collect and re-use storm water without any hygiene concerns.

6.2 The trial study of ZIS at public housing estate at Tuen Mun Area 18

The objectives of the trial study were focused on the performance of plants growth, the effectiveness of capillary action and water consumption of ZIS. After installation, the trial system was monitored for 24 months since November 2013. The construction of ZIS was illustrated in Figure 7.

6.2.1 Findings

6.2.1.1 Plant growth condition

During the monitoring period, only general horticultural maintenance was carried out; no manual watering was applied. Six types of shrubs which are commonly adopted in HA's project were planted in the trial and they were found well established. No die-back or replacement was recorded.

6.2.1.2 Irrigation water consumption

After an initial infill of water to the system, no further manual watering was applied since 11/2013. The average water consumption was 2.2 litre/m^2/day. The system collected, stored rainwater and delivered the water by itself. The lowest water depth during the driest period was about half of the maximum holding capacity. The record of water level in ZIS planter was in Figure 8.

Figure 8: Records of water level of ZIS at Tuen Mun Area 18

6.3 The trial study at Homantin Site

With the success of the trial study at Tuen Mun Area 18, the system is further refined to support tree planting. Another trial ZIS planter with tree planting pit was constructed at Homantin Site. Two tree pits were constructed inside the ZIS planter. The trial system was then monitored for around 21 months since November 2014. The construction of ZIS with tree pits was illustrated in Figure 9.

Figure 9: Construction of ZIS at trial planter at Homantin Site

6.3.1 Findings

6.3.1.1 Plant growth condition

Same as the trial at Tuen Mun Area 18, no manual watering was applied after initial infill. However, one tree was found wilting after 8 months and needed replacement. This may be caused by planting the trees during winter dry season. We also considered that the tree roots required more time for establishment to take up water from the ZIS. Therefore, we recommended planting the tree during wet season and providing first month manual irrigation for the tree roots to establish.

6.3.1.2 Irrigation water consumption

In the trial study, the water consumption was 1.4 litre/m^2/day. Same as the trial at Tuen Mun Area 18, the lowest water depth during the driest period maintained at half of the maximum holding capacity (Figure 10).

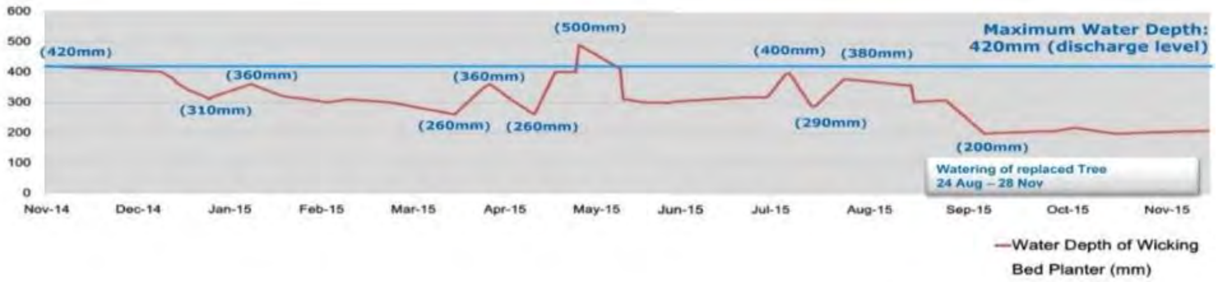

Figure 10: Records of water level of ZIS at Homantin Site

6.4 Benefits and limitations

ZIS is an effective, self-sustained sub-irrigation planting system. The evaporation rate of irrigation water is greatly reduced. No manual watering is required to supplement the water stored in the retention cells. The system also serves as an effective system in reducing storm water run-off. The water consumption records indicated the system performed satisfactorily under both wet and dry seasons.

However, the ZIS system is not suitable for planters on slopes or with complicated underground utilities as the retention boxes should be laid at same level for water storage.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

7. CONCLUSION

The ultimate goal of this paper is to share our knowledge and experience in applying the innovations or initiatives on green infrastructure components for the benefit of the society so as to achieve sustainable green infrastructure, provide better living environment, enhance human comfort and contribute to management of natural resources. All these promising results of the pilot studies on green and water management provide a firm keystone for us to plan the green infrastructure and to provide a better and a more sustainable green environment.

Among the various innovative studies, the Zero Irrigation System is the most effective sub-irrigation system for water saving and storm water management. We have been very encouraged by the result of the ZIS trial, which has proved effective both in saving water and reducing the manpower resources required for maintenance. ZIS has great potential for extensive application in new estates, and we are now conducting further research study with the aim of refining the design and reducing construction time and costs through modularisation.

ABSTRACT

Over the last few decades, Hong Kong has made tremendous progress in managing the landslide risk through a comprehensive slope safety management system developed by Geotechnical Engineering Office (GEO) of Civil Engineering and Development Department. One of the key components of the system is the implementation of slope retrofitting and landslide hazard mitigation works under the Landslip Prevention and Mitigation (LPMit) Programme. While the primary objective of the LPMit Programme is to contain the landslide risk, the GEO strives to attain and promote sustainability when carrying out the LPMit works. The GEO integrates the concepts of sustainability in the works implementation process. The GEO also embraces new technologies and makes continuous improvements in slope engineering and landscaping practices through applied research and development work.

This paper presents the continuous efforts made by the GEO to strive for green and sustainable engineering practices in LPMit works in Hong Kong. Recent initiatives that have made notable contributions to more sustainable practices under the LPMit Programme would be highlighted in the paper, including slope greening and ecological enhancement, carbon footprint assessments of slope works, and adoption of sustainable construction practices.

Keywords: slope greening, carbon footprint, green construction technology

1. BACKGROUND

Hong Kong has a population of over 7 million but only a small land area of about 1,100 km2, much of which comprises steeply sloping terrain. Development pressure resulting from population growth and economic expansion since the 1950's led to intensive urbanization of the lower portions of hillsides in many parts of Hong Kong. The dense urban development, coupled with hilly terrains and high seasonal rainfall, renders the landslide problems in Hong Kong particularly acute.

In the aftermath of several serious landslides with multiple fatalities in the 1970s, the Landslip Preventive Measures Programme was launched in 1977 by the Geotechnical Control Office (renamed Geotechnical Engineering Office (GEO) in 1991) to deal with substandard man-made slopes that pose a significant safety risk to the community. In 2010, the Landslip Preventive Measures Programme was successfully completed and dovetailed by a long-term Landslip Prevention and Mitigation (LPMit) Programme, the scope of which has been extended to cover both upgrading of substandard man-made slopes and landslide hazard mitigation works on vulnerable natural terrain. The annual expenditure under the LPMit Programme is about HK$1,000 million.

While the primary objective of the LPMit Programme is to contain landslide risk, the GEO strives to attain and promote sustainability when carrying out the LPMit works. Sustainability is regarded as a necessary and attainable goal under the LPMit Programme, through process improvement, innovation and promotion of shared learning. Recent initiatives that have made notable contributions to more sustainable practices under the LPMit Programme are highlighted in the paper, including slope greening and ecological enhancement, carbon footprint assessment of slope works, adoption of sustainable construction practices, enhancement of biodiversity, etc.

2. SLOPE GREENING AND ECOLOGICAL ENHANCEMENT

Slopes are found almost everywhere in Hong Kong, with a substantial portion of urban developments being located near to hillsides or formed slopes. It is Government's policy to make slopes look as natural as possible, with a view to achieving the overall aim of creating a visually acceptable and ecologically sustainable slope environment (Figure 1). With the growing awareness of sustainability and greater demand for a better living environment by the public, landscape treatment of slopes has become an integral part of LPMit works. Input by professional landscape architects is provided at the early stage of the design process to ensure that landscaping input is fully integrated with geotechnical input.

Figure 1: Slope greening above Bowen Road before (left photo) and after (right photo) works

Under the LPMit Programme, existing vegetation, including trees and shrubs, is preserved wherever practicable. As for man-made slopes, vegetation is used as surface cover wherever possible. The finished slope profile is designed to be suitable for hydroseeding as far as practicable. Any use of hard surface cover, which could generate undue heat island effect, is under stringent control. If hard surfacing is found unavoidable e.g. on slope safety grounds, visual impact mitigation measures such as planter holes, screen planting at the toe and decorative facing are provided wherever practicable. As regards natural terrain mitigation works, landscape treatments such as vertical greening, screen planting and toe planters are provided to minimize the visual impact of mitigation works and blend them with their surrounding environment (Figure 2). With the concerted efforts by the local geotechnical professionals, more than 300,000 nos. of shrubs are planted annually as part of the LPMit works, and that largely enhance the appearance of the city as well as contribute to providing a greater carbon sink to remove carbon dioxide in the atmosphere.

Figure 2: Vertical greening at a rigid barrier above Yu Tung Road, Lantau

The GEO has been establishing and advancing the best practice of landscape treatment on slopes through applied research and development work. In the early 2000s, the GEO worked with the Kadoorie Farm and Botanic Garden to conduct a planting trial of native small tree and shrub species on steep slopes. Later on, further studies on the application of various vegetation species for slope greening helped to develop various planting methods and suitable vegetation species for landscape use on slopes (Choi et al., 2009). Studies were also undertaken to assess the performance of different greening techniques, such as mulching systems and cellular systems, and to identify vegetation species that can successfully establish and self-sustain on steep slopes (Lui & Shui, 2006). In the mid-2000s, the GEO completed a study of old masonry walls with trees in order to develop a methodology for assessing the effects of trees on the stability of masonry walls. In addition, GEO proposed various methods for preserving the constituent wall trees and the wall fabric when upgrading a substandard masonry wall (CM Wong, 2011).

In recent years, GEO carried out studies on the use of solar panels for automatic irrigation systems for slope planting works (Lui, 2006), use of bio-engineering techniques that involved direct planting, live fascines and cribwalls, etc. to repair large landslides scars (Campbell, 2007), enhanced detailing of tree rings and improved specifications for erosion control mats on slope surface. The key findings of these studies, together with the latest best practice on slope landscaping, have been promulgated in the "Technical Guidelines on Landscape Treatment on Slopes" (GEO, 2011), which largely promotes shared learning across the industry.

Apart from slope greening, the GEO explores ways of enhancing the ecology while implementing the slope works. In particular, the GEO promotes the use of native plant species in landscaping of slopes, in view that native vegetation species can provide habitats for birds and insects, which in turn will enhance biodiversity and natural succession. The goal is to provide a bio-diversified vegetation cover, which is ecologically stable and hence more sustainable.

The GEO's efforts in enhancing local ecology were showcased by a project which involved upgrading a group of 24 slopes along South Lantau Road in Lantau Island. The project replaced the hard surface covers on these slopes by vegetation with suitable native plant species. Based on detailed ecological surveys conducted at different stages of the project, a gradual increase in the various species of plants and animals, such as birds, insects and reptiles, was recorded at the slopes after completion of the upgrading works, with signs of regeneration of local plant species (Figure 3).

Figure 3: Enhanced ecology and biodiversity at South Lantau Road, Lantau

The GEO is particularly mindful of any possible adverse ecological impact arising from the LPMit works. For slope works affecting environmentally sensitive areas such as Country Parks or Sites of Special Scientific Interest, ecological experts are engaged to conduct ecological surveys. Where there is presence of rare plant or animal species e.g. wild orchids, egrets, etc. that could be affected by the slope works, appropriate special measures, such as transplanting, or in-situ protection before the works and close monitoring during construction, would be adopted to abate such adverse impact. In one recent LPMit project near Tai Po Market Egretry, which was the fourth largest colony in Hong Kong for egrets, the GEO has adopted a pragmatic approach and properly programmed the LPMit works in order to minimize the possible impacts or disturbances to the breeding of special bird species, with close monitoring to verify that the proposed strategy has worked well in practice.

3. CARBON AUDIT AND ASSESSMENT OF GEOTECHNICAL WORKS

There has been a growing demand to improve practice in the construction industry to help combat the problems of global warming and climate change. Various studies have been initiated by GEO in recent years with a view to reducing the carbon footprint in the implementation of LPMit works.

In the early 2010s, the GEO arranged for a detailed carbon audit of the implementation of LPMit works. The carbon audit was carried out at 54 selected sites, covering a range of typical LPMit works including soil nailing, reinforced concrete construction, slope cutting, filling and compaction works, rock slope treatment works, construction of steel flexible barriers, etc. The scope of the audit included direct greenhouse gas emission and removal, such as combustion of fuels in stationary sources and mobile sources, as well as indirect greenhouse gas emission such as electricity assumption, staff travel and embodied carbon in raw materials. The carbon audit provided valuable data to GEO for carbon management in respect of LPMit works.

The GEO attempted to further improve the LPMit design practice by incorporating the evaluation of carbon emissions of different design options in the option assessment stage. In this regard, a simple calculation tool, which allows quantification of the carbon emission of typical LPMit works, has been developed. The scope of the present carbon assessment focuses primarily on the carbon emission during the construction phase of LPMit projects, covering the following sources of carbon emission:

- Embodied carbon content of the construction materials (i.e. cradle to site approach) due to extraction, processing and transportation involved during the production of the materials;
- Carbon emission arising from the transportation of materials and construction plant, both within and outside the territory of Hong Kong;
- Carbon emission arising from the fuel consumption of the construction plant or machinery;
- Carbon emission arising from waste treatment; and
- Carbon impact due to felling of mature trees.

Assumptions on carbon emissions are mainly based on published data (EPD & EMSD, 2010, Hammond & Jones, 2011, Leung et al., 2010) as well as other reliable and locally surveyed data. These assumptions are subject to refinement when more reliable and updated data become available, and flexibility is allowed in the tool for such updating in future.

The tool allows local geotechnical practitioners to better appraise the carbon emission of various design options in a consistent and transparent, albeit simplified, manner, and the decisions made can be communicated more readily to the public or other stakeholders. It also provides useful insight on where potential carbon reductions can be made. For example, in soil nailing works, which is a common type of slope treatment works in Hong Kong, the main carbon emission would be the embodied carbon emission of materials (Figure 4). A study was therefore initiated to look into the possibility of reducing the embodied carbon emission of materials for soil nailing by partly replacing the cement in grout by ground granulated blast furnace slag (GGBS).

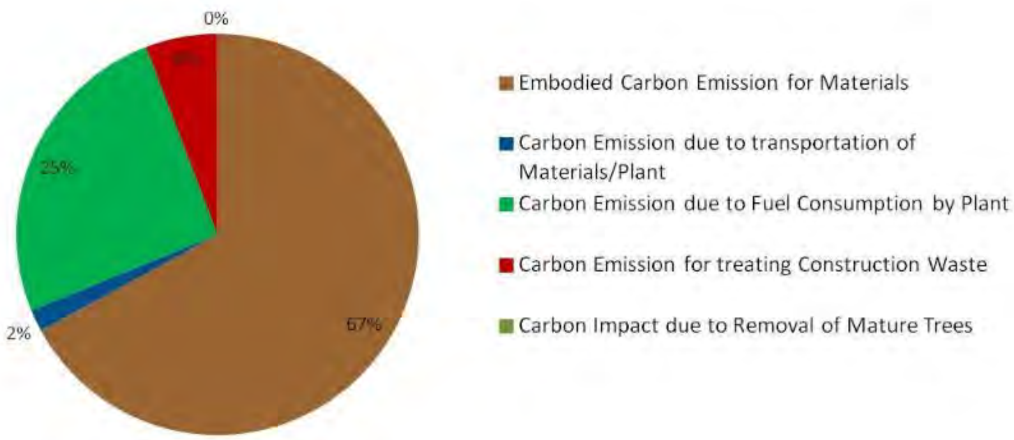

Figure 4: Example of carbon assessment of soil nailing works

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4. SUSTAINABLE CONSTRUCTION PRACTICES

The GEO makes every endeavour to minimize the environmental impacts arising from the construction of LPMit works. A comprehensive site supervision system has been established to audit the workmanship and hence the reliability of the completed LPMit works. The works are closely monitored for strict compliance with the contractual and statutory environmental requirements and agreed mitigation measures. Surface runoff from the LPMit works sites is treated by adequately designed silt-removal facilities before discharging into stormwater drains (Figure 5). The area of exposed earth surfaces is kept to a minimum, and is covered with properly secured tarpaulins sheets for dust suppression (Figure 5). Caring site visits are regularly conducted by the directorate officers of GEO to ensure that the LPMit works are carried out in a safe, green and sustainable manner.

Figure 5: Water pollution control measures (left photo) and air pollution control measures (right photo) for the LPMit works

The GEO adopts green construction practices whenever applicable. As the combustion of fuel is one of the major sources of carbon emission during the construction of LPMit works, the contractors are encouraged to connect to the power grid as far as possible, instead of employing site generators, in order to reduce fuel combustion. B5 diesel (i.e. 5% biodiesel blended with 95% Euro V diesel) has to be used in all non-road based construction machinery, such as air compressors, excavators and compaction plant, for all LPMit works contracts. The use of electric vehicles with no carbon emission is also supported by the GEO, with active participation in their trial use and the incorporation of suitable provisions in the LPMit works contracts.

It is one of GEO's goals to reduce construction wastes generated by the LPMit works. The contractors are encouraged to adopt the 3R principles (i.e. Reduce, Reuse and Recycle) as far as practicable on site. For example, a tree shredding machine has been used in one of the LPMit works sites for chipping felled trees into wood chips that can be reused as mulch. Rubbish bins are provided in pairs at each LPMit works site, one for aluminum cans, one for plastic bottles and one for general refuse, in order to encourage recycling of workers' wastes. Re-usable construction materials, such as steel moulds for surface channels and steel accessories for temporary access, are adopted on site to reduce wastes. The excavated materials are reused on site for backfilling or as top soil for landscaping wherever possible. The contractors are also encouraged to use their best endeavours in identifying recycling facilities or other suitable construction sites where the construction and demolition (C&D) materials can be used in a beneficial manner.

Green site offices with various sustainable designs and features have been adopted in LPMit works contracts since 2015. These sustainable designs and features include measures to allow natural light and ventilation as much as possible, and the use of reusable materials, modular accommodation units, energy and water saving devices. Re-use of site offices, which can minimize waste generation due to the demolition and constriction of office, is encouraged by the incorporation of suitable provisions in the LPMit works contracts. In addition, GEO pays particular attention to the aesthetics of site hoarding. In this regard, decorative panels for reducing visual impact of site hoardings are adopted (Figure 6). These decorative panels are durable and reusable, as well as aesthetically pleasing to the public.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 6: Decorative panels on LPMit site hoardings

The GEO embraces and adopts green construction technologies that help to reduce carbon emissions. The trial use of GGBS concrete in the construction of check dams has been initiated, noting that the carbon emission of GGBS concrete is up to 40% lower than normal OPC concrete. A number of other studies, such as green procurement, lean construction and Building Information Modelling, are ongoing with a view to further enhancing the sustainability of LPMit works.

5. CONCLUSION

The GEO is implementing a long-term LPMit Programme to contain landslide risks in Hong Kong to within an As Low As Reasonably Practicable (ALARP) level. Sustainable landscaping, engineering and construction practices have been adopted by the GEO in the implementation of LPMit works, in order to contribute to a green and safe living environment in Hong Kong. The GEO is dedicated to seeking continuous improvement for the enhancement of sustainability in the delivery of LPMit projects.

ABSTRACT

Based on the experience of East Japan Earthquake in 2011, demand response is expected to be one of the effective measures to deal with tight supply-demand balance by motivating consumers to contribute peak cutting of electric power demand.

Cogeneration systems are one of the well-known major options for efficient energy use for demand side. Currently cogeneration systems have been adopted in buildings for the purpose of increasing self-sufficiency of power supply. In addition, they are expected to play a role to contribute demand response (DR) in the electric power market to reduce fluctuation within power grid caused by certain amount of renewable energy in the future.

This study is a pilot study of simulation by use of The Building Energy Simulation Tool (BEST). BEST has been developed under the initiative of Ministry of Land, Infrastructure, Transportation and Tourism, which handles housings and facilities in an integrated manner in order to assess the energy performance of buildings as a whole.

Focusing on DR periods and incentives, several DR controller models for the BEST has been developed which operate equipment modules depending on some conditions such as outside temperature, grid power demand, etc. to be considered to determine DR signals. This paper shows some examples of cases of a variety of demand-side options such as cogenerations, heaters and chillers by use of the BEST program. In this study, as a pilot case, assuming automatic demand response (ADR), five-steps of DR signals are available to simulate several situations and evaluation of effectiveness of some incentive options.

Key findings is that the BEST simulation adapting to DR, trade-offs between cases are clarified, such as that DR control using CGS contributing to provide economic incentives by alternating grid power in DR period, keeping the thermal environment for office workers.

Keywords: demand response, cogeneration system, building energy simulation

1. INTRODUCTION

Japan experienced serious restrictions on the electric supply capacity after the Great East Japan Earthquake in 2011, which played an important role in changing nation-wide electric power supply systems and influenced the Electricity Business Act to be amended for the first time in 60 years. As part of the amendment, measures are being sought to effectively supply electric power throughout the country. The government expects that by making use of the capabilities of companies and individuals through use of surplus electric power (negawatts) generated by power saving and energy saving, reduction of electric power demand according to the tight balance between

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

supply and demand (Demand Response: DR) and so forth, the supply cost can be reduced while the stable supply of the system power can be secured.

When DR is implemented and power usage is restricted, the need to avoid inconveniences in economic activities and daily life due to excessive power saving would arise on the consumer side. It is considered that effective measures are to use self-supporting power supply systems (cogeneration, solar power generation, and so forth), to use heat-driven chillers and heaters in addition to electrically powered chillers and heaters and to have power storage or heat storage functions on the consumer side.

In this study, on the assumption that DR would be implemented, the BEST (Building Energy Simulation Tool) is proposed to be used as a simulation tool for appropriate system configuration or operation planning in the case of the introduction of a cogeneration systems. The BEST has been developed under the initiative of Ministry of Land, Infrastructure, Transportation and Tourism, which handles building envelops and building facilities in a coupled mode and which calculates load and energy consumption by minutes in order to accurately assess the energy performance of a building as a whole. This study is a pilot study applying BEST simulation to deal with DR on the building facilities and be used in estimation of peak-cut effects brought about by implementation of DR and verification of incentives.

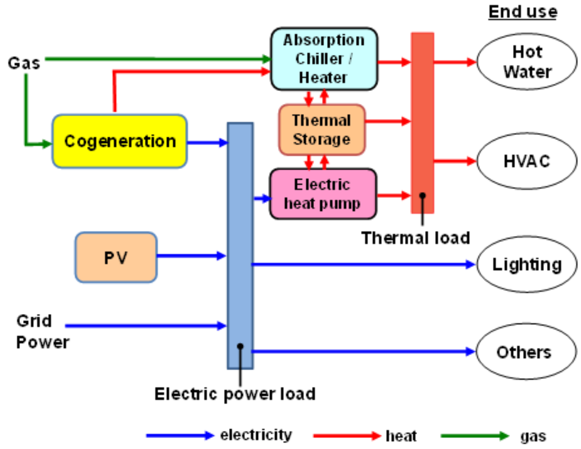

Figure1: Example of demand side energy system adaptable to DR control

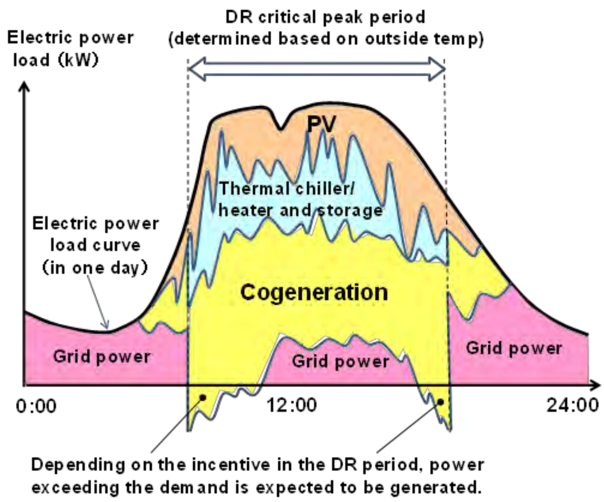

Figure 2: Image of power supply on the demand side in one day

2. BASIC CONCEPT

In the U.S., various methods already exist. Here, the following measures are focused on as the consumers' efforts:

- Change to power supply from the grid power using self-supporting power supply systems (Cogeneration, solar power generation, and so forth) on the consumer side
- Shift from electrically driven chillers and heaters to those of heat-driven for air conditioning system

It is considered that for a building where a cogeneration system is planned to be introduced, it is necessary to select the power source and heat source with an appropriate capacity and to make a plan so that the system can be flexibly operated with consideration given to the following items assuming that DR is implemented in the future:

- Avoidance of restrictions on business operations and daily life while DR request is made
- Continuity of energy saving while DR request is made
- Economic incentives for those who have the DR adaptive equipment

To verify the above requirements in the planning stage, the BSET program which has already developed in consideration of the characteristics of cogeneration system can be used. As a pilot study, operation simulation for some cases including cogeneration is conducted by use of the BEST program assuming that the DR request is effective. Specific case studies are described below.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. CASE STUDIES

3.1. Case studies

For the case study, a provisional office building located in Tokyo that has 14 stories above ground and one story below and has a gross floor area of 20588.88m².is selected. Depending on the presence or absence of a cogeneration system and the presence or absence of DR control, several cases are assumed. The assumptions of the cases are shown in Table 1, in which a cogeneration system (CGS) is comprised of two gas engines (370 kW) and heat source equipment consisting of an exhaust heat input-type absorption water cooling/heating machine and a heat exchanger for heating.

Building type: office Gross floor area : 20588.88m² 14 stories + 1GL Location: Tokyo

	Equipment		DR control method in demand side
	Power Generation	Chiller / Heater	
Case 1 **CGS + DR control**	Gas engine 370kW x2 Generation efficiency: 41% (LHV)	Waste heat absorption chiller / heater 400kW	When the DR request is issued, the equipped CGS is operated with the maximum power generation output so that it is adapted to the air conditioning/power loads without deteriorating the thermal environment in the office and further, surplus electric power is provided outside of the premises.
Case 2 **CGS** Without DR control			As a comparative case with Case 1, regardless of the presence or absence of the DR request, the operation of CGS following the power load curve in the premises is assumed.
Case 3 Non CGS **DR control**	(non CGS)	Electric Heat Pump (Air cooling) 750kW x2 COP=4.45	When the DR request is issued, the set temperature for the air conditioning equipment is changed to reduce the load of the electricity driven chillers and heaters and the load processing is partially restricted by power saving. To compensate for this, the thermal environment in the office deteriorates, forcing office workers to endure such conditions during DR control.
Case 4 Non CGS Without DR control			Even if the DR request is issued, the set temperature is not changed. The indoor environment is maintained through purchase of expensive peak period electric power. In this case, a trade-off between performance and cost can be evaluated.

Table 1: Overview of the case description

Depending on the outside air temperature, the DR request signal is issued, and the gas engines and the chillers and heaters are controlled. In this study, when the outside air temperature is 30°C, 31°C or 32°C, the DR control level is changed in three stages: Level 1, 2 and 3. When the DR request is issued, the assumed control menus are as follows:

- The gas engine operation are changed to the maximum power generation output.
- The heat source outlet temperature is changed to 7°C, 8°C and 9°C, in that order.
- The set room temperature for the air conditioning equipment is changed to 27°C, 28°C, 29°C, in that order.

3.2. Control methods to deal with DR request

Table 2 shows control methods to deal with DR request issuing conditions assumed in this study. For the outside air temperature exceeding 30°C, three levels are set. The outside air temperature was assumed using data for Nerima Ward in Tokyo in August 1995. In 1995, the average temperature in the same area in August was the highest in 25 years, and the number of days when the daily maximum temperature of 35°C or higher was recorded was relatively large.

For this pilot study, a DR controller for the BEST program has been developed which includes levels 1 to 5. The gap (differential) between operations for making the control stable can also be set arbitrarily.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Category	Devices to be controlled	Control method for DR critical peak period
Power generation	Gas engines	The power generation control is changed to "maximum power generation output".
		The power generation output is changed.
Air conditioning (Secondary side)	Rooms	The set room temperature is moderated.
	Air handling units	The air blowing temperature is moderated.
		The intake amount of outside air is limited.
		Air conditioner is stopped (intermittent operation).
Air conditioning (Primary side)	Heat source units	The heat source outlet temperature is moderated.
		The chilled water supply temperature is moderated.
		The electric heat source is stopped.
	Heat storage tanks	Heat is dissipated during the DR time period.
		Surplus heat is stored.
Lighting	Lighting	Thinned-out lighting
Storage battery	Storage batteries	Electric discharge is operated during the DR time period.

Table 2: DR control methods in the demand side

3.3. Results and considerations

The examples of the results of the simulations for three months (July to September) in the summer season are shown in Figure 3 and Figure 4.

3.3.1 Operation status of the system

Figure 3 describes some of the results in Case 1. In Case 1, for the DR control, CGS was operated at the maximum capacity, and the exhaust heat was used for cooling as much as possible, and the surplus electric power was flowed in reverse to the grid power and contributed as supply capacity to the system

3.3.2 PMV frequency distribution

Figure 4 shows the PMV frequency distribution for three months in summer season in Case 1 (with CGS and absorption chiller) and Case 3 (electric HP). In both cases, the frequencies were counted only in the time frame when air conditioning was operating. In Case 1, PMV was maintained at around 0.5, while in Case 3 where office workers are forced to endure the conditions, PMV became around 1.5 in the time frame when the DR request was issued, which shows that the conditions worsened and people in the room were forced to endure such conditions.

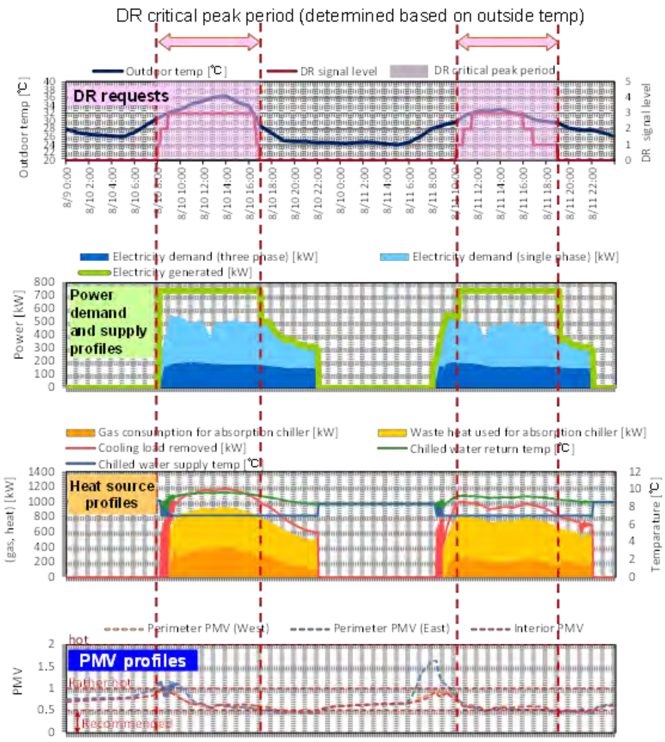

Figure 3: Example of simulation results (Case 1: CGS with DR control; Aug 10–11)

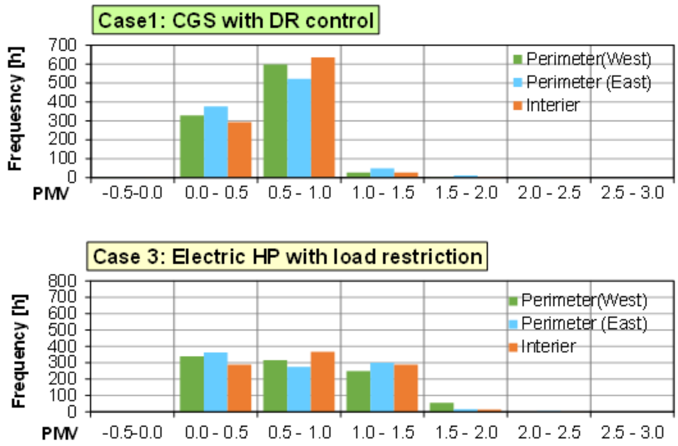

Figure 4: PMV frequency distribution (Case 1 and Case 3)

3.3.3 Primary energy consumption

Figure 5 shows the comparison result of the primary energy consumptions, with the evaluation of the peak time period added, for three months (July to September) in the summer season in the Tokyo area. Some of the generated power is provided to outside of the site, and at the same time, the operating rate of the exhaust heat input-type absorption refrigerator is increased by use of exhaust heat from power generation. Further, according to the guideline concerning levelling of electricity demand newly incorporated into the Energy Conservation Act amended in 2013, when 1kWh of the system electric power consumption in the specific time zone (8:00 - 22:00) is reduced, it will translate as 1.3kWh of the consumption being reduced (energy saving bonus). As such, it is considered that as a result, the net primary energy is saved and the energy saving performance is maintained.

	Case 1	Case 2	Case 3	Case 4
Generated power for sale	-44.77	-1.62	0.00	0.00
Generated power for self-use	-186.07	-184.59	0.00	0.00
Gas consumption for waste-heat-use gas absorption chiller	31.46	35.14	0.00	0.00
Gas consumption for gas engine	243.20	205.69	0.00	0.00
Purchased power at non-peak	0.90	0.90	0.90	0.90
Purchased power at critical peak	5.63	7.40	267.27	281.67
Gross primary energy consumption	281.20	249.13	268.17	282.57

Figure 5: Primary energy consumption by cases

3.3.4 Additional financial incentive for cogeneration owner

In some of the DR cases in the U.S., the demonstration experiment in Kitakyushu City and so forth, incentives 6 to 10 times higher than the normal electric power charge for 1 kWh electricity during DR control were provided. In this pilot study, referring to past research (Yokohama Smart City Project (YSCP), the result of the demonstration in summer 2014 (preliminary) in the building sector in Yokohama City (October 28, 2015)), the incentives were estimated as 15 to 30 yen/kWh.

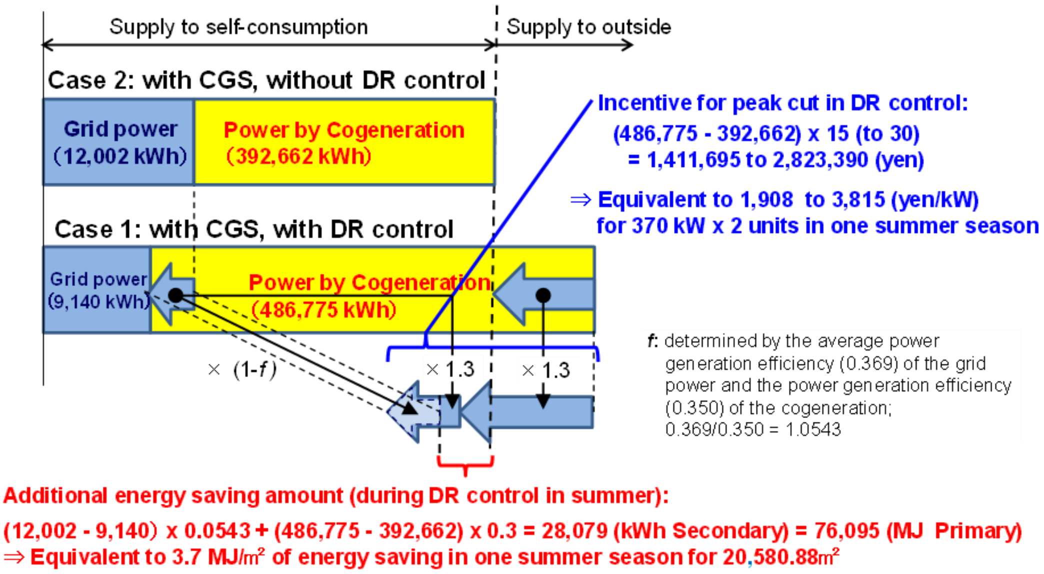

Figure 6: Estimated additional financial incentive to cogeneration with DR control

According to this estimation, in this case, the incentives by DR peak cut became 1.4 to 2.8 million yen and about 1.9 to 3.8 thousand yen for 1 kW of the capacity of the introduced cogeneration power.

3.3.5 Overall evaluation

According to the results (Figure 4, Figure 5 and Figure 6), in Case 3, without CGS, office workers are forced to endure the conditions. Alternatively, in Case 4, without CGS, they are forced to pay additional cost as peak price. But in Case 1 with DR control using CGS, although the energy consumption increased by about 5%, the values as a regulated power supply that contributes to the grid power were provided. In addition, PMV is maintained, that is, deterioration of the thermal environment is avoided and the quality of business operations and daily life is maintained. Through the BEST simulation to adaptation to DR, a trade-off relationship is clarified.

4. CONCLUSION

In this study, as one of the methods of dealing with DR on the building side, using the BEST simulation is proposed to determine system configuration or operation plan in the case of use of cogeneration power. In this study, pilot case study is conducted to simulate DR control in several assumed cases including the case where relatively large-sized gas engine cogeneration is introduced in an office building of about 20,000m^2.

The comparison of the net primary energy consumptions between the cases showed that in the case of DR control using CGS, the energy consumption increased by about 5% compared to the case where office workers were forced to endure the conditions, but the values as a regulated power supply that contributes to the grid power were provided, and in addition, PMV was maintained, that is, deterioration of the thermal comfort was avoided and the quality of business operations and life was maintained. A trial calculation of this economic value is also made and clarified the trade-off relationship. When such a value trading market is formed, it can be expected that projects are undertaken with consideration given to added financial values created by cogeneration capacity and prosumers positively participate in the market.

In this study, the DR control level according to the temperature was set. In view of the increasing tendency of electric power originating from renewable energy, however, it is also necessary to conduct simulations for DR based on the conditions of sunshine, wind and so on that are not always based on temperature. With the regional weather data such as sunshine and wind conditions with which BEST is provided, further simulations of DR control in which the behaviour of various component devices (heat storage, electricity storage and lighting) is also reproducible.

ACKNOWLEDGEMENT

This paper is one outcome of the work of the Cogeneration Study SWG (led by Professor Takashi Akimoto of the Shibaura Institute of Technology) of the BEST Development Promotion Forum (chaired by Shuzo Murakami, President of the Institute of Building Environment and Energy Conservation), which was established by the government, representatives of industry, and academia in the Japan Sustainable Building Consortium. The authors are greatly acknowledging the support of everyone involved.

ABSTRACT

Buildings are major components in a city and they account for more than 40 percent of global energy usage. Together with the long life-cycle of buildings, their performance has significant impact to the sustainable built environment. The building performance relies heavily on electrical and mechanical (E&M) systems and services. The E&M systems in modern high rise buildings have become more comprehensive and sophisticated. This paper will discuss the technological changes for building performance indicators, including availability, maintainability and reliability (AMR), and energy efficiency. Emerging data and information and communications technologies (ICT) bring in new concept and development of smart E&M system and services for driving ultimate building performance and sustainable building environment.

Keywords: sustainability, built environment, energy efficiency, availability, maintainability, reliability, data, information and communications technologies, driver, E&M systems

1. INTRODUCTION

The built environment refers to everything manmade to modify the spaces in which we live and work, including buildings of all types, roads, parks, and landscaping, etc. It has a broad spectrum of impacts on our lives. For a built environment to be sustainable, it shall meet the needs of present without compromising the ability of future generations to meet their own needs ("Our Common Future", 1987). It must also be flexible and adaptable to future uses, has low carbon emission and be resilient to cope with imminent threats of climate change. With the continuous world population growth, the rate of urbanization is increased and the built environment in cities is affected, e.g. constructing roads, utility and transportation facilities, as well as commercial and residential buildings. Buildings are major components in a city. They account for more than 40 percent of global energy usage and as much as one third of global greenhouse gas emissions which is the major cause of global climate change. In Hong Kong, the residential and commercial buildings consume around 51 percent of total energy use in which around 90% are used in electrical and mechanical (E&M) systems, e.g. air-conditioning, lift and escalator, fire services, lighting, etc. Performance of building depends largely on the E&M system design and service performance, and it is an essential element for sustainable built environment. Buildings' expected life span can reach 50 years or more while the lifecycle of typical E&M systems is about 15-25 years. How the E&M systems and services performance can sustain within the expected lifecycle and what will be the optimal time to replace them will affect the building performance. Conventionally, managing the availability, maintainability and reliability (AMR) and energy efficiency of E&M systems and services is crucial to building performance. With the advancement of data and information and communication technologies (ICT), E&M system performance will have substantial changes. This paper will discuss the challenge on some performance indicators of E&M systems from such technological change. The data and ICT will bring in the smart building concept and development which drive ultimate building performance and sustainable built environment. Sustainable built environment for buildings will include smart data technology on top of energy efficient, green and low carbon.

2. SMARTER E&M SYSTEMS DRIVING BETTER BUILDING PERFORMANCE

In large scale and high rise buildings, the demand of E&M systems and services for meeting the needs of users are increased and the requirements for managing them are complicated. Interruption of the E&M systems will cause inconvenience or even disastrous consequences, resulting in unacceptable building performance. Therefore, enhancing AMR on E&M systems is important for preventing service interruption. Apart from this, as E&M systems consume 90% of energy used in buildings, inefficient use of energy in them will decrease the energy

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

performance and also lead to high electricity bill. As energy performance of E&M systems will affect building performance, managing their use is very important. Therefore, AMR and energy efficiency are considered as the major performance indicators for building performance.

With the fast advancement of data and ICT, it brings in the new concept of smart building and development on smart E&M systems and services. It enables more automatic, intelligent, remote monitoring and control features to be built in E&M systems. This will drastically change the mode of operation and maintenance of E&M systems with increase in intelligence but less manpower resources. This will become the key driver in raising the capability of E&M systems for enhancing the AMR, energy efficiency and ultimately the smart building performance. AMR, energy efficiency, and data and ICT will be further discussed in the following sections.

2.1 Availability, maintainability and reliability

2.1.1 Availability

Availability of E&M systems is an important indicator to measure the operational effectiveness of the building. It is the probability of a system to operate and perform its intended function over its expected life-cycle. In modern financial cities and densely populated areas, the operation of both commercial and residential buildings, in particular the high rise ones, relies heavily on the availability of various E&M systems. Inability to access to service of an E&M system, e.g. lift, fire services installations, etc., will cause inconvenience or even safety impact to the building performance. Availability is inter-related with maintainability and reliability.

2.1.2 Maintainability and reliability

Maintainability refers to the ease and rapidity of restoring a system back to operational status. Conventional maintenance approaches on E&M systems are basically to carry out regular preventive maintenance to prevent failure and corrective maintenance after failure occurrence. Regular preventive maintenance is carried out through inspection, scheduled servicing or even overhaul so as to maintain the performance and prevent the occurrence of failure. Since this approach does not consider asset condition, excessive maintenance and provision of extra manpower resources. For corrective maintenance, it is essential to respond to unpredictable service interruption. However, neither of these approaches is desirable for sustainable built environment as they involve excessive resources and unpredicted failure, i.e. system not available.

The rapid advancement of technology on sensors and IoT, condition monitoring and data analytic has permeated into E&M industry and leading to a paradigm shift in maintenance approach. The techniques and manpower resources for maintaining E&M systems will become smarter. Through connecting sensors, controlling and monitoring equipment and software, E&M system data can be collected for analysis to enhance the maintainability. For example, various remote monitoring and self-diagnosis systems for lift installations have been put into operation. The operating data of lift, including travelling speed, lift car vibration spectrum, door opening and closing speeds, hoisting rope condition, etc. can be collected remotely for central monitoring and trend analysis. Through continuous condition monitoring and automatic self-diagnosis functions, the frequency of on-site inspection, the maintenance costs and manpower can be reduced. The pre-mature fault can also be detected for early rectification before a real fault occurrence. In case of failure, the fault attendance time can also be shortened since maintenance staff will be alerted instantly. Trouble-shooting and system downtime will also be reduced because maintenance staff can realize the cause of failure before arriving the site. This has changed the traditional work process in maintenance, repair and service, and enhanced their maintainability as well as availability.

In addition, advanced technology also brings in new challenges to maintainability of E&M systems. Nowadays, electronic or software control are widely used in E&M systems as more advanced and sophisticated functions are built in. Since electronic control is an integral part of the E&M systems and the core component of controlling their operation, its failure can cause complete malfunction of the system. Comparing with conventional E&M components, electronic parts are more vulnerable and have a shorter lifecycle as they are tightly coupled with the fast pace of technology advancement. These bring challenges to the maintenance of this kind of E&M systems because of replacement or repair of the electronic control or software will have obsolete or incompatibility issues after several years of service. Stocking more spare parts may alleviate the situation but the challenge to the maintainability as well as lifecycle asset management of these E&M systems still exist.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Reliability is the chance of a failure occurring over a specified time interval. In practice, components faults or aging issue will affect the reliability of the E&M systems. Typical approach to increase the reliability of E&M systems is to set up redundancy in the design which will automatically cut in to provide service in case of failure of the duty unit.

In order to reduce unpredicted interruption to E&M systems, innovative condition monitoring technology and smart sensors will come into play. These technologies can be used for keeping consistent system performance by monitoring deviation of various operating parameters such as vibration of compressor, component temperature and current, etc., so that building managers can timely examine and make necessary adjustment to the system. By integration of various E&M systems and deployment of an integrated Building Management System (iBMS) – aggregating and analyzing E&M systems and services information in a building or cluster of buildings, building managers can use remote monitor system and be fully aware of the condition of each system under a single platform. This system can facilitate building managers to take early action on potential problem in a well-planned manner and minimize the interruption to achieve a better reliability of the E&M systems and services.

2.2 Energy efficiency

Apart from AMR, effective use of energy in building is another key indicator for building performance. Buildings can be considered as energy-intensive system through their whole life-cycle. Knowing the current energy performance of a building is important to building managers. The commonly used metrics of building energy performance is Energy Use Intensity (EUI), which is presented as annual building energy use per building area. This unit is adopted for designing E&M systems in new green buildings and assessing the energy use in the existing buildings. Building managers can use the EUI to benchmark their buildings' energy performance and look for improvement on energy efficiency.

Energy audit is widely used to examine E&M systems' energy performance of a building. Through the process of energy consumption checks, energy management opportunities (EMOs) are identified for energy saving. The EMOs will then be realized through developing new operation and maintenance strategy, retrofitting of existing systems and thus bringing in higher energy efficiency system to improve building energy performance. The Hong Kong government led by example had carried out energy audits in 120 existing government buildings and achieved around 16% of reduction in electricity consumption in 9 years since 2003through the implementation of energy efficiency measures. In 2015, another round of energy audits for around 340 existing government buildings has been rolled out targeting for further 5% electricity saving in the coming 5 years with 2014 as the baseline.

The traditional energy management approach by monitoring annual building energy use and auditing energy used is time-consuming, labor intensive and costly. Recent technology advances of sensors, meters, and Building Energy Management System (BEMS) allow the building manager to visualize real-time energy consumption of E&M systems. With energy usage data in real time, building energy profile and energy consumption in different zones of the building will be automatically available for monitoring and managing E&M systems. Having online BEMS, the building manager can monitor the energy usage and engage occupants on energy efficiency. The building managers can use those data analysis tools to set energy saving targets and to control the E&M systems to optimize energy performance of the building.

Throughout the long life span of a building, changes to the existing building due to alternation and addition works, different occupants, different landlords or usage are not uncommon. The original settings in various E&M systems during commissioning, in particular air-conditioning system, may not optimize energy efficiency in the changed building environment. Retro-commissioning has been introduced recently which enables the E&M systems to adapt to changes and demand for services. It applies smart sensors, uses data mining and implements control algorithms such that the E&M system can respond to changes in building dynamically and to determine the optimal operation mode. In a research study, it is revealed that 15% of saving on energy use can be achieved by retro-commissioning.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.3 Data and Information and Communications Technologies

Over the past decades, technological progress, building deployment, and falling prices have brought data and ICT, such as IoT, big data, cloud computing, analytic tool, smart senor, etc. to be widely used in E&M systems and services. The smart E&M systems described above have substantially improved the AMR and energy efficiency to result in enhancing building performance. In the context of smart cities, E&M systems and services in buildings are no longer standalone. E&M systems are connected in the building and interacting with people, environment, and city activities to deliver a better built environment. Modern data and ICT therefore become the key driver for ultimate building performance for sustainable built environment.

Buildings are full of data, information and assets from design, construction to operation phase. The inability to centralize building information and manage E&M assets are the challenges to sustainable built environment. Recently, Building Information Modelling (BIM) has made a revolutionary change in the construction industry which enables building and E&M system design and construction works to be more efficient. The information of building and E&M systems in BIM can be easily searched, accessed and updated. However, such 3D application has not reached the building operation phase yet. Being the largest E&M maintenance agency for the public sector in Hong Kong, the Electrical and Mechanical Services Department (EMSD) has developed a novel architecture for exploiting BIM in asset management (AM) and realised the concept in an integrated BIM-AM system featuring multiple operation and maintenance systems and tools in a single platform. Results of the pilot project demonstrated that BIM-AM is a highly visual operation and maintenance system and asset management tool can enhance the maintainability and availability of E&M systems, especially in fault location and service restoration. The integrated platform has proved effective in streamlining workflow, facilitating incident response, and AM. It is envisaged that the emerging BIM-AM system can improve the building performance and leading building industry to attune to smart E&M systems.

3. OTHER AREAS FOR BUILDING PERFORMANCE

There are other areas that should be considered for building performance. Safety is an issue affecting the building performance in built environment. Fire services and security systems are the E&M systems for protecting the safety of a building. In high rise and commercial buildings, the fire services and security systems are becoming sophisticated and they are no exemption in the trend of smarter technology and data driven system. Building management and security guards shall better utilize these systems to increase the building performance in safety aspect.

Resilience of E&M systems in building is another issue that should be considered when designing a sustainable built environment. Design for resilient E&M system to cope with impacts of extreme weather conditions arising from global climate change and minimizing the damages to buildings is a new challenge.

4. CONCLUSIONS

The aim of enhancement of building performance is to create a better and a more sustainable living and business environment for the purpose of meeting needs of the built environment. The building performance depends heavily on the design, operation and maintenance of E&M systems and services. The smart and data technology has brought smart concept in E&M system in driving ultimate building performance.

While the advancement of E&M systems is to enhance the building performance, designers, building managers, engineers and technicians are facing challenges of maintenance strategies for buildings. Smart and data technology has brought drastic change of AMR from traditional preventive maintenance and post-fault rectification to predictive maintenance and pre-fault rectification. The iBMS enables the building managers to monitor and control the availability of the E&M systems and services. To ride on the smart meters and big data analytics, building energy performance can be visualized in real-time, energy used data can be audited automatically, and energy usage can be optimized continuously. To implement the smart E&M technology in buildings, the emerging technology BIM-AM provides a single platform to centralize building information and to manage E&M assets effectively.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

With the collaboration of all building stakeholders, including designers, the construction industry, operation and maintenance and facility management personnel who are acquainted with smart data technology and capability, delivery of smart E&M solutions will be the trend to make sustainable built environment a success. Let us stay connected, join hands and make every possible effort to drive ultimate building performance for sustainable built environment.

ABSTRACT

There is a growing need for developing buildings and a built environment capable of interacting with the smart grid. One smart grid benefit for buildings includes potential participation in demand response programs. This capability is more readily implemented with new construction or renovations, but is a considerable challenge with older, legacy systems. This paper outlines work being done to identify strategies for implementation of demand response on one university campus in the United States with nearly 300 buildings located on over 300 hectares. The building and campus control systems range from modern controls that could fairly easily be incorporated into a smart grid down to older legacy systems incapable of adapting without significant upgrade and capital investment.

This campus is on a real-time price tariff for electricity and thus can benefit immediately from any improved methods for demand response. We have focused our study to date on the various chilled water distribution networks that provide comfort cooling to campus buildings. We have tested strategies for taking advantage of the inherent ability of the distribution piping to store thermal energy (‘coldness’) combined with modifications to building HVAC control set points. We are studying thermal comfort perceptions of occupants in real (non-laboratory) settings to help optimize the changes. Initial tests show a minimum reduction in peak electrical demand of 10-15% in these chilled water networks which has the potential for hundreds if not thousands of US dollar cost savings per day for the campus during periods with relatively high real-time prices. Strategies are also being tested to achieve this peak demand reduction while also decreasing (or at least not increasing) total energy consumption through the day. The study is also identifying technical, economic and operational barriers to retrofitting existing campus facilities with the capability to participate in demand response systems.

Keywords: demand response, smart grid, thermal comfort perception

1. INTRODUCTION

The potential for automated demand response (ADR) is one of the key benefits of a smart grid connected with smart buildings. Many of the prior studies have focused on the technical aspects for peak energy savings and reduced (or at least not increased) total energy consumption. This paper outlines work on one university campus in the United States to identify strategies for implementation of demand response. This is being done within the context of a campus energy system that has a wide range of control system capabilities. We are also including human factor considerations in these studies, such as thermal comfort perceptions within these real world settings.

1.1. Overview of the smart grid and automated demand response (ADR)

The smart grid and smart buildings are relatively new and evolving terms used in various contexts, and there have been many studies on the interactions between a smart grid and smart buildings, for example Georgievski et, al., (2012). These terms are generally used to define a building system that has advanced control systems and technologies that allow for interconnected operability giving the capability to operate efficiently in response to external and internal communications. Smart buildings and their associated controls and equipment are capable of responding to demand response requests from the utility or system operator to manage peak demand. The request for demand response implementation could be done directly via a signal from the grid operator or indirectly using real-time electrical pricing signals. When the request and response are done automatically, this is referred to as “Automated Demand Response” or ADR. The need for demand response can arise when: (a) peak demand is high compared to baseload conditions; (b) a relatively high percentage of the electricity supply comes from

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

intermittent renewable energy sources, such as wind or solar, requiring flexibility in electricity use (as is the case in Germany now and becoming more so in California); or (c) when trying to manage for lower carbon energy production and avoid the use of inefficient fossil fuel based generation.

Demand response can be run under manual control and operation, but that is not as efficient and can be labor intensive. The interconnectivity that is rapidly developing (the Internet of Things, or IoT) is allowing for the development of ADR. Lawrence, et. al. (2016) provide answers to ten basic questions in the area of how smart buildings will connect to a smart grid.

1.2. Implementation of ADR

Implementation of ADR is being driven by several mechanisms. Capacity driven models ensure that sufficient capacity is available in terms of a built-in reserve margin and use of various mechanisms to curtail peak loads. Market-based programs focus on economic benefits gained by participating customers; e.g., with real-time pricing or incentive based programs. Utilities and system operators may use other ancillary methods to maintain grid operations such as energy storage. Participation in ADR programs may also be required by regulations, for example with the International Green Construction Code or IgCC (ICC, 2015), by market solutions, or voluntary incentives like the U.S. Green Building Council's LEED rating system.

The methods chosen for ADR vary based on the energy loads and system types. For example, a university campus or office building will primarily look at the demand for cooling, heating or lighting, etc., within its various buildings whereas an industrial user's response may be heavily weighted toward process loads. The evolution toward automated demand response (ADR) identifies the need for standardized method(s) for communication between electric utilities and agents on the demand side of the meter about grid status, etc. There are a number of developments needed to make ADR work, ranging from policy to economic measures to technology needs. For example, a control protocol is needed to allow equipment and systems from various manufacturers to communicate in a standardized way with each other and with the grid; this is the purpose of OpenADR (OpenADR Alliance, 2015). In addition, a new standard was recently released (ASHRAE, 2016a) that defines an object-oriented information model to enable management of electrical loads and generation sources in response to communication with the smart grid.

Developing methods and algorithms to coordinate building operations in a manner that adequately serves customers and building occupants, factoring in the capabilities of the existing control systems, while improving electric grid efficiency and renewable resource utilization, is also needed. Approaches have often explored top-down strategies where lower-level devices are directed by higher-level coordinating entities.

1.3. Challenges with existing facilities

Depending on the age and degree of sophistication with the existing building automation and control systems, ADR may be fairly readily implementable or pose extreme challenges. This situation is magnified in a typical university campus, such as the one discussed in this study, because the building control systems likely vary widely in terms of complexity, vintage, capabilities, and achieved performance. Moreover, individual buildings may have evolved and hybridized organically. This presents a significant barrier to the rapid and full-scale market penetration of smart buildings in such settings. Another key barrier to the transition of legacy buildings is the cost of upgrading building control system(s). Few small to medium sized buildings are equipped with a centralized Building Energy Management Systems (BEMS), impeding smart grid functionality. Instead, for those legacy buildings, smart grid control features are increasingly offered at the component and subsystem level. One new technology can allow for legacy pneumatic thermostats to be wirelessly connected to building control systems, thus giving control functionality similar to modern direct digital control.

The remainder of this article provides more detail about methods to implement ADR and human factors considerations. In addition, results from initial studies and testing on one university campus in the United States are also presented.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2. METHODS FOR IMPLEMENTATION OF DEMAND RESPONSE IN BUILDINGS

Control systems for building HVACs have evolved from simple on-off switching. For much of the 20th century, pneumatic controls were the dominant technology. They offered adapting proportional, integrative and derivative (PID) control logic and remained popular until the 1990s. They provide reliable and steady control functions but have limited flexibility and are reliant on a steady supply of compressed air, which requires energy. Direct digital control (DDC) development began in the 1960s, but it took time for DDC systems to replace pneumatic control. The development of DDC and the higher level building energy management systems, along with communication protocols between buildings, their equipment and the grid, paved the way for buildings to participate in demand response. Within buildings, the best potential for temporarily adjusting energy demand is with the HVAC, lighting systems, and in some situations other services such as water heating and plug loads.

2.1. Heating, ventilation and air conditioning (HVAC) systems

Zone temperature set points can be adjusted to reduce cooling or heating demand, but there are concerns with occupants' thermal comfort perceptions and humidity control. Supply air temperatures and flow rates can also be adjusted. Temporary adjustments can be made in the chilled and hot water or variable refrigerant flow systems. In all cases, there is a need to coordinate actions to achieve the desired reduction in electrical demand. Also, the timing for any changes and transitions needs to be set to avoid problems such as a rebound effect when the demand response event is over and system control reverts to normal operations.

Although each building has a unique set of circumstances regarding usage type, climate, utility demand response programs, regional expectations for occupant acceptance of temperature (and humidity) changes, and occupancy diversity, etc., there can be some generalizations made as to how far HVAC system operations can be temporarily adjusted to reduce demand without adversely affecting equipment operation, occupant thermal comfort, or indoor air quality. Other guidance for the degree of changes that should be acceptable can be found from building codes or standards that relate to demand response. Along these lines, the IgCC requires that HVAC systems with DDC shall have a capability to remotely change the operating temperature set points by 2.2ºC (4ºF) or more (upward in cooling mode, downward in heating mode) in all non-critical zones given a signal from a centralized contact, such as a building energy management control system (ICC, 2015). This code also requires that the ADR strategy include logic to prevent a rebound peak energy demand. A discussion on thermal comfort perception and demand response is given later in Section 3 of this paper.

Other HVAC system adjustments can be made upstream of the occupied zones, such as setting upper limits on supply fan speeds, changes in supply air, chilled water or hot water temperatures. Any demand response strategy must still provide adequate ventilation rates to maintain acceptable indoor air quality as well as not lead to too high humidity levels in the space. ANSI/ASHRAE Standard 62.1-2016 (ASHRAE, 2016b) requires that relative humidity levels not exceed 65% (unless higher levels are dictated by the space usage type) and also specifies the required ventilation rates to occupied spaces based on occupancy type.

2.2. Lighting

It could be argued that in a perfect world, lighting controls would be in place to provide the minimum amount of lighting needed in a space based on the expected occupancy type and occupancy patterns, and that daylighting control would actually be part of that strategy. However, if we were in the perfect world within the built environment then there would be no need for papers such as this. In spaces where daylight responsive controls are not installed and the installed lighting power density is at or exceeds the levels set by relevant energy codes, the ADR strategy could include temporary reductions in the total lighting power in the range of 10-15%. Lighting power density is defined as the total connecting lighting power (Watts) divided by the conditioned floor space, for a resulting W/m² metric. This requires luminaires that are dimmable or electrical circuity to adjust lighting fixtures separately or in small groups. The best options for this exist in business offices, retail stores and educational facilities. Decisions as to exactly what spaces and luminaires to adjust require some thought and engineering analysis, and the lighting power reduction must be set up to ensure that it would not endanger occupant safety or security.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.3. Thermal energy storage

Thermal energy storage is a common way to shift HVAC demand, particularly for cooling loads. The dominant method probably is through the use of ice or cold water storage systems, although other technologies such as phase change materials are becoming more common. Besides equipment purposely designed and installed to store thermal energy, passive thermal energy storage can be incorporated by methods such as pre-cooling of buildings using mechanical systems or cooler ambient air during evening when possible. Another more novel technique that has been tested at our campus is the pre-cooling of large chilled water distribution networks and then using that stored "coolth" to help reduce cooling load during peak demand periods.

2.4. Other measures

Another argument that can be made concerning demand response is that the building operations should ensure maximum overall energy efficiency as a first step. This reduction in energy consumption naturally carries over into peak demand periods and in many situations may be the most economical method. However, the definition of 'demand response' set by the local utility or electrical system operator may be based on the peak demand expected for the "as-built" condition of this building or even just the current demand in real-time.

Additional demand response measures that could be considered include turning off plug loads when not absolutely needed, reducing temperatures of domestic hot water in storage tanks, or encouraging work from home on a particular day when ADR is anticipated (although that may not reduce overall grid demand if the home HVAC systems are then used more).

3. INDOOR ENVIRONMENTAL QUALITY AND OCCUPANT THERMAL COMFORT PERCEPTION

Fanger proposed the concept of the Predicted Mean Vote (PMV) in the 1960's and this has since served as the basis for many of the thermal comfort guidelines and standards. The adaptive principal (Bedford, 1936) is based on the concept that if people are in thermal discomfort, they will react in ways that tend to restore their comfort and thus they are not passive recipients of their thermal environment. The range of comfort temperature in field studies has proven to be wider than that of the rational approach that is used by ASHRAE (2016c) and ISO 7730 (ISO 2005). Nicol and Humphreys (2002) reported that the optimum temperature of comfort strongly correlates with the mean temperature that people have recently experienced, and the predicted mean vote (PMV) is only weakly correlated with the indoor temperature. They relate this discrepancy to the adaptive behavior of subjects as the result of feedback between personal comfort and behavior. Some researchers have also proposed that the range of neutral temperature was too wide to be specified through the PMV equation (Hoyt, et al., 2009). However, the actual thermal comfort experienced by occupants depends greatly on a wide range of factors such as demographics, context, environmental interaction, and cognition as well as the occupant's past thermal history and time of exposure at this the current temperature. When we consider individuals as active agents that go through a series of behavioral, psychological, and physiological adaptations, it should be possible to account for human adaptive capability when implementing ADR programs. Based on the adaptive thermal comfort model "there is no absolute reference point or threshold on comfort continuum" (de Dear and White, 2008). As a result, occupants with repeatedly exposed to increased indoor temperatures eventually increase their tolerance to warmer indoor temperatures as they "re-acclimatize" or get accustomed to those temperatures.

Therefore, making adjustment to the building's HVAC zone temperature set points has significant potential for inclusion in ADR measures. However, the actual level of change needs to factor in a number of parameters. Thus, it is more complicated than just specifying a set temperature change value. The next section briefly describes some of the testing that has been done at one large university in the south-eastern region of the United States.

4. TESTING AND RESULTS TO DATE

To date, most research about the real-world testing of demand response measures has focused on the energy savings alone; indeed, very few studies include an analysis of any corresponding thermal comfort impact. It is, however, impossible to optimize the energy saving potential for ADR without understanding its impact on occupants. Our research group has been investigating methods for implementing ADR and the effects on building occupants

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

in a "real world" setting, i.e., a major research university in the United States. Cooling for most of the campus's buildings is provided using a chilled water distribution network, which is itself a potential source of thermal energy storage due to the thousands of meters of relatively large pipes needed to transport chilled water to buildings. Tests were run on several buildings investigating coordinated changes in the HVAC systems, such as zone set point changes, supply air flow and temperatures and chilled water supply temperatures. Only relatively small changes have been made to date in the coordinated peak demand reduction studies, for example supply air and zone air temperature set points were increased by 1.7°C (3° F). The tests also involved a scheduled pre-cooling of the chilled water supply during the off-peak hours in the morning followed by allowing the chilled water temperatures to gradually rise in the network during the peak cooling hours, thus effectively tapping into the thermal energy storage capacity built into the network.

Figure 1 below depicts sample results for energy saving at one of the central chilled water plants from a test run in August 2015. The results revealed that a decrease of 11.1% in total energy consumption and 11.5% in peak demand compared to a baseline day (the next day) that had nearly identical weather conditions, and this is significant because changes were only made in a portion of the just a couple of buildings connected to this particular chilled water network. A thermal comfort survey of building occupants during the test date and a baseline date the following day indicated no real difference in thermal comfort perceptions (Figure 2), thus indicting that additional energy savings should be possible without compromising thermal comfort.

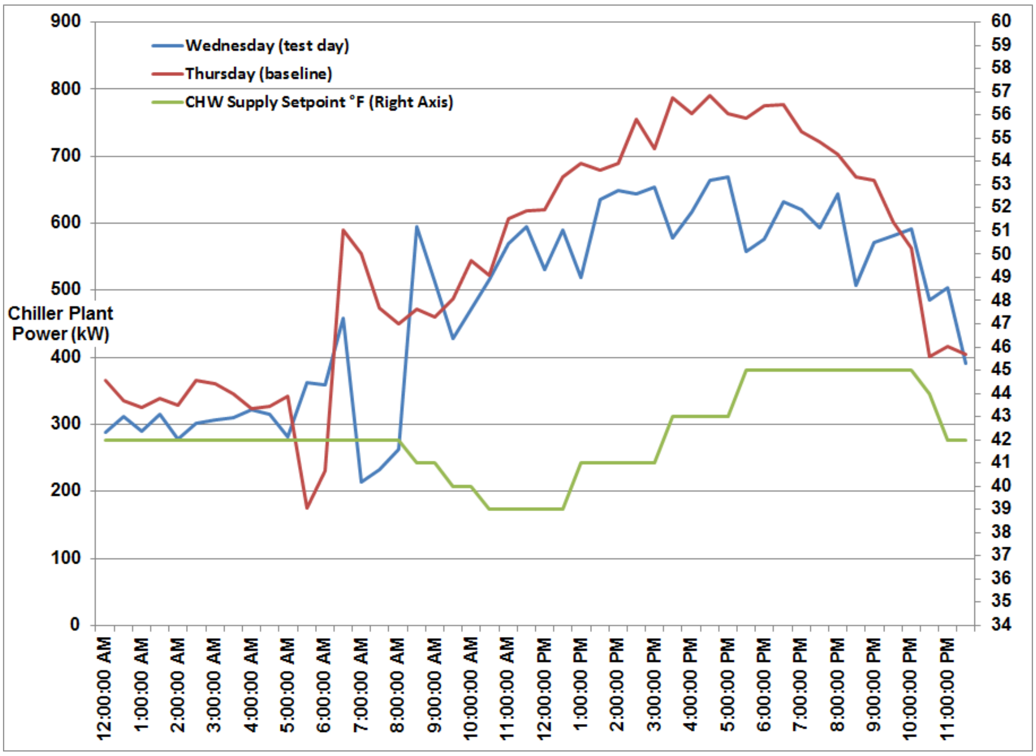

Figure 1: District energy chiller plant power and water temperatures for test day vs. baseline

Figure 2: Occupant thermal comfort survey results for test day vs. baseline

Another study that started in the summer of 2016 is focusing more on human factors and occupant thermal comfort associated with ADR. Several classrooms, offices, lobbies, and one dining hall were investigated with various zone temperature set points of up to 23.3°C without informing the occupants that testing was ongoing. The results revealed that not only was thermal comfort not compromised, but also the PMV value was marginally improved in some cases. While temperature level may seem still low compared to values used in other regions of the world, it should be considered in context of the current level of expectations for this population and in this region. The next phases of this study will try to reveal more about thermal comfort thresholds in real world for buildings with different applications, enabling a better optimization between energy consumption and occupant thermal comfort.

ABSTRACT

Introduced in this paper are our recommended weather forecasting model and the associated prediction procedure. These facilitate the formulation of a convenient and accurate short term energy consumption forecasting method. We started with an overview of the building related energy forecasting. A simplified weather model was then proposed for the output of key weather data, including dry-bulb temperature, relative humidity and global solar radiation. On top of this, a framework of energy-use forecasting technique is introduced, which brings in the data filtering and raw data set regrouping methods. Our result comparisons show that the predictions of the Mean Absolute Percentage Error (MAPE) from the weather data on record, or from the model-generated data set, differ very little. Illustrating examples via a university building case are discussed. The above indicate that our proposed weather prediction model is convenient and suitable for the mentioned purposes. Comparisons among the different input data sets also demonstrate that the forecasting accuracy has been enhanced through input data filtering and regrouping.

Keywords: weather prediction, energy consumption forecasting, energy saving

1. INTRODUCTION

Global warming and fossil fuel depiction lead to international protocols formulation, that in turn drive the building owners, operators and customers to improve the overall system energy efficiency and to search for new technologies with better saving potential. Along this direction, an accurate short-term load prediction tool is mostly in need. It is crucial for the operation plan of the utility systems and for the smart micro-grid applications as well, to allow the utility to take action, or to balance the supply and demand side(s) in principle, or to reduce the overall energy consumption.

Generally speaking, energy consumption forecasting methods can be grouped into three categories based on their time-horizon [Gonzalez-Romera E, 2006], i.e. long-term forecasts of more than one year, medium-term load forecasts from one week ahead to one-year ahead, and short-term load forecasts (STLF) used for predicting the load from a few hours up to weeks ahead. Among these, STLF with the time-horizon of 24-hour ahead is often focused on [Borges CE et al., 2013]. Accurate STLF of the micro-grid can enhance the system ability to use renewable energy resources and to improve the system efficiency and economics in response to the electricity markets [Massana J et al., 2015]. This will enable the utility provider to take action to control the balance between the supply and demand sides. However, there are many influential factors like the weather conditions of tomorrow that affect the building operation and make the building electricity load more difficult to predict. Many researchers worked on the sensitivity of these factors and introduced various black-box or grey-box forecasting models [Chitsaz H et al., 2015 and Chae YT et al., 2016]. Many external factors employed were actually the weather data on record of the following hours instead of truly acquired from weather forecast. In view of this, some researchers [Friedrich L et al., 2015, Roldan-Blay C et al., 2013 and Lazos D et al., 2015] propose to use the weather forecast data from third party institutions, or using a forecasting model to generate the unknown weather data. However, this kind of data is not always available and often has cost implication. It becomes worthwhile to develop new weather forecast methodology for acquiring the unknown weather data set (or the next day 24-hour weather profile) for STLF applications.

2. WEATHER FORECAST MODEL

The new weather forecasting model here introduced serves to generate predicted weather data of tomorrow simply based on the publicly available weather forecast information, like those from internet. A generated sample of the discrete 24-hour dry-bulb temperature and relative humidity are shown in Figure1(a), and the predicted horizontal global solar radiation curve is in Figure1(b).

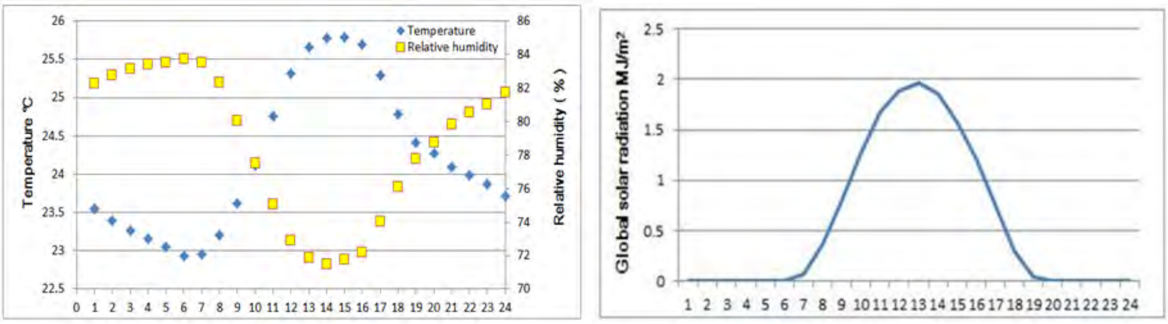

Figure 1: Generation of predicted weather data for the next day 24-hour profile

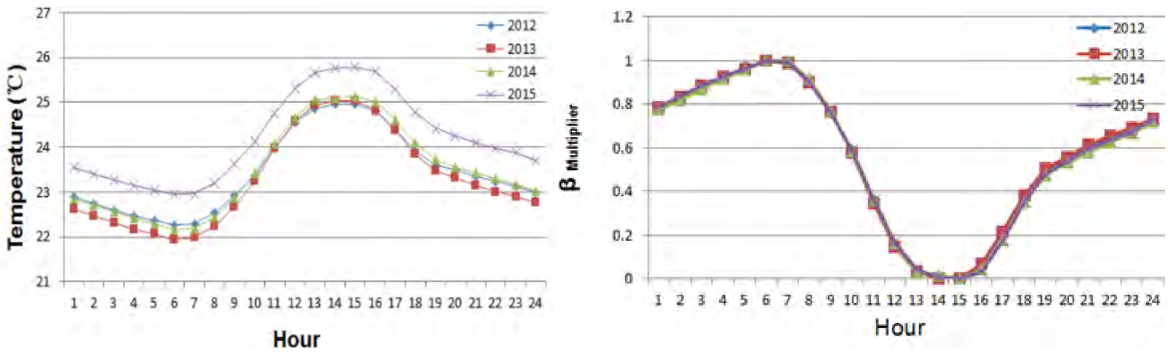
2.1 Dry-bulb temperature prediction

The dry-bulb temperature profile across the day embraces the range between its maximum and minimum values, T_{max} and T_{min}. It disseminates regular pattern geographically that can be approximated by the use of a daily range of multipliers, each of which provides the deviation ratio between T_{max} and that of the given hour $T_{current}$. Hence,

$$\mathrm{T_{current}} = \mathrm{T_{max}} - \beta_{Multiplier} \times (\mathrm{T_{max}} - \mathrm{T_{min}})$$

Equation 1

The range of multiplier values $\beta_{Multiplier}$ can be generated from the historical weather record. For example, based on the Hong Kong Observatory weather data record from 2012 to 2015, the average daily temperature profiles are shown in Figure 2(a), and the multiplier values generated are shown in Figure 2(b). It can be seen that the multiplier values across the day are more or less the same for these 4 years although 2015 was actually much warmer than the other 3 years.



(a) Average daily temperature profile (b) Multiplier value profile

Figure 2: Averaged hourly weather data profiles: (a) Daily temperature, and (b) Multiplier value

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.2 Relative humidity prediction

Based on the predicted temperature value and its relationship with the water vapour saturation pressure, the relative humidity (RH or φ) can be determined.

Step 1: Calculate water vapour saturation pressure

$$p_{qb} = 610 \times 10^{\frac{7.45T}{235+T}}$$

Equation 2

where p_{qb} is the water vapour saturation pressure and T is the temperature.

Step 2: Generate reference water vapour pressure P_c

The RH of the daytime and night-time can be acquired from local weather forecasting report. Since Hong Kong is a coastal city, P_c is relatively stable within a day. Then the constant value of P_c can be taken as the average of the daytime and night-time RH.

Step 3: Calculate relative humidity (RH)

$$\varphi = \frac{\mathrm{P}_c}{p_{qb}} \times 100\%$$

Equation 3

2.3 Global solar radiation prediction

In order to predict the global solar radiation for the next day 24 hours, the sunrise time (t_{sr}) and the sunset time (t_{ss}) on the day of prediction are first calculated [Roldan-Blay C et al., 2013).]. d_n denotes the day number of the year from 1 to 365, taking February 29 the same as February 28. Thus, the daily angle θ is calculated as:

$$\theta = \frac{2\pi}{365}(d_n - 1)$$

Equation 4

The equation of time (et) denotes the difference between the true solar time and the mean solar time, in that

$$\begin{aligned} \mathrm{et} = (&0.000075 + 0.001868\cos(\theta) + 0.032077\sin(\theta) - 0.014615\cos(2\theta) \\ &- 0.04089\sin(2\theta))229.18 \end{aligned}$$

Equation 5

Solar declination δ is the angle in radians between the equatorial plane and the line connecting the centre of the sun and the earth. It can be shown that:

$$\delta = 23.45\cos(2\pi\frac{d_n - 173}{365})\frac{\pi}{180}$$

Equation 6

The solar angular hour (h) is calculated as:

$$\mathrm{h} = \cos^{-1}\left(\frac{\sin\left(\frac{-0.833\pi}{180}\right)\sin(\delta)}{\cos(\varphi)\cos(\delta)}\right)$$

Equation 7

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The number of hours of daylight (n_d) is a function of h, in that

$$n_d = \frac{h}{7.5}\frac{180}{\pi}$$

Equation 8

Then the sunrise (t_{sr}) and sunset time (t_{ss}) are:

$$t_{sr} = 12 - \frac{nd}{2} - \frac{et}{60}$$

Equation 9

$$t_{ss} = 12 + \frac{nd}{2} - \frac{et}{60}$$

Equation 10

Finally, the solar radiation model can be based on the simple sky model [Iqbal, M 1983], which is characterised by the parameters of the peak solar irradiance (I_{max}), the sunrise time (t_{sr}) and the sunset time (t_{ss}).

2.4 Results of weather prediction

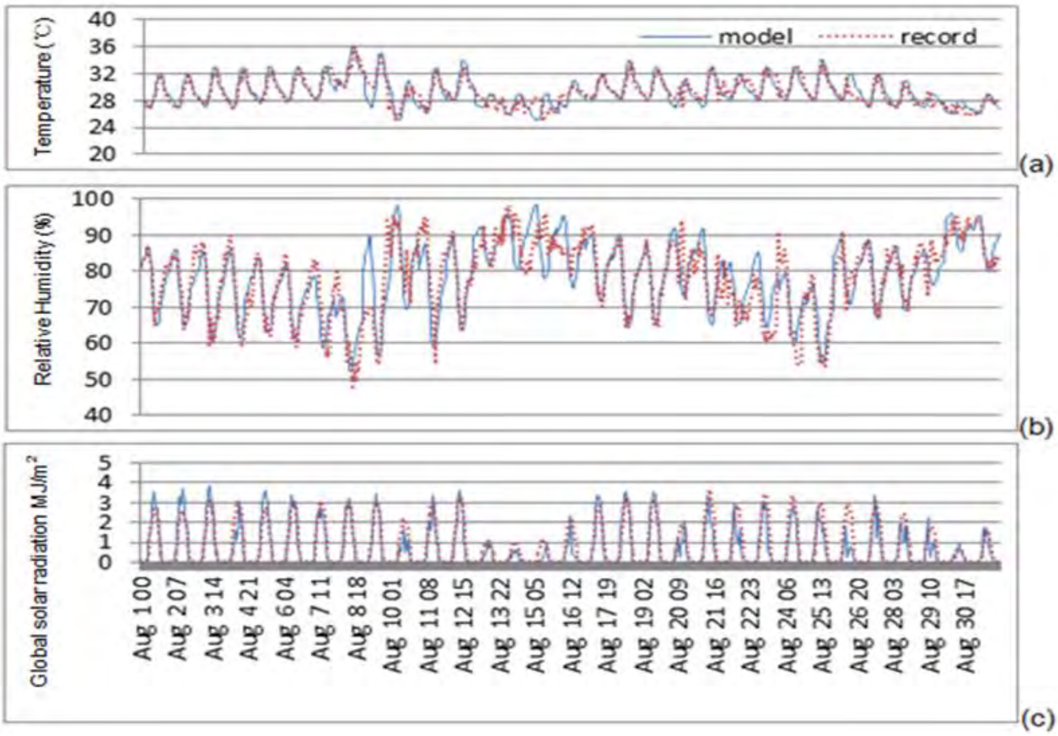


Figure 3: Results comparisons: (a) Dry-bulb temperature (b) Relative Humidity, and (c) Horizontal global solar radiation

The deviations of weather data between our proposed model and the record data from 2013 were determined. The comparison results of temperature, relative humidity and global solar radiation in January are shown in Figure 3 (a) to (c). The overall forecasting mean absolute percentage error (MAPE) of dry-bulb temperature, relative humidity and global solar radiation are 3.2245, 5.6978 and 11.3064 respectively. This indicates that the proposed model is able to give predictions with good accuracy.

3. FORECASTING METHODOLOGY

In the forecasting framework, the raw data is first prepared. Then the influence factors are ranked by their importance, and the less important factors will be filtered. Then the remaining input data are regrouped based on their building energy consumption characteristics. Once the filtering and regrouping processes are completed, the forecasting model structure is subject to optimization. The following shows its application to an illustrating case.

3.1. The study case

The presented case is a university building having an overall floor area of 70,000 m^2 and is a two northwest-oriented blocks each with seven floors. The daily operation hours are from 07:00 - 23:00 on workdays and 07:00 - 18:00 during weekend. Space cooling is required throughout the year. ANN is adopted as the forecasting model, with the LSSVM applied as a reference model [Hyun Chul Jung et al., 2015]. These two models program was developed in MATLAB 2015a version, running on the computer with 32G memory and 2.67GHz process. The test period was from July to September 2014. The rest of data was used as the training sample.

3.2. Data preparation and filtering

The 2013- 2014 weather data, historical energy consumption record, and building operation schedule were used as input parameters to predict the next day 24-hour energy consumption. The weather data include dry-bulb temperature, relative humidity, global solar radiation, rainfall, clearness of sky, cloud condition and wind speed. The historical energy consumption record was from the building management system. The operation schedule information was based on the day types, hours of the day and the periods of the whole academic year. These include the semester, student revision period, examination period, and semester break - all are in the university academic calendar.

The input data were filtered before loading into the forecasting model. The test was by means of the mutual information (MI) criterion, in that the influence factors were collected with the MI value calculated, and then their importance were ranked [Keynia F, 2012 and Esmaeili S et al., 2014].

3.3. Data regrouping

Figure4 shows the energy consumption contour of this building, through which the overall daily profile and weekly trend can be readily visualized. The X-axis shows the dates in August and the Y-axis is the 24-hour across the day. It can be seen that from 00:00 AM to 8:00 AM, the energy consumption is low. Then after 8:00 AM, the energy consumption is increasing rapidly. The peak load occurs between 14:00 PM and 17:00 PM. After 20:00 PM, the energy consumption is decreasing. On the other hand, the daily consumption during weekday is relatively stable. Those during weekend are comparatively low. But there are exceptions. For instance, because of the typhoon on August 14, the consumption was low throughout this weekday. In our model, the energy consumption forecasting on holidays or under special circumstances were handled separately. Accordingly, the input data are divided into two parts. One part includes only the normal working day information, as data set 1. The rest consists of the holidays, weekends and days with emergency; the information are referred as data set 2.

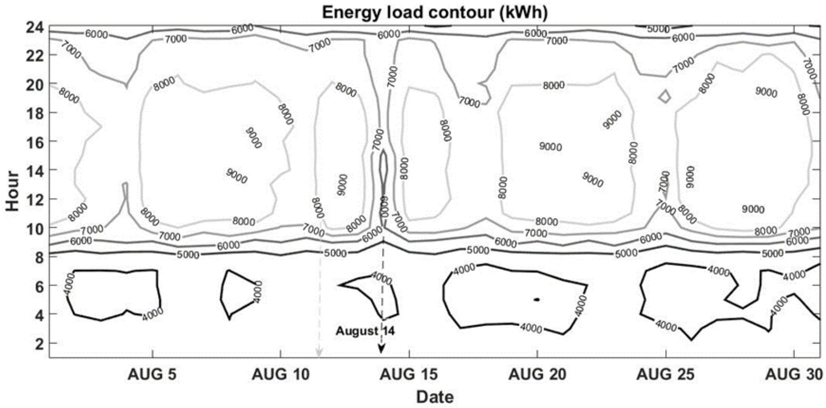

Figure 4: Hourly energy consumption contour

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4. FORECASTING RESULTS

The details of forecasting accuracy can be found in Tables 1 to 3. The accuracy criteria adopted are the Mean Absolute Percentage Error (MAPE), Daily Peak MAPE, Coefficient of Variance of the Root Mean Squared Error (CVRMSE) under 95% confidence limits.

The results of forecasting are found agreeing well with the real consumption load. The overall MAPE values are found similar by using either the record weather data or the proposed weather forecast data. The simulation results are also compared with different input data sets, such as those without filtering or regrouping. The results indicate that filtering and regrouping are the effective ways to improve the forecasting accuracy. Figure 5 is the energy consumption profile comparison between the two different forecasting models and the actual load curve. The black solid line represents the real electrical consumption, while the red and blue broken lines represent the ANN and LSSVM forecasting energy profiles respectively. The comparison confirms that the forecasting results agree well with the real consumption load. The overall MAPE are no more than 6.1% and 5.5% for the ANN model and the LSSVM model respectively.

Model	record weather data			modelled weather data		
	MAPE	Daily peak MAPE	CVRMSE	MAPE	Daily peak MAPE	CVRMSE
ANN	5.9775	4.9217	7.9112	6.0245	5.2247	8.1223
LSSVM	5.2496	4.1713	8.0707	5.4432	4.5712	8.3210

5. CONCLUSION

A new method is proposed to generate weather data by prediction based on information publicly available. Data of influence factors were carefully collected. The importance of different input data was analysed with the application of mutual information in a study case. The proposed method has been shown able to achieve good forecasting results for the next day 24-hours energy consumption. The comparison of forecasting results shows that by regrouping and filtering the input data, the forecasting accuracy can be improved. It is also confirmed that the weather prediction model here proposed is convenient, and suitable for short-term load forecasts of buildings.

ABSTRACT

CO_2 is one of the primary indicators for the regulation of Demand Control Ventilation systems, as it is directly linked to occupancy. CO_2 can also serve as a surrogate indicator of indoor air quality and a proxy to other occupant generated pollutants. Although the use of CO_2 in control strategies has been fairly common in the industry for several years, there is still very little research to evaluate model predictive control incorporating future CO_2 levels. In essence, model predictive control is created around a model, or a set of models, which provides an estimation of the evolution of a process or system over time, subject to the effects of disturbances. It provides information of the system response under various control inputs and, ultimately, it decides on the optimal combination of controls. The more accurate the model, the better the performance of the controller. For accurate CO_2 prediction, it is important to know how the occupancy varies on a daily basis. Standardised occupancy schedules are not able to provide this level of resolution, since they are more of an averaged pattern. For building energy consumption this may be enough to produce accurate annual, monthly or even daily predictions, but for CO_2 levels an "average" pattern is likely to be flawed more often than not. In this study, highly granular predictive CO_2 models are developed through the combination of CO_2 measurements and an EnergyPlus model. A finely calibrated EP model acts as a data generator for a model identification procedure, which can lead to robust CO_2 concentration models of selected spaces.

Keywords: CO_2 prediction, occupancy estimation, energy us

1. INTRODUCTION

Globally buildings are responsible for 20-40% of total final energy consumption and in developed countries this figure is increasing annually at a rate of 0.5-5%, while the building sector accounts for 33% of global CO_2 emissions (Pérez-Lombard et al., 2008). In the USA alone 41% of primary energy use is attributed to buildings, excluding industrial facilities (DOE, 2011). Typically the main components of building energy consumption are the Heating, Ventilation and Air Conditioning (HVAC), as well as the lighting systems, so improvements in the respective technologies and operational efficiency of these systems are of great interest to researchers and industry alike (Hochstein et al., 2012), since significant environmental and economic benefits can be achieved. One particular strategy that is applied in HVAC systems is demand-controlled ventilation (DCV). DCV is meant to provide appropriate ventilation rates to cater for changing occupancy conditions, thus unlocking potential energy minimisation opportunities. Therefore it is most suitable and beneficial for spaces that experience frequent and irregular occupancy variations, such as restaurants, auditoria and institutional spaces like lecture theatres (Brandemuehl and Braun, 1999). Proper ventilation is considered as being able to supply enough fresh air in a space to maintain a healthy and comfortable environment, both in thermal and indoor air quality terms. In DCV systems carbon dioxide (CO_2) is typically used as an indicator of human occupancy (Yang et al., 2015) due to its link to respiration and the ventilation rate is adjusted accordingly to maintain the indoor CO_2 levels under a predefined set point. Occupancy detection on the whole is of great interest since knowing the current and historical occupancy patterns can assist in building control decisions. As such, the measurement of CO_2 concentration in buildings is becoming increasingly important, especially as cheap and robust CO_2 sensors are becoming more common and smart buildings supported by connected and wireless sensor networks. The energy saving potential of CO_2 based ventilation control has been intensively investigated and a thorough review of the literature that includes field studies, simulations and sensor location evaluation has been conducted by Emmerich and Persily (2001).Currently, most Building Energy Management Systems (BEMS) equipped with automated control systems are reactive and adaptive to changing climatic conditions and operational parameters. The inclusion of predictive control in a BEMS permits the calculation of optimum control strategies for various steps into the future (Clarke et al., 2004). Thus, while an adaptive online control scheme can only react to changing building conditions (Doukas et al., 2007), a model-based predictive control works by evaluating different control scenarios based on predefined objective functions and select those that offer optimum predicted performance (Kolokotsa et al., 2009). Given that most DCV systems currently try to maintain CO_2 within certain levels, it is worth investigating how moving this control decision from a reactive to a predictive protocol may affect the energy consumption of the HVAC system.

In this paper we show that it is possible to develop accurate predictive CO_2 models for a university lecture theatre using a simple array of a few CO_2 sensors. Furthermore, the same setup can be used as a current occupancy estimation system to a reasonable degree of accuracy, thus avoiding the privacy issues emerging from other occupancy detection systems such as cameras. First the experimental setup will be described, followed by a description of the method used to develop the predictive model for CO_2. Finally, it is shown how a reverse model can estimate occupancy and a comparison is made to the ground truth.

2. MODEL DEVELOPMENT

2.1 CO_2 prediction

A general model that can be considered for depicting the change in CO_2 concentration, *C*, in a room or zone with volume V is the following:

$$V\frac{dC}{dt} = Q_{ven}(C - C_{out}) + G_{CO_2}$$

Equation 1

where G_{CO2} is the generation rate of CO_2 in the room, which depends on the number of occupants and type of occupant activity. The ventilation rate term Q_{ven} only refers to the outside air entering the zone and can be considered as the sum of mechanically supplied ventilation and infiltration. From Equation 1, and assuming a standard level of activity, the discretised form of this relationship can be expressed as:

$$C_{t+1} = f(C_t, N_t, Q_{ven,t}, C_{out,t})$$

Equation 2

which is a relationship with parameters specific to the conditions of the room where CO_2 is measured. Of these quantities, in this study the zone concentration of CO_2 is the only that is available through measurements. Ambient CO_2, C_{out}, is taken as a constant 400 ppm due to lack of historical ambient data. In order to complete the data set for model identification, the number of occupants and the ventilation rate are needed. These are made available with the use of an EnergyPlus (DOE, 2016) model of the lecture theatre. EnergyPlus has a carbon dioxide estimator, and this function is used to calibrate the number of occupants at various times. The ventilation and infiltration rates are known from the HVAC system properties and a previous energy audit of the university. Thus, the data set is complete and can be used for model identification.

The MATLAB (MathWorks, 2000) System Identification Toolbox is used for this task. The toolbox offers several structures for identifying a system, and we have chosen the discrete time state space representation:

$$x(t+1) = Ax(t) + Bu(t) + Ke(t)$$

$$y(t) = Cx(t) + Du(t) + e(t)$$

Equation 3

where *x* is the state vector, *u* is the input vector, y is the output vector, *e* is a generalised disturbance and *A*, *B*, *C*, *D* and *K* are matrices with estimable parameters. The dimension of the matrices corresponds to the model order. The focus of the identification procedure is set to prediction, meaning emphasis is placed in minimising the error for next step prediction assuming the output (i.e. CO_2) is known up to the present. Prediction can be made for a certain prediction horizon that can be several steps ahead. In each case, the output (CO_2) at present time is a measured value and the future outputs are predicted based on assumed inputs (occupancy and ventilation).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.2 Occupancy estimation

By reversing the model of Equation 1 it is possible to express the number of occupants as a function of CO_2 concentration and ventilation. In this case however, we are not interested in predicting the future number of occupants, which is meaningless in this context, but rather estimating the current number. Again the MATLAB System Identification Toolbox is used in the structure of Equation 3, however this time the focus of the identification procedure is set to simulation, meaning emphasis is placed in minimising the error for a model computed using input data (in this case, CO_2 and ventilation rate) and initial conditions.

3. EXPERIMENTAL SETUP

3.6 Sensor deployment

Three CO_2 sensors have been placed in the lecture theatre, one at the lecturer desk low in the room, the other on a side wall at the middle row and the third one at the final, highest row, as can be seen in Figure 1. The placement of different sensors at varying heights has been done to ameliorate the potential effects on the measurements of both an uneven student distribution and the tendency of warmer air to rise higher, by taking the average of the three sensors as the lecture theatre average.

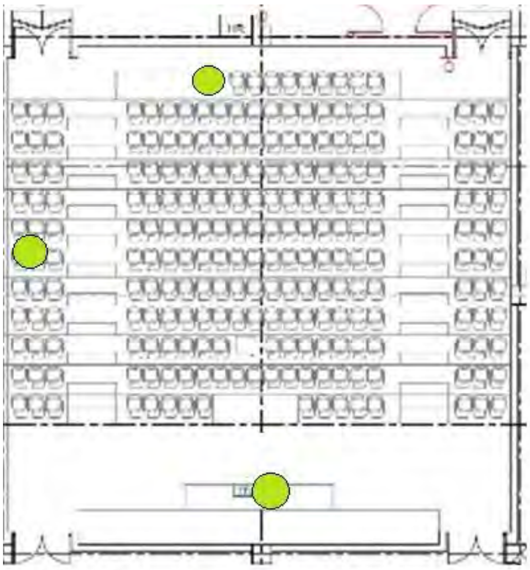

Figure 75: Placement of CO_2 sensors in the lecture theatre

The CO_2 sensors have an accuracy of 30 parts per million (ppm) plus 3% of the reading. The sensors are connected wirelessly via the university network to a server and transmit their measurements at one minute intervals. These measurements are updated and saved in the server so they can be viewed either as historical or current data and can be downloaded for further processing.

Apart from the CO_2 sensors, a camera placed on the ceiling was able to capture an image of all the occupants in the theatre at five minute intervals and log it for further use. This camera was not used in the estimation of the CO_2 prediction model but was used to provide validating data for the occupancy estimation mode

3.7 Data collection

Data was collected for a period of five days during which the lecture theatre was fully active and experienced great fluctuation in occupancy. The CO_2 measurements were taken at a one minute frequency but were grouped in five minute averages for use in the calibration of the EnergyPlus simulation. The result was a set of 1440 data points that were used in the model identification procedure. Of these, 288 (20%) were used to train the models and the rest were used to validate them. The EnergyPlus simulation was run accordingly for a period of five days on a five minute time step and a corresponding reporting frequency. As mentioned previously, this makes available the data for occupancy and ventilation rate.

4. RESULTS

4.1 CO_2 model

The performance of the best estimated model can be seen in Table 1 and Figure 2. On the whole, the model is able to accurately predict the CO_2 concentration even at the furthest prediction horizon that was tested, which corresponds to 20 time steps or 100 minutes. There is however a notable performance drop after the third and especially after the fifth step. Even so, the model is performing very well for predictions between 5 and 25 minutes, which are time periods that are highly relevant for HVAC control actions.

Prediction horizon	R^2	RMSE (ppm)
1	0.9982	11
2	0.9925	21
3	0.9817	33
5	0.9510	55
10	0.8973	82
20	0.8918	85

Table 14: Coefficient of determination (R^2) and Root Mean Square Error (RMSE) for different prediction horizons

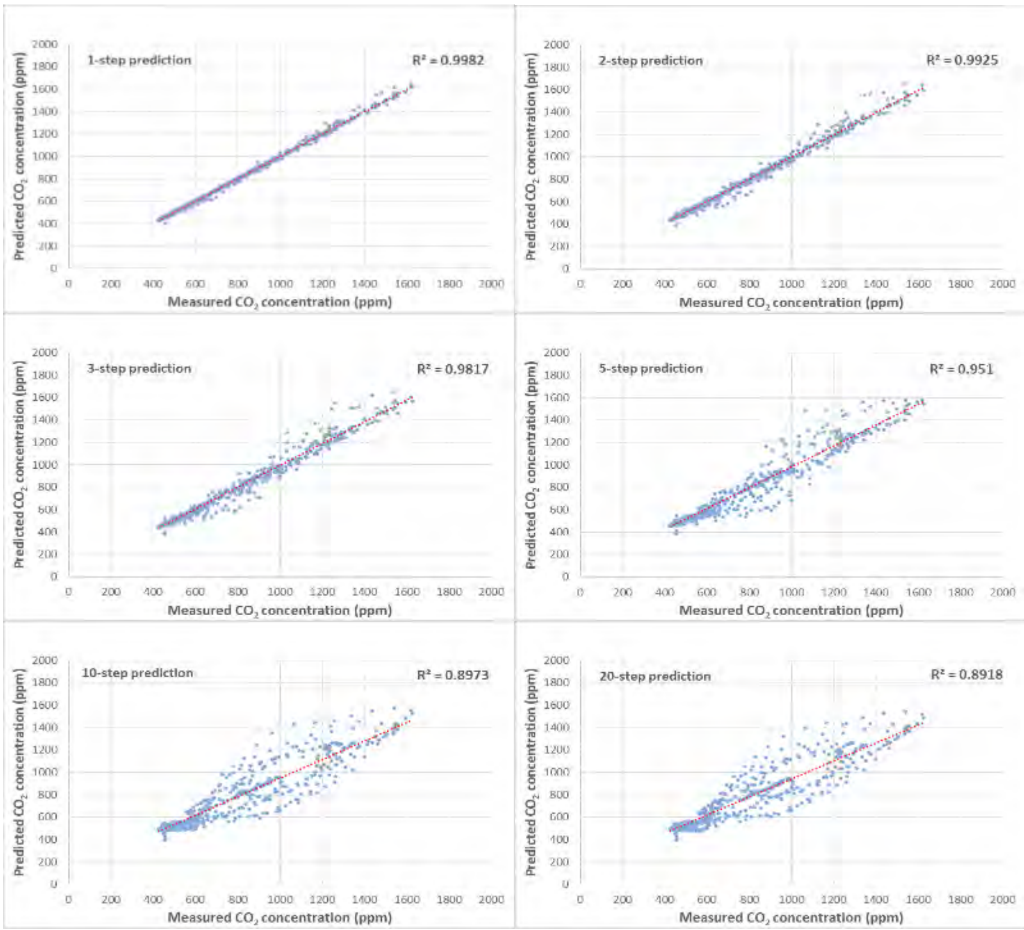

Figure 76: Measured vs predicted CO_2 concentration for different prediction horizons

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4.2 Occupancy model

The performance of the best estimated model can be seen in Figure 3, with its associated R^2 and RMSE (in number of occupants). Although the model performs well on average, it generally overestimates the number of occupants, especially when the occupant number is low.

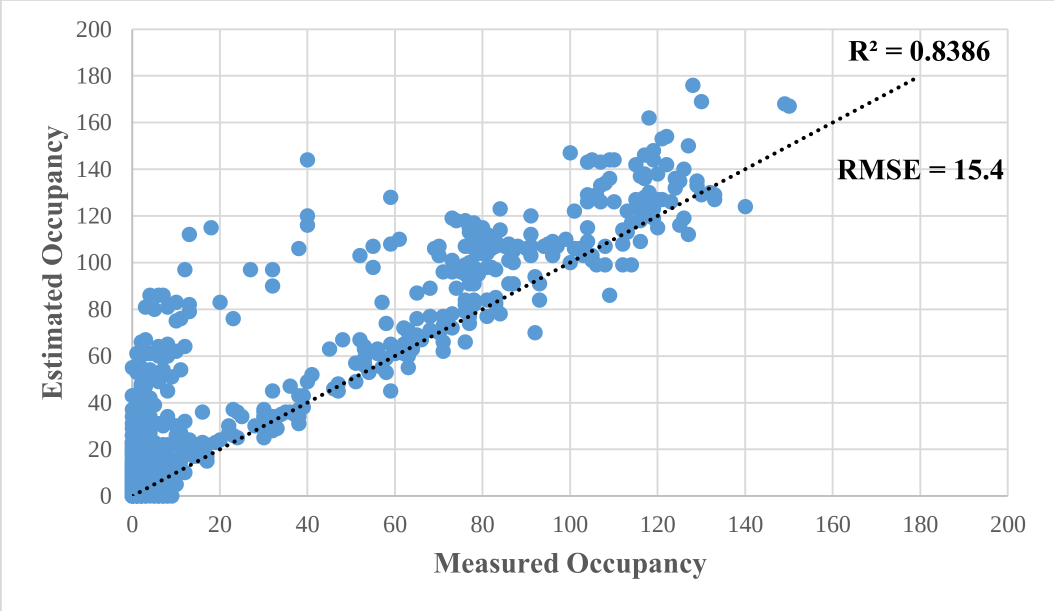

Figure 77: Measured vs estimated occupancy

Most of the larger differences between estimation and actual occupancy occur at transitional periods at the end of classes, which may explain the much bigger discrepancy at low occupancies. For example, at the end of class the students empty the theatre very quickly, while the CO_2 sensors are still picking up high values. The opposite effect doesn't happen as often, since the increase in CO_2 upon student arrival is much sharper than the decay during their departure.

5. CONCLUSIONS

This study has shown that it is possible to create an accurate predictive model of CO_2 for a selected space using only a few commercially available CO_2 sensors. The model performs very well within the prediction horizon that is relevant in HVAC control adjustments and thus is promising for use in the calculation of a CO_2 related performance parameter in model predictive control systems. Using the same easy and non-intrusive setup, this study has shown that it is also possible to have an estimation of the current number of occupants, although to a lower degree of accuracy, due to the fact that the transitional periods at the end of classes introduce a large degree of error. However, it is beyond the scope of the current study to investigate this issue further.

ABSTRACT

This paper presents a case study of a large-scaled retail mall air-conditioning system testing and commissioning (T&C) as well as retro-commissioning during the whole process from the construction stage to the 2-year operation stage. The system efficiency was improved significantly by cooling tower air flow distribution study, chilled water system and condensing water system balance, major equipment fine-tuning, etc.

The T&C works started with the system design review and site instruments provision survey. The sufficient and accurate measurement data are the important part to evaluate the equipment and system performance. Further in-depth analysis of the system resistance, hydraulic balance as well as the plant overall efficiency, during the retro-commissioning stage, revealed the common problems and the root causes.

The Building Management System (BMS) provides great potential and capacity for the automatic commissioning, preventive maintenance and intelligent control. Early ready of the BMS could play a very important role for the T&C. However, the BMS is always behind the schedule for the handover. Sensor soft errors are another common problem in the system, which affects the application of the control strategies.

In this paper, the challenges and the corresponding technologies of the performance tests and the improvement measures are summarized for sharing with the building industry.

Keywords: retail mall, retro-commissioning, energy saving

1. BACKGROUND

There have always been many challenges during the commissioning (Cx) of the heating, ventilation and air-conditioning (HVAC) systems. Cx has become an important process to guarantee the building energy efficiency in developed countries such as America. Quantities of research works and engineering practices at this aspect have been conducted by ASHRAE, NEBB and US General Services Administration, and completed criteria and standards have been formulated. In Japan, the performance tests for the major energy consumption components of HAVC systems are compulsory. The introduction of the methodology for HAVC system Cx started in China during the 1990s. The local research institutions began to conduct many studies and practical works in order to promote the Cx implementation. However, Cx is still at developing stage in China, to which the building industry does not pay enough attention. The Cx procedure and quality control methodology are still not well developed.

For HVAC systems operation, the annual energy consumption increases due to lack of the detailed commissioning in many projects. Moreover, the hidden problems cannot be found and solved by the operators because the numerous equipment and complicated systems are involved. Therefore, the in-depth analysis for the Cx works and the retro-commissioning (Retro-Cx) exercise are especially important.

To solve the above problems, this paper discusses the methods, experience and challenges of the Retro-Cx comprehensively from three levels, which are equipment performance commissioning, system performance commissioning and annual operation commissioning. This text also presents a case study of a large-scaled retail mall air-conditioning system in Chengdu to evaluate the practical applicability of the Retro-Cx method.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2. THREE LEVELS OF RETRO-COMMISSIONING APPROACH

Retro-Cx is a process which involves detailed diagnose and improvement for each system. It can solve the existing problems, reduce the energy consumption and enhance the performance of the whole building through the conventional but effective measures. The Retro-Cx had been classified into three levels. Figure 1 shows the key points of the Retro-Cx at each level.

As shown in Figure 1, the performance of the main equipment would be measured through Level 1 exercise of the Cx. By means of Level 2, the procedure can ensure the system performance and the hydraulic balance. Furthermore, through Level 3, the process can ensure higher efficiency for the long-term operation. For the three levels of Retro-cx, specific commissioning methods and results will be discussed in detail, with the reference to the practical cases.

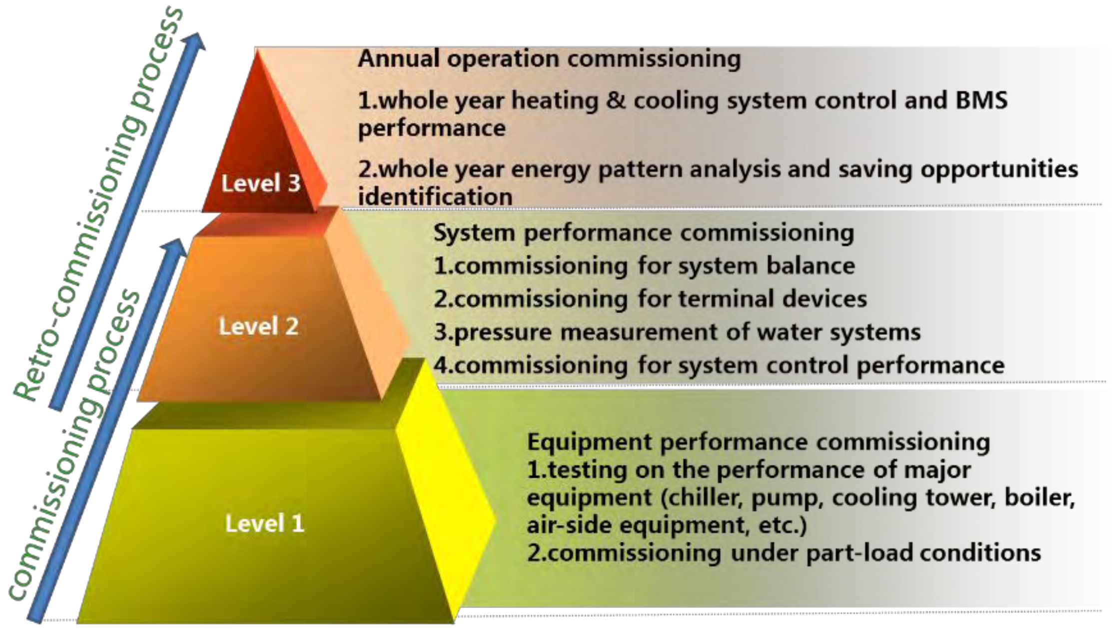

Figure 1: Commissioning and retro-commissioning

3. CASE STUDY ON A RETAIL MALL

3.1. Building Information

This case study is a large-scale retail mall in Chengdu, which is the low rise development with lanes, alleys, courtyards, streets and squares (Figure 2). The total area is about 220,000 m^2. The cooling source of the HVAC system comprises three centrifugal chillers and three screw chillers, with the primary variable chilled water system for cooling energy transmission. During winter and transitional seasons, free cooling plate heat exchangers will be used for the cooling. The heating source adopts five oil & gas boilers.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 2: Retail mall panorama

3.2. Level 1: equipment performance commissioning

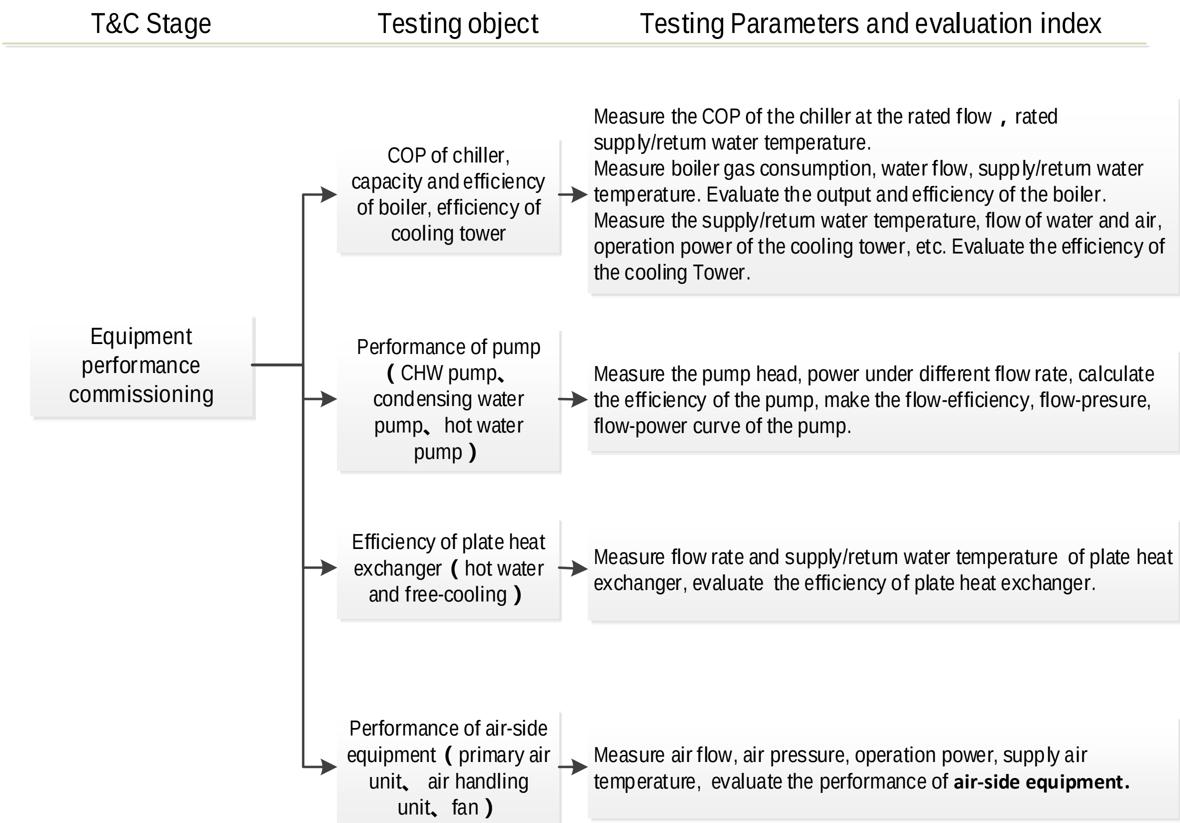

Figure 3: Key points of equipment performance commissioning at Level 1

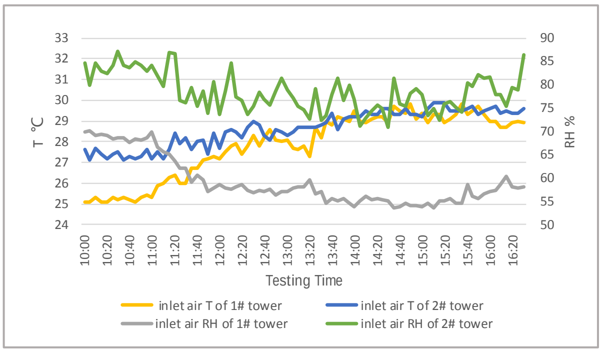
As shown, Figure 3 summarizes the Cx key points of Level 1. The case study for cooling towers of the retail mall would be presented in detail.

3.2.1. Case study of cooling towers



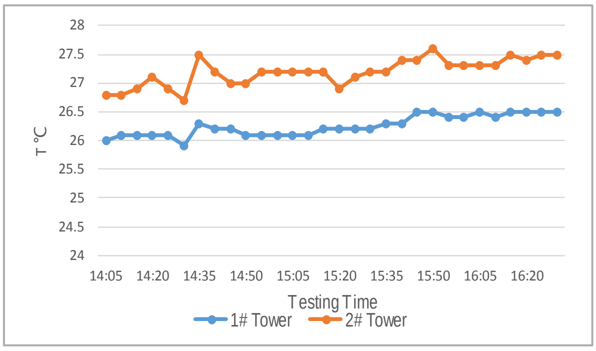


Figure 4: Inlet air parameters of the cooling towers before improvement

Figure 5: Outlet water temperature of the cooling towers before improvement

In this project, the cooling towers are located on the roof of the eight-storey hotel beside the mall. One side of the roof is enclosed with the curtain wall, while the other side is provided by the louvers. During the efficiency tests of the cooling towers, it was discovered that the big difference of the inlet air temperature and relative humidity between the two adjacent cooling towers (Figure 4).

After the site investigation, the big temperature and relative humidity difference of the inlet air for the cooling towers on the curtain wall-side and on the louver-side were found. The discharged air of the cooling towers is blocked by the roof structure. The short circuit led to the increased temperature of the cooling tower outlet water (Figure 5).

The power consumption of the chillers increases by about 3% as the temperature of the cooling tower outlet water increases by 1°C. During the peak summer, the potential risk of chiller shut-down was also seriously considered if the cooling towers' performance could not be improved.

According to the measurement data and the simulation results, the retrofitting was conducted to improvement the overall performance by adding the exhaust ducts (Figure 6). The temperature and the relative humidity of the inlet air had been measured again after the retrofitting and the comparison results showed that the inlet air parameters were much more reasonable (Figure 7).

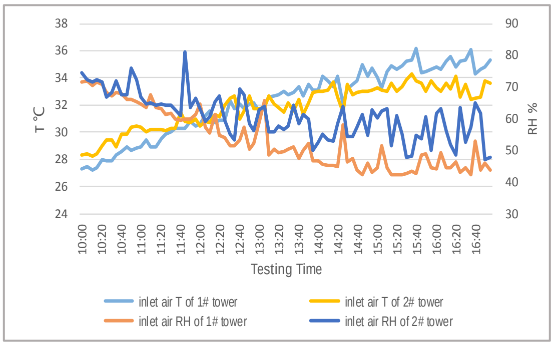

Figure 6: Cooling tower exhaust before and after retrofitting

Figure 7: Inlet air parameters of the cooling towers after improvement

Site investigation on many other projects demonstrated that affected by the façade design and the location of the cooling towers, the outlet-inlet air short circuit is common. Consequently, the adequate louver areas and the better airflow design need to be addressed during the design stage. Measurements are recommended to be taken to verify the heat rejection efficiency.

3.3. Level 2: System performance commissioning

Figure 8 summarizes the key points of Level 2. The case study for chilled water system pressure drop measurement would be introduced in detail.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.3.1. Chilled water system pressure drop measurement

The pressure drop analysis of the chilled water system is described to introduce the specific methods of system performance commissioning.

After measuring the pressure at the critical points of the chilled water system, it was discovered that the pressure drop between the chilled water pump outlet and the strainer inlet reached 0.2MPa. The excessive pressure drop indicated the potential problem(s) in chilled water system. The provisions of the chilled water system are illustrated in Figure 9.

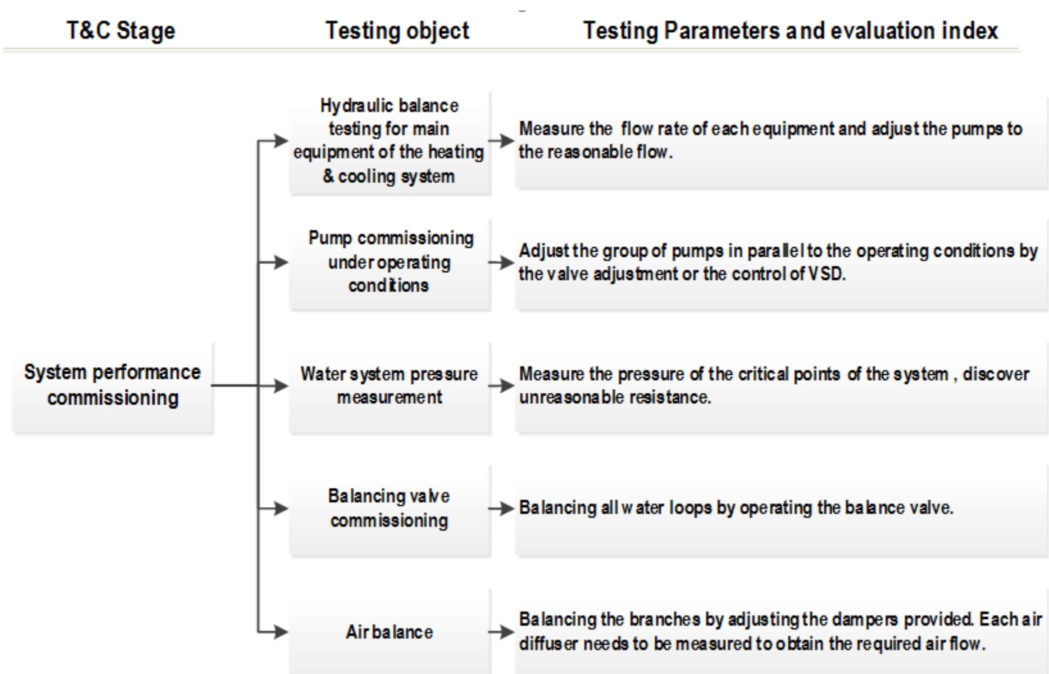

Figure 8: Key points of system performance commissioning at level 2

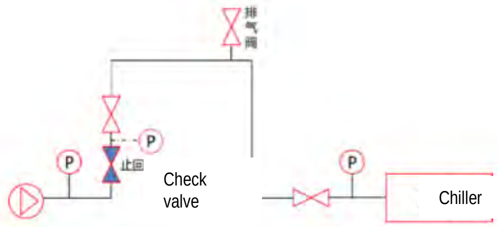

Figure 9: Pipes and fittings between chilled water pumps and chillers

There are two butterfly valves and one check valve between the two pressure gauges, one at the chilled water pump outlet and the other one at the inlet of the chiller. In order to check the problems, the air vent at the top was initially opened to discharge air. To study on the cause(s), a pressure gauge was installed after the check valve, which showed that the pressure drop of the check valve reached 0.15MPa, while the pump operating at the rated frequency (Figure 10). In this way, it was confirmed that the check valve was the reason for the unnecessary pressure drop. A check valve of new type was chosen to replace the existing valve, and the pressure drop was reduced to 0.03MPa. This could reduce the pump head by 12mH_2O (around 0.12MPa). The promising energy saving could be about130,000 kWh/year.

At the project design stage, all the relevant parties would pay more attention to the performance parameters of the major equipment. However, the selection of valves and fittings is also important for the system efficiency. The detailed specifications for both the major equipment and the relevant fittings are strongly recommended.

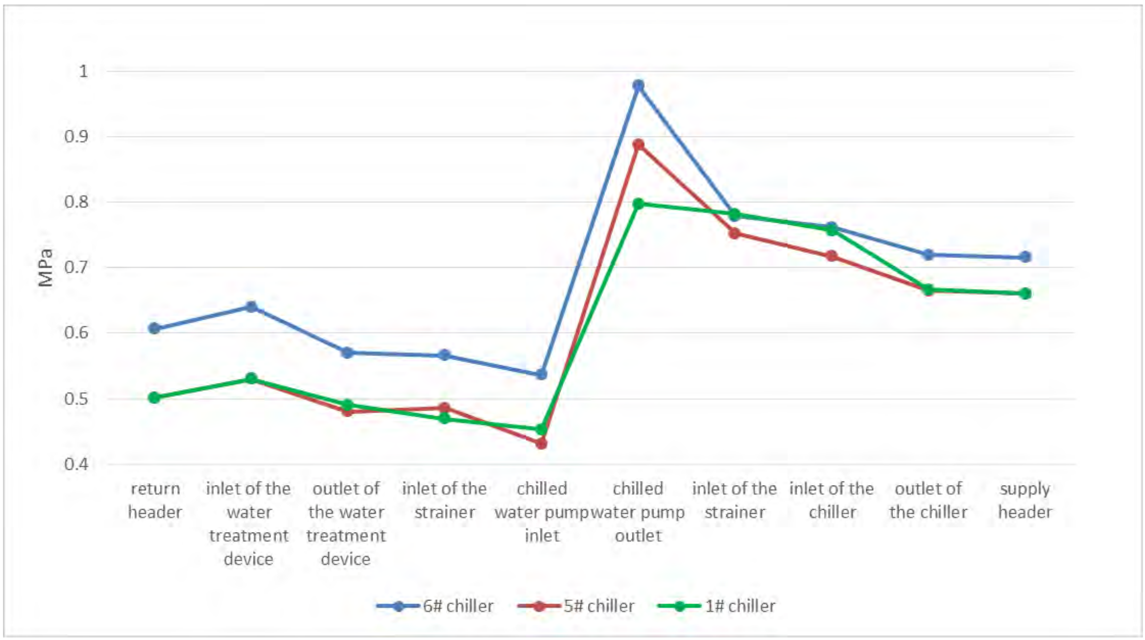

Figure 10: Pressure measurement of chilled water system

3.4. Level 3: Dynamic Operation Commissioning

Figure 11 summarizes the Cx key points of level 3, which is much more focusing on the Retro-Cx about system optimization. The case studies for plant sequencing control and BMS function for the control valves are presented.

3.4.1. Case1: Strategy optimization for plant sequencing control

In this case, the cooling source of the HVAC system comprises three large centrifugal chillers and three small screw chillers. The original control strategy was provided by the manufacturer. The strategy for adding/subtracting chillers, is based on a certain percentage of chiller load. However, the combination of the chillers with different rated capacities was not considered. The original strategy would lead the large chilled to inefficient operation and the small chillers are always switched off during the operation.

For the problem mentioned, the strategy of adding/subtracting chillers was reviewed considering the combination of large/small chillers. The criteria of adding/subtracting chillers are based on the different percentage of the chiller output, which was determined with the reference to the chiller performance curves. Table 1 demonstrates the criteria of subtracting the chillers.

According to the above criteria, if the plant is under the operation mode of two large chillers and two small chillers, once the part load percentage of any of the chillers is lower than 83% for 15 minutes (the specific period could be reset according to the different situations), the system would switch off one small chiller and shift to the next mode (2 large + 1 small).

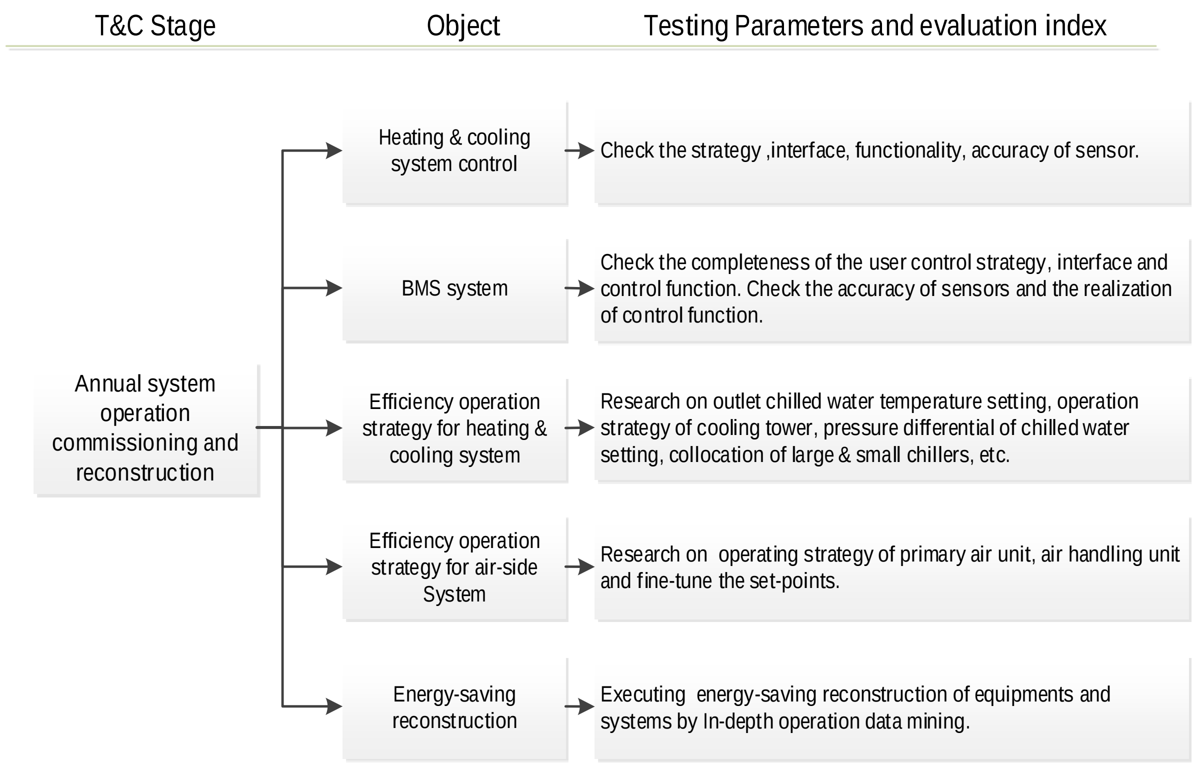

Figure 11: Key points of system dynamic operation commissioning at level 3

	→subtracting in order→									
The order of subtracting	2 large +3 small	2 large +2 small	2 large +1 small	2 large	1 large +3 small	1 large +2 small	1 large +1 small	1 large	3 small	2 small
Part load %	83%	83%	82%	80%	79%	77%	75%	53%	60%	45%

Table 1: The criteria of subtracting the chillers

Remarks:

- This table only presents the operation modes of chillers for this special project.
- Under the operation mode of large/small chillers combination, first subtract the small one, then the large one.

The manufacturers usually slightly modify the general control logics and apply for different projects. The characteristics of each project are not well studied. Thus the strategies provided by the manufacturers may not suit the practical chiller combination and cooling load patterns. More detailed requirements of the control strategy are recommended to be added into the tendering documents during the tendering stage.

3.4.2. Case 2: BMS function of control valves

The BMS control system affects the service quality for the users and the energy efficiency of the systems. Usually, the BMS control is not ready to use until more than one year operation. During this period, some of the control devices are not ready to realize the control ability.

For the retail mail, the chilled water system is serving a large number of tenants. Due to the special requirements of additional chilled water supply after the normal air-conditioning supply period (10:00 - 22:00) from some tenants, the plant is most likely under the operation from 6:30 to 1:00 of the next day. There are six branches of the chilled water system. According to the records, the tenants requesting the additional chilled water supply are served by some of the branches. However, the flow rate percentage of each branch maintains the similar level during the normal operation period and the additional air-conditioning supply period (Figure 12). The measurement of the chilled water supply and return difference showed that the ΔT of some branches are very small, which indicated the chilled water by-pass of those branches.

A control valve is provided for each tenant for two functions. One is the on/off control for the chilled water supply according to the pre-set schedule. The other one is to control the supply return temperature difference of each tenant by modulating during the operation. However, the above measurement data revealed that the control ability of the valves was not properly commissioned yet. The defect caused the increase of the pumping energy consumption.

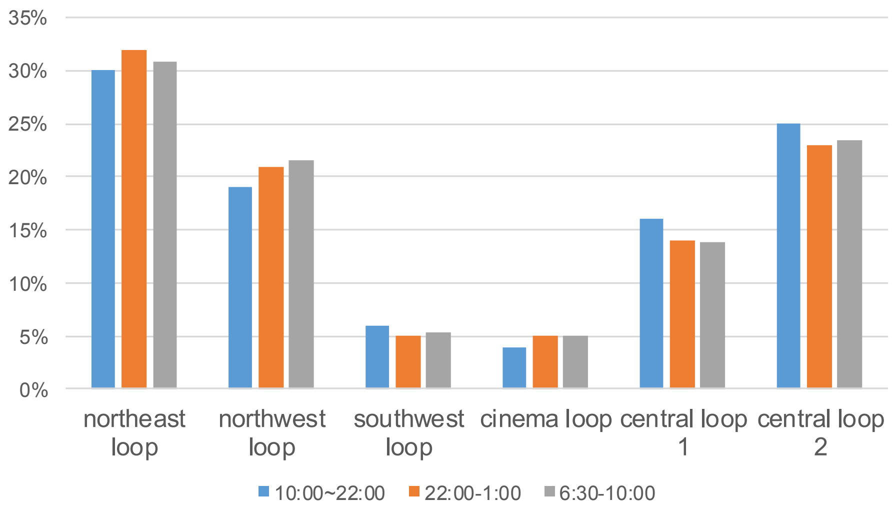

Figure 12: Flow rate percentage of each chilled water system branch in a typical day

During the process of the analysis for the control ability of the valves, it can be discovered that the BMS control functions were not ready after a certain period of operation. The systems are operated manually without some of the terminal control functions, which may lead to significant energy waste. Therefore, the reasonable plan of control system commission is necessary. The particular attention should be paid to the sensor soft errors which are always neglected by the contractors.

4. CONCLUSION

The paper introduces three main levels of the Retro-Cx in detail with the real engineering practices presented. Through the whole process, the full set of data about the equipment and system performance can be obtained, the problems can be discovered and figured out, and the equipment and system can be controlled to good operation efficiency, so that the both comfortable environment and energy conservation operation can be ensured.

The realization of the design intention needs to be guaranteed by proper Cx works assisted by the sufficient provision of the measurement devices. The Cx and Retro-Cx works for the case of the said retail mall would achieve about 900,000 kWh/year energy saving. Further control optimization is targeted to save the energy consumption of 500,000 kWh/year.

5. ACKNOWLEDGMENTS

The research works presented in this paper were under Tsinghua University – Swire Properties Joint Research Center for Building Energy Efficiency and Sustainability. The retail mall is Sino-ocean Taikoo Li, Chengdu.

ABSTRACT

16% of total energy or 30% of total electricity was consumed by space conditioning, primarily cooling, in Hong Kong. Hence, chiller efficiency is key to achieve Hong Kong's low carbon vision. Hong Kong's Building Energy Code has regulated chiller efficiency through rated COP. However, chillers rarely operate under rated condition in real case operation. IPLV and NPLV were first introduced in ARI 550/590-98 as a numerical rating tool to create a metric of part-load/ reduced ambient efficiency to provide a useful means for regulatory bodies to specify minimum chiller efficiency levels and Engineering firms to compare chillers of like technology. However, IPLV/NPLV formula were derived primarily based on US climate and US building energy code, and ideally for single chiller plant use only.

The objective of this paper is to describe the derivation of a preliminary Hong Kong (or alike cities) specific PLV equitation through several projects undertook by our building sustainability group in Hong Kong. The process involves energy simulation as well as real building data analysis.

Keywords: chiller selection, COP, EER, IPLV, NPLV, part load value, building energy code, building energy, efficiency

1. INTRODUCTION

The HVAC industry has struggled to find easier ways to quickly evaluate the performance of central chiller plants. In addition, the increase use of variable speed drive chillers and the increase in energy cost has resulted in an escalating pressure on the development of accurate chiller energy evaluation tool. A simple and accurate evaluation method to analyse chiller plant performance will accelerate the roll out of high performance chillers. IPLV (integrated part load value) as a substitute for executing a complete hour-by-hour modelling analysis were created.

PLV limitations

IPLV was created by the Air Conditioning, Heating, and Refrigeration Institute (AHRI) and frequently promoted by manufacturers as the method to analyse chiller performance. However, AHRI acknowledged that IPLV and NPLV (non-standard part load value) does not accurately represent a chiller plant's operating characteristics.

The following limitations of the standard IPLV is listed below:

- The climate data of which IPLV is derived is an weighted average climate of 29 cities across the United States
- IPLV evaluates a single chiller application only. Appendix D, D2.1 of AHRI Standard 550/590 states: "The [IPLV] equation was derived to provide a representation of the average part-load efficiency for a single chiller only." It is not applicable for multiple-chiller installations

Despite that a non-standard PLV (NPLV) was also introduced to allow user to change test conditions, chiller plant design practitioners in Hong Kong still rely heavily on rated chiller COP for design and specification due to the limitations listed above.

Thus, the aim of this paper is to adjust the IPLV using conditions specific to Hong Kong and to explore the possibilities of using an improved single number chiller performance indicator to improve the accuracy of chiller energy performance evaluation.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

$$IPLV = \frac{1}{\frac{0.01}{A} + \frac{0.42}{B} + \frac{0.45}{C} + \frac{0.12}{D}}$$

A = kW/ton$_R$@ 100% Load and 85°F ECWT or 95°F EDB
B = kWton$_R$@ 75% Load and 75°F ECWT or 80°F EDB
C = kW/ton$_R$ @ 50% Load and 65°F ECWT or 65°F EDB
D = kW/ton$_R$@ 25% Load and 65°F ECWT or 55°F EDB

Figure 1: IPLV equation

2. PLV EQUATIONS FOR HONG KONG

2.1 Standard and guidelines

Due to the limitations listed in earlier, design standards and guidelines in Hong Kong have never adopted IPLV. Hong Kong Code of Practice for Energy Efficiency of Building Services Installations (BEC) used the Rated COP of chillers to regulate chiller performance in the 2007 version and 2012 version. In 2015, BEC has introduced an additional control points for VSD chillers which regulate the chiller performance at 75% load condition and 24°C ECWT (Entering Condenser Water Temperature). This is a right step forward but 24 °C ECWT is considered to be too low for Hong Kong climate.

2.2 Hot and humid climate

IPLV were derived based on the weighted weather average of 29 cities across the U.S.A, specifically targeted because they represented areas where 80% of all chiller sales occurred over a 25 year period (1967-1992).

Hong Kong is located in the hot and humid subtropical climate with high wet bulb temperature. Figure2 shows that the ECWT of chillers of a real office building is above 24 °C in more than 85% of time. On the other hand, based on the standard IPLV conditions, 3 out of four reporting points were below 24 °C. As the result, designer using IPLV to evaluate chiller performance in Hong Kong can be misled. Subsequent studies will show that the optimised reporting condition for Hong Kong chillers are 18-23.8 °C, 24.6-27.2 °C, 29.6-30°C, 30.8-32.3 °C, for 25%, 50%, 75% and 94% respectively.

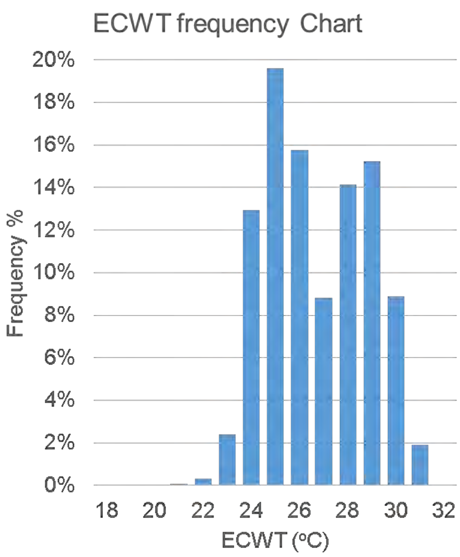

Figure 2: Entering condensing water temperature of chilles measured in an office building in Hong Kong

Apart from the reporting conditions, the hot and humid climate also affect the load profile and operation weightings of chiller plant. Figure 3shows that chiller plant in Hong Kong climate could have a very different operation weightings compare to the standard IPLV.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

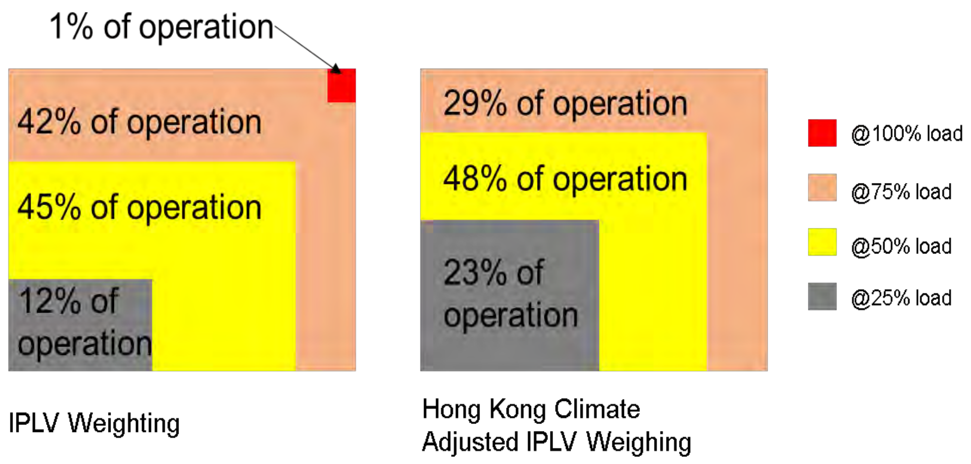

Figure 3: Operation weightings of chiller plant

2.3 Multiple chiller plant

IPLV is only suitable for evaluating a single chiller system. AHRI Standard 550/590 states that "The IPLV equation was derived to provide a representation of the average part-load efficiency for a single chiller only." On the other hand, it is estimated that almost all central water-cooled chiller plants in Hong Kong are multiple-chiller installations, and most of them have 2 to 5 chillers. The number of chillers has a significant impact in the weightings. The previous section showed that chiller rarely operate in 100% loading conditions and it's often argued that chillers simply do not operate at 100% load under good control, the performance at 100% load is therefore not very useful. A 94% part load condition is included to reflect the chillers performance for chiller perform above the 75% load range.

Figure 4 shows the chiller PLV weighting and average ECWT temperature for plants with different number of chillers. The increasing number of chillers result in a decreasing trend in weightings under 25% load condition and an increasing trend under 94% load condition.

According to the figure, Chiller Plant with more than 3 chillers shows that the chiller performance at 75% load is the most important factor for evaluating chiller performance in Hong Kong, this is in line with BEC 2015's requirement. However, this figure showed that the reporting condition should be at ECWT of 29.4-30 °C instead of 24 °C.

Our experience suggests that the PLV table for 4 chillers above representative most cases for buildings in Hong Kong. However, further study looking into the most common number of chillers in a chiller plant in Hong Kong could be conducted to construct a more representative weighting equation.

Figure 4: No. of Chillers and PLV weighting for an Office building in Hong Kong (result obtained through simulation using energy plus)

2.4 Office and multi-usage composite buildings

Apart from climate factors and number of chillers, the building usage also plays an important role. Among buildings with central cooling plant, a majority of them are office buildings and composite buildings.

Figure 5 describes the chiller operation weightings for an office building and a composite building (54% office, 31% retail, 15% others). It shows that for the same no. of chillers, composite building's chillers tend to operate in a lower range of the part load. This is due to the higher diversity factor of the composite building. The higher diversity factor is caused by the diverse load pattern from different building usage and it can often lead to an over sizing of chiller plant.

Figure 5: Office vs composite buildings

In these paper, office and composite buildings are studied to illustrate the different chiller part load weightings, however, more study could be conducted to cover more building types such as pure retail buildings and hotels.

2.5 PLV equations for Hong Kong

Despite that using a single equation to evaluate chiller performances has many shortcomings, the use of a single equation PLV is desired due to the accelerating pressure to increase design productivity without sacrificing the accuracy of energy performance evaluation.

Therefore, based on the study outlined above, preliminary PLV equations adjusted to represent Hong Kong buildings could be derived. The following equations are proposed:

Hong Kong PLV for Office Buildings:

$$HKPLV = \frac{1}{\frac{19\%}{A} + \frac{64\%}{B} + \frac{16\%}{C} + \frac{1\%}{D}}$$

Where: A = COP @ 94% load and 31.2 °C ECWT

B = COP @ 75% load and 29.6 °C ECWT

C = COP @ 50% load and 25.9 °C ECWT

D = COP @ 25% load and 18.9 °C ECWT

This equation is based on a three-equal-chiller water cooled plant configuration. The decision to use this configuration is based on our database and design experiences.

Hong Kong PLV for Composite Buildings:

$$HKPLV = \frac{1}{\frac{17\%}{A} + \frac{51\%}{B} + \frac{17\%}{C} + \frac{15\%}{D}}$$

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Where: A = COP @ 94% load and 31.5 °C ECWT

B = COP @ 75% load and 30 °C ECWT

C = COP @ 50% load and 26.4 °C ECWT

D = COP @ 25% load and 22.1 °C ECWT

This equation is based on a four-equal-chiller water cooled plant configuration. The decision to use this configuration is based on our database and design experiences.

These equations are not intended to produce the most precious chiller performance results, but to provide better benchmarks than the rated COP commonly used in Hong Kong HVAC industry.

3. WAY FORWARD

Due to the limitation of our database and experiences, further review of different building types, combinations and building scale could be evaluated to further improve the PLV equation. The PLV equations outlined in this paper could be used as a starting point for establishing a Hong Kong specific PLV equation to evaluate and compare chiller efficiency in a cost effective manner. The intention of this paper is to inspire similar investigations into Hong Kong's or other similar built environments' HVAC design practice to promote energy efficient design in a large scale.

Other than a single equation outlined in the section above, advanced chiller performance study could be conducted in order to produce a near optimised design solution. Designer should follow the 8 steps listed in (Taylor, 2012) to conduct any chiller design if resources allowed.

In our group, energy modelling and in-house developed chiller annual COP calculator are used to determine the performance for specific building design and operation to ensure the most energy efficient chillers will be selected.

ACKNOWLEDGMENT

This research is inspired by the chiller design study conducted during the design of One Taikoo Place and supported by Swire Properties, especially its Technical Services and Sustainability Department and Projects Department, The authors wish to thank them for their supports and assistances in this project.

ABSTRACT

Recently, redevelopment projects which arrange densely buildings with large floor area are moving ahead in Tokyo. Tenant office business particularly requires not only high-standard office space but also resilient and environmentally friendly design. A building described in this paper is a 30-story complex building composed of tenant office, rented housing and retail, and designed for realization of safety, functionality and environmental performance that are required of next-generation high-rise buildings. In facade design, building envelope heat load was reduced by 35% compared to office baseline using precast outer frame structure with ultra-high strength concrete and original high-performance glazing. In heat source system design, high-efficiency inverter centrifugal chillers and temperature-stratified-type thermal storage tanks with variable capacity were introduced and the high efficiency was verified in actual operation around the year. Air-conditioning system with separation of sensible and latent heat was selected and unique control, which stops VAV air-handling unit automatically in low load operation, was implemented. By these energy-saving technologies, annual primary energy consumption for the whole building was 1,266 MJ/m2 and reduced by 40% compared to the averaged actual performance value for office buildings in Tokyo. An example of HVAC system design in high-rise tenant office buildings can be produced for actual practice of low-carbon when high functionality and redundancy are required in condition of uncertain users.

Keywords: energy saving, high-rise tenant office building, HVAC system design

1. INTRODUCTION

Japanese government provides grant-in-aid for promoting energy saving, utilization of renewable energy and smart community, and promotes nation building for low carbon, safety and security (METI, 2016). Recently, redevelopment projects that arrange densely buildings with large floor area are moving ahead in Tokyo, Japan. Tenant office business particularly requires not only high-standard office space but also resilient and environmentally friendly design. For HVAC system design of tenant office buildings, redundancy is required because it is designed when tenants are not determined and human behaviour of users is uncertain. A building described in this paper is a 30-story complex building composed of tenant office, rented housing and retail. We received the grant-in-aid for promoting low-carbon building from MLIT (The Ministry of Land, Infrastructure, Transport and Tourism) and aimed for realization of safety, functionality and environmental performance which are required of next-generation high-rise buildings. This paper describes the outlines of the systems employed in this building and analyses the measured performance of these systems in detail.

2. OVERVIEW OF BUILDING

The building discussed in this paper is a 30-story high-rise building complex containing lease offices, lease apartments and retail stores. It has been designed to provide the safety, functionality and environmental performance needed for a next-generation ultra-high rise building. The building has a total floor area of 47,982 m^2 for offices and 5,795 m^2 for apartments. Figure 1 shows an exterior view of the building. The facade plan integrates the building and equipment functions to achieve a simple exterior that offers high heat insulating performance. The facade is made up of a precast outer frame structure (Figure 2) with an eaves effect that can be expected to cut annual direct solar radiation by 75%, and proprietary ultra-high performance Low-e glazing that achieves a solar shading coefficient of 0.29 for the glass alone. Combining this facade with automatically controlled blinds results in a 35% reduction in outer skin load as compared to the standard value for offices, and this system has been confirmed to provide performance equal to or better than airflow windows. Cold draft intake ports have also been

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

provided at the base of the windows to improve the upper and lower temperature distribution near the window in winter (Figure 3).

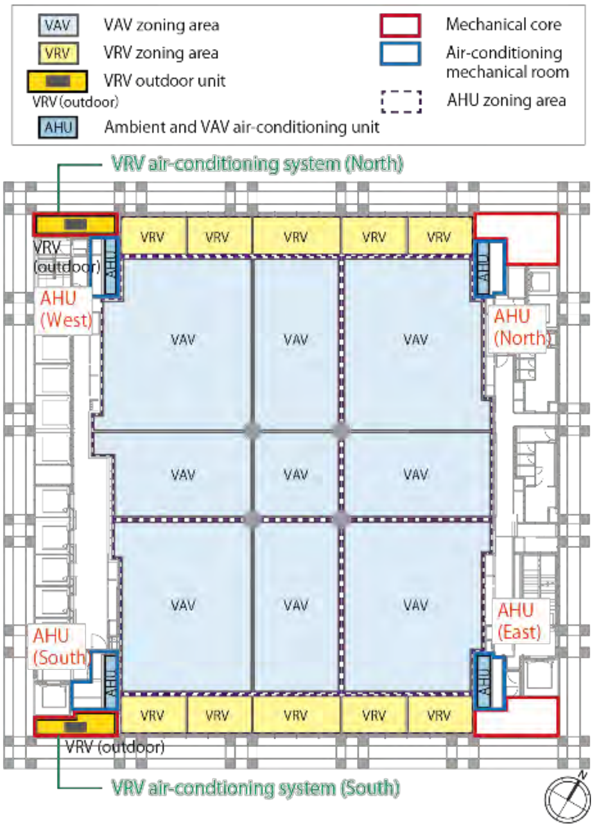

Figure 4: Zoning of air conditioning

3. OVERVIEW OF AIR-CONDITIONING SYSTEM

A single duct variable air volume (VAV) air-handling system has been adopted as the basic air-handling system for the building, out of consideration for the need to track changes in partitioning of the tenant building. Up to four tenants per standard floor can be accommodated, and operation and control can be designed in accordance with partitioning needs, with nine zones for the interior VAV and 10 zones for the indoor unit zoning for the perimeter individual distributed type HP (Heat pump) variable refrigerant flow (VRF) air conditioning units (Figure 4). In addition, an active effort has been made to reduce transport power consumption through integrated control of air-handling system units. The air-handling systems on standard floors are a combination of centralized and independent systems, with ambient outdoor air-handling units, VAV air-handling units and a VRF air conditioning system for the perimeter. The ambient outdoor air-handling units bring in fresh air from outside and regulate the humidity environment. The VAV air-handling units are treated as task air-handling units that track the increase and decrease in internally generated heat and regulate the room temperature. The VRF air-conditioning system in the perimeter controls the thermal load near windows and is designed to accommodate room partitioning. Since the nature of tenant use has not yet been determined, this air-handling system is designed to enable high-efficiency operation under a variety of conditions. This is accomplished by switching the three air-handling systems to the following modes in accordance with the load status and outside air conditions (Figure 5).

- High-load mode (cooling)

This is the so-called normal rated cooling operation in which the ambient outdoor air-handling units, VAV air-handling units and perimeter VRF air conditioning system are operated simultaneously.

- Medium-load mode (cooling)

When the cooling load decreases, the ambient outdoor air-handling units are operated on a priority basis to handle the cooling load. The VAV air-handling units are switched to start-stop control status (Suzuki et al., 2012) when tracking is determined to be unnecessary. The perimeter VRF air-conditioning system is controlled when the cooling medium evaporation temperature rises in response to the load.

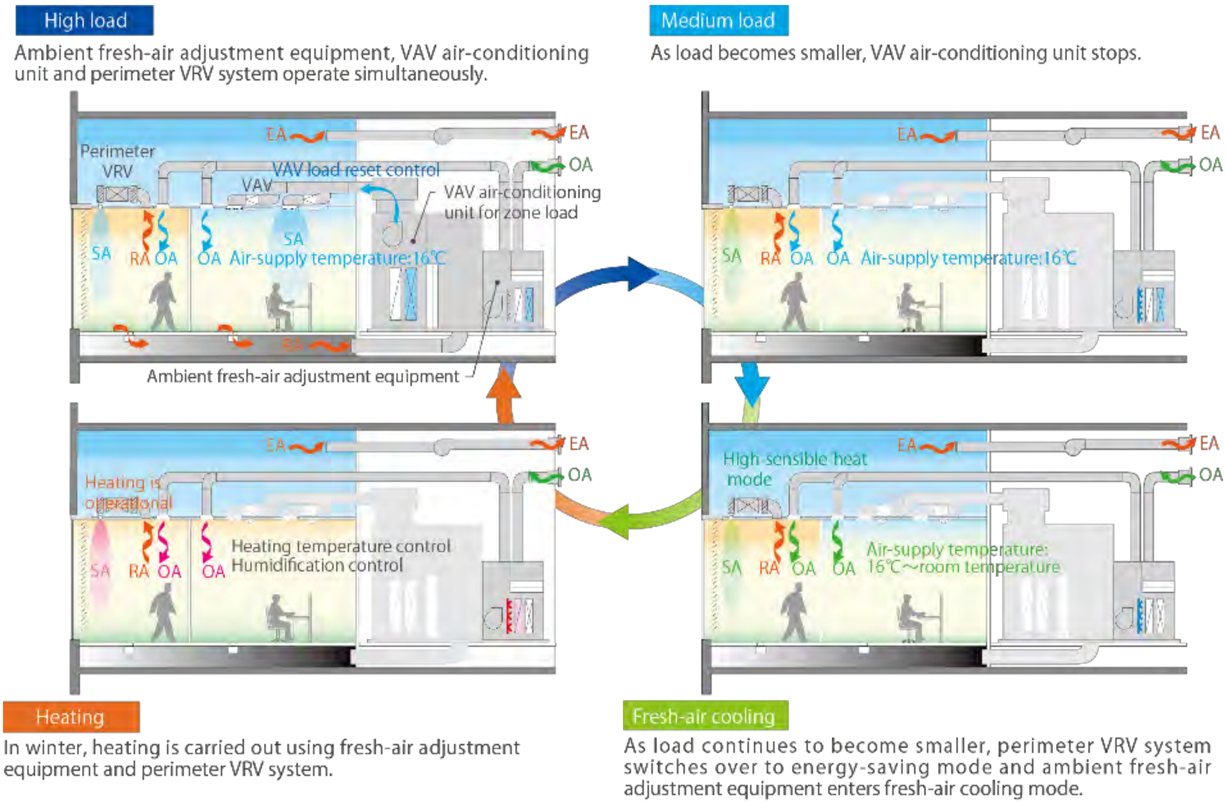

Figure 5: Four operation modes of air-conditioning system

- Outside air cooling mode:

When the load decreases further, the VAV air-handling units remain off and the ambient outdoor air-handling units switch to outside air cooling mode.

- Heating mode:

Heating is conducted using the ambient outdoor air-handling units and perimeter VRF air- conditioning system only.

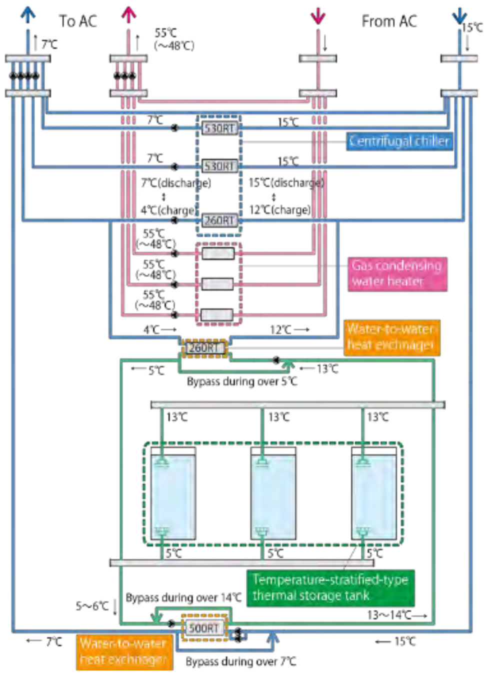

Figure 6 System diagram of heat source

4. OVERVIEW OF HEAT SOURCE SYSTEM

High-efficiency heat source equipment makes a major contribution to reducing the overall energy consumption of the building. The chilled water is provided by two high-efficiency inverter centrifugal 530 RT chillers and one 260 RT chiller (for heat storage), and the skeleton pit houses a variable capacity temperature-stratified-type thermal storage tank (2000 RT/h) (tank capacity 800 m^3, inlet/outlet temperature differential 8^oC). The heating water is provided directly by three latent-heat-recovery-type water heaters (655 kW x 3) and the thermal storage tank is not used. Figure 6 shows a system diagram of the heat source. In addition to the stand-alone heat source units, the temperature-stratified-type thermal storage tank was split into three tanks to enable control of the number of storage tanks being operated according to the daily cumulative load for the season, in order to increase the overall efficiency of the entire heat source system. In addition, the chilled water inlet and outlet temperature differential was increased (Δt = 8^oC), and variable flow control was used for all cooling water and heating and chilled water pumps. In this way, the heat source system also provides high-efficiency operation under a variety of load conditions. In order to equalize the power load during cooling in summer, top priority is given to the discharge operation of the thermal storage tank during the 1:00 - 4:00 p. m. time period. During the daytime in winter when not only the heating load but also the cooling load arises, the chilled water is generally provided exclusively by means of discharge operation.

5. ASSESSMENT OF THERMAL ENVIRONMENT NEAR WINDOWS

Measurements were made to assess the thermal environment of the area near the windows in the 3rd floor (oriented toward the southeast) in summer and winter.

Figure 7 shows the results of measurements on a typical summer day (September 7, 2012). The room temperature was approximately 29^oC before air conditioning was initiated. When air conditioning was initiated at 8:30 a.m., the temperature began to drop, and at around 10:00 a.m. it was 25 - 26^oC. At around 1:00 p.m. and thereafter, the temperature was controlled to around 26^oC. During the daytime, even the maximum globe temperature was around 27^oC (an increase from room temperature of 1.1^oC at most). Thus the radiant thermal environment was good, with not much sensation of warmth coming from the window. The predicted mean vote (PMV) in perimeter areas was held to around 0.4 - 0.6 when air conditioning was conducted. The combination of the reduction in direct solar radiation during the day by the outer frame and the high shading performance of the window glazing was confirmed to create a good indoor thermal environment near the window.

Figure 8 shows the results of measurements on a typical winter day (February 13, 2013). The room temperature was approximately 15^oC before air conditioning was initiated. When air conditioning was initiated at 8:00 a.m., the temperature began to rise, and it was 22^oC at around 9:00 a.m. Thereafter the temperature was maintained at around 22 - 25^oC. The globe temperature was approximately the same as the room temperature. The PMV was held to around 0.3 - -0.5 during the time period when air conditioning was conducted, forming a good indoor thermal environment.

6. VERIFICATION OF START-STOP CONTROL

When the system determines that the air-conditioning load of the VAV air-handling units is low, start-stop control is initiated to stop the intake fan for a certain period of time to reduce fan power consumption. Normally, air-handling units continue to operate the fan even when the load is low. As this increases transport power consumption and reduces efficiency during low-load operation, there was thought to be room for improvement. The specific control logic is that the fan is stopped when the cold water valve of the target VAV air-handling unit continues to be open 40% or less for 10 minutes and the VAV control mode is not cooling request mode. The fan is restarted when, after a period of 30 minutes has elapsed since start-stop control was initiated, the average divergence between the set temperature and the measured temperature is 2^oC or more.

Figure 9 shows the measurement data of the AHU that is installed in the south area of the 20th floor on a typical day (October 15, 2015) in medium-load mode during the core time (8:30 a.m. - 6:30 p.m.). The AHU was in start-stop control status up until 1:00 p.m., and subsequently the cold water valve opening was controlled to 40% or greater, so the system was operated continuously. In intermediate seasons, the VAV units are stopped for a long

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

period of time, so a certain degree of improvement in transport efficiency can be anticipated. There was concern that start-stop control might deteriorate the thermal environment, but the measurement data revealed that there was no change in room temperature regardless of whether start-stop control was conducted.

A simulation of cooling operation was conducted for the AHU in the south area of the 20th floor for six months, from April through September, and this simulation confirmed the effectiveness of start-stop control in reducing energy consumption. The simulation tool was a proprietary Energy Network Simulation Tool (ENe-ST) (Mihara et al., 2015). The ENe-ST is based on the MATLAB programming environment and is used to perform energy and control simulations that combine models for air-handling, water heater, electricity and renewable energy equipment (Figure 10). Figure 11 shows the results of calculations of fan power derived from the simulations. There was a total reduction of 35.8% in energy consumption for the six-month period. Start-stop control was performed for 70 - 150 hours each month, representing 28.0% of the cumulative air-conditioning time for the six-month period.

Based on these results, it was confirmed that start-stop control was effective in reducing energy consumption when the thermal load is low.

7. RESULTS OF HEAT SOURCE SYSTEM OPERATION

Figure 12 shows the quantity of heat produced by the hot and cold heat sources in FY 2014. Figure 13 shows the results of an assessment of the primary energy consumption for each month. The quantity of cold produced each year was 8.25 TJ/year, and the quantity of heat produced was 5.00 TJ/year. The primary energy consumption for cold and heat was 4.39 TJ/year and 6.51 TJ/year, respectively. Cold energy consumption was less than heat energy consumption despite the fact that more cold than heat was produced. This is because the coefficient of performance (COP) for the cold source system is maintained at an extremely high level. Figure 14 shows the system COP for the cold water heat source, the system COP for the hot water heat source and the COP for the heat source systems overall for primary energy each month. The annual average system COP for the cold source is 1.59, while in summer the value is high at 1.6 - 1.7. In winter, the value is approximately 1.0 - 1.3 due to the low load. The annual average COP for the hot water system was 0.78, while the annual average system COP for heat sources overall was 1.10. The annual cumulative transport efficiency (Water Transportation Factor or WTF) for the secondary pump was high at 135 for the cold water system and 115 for the hot water system. Figure 15 shows a graph of the thermal storage tank efficiency (= heat discharge / heat storage), assessed annually and monthly. Annual performance of 93.6% was achieved through appropriate operation of the thermal storage tanks (which had been split into three tanks), temperature control of the surroundings of the thermal storage tank and so on. A comparison of the heat quantity with Figure 12 reveals that, even at the height of summer, 30% or more of the produced eat and cold was provided by the thermal storage tanks.

8. ASSESSMENT OF ANNUAL ENERGY CONSUMPTION

As the building is a combined office and apartment complex, the sections for apartment use needed to be excluded in order to make a comparative assessment of the basic units for energy consumption as an office building. Figure 16 shows the primary energy consumption and percentage for each type of use for FY 2014. The average value for primary energy consumption for office buildings in Japan with a floor area of 10,000 m^2 or greater is 2,067 MJ/m^2 per year. In contrast, the value for this building for FY 2014 was 1,266 MJ/m^2 per year, demonstrating that a high level of overall energy-saving performance had been achieved despite the fact that the building is a high-rise tenant building. In addition, the total percentage of energy consumption for lighting, electrical outlets and air conditioning for standard office floors was 49%. Furthermore, based on the FY 2014 results, estimates were performed for the case in which the grid ceiling lights in the offices on standard floors were changed from the current Hf fluorescent lights to the LED lights coming into general use (Figure 17). When the building was planned, fluorescent lights were the type of lighting most commonly used, and brightness seniors + movement sensors are used for dimming control in this building. When the effect of switching the lighting in offices to LEDs was calculated based on the same average illumination as the current operation (700 lux), the result was 1,136 MJ/m^2 per year, meaning that a further reduction in primary energy consumption of around 6% could be anticipated.

9. CONCLUSION

This paper presents an example of an air-conditioning system plan that takes into account the uncertain use situation of tenant users in a high-rise tenant office building. In the facade plan, a precast outer frame structure using ultra-high strength concrete and original ultra-high performance glazing achieve a 35% reduction in outer skin load as compared to the standard office buildings in Japan. The measurements confirmed that a comfortable thermal environment has been achieved in both summer and winter. The heat source system, which uses high-efficiency inverter centrifugal chillers and variable capacity temperature-stratified-type thermal storage tanks, was confirmed to have achieved a high system COP throughout the year. The air-conditioning system uses a stand-alone tank configuration, and control system has been introduced to stop the operation of the VAV air-handling units when the load is low, reducing transport power consumption. The use of such energy-saving technologies achieved a value of 1,266 MJ/(m2·year) for the annual primary energy consumption for the whole building — a 40% reduction as compared to the average office buildings in Japan. Ultra-high rise buildings whose main goal is business viability emphasize high performance and require redundancy. This proposal is offered as one example of an equipment plan that is designed to achieve a low carbon footprint in a way that is unobtrusive to building users.

ABSTRACT

A detailed building energy simulation study showed that it is possible for a building owner in a proposed multi-tenanted high rise office tower to reduce up to 73% energy consumption as the operator of the building. This energy reduction reduces the energy running cost for the building owner from a baseline of RM 2 million per year to a running cost of RM 500,000 per year. The building energy intensity of the building (including tenant energy consumption) reduces from 212 kWh/(m².year) down to 82 kWh/(m².year)

A holistic energy efficiency approach was proposed to achieve such high efficiency gain. Approximately 50 passive and active energy efficiency features were tested for this building. Many of the efficiency gains are in the region of 1~2% energy reduction per design improvement. In addition, the peak cooling load of the building was reduced by 34% due to these design improvements, allowing a smaller air-conditioning system to be implemented for this building.

The energy efficiency passive and active design features that will be implemented in this building is largely considered conventional design practises. However, by making small improvements at every design opportunity, the building can be made very efficient at minimal additional cost to the building. In addition, due to the smaller air-conditioning system, there is a cost reduction that would help to finance the design improvements proposed.

Keywords: building energy simulation, high-performance building, energy saving

1. INTRODUCTION

Johorland Tower is a proposed multi-tenanted office tower to be located on the podium of Komtar JBCC building. The building is located in the heart of Johor Bahru city, just north of Malaysia-Singapore boundary, approximately 5 minutes' drive from the immigration check point.

The construction of the building started in December 2014 and it is scheduled to complete mid of 2017. It is constructed above an 8-storey podium block and has 27 storeys of office levels as shown in Figure 1. The building will be owned and operated by owner, JohorLand, with the office space leased out to tenants as a multi-tenanted building.

The façade of the building has a curtain wall design (Figure 1) with an average of window to wall ratio of 63%. Large windows give opportunity for good internal daylight but also increases solar heat.

Figure 1: Architectural perspective of JohorLand Tower

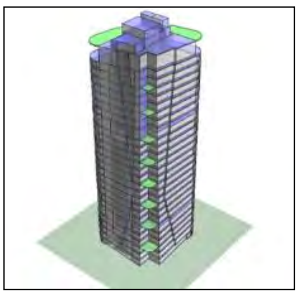

Figure 2: 3D energy model of Johorland Tower

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The building will be completed with full mechanical and electrical (M&E) services, providing the design team total control over M&E equipment design and specification.

A range of simulation studies were made to assess the improvements of 47 design enhancements, to reduce the energy consumption of JohorLand Tower. Each simulation case is an incremental step improving the building energy performance.

The energy consumption for this building is reported as Building Energy Intensity (BEI) with units in kWh/(m^2.year). The BEI is a methodology of calculating a building's energy that is used by all major Green Building Rating System in Malaysia, i.e. the Malaysian Green Building Index and GreenRE. In simple terms, the BEI is the total energy consumed per year over the gross floor area of the building.

2. METHODOLOGY

A base case building is initially modelled with a building energy modelling software, using conventional building construction parameters. Design improvement is then incrementally applied to the building. The energy consumption and peak cooling load is then tabled as the output for each scenario.

Such a methodology allows the computed energy consumption and peak cooling load due to each case to be compared to the previous case. In addition, the combined effect of previous improvements made to the building will be accounted at all time.

Dynamic building energy simulation software IES<VE> was used to accurately simulate the building geometry (Figure 2), weather, heat gain and systems of the building. A detailed air-conditioning system of the air-handling unit and chiller plant was also modelled using the HVAC module of the software.

3. WEATHER DATA

Malaysia is located in the hub of a tropical climatic zone. It is summer all year long, with fairly consistent daily air temperature, relative humidity and solar radiation. The average air temperature ranges from a low of 24^{o}C to a high of 31^{o}C with a fairly consistent hourly moisture content of 18 g/kg day and night.

The simulation hourly weather data was based on a Test Reference Year (TRY) developed in University Teknologi Mara (UiTM) under DANCED (Danish International Assistant) project for Energy Simulations for Buildings in Malaysia. The TRY is based on 21 years (1975 to 1995) of weather data from a Malaysian Meteorological Station.

4. BASE BUILDING

The base case building was modelled with conventional building design practises in Malaysia. It complies with the minimum requirement of Malaysian Standard (MS) 1525 for Energy Efficiency in Non-Residential building on all Mechanical and Electrical requirements. Base building represents Case 1 of the study with simulation results of BEI = 212.08 kWh/(m^2.year) and peak cooling load of 7,394 kW

5. PASSIVE STRATEGIES

Passive strategies of daylight harvesting, envelope insulation, glazing properties and building air-tightness were assessed from Case 2 to 12. The results are shown in Table 1 below.

Cases	Descriptions	BEI (kWh/(m^2.year))	Peak Cooling Load (kW)
1	Base Case	212.08	7,394
2	Daylight 3m depth	200.63	7,260
3	Daylight 4m depth	197.24	7,220
4	Daylight 5m depth	194.28	7,182
5	Roof Insulation 50mm	193.44	7,153
6	Roof Insulation 100mm	193.00	7,149
7	Wall Insulation 25mm	191.46	7,012
8	Single Glazing Low-E	178.55	6,240
9	Partial Double Glazing Low-E	176.13	6,141

10	Full Double Glazing Low-E	172.51	5,924
11	Infiltration 0.25 ach	167.96	5,714
12	Infiltration 0.10 ach	165.12	5,584

Table 1: BEI and peak cooling load result for case 2 to 12

Table 1 showed that the implementation of passive features reduces the BEI down to 165 kWh/(m².year), while the peak cooling load reduces by 24%.

- Daylight Implementation

Cases 2 to 4, simulated a scenario of daylight harvesting. Malaysian climate has consistent daylight from the hours of 9am to 5pm daily, which is perfect for an office building. A daylight harvesting strategy was proposed with inclusion of daylight sensors at the office perimeter on each floor, and a window design to draw daylight deeper into the office area while preventing glare.

The window design consists of horizontal venetian blinds, light shelf and a sloped false ceiling as shown in Figure 4. Quantity of natural indoor daylight is measured by Daylight Factor (DF) as shown in Figure 5. An acceptable DF values for an office building in Malaysia are in the range of 1% to 3.5%. The final daylight simulation showed that usable daylight exceeds 5m providing 47% office areas daylit.

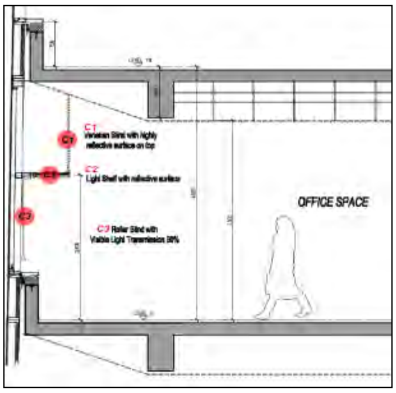

Figure 4: Section view of blinds and light shelf system.

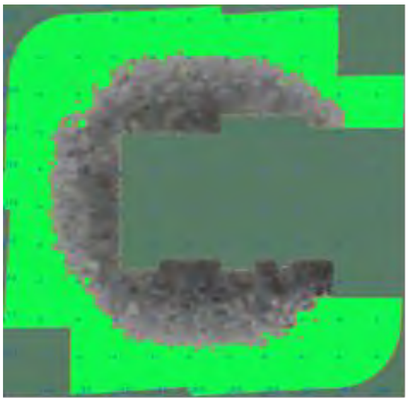

Figure 5. Plan View of DF in the range of 1%-3.5% coloured in green

- Roof and Wall Insulation

Base building was modelled with uninsulated concrete roof. Polystyrene roof insulation of 50mm (U-value 0.5228 W/m²K) and 100mm (U-value 0.2794 W/m²K) thickness was applied to Case 5 and 6. The BEI improves marginally from 50mm to 100mm, indicating that 50mm insulation is sufficient insulation on the roof. 25mm thick Rockwool insulation were then applied to all external walls in Case 7, reducing the wall insulated U-value to 0.8037 W/m²K from an uninsulated scenario of 1.79 W/m²K.

- Glazing Properties

The building consists of 2 types of glazing with different tint as an architectural feature. Case 8 replaces standard glazing (both dark green and light green) with low-E properties. Case 8 reduces the average glazing SHGC to 0.27 from 0.43 and U-value to 3.8 from 4.8 W/m²K. Case 9 replaces the light green glazing as double glazed low-E with SHGC = 0.39 and U-value = 1.95 W/m²K with dark green glazing remaining as single glazed low-E. Case 10 is then simulated with all glazing specified as double glazed low-E. SHGC for the dark green double glazing is 0.23 and U-value = 1.95 W/m²K. Glazing performance was found to have a significant impact with a reduced BEI of 10% and cooling load by 15%.

- Air tightness

The average infiltration rate in office buildings in Malaysia was measured to be 0.5 air change per hour (ach). Improvements to the air tightness details and specification will be made on all external doors, windows and wall finishes. An assumption of infiltration rate reduced to 0.25 ach for Case 11 and 0.10 ach for Case 12 were made. BEI reduces by 1.3% and peak cooling load by 4.5%.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

6. LIGHTING STRATEGIES

The lighting improvement strategies were largely based on selection of efficient luminaires to reduce the lighting power density (LPD) and controls to switch off the lights when the space is not used. The results of implementing lighting strategies are presented in Table 2 below.

Cases	Descriptions	BEI (kWh/-(m².year))	Peak Cooling Load (kW)
12	Base Case for Case 13	165.12	5,584
13	Office LPD 15 to 9 W/m²	156.89	5,479
14	Office LPD 9 to 7 W/m²	154.23	5,459
15	Walkway/Lift Lobby LPD 20 to 9 W/m²	144.51	5,300
16	Walkway/Lift Lobby LPD 9 to 7 W/m²	141.72	5,267
17	Walkway/Lift Lobby LPD Night 50% to 33% on	140.83	5,248
18	Toilet LPD 10 to 7 W/m²	140.61	5,248
19	Toilet Occupancy Sensor (50% off)	140.33	5,244
20	Fire Escape Stairwells LPD 15 to 3 W/m²	135.67	5,168

Table 2: BEI and peak cooling load result for case 13 to 20

The implementation of all the lighting improvement strategies will further reduce the building BEI down to 136 kWh/(m².year). In addition, the peak cooling load of the building is reduced down by 30% from the base case.

- Office LPD

The MS1525 guideline states that the maximum allowable office LPD is 15 W/m2. Case 13 and 14 improves the LPD down to 9 W/m2 and 7 W/m² respectively. Significant savings are achieved by addressing these items (Table 2).

- Walkway/ lift lobby LPD

Case 15 and 16 showed that the LPD for Walkway and Lift Lobby has a significant influence in the building efficiency. While the MS 1525 allowed such spaced to have a LPD of 20 W/m², the JohorLand Tower is proposed to have a lighting power density of 9 W/m² for Case 15 and 7 W/m² for Case 16. Results in Table 2 showed that BEI reduce by 5.9% and cooling load by 2.6%.

- Walkway/ lift lobby night light

Case 17 proposed that the night lights be reduced from 50% to 33% (i.e. 1/3 of the lights remains on, instead of half), through strategic placement of light fittings adequate to give a sense of safety and security.

- Toilet lighting power density

Case 18 optimizes lighting power at the toilets from 10 W/m² to 7 W/m². Results in Table 2, showed marginal change, indicating that this feature is not a significant contributor to energy efficiency.

- Toilet occupancy sensor

Case 19 introduces an occupancy sensor for all the toilets. An assumption is made that 50% of the time, the lights are switched off. This is modelled by reducing toilet LPD from 7.0 to 3.5 W/m². Results showed marginal reduction.

- Fire escape stairwells LPD

Case 20 improve these fire escape stairwells LPD from the MS1525 standard of 15 W/m² to 3 W/m². Staircase lux lighting levels is optimized to provide just enough light for access and as an escape route.

7. AIR-CONDITIONING STRATEGIES

There are many opportunities to optimise energy efficiency in an air-conditioning system. These are listed from case 21 to 47 as shown in Table 4 below.

Cases	Descriptions	BEI (kWh/-(m².year))	Peak Cooling Load (kW)
20	Base Case for Case 21	135.67	5,168
21	CAV to VAV	127.09	5,179
22	Duct Static 900 to 500 Pa	120.20	5,165
23	Duct Static 500 to 250 Pa	116.22	5,140
24	Air Filter Static 150 to 80 Pa	115.11	5,135.27
25	Air Filter Static 80 Pa to 50 Pa	114.64	5,130.60
26	Fan Eff. Backward curved to airfoil blade	113.54	5,128.65
27	Fan High efficiency motor used	113.38	5,127.10
28	CO_2 Controlled Fresh Air Intake	110.56	4,973.87
29	Heat Recovery	108.16	4,924.63
30	Chilled Water ΔT 6.67°C-13.34°C to 5.56°C-14.44°C	107.09	4,864.44
31	Chilled Water ΔT 6.67°C-15.56°C	106.75	4,880.72
32	Chilled Water Pump Head 40m to 30m	105.60	4,875.36
33	Chilled Water Pump Head 30m to 20m	104.46	4,869.99
34	Chilled Water Pump Eff. 70% to 80%	104.18	4,868.64
35	Chilled Water Pump High Efficiency Motor	104.12	4,868.33
36	Variable Chilled Water Pump	102.64	4,866.38
37	Chiller Efficiency COP 5.5 to 6.2	98.69	4,837.72
38	Chiller Efficiency COP 5.5 to 6.6	96.81	4,807.00
39	VSD Chiller	91.28	4,772.84
40	Condenser Water ΔT 5.56°C to 6.67°C	89.62	4,772.78
41	Condenser Pump Head 40m to 30m	87.46	4,772.78
42	Condenser Pump Head 30m to 20m	85.30	4,772.78
43	Condenser Pump Eff. 70% to 80%	84.76	4,772.76
44	Condenser Pump High Efficiency Motor	84.64	4,772.77
45	Cooling Tower High Efficiency Fan	82.59	4,772.77
46	Variable Speed Cooling Tower	81.17	4,772.77
47	Upsized Cooling Tower	80.83	4,772.77

Table 4: BEI and peak cooling load result for case 21 to 47

The implementation of all the air-conditioning system improvement reduces the building BEI down to 80 kWh/(m².year). In addition, the peak cooling load of the building is reduced down by 35.5% from the original base case.

- Variable air volume

A constant air volume (CAV) system is typically installed for office buildings in Malaysia. Case 21 improves the system by implementing a variable air volume (VAV) system. Supply air flow will be regulated according to the cooling needs, reducing fan energy consumption. Table 4 showed that BEI reduces by 4%.

- Duct static pressure

Larger duct with less bends reduces the fan static pressure. Case 22 reduces the duct static pressure from 900 to 500 Pa and Case 23 further reduced it to 250 Pa. By optimizing duct design BEI reduces by 8.5% and cooling load by 0.7%.

- AHU air filter

Case 24 and 25 further improves the AHU static pressure by using improved filters. Case 24 specifies a low efficiency air filter which reduces total static pressure to 580 Pa. Case 25 specifies an electronic air filter which further reduces total static pressure to 550 Pa.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Fan efficiency

The conventional fan selection for AHU is based on backward curve blades. Case 26 implements an airfoil type fan blades to improve the fan total efficiency to 70.2% from 61%. Case 27 uses a higher efficiency IE3 fan motor to improve total fan efficiency to 71.8%.

- CO_2 sensor

CO_2 sensors are introduced in Case 28 to regulate the fresh air intake system. This sensor allows the fresh air supply to be reduced when occupancy is low or when there is adequate fresh air in the building due to infiltration.

- Heat recovery system

A heat recovery system was introduced in Case 29 to recover energy rejected by the toilet exhaust system and transfer it to the outdoor air intake system located on the roof. The heat recovery system was specified with 50% efficiency for latent and sensible load.

- Chilled water delta-t

A high delta-T chilled water system reduces the flow rate, thus chilled water pumps is smaller reducing energy consumption. Both Case 30 and Case 31 assumes a delta T of 16 °F. Case 30 has supply and return temperature of 42 °F and 58 °F respectively. While Case 31 has supply and return temperature of 44 °F and 60°F respectively. The results indicate that given the same delta-T, higher supply / return temperature gives a better BEI value.

- Chilled water pump pressure:

Chilled water pump pressure is reduced by optimizing pipe size, reduce bends, tees, and transitions Case 32 simulates results for a pump pressure of 30m while Case 33; 20m. Results are shown in Table 4.

- Chilled water pump efficiency:

Case 34 improves total pump efficiency from 63% to 72% and then further improve efficiency to 74.4% by specifying an IE3 motor instead of an IE2 motor for Case 35.

- Variable primary chilled water pump:

Case 36 upgrades the chilled water pump from a constant flow to a variable flow pump. The pumps are able to vary flow rate according to demand and heat load, hence have better performance at part load.

- Chiller Coefficient of Performance (COP)

The chiller is the biggest energy consumer in the air conditioning system. Standard chiller COP in the market currently ranges from 5.5 to 6.0. Case 37 and Case 38 simulates results for higher efficiency chillers, with COP at 6.2 and 6.6 respectively. A COP of 6.6 can be achieved by many high efficiency chillers in the market today. The results shown in Table 4, a chiller COP of 6.6 reduces BEI by 5.7%.

- Variable Speed Drive (VSD) chiller

To further improve the chiller performance, a variable speed drive was specified on the chiller and simulated in Case 39. VSD chillers have a variable speed compressor hence have better part load efficiency. BEI reduces by a further 5.7%.

- Condenser water delta-t

Case 40 increases condenser water delta-T from 10 °F to 12 °F. As a result, condenser water pump flow rate decreases, thus reducing pump power. BEI reduces by 1.8%. The efficiency of the chiller was simulated to drop marginally. The resulting pump power reduction provided an overall higher energy reduction.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Condenser pump pressure

Decrease condenser water pump pressure by optimizing pipe size, reduce bends, tees, transitions and any others that will add to the pump pressure. Case 41 simulates results for a pump pressure of 30m while Case 42; 20m.

- Condenser pump efficiency

Case 43 improves total pump efficiency from 63% to 72% by using a higher efficiency pump. And Case 44 further improves total efficiency to 74.4% by specifying an IE3 motor.

- Cooling tower efficiency

Case 45 improve cooling tower efficiency to 0.0275 kW/HRT by specifying a more efficient fan motor.

- Variable speed cooling tower

Case 46 assess a variable speed fan on the cooling tower. Results show BEI reduces by 1.7%.

- Oversized cooling tower

Case 47 oversize the cooling tower by designing the return temperature from 29.4 °C to 28.5 °C.

8. SUMMARY OF RESULTS

The results of the simulation are summarized on two levels:

- Energy efficiency

Overall, BEI reduces by 62% from base building to Case 47. Passive systems contribute to a reduction of 22%, lighting 14% and air conditioning 25%. Each case give a reduction of about 1 to 2%. Large reduction are provided by daylight implementation, glazing performance, office lighting and chiller performance. Total energy consumed per year by the building reduces by 5,041 MWh. With energy cost in Malaysia rated at RM0.51 per kWh, this is a savings of RM2.57 million (USD 600,000) per year. Since Johorland Tower is a multi-tenanted building, energy consumed by the owner can be estimated by deducting electrical energy for lighting & small power for all office spaces from Total Energy per Year. In which reduction energy cost per year by owner is RM1.49 million.

- Peak cooling load

Overall peak cooling load reduces by 2,622 kW which is a reduction of 35.5%. Figure 9 shows cooling load reduction. The Passive design strategies contributed to more than 68% of the peak load reduction. Peak cooling load does not show much decrease after Case 30 because these cases improves air conditioning equipment performance and does not have significant impact on the cooling load. The reduction in peak cooling load means all air conditioning equipment capacities can be reduced thus reducing capital cost.

9. CONCLUSION

Simulation software allowed a possibility to track each improvement case and know its effectiveness in reducing overall energy consumption and air conditioning load. Each individual case brings small contributions to overall energy savings. However, when all these small contributions are added up, a substantial overall energy saving is achievable.

ABSTRACT

Good decisions are based on the high-quality and timely information. Meaningful information comes from meaningful data. Data transparency encourages more transformational knowledge creation. The presented software solution (PowerBox) offers the analysis and monitoring of energy usage in buildings. Such system enables users to analyze the power usage from various components. Compare different building's energy data in the same category is an effective way to understand the building performance. It gives more efficient use of energy potentials and provides building owner for identifying energy management opportunities. Beyond increasing awareness in energy consumption, the energy management solution provides analyses that reveal patterns and trends, compare outlets, and identify maintenance issues and retrofitting necessary to prevent the failure of major building equipment. The building owners/engineers can craft more realistic energy reduction targets that coincide with current energy consumption data and strive to reduce energy consumption as low as possible without affecting the function of the building. Its graphical user interfaces allow simple visualization of current readings from the installed sub-systems, and dashboards are available for the analysis of the building performance over a specific time period. The presented case reveals the hotel engineers leverage the actionable insights to optimize their energy use and reduce consumption throughout the modification works of chiller plant control optimization and integrated heat pump system to the existing Heating, Ventilation, and Air Conditioning (HVAC) system.

Keywords: energy saving, retro-commission, building performance monitoring

1. INTRODUCTION

This paper presents a case study of a commercial hotel, which focuses on enhancing data transparency, thus helping building owner to reduce energy consumption and to drive down energy costs, increase energy efficiencies and optimize processes. PowerBox can be regarded as a real-time building performance monitoring solution, which provides a platform to store, analyze and display building energy data. Time-series data from building-device sensors and electricity meters are used to perform analyses such as HVAC device profiling and benchmarking. Figure 1 describes the basic system infrastructure of PowerBox solution and its web-based graphical interfaces.

Figure 1: PowerBox - Basic System Infrastructure and its web-based graphical interfaces

Mills (2009) reported that the actual building performances rarely meet the expected one during design stages. Diamond (2011) and Göçer et al. (2015) also came with the same concluding remark. Both indicated that the most frequently cited barrier was down to lack of information to evaluate building energy performance. Nativi et al. (2015) published the qualitative benefits with enhanced data transparency. Li et al. (2013) emphasized the importance to enhance data transparency in energy consumption, thus influencing building occupants and residents to change their day-to-day behavior or to invest in efficiency measures. Petersen et al. (2007) demonstrated how an enhancement in data transparency can stimulate resource conservation for dormitory residents. His report concluded that, with greater data transparency, combined with education and an incentive, could achieve a 32 percent reduction in electricity consumption (amounting to savings of 68,300 kWh).

Apart from data transparency issue, the analysis of energy performance data is also essential to improve building efficiency. Keyvanfar (2014) conducted interviews with building operators and energy managers in order to measure the benefits through the analysis of building energy data. Case investigations conducted by Granderson et al (2011) indicated that most common energy savings came from rectification of inefficient operations and scheduling errors of building devices. Aman (2013) reviewed the essential monitoring and analytic features for web-based building control systems. Technologies and features embedded in PowerBox are well aligned with the modern requirements for building performance monitoring solution.

2. CASE STUDY

A commercial hotel was selected, namely the Holiday Inn Express SoHo, located in 83 Jevious Street in Sheung Wan, Hong Kong. The hotel was opened in September 2012 with 274 rooms and 36 storey high. The HVAC system of the hotel consists of two chillers with twin compressors, two cooling towers, one air handling unit and three primary air units and the other necessary chilled water and condensing water pump, as stated in Figure 2.

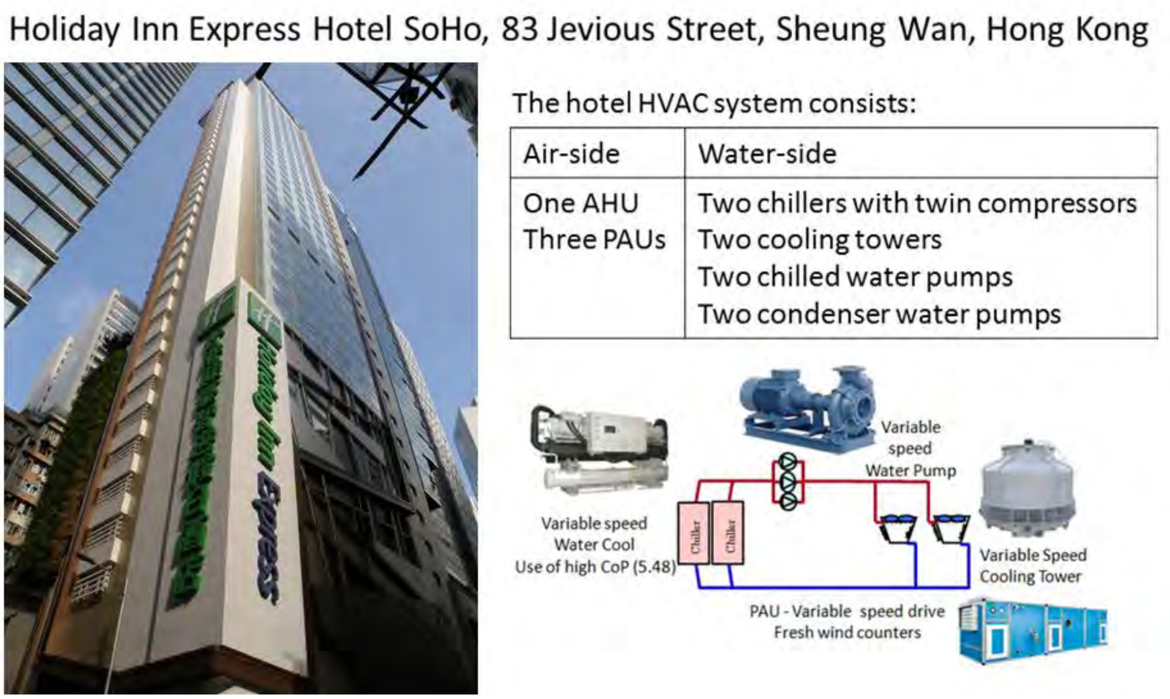

Figure 2: Appearance of commercial hotel and description of major HVAC system devices

Energy Management Opportunities (EMO) were considered in the design stage of the hotel. It was equipped with many sensors in order to monitor the building performance and provide data to the Building Management System (BMS) and Power Quality Monitoring (PQM) System. The energy consumption data recorded by BMS and PQM is stored in the PowerBox database while the operators can review the past building energy performance based on any required time range. The selected data can be displayed in tables, trend lines as well as customized design report for the energy audit submission.

Figure 3 describes the general PowerBox functionalities, which illustrates the typical information exchange between BMS & PQM and the power meters on the field via Ethernet. The electricity data can be used to analyze the energy usage pattern, allocate the energy cost, and develop Energy Utilization Index (EUI) and Energy Performance Index. PowerBox solution can display the real-time energy information generated by BMS and PQM System in interactive versatile formats including graph, trend, spreadsheet and report. Moreover, PowerBox solution has the ability to display those diagrams, trend, spreadsheet, and reports, which may consist of both real-time and historical data, via a standard web browser interface. This allows operators and management staff can access the system through the workstation, smartphones or tablets as long as internet connection is available. Thus, energy management can be monitored at anywhere and anytime through PowerBox solution.

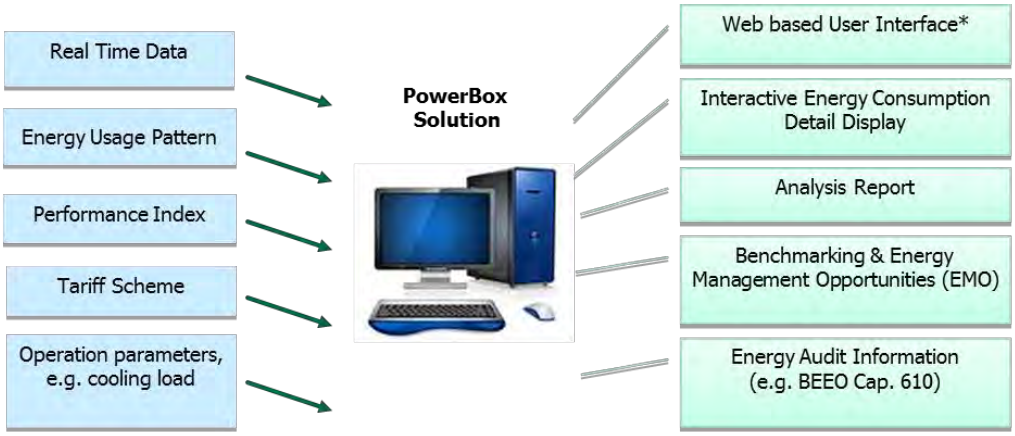

Figure3: PowerBox System Functionalities

a) Energy management opportunity – hot water circuit

The PowerBox solution was implemented since the turn of 2013. In early August 2013, hotel engineers noticed the frequently switch-on and off of the 3000L Calorifier (Figure 4), which was used to maintain the high temperature of hot water system. Such observation was not normal in the summer time. After detail investigation, heat loss was observed during hot water re-circulation, despite very little hot water usage.

After ruling out deterioration of the insulation in the hot water system, hotel engineers had concluded that a modification of hot water circuit was a possible solution. Consequently, a heat pump was re-assigned to the hot water supply to minimize electric heater operation (Figure 5). Moreover, a hot water recirculation return pipe was installed to ensure heat pump heat generation to compensate the heat loss induced during hot water re-circulation regardless to the actual hot water usage (Figure 6). After modification, the energy consumption was reduced by 95% (Figure 7).

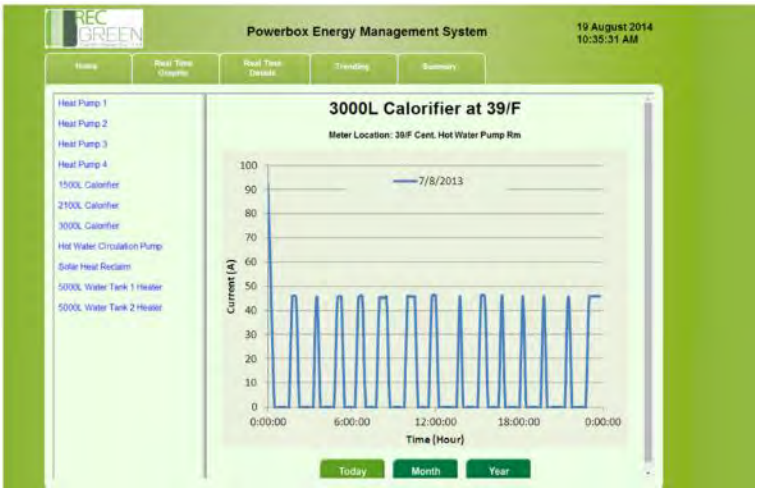

Figure 4: High energy consumption by 3000L Calorifier operation in August 2013

Before modification:
No connection between heat pump and hot water supply

After modification:
A heat pump was re-assigned to hot water supply

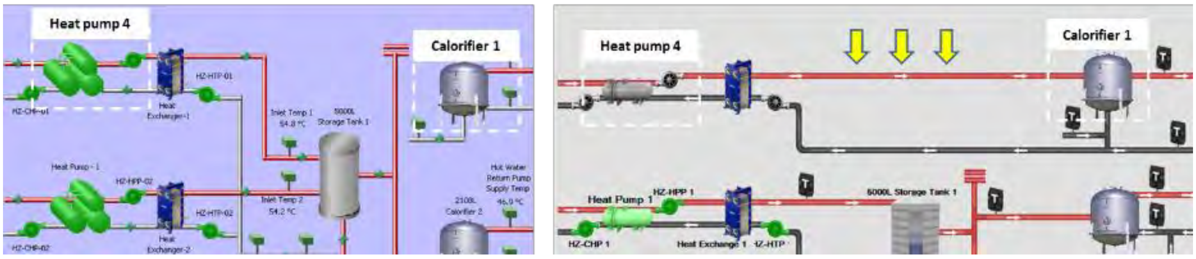

Figure 5: Re-assign heat pump to hot water supply

Before modification:
No hot water re-circulation design

After modification:
A hot water recirculation return pipe was installed

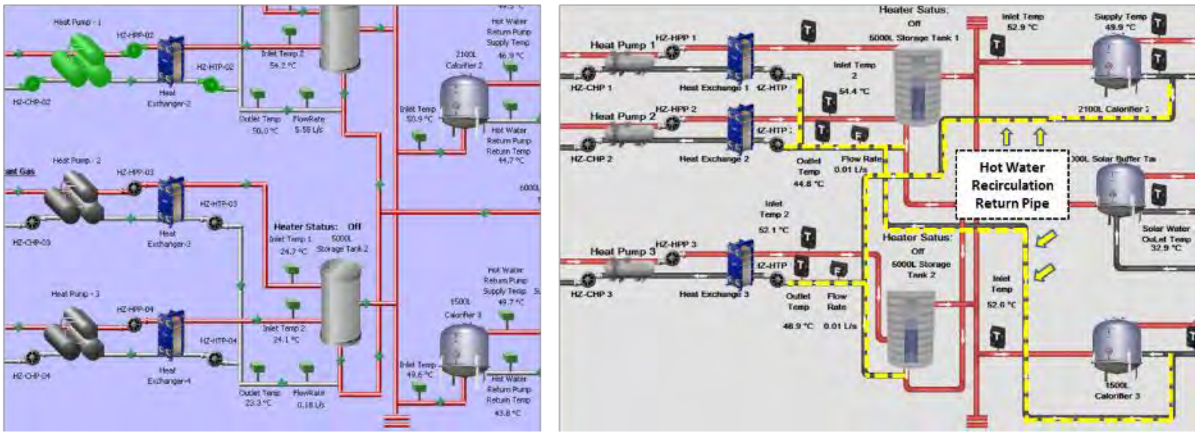

Figure 6: Installation of hot water recirculation return pipe

Figure 7: Low energy consumption by 3000L Calorifier Operation in August 2014

b) Energy management opportunity – central chiller system

After the completion of the hot water circuit modification, hotel engineers had noticed frequent switching of chiller during low ambient temperature season. Although the chilled water generated from heat-pump operation benefited the chilled water return temperature, it resulted in more frequent chiller switching. In view of this, cooling towers and condensing pumps continued to run in order to keep the chiller in a standby condition even at a very cool ambient environment, thus leading unnecessary energy consumption.

The hotel engineers concluded that an EMO could be achieved through conducting an optimization of chiller plant control. A chilled water recycling mode was introduced for low ambient temperature operation. Such mode had included the switching off of chillers, cooling towers, and condenser pumps, as well as the directing of chilled water source (generated from heat pump operations) as a primary support for thermal comfort (Figure 8).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

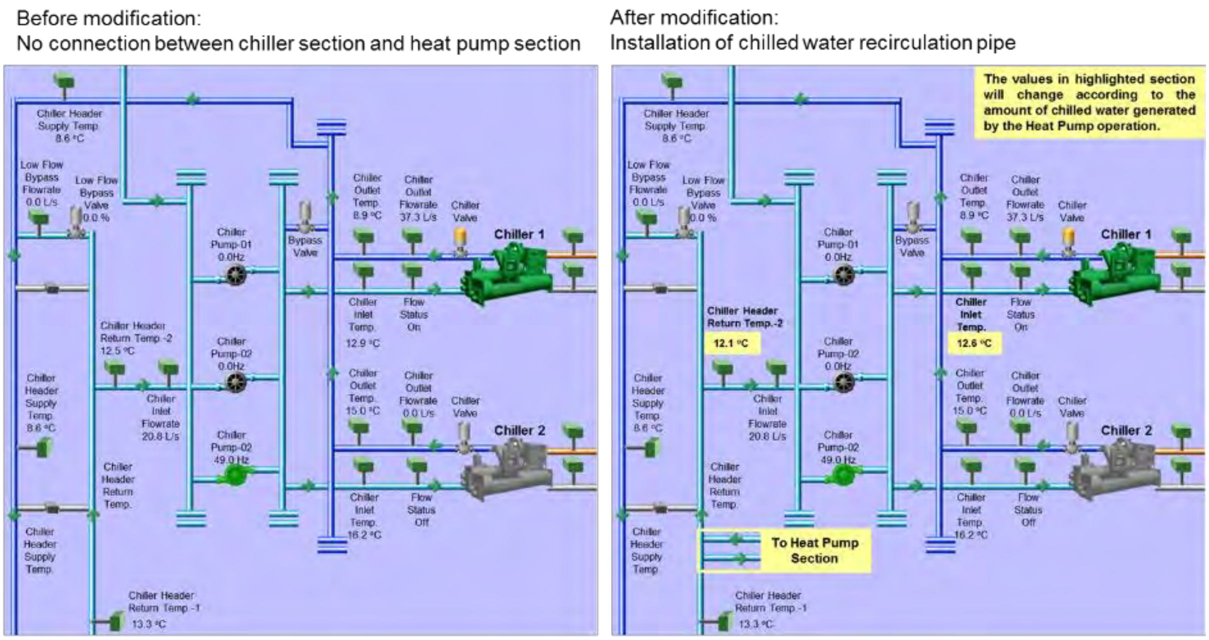

Figure 8: Installation of chilled water recycling pipe

The Chiller Plant modification, which included implementation of control strategies for chillers, chiller pumps, cooling towers and cooling tower pumps, was completed in February 2015. Table 1 described the energy consumption of Chiller Plant between [i] January 2015 and January 2016; [ii] February 2015 and February 2016. Energy consumption in January 2016 decreased by 14 per cent compared to January 2015, while the one in February 2016 decreased by 42 per cent compared to February 2015.

Chiller Plant	2015	2016	Difference
January	17417 (kWh)	14955 (kWh)	↓↓ 2462 (kWh) / 14%
February	17517 (kWh)	10134 (kWh)	↓↓ 7383 (kWh) / 42%

Table 1: Comparison of energy consumption between [i] January 2015 and January 2016; [ii] February 2015 and February 2016 for Chiller Plant

c) Abnormal energy consumption – cooling tower system

At the end of February 2015, hotel engineers noticed the non-stop running of cooling towers throughout the entire month. It was an abnormal observation because cooling towers were kept operating for every minute during whole February, as shown in Table 2. Even if the cooling tower was required at that frequency, often a tower-switch pattern should be observed, as shown in Figure 9. However, as shown in Figure 10, only Cooling Tower 2 was in operation throughout February. After detail investigation, hotel engineers identified the malfunction of the water level sensor in the cooling tower tank. After replacement of the device, no abnormal pattern was observed further.

Cooling Tower	2014-February	2015- February	Difference
Runtime	16187 (mins)	40320 (mins)	↑↑ 24133 (mins) / 149%
Energy Consumption	572 (kWh)	1886 (kWh)	↑↑ 1314 (kWh) / 230%

Table 2: Comparison of runtime and energy consumption between February 2014 and February 2015 for Cooling Towers.

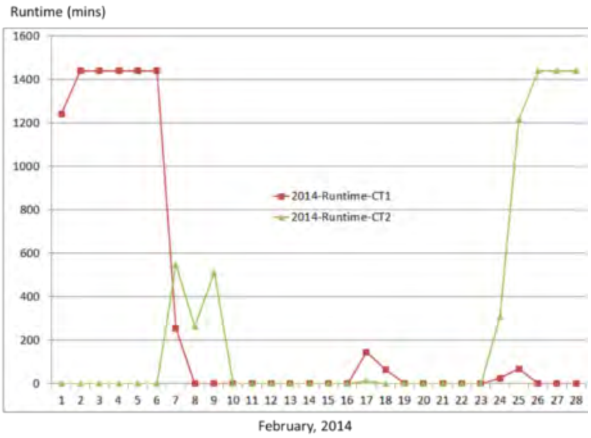

Figure 9: Runtime of Cooling Tower 1 and 2 in February 2014

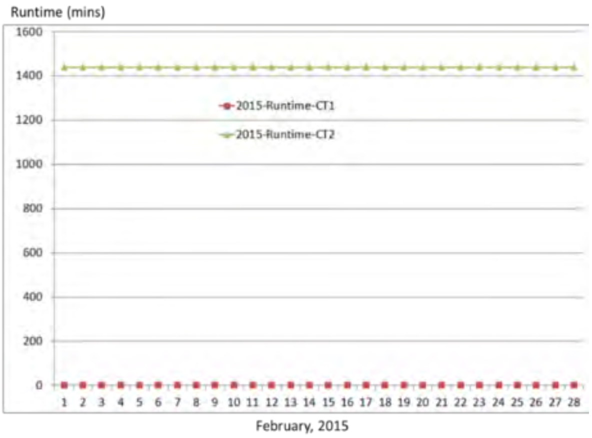

Figure 10: Runtime of Cooling Tower 1 and 2 in February 2015 (with malfunction of the water-level sensor)

3. DISCUSSION

The secret to implementing a successful EMO is not only about software, but the human inputs. Fresh data insights only truly matter if engineers can use them to identify and solve problems. Based on the hot water circuit case, the PowerBox platform can notify hotel engineers for early maintenance and conduct optimization. As shown in both the hot water circuit and cooling tower cases, such platform allowed hotel engineers to facilitate the understanding of the energy consumption pattern and to identify inefficient consumption among the building facilities. As for the central chiller plant case, the embedded analytical features can assist hotel engineers to conduct energy optimization, as well as to avoid wastage and unwarranted capacity expansion. With sufficient data being collected and the evolvement of artificial intelligent technologies, hotel engineers can use the PowerBox platform to develop advanced decision support tools to reflect abnormal patterns and to identify more energy management opportunities.

4. CONCLUSION

With the advancement in sensor and sensing technologies, many building owners and engineers are overwhelmed by data and feeling lost in these complex situations. This paper highlighted the power of data transparency and demonstrated how a platform to turn data into usable information, then allow building owners and engineers to identify EMO. Based on the presented cases, enhancing data transparency led to value creation in two key areas. Firstly, hotel engineers can make use of the analytical tools for better resources allocation, thus driving down energy consumption. Secondly, the implementation of PowerBox has created a platform where hotel engineers can use building energy data to conduct analytics and optimization tasks. Encouraging them to identify EMO and provide smart solutions that can yield a positive and lasting energy savings.

ABSTRACT

Improving the energy efficiency of existing buildings is recognised worldwide, as one of the priorities in combating climate change. The HKSAR Government launched the "Energy Saving Plan for Hong Kong's Built Environment 2015~2025+" in 2015. The plan aims to achieve an energy intensity reduction of 40% by 2025. One of the key strategies to achieve the above target is to drive the existing building stocks to carry out retro-commissioning and retrofitting.

Retro-commissioning is complicated, highly specific to individual buildings and cannot just follow guidebooks as with new designs. "Knowledge-based" approach enables informed decisions to be made based on information generated through the analysis of operating data and application of engineering theories.

Two major barriers in adopting this approach by the industry include:

- The lack of adequate hardware for data collection and storage in buildings
- The lack of qualified engineers with knowledge-based retro-commissioning experiences

In order to tackle these barriers and discover potential challenges, the HKGBC is engaging different building practitioners to join the "ACT-Shop" Programme to implement knowledge-based energy management and retro-commissioning practices. The objectives of this Programme are: 1) to provide a collaborative platform for a group of participating companies to work step-by-step with experienced facilitators to carry out retro-commissioning for their buildings; 2) to work as peers to develop standardised methodologies for achieving comprehensive data collection and analysis, with the help of metering systems. Last but not the least, this Programme aims to build up their in-house competence on re-commissioning practices so as to plan for major retrofits and make ready for the next mandatory energy audit in the near future.

This paper reviews the process of the "ACT-Shop" Programme, the benefits to participating building owners, the effectiveness of the outcome in building capacities and driving changes to the industry.

Keywords: retro-commissioning, existing building, energy performance

1. INTRODUCTION

Experience-based operations are the main stream practices adopted by the Operation and Maintenance (O&M) practitioners in Hong Kong. Chiller plants are normally operated manually based on operators experience. Reliability is usually their key consideration in determining the operation strategies of their HVAC plants. Reference is usually made with the design parameters when the building is designed rather than based on the actual load profile and performance characteristics of their plant. Most buildings lack adequate provisions for the collecting and storage of operating data. Plant operators often lack the skills and knowledge in analysing and making good use of operating data to facilitate them in optimising the efficiency of their plants.

In recent years, with the advancements in Building Management Systems (BMS), operating data and information is becoming more accessible for plant operators. The industry is gradually recognising the value of retro-commissioning, i.e. the process of fine tuning the operating strategies of their plants and equipment based on actual load profile and plant performance characteristics. Significant savings in the order of 8 to 15 percent can be achieved with relatively short payback period of between 0 to 3 years.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

While more appropriate hardware is becoming available, the industry is now facing the challenge in building up the capacity of operational professionals to be able to adopt a "knowledge-based" approach in energy management and retro-commissioning. Unlike designing new systems, training up professionals to do retro-commissioning by using guidelines, handbooks and training classes are not effective.

2. THE ACT-SHOP PROGRAMME

2.1. Features of the programme

In view of this, the Hong Kong Green Building Council (HKGBC) initiated an "ACT-Shop" Programme with the aim to build up the capacity of the industry on adopting "knowledge-based" approach retro-commissioning practices for central air-conditioning systems.

Under the Programme, the HKGBC will provide a platform where participants of up to five buildings with their technical representatives will go through a retro-commissioning process together.

The Programme is facilitated by experts with the knowledge and experiences on "knowledge-based" energy management and retro-commissioning.

The key features of the ACT-Shop Programme are:

- Using real buildings as living laboratory;
- Working together with the technical staff of those buildings instead of doing the study for them in order to build up their competence;
- Emphasising on the use of operating data to provide the necessary information for the process;
- Participants will be expected to carry out the improvement measures and verify the savings together; and
- Building up the necessary energy management system so that their technical staff can implement an on-going knowledge-based energy management system after participating the Programme.

2.2. Objectives of the programme

The key objectives of participants participating the ACT-Shop Programme are:

- Actively supporting Hong Kong Government's Energy Saving Plan;
- Building up the competence for the industry on retro-commissioning through:
  - Developing a data/knowledge base;
  - Developing a systematic approach for retro-commissioning;
  - Demonstrating the value of retro-commissioning;
  - Transferring knowledge and skills to the industry; and
  - Establishing a practical operation and management system;
- Promoting the adoption of best practices to the industry.

The benefits of ACT-Shop to various stakeholders and how it can build up the competence of the industry is illustrated in Figure 1 below.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

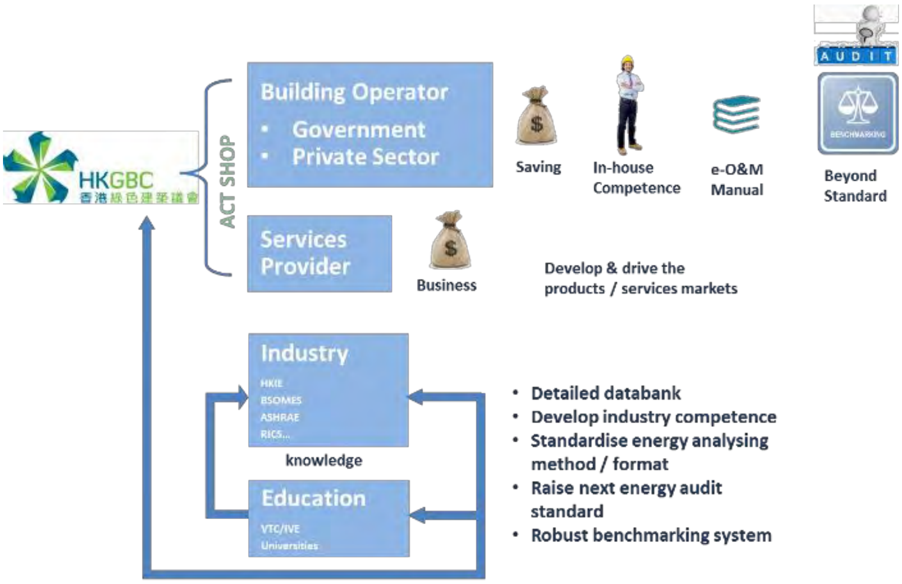

Figure 1: The idea of ACT-Shop to establish a knowledge sharing platform.

3. PILOT STUDY FOR 5 BUILDINGS

Five buildings were selected as pilot cases. The buildings were specifically selected with different design, usage and age.

3.1 Methodology of the programme

The programme includes on-site evaluation and progress review meetings. These can provide a general understanding on the design and conditions of the Heating, Ventilation Air Conditioning (HVAC) plant. Participants will be asked to provide the following data and information for the preliminary analysis, discussions among participants and exploring system optimisation opportunities.

- Log sheets
- Equipment Schedule
- BMS Data
- Availability of metres and sensors
- Conditions of equipment
- Schematics of HVAC Systems
- Service Reports

Through the process of ACT-Shop, some common problems regarding data collection were observed from the pilot buildings, for example: 1) lack of BMS database, 2) incomplete log data in certain time, 3) incomplete equipment schedules, 4) limited provisions of in-situ metres, and 5) limited knowledge of energy management in building operations.

Although the quality of information available is not ideal, it is still possible to identify the issues of the chiller plants based on limited data through data analysis. The Programme has proven that the readily available data is sufficient to carry out retro-commissioning process.

3.2 Data analysis

Based on the data and information collected, a number of Key Performance Indicators (KPI), such as Full Load Current (FLA), Differential Temperature of Chilled Water (Delta T), are plotted against Cooling Load to determine operating conditions of the chiller plants (ASHRAE, 2002). These charts are used to identify current operation practices and potential to improve the chiller plant performance. By fine-turning the control setting, the performance of chiller plant will be enhanced progressively (Xiao, F., & Wang, S., 2009).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4 FINDINGS FROM THE PILOT CASES

4.1 Analysis results of operating data

Restricted by the length of the paper, only two issues observed are discussed in this paper as illustration.

Chiller operation problems were found by analysing the data provided by the participants. Chart 2a shows the FLA of each chiller against the percentage of part load of the chiller plant for one of the pilot buildings. The green line is the reference line, representing the theoretical FLA of individual chillers at different chiller combinations. For this pilot building, the chiller plant consists of four 190-ton air-cooled chillers. The blue dots indicate the FLA for three individual chillers in operation whilst the orange dots represent those for two chillers in operation.

Before ACT-Shop After ACT-Shop

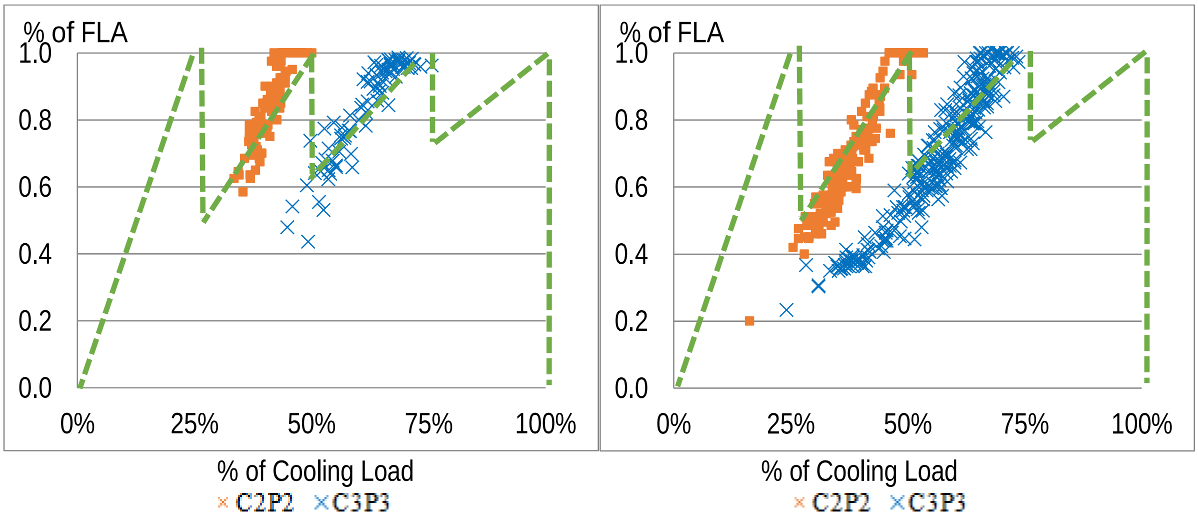

Chart 2a (left) and 2b (right): Sequencing profile - percentage of full load ampere versus cooling load before and after ACT-Shop

Before ACT-Shop After ACT-Shop

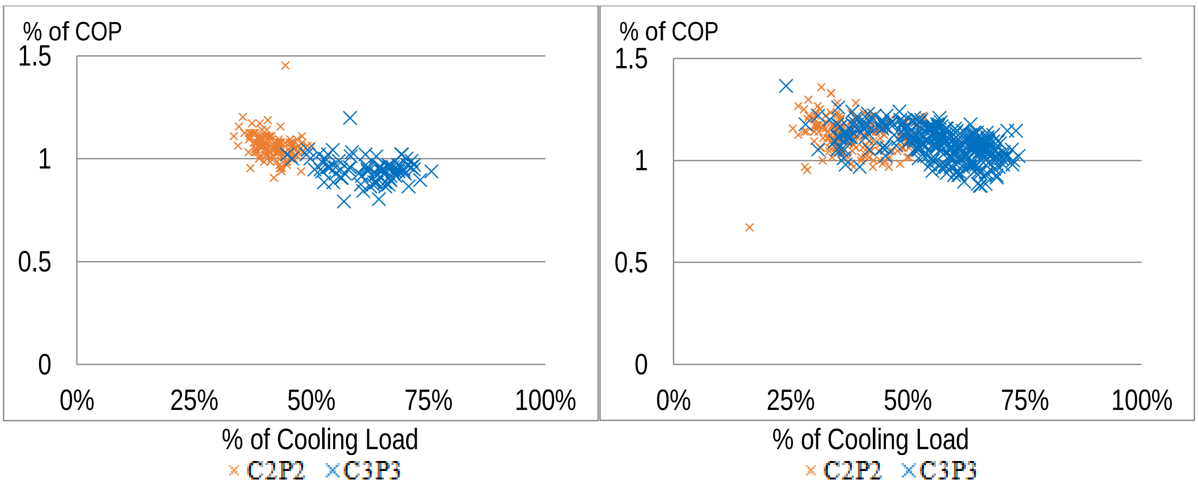

Chart 3a (left) and 3b (right): Overall chiller COP versus cooling load before and after ACT-Shop

Before the ACT-Shop, the number of chillers was operated based on the reference line (Chart 2a). Orange dots and blue dots representing 2 chillers and 3 chillers in operation accordingly were shown in Chart 2a. The chart indicated that within the range of 25% to 50% part load condition, the FLA for three chillers is lower than two chillers in operation. By analysing the COP of the individual chillers, the COP for chillers within the range is higher.

With these findings, the chiller sequencing control was revised from two chiller operation to three chiller operation within the range of 25% to 50%. Chart 2b shows the revised chiller operation.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Chart 3a and 3b illustrate that the overall chiller COP for three chiller operation is higher than that for two chiller operation under the range of 25% to 50%. The average COP for three chiller operation is 3.67, which is higher than that for two chiller operation (3.39) within that range.

This case study illustrates that through this simple screening method, operators can identify potentials to improve the COP of their plant sequencing and the same chart can be used regularly to monitor the plant efficiency and determine the sequencing strategy.

The estimated saving of adopting the new strategies is approximately 120 MWh per month, equivalent to an approximate HKD 117,000 saving per month while little cost was involved.

The other illustration is a building with a chiller plant using a single loop chilled water system with differential pressure bypass. The differential temperature of chilled water (Delta T) was plotted against cooling load. In principle, the level of Delta T should theoretically follow the blue reference line under various cooling load conditions. From Chart 4, the level of Delta T can reach the reference line in the high cooling load region. However, at the low cooling load region, the level of Delta T is far below the reference line. A low Delta T will require more pumping power for the same cooling load and decrease the COP of the chillers due to a lower than required evaporating temperature.

The low Delta T is usually caused by the faulty control valves of the terminal units (FCUs and AHUs) and/or the differential pressure bypass valve. The differential pressure valves were checked and confirmed to be faulty. At the writing of this paper, the faulty valve is being replaced and the checking of the other control valves are in progress. After rectifying those, the differential pressure and hence the amount of bypass will be properly controlled. Significant savings will be expected from pump power and improvement in chiller COP.

This illustrates another simple screening method for operators to monitor the conditions of the chilled water loop which can lead to significant wastage in energy to the chiller plant.

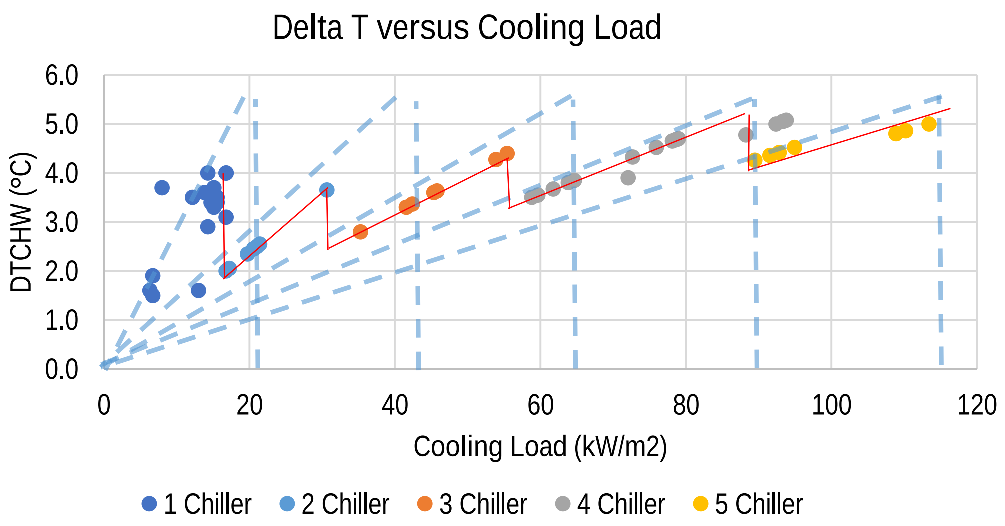

Chart 4: Delta T versus Cooling Load

4.2 Obstacles and limitations

A number of obstacles and limitations were found in the pilot cases which might affect the progress and outcome of this retro-commissioning process.

- Quality of data

As mentioned, the quality of data, including accessibility, format and accuracy is relatively low. This will affect both the process and depth of the study. However, as this is still the norm of the industry for the short and medium term, the Programme is therefore focusing on how to use the data and information available from the limited provisions of instrument in a building.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Faulty equipment, valves and controls

From the five pilot buildings, a number of equipment which is critical for the control of the system such as valves, temperature control etc. are found to have been seriously deteriorated. A considerable time and effort will be required to rectify those faults before the process can be continued.

- Tenancy commitment

Some tenants, especially for data centre or server room, require a fixed chilled water supply temperature for reliability reasons. However, this limits the reset of chilled water supply temperature. It is worthwhile to consider having a separate system for tenants that has such requirement or provide them with condensing water supply instead of chilled water supply.

- Oversizing of equipment

It was found that a lot of equipment is oversized. Even when they are replacing such equipment, it is uncommon that the capacity of the plant will be reviewed. Although most of the equipment such as pumps and chillers are now provided with variable speed drives, oversizing the equipment will limit the control range and hence the efficiency in part load conditions.

4.3 Effectiveness of ACT-Shop

A survey was carried out with the participants to investigate the effectiveness of the programme and their opinion on the future development of the programme. The results are as below:

Knowledge gained - Participants were asked of the degree of knowledge gained on 11 types of knowledge on retro-commissioning. The feedback is very positive with knowledge gained in all aspects. The two type of knowledge with the most significant gain are “Key parameters for system control” and “Regular re-tuning”

Contents of ACT-Shop - Three types of contents were seen by participants as “Absolutely necessary”. They are 1 Preliminary system diagnosis; 2 Interpretation of Analysis results and 3 System performance forecasting technique.

In general, knowledge and skill transfer were successfully observed via the Programme. Participants felt that they become more knowledgeable on their buildings’ HVAC systems and retro-commissioning techniques. Extra resources of not more than 20% were expected to be needed during the participation of the Programme.. They believed that the Programme duration should be one year or longer. All of them were satisfied with the pilot Programme.

The participants recognised the importance of retro-commissioning, and agreed that there should be trainings for retro-commissioning professionals.

5. CONCLUSION AND THE WAY FORWARD

From this pilot project, we can conclude that

In the participated buildings as mentioned in the previous sections, the lack of equipment for data collection will cause challenges in carrying out retro-commissioning. The low quality data will also increase the difficulties for data analysis. That being said, the Programme has used the readily available data for data analysis. Suggestions have been provided to improve the energy performance of the system and achieve savings on energy and operation cost.

From the survey, through the ACT-Shop, participants have knowledge gain on data collection, data analysis and retro-commissioning. Hence, this participative approach can effectively build up the competence of the industry practitioners in terms of knowledge-based energy management.

The Way Forward

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

This Programme is well recognised by the Environment Bureau, HKSARG in driving retro-commission to the industry. The Electrical and Mechanical Services Department (EMSD), HKSARG also shows support to the Programme. ESMD will carry out retro-commissioning in Government buildings whilst the HKGBC will be responsible for the private buildings in Hong Kong (Environment Bureau, 2015).

The Programme enables O&M professionals and energy services companies to better identify and actualise the value of retrofitting and retro-commissioning opportunities. This will boost the related demand for such works.

The HKGBC will review the Programme and liaise with EMSD continuously based on our experience and findings within 2017. The Programme is expected to be scaled up to the market in 2018. It will also facilitate the owners of commercial buildings to prepare for the coming energy audit as required by the Building Energy Efficiency Ordinance (BEEO).

ABSTRACT

Taiwan established the green building label evaluation system in 1999, and implemented the special label for green buildings of Building Technical Regulations. Since the legalization of green building policy, the "green building" has been popularized to folk buildings. However, as Pingtung is located to the south of Tropic of Cancer, in the southernmost tropical climatic region of Taiwan, in comparison to other counties and cities, the existing green building related criteria are obviously insufficient for the peculiar climate of Pingtung. Therefore, the "green building self-government ordinance of Pingtung County" is stipulated.

According to the climate characteristic and agricultural industry characteristic of Pingtung County, the green concepts of roof insulation, photovoltaic, water-saving facilities, bicycle parking space, permeable pavement and low energy-consuming lamps are proposed. In order to build an energy-saving, healthful and comfortable living environment, responding to local climate, from the site development and building planning and design stages, the concept of “in harmony with nature” is popularized. The passive design techniques of pervious basal disc, green energy rooftop, vertical greenery, general design and deep shading are used, and effective vents and paths are created.

The new and existing buildings are divided into five classes, the criteria are made in details, and the new intelligence and new technology are imported actively, such as photovoltaic. The environmental objective for energy saving and carbon reduction is attained, and the value of local industry is increased.

Keywords: green building self-government ordinance of Pingtung County, passive design, in harmony with nature

1. INTRODUCTION

A total of 31 cities in the world were listed in the 2013 global "Smarter Cities Challenge". The renewable energy innovation and application plan, which was proposed by the Taiwan Pingtung County government, was the only selected city in Taiwan. In recent years, Pingtung County has made continuous efforts to become a non-nuclear home, and actively promoted the local production and consumption of renewable energy in order to revitalize the local economy. Taiwan established the green building label evaluation system in 1999, and implemented the special label for green buildings of Building Technical Regulations. Since the legalization of green building policy, the "green building" has been popularized to folk buildings. However, as Pingtung is located to the south of Tropic of Cancer, in the southernmost tropical climatic region of Taiwan, in comparison to other counties and cities, the existing green building related criteria are obviously insufficient for the peculiar climate of Pingtung. Therefore, the "green building self-government ordinance of Pingtung County" is stipulated.

The new and existing buildings are divided into five classes, the criteria are made in details, and the new intelligence and new technology are imported actively, such as photovoltaic. The environmental objective for energy saving and carbon reduction is attained, and the value of local industry is increased.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2. LATITUDE AND LONGITUDE OF THE PLAN

Pingtung County, situated in the southernmost Taiwan, is warm all the year around and enjoys sufficient sunshine. Most of its people are engaged in agriculture and aquaculture. In order to implement and create a non-nuclear home and fuel the economy, from 2011, the county government started to launch green energy demonstration, solar plant on water, stilt houses and other experiments. By virtue of using renewable energy, the government aims to encourage the buildings to be self-sufficient, attain the goal of energy conservation and carbon reduction, form innovative industries and pursue environmental sustainability.

Three important strategies are developed as follows: In terms of land restoration plans, the "water conservation and solar power generation" is popularized. With regard to promoting green energy industry, "bidding-free solar photovoltaics 50 MW". In respect of buildings, "green building self-government ordinance of Pingtung County" is formulated. The breakdown is as follows:

2.1 Water conservation and solar power generation

On August 8, 2009, Typhoon Morakot hit all counties and cities in south Taiwan, and Jiadung and Linbian under Pingtung County in south Taiwan were mostly seriously affected. This area is coastal and low-lying. Worse still, over-pumping of groundwater by illegal aquaculturists contribute to subsidence, giving rise to increasingly severe disasters. Besides, the land in the disaster areas was subject to severe salinization. The well-known "black pearl" wax-apple orchards in Pingtung County were soaked in the water so that the wax-apples could not be grown and people lost their livelihoods. Therefore, Pingtung County initiated the land restoration program of "water conservation and solar power generation" in order to improve the long-standing subsidence, and to use the land affected by the Typhoon Morakot and meanwhile to satisfy people's demand of making a living.

Taiwan's solar photovoltaic systems are mainly set on the roofs of government institutions, schools or general buildings. In the reconstruction areas of Typhoon Morakot in remote mountainous villages, the solar power generation systems are also constructed by the government for the use the public facilities. In the event of serious disasters and traffic disruption, such power can be used as the backup power for emergency rescue communications. This program was authorized in March 2010 by the Council for Economic Planning and Development, Executive Yuan, and the full name was "Program of Building of Solar Photovoltaic Power Generation Systems in Severe Subsidence Areas and Land Damaged by Typhoon Morakot in Pingtung County Government", referred to as "Water Conservation and Solar Power Generation Program".

"Water conservation" is mainly designed to assist the fishermen to change their occupation, not to raise fish and not to withdraw groundwater in order to reduce subsidence, land salinization and other problems. "Solar power generation" means that the fish farms and wax-apple orchard land which cannot be used are leased to power plants. Solar panels are built on the ponds, and under the solar panels are set detention ponds so that the originally subsided land can be recovered and regenerated. The original farmers growing wax-apple or running fish farms are engaged in "power generation". They serve as the landlord of the power generation areas or the professional managers of the photovoltaic areas. Meanwhile, the use of agricultural land meets economic benefits and the affected land can be used otherwise.

The characteristics of the "water conservation and solar power generation program" are as follows:

- The program is currently the largest commercial solar photovoltaic system application in Taiwan.
- During the implementation of the program, apart from the public authorities playing an important role, the public participation is of greater significance, especially the investment by solar photovoltaic manufacturers. Coupled with the mobilization by local farmers and fishermen, this program is a pioneering undertaking in Taiwan's history of photovoltaic industry development. The program is a cooperation example where the local governments, industries, enterprises, communities, farmers and fishermen jointly participate to create a friendly environment, make use of green energy and promote sustainable development of the communities. For the photovoltaic manufacturers involved in this program, apart from commercial considerations, they also assume the corporate social responsibility of returning their hometown.
- The county government acts as an agency and invests in the manufacturers and farmers landlord to safeguard the interests of farmers and help the manufacturers to successfully obtain investment land. The

mutual cooperation between the farmer landlords and the investors shall be subject to the contractual matters signed by both parties. The outline is as follows:

- o The development is based on the agricultural land of small farmers, and the land can be filled and recovered, so that land use can gain economic efficiency. The revenue from the power generation is used to pay the rent for farmers and fishermen so that farmers and fishermen can make a stable livelihood, promoting transformation of land use and benefiting land restoration.
- o With the investment in preventing warming and avoiding disaster, solar power generation facilities are ground-based for land protection and disaster preparedness.
- o The government helped the investment manufacturers to complete power transmission before December 31, 2011 so that the 2011 photovoltaic electricity wholesale rates are applicable.

2.2 Bidding-free solar photovoltaic 50MV

Pingtung County is a large agricultural county, and its government sets the target of establishing a sustainable living environment and proactively develops green energy industries. Meanwhile, owing to the climate pattern of high temperature and humidity around the year, the poultry farmers in the county often suffers from heavy losses because of avian influenza. In order to reduce the incidence of avian influenza and assist the transformation of the poultry houses, the county magistrate Men-an Pan fought with the Bureau of Energy for the photovoltaic poultry house scheme of bidding-free solar photovoltaic 50MV, and promulgated the code of practice "Inclusion of Building Poultry Houses and Solar Energy by Solar Energy Manufacturers and Poultry Farmers into Bidding-free Scheme". The county government accepts the application for bidding-free schemes.

According to the county magistrate Men-an Pan, fighting for the bidding-free scheme for poultry houses aimed to help the farmers to apply for the licenses to use the poultry houses, receive structural reinforcement and gain extra income besides solar power generation in the ways of the solar energy manufacturers' capital and human resources. For instance, solar panels are equipped on the roof of a 1,500-square-meter poultry house and the capacity is set to be 499KW. The farmers' annual income is about RMB 180,000 for 20 years without bearing the maintenance costs of the solar panels. Solar photovoltaic settings can lower temperature and generate power, and roof can receive 20-year leakage-proof and protection. Besides, the farmers can gain additional income by renting the roof.

2.3 Green building self-government ordinance of Pingtung County

This self-government ordinance aims to implement green building design in all types of target buildings and to respond to the local hot climate, and by renewable energy, greening, energy conservation, environmental design and other ways to create exclusive negative carbon equations of the county and make the county become a carbon and disaster-reduction township-type livable county. In January 1, 2016, the ordinance was announced to be implemented. The publicly-owned and public buildings meeting the targets are taken as the key demonstrations to develop local green buildings and promote a living environment of green buildings.

In order to build an energy-saving, healthful and comfortable living environment, responding to local climate, from the site development and building planning and design stages, the concept of "in harmony with nature". PASSIVE DESIGN techniques are encouraged, such as pervious basal disc, green energy rooftop, vertical greenery, general design and deep shading. Also, effective vents and paths and paths are created. In terms of operation methods, green concepts are proposed, such as "roof insulation", "solar photovoltaics", "water-saving facilities", "bicycle parking space" and "low energy-consumption lighting".

The draft self-government ordinance consists of a total of 29 provisions, and the applicable buildings are divided into five categories, and summarized as follows.

- The first type of buildings: Refer to the public new buildings. The buildings are excluded whose budget has been examined and approved prior to the implementation of this self-government ordinance or whose project costs are less than NTD 30 million. The significance of demonstration and public education can be effectively attained through large-scale public sector buildings. Such buildings can serve as a benchmark.

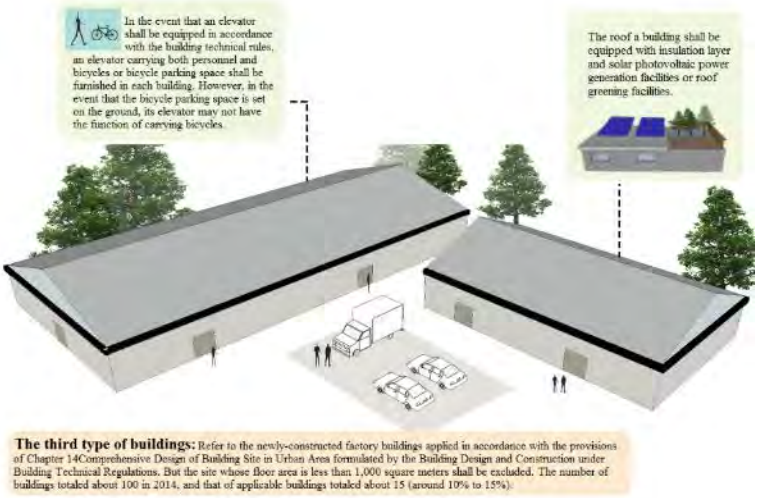
The provided items are as follows: "The roof a building shall be equipped with insulation layer and solar photovoltaic power generation facilities or roof greening facilities", "garbage disposal facilities and garbage storage space shall be furnished within the site", "water-saving toilets shall be adopted in the buildings", "bicycle parking space shall be equipped", "an elevator carrying both personnel and bicycles or bicycle parking space shall be furnished", and "power lines and traffic lines for electric vehicles (motorcycles) shall be reserved in the site".

- The second type of buildings: Refer to the newly-constructed buildings and newly-constructed buildings with over 16 floors applied in accordance with the Regulations for the Multi-purpose Land Use of Public Facility on Urban Planning and the provisions of Chapter 15 Integrated Design of Building Site in Urban Area formulated by the Building Design and Construction under Building Technical Regulations.

The majority of such second types of buildings are "multi-purpose integrated design" and "large-scale congregate housing". They are the buildings which the county people are most closely connected to. The existing studies suggest that the total life cycle carbon emissions of large-scale congregate housing are no less than those of the office buildings. Such buildings can find their ways into people's daily lives by virtue of "green roof", "water-saving appliances and facilities", "bicycle parking space" and design. In this way, people's living habits can be gradually changed, and the next generation can become environment-friendly.

Basically, the requirements for the second types of buildings are similar to those for the first types of buildings. The additional requirements are as follows: Garbage disposal facilities and garbage storage space shall be furnished in the buildings of more than 16 floors", "the utilization rate of green building materials by buildings' interior decoration materials, floor materials and windows shall exceed 45% of total area", and "the bicycle parking space with management functions shall be furnished".

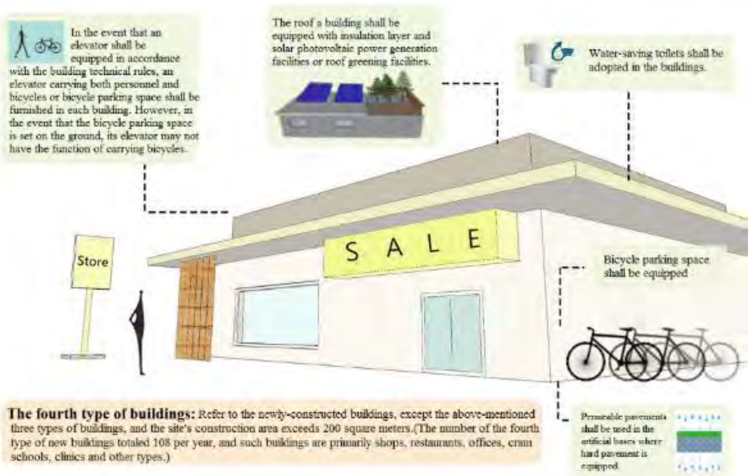
- The third type of buildings: Refer to the newly-constructed factory buildings applied in accordance with the provisions of Chapter 14Comprehensive Design of Building Site in Urban Area formulated by the Building Design and Construction under Building Technical Regulations. But the site whose floor area is less than 1,000 square meters shall be excluded.



Factories are featured by "heavy electricity consumption". Additionally, compared with metropolitan cities and counties, Pingtung County has a low land density, and is an important area for building factories. As a result, substantial results can be anticipated by improving the design and use habits of factories. There are only two provisions of such buildings as follows: "The building roof shall be equipped with solar photovoltaic power generation facilities or roof greening facilities" and "water-saving toilets shall be used throughout the buildings".

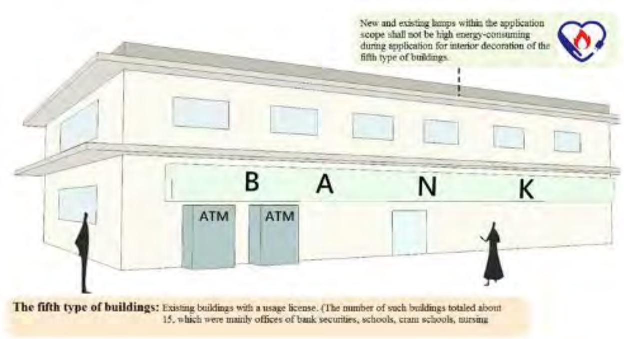
- The fourth type of buildings: Refer to the newly-constructed buildings, except the above-mentioned three types of buildings, and the site's construction area exceeds 200 square meters.

Most of such buildings are small and medium-sized public facilities and shops and most easily reached by the public in life. When such buildings are constructed, the design of new concepts is included. The buildings bring substantial economic benefits to the businesses, and produce a subtle influence on people. It is expected that the concept of healthy and sustainable building environment is integrated into people's life, and can be naturally presented in the county's philosophy of life.



The provisions of such buildings are similar to the foregoing provisions: "The roof a building shall be equipped with insulation layer and solar photovoltaic power generation facilities or roof greening facilities", "water-saving toilets shall be used throughout the buildings", and "bicycle parking space shall be equipped". The special provision is that "permeable pavements shall be used in the artificial bases where hard pavement is equipped".

- The fifth type of buildings: Buildings with a usage license. That is, the specifications of improving the existing buildings. Since an application for "interior decoration permit" shall be filed in accordance with provisions when the buildings for public use are subject to change of use and interior decoration (Interior Decoration Management Method, 1996), it is stipulated that "new and existing lamps within the application scope shall not be high energy-consuming during application for interior decoration of buildings". The people are encouraged to turn to green buildings during decoration and alteration.



3. CONCLUSION AND RECOMMENDATIONS

It is projected that through this policy, 3.1 million kWh of electricity/ year can be saved each year (for the total electricity consumption of 900 households in a year). 2,190 tons of water/ year can be saved (approximately one international standard swimming pool). 1,912 tons of carbon/ year can be saved (equivalent to190,000 trees). The total green area reaches 34,500 m^2/ year (about 6 football pitches). Therefore, the overall efficiency is considerable.

The "water conservation and solar power generation" program turns the fish farms with subsidence into power plants, and the disaster areas into an emerging area of ground-based solar photovoltaic systems. Three years after the Typhoon Morakot, the "Black Pearl Hometown" and "Breeding Kingdom" have become a "special area of solar energy industry", thereby allowing Pingtung County to become the county with the largest power generation via solar panels and the involved manufacturers to undertake social responsibility. Presently, the targets of Phase 1 have been attained, but there are still uncertainties in the future development. In particular, whether the central government can provide sufficient economic incentives to electricity pricing structure and green energy policies will be the key to sustainable development of Pingtung County's new industries.

Subsequently, by carrying out supporting policies, the annual carbon reductions will grow by multiplication. Gradually, relevant laws and regulations and subsidy regulations will be updated, such as solar photovoltaic facilities, design feedback of Pingtung, three-dimensional green subsidies, existing green building transformation, smart site design, building green highlights and other related methods, plans and activities. Local buildings for Pingtung are found. The overall township styles are progressively connected. Buildings, be they new, old, public or private, can be involved in green building policy. Popularization of green buildings is implemented. The green building self-government ordinance of Pingtung County will become a leading green building self-government ordinance in townships so as to achieve the goal of carbon reduction and disaster relief and township transformation.

In the future, the government's smart grid policy is implemented, so that the achievements of advanced power generation, transmission and distribution, storage, utilization and management can be implemented into the local construction. Meanwhile, Pingtung County can be successfully built through IBM's global promotion of "smart grid city" and the successful experience in helping urban reconstruction of Japan after earthquake in March 31, 2011.

ABSTRACT

Building ventilation provides comfortable environment and maintain acceptable indoor air quality. One bedroom condominium in Thailand commonly uses a split type system with no outdoor air intake, which the room ventilation comes from air infiltration through the envelope components only. Insufficient and uncontrolled ventilation rate from the air infiltration might not provide healthy environment for occupants. This paper evaluates the ventilation performance and carbon dioxide concentration in one bedroom condominium with double occupancy based on the ventilation rate performance (VRP) and indoor air quality performance (IAQP) prescribed in ASHRAE Standard 62.1. The room air exchange rates are calculated via using carbon dioxide as a tracer gas. To improve air quality, the energy recovery ventilator (ERV) is installed and supplies two airflow rates of 40 m^3/hr and 60 m^3/hr. It is found that, the air exchange rates for the bedroom range from 0.40 - 0.64 ACH with an average value of 0.48 (s.d. = 0.09), which is considered as an airtight envelope. The room carbon dioxide concentration rose up to approximately 2,000 ppm when the ERV was not operated. The calculated ventilation rate of 28 m^3/hr following the VRP is not sufficient to maintain carbon dioxide concentrations within 1,000 ppm To maintain acceptable carbon dioxide concentration, the ERV should be operated at 60 m^3/hr The increase of air exchange rate through the ERV system does not affect indoor humidity.

Keywords: energy recovery system, CO_2 concentration, indoor environmental quality

1. INTRODUCTION

Most people spend an average of 6-8 hours sleeping a day that about one-third of their life. Sleep is a basic human need and the quality of those hours of sleep plays a significant role on physical health such as learning and memory function. The indoor environment including air temperature, relative humidity, and carbon dioxide concentration level could affect the sleep quality and next-day performance.

For studio and one bedroom types of condominium in Thailand (hot humid climate) typically use a wall mounted split type air conditioning with no outdoor air intake to provide human comfort. The room ventilation during the night time comes from the air infiltration through envelope components only. In addition, with the design for high energy efficient building, the room has built tighter thermal envelope, which decreases the room ventilation rate and consequently increases indoor contaminant concentration. Indoor carbon dioxide concentration can be used as indicator of room ventilation rate. According to the ASHRAE ventilation standard, the target of indoor carbon dioxide concentration should not exceed the local outdoor concentration by more than 650 ppm. The National Institute for Occupational Safety and Health (NIOSH) considers that indoor carbon dioxide level above 1,000 ppm indicates inadequate ventilation.

The energy recovery ventilator (ERV) is one of solution to provide sufficient fresh air to improve the air quality. The warm and moist air is preconditioned via energy transfer process before delivering to the room. The objective of the present study was to evaluate the effect of room ventilation via the ERV unit on indoor carbon dioxide concentration, air temperature, and relative humidity in a bedroom in condominium with double occupancy.

2. METHODOLOGY

The experiment of this research was performed in a master bedroom unit of condominium with an area of 10 m^2 and 2.7 m ceiling height. A 9,000 Btu wall mount split type air condition provides occupants thermal comfort during occupied period while an ERV unit provides the fresh outside air into the bedroom. The study investigated the ventilation and indoor air quality performance for normal operating (no OA intake) and ventilated room conditions with two different airflow rates of 40m^3/hr and 60m^3/hr by ERV unit. Two occupants normally lived in the room during 6 pm to 8 am.

The indoor carbon dioxide concentration, air temperature, and relative humidity were continuously monitored with HOBO MX carbon dioxide data logger (accuracy of ± 0.21°C for temperature sensor, ± 50ppm for carbon dioxide sensor, and 2% RH for relative humidity sensor). The data was collected every five minutes interval. Figure 1 presents the instrument location installed in the bedroom. One indoor sensor was placed at 1.10m above floor level, which the location avoided exposure to occupants. Another sensor was attached in front of the exhaust of the ERV unit. Outdoor sensor was located in front of the outdoor air intake damper of the ERV unit. After the occupants left the room, the decay of indoor carbon dioxide concentrations were conducted to determine the room ventilation rate.

The air exchange rates were calculated using a linear regression method as shown in Equation (1), where C_a is the background concentration. C(t) and C(0) are the carbon dioxide concentration at time t and 0, respectively.

$$\ln(C(t) – Ca) = -At + \ln(C(_0) + C_a)$$

Equation 1

Figure 1: The experiment room and the physical measurements

3. RESULTS AND DISCUSSION

This part shows the comparisons of measured ventilation rates including air infiltration, which influences the indoor environment performance. The investigated results are also compared with the standard recommended limits.

3.1 Room ventilation rate

This present study used carbon dioxide concentration as a tracer gas and the concentration decay data after occupants left the room was used to determine the room air exchange rates. Figure 2 presents the measurement results of indoor and ambient carbon dioxide concentrations for three days during occupied and unoccupied hours when the room operated at normal condition (no OA intake). From the figure, the concentration level rose up to 2,400 ppm. The local outdoor carbon dioxide concentrations typically ranged from 400 - 500ppm. Thus the indoor concentrations should be below 1,000-1,200ppm as defined in the ASHRAE Standard 62.1 - 2010 and NIOSH. Figure 3 shows the concentration decay data when the ERV unit supplied outdoor airflow rate at 40m³/hr and when the unit was switched off (no OA intake) after the occupants left the room in daytime. The room had perfectly well-mixed condition, which an average error of carbon dioxide concentration measured in the room and at exhaust was 4 percent.

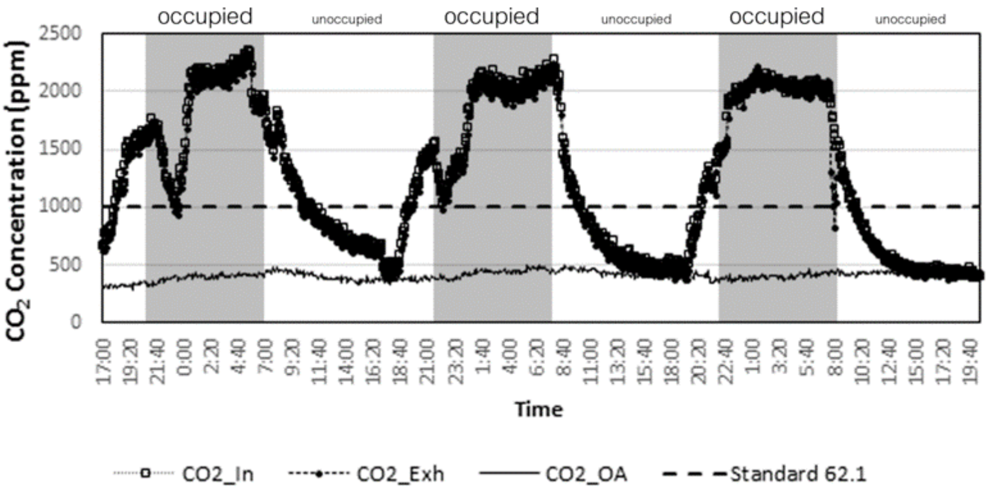

Figure 2: The measured ambient and indoor carbon dioxide concentrations for normal operating condition

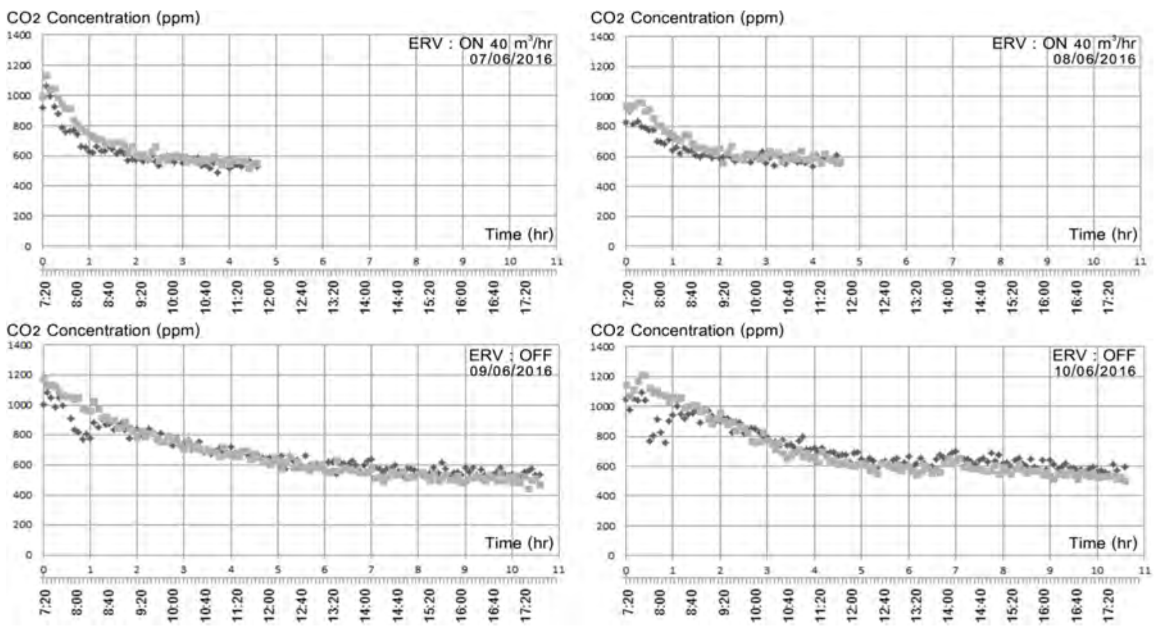

Figure 3: The plot of carbon dioxide concentration decay when the occupants left the tested room at various OA rates

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The calculated air exchange rates used optimal regression analysis method. The concentration data was plotted on axes of ln C(t) against time, t, as prescribed in the ASTM E741 - 2011. In Figure 4, the sample of carbon dioxide concentration decay data when the ERV was switched off (no OA intake) is presented in graph (1) and (2) and graph (3) and (4) illustrates the concentration when the ERV supplied 40 m³/hr outdoor airflow rates. The data typically follows a straight line with a small scatter. From the figure, when the ERV unit was switched on, the indoor carbon dioxide concentration took approximately 2 hours to reach the background concentration that was faster than those for normal operation, which took 3 - 5 hours.

For normal operating condition (no OA intake), the room air exchange rate represented the air infiltration through envelope leakage areas and penetrations since the room has no outdoor air intake from the split type unit. The calculated air exchange rates range from 0.40 - 0.64 h-1 (an average value of 0.48, s.d. = 0.09), which was lower than the required ventilation rate of 1.07 h^{-1} (28 m³/hr) calculated based on the ventilation rate procedure (VRP) prescribed in ASHRAE Standard 62.1 – 2010. The operation of ERV unit with supplied 40m³/hr outdoor airflow rates can provide acceptable ventilation rate of 1.5 h^{-1}. Figure 5 presents the calculated air exchange rates for normal operating condition and operating ERV unit with outdoor airflow rate of 40m³/hr.

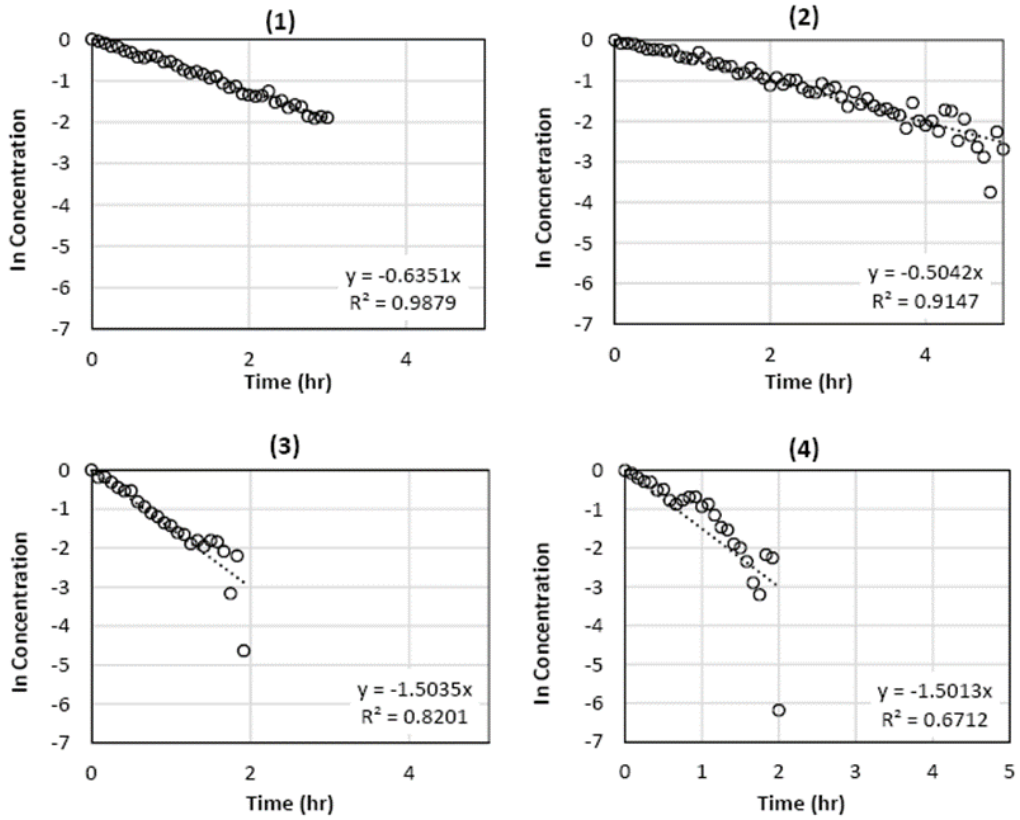

Figure 4: Linear regression analyses for carbon dioxide concentration decay when the ERV supplied outdoor air at 40m³/hr and no outdoor air intake

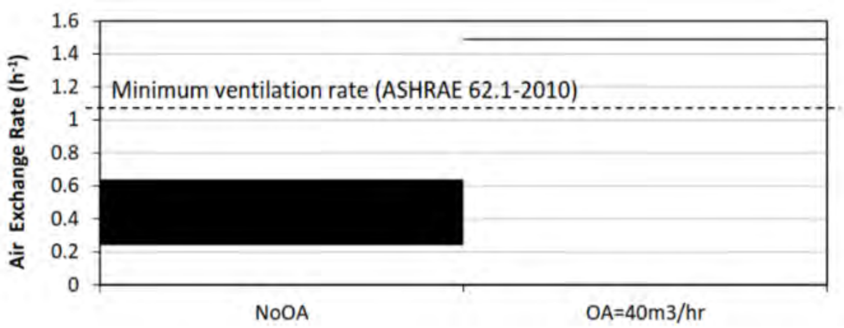

Figure 5: The range of air exchange rates for normal operating condition and the rate for ventilated room with outdoor airflow rate of 40m³/hr.

Considering the envelope air tightness as prescribed in the CIBES Guide A, the room is considered having an airtight envelope, which the air infiltration rates ranging from 0.40 - 0.64 h^{-1}. Such investigated air infiltration rates have the same range when compared to those calculated in modern Thai houses and is considerably lower than the infiltration rate for a traditional Thai house as shown in Figure 6.

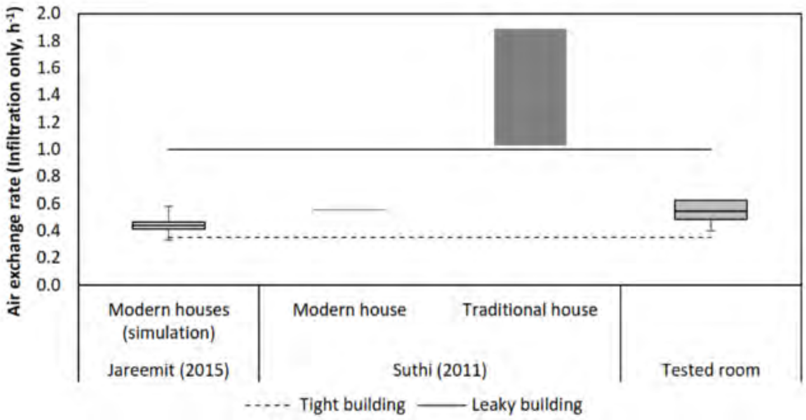

Figure 6: A comparison of air infiltration ranges observed in the tested room and Thai houses.

3.2 The effect of air exchange rates on indoor carbon dioxide concentrations

Figure 7 presents the box plots show the 25th to 75th percentile of the indoor carbon dioxide concentrations with different supplied outdoor airflow rates at 0m³/hr (no OA intake), 40m³/hr, and 60m³/hr by ERV unit when two occupants normally lived in the room during night time; the line in the box shows the median; the circle shows the average. For normal operating condition during occupied period, the indoor carbon dioxide concentration measured in the room exceeded 1,000 ppm (an average value of 1,721 ppm) as recommended in the standard health guidelines. During the week that the ERV unit was operated at 40m³/hr, the indoor carbon dioxide concentrations during the occupied hours were reduced to half with an average value of 930 ppm. During the ERV unit was operated at supplied 60 m³/hr outdoor airflow rate, the carbon dioxide concentrations ranged from 750 – 1,100 ppm (an average value of 853 ppm); however, some of those were higher since the occupants did not switch on the ERV unit.

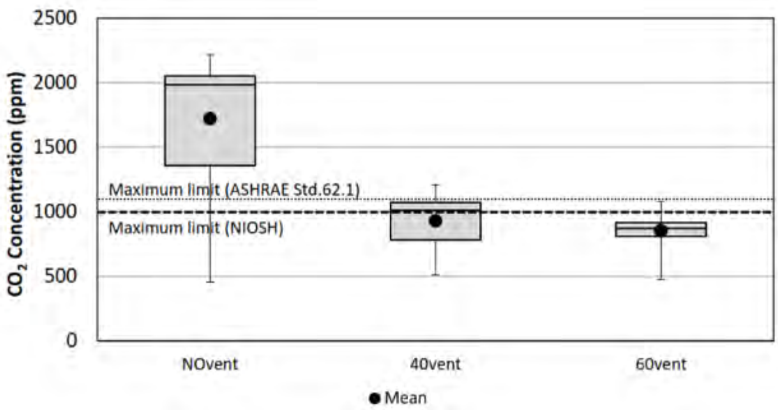

Figure 7: The distributions of measured carbon dioxide concentrations at different outdoor airflow

3.3 The effect of ERV operation on indoor temperature and relative humidity

The indoor air temperature and relative humidity were also measured during the test period. Normally, the room air temperature was controlled within 23 - 28°C with an average value of 24.7°C and the relative humidity ranges from 57 - 75 percent (an average value of 70.4 percent) as shown in Figure 8. Overall, the ERV unit effectively controls moisture content from warm and humid air from outside. Thus, the adjusted outdoor airflow rates slightly affect the room air temperature and relative humidity.

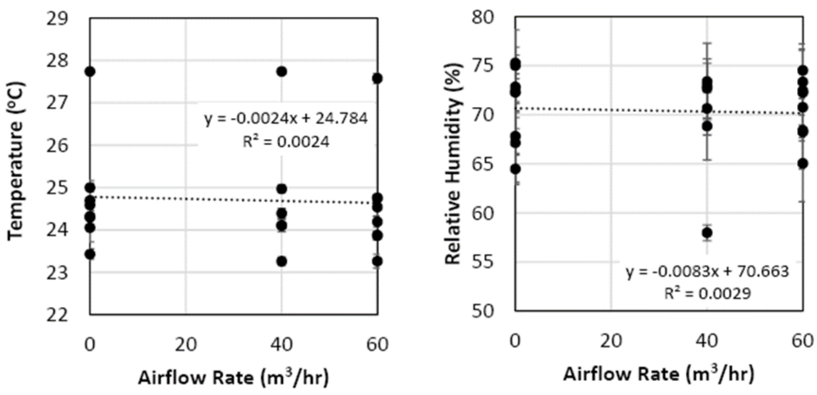

Figure 8: An influence of adjusted outdoor airflow rates on indoor air temperature and relative humidity

4 CONCLUSION

This present study evaluates the indoor carbon dioxide concentrations and thermal performances with various outdoor air intake rates brought through the energy recovery ventilator unit. The operated outdoor airflow rate at 40 m^3/hr provided acceptable ventilation rate following the ventilation rate procedure (VRP), which can reduce the indoor carbon dioxide concentration into the half of the concentration in normal operation. However, it is insufficient to provide adequate ventilation rate, which controls indoor carbon dioxide concentration below the recommended limit as defined in the indoor air quality procedure (IAQP). To maintain the carbon dioxide concentration level within the maximum limit, the ERV unit should be operated at maximum capacity with the supply outdoor airflow rate at 60 m^3/hr. Overall, the ERV unit provides pretty good controlled air ventilation. Introducing outdoor air intake through the ERV unit slightly affects the change in room temperature and indoor relative humidity. However, the operation at high flow rates could make nuisance sound and lead high energy consumption. Future studies should investigate how occupant's satisfaction with the noise caused by the system operation and the impact of increasing ventilation rates on energy consumption.

Session 5.10: Zero Energy

Achieving Net Zero: A Case Study of Hong Kong's First Zero Carbon Building

ABSTRACT

In line with the urgent international agenda to reduce carbon emissions and mitigate climate change, Hong Kong has pledged to reduce its carbon intensity by 50-60% by 2020. To achieve this target, there is a need to reduce the electricity consumption in buildings which contribute to 60% of the city's carbon emissions. Net Zero Energy Building (NZEB) and Net Zero Carbon Building (NZCB) are key approaches to meet energy and carbon reduction goals. To lead the effort to reduce energy and carbon intensity, the Construction Industry Council (CIC) constructed ZCB—the first zero carbon building in Hong Kong. ZCB showcases passive design, energy efficient active systems and explores some new possibilities in renewable energy generation in Hong Kong such as trigeneration using biodiesel. With over three years in operation, this paper presents an evaluation of ZCB's energy and carbon performance based on actual performance data.

This paper will first examine the concepts of NZEB and NZCB in tackling climate change. The designed and operational energy and carbon performance of ZCB over its first three years of operation is then presented with experiences and lessons learned. The feasibility of achieving zero energy/carbon in a subtropical climate is then considered within the broader context of practice, policy and development of a low carbon built environment in Hong Kong. Having achieved energy positive status in 2015, the design, construction and operation of ZCB demonstrates that zero carbon building is a potential strategy to abate greenhouse gas emissions. However, careful consideration of operational use, ongoing testing and commissioning, occupant comfort and satisfaction, reliable renewable energy generation and ongoing monitoring, diagnosis and correction are critical for effective performance.

Keywords: building performance, Net Zero Energy Building, Net Zero Carbon Building, subtropical climate

1. CLIMATE CHANGE AND NET ZERO

There is an urgent need to minimise the impacts of construction sector activity on the natural environment and to develop low carbon cities (DCLG, 2007; Environment Bureau, 2015a). Having reached an unprecedented first ever-binding agreement to combat climate change at the Paris climate conference (COP21) in December 2015, 195 participating nations are committed to actions and investments toward low carbon economies. The Paris Climate Agreement aims to limit global warming to well below 2°C with a long-term goal of net zero emissions for this century (UNFCCC, 2016).

To reduce carbon emissions, Hong Kong aims to reduce its carbon intensity by 50-60% by 2020 (Environment Bureau, 2015a). In line with this goal, the Hong Kong SAR Government has also launched an "Energy Saving Plan for Hong Kong's Built Environment (2015-2025)" (Environment Bureau, 2015b), which outlines the Government's energy saving policy, strategy and targets. A target is to reduce Hong Kong's energy intensity by 40% by 2025 relative to the 2005 baseline. NZEB and NZCB are recognised as viable approaches to help reduce energy use and carbon emissions in the built environment (Cole, 2015; Crawley *et al.*, 2009; Deng *et al.*, 2014).

2. TOWARDS NET ZERO

There is a growing number of NZEBs and NZCBs worldwide (Dean, 2014; Pena, 2014; Reeder, 2016) and an increasing net zero certifications (ILFI, 2016). Some of these examples are even energy positive and recent trends have seen a shift to the concept of regenerative design in buildings and developments (Hes and Du Plessis, 2015). Most examples of NZEBs and NZCBs are located in relatively cool or temperate climates. There are relatively

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

fewer examples in a subtropical climate, more particularly, in a highrise and densely populated city such as Hong Kong.

Hong Kong is characterised by a subtropical climate—hot humid summers and mild to cool winters (Hong Kong Observatory, 2015). The typical cooling season in Hong Kong is estimated at 2000 degree-hours, which differs quite significantly to London's 200 degree-hours for example. Meeting the cooling demand for buildings is therefore a significant challenge in Hong Kong (Cheng *et al.*, 2014). Integrating NZEB and NZCB design strategies and technologies that perform effectively in a hot humid subtropical climate is therefore critical.

3. FIRST ZERO CARBON BUILDING IN HONG KONG

The CIC ZCB aims to achieve zero carbon emissions through balancing the energy consumed with energy generated from renewable energy sources on an annual basis. Surplus renewable energy generated is used to offset the embodied carbon of its construction process and major construction materials. Completed in June 2012, ZCB is a 1400m² building situated on a 14700m² site in the industrial and commercial district of Kowloon Bay. It is a three-storey exhibition, education and information centre with indoor and outdoor exhibition facilities, an eco-office, meeting rooms, an eco-home, a multipurpose hall, an eco-cafe and shop. The building is surrounded by an open landscape area with an urban native woodland. Over 50,000 visitors have toured ZCB since its official opening in January 2013. In 2015 alone, there were visitors from over 400 local and overseas organisations including educational institutions, community organisations, professional groups and government departments.

ZCB's energy strategy combines passive design, active systems and onsite renewable energy generation. Over eighty technologies based on principles of sustainable site planning, energy use reduction, low carbon construction and material selection, water use minimisation, building flexibility and adaptability have been integrated into ZCB. 2800 sensors installed throughout the building monitor key environmental performance parameters. Information including carbon dioxide levels, temperature, humidity, renewable energy generation, energy consumption, energy import and surplus energy export to the electricity grid, is collected by the Building Management System (BMS). This data is evaluated to identify areas for energy performance improvements and to optimise operational performance.

4. PERFORMANCE EVALUATION OF ZCB

4.1 Designed performance

The energy demand for ZCB and its surrounding landscape area was expected to be 116MWh/year and 15MWh/year respectively as shown in Figure 1 below.

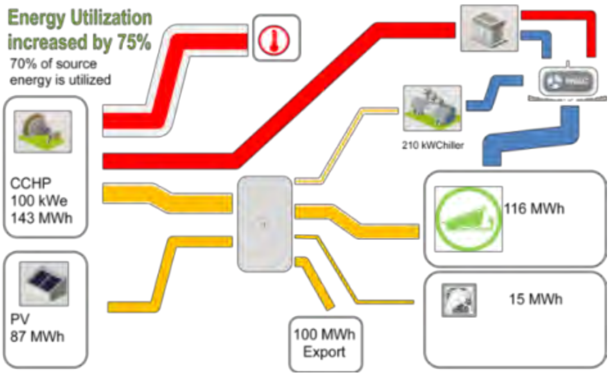

Figure 1: Designed energy performance

The photovoltaic (PV) systems and the Combined Cooling Heating and Power (CCHP) system or tri-generation using biodiesel (B100 waste cooking oil) were estimated to produce 87MWh/year and 143MWh/year respectively. A projected 100MWh/year surplus electricity would be exported to the local grid to offset the embodied carbon accrued during the construction process and for major construction materials. This equates to a carbon reduction of about 45-50 tonnes/year over an assumed 50 year building lifespan as shown in Figure 2.

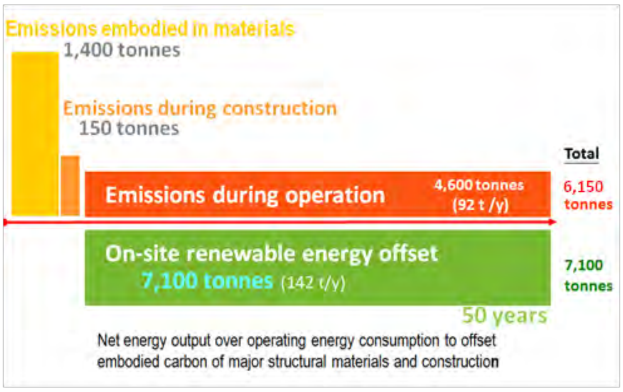

Figure 2: ZCB's carbon strategy

4.2 Operational performance

Three energy audits conducted for ZCB over 2013-2014, and daily monitoring, led to continuous testing and commissioning to finetune the operation of different building services systems. Thus in 2015, ZCB's total renewable energy generation (377MWh) exceeded total energy consumption (355MWh). This resulted in a carbon footprint of -16 tonnes for 2015. Overall, the average yearly energy consumption for 2013-2015 was 339MWh/year—160% over the design estimate of 131MWh/year. The designed and actual energy consumption for 2013, 2014 and 2015 are shown in Figure 3. The following factors can be seen to contribute to this performance gap:

- ZCB is currently operating 7 days a week resulting in an approximate 40% increase in energy consumption over the designed estimate for a 5 day operation week. It has been estimated that 90MWh/year of electricity is consumed for the 2 extra days per week;
- Minor energy consumption was assumed for non-operation hours (19:00 to 08:00) for lighting and power, however actual energy consumption accounted for 22% of total daily energy consumption in summer, and 30% in winter. A base load of 18-20kW was measured for a typical daily lighting and power load profile;
- Higher than expected energy consumption related to non-essential services such as landscape lighting and plumbing and drainage. There is also higher than expected basement plant floor energy consumption.

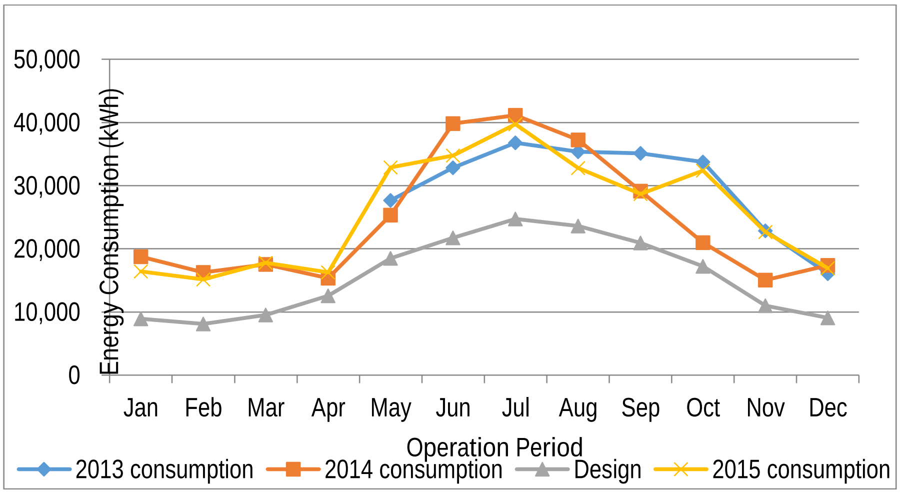

Figure 3: Monthly energy consumption

Renewable energy generation was 14% below the design target for 2013-2014. The CCHP system suffered major breakdowns from May-June 2013 and from August-November 2014. As a result, there was a shortage in energy generation compared with the original design target (Figure 4). In 2015, overall energy generation was 11.5% above the design target. This was mainly due to smooth operation of the system and extension of system operation beyond summer months (May-September) to all year round. PV energy generation is shown in Figure 5. The three types of PV systems (polycrystalline, building integrated PV and CIGS) generated 106MWh of electricity in 2013, 107MWh in 2014 and 105MWh in 2015. This exceeded the predicted annual output of 87MWh by 22%, 24% and 21% respectively.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

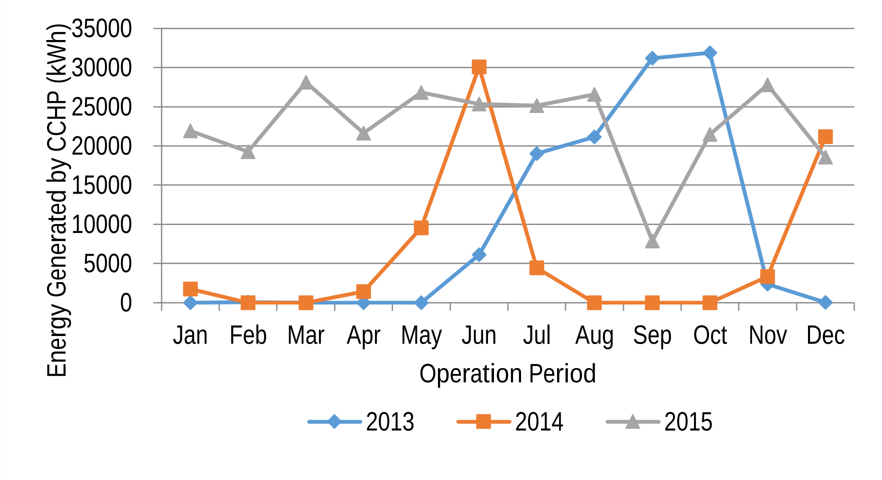

Figure 4: Monthly energy generation by the CCHP system

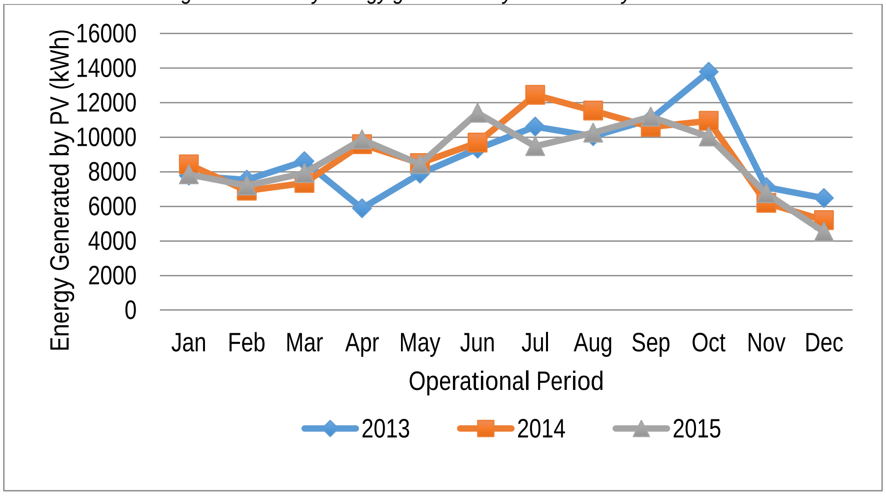

Figure 5: Monthly energy generation by the PV systems

5. EXPERIENCES AND LESSONS LEARNED

5.1. Designed vs. operating target

A major factor that contributed to the current energy performance gap is the disparity between the intended 5 day and actual 7 day use of the building resulting from the demand for ZCB facilities. A significant challenge arising from the evaluation of ZCB is how to accommodate increased activities and changes in operational needs over time while striving to achieve the zero carbon objective. Studies into the performance of NZEBs and NZCBs have found that there is often a wide gap between design objectives (simulated building energy use) and actual measured performance (actual energy consumption). Measured energy consumption can be up to 3.5-5 times initial design estimates (Carbon Trust, 2012). This is often attributed to buildings rarely having a realistic design stage energy use prediction against which operational energy use could be compared. Corney *et al.* (2014) assert that net zero energy and carbon is 'more about designing a building to an operating energy target and then achieving that target'. Post occupancy evaluation and periodic feedback is therefore critical to improve building performance and to the development of future energy use models. Further analysis to examine the effects of different types of activities or uses on ZCB's energy and carbon performance will be carried out.

5.2. Ongoing testing and commissioning

ZCB underwent extended testing and commissioning since its opening in January 2013. Most prominent was the ongoing testing, fine-tuning and performance optimisation of various components of the CCHP system (including the biodiesel generator, pumps, cooling towers and adsorption chiller). Delays in procurement of replacement parts and contractor inexperience in rectifying problems contributed to lengthy gaps in operation. This resulted in a generation shortfall of 36% for the system in 2013-2014. Contingencies should be provided for building systems not operating as designed. A strategic maintenance strategy should be established with preventive measures, ongoing commissioning, and re-commissioning to align with changes in the operating environment and to improve systems performance over time.

5.3. Occupant behaviour, comfort and satisfaction

Balancing the goal of zero carbon with creating a comfortable indoor environment is a significant challenge. ZCB is naturally ventilated in the spring, autumn and winter months—accounting for 40% of the year in 2013, 50% in 2014 and 40% in 2015. However, staff showed dissatisfaction with the thermal comfort level in the building when indoor temperatures on occasion reached a low 9-10°C in winter, and a high of 28-29°C in summer, while the postulated internal comfort range is 18-25.5°C. Opened windows in winter created uncomfortable workspaces. Unanticipated plug loads, including portable heaters in winter and portable fans in summer to attain the desired level of thermal comfort, point to differences in individual preferences and automated controls and temperature set points. Further effort is needed to align user expectations with the zero carbon objective. Periodic user feedback, further education, and behavioural changes are critical to achieve a more optimal balance between the zero carbon objective, a more comfortable indoor environment, and sustainable building operations.

5.4. Reliable renewable energy generation capacity

Reliable renewable energy generation play a critical role in achieving the zero carbon objective. Although the CCHP system underwent trouble shooting and rectifications in 2013-2014, the system generated 272MWh of energy in 2015, almost doubling the designed figure of 143MWh. The facility management staff learned a great deal about the maintenance procedures for the biodiesel generator, the frequency for refueling, optimal water temperatures etc. Balancing the risk of applying more innovative and experimental systems with more tried and tested methods to achieve zero carbon emissions is a significant challenge. With careful consideration for significant overshadowing from surrounding tall buildings during the winter time, the performance of the three PV systems at ZCB exceeded designed output. The suitability and effectiveness of renewable energy systems for a specific site or context is therefore a critical consideration to maximise energy generation.

5.5. Ongoing monitoring, evaluation and performance improvements

An extensive monitoring and data collection system led to complexity in data analysis and interpretation. Consideration should be given to the ease of BMS data extraction for frequent reporting and feedbacks for facility managers and building users on actions to improve operational performance. The scope and level of detail for performance evaluation should also be carefully defined at project outset such that the BMS framework and electrical systems are initially set up to facilitate this process. A new data extraction and analysis system is being installed at ZCB to facilitate more timely analysis and optimisation of systems and technologies.

6. IMPLICATIONS FOR THE HONG KONG CONTEXT

ZCB highlights a number of factors that pose significant challenges for the wider application of NZEB/NZCB principles, systems and technologies in Hong Kong. One factor is whether passive design integrating natural ventilation is a widely applicable strategy in Hong Kong's subtropical high density environment with potentially high levels of humidity, air and noise pollution in Hong Kong. The feasibility of large scale applications of PV systems when overshadowing is common in a highrise environment is another critical consideration. Such limitations to the application of passive design strategies and renewable energy options significantly influence whether net zero energy or carbon can be easily achieved in Hong Kong.

The regulatory and policy framework and the energy infrastructure could be further developed to facilitate the wider adoption of NZEBs and NZCBs in Hong Kong. The application of a new CCHP system with grid feed-in at ZCB highlighted that incentives for grid feed-in could support wider adoption and rebates could help to develop the markets for NZEB/NZCB technologies. Another challenge is how zero energy/carbon principles, systems, technologies and lessons learned from ZCB could be transferred to highrises. More demonstration projects for different building types would be needed. Furthermore, there is untapped potential for applications in the renovation of existing buildings which constitute majority of the building stock in Hong Kong. The ZCB experience also identified the importance of upgrading contractor skills and improving facility management knowledge and user understanding for effective building delivery and operations. There is also scope to develop the business case,

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

stimulate the private sector, collate and disseminate operational and financial performance data, educate for behavioural change, and to develop zero carbon building policies for a low carbon Hong Kong.

7. CONCLUSION

As a demonstration project, ZCB has shown that the objectives of zero energy and zero carbon can be successfully achieved in Hong Kong. Although implications for highrise buildings in a high density urban context remain to be seen, the insights gained, lessons learned, and potentially applicable solutions in a subtropical climate, is a significant point of departure for further development of strategies for highrises. Projects and research in Hong Kong should investigate beyond current concepts of NZEBs and NZCBs to more recent concepts of net positive energy buildings and regenerative design as well as applications for renovations of existing buildings. Further investigations into how economic, behavioural and social criteria with policy efforts can support the diffusion and implementation of these concepts are needed.

ABSTRACT

This paper presents an analysis of the implication design choices have on embodied material emissions, with a view to better understand how the life cycle assessment of buildings can be better integrated into the building design process. The analysis is applied to a pilot net zero emission building (nZEB) called the Living Laboratory, which has been developed by the Norwegian Research Centre on Zero Emission Buildings. The impact of embodied emissions is presented through a series of sensitivity analyses that consider the definition of a functional unit and system boundary. The results for embodied emissions are presented for each building component, and highlight important design drivers for the reduction of emissions in building construction. Compared to the previous ZEB projects, the total embodied emission result from the Living Laboratory of 23.5kgCO_{2eq}/m^2/yr is considered high. This is due to the building having a more comprehensive material inventory, which includes more life cycle phases, and uses a higher level of technical equipment and state-of-the-art materials. The results show that the outer roof, photovoltaic system and outer walls drive the highest emissions. Further analysis revealed that in some cases high emissions came from the production phase, whereas in other cases it originated from the replacement phase. The results show that timber, electrical components and metal were responsible for driving the highest emissions. The results show that certain design choices, such as a change in foundation design, can reduce embodied emissions by 21%, which could be further reduced if low carbon concrete was used.

Keywords: net zero emission buildings, embodied emissions, design process

1. INTRODUCTION

1.7 Background

Previously, the Research Centre on Zero Emission Buildings (ZEB) carried out two simplified concept studies in autumn 2011, with the goal of achieving a ZEB-OM ambition level. In the beginning of 2012, it was decided to develop these concepts into more realistic building models; one of the concept studies was an office building, (Dokka et al., 2013) whilst the other was a single-family house (Houlihan Wiberg et al., 2013). The two ZEB concepts were designed to 'provide a benchmark for Nordic conditions (i.e. cold climate) and [as] a starting point for comparison' of embodied emissions (Georges et al., 2015). The Living Laboratory is one of the first net ZEB pilot studies to be built and tested. This report builds upon the embodied emission methodology developed by the ZEB centre, and applies it to the real case of the Living Lab; with a view to better understand the implication of design choices on embodied material emissions. The Living Lab is an experimental facility that uses state-of-the-art materials and technical equipment. It will be tested and occupied by researchers, students and professors from the Norwegian University of Science and Technology (NTNU).

2. BUILDING DESCRIPTION

The Living Laboratory is a single storey, temporary, multi-purpose demonstration and experimental facility. The building is of a detached, single-family house typology, which represents over 52% of the Norwegian building stock (SSB, 2013). The building is located on NTNU's Gløshaugen campus, Trondheim, Norway. A photograph and section of the building can be seen in Figure 1. A comprehensive explanation of the building envelope, services and energy supply system can be found in Inman and Houlihan Wiberg, 2015.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

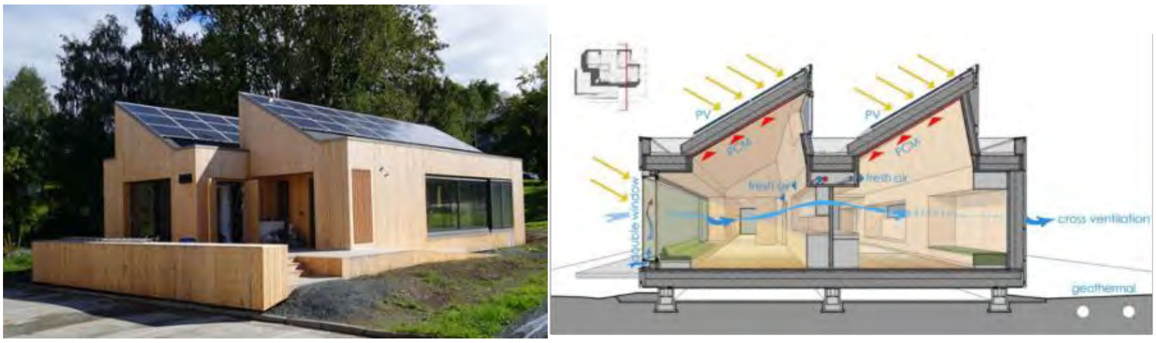

Figure 1: Photo and section of the Living Lab (Finocchiaro et al., 2014).

2.1 Building envelope

The building is comprised of a timber-framed loadbearing structure, with a raised timber floor construction, mineral wool insulation and parquet timber flooring. The building envelope consists of a timber-framed construction, mineral wool insulation, timber cladding, whilst the roof comprises of the same construction with additional integrated phase change material (PCM) and in-roof building adapted photovoltaic panels (BAPV). The north and south windows comprise of triple-glazed units with double-skin insulated aluminium frames. The east and west doors comprise of aluminium-clad timber-framed triple-glazed units with integrated vacuum insulated panels (VIP). The building consists of two adjoining rectangular cells approximately 12.5 x 4.1 metres, with elongated facades facing north and south. The Living Lab contains two bedrooms, one bathroom, a living area, a kitchen, a study, as well as an entrance hallway and technical room. The ground floor has a heated floor area (BRA) of 102 m^2, a gross floor area (BTA) of 132 m^2, a net floor area (NTA) of 97 m^2 and a built up area (BYA) of 219 m^2. The choice of definition of area plays an important role in the sensitivity of the functional unit which is explained in more detailed in Inman and Houlihan Wiberg, 2015. The total window and door areas are 47.3 m^2, which gives a window/door to floor area ratio of 46.4%.

2.2 Building services

The building services category includes sanitary installations, heating, ventilation and air conditioning, as well as lighting and common household appliances. In order to simulate multiple energy scenarios, the technical systems for the Living Laboratory have purposefully been over specified. Any additional technical equipment, control systems, sensors or probes used to document the performance of the Living Lab, have been purposefully left out of the material inventory.

2.3 Energy supply system

The energy supply solution for heating, cooling and electricity is an 'all electric' solution based on: 1) High-efficiency PV on the roof, 2) solar thermal collectors on the south façade, 3) geothermal heat pump. An explanation of the passive and active design strategies used, to optimise the design of the Living Lab, can be found in Inman and Houlihan Wiberg, 2015.

3. METHOD

3.1 Goal and scope

The goal of these calculations is to estimate, and thus provide an overview of the materials and components in the Living Laboratory, which contribute the most to embodied CO_{2eq} emissions. The calculations are based on the principals of environmental assessment through life cycle assessment, according to ISO 14044: 2006. The functional unit is set to 'emissions per 1m^2 of heated floor area (BRA) per year of operational building lifetime', so that the results are comparable with the other ZEB pilot projects. The results are normalised according to a BRA of 102m^2 and a building lifetime of 60 years. For transparency, a sensitivity analysis of the functional unit, in terms of definition of area and building lifetime, shall be presented.

3.2 System boundary and material inventory

The material inventory was calculated manually using the architect's drawings, and has been cross-referenced with product literature and on-site observations. The system boundary is defined according to EN 15978: 2011 and is limited to the extraction of raw materials and the manufacture of products and materials (A1 - A3), the transport of goods to site (A4) and their installation into the building (A5). Replacement of new materials over the lifetime of the building is also included (B4), including the transportation of these new materials to site (A4). Full details on what is included in the system boundary and material inventory can be found in Inman and Houlihan Wiberg, 2015; as well as information on the reference service lifetimes (RSL) for the different materials and component, which are based on manufacturer's literature, BKS 700.320 and 700.330, Ecoinvent reports and previous ZEB pilot projects. An assumption has been made that the PV panels will be produced 50% better in 30 years' time.

3.3 Calculation method

Generic life cycle inventory data has been accessed from SimaPro Analyst version 8.0.5, and uses datasets from Ecoinvent version 3.1. (PRé, 2015) (Ecoinvent Centre, 2014). All the calculations have been structured in MS Excel according to NS 3451: 2009 Table of Building Elements (NS3451, 2009). The IPCC GWP 100 year scenario method has been used, for the impact assessment of the material inventory (PRé, 2007). The choice of electricity mix used in the production of materials is based on those specified in the Ecoinvent database. For example, the concrete dataset used in the analysis, is based on a concrete process from Switzerland, using the Swiss electricity mix as an input. The photovoltaic modules use a rest of world (ROW) electricity mix factor, since they are produced in Singapore.

4. RESULTS

4.1 Total embodied emission results

The results show that the total embodied emissions are calculated as 23.5kgCO_{2eq}/m^2/yr, see Table 1. The majority of emissions come from the production (50%) and replacement (40%) phases. Transport to site and construction emissions account for 5% each.

Life Cycle Stage	kgCO_{2eq}	kgCO_{2eq}/yr	kgCO_{2eq}/m^2	kgCO_{2eq}/m^2/yr
Initial Materials (A1 - A3)	74,121	1,235	727	12.1
Transport to Site (A4)	6,188	103	61	1.0
Construction (A5)	7,412	124	72	1.2
Replacement (B4)	56,067	934	550	9.2
TOTAL	**143,788**	**2,396**	**1,410**	**23.5**

Table 1: Carbon dioxide (eq) emissions from material use in the Living Laboratory.

When compared to other ZEB projects such as the ZEB single-family house (SFH), the total embodied emissions from the Living Laboratory are considered high. For the same system boundary (A1-3, B4), it can be seen that the Living Lab (21.3kgCO_{2eq}/m^2/yr) has three times higher emissions than the SFH (7.2kgCO_{2eq}/m^2/yr). During the 60-year lifetime of the two buildings, it can be seen that the Living Lab (130,188kgCO_{2eq}) has double the amount of total emissions than the SFH (69,139kgCO_{2eq}).These higher emissions from the Living Lab can be explained by the fact it has a more detailed material inventory, and a more comprehensive system boundary than the ZEB SFH. Both of these factors contribute to higher total embodied emissions. In addition, the Living Lab has an area of 102m^2, whilst the ZEB SFH has an area of 160m^2, which means that the Living Lab has a higher concentration of material and emissions per m^2 of BRA than the SFH.

The results show that the majority of total emissions (65%) originate from the building envelope, whilst one quarter comes from the PV in the outer roof. The remaining 12% of emissions come from 'heating, ventilation and sanitation' of which appliances account for 8%.

The definition of area plays an important role in the sensitivity of the functional unit, resulting in a two-fold variation in total embodied emissions. The results show that choosing a gross floor area (BTA) scenario results in 18.2kgCO_{2eq}/m^2/yr compared to 23.5kgCO_{2eq}/m^2/yr in the heated floor area (BRA) scenario. If a net build up area

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

(BYA) definition is used, emissions are almost half 10.9kgCO_{2eq}/m^2/yr, and conversely increased to 24.7kgCO_{2eq}/m^2/yr if net built up area (NTA) is used.

The functional unit is also sensitive to the definition of building lifetime. Given that the Living Lab is a temporary building, it is likely that the building lifetime will be shorter than the standard 60-year lifetime specified. For that reason, a sensitivity analysis of the results, in relation to the length of building lifetime has been calculated. Even though this is a theoretical exercise, the results show more than a 74% decrease in emissions relative to a doubling of building lifetime, from 30 to 60 years. When this lifetime is extended to 75 years, the decrease in emissions is 71%, and 65% when increased to 100 years.

In terms of replacement, the SFH has 1.95kgCO_{2eq}/m^2/yr, whilst the Living Lab has 9.2kgCO_{2eq}/m^2/yr. This difference is explained by the fact that less than 30% of the materials used in the SFH were replaced during the lifetime of the building, compared to over 40% in the Living Lab, which is explained by the fact that all replaced materials in the Living Lab include transport and construction emissions.

4.2 Building envelope results

One quarter of emissions arise from the outer roof because of the complex roof form, aluminium flashings, roof lights and over-dimensioned PV mounting frame. The PV is the next highest driver, contributing just over one fifth of total emissions, followed by the outer walls with 15% of emissions. Appliances contribute 8.2%, followed by the 'Groundwork and Foundations' (4.5%) and 'Floor Structure' (3.3%). An interesting design driver for reduced emissions was the decision to omit the concrete footing from the strip foundation, which resulted in almost half the quantity of concrete being used (16m^3 to 9m^3) and a 20% reduction in embodied emissions from concrete. Timber contributes to almost one fifth of emissions, because the building is predominantly of timber construction. Similarly some of the wood products have been processed (e.g. plywood processing involves glue additives) which may lead to an increase in embodied emissions compared to unprocessed timber products.

4.3 Building services results

The emissions from appliances account for 8% of total emissions in the building. The replacement emissions originate from the replacement of white goods, which have a product service lifetime of between 10-15 years, and therefore are replaced 4 to 6 times during the lifetime of the building. The washing machine accounts for driving the highest emissions (33%), followed by the dishwasher (20 %), oven (19%), fridge freezer (15%), tumble dryer (10%) and hob (4%). Both the sanitary, lighting and electrical categories contributed negligible emissions to total embodied emissions. These categories experience low emissions because at the time in which calculations were carried out, a complete material inventory was not available for these items. The heating system contributes only 3% to total emissions. The solar thermal collectors have an RSL of 25 years and are replaced 2.4 times, whilst the hot water tank and heat pump have an RSL of 20 years and are replaced 3 times. The heat pump accounts for driving the highest emissions (31%) in this component, followed by the solar thermal collectors (26.7%), hot water tank (20%), PEX pipes (12.3%) and heat emission plates (10.1%). The ventilation and air-conditioning category is also responsible for negligible emissions. There are no replacement emissions due to the 60-year RSL. The steel ventilation ducts are responsible for driving the highest emissions (43.6%) in this component, followed by the combi-exhaust (35.8%), supply grill (10.2%), air handling unit (5.5%), combi-intake (3%), extractor fan (1.1%) and flexible duct (0.75%).

4.4 Energy supply system results

The ‘other electric’ power category is responsible for 23% of total emissions in the building. The PV balance of systems (BOS) accounts for 68% of the replacement emissions, of which the inverters account for 91% of these emissions. The PV replacement emissions account for over one third of emissions. The product service lifetime for PV is 30 years, so they are replaced twice during the lifetime of the building. However, it has been assumed that the panels will be produced 50% better in 30 years' time, with half the amount of material emissions per m^2. In contrast, the inverters have a 15-year RSL, and are replaced four times. The ZEB emission factor for electricity has been used (0.136kgCO_{2eq}/kWh), to calculate a PV cumulative energy yield of approximately 8996 kWh/m^2/yr over a 60-year lifetime per m^2 of module (Graabak and Feilberg, 2011) (Kristjansdottir et al., 2016). On-site PV energy production counterbalances 94,054kgCO_{2eq} of 143,788kgCO_{2eq} emissions, which equates to 65% of total

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

embodied material emissions. In order to compensate for all emissions relating to material use, a total of 121m^2 PV is required, meaning that an additional 42m^2 of PV would need to be installed on-site (this does not account for the additional material emissions from the installation of additional PV modules and supporting services).

5. DISCUSSION AND CONCLUSION

This report has documented the design and construction of the Living Laboratory in terms of its embodied material emissions. Compared to previous ZEB projects, the results show relatively high-embodied emissions, with total emissions of 1410kgCO$_{2eq}$/m^2 over a 60-year lifetime and 23.5kgCO$_{2eq}$/m^2/yr. There are multiple reasons for this. Firstly, a more comprehensive material inventory was available for the Living Lab as an 'as built' project. In addition, the system boundary includes more life cycle stages. Furthermore, since this is a ZEB demonstration building, it has higher emissions than a normal building of its size, since a high level of technical equipment and state-of-the-art materials are used.

The key components, which drove the highest emissions, were found to be in the building envelope (65%). Other key drivers were found in the PV modules (22.7%), and appliances (8.2%). It was interesting to note that the VIP, which is typically identified as a high driver of emissions, was found to be responsible for only 2.2% of emissions, which is largely due to the small quantity used sensitively in the design. The results show that state-of-the-art materials, such as VIP and PCM, may be used sensitively and effectively without contributing significantly to embodied material emissions. A significant finding was found in the choice of a three-strip foundation design, which reduced emissions by almost one third, compared to the raft foundation design used in the single-family house (SFH). As a result, the Living Lab has used half (16m^3) the volume of concrete compared to the SFH (32m^3). The findings also show that omitting a concrete footing from the foundation, between the design and construction phase, has led to over a 40% reduction in the amount of concrete used (9m^3), and a 20% reduction in emissions. This could be further reduced if low carbon concrete was used.

The findings show that components with a high proportion of materials with long RSLs, e.g. 60 years, experience the majority of emissions during the production (50%) phase, whereas components with materials with short RSLs, e.g. 15-20 years, typically have a higher proportion of emissions originating from the replacement (40%) phase. Transport to site and construction emissions account for 5% each. In the outer roof, the majority of emissions came from the production phase (57%) compared to the replacement phase (34.3%), whereby the complex roof form together with the PV mounting frame and flashings drove higher embodied emissions. In contrast, the appliances have one third less (20%) total emissions from the production phase, and 40% higher emissions (80%) from the replacement phase. This is due to the RSL of appliances being 10-15 years, compared to the 60-year lifetime of the building.

The PV emission balance highlights that further measures are required to reduce the amount of emissions relating to material use, and to improve the efficiency of energy production from photovoltaic panels or other renewable sources on-site. Given that the outer roof, PV modules and mounting frame contribute almost half to total embodied emissions, further work could investigate building integrated, instead of building adapted PV, and a less elaborate roof form, which may save on material emissions, simply because less material is used. Further work could include comparing these two types of systems with a non-integrated PV solution that uses a less-complicated flat roof construction. It would be interesting to see how much extra energy could be produced on-site if a one-sloped roof design was implemented, with no overshadowing. The material emission balance highlights that further measures are required, to reduce the amount of emissions relating to material use, and to improve the efficiency of energy production from photovoltaic panels or other renewable sources on-site.

The functional unit sensitivity analysis raises the question of whether or not a 60-year lifetime is appropriate for the Living Lab, since the building is temporary, and will be dismantled at its end-of-life (EOL). In these circumstances, there should be more focus on the demountability and recyclability of the building, rather than the durability of materials. The results also show that the definition of area plays an important role in the sensitivity of the functional unit, resulting in a two-fold variation in total embodied emissions.

In conclusion, it was found that material optimisation should be considered at an early stage in the design process, in order to reduce embodied material emissions. These results provide useful approximations for embodied material emissions, for use by designers during the early design phase, when a detailed material inventory may not necessarily be available. It also highlights methodological and design considerations when carrying out a life cycle assessment of a building. Furthermore, the Living Lab provides alternative solutions for low embodied emission design.

Paradoxical Feasibility of High-rise Zero Carbon Buildings

PAN Wei[a], YU Cong[b]

[a] *The University of Hong Kong, Hong Kong SAR, wpan@hku.hk*
[b] *The University of Hong Kong, Hong Kong SAR, yucong@connect.hku.hk*

ABSTRACT

Zero carbon building (ZCB) has emerged as a most innovative approach to addressing anthropogenic climate change, evidenced by at least the relevant policy formulation and project deliveries in many countries. However, such approach only prevails in contexts where low-rise buildings dominate, while delivering high-rise towards zero carbon is normally arbitrarily perceived to be infeasible, substantiated by the lack of knowledge of high-rise ZCB and worsened by the absence of systems approaches to examining feasibility. This paper aims to contribute to a better understanding of the feasibility of high-rise ZCBs using a paradoxical framework. The research was conducted through the integration of a literature review of ZCB related research and practices worldwide and a study of the five-fold feasibility of high-rise ZCB in Hong Kong. This five-folder feasibility covers the technical, commercial, supply chain, regulatory and socio-cultural aspects. Two real-life high-rise buildings, residential and office, were used to develop energy simulation and carbon estimation baseline models for sensitivity analyses. The results indicate potential of reductions up to 57% energy use and 58.3% carbon emissions of the case buildings based on quick-win and optimisation design solutions and of nearly net-zero with strategic scenarios. However, such technically feasible solutions and scenarios are found to be institutionally difficult if not entirely infeasible. The five-fold feasibility is revealed to be interactive, dynamic and value-laden, with the specific aspects subject to their systems boundaries such as energy and carbon scope and calculation methodology. The resultant solutions and scenarios will inform future practices of reducing building energy and carbon emissions. The contributed paradoxical framework challenges conventional perceptions on feasibility and will guide the quest for high-rise ZCBs as complex socio-technical systems as they are.

Keywords: zero carbon building, high-rise building, feasibility, socio-technical system

1. INTRODUCTION

Buildings worldwide account for as much as 45% of energy consumption and carbon emissions (Butler, 2008), and therefore stand out as the biggest contributor to anthropogenic climate change. Low or Zero Carbon Building (L/ZCB) has been regarded as a most innovative model of sustainable development in the built environment. Many governments have adopted the L/ZCB model as an important strategy for addressing climate change, achieving a low carbon economy and uplifting quality of people's life (Wilford and Ramos, 2009, Pan and Garmston, 2012). In Hong Kong, buildings consume 92% of electricity and contribute 60% of carbon emissions in the city (EMSD, 2015b), which are much higher than the worldwide averages (Pan and Garmston, 2012). The HKSAR government has pledged to achieve a reduction in carbon intensity of at least 50% to 60% on the 2005 baseline by 2020 (ENVB, 2010). There are roughly 2,671,900 stocks of living quarters in Hong Kong as at end-October 2014 (HKCSD, 2014), with a substantial increase annually. Tackling carbon emissions from buildings is a critical component to achieving governmental goals for substantial carbon reduction and long-term sustainability in Hong Kong.

Many countries and regions have promoted Low or Zero Carbon Building (L/ZCB) as a most innovative model of sustainable development, which however present unprecedented challenges to both research and practice. First, there is a lack of consistent L/ZCB definition and methodology. Second, the vast majority of L/ZCBs to date are located in cold and temperate climates. Third, few high-rise L/ZCBs have been reported worldwide.

The aim of this paper is to contribute to a better understanding of the feasibility of high-rise ZCBs using a paradoxical framework. The research was conducted through the integration of a comprehensive literature review of ZCB related research and practices worldwide and a study of the five-fold feasibility of high-rise ZCB in Hong Kong. This five-folder feasibility covers the technical, commercial, supply chain, regulatory and socio-cultural aspects. Two real-life high-rise buildings, public residential and private office, were used to develop energy simulation and carbon estimation baseline models for sensitivity analyses. Scenario-based design solutions are developed to delivering high-rise buildings towards zero carbon.

2. A L/ZCB DEFINITION OF HONG KONG

To address the high-density, high-rise and hot-and-humid features of buildings in Hong Kong, the definition needs to regard L/ZCBs as complex socio-technical systems (Pan and Ning, 2015) and recognise their multidimensional systems boundaries and wide-ranging stakeholder groups' engagement (Pan, 2014). A ZCB (or a LCB) is defined as a building within its defined systems boundaries with net-zero (or very low) carbon emissions on an annual basis during the operational stage of this building.

The systems boundaries should be defined in terms of the technical components of the definition within the relevant regulatory, geographic and social contexts (Figure 1).

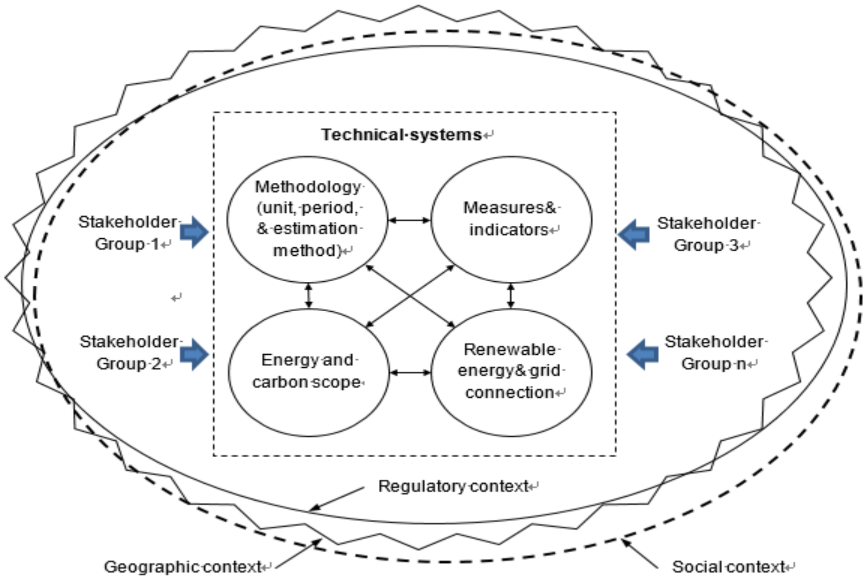

Figure 1: A conceptual model of L/ZCBs as socio-technical systems
(After Pan and Ning, 2015) Note: The contexts interact with each other.

3. HIGH-RISE L/ZCB FEASIBILITY, SCENARIOS & SOLUTIONS

The high-rise L/ZCB feasibility was examined of two types of buildings, public residential and private office buildings (Figure 2). Using two sampled typical real-life building projects, the Base Cases, Quick-win and Optimisation Scenarios were developed.

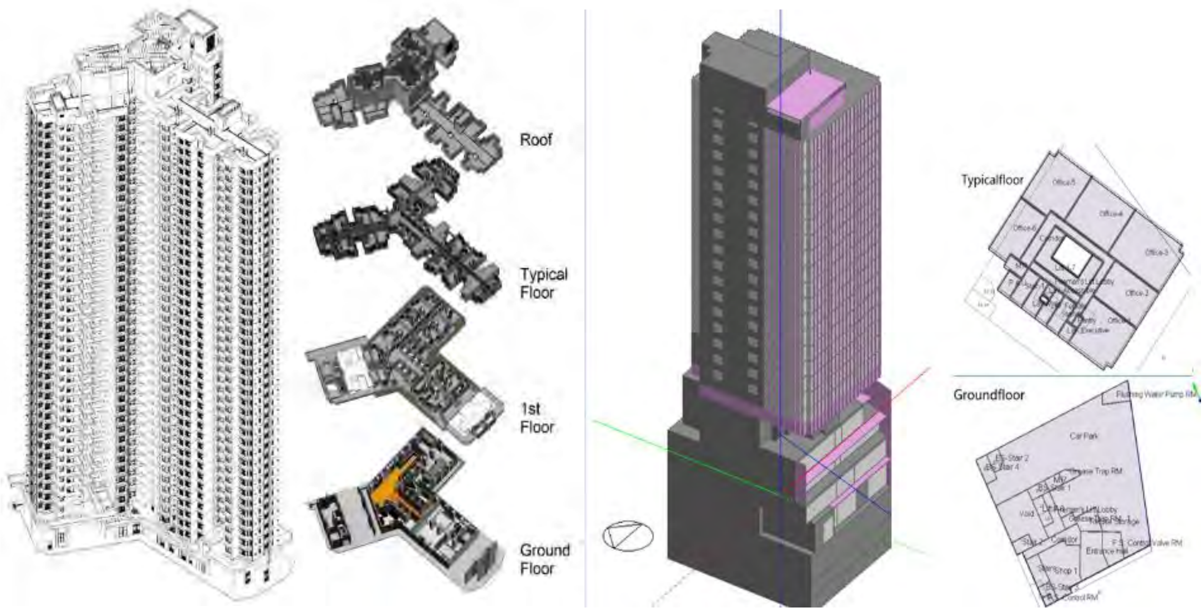

Figure 2 Public residential case building and private office case building and different floors
(Courtesy of Hong Kong Housing Authority, Yau Lee and Sun Hung Kai)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Public residential building

The residential building used for study was a typical 40-storey public housing block adopting modular flat design, completed and occupied since 2013. The Base Case was established through an iterative process of energy simulation and verification drawing on EMSD released end-use energy data, metered energy use and engagement with professionals. The energy use intensity (EUI) was estimated to be 106.6 kWh/(m^2-yr), covering in order of significance, cooling electricity (23.5%), cooking gas (22.41%), appliances (20.84%), DWH gas (16.22%), lighting for communal area (4.71%), lighting for residential units (4.55%), lift (3.24%), water pump (2.59%), and other communal area use (1.94%). The carbon emissions intensity (CEI) was calculated as 55.51kg/(m^2-yr) (Table 1).

Category	Base Case		Quick-win Scenario		Optimisation Scenario	
	Energy use kWh/m^2	Carbon emissions kg/m^2	Energy use kWh/m^2	Carbon emissions kg/m^2	Energy use kWh/m^2	Carbon emissions kg/m^2
Electricity consumption	65.44	45.81	50.34	35.24	45.07	31.55
Towngas consumption	41.16	9.70	41.16	9.70	31.39	7.40
Total	106.6	55.51	91.5	44.94	76.46	38.95
PV	n/a	n/a	-10.37	-7.26	-21.23	-14.86
Wind turbine	n/a	n/a	-1.39	-0.97	-1.39	-0.97
Net Total	106.6	55.51	79.8 (-25%)	39.71 (-28.5%)	53.88 (-49%)	23.12 (-58.3%)

GFA: 36,286 m^2; carbon emission factors for electricity and towngas: 0.7 kg/kWh and 0.2356 kg/kWh.

Table 1: Public residential L/ZCB scenarios

In the Quick-win Scenario, the most energy-sensitive energy saving measures were found to be, in order of significance, cooling set point, gross rated COP of air-conditioner, airtightness, window to wall ratio, window glazing properties, and solar absorptance of wall. The most energy-sensitive design features/parameters were found to be natural ventilation rate and orientation. The U value of wall and window was found to have negative influence on energy consumption when cooling set point is 26 degree C or higher. The solar absorptance and U value of roof were found to have little influence on the overall energy consumption. The impact of the cooling set point on energy saving was revealed to be far larger than that of the building design features/parameters. Renewable energy technologies (PV and wind turbine) with standard efficiency were included, which together could provide electricity that might offset nearly 13% of the building's total energy consumption.

In this Optimisation Scenario, the most important energy saving measures adopted included the change of shower time along with the improvement of efficiency of hot water boiler, the improvement of domestic appliance efficiency, cooking stove efficiency, lift with regenerative power and more efficient water pump system. The impact of changing shower time on energy saving was found to be far larger than that of improving equipment efficiency. Renewable energy technologies (PV and wind turbine) with advanced efficiency were included, which could generate electricity that might offset nearly 30% of the building's total energy consumption.

To sum up, the developed Quick-win and Optimisation Scenarios could achieve up to 49% EUI and 58.3% CEI reductions from the Base Case, which represents very low energy and carbon high-rise residential buildings, particularly in the hot-and-humid climates. The solutions require the systems integration of passive design, efficiency, behaviour changes and renewable energy, and thus shake conventional perceptions from the political, economic, social and technological perspectives.

Private office building

The office building used for study was a 26-storey typical new private office block adopting insitu concrete method. The Base Case was established through an iterative process and energy simulation and verification drawing on EMSD released end-use energy data and engagement with professionals. The EUI was estimated to be 282.4 kWh/(m^2-yr), covering in order of significance, cooling electricity (41.9%), fans (23.6%), appliances (17.5%), interior lighting (16.5%), and then pumps (0.4%). The CEI was calculated as 197.7kg/(m^2-yr) (Table 2).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Category	Base Case		Quick-win Scenario		Optimisation Scenario	
	Energy use kWh/m²	Carbon emissions kg/m²	Energy use kWh/m²	Carbon emissions kg/m²	Energy use kWh/m²	Carbon emissions kg/m²
Electricity consumption	282.40	197.70	188.86	132.20	149.52	104.66
PV	n/a	n/a	-11.64	-8.15	-27.6	-19.32
Wind turbine	n/a	n/a	-1.72	-1.20	-1.72	-1.20
Net Total	282.40	197.70	175.5 (-38%)	122.85 (-38%)	120.2 (-57%)	84.14 (-57%)

GRA: 29,305.9 m^2; carbon emission factor for electricity: 0.7 kg/kWh.

Table 2: Private office L/ZCB scenarios

In the Quick-win Scenario, the most energy-sensitive energy saving measures were found to be water-cooled chiller system, daylighting control and underfloor air supply, each of which can reduce the building's total energy use by around 10%. The most energy-sensitive design feature was found to be fan efficiency, a 0.9 value of which can reduce the building's total energy use by nearly 30% from that of a 0.3 efficiency. Renewable energy technologies (PV and wind turbine) with standard efficiency were included, which however could only offset around 7.1% of the building's total energy use. In this Optimisation Scenario, the most important energy saving measures adopted included District Cooling System (DCS), Shorten HVAC operation time, turning off unoccupied equipment and other social aspects. The most important design features/parameters used included raising equipment efficiency, reducing heat gain with better building orientation. The impact of the energy saving measures on energy savings was found to be far larger than that of the building design features/parameters.

To sum up, the developed Quick-win and Optimisation Scenarios could achieve up to 57% EUI and CEI reductions from the Base Case, which represents very low energy and carbon high-rise office buildings, particularly in the hot-and-humid climates. The solutions require the systems integration of passive design, efficiency, behaviour changes and renewable energy, and thus shake traditional perceptions from the political, economic, social and technological perspectives.

Strategic scenarios

Although significant EUI and CEI reductions are attainable (see results outlined in Tables 1 and 2), it is still infeasible to achieve net-zero carbon or net-zero energy for high-rise L/ZCBs in Hong Kong given the current carbon-intensive energy supply and the renewable energy and carbon reduction technologies available in the market. To achieve high-rise net zero carbon, more efficient or emerging renewable energy technologies and/or decarbonisation measures must be explored and adopted. Examples of renewable energy technologies include fuel cells (FC), combined heating, cooling and power (CCHP), district cooling systems (DCS), and examples of decarbonisation measures include carbon capture and storage (CCS), planting trees, changing fuel mix, and decarbonised electricity supply.

Two strategic scenarios are developed (Figure 3). Emerging Renewable Scenario is based on the Optimisation Scenario and takes into account emerging renewable energy technologies such as CCHP, DCS, Fuel Cells (FC) that together may further reduce the net energy use (hence net carbon emissions) of the building towards zero or negative. Decarbonisation Scenario is also based on the Optimisation Scenario but takes into account solutions such as decarbonised electricity generation, changing fuel mix, CCS, tree planting that together may further reduce the net carbon emissions of the building towards zero or negative. It is more realistic to integrate (some of) the technologies and measures proposed for the two strategic scenarios in order to more effectively achieve energy use and carbon emissions reductions while addressing the non-technical aspects of the feasibility.

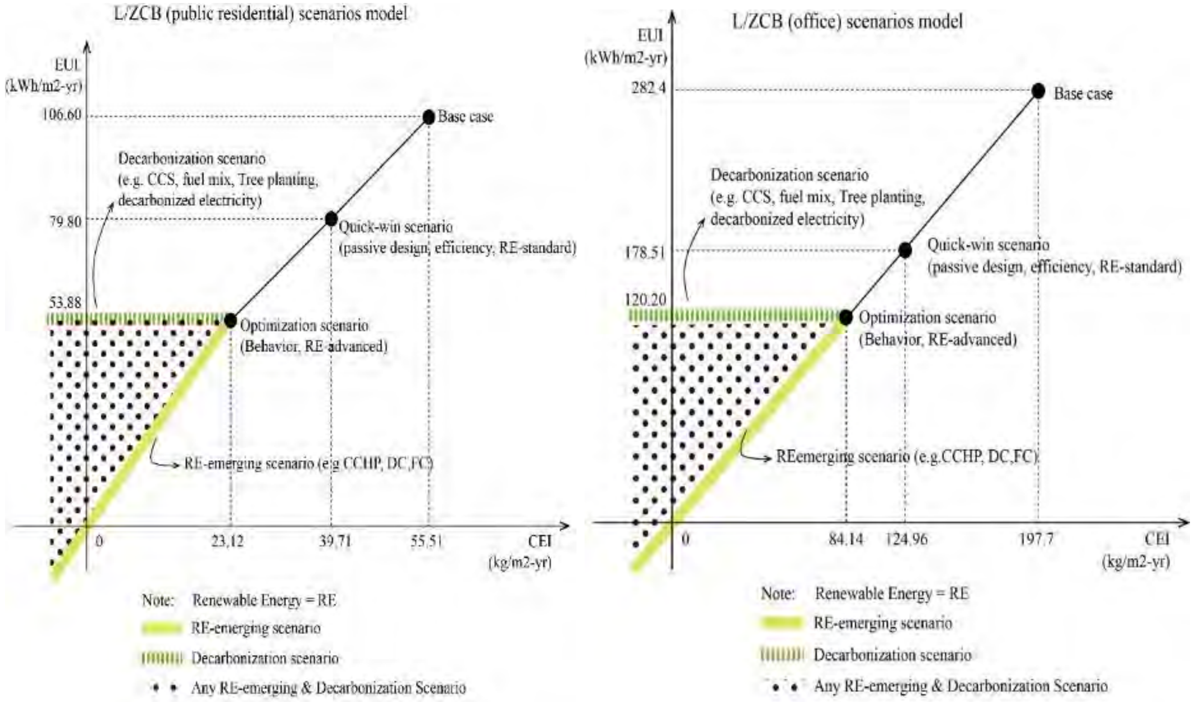

Figure 3: L/ZCB case and scenarios model (left: public residential, right: private office)

High-rise L/ZCB design strategies

A wide range of high-rise L/ZCB design strategies have been developed, which are grouped under ten elements of building energy use and carbon emissions: 1) Reduce and minimize energy demand by user behaviour changes, e.g. reasonably increase cooling set point; 2) Reduce energy loss through building envelope in dynamic trade-off with natural lighting, e.g. reduce heat gain and adopt overhangs and side-fins; 3) Reduce and minimize energy use for M&E systems, e.g. adopt LED and lighting control, increase COP of air conditioner; 4) Reduce and minimize energy use for appliances, e.g. adopt higher efficiency appliances, or adopt towngas driven appliances; 5) Reduce and minimize energy loss in transmission or explore towngas driven counterparts; 6) Decarbonize energy production and supply, e.g. decarbonize electricity generation by using CCS, change fuel mix, use bio-fuel; 7) Adopt and maximise on-site renewable energy generation in dynamic trade-off with land, space and view availability, e.g. adopt BIPV, explore CCHP; 8) Adopt and maximise off-site renewable energy generation in dynamic trade-off with land and space availability and energy loss in transmission, e.g. adopt DCS, solar farm; 9) Adopt accredited renewable energy and/or carbon reductions, e.g. use nuclear power, promote carbon trading; and 10) Adopt carbon offset, capture and storage measures, e.g. plant trees and adopt CCS in dynamic trade-off with land and space availability.

Underlying these strategies is systems theory of dynamical integration, which is required for possibly achieving net zero carbon. Systems optimization is required for achieving different levels of low carbon while addressing socio-technical trade-offs.

4. NON-TECHNICAL FEASIBILITY OF HIGH-RISE L/ZCB

The non-technical feasibility aspects, i.e. socio-cultural preference, commercial viability, supply chain competency, and statutory and regulatory acceptance, were found to be interactive, dynamic and value-laden.

They interacted with each other and as a whole interacted with the technical feasibility. The socio-cultural preference was largely shaped and guided by the political and regulatory acceptance. The supply chain competency had an important implication for the commercial viability. The technical feasibility would determine the commercial viability. The relevant technical scenarios and design solutions would be governed by the political agenda and regulatory framework, and if adopted, be influenced by the other aspects.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Being dynamic, how feasibility the non-technical aspects were (or not) would depend on the technical scenarios and design solutions developed. Although the Quick-win Scenarios were developed using more established efficiency and renewable technologies, the Optimisation Scenarios based on more predicted behavioural changes and adopted more advanced renewable energy technologies, hence embedding uncertainties. The two strategic scenarios, Decarbonisation Scenario and Emerging Renewable Scenario, were then more exposed to political, economic, socio-cultural and technological risks.

Being value-laden, how the non-technical feasibility aspects were perceived by different stakeholders would be subject to their interests in the multi-dimensional aspects of the complex systems boundaries of L/ZCBs.

Nevertheless, the statutory and regulatory acceptance was considered fundamental and the most important in all the non-technical feasibility aspects to delivering high-rise L/ZCB in Hong Kong. The statutory and regulatory acceptance would largely shape and guide the socio-cultural preference. An ambitious but clear carbon reduction target could motivate the industry and market for L/ZCB. This would then enhance the supply chain competency. The government itself is a major client for buildings. The government can lead the adoption of the developed technical scenarios and design solutions and nurture a sharing culture in industry.

5. CONCLUSIONS

This paper has established a socio-technical systems L/ZCB definition, examined the feasibility for two building types: public residential and private office, and developed design strategies and scenario-based design solutions in Hong Kong. The established Base Cases were status quo real-life green buildings. For residential, the developed Quick-win and Optimisation Scenarios could achieve up to 49% EUI and 58.3% CEI reductions from the Base Case. For office, the developed Quick-win and Optimisation Scenarios could achieve up to 57% EUI and CEI reductions. Both represent very low energy-and-carbon high-rise particularly in hot-and-humid climates. The solutions required the systems integration of passive design, efficiency, behaviour changes and renewable energy, and thus shake conventional perceptions from the political, economic, social and technological perspectives. However, such technically feasible solutions and scenarios are found to be institutionally difficult if not entirely infeasible. The five-fold feasibility is revealed to be interactive, dynamic and value-laden, with the specific aspects subject to their systems boundaries such as energy and carbon scope and calculation methodology. To achieve high-rise net zero carbon, more efficient or emerging renewable energy technologies and/or decarbonisation measures must be explored and adopted, yiedling the two developed strategic scenarios.

The findings will encourage the take-up of innovative low energy and low carbon technologies in the building sector, which will ultimately accelerate the transition of Hong Kong built environment towards low carbon and sustainability. The findings also contribute to a better understanding of high-rise L/ZCBs in a paradoxical socio-technical systems approach, which challenges conventional perceptions on feasibility and will have profound implications for the future design and delivery of high-rise buildings.

ABSTRACT

This paper studies a number of energy-efficient measures and renewable energy (RE) facilities in creating zero energy buildings (ZEBs). Passive building schemes include energy-efficient building envelope designs, raising the thermostat settings during the hot summer, using natural ventilation in circulation area and installing energy-efficient light fittings with daylight–linked lighting controls. Opaque building integrated photovoltaics (BIPV) are adopted to generate electricity for achieving the ZEB. The analysis was conducted based on a building simulation software eQUEST. The results show that ZEB can be achievable in hot and humid climate areas.

Keywords: energy simulation, school building, zero energy building, renewable energy

1. INTRODUCTION

Buildings account for 40% of worldwide energy consumption and one-third of greenhouse gas emission. Designing zero energy buildings (ZEB) has thus become an international aim to help alleviate the energy sources depletion and the environment deterioration. The ZEB designs need to reduce the energy use through energy-efficient approaches and to adopt renewable energy (RE) to meet the minimum energy needs. In subtropical areas, most of the energy consumption in commercial buildings is used to create a thermally and visually comfortable environment. Solar energy has been identified as having the potential to generate sustainable, inexhaustible, clean, and safe energy in Hong Kong on a wide-scale. Strategies to limit summer heat gain through the building envelope include thermal insulation, thermal mass, window/ glazing, green roofs, raising the thermostat settings during the hot summer, and using natural ventilation in circulation areas. Using energy-efficient lighting fixtures with dimming controls and proper daylighting schemes can reduce the energy used in lighting. Natural light can help reduce the electrical demand and the sensible cooling load. For high-rise buildings, vertically installed semi-transparent and opaque building-integrated photovoltaics (BIPV) are appropriate RE facilities.

To achieve zero energy, it is essential to determine the building demands and PV energy production with the accessible energy saving techniques and the available PV installation space on the building envelop. Building-energy simulation programs are suitable design tools to depict the trade-off between various design alternatives. The annual and monthly building energy expenditures and renewable energy generations can be modelled by comprehensive computer simulations. Recently, the HK government has issued several compulsory and voluntary building-energy codes which accept computer simulations to illustrate compliance. This study presents the energy saving designs of an institutional building, simulates the building's energy consumption and discusses the findings and implications. The occupancy, lighting, and office equipment schedules are representative to general office buildings. The similar working procedures can be employed in building designs elsewhere.

2. COMPUTER SIMULATION APPROACH

Energy performance of a building depends on the subtle interactions of many architecture features and building-services equipment. Computer-based building-energy simulations are valuable design aid in giving a comprehensive picture of the building's energy-behaviour and the trade-off alternatives in detail. The simulation tool employed in the study is the eQUEST building energy program. The software builds on the well-validated DOE-2.2 program and contributes to various worldwide green building crediting schemes such as LEED and BEAM Plus.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The eQUEST package conducts hour-by-hour calculation, using 8,760 hourly records of measured weather data to analyse the heating and cooling loads, and calculates the energy consumptions. Weather data, however, may vary year-by-year. The typical meteorological year (TMY) of Hong Kong employed for the study was developed by 30 years of the weather recordings which represents the typical year-round local climate for the building energy performance analysis.

3. REFERENCE BUILDING

The institutional building has 13 floors with a total area of around 14,000 m² excluding the open corridors and landscape areas. It has 51 lecture rooms, 4 activity rooms, 7 computer rooms, 6 studios, 2 laboratories, 42 staff offices, a library, a hall and a shop. The electrical, mechanical rooms and car parks are located on the ground floor. The lecture, activity and computer rooms, laboratories, and studios are in the 1st to 10th floors. The 11th floor is for installing cooling towers and other equipment. Most of the offices are in the 12th and 13th floor. There are nature ventilated corridors, atrium and landscape in the building which are not accounted in the total building area. Table 1 gives the occupant densities, fresh airflow rate and equipment densities for different areas according to ASHRAE Standard 62.1-2007, Hong Kong BEAM and ASHRAE handbook. With an efficacy of 100lm/m², the T5 fluorescent lamp can keep the illuminance levels of lecture room at 500 lux, staff office at 300 lux and assembly hall at 200 lux which can meet the required criteria. High frequency dimming controls were used to save the energy consumption of artificial lighting by the daylight.

Area	Area (m^2)	Space cooling?	Occupancy (m^2 $head^{-1}$)	Equipment (W m^{-2})	Lighting (W m^{-2})	Fresh air (m^3 h^{-1})	Daylight control?

Table 1: Areas of the Building

The floor-to-floor height is 3.6 m (4.3 m for G/F) and the floor-to-ceiling is 2.8 m. The window-to-wall ratio (WWR) in North, East, South and West are 24.4%, 31.2%, 24.9% and 28.6%, respectively. Properties of the building envelop were assumed according to a previous study and manufacturer catalogues, and are summarized in Table 2.

	U-factor (*W m^{-2} K^{-1}*)	Reflectivity	Shading coefficient	Visible transmittance
Roof	0.8625	0.5	-	-
Wall	4.925	0.7	-	-
Window	5.2	0.86	0.3	0.6

Table 2. Parameters of building envelop

Table 3 specifies the settings of the air-conditioning. The water cooled chiller was used because of its high energy efficiency. The COP of 5.64 was greater than the minimum of ASHRAE Standard 90.1 yet can be achievable by the advanced chillers. Zone air temperature was 25.5°C according to the local suggestions. Zone entering minimum temperature was 14.5°C to keep an 11°C difference from the zone air temperature. Other settings followed the default of the software. During transitional and winter seasons, the outdoor air was introduced as free cooling.

Inputs	Specifications
Air-conditioner type	Water cooled chiller
Coefficient of Performance (COP)	5.64
Number of Chillers	3
Minimum Load Ratio of Chiller	25%
Fan pressure	Supply: 88.9 mm, Retrun44.5 mm
Total Efficiency	0.85
Fan control	Variable speed
Zone set air temperature	25.5 (°C)
Zone entering minimum temperature	14.5 (°C)
Zone air flow	18 (m^3 h^{-1} m^{-2})
Maximum outside air temperature for free-cooling	18.33 (°C)
Maximum outside air enthalpy for free-cooling	69.78 (kJ kg^{-1})

Table 3. Description of HVAC system

The daily occupancy, lighting, and HVAC schedules followed the specifications of ASHRAE Standard 90.1 User's Manual given in Figure 1. The schedule assumes a level of occupancy in the lecture room after 17:00 and on Saturday, which is quite different from normal schools but are similar to office buildings. Thus the schedules are referred to the office buildings.

Table 4: Holidays of the school

To meet the building power needs by renewable energy, opaque photovoltaic (PV) panels were assumed to be installed on the walls and roof of the building. The semi-transparent PV was not used because of the low transparency and efficiency. The PV panels were assumed to account for 90% of the available areas and modelled using the in-built algorithm of eQUEST software. The generated electricity is fed the grid over the entire year. Table 5 specifies the installed PV module according to the manufacturer catalogue. The crystalline Silicon PV (cS-PV) with high efficiency is suitable to produce electricity on the building envelop with limited space. Table 6 gives the PV installations in the 4 cardinal directions and on the roof (22.3° due South). More PV panels were installed on the roof, East, West and South directions to harvest the maximum amount of energy.

Parameters	Open circuit voltage V_{oc} (*V*)	Short circuit current I_{sc}(*A*)	Max power voltage V_{mp} (*V*)	Max power Current I_{mp} (*A*)	V_{oc} temperature coefficient (*V/°C*)	I_{sc} temperature coefficient (*A/°C*)	Area (*m*²)

4. RESULTS AND DATA ANALYSIS

Figure 2 gives the annual electricity consumption and production by all power users and PV panels. Figure 3 presents the percentage of annual energy consumption and production. The annual electricity consumption was 634 MWh. The energy for chiller plant (chiller, heat rejection, and pump), lighting, equipment, and fans accounted for 51%, 25%, 16% and 8% of the total energy consumption. The great chiller and lighting power consumptions are due to the long summer season and year-round lighting needs, respectively. The annual energy consumption per area was 47 kWh/m^2, which is significantly less than the current benchmarks of 132 kWh/m^2 for building with central air-conditioning supply for tenants because of the efficient lighting, daylighting dimming, water cooled chiller and nature ventilation.

Since eQUEST assumes unshaded PV panels, the simulated PV panel power output was corrected by their percentage of unshaded hours. The annual electricity generation by PV panels is 640 MWh. The production by PV in East and West directions and the PV titled by22.3° due South accounts for 17.7%, 18.1%, and 42.0%, respectively. The power generation of vertically installed PV panels was 372 MWh, which is 58% of the annual building electricity demand.

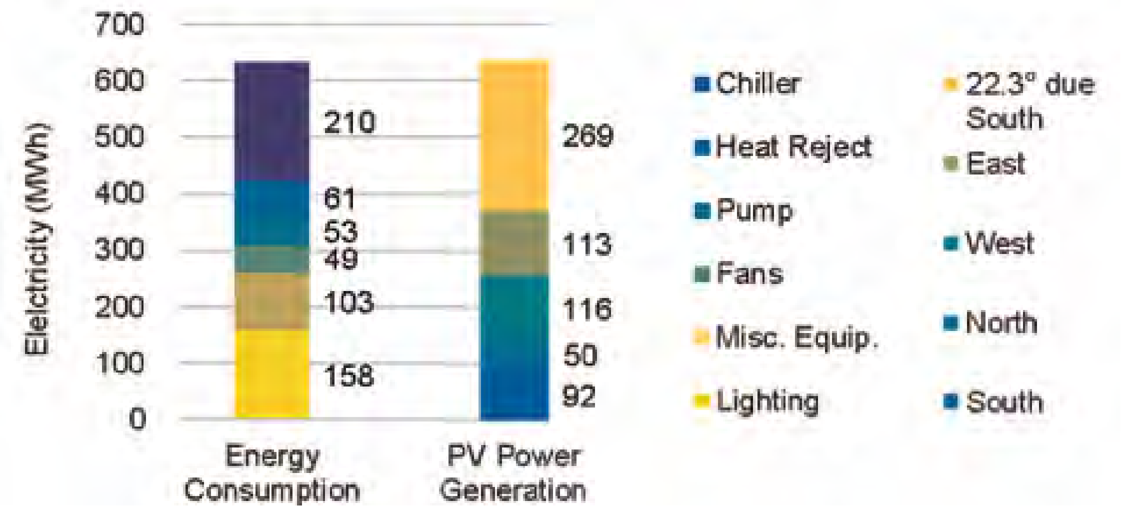

Figure 2: The annual power consumption by building and generation by PV

Figure 4 shows the monthly electricity consumption by different energy users of the building. The large energy consumption in Jul and Aug was because of the hot and humid summer in Hong Kong. The monthly lighting, and equipment energy use are similar because of the similar monthly schedule. The slight variations between months are because of the different public holidays indifferent months. The fan energy during winter seasons were consumed to meet the cooling demand due to internal loads by the outdoor air.

Figure 3: The percentage of year-round (a) Power consumption and (b) PV power production

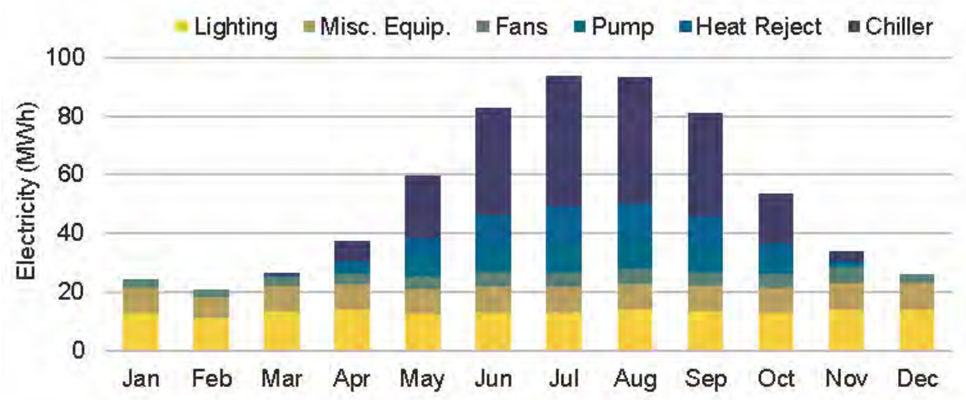

Figure 4: Monthly electricity consumption of different energy users in the building

5. CONCLUSIONS

The eQUEST energy simulation showed the annual energy consumption of an institutional building was about 634 MWh in total corresponding to 47 kWh/m². The energy was saved by daylighting in occupant zones, nature ventilation in the open corridor and atrium, high efficiency HVAC and building integrated photovoltaic (BIPV) panels. Such energy saving techniques were accessible from the present market and not complicate to impose. The annual energy production of vertically installed PVs covered 58% of the electricity use, installation on the roof balanced the reset 42%, which trade-off the annual energy consumption. The results are representative to buildings with the similar plans, load densities and schedules of occupancy, lighting, and equipment. The results show that the zero energy building in hot and humid climate can be achievable by energy saving measures and BIPV. Future work involves the analysis of life cycle cost, carbon savings and environmental benefits of such PV installations.

Net Zero Energy Building Policy: Benchmarking Australian Practices Against Some Asia Pacific Countries

Usha IYER-RANIGA[a]

[a] RMIT University, Australia, usha.iyer-raniga@rmit.edu.au

ABSTRACT

There is no doubt that the built environment is a key player in contributing to global greenhouse gas emissions. Globally, both best practices from industry and increasingly more stringent regulatory approaches have been used to arrest greenhouse emissions with varying success. In recent years, net zero energy building (NZEB) policies have been announced in Asia-Pacific countries such as Japan and Korea as radical measures to curb energy use so as to mitigate overall emissions.

NZEB definitions and approaches vary. Generally, however, they aim to increase energy efficiency in buildings, while also increasing the use of renewable energy in buildings and renewable energy use generation on site. Japan and Korea both have explicit NZEB policies with varying timelines.

Neither China nor Australia have explicit NZEB but both countries have used varying approaches to increase energy efficiencies in the built environment. This paper examines Australia's regulatory policies in the building and construction sector in the context of such strong desires by governments in the Asia-Pacific to curb emissions. South Korea and Japan with their explicit policies on NZEBs and China with increased stringency all provide a point of comparative study to determine, what, if any, Australia needs to learn from its Asian counterparts.

Australia's per capita energy use is one of the highest in the world. The paper commences by exploring the past and current regulatory policies and programs in Australia and a comparison is undertaken with the policies and programs of the identified countries: Japan, South Korea and China. Criteria for comparison are drawn, including; building types covered, energy efficiency approaches, role of various levels of government and compliance. Gaps are identified between these policies with discussions following focusing on the value of NZEB policy for the future of Australia.

Keywords: policy and standard, zero energy buildings, Australia

1. INTRODUCTION

A key message from the Rio+20 Conference in 2012 was that during the 20 years from the first Rio conference in 1992, the pace of change to make lasting changes to anthropogenic emissions needs to be accelerated. This is more so in the Developing Countries, where rapid building and construction activities are taking place. For example, China contributes to billions of sqm of new construction every year. In just one year, from 2010-11, new urban construction increased from 1.7 billion sqm to 2.2 billion sqm (Wei, 2012).

Being a part of the Asia-Pacific, it is in Australia's interest to keep abreast of policies and programmes with her Asian neighbours. South Korea and Japan have introduced Zero Energy Building policies (ZEB) in recent years, as has India. China, Australia's largest trading partner has not set up any such policies, but they have a strong energy efficiency programme led by the central government in China. Australia does not have a ZEB policy yet, but this is changing.

Energy efficiency in buildings has at least a forty-year history. The literature is rich with examples of energy technology in theory and practice, thermal comfort, energy use, role of behaviour in energy use and operational waste associated with energy use in buildings in residential and non-residential buildings (Masoso and Grobler 2010, Choi et al 2011, Hauge et al 2011, Sandy 2011 to name a few). Regulatory impacts on energy efficiency have been studied by authors such as Heijden (2016).

The aim of this paper is to undertake a comparative study to examine whether a lack of current ZEB policy is a lost opportunity for the building and construction sector in Australia. A comparative study of the policies in the countries identified is undertaken using a range of pre set criteria including legislative underpinnings, energy efficiency regulation through the building code, operational performance of buildings and other market based schemes.

This paper commences with definitions of ZEB and associated terms. This is followed by the regulatory landscape in Australia with respect to buildings, both from a design and performance perspective. The regulatory landscapes in Japan, South Korea and China are then presented with attendant roadmaps for ZEBs where applicable. Discussions follow, focusing on the similarities and differences between these approaches leading to the conclusions. The paper concludes that despite a lack of a national ZEB policy, Australia can still make some inroads in reducing its overall emissions due to the focus on reducing operational energy in buildings.

1.1 Definitions of zero energy building (ZEB)

There is no acceptable standard definition of ZEB. Most of the definitions of ZEB do not consider the energy used to build a building, the capital energy or the embodied energy using standard approaches of life cycle inventory analysis. Nor does it refer to the embodied energy for household products and appliances. Yet, this information is critical as the popular meaning attributed to ZEB refers to operational energy use; that is, energy drawn from the grid to operate the building being the same as the energy given back to the grid. The operational energy is typically used for heating, cooling, ventilation, lighting and cooking and for using household appliances in the residential sector and similar uses in the non-residential sector. Net zero from this perspective offers the grid as a source and a sink for energy (Hernandez and Kenny 2010), thus the term 'net' refers to the energy balance between energy used and energy sold or drawn from the grid. This offers the opportunity to avoid using energy storage systems, making the system more flexible, though not necessarily cost effective.

Net zero site energy means that a site produces at least the same energy as it uses in a year, independent of the type of energy produced or used (Torcellini and Crawley 2006). Net zero source energy concerns imported and exported energy multiplied by a primary energy conversion factor, enabling flexibility in the heating fuels (Torcellini and Crawley 2006, Torcellini et al 2006). Emissions zero energy refer to renewable supply options on site and off site, based on the fuel supply and associated emissions. Zero energy costs involves the costs only where the use and purchase of energy ends up with a zero balance (Marszal et al 2011).

Recently green buildings have also made its way into the lexicon alongside discussions of energy efficient, low energy and passive buildings. Green buildings generally take a more holistic approach, where energy is one of many considerations; alongside water, waste, materials, building management, site responses, access to transport and indoor environmental quality (Hauge et al 2011). In addition to green building, low carbon has also been included in the discussions where the source of energy use may be low carbon, such as nuclear energy (Kibert and Fard 2012).

The next section considers the regulatory landscapes in Australia, Japan, South Korea and China.

1.2 Regulatory landscape in Australia

Australia aims to reduce emissions to 26-28% on 2005 levels by 2030 (Australian Government 2015a). The main aim to achieve this is through direct action policies to reduce emissions, increase energy productivity and improve the environment. In addition to emissions reduction fund, Australia has a renewable energy target, energy efficiency improvements, phasing out greenhouse gases and direct support in low emission technologies and practices.

There are two recent developments in Australia, focusing on two standards: The National Carbon offset Standard for Buildings and the National Carbon offset Standards for Precincts. While these are in a consultation stage, it is anticipated that Australia is developing not only clear definitions, but also voluntary standards for carbon neutrality and net zero including, NZEB for buildings and precincts. These developments support global and regional developments focusing on reducing global net carbon emissions.

From a regulatory perspective the country has a centralised approach to building code administration through the Australian Building Codes Board (ABCB). The Australian Building Codes Board (ABCB) is a joint initiative of all three levels of government and includes representatives from the building and plumbing industries. The Board was

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

established by an Inter-Government Agreement (IGA) signed by the Commonwealth, States and Territories on 1 March 1994 (ABCB, 2016a, ABCB 2016b).

The Board's mission is to address issues relating to safety, health, amenity and sustainability in the design and performance of buildings through the National Construction Code (NCC) and the development of effective regulatory systems and appropriate non-regulatory solutions (ABCB 2016b). The ABCB therefore, has input from the Australian States and Territories in the development of the NCC for Australia. The ABCB develops, maintains and administers the NCC. While the ABCB set the agenda for the future of Australia, the ABCB recognises regional differences in the form of state based variations. Compliance for the building code is undertaken at the local level through state based jurisdictions. Building code compliance is generally seen as base level and therefore, represents minimum standards.

Energy efficiency and sustainability became key objectives of the Building Code in 2000 (ABCB 2016a). Commercial and residential sectors are covered. Market leadership and transformation is led by voluntary rating tools, spear headed by the Green Building Council of Australia (GBCA). The Green Star suite of tools developed by the GBCA ensures existing and new buildings conform to overall sustainability, with a major focus on energy-efficient building designs. The National Australian Built Environment Rating System (NABERS) developed by NSW government, but now applied nationally, focuses on actual performance of operational parameters in a building through evidence of the use of energy, water, waste and indoor environmental quality (NABERS 2016). Therefore, NABERS focuses on operational performance unlike the NCC and the Green Star suite of tools.

In 2000, the ABCB announced that it would mandate energy efficiency requirements in the Building Code of Australia (BCA). In 2003, energy efficiency housing provisions were introduced (performance of the building fabric, choice of glazing, sealing the building and such similar measures), with multi residential building provisions introduced in 2005. Non-residential building provisions were introduced the following year; and in 2006, housing stringency was increased to a minimum 5 Star requirements. In 2010, non-residential building stringency and multi residential building stringency was increased, with housing stringency also increasing to 6 Star minimum (ABCB 2016a). At the same time, the Building Energy Efficiency Disclosure Act 2010 was introduced (Australian Government, 2015b), where non-residential buildings over 2000 sqm were required to display their energy use as determined by NABERS rating at the point of lease or sale. This Act was further updated recently in 2015, where 'lighting energy efficiency assessment in relation to a building—an assessment of the energy efficiency of lighting if the building is sold, let or sublet'; or as applied in relation to an area of a building (Australian Government 2015c).

1.3 Regulatory landscape in Japan

Japan's long term target is to reduce CO_2 emissions by 60% to 80% by 2050. The Japanese government estimated in 2015 that if current energy saving measures were to continue, the energy consumption to 2030 would be more than 10% percent of the 2013 figures (IEE Japan 2015). The genesis of the changes commenced in 2008 when the energy conservation law was passed. Buildings over 2000 sqm were required to submit a report for energy saving. Aligned with this was a recommendation made for middle to small scale housing project of 300 sqm to present reports on energy use (enforced in 2010 as a recommendation rather than than mandatory compliance), introduction of a "top runner" program for a single house supplied by builders selling 150 or more houses annually. In addition to these are a labelling system for energy saving performance of house or building (Terao 2012).

It is anticipated that by 2030, all new homes would be Zero Energy. Examples of zero energy will need to be made available to the market by 2020. Some of the ways to achieve this are to increase energy efficiency standards, strengthening enforcement of the energy saving act, promoting energy efficiency residentially with appropriate rating and enhancing the more stringent regulations with tax incentives. Supporting technological innovations is critical, but it is acknowledged that this is not the only driver to achieve ZEB. Control interface for lighting, air conditioning, and data specs for energy efficiency in small and medium sized building has also been included.

1.4 Regulatory landscape in South Korea

Building energy consumption contributes to 21% of the total Korean energy consumption, and is expected to increase to 40% by 2030 (Schuetze 2015). The goal is to reduce the greenhouse gas (GHG) emissions in the building sector by a third of business as usual by 2020. The approaches used to achieve emissions reduction are

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

strengthening building energy regulations and standards. This includes improving energy efficiency of existing buildings, encouraging energy conscious behaviours by users and development of green building technologies and infrastructure systems.

Energy efficiency improvement during the period 2012-2025 takes a stepped approach, such that by 2025, residential buildings have a net zero energy consumption and non-residential buildings have an energy saving rate of 60% of the current energy use. Similar to Japan, the move to the zero energy house is to progress from an energy intensive house in 2009 to a low energy one in 2012, and improve the stringency further thereafter to 2025. This is undertaken through the use of passive house approaches in 2017, leading to ZEB in 2025. A low energy house is expected to save 30% energy and a passive house 60%. Likewise, for non-residential buildings, savings in 2012 was expected to be 15%, 30% in 2017 and 60% in 2025 (Choi 2012).

In South Korea, the government formulated the Low Carbon Green Growth in 2009 (Kang et al 2012). In developing this policy, three main areas were focused upon: regulations, incentives and information. Building energy codes focus on energy efficiency for new and existing buildings (Evans et al 2009). Furthermore, since the residential sector dominates energy use and associated impacts, this has been a key area of focus (Choi 2012). An obvious downside to this plan is that the cost of energy efficiency is still being worked out.

1.5 Regulatory landscape in China

China does not have an explicit ZEB policy. However, there is a very strong focus on energy efficiency, which is a critical path forward for zero energy policies. The Chinese government has enacted several laws on energy conservation and emission reduction; being the Law of the People's Republic of China on Conserving Energy, the Law of the People's Republic of China on Renewable Energies, and the Regulation on Civil Building and Energy Conservation. Five year plans are drawn by the national government enacting various policies, and building energy efficiency is a crucial part of these five year plans. China has just moved from its 12th and is currently in its 13th 5 year plan (Wei 2012). Given the scale of building and construction in China, the potential for energy conservation is huge. In China, the proportion of end use energy through building and construction is about 28% whereas in most Developed Countries this figure is approximately 40% (Wei 2012).

As far back as 1986, China brought in energy efficiency codes for buildings, wherein depending on the location, the building was required to meet 50% or 65% energy efficiency. Compliance information demonstrates that new builds have met the energy efficiency requirements and therefore, provide improvements of 46% and 49% over 2005 levels. In the current 13th 5 year plan, the aim is to further increase energy efficiency by another 30%. This is supplemented by monitoring of energy use in state office and public buildings.

In addition to energy efficiency, materials use through construction process and methods has also been an area of focus. Use of green construction methods has the potential to reduce energy consumption by 20% per sqm, water consumption by 63%, timber formwork construction by 87% and general construction waste may be reduced by up to 91% (Wei 2012). Since housing is a huge demand in China, pre fabrication technology, demonstration projects, use of new technology and new construction methods are all being disseminated through information and training, which can be applied to both the high end developers and the small-medium enterprise. Renewable energy use particularly for water heating has a growing market in China and use of photo voltaic for building operation is gathering momentum both in urban and rural housing. The next section presents discussions resulting from these ZEB policies.

2. DISCUSSIONS

The aim of establishing and effecting ZEB policies and programmes are to ultimately impact global carbon emissions. This section considers the various ZEB policies to understand whether the lack of a current ZEB policy deters Australia's ability to guide and lower carbon emissions. Building regulations generally commence from a base of meeting minimum standards of safety and amenity. Energy efficiency and sustainability are recent objectives added to these minimum criteria from the year 2000 in Australia. Building regulations have also generally moved from prescriptive to performance based codes and this has assisted in ensuring minimum benchmarks outcomes are realised for the building industry in Australia. Australia's compliance with the building code may be through deemed to satisfy measures, performance based approach or a combination of the two.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

While energy efficiency is a central tenet of policies in a number of countries as shown in Table 1, very few countries consider or monitor actual energy use through building performance. Furthermore, the type of energy use is not mandated or referred to in any way. Yet, the definitions of ZEB and relating discussions refer to renewable energy sources located on the building, on site or off site; source or primary energy and delivered or site energy; and energy sources and their associated utilisation factors accounting for the efficiencies in processing, transporting, converting and delivering fuel or energy from the point of extraction to the building site.

Policies/ legislation	Australia	China	Japan	S. Korea
Sustainability as a guiding principle as policy/ guideline	Yes	Yes	Yes	No
Zero energy building policy	No (in early stages of development)	No	Yes	Yes
Energy efficiency in the building code/ energy efficiency mandated through regulation	Yes	Yes	Yes major renovations above a certain size	Yes
Applicability of energy efficiency to existing buildings	Yes not blanket though	Yes	Yes major alternation or renovation	Yes voluntary labelling
Operational energy performance mandated	Yes	No	No	No
Other market based mechanisms/ voluntary schemes	Yes (Green Star)	Yes	Yes (BELS and CASBEE)	Yes

Table 1: Comparative table of ZEB/ energy efficiency policies in chosen countries

Thus, while other countries may strive to achieve real targets set for energy efficiency through ZEB as Japan or South Korea have done or through increasing stringency in energy compliance as China has tried to achieve, the fact remains that none of these countries have any policies or targets that evidences actual energy use as Australia has mandated, through the NABERS rating. Even though these targets are not mandatory annual reporting targets, it does place pressure on demonstrating energy efficiency in buildings, albeit at the point of lease or sale. Building owners need to pay attention to energy efficiency in their own buildings, particularly when considering rising costs of energy and to stay abreast of market competition. It does not mean that there will be flurry of activity for building owners to start retrofitting their buildings but the link between energy use and sale does act as a clear driver as a first step to demonstrate and provide evidence of energy efficiency.

3. CONCLUSIONS

This paper set out to understand if Australia's lack of a currently stated ZEB was hindering Australia from meeting its energy efficiency goals in the built environment. Energy efficiency is considered to be an important aspect of sustainability. Sustainability objectives have become part of building regulations not through the building regulatory process itself, but due to other national and international pressures and these have yet to be fully assessed. In Australia, energy efficiency measures have been mandated, both from a design and a performance perspective but is not consistently applied in the residential and non-residential sectors.

Lack of explicit ZEB policy in Australia is not necessarily a down side. As long as there are mechanisms to monitor actual performance, Australia is in a better place as this squarely places the debate from intent to actual disclosure and how best to fit technology, people and processes to enhance disclosure. Regulation alone is insufficient to realise energy reductions. The question remains however, as to how best to enhance disclosure in the market, most notably in the residential sector so to maximise impact. A more holistic approach needs to be reinforced such that greater collaboration between all sectors (regulatory and non-regulatory) can create positive synergies between market pressures, regulation and current energy efficiency instruments such that leading edge practice today can become tomorrow's minimum standard, reinforcing current paradigms towards energy efficiency and sustainability.

Comparative Analyses: Urban Quality, Living Standard, Sustainability. Modernist Housing Estate Vs 21st Century City

Aleksandar TEPAVCEVIC[a]

[a] *Graz University of Technology, Austria, aleksandar.tepavcevic@tugraz.at*

ABSTRACT

Observed in the context of the position of large modernist housing estates against contemporary living standards, there are few dominating problems regarding the large modernist housing estates: high energy consumption and the mono-functionality and lack of identity of the urban quartiers which question the legitimacy of their existence. Therefore, their future will be largely dependent on their potential to successfully re-integrate themselves into the proclaimed vision of self-sustainable cities and society for the 21st century. In order to explore their current status regarding the requirements of the future city, this paper is analyzing representative example of the modernist housing estates and comparing it with selected examples of the latest contemporary urban development projects in Europe. As a result, this paper provides a comparison chart which involves most important categories of all four masterplans, including building and population density, urban structure, traffic and energy concept, and apartment standards. The chart serves to highlight their similarities and differences, which will visualize the actual gap between the modernist housing estate from the 1960's and contemporary urban design projects promoting the 21st century living standards.

Keywords: housing estates, refurbishment strategy, urban development, 21th century city

1. INTRODUCTION

The demands of the envisioned standards for the 21st century society are putting serious pressure on our eco-system and environment. Growing population accompanied with increased living standard expectations and consumer oriented lifestyle is leading towards ever-growing demand for new resources and energy production. This "hunger" for energy and resources which continuously modifies the earth's surface, is resulting with decrease of agricultural land and fresh water supply, deforestation, and causing serious climate changes. As a significant contributor to the "global warming" phenomena, the building industry is responsible for about 40% of total energy consumption and therefore potentially could play a big role in the switch towards a green and self-sustainable society. In this process the concepts of renewable production, recycling and reuse of the resources and energy are inevitable factors which can contribute and secure the desired development goals and standards. Their implementation, both in the area of energy production and in the development of recycled building materials have opened new possibilities for the construction industry. The Nearly ZEB energy standard [1], introduced by European Commission and set for year 2020 for all new buildings, is one of the key parameters which define the sustainability standards of the 21st century city. Pioneering projects of new buildings, quartiers and urban masterplans with aforementioned requirements are being built worldwide. The Masdar City, in the UAE, is planned to be one of the first zero-carbon cities driven solely on renewable energy supply [2]. However, most of these promising projects are built on vacant agricultural areas detached from existing urban settlements, which offer no constraints in terms of urban planning and solar exposure, density, etc. Therefore, the application of the, so called, "tabula rasa" approach might not be suitable in case of already built cities. In this context, one of the crucial questions for the future is how to deal with the existing cities and neighborhoods which were built under different social and political concepts and premises. Until present, very few project have been realized in this field. The new-built "Aktiv Stadthaus" – a residential project in Frankfurt, GER [3] constructed in dense urban environment and the "Plusenergie Haus" – a 1960's prefab housing refurbishment project in Kapfenberg, AT [4] are among first built representatives of the active house solutions on a single building level. On the urban quartier level, there are no comprehensive attempts to tackle this challenge. Neighborhoods erected in different epochs of the city's development might require substantially diverse approaches. This research will focus on modernist housing estates. Understanding and comparing their urban concept with latest planning policies, should give insight in their overall condition and level of matching their standards with the up-to-date living requirements. The discussion will be presented in the comparative analysis chapter.

2. THE 21st CENTURY CITY

In order to accomplish this task, it is necessary to analyze and understand the living standards of the 21st century city, set by the society. Numerous architectural theoreticians and practitioners are discussing the validity of current urban and architectural practice, stating that a city for the 21st century should be led by a vision independent from current dominating practices and organized in a more efficient way in order to better respond to global challenges [5, 6]. In some aspects this theoretical approach proposes parallel reform and improvement of our socio-economic system, and therefore remains at this stage more in the domain of conceptual contribution towards the idea of the future society. After failure of modernist urban principles and clear separation of urban functions which created segregated the city structure, current policies favour the return to mixed use urban quarters which should improve everyday life quality in the neighborhoods and city quarters. Distribution of different typologies within the mixed use scenario is mostly affected by “free market” laws of demand and supply and does not follow any theoretical premises. Although the rapid urbanization process of the South-East Asia region, especially in countries like China and India, produce enormous urban activities, for the purpose of comparative analysis, as case study examples have been chosen 3 masterplan projects in Europe: Seestadt Aspern – satellite city in the outskirts of Vienna, Austria; Hafencity – city core expansion on the former docklands of the Elbe River in Hamburg, Germany; and Nordhavn – an urban district built on the former harbour area of Copenhagen, Denmark.

These particular urban development projects were chosen for several reasons. All of them are situated in countries with the highest level of economic and social development, which serve as landmarks for life standard quality on a global level. In these countries the social aspect of the city planning and the “human scale” approach is traditionally playing a significant role. Cities like Vienna, Hamburg and Copenhagen are internationally recognized as eco-friendly cities with good social system and social housing infrastructure, efficient traffic organization, introduction of new and green mobility concepts, diverse and rich offer of green and leisure areas, shopping facilities and touristic attractions. All these qualities place them, according to respective surveys [7], on top of the list of most livable cities worldwide. Their desire to take a leading role in remodeling existing cities upon “smart organization” and “sustainable development” criteria, should be reflected through these development projects. Application of advanced building technologies and innovative heating and cooling concepts, introduction of new mobility concepts, green energy supply, limitation of energy consumption, are qualifying them as cutting edge urban development projects in Europe and worldwide. All of them tend to promote themselves as examples of 21st century city which represent the high-quality urban living standards set for the future society. At last, the similarity of their size, urban program and climatic environment with modernist housing estates, indicates that conclusions gained from the 3 case study examples might be applicable during housing estates reconstruction.

3. MODERNIST HOUSING ESTATES

Built after WWII, as a reaction to postwar housing shortage, the modernist housing estates were often used as a part of the rebuild process of the cities throughout Europe and worldwide. Originally, due to small budgets, housing estates were imagined as low cost transitional accommodation solutions for the period of country’s fragile uprising economy. They represent first standardized urban design schemes – housings units made out of prefabricated concrete construction and façade-enclosing elements, which allowed quick assembly on site and relatively long durability. Huge demand on affordable living space and fast construction process triggered their hyper production. These housing estates still make a great portion of the urban tissue in many cities. Due to increased concerns over high energy consumption, their mono-functionality, lack of urban qualities and public depreciation, these housing are often being demolished and replaced with new development schemas [8, 9]. Demolition process is usually connected with both big financial efforts and energy consumption (grey energy). On the other hand, the similarity of their construction and functional logic with contemporary housing buildings indicates that, with a reasonable amount of efforts, a comprehensive reconstruction approach could lead to plausible results.

As a case study example, for the purpose of comparative analysis, has been chosen Nordweststadt housing estate in Frankfurt, Germany, located in the north-west suburban area of the city and built in period 1961-1972. An original, open, pavilion type of urban configuration brought different type of urban qualities in the relatively coherent city layout of Frankfurt. Over the decades, Nordweststadt retained in most of the aspects its positive image as a peaceful, family-oriented city quartier, favorable among its inhabitants. Still, due to aging of the materials and the construction

which point out on necessary maintenance of the building and public feedback of the residents about living conditions, which clarified the deficiencies of the housing estate, a sort of “cosmetic” reconstruction proposal has been requested from the local authorities. For this purpose, an architectural competition for the area has been announced and carried out, but the prize-winning results remained on paper, with uncertain future scenario regarding their completion.

4. COMPARATIVE ANALYSIS

The comparative analysis chart represents the “ID card” of the case study projects. The chart has been divided into four sub-categories, each focusing on different aspects of the masterplan and representing their most important figures and characteristics: masterplan features (Table 1) urban design concept (Table 2), residential quartier concept (Table 3), residential building concept (Table 4). Accompanying text, under the table, serves to highlight the most important conclusions and to explain relevant details and situations, not presentable in tabular overview. For the purpose of better orientation in the text, the case studies will be represented under following abbreviations: [SA] for Seestadt Aspern, [HC] for Hafencity, [NH] for Nordhavn and [NW] for Nordweststadt.

4.1 Masterplan features

In Table 1, most important general facts and figures of selected projects regarding the construction date and volume, density, population and location are presented.

Location	Seestadt Aspern [10]	Hafencity, Hamburg [11]	Nordhavn, Copenhagen [12]	Nordweststadt, Frankfurt [13]
Facts & Figures				
Year of construction	2007-2030	2001-2025	2012-2060	1961-1972
Area size (ha)	246	155	350	170
Total built area GFA (m^2)	2 600 000	2 500 000	2 875 000	1 150 000
Population	20 000	14 000	40 000	17 000
Workplaces	26 000	45 000	40 000	n/a
Population density (person/ha)	100	110	87.5	106
Building density (m^2/ha)	10 569	16 129	8 215	6 765
Distance to center (km)	13	2	4	8

Table 1: Masterplan features

The data analysis, shows that the population density remains relatively similar on all analyzed sites, regardless of construction period or the size of the design scheme. Regarding the position of the urban districts within the city and their distance to city center, despite obvious advantages of the two new masterplans [HC, NH] all 4 locations have good connection with the city center, reachable within 30 minutes by car or public transportation. On the other hand, an obvious difference is noticeable when comparing the number of workplaces provided on the site. Despite having a commercial center and public facilities which offer a certain amount of jobs, most of the residents of NW are commuting to other part of the city for the work purpose. Relatively low building density in NW, allows possibility for meaningful densification which would try to bridge the gaps towards new development proposals [SA, HC, NH].

4.2 Urban design concept

Table 2 is consisted of the categories, important for the understanding of the structure and functioning of the urban design scheme: urban structure, transportation concept and energy concept.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Location	Seestadt Aspern [10]		Hafencity, Hamburg [11]		Nordhavn, Copenhagen [12]		Nordweststadt, Frankfurt [13]

Geothermal energy	used		used		used		not used	
Energy standard	passive house		DGNB gold		passive house		not defined	

Table 2: Urban design concept

All four projects [SA, HC, NH, NW] represent mixed use urban developments which mix residential with other urban functions - commercial, educational, cultural, religious, public, sport, leisure, etc. Two main differences between the modernist housing estate [NW] and the new development projects [SA, HC, NH] are high share of residential function in NW against the other functions (89% -11%) - which gives this district predominantly residential character, and the urban function distribution concept. The structure in the NW is following modernist design guidelines, which assume clear segregation of functions, and separate the urban tissue into few mono-functional clusters. Opposite to that, SA, HC and NH are successfully mixing functions, securing vibrant and dynamic neighborhoods which have significant impact on the increase of the life quality. Possible solution for neutralization of these differences, could be a solar optimized densification approach in respect with urban logic of the NW, with necessary functional typologies (commercial, office, cultural) and restructuration of the existing space, which could introduce new qualities to the district.

The transportation concept is based on the idea of a "5-minute district" (public transport station is reachable within 5-minute walk distance) and offers similar qualities for all selected locations [SA, HC, NH, NW]. Good traffic infrastructure, including metro and bus lines, light trains, boats [HC, NH], car sharing, etc. provide fast connection with the city center. Parking facilities are provided in underground parking garages or as a part of the street profiles, located within close proximity to the apartments. Still, due to absence of an adequate direct connection between the resident's apartment and his parking place in the garage, almost 50% of the capacity in NW is unused. A qualitative difference is visible in the circulation inside the districts and in the quality of public green areas. The pedestrian communication through the green areas is not disabled-friendly on all segments, while the absence of the road hierarchy make orientation in the district [NW] difficult. Lack of planned biking lanes forces cyclists to use alternative paths. Untrimmed greenery combined with inadequate public lighting system create "dark pockets" which cause a feeling of insecurity and fear among the residents, especially by night. Qualitative features of other 3 masterplans [SA, HC, NH] such as: construction of separate biking lanes [SA, HC] and the implementation of the "cycle superhighway" concept in NH, disabled friendly pedestrian road network created with systems of ramps and terrain regulation, road hierarchy achieved through variety of designed road profiles, and application of new materials and coloristic schemes on the urban equipment, could all be implemented to improve the quality of the public spaces and the communication inside the NW housing estate.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

In terms of energy concept, for the purpose of sustainable energy supply for the districts, in case of NW, it was built a “waste to energy” power plant, but no limitation in terms of energy consumption has been determined. Rest projects [SA, HC, NH] use renewable energy sources - sun, wind and geothermal energy and have set at least a passive house standard for energy consumption of the buildings. Low building density and big gaps between the buildings in NW, secure their above-average sunlight exposure, both on roof and façade surfaces, and could ensure significant energy production through implementation of photovoltaics and solar thermal panels. This approach could improve its energy balance and raise their overall sustainability.

4.3 Residential quartier concept

Table 3 is mostly focusing on categories necessary to describe the structure of the residential quartier: block typology, housing typology and the apartment structure.

<table>
<tr><th colspan="2">Location</th><th>Seestadt Aspern [10]</th><th>Hafencity, Hamburg [11]</th><th>Nordhavn, Copenhagen [12]</th><th>Nordweststadt, Frankfurt [13]</th></tr>
<tr><td colspan="6">Residential block structure</td></tr>
<tr><td rowspan="4">Block typologies</td><td>Housing</td><td>23%</td><td>22.5%</td><td>90%</td><td>90%</td></tr>
<tr><td>Housing + commercial ground floor</td><td>67%</td><td>43.75%</td><td>10%</td><td>10%</td></tr>
<tr><td>Housing + commercial (25-50%)</td><td>6%</td><td>18.75%</td><td>/</td><td>/</td></tr>
<tr><td>Housing + commercial (50-75%)</td><td>3%</td><td>15%</td><td>/</td><td>/</td></tr>
<tr><td colspan="2">Mixed use</td><td>yes</td><td>yes</td><td>yes</td><td>no</td></tr>
<tr><td colspan="2">Plot ratio</td><td>2-3</td><td>3.7-6.1</td><td>1.8</td><td>0.78</td></tr>
<tr><td rowspan="3">Housing typologies</td><td>single-family</td><td>/</td><td>/</td><td>/</td><td rowspan="2">14%</td></tr>
<tr><td>terraced</td><td>/</td><td>/</td><td>5%</td></tr>
<tr><td>multi-family</td><td>100%</td><td>100%</td><td>95%</td><td>86%</td></tr>
<tr><td rowspan="4">Apartment structure</td><td>1-room</td><td>4%</td><td>13%</td><td>5%</td><td>5%</td></tr>
<tr><td>2-room</td><td>37%</td><td>39%</td><td>15%</td><td>20%</td></tr>
<tr><td>3-room</td><td>40%</td><td>33%</td><td>50%</td><td>60%</td></tr>
<tr><td>4+ room</td><td>19%</td><td>15%</td><td>30%</td><td>15%</td></tr>
<tr><td colspan="2">Ground floor height (m)</td><td>4.5</td><td>4.5-7</td><td>4</td><td>2.5</td></tr>
<tr><td colspan="2">Ground floor function</td><td>mix use</td><td>mix use</td><td>mix use</td><td>residential</td></tr>
<tr><td colspan="2">Green area function</td><td>public/private</td><td>public/private</td><td>public/private</td><td>public</td></tr>
<tr><td colspan="2">Parking facilities</td><td>park garage</td><td>park garage</td><td>park garage</td><td>park garage</td></tr>
</table>

Table 3: Residential quartier concept

Residential blocks in NW are consisted of few multi-storey housing prototypes, which in combination with detached houses and terraced housing, create porous pavilion type urban quartiers with residential ground floor use. This logic allows big green areas between the buildings, but offers no private courtyards for residents. Insufficient distribution of playgrounds and urban equipment cause public ignorance of these spaces and their further decay. Enclosure of these quartiers on the ground floor area would separate public from private green area, while introduction of various urban functions for all citizen categories including children playgrounds and social spaces for senior citizens would raise the quality of green surfaces on a level of other 3 masterplans [SA, HC, NH]. While apartment structure remains relatively similar in all four cases, the social structure of buildings in SA, HC and NH offers living space in all categories from low income to luxury apartments. By adding roof extension projects on top of the modernist housing estates [NW], new forms of living units including penthouses could occur and eliminate this disadvantage.

4.4 Residential building concept

Table 4 is reserved for the categories needed to judge the quality of the housing unit: apartment size, accessibility, building technology and energy concept.

<table>
<tr><th colspan="2">Location</th><th>Seestadt Aspern [10]</th><th>Hafencity, Hamburg [11]</th><th>Nordhavn, Copenhagen [12]</th><th colspan="2">Nordweststadt, Frankfurt [13]</th></tr>
<tr><td colspan="7">Housing unit structure</td></tr>
<tr><td rowspan="4">Average apartment size (m²)</td><td>1-room</td><td>37.74</td><td>45</td><td>30</td><td colspan="2">32</td></tr>
<tr><td>2-room</td><td>57.68</td><td>65</td><td>60</td><td colspan="2">58</td></tr>
<tr><td>3-room</td><td>74.46</td><td>110</td><td>95</td><td colspan="2">72</td></tr>
<tr><td>4+ room</td><td>97.73</td><td>130</td><td>110</td><td colspan="2">84</td></tr>
<tr><td colspan="2">Vertical circulation</td><td>stairs/elevator</td><td>stairs/elevator</td><td>stairs/elevator</td><td colspan="2">stairs/elevator</td></tr>
<tr><td colspan="2">Barrier free</td><td>yes</td><td>yes</td><td>yes</td><td colspan="2">partly</td></tr>
<tr><td colspan="2">Heating system</td><td>district geothermal</td><td>district geothermal</td><td>district geothermal</td><td colspan="2">district powerplant</td></tr>
<tr><td colspan="2">Cooling system</td><td>none</td><td>individual</td><td>district cooling</td><td colspan="2">none</td></tr>
<tr><td colspan="2">Mechanical ventilation</td><td>provided</td><td>provided</td><td>provided</td><td colspan="2">provided</td></tr>
<tr><td colspan="2">Natural ventilation</td><td>provided</td><td>provided</td><td>provided</td><td colspan="2">provided</td></tr>
<tr><td colspan="2">Energy production</td><td>none</td><td>exceptionally</td><td>solar</td><td colspan="2">not provided</td></tr>
<tr><td colspan="2">Energy consumption (KWh/m²a)</td><td>15 (heat)</td><td>40 (overall)</td><td>20 (heat)</td><td>160-170 (heat)</td><td>80-95 (heat)</td></tr>
</table>

Table 4: Residential building concept

The size and the quality of an average apartment in each category, are better in SA, HC and NH. Thanks to the bigger storey height, new buildings usually offer more possibilities for advanced building technology such as floor heating, improved mechanical ventilation and smart energy concepts. They are also often equipped with solar panels for hot water or energy production, and consume little amounts of energy. Space division with non-load bearing partition walls ensure spatial flexibility. In terms of spatial organization of the apartments, buildings in NW could still match qualities of the modern apartments. Barrier-free access could be achieved with reconfiguration of the communication core and integration of ramps, while application of new energy concepts and smart/double skin facades on housing units, as a part of the thermal refurbishment concept, could significantly reduce the energy consumption and improve their visual qualities, which would give these housing character and identity.

5. CONCLUSION AND PROSPECTIVES

Despite some unarguable disadvantages against new development projects, with the implementation of the aforementioned strategies, Nordweststadt housing estate could find a way to adapt itself to the 21st century city standards. Future research work will focus on creating design proposals both in the urban quartier and residential unit scale in order to visualise theoretical premises and strategies stated in this paper.

ACKNOWLEDGEMENT

The author would like to thank to the employees of the selected companies [10,11,12,13] for participating in this research and for their assistance in providing the data for the analysis.

Build Less and Make Cities Smarter by Unleashing Potential of Vacant Spaces

CHAN Lai-kiu[a]

[a] arQstudio Ltd, Hong Kong SAR, qlkchan@gmail.com

ABSTRACT

aTTempspace, which won 2015 Techathon by Hong Kong Science Park, attempts to optimize the use of commercial vacant spaces to reduce demands for new buildings and urban footprint of a city. With the support of a major developer and other landlords in Hong Kong, the paper contributor put the ideas into actions, and turn temporarily vacant spaces, such as vacated buildings waiting for redevelopment, shops to be let and atria in shopping malls, into pop up event spaces, bazaars, shops or temporary storage. It provides affordable offline spaces for non-profit organizations, entrepreneurs, SMEs and startups to try out new ideas and to drive social innovation. This is vital for a city to fuel its growth with new jobs for young people and new business in the development cycle. It also removes deserted spots and unsightly defaced street frontages from the city. Activities and services at these temporary locations bring convenience and choices to the neighbourhood, break the monotony from chain stores, and enriches city life, and ultimately, make high density cities more livable.

To unleash the potential of temporary vacant spaces, innovative solutions are required to tackle the following major challenges:

- A creative business model that brings benefits to all stakeholders, including space providers and users, operators, community and environment.
- Cost-effective, quick-to-install temporary or reusable furniture and basic services (in hot summer months, also cooling) to make spaces usable and reasonably comfortable. In long run, green lease that facilitates these, should be promoted as part of the standard practices.
- Contents readily curated
- Effective promotion via social media and public engagement.
- Meeting various statutory requirements that should be updated to face disruptions caused by technology and new economy.
- Simplified liability protection that avoid the vacancy period spent on tedious legal agreements.

Keywords: green economics, smart neighbourhood, green lease

1. BUILDING LESS, NOT JUST BUILDING BETTER

Building less, not just building better to consume less, is a highly effective and even more direct approach to reduce human footprint on earth. Not only that less lands, whether greenfield or brownfield, will be used up by buildings, less materials and energy will be consumed by building constructions, and less waste and pollutants will be released in the processes. To achieve this, buildings have to be used in highly efficient ways, not only through improved planning that increases spatial density three dimensionally, but also involving the time dimension to reduce vacancy. Reduced vacancy and improved usage of buildings will also bring more activities and life to a neighbourhood making it more livable and smarter.

1.1 Time sharing and reduced vacancy enabled by technology

Progress in technology makes information flow highly efficient and cost-effective. People also gradually establish trust to online credit systems that rate service providers who may be total strangers to them. These lead to the success of new sharing platforms and applications like Airbnb, Uber and Lyft, that facilitate quick matching of supply and demand, and allow people to make better use of vacant units, cars or passenger spaces. They bring new convenience to people and reduce the need for building more hotels and cars or using fuel. The sharing concept revolutionizes the way spaces are used and bring disruption to many traditional business and industries.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The wide application of technology in daily life, which brings direct benefits to people, is core to a smart neighbourhood and city. According to Cohen, the movement was initially driven by technology, and then by government, and now, the world are proceeding to Smart City 3.0 which are co-created by people. Entrepreneurs start up new business all over the world to explore the opportunities from this sharing concept in every sector of life.

aTTempspace, a technology startup founded by an experienced architect with strong background in sustainable design and solid experience in real estate, attempts to unleash the potential of vacant commercial spaces in the city. This is particularly relevant in a city like Hong Kong, which is notorious for its high rent, but at the same time renowned for its high density model and clever use of spaces.

1.2 Wastage of spaces caused by vacancy in cities

Airbnb makes temporary vacant homes available for visitors stay. But there are still a lot of wastage of spatial resources in cities. Having been the senior executive of a real estate developer and award-winning designer, the paper contributor hopes to find better ways in using vacant spaces and frontages in commercial premises. These includes:

- Vacant units to be leased
- Shopping mall atria or event spaces emptied between activities
- Office lobbies, meeting rooms and other public areas after work and during weekend
- Vacated spaces in buildings waiting for complete acquisition of titles or submission and approval process before redevelopment

Some of these spaces could be at prime locations and of great value to young people, new startups and small business who cannot afford the high rent at these locations.

Without proper attention and management, street frontages of vacant spaces often become the victims of unauthorized advertisement making them very unsightly and messy. Good temporary uses of these frontages will help to improve streetscape and living environment of a neighbourhood (Figure 1).

Figure 1: Better use of street frontage of vacant space will help to improve streetscape and living environment of neighbourhood.

2. BUSINESS CASES AND CHALLENGES FOR TEMPORARY USE OF VACANT SPACE

To lay people outside the real estate industry, it seems easy and obvious to use these vacant spaces. However, there are a lot of challenges in putting the ideas into practices:

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Short term rent means little to landlord

Properties are expensive commodities in cities. Real estate developers are often public listed companies of high value. Even smaller private developers or landlords are mostly millionaires. To them, the return from temporary leasing of their properties are very minimal as compared to the trouble and procedures involved.

- Short time for finding the right user and content.

Commercial business depends very much on locations and its target customers. It requires a good match of location and brands. To find the right user and content for a space in a very short time could be very difficult.

- Liability and protection

Use of space involves certain liability to the space providers as well as the space users. To protect each other, a license, often with lengthy terms and conditions need to be agreed and signed in advance and insurance need to be secured. These processes could easily use up the period of vacancy.

- Short time for making space usable and running

For the space users, to use a space also means fitting out the space to a minimal standard, bringing in goods and merchandises and securing work forces in a very short period of time.

- Promotion and publicity

Being new in a location, it is not easy to draw sufficient attention and traffic to these temporary pop up activities or outlets.

Core to the problems is to find a good business model that brings benefits to all stakeholders and gives sufficient initiatives for them to overcome the problems described above.

- To the building owners

They will be more interested in happenings that can speed up the sale or leasing of a place and ultimately add value to their properties, rather than collecting the minimal rent from temporary uses. For commercial sectors, value of a property often relate to the amount of foot traffic and publicity of a location to people.

- To the space users

They will be most interested in promoting their brands, expanding their customer bases, not only the limited transactions or business done during the temporary period.

In both cases, the success lies in the ability to bring people to a location and to make a location known to public, which practically is a branding exercise.

3. EXPERIMENTAL PROJECT: CREATIVE USE OF VACANT SPACE AS AREA BRANDING TOOL

With the support of a visionary developer, a 6000 sq. ft. high ceiling ground floor vacant space in a factory building were made available and usable for different organizations to pop up different events in three months before its demolition. (Figure 2)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 2: Space vacated waiting for demolition

The project, not only makes the location better known to the public, it re-brands the area as a fun and cool destination. Events conducted includes:

- Old kisses New: TKT (Figure 3)

The first pilot event on a theme that celebrates the mix of old and new culture in Tai Kok Tsui area through the juxtaposition of old craft market with new maker fair, old sugar craft with new 3D sugar printing, new photos of the old districts, history talk about the area and a wide array of performances and games.

Figure 3: First pilot event was arranged in a short period of two months

- A family art and design fun day (Figure 4)

Figure 4 The second event held in the vacant space

- A recycle book fair and lantern art exhibition (Figure 5)

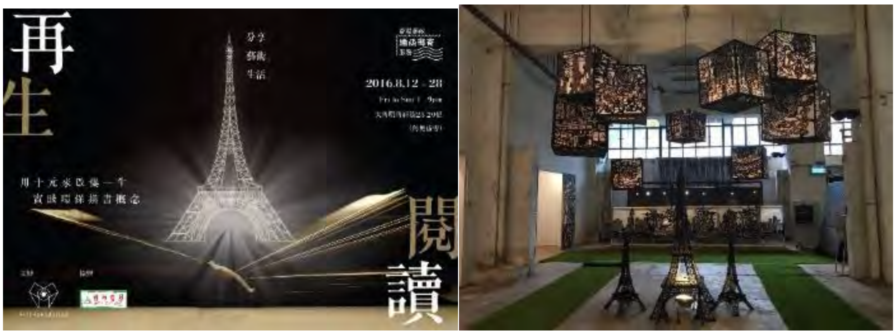

Fig 5 A recycle book fair and a lantern art exhibition

- A drone race and fun day (Figure 6)

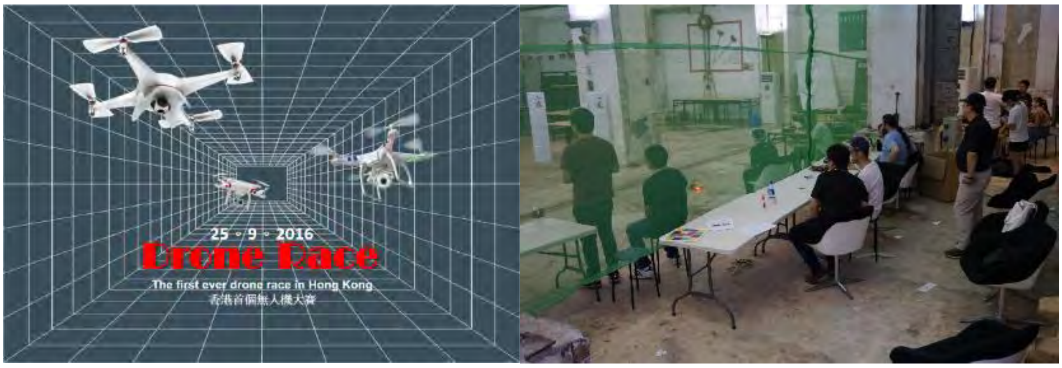

Figure 6: It is a very unusual opportunity to play drone indoor

4. SOLUTIONS TO PROBLEMS TESTED OUT THROUGH THE PROJECT

The following solutions have been tested out in overcoming various problems encountered in temporary use of spaces:

- Provision of basic services

As the building was mostly vacated, temporary power was spared from existing building while sockets units and floodlight were borrowed from construction site to provide power points and general lighting.

- Mobile and reusable systems integrated with lighting provide multi-purpose panels for exhibition and screen for projection. A set of giant mahjong was also done to serve as seating, stands, games and art installation (Figure 7)

Figure 7: Mobile and reusable units provide basic furniture to the space

To further enrich the space, environment artworks using waste materials were installed. (Figure 8)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 8: Environmental artworks

- Temporary air conditioning

As the period of vacancy falls into the summer months, basic air conditioning was provided by 4 nos. temporary standing split units and large number of evaporative cooling units. However, the result is far from satisfactory and better solutions need to be sought.

- Meeting regulatory control

Careful checking of town planning, building and lands control were done. However due to the short preparation period, it is totally impossible to properly secure the Place of Public Entertainment License. As compromise, all the events are limited to "people invited" instead of to public.

- Liability and protection

As the developer has the vision to facilitate the temporary use, license conditions are kept to the minimum and allow the agreement to be signed by a limited company without personal guarantee. Furthermore, proper third party indemnity insurance was requested in the license agreement to indemnify the owner from liability.

- Promotion and publicity

Knowing promotion is key to the success of such event, a PR agency was brought in at early stage. In an era when content is king, creative ideas go viral in social media. A video of playing the mah-jong done for this project attract over 2 million views and 60 K share on Facebook (Figure 9).

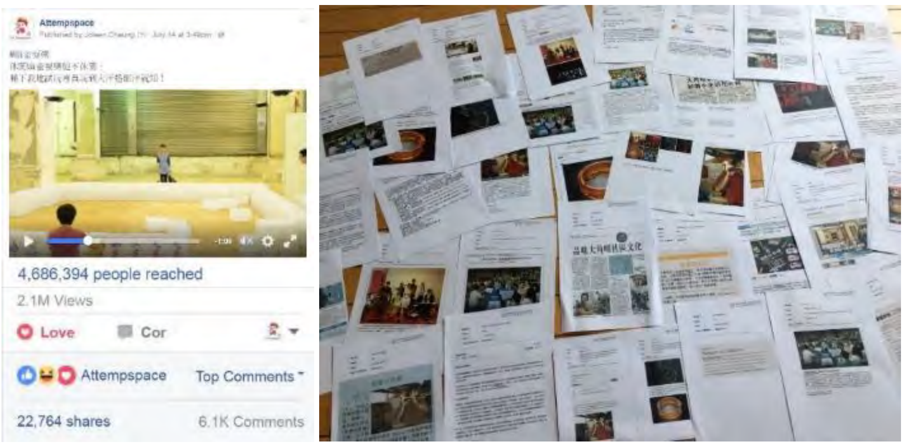

Figure 9: The project enjoys great success in publicity

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

5. CONCLUSIONS AND LEARNINGS FROM THE PROJECT

The projects prove that the idea is viable and valuable learnings are gained:

- Experience from temporary uses draws traffic and encourage interaction

Temporary pop up events and uses bring new experience and interaction.

In a world people get overwhelmed by information and over-rely on online platform for interaction, the pop up events bring new experience to people, allow them to meet face to face, and foster community interaction.

- Temporary uses are sources of novelty and creativity

Through temporary uses and installation, people can test out new ideas and carry out experiments. And often, these contents are very interesting and novel to visitor. In the creative process, chances of realizing an idea and be allowed to make mistake are highly valuable. All these help to cultivate a creative and innovative culture in a city.

- There are solutions to problems involved in temporary use of space

With a will to try out the idea, the developer and aTTempspace work as a team to overcome various problems encountered and act very fast in making things happen so that the short vacancy period will not be wasted.

- There is a business case for creative use of vacant space

The project proves that creative use of vacant space is a good vehicle for branding both for the space provider and the temporary users. It brings foot traffic to the area, business to its adjoining shops and restaurants, and activities to its neighbourhood, and ultimately enrich city life.

- Temporary use of space can be further enhanced by:

Green lease that does not request the tenants to reinstate a premises to bare shell and disconnect all utilities after expiry of lease.

Corresponding provisions in regulations and statutory controls that shorten applications and approval process.

- Better use of technology

Due to the short preparation time for the pilot project, technology has not been fully employed. In near future we hope to do more projects and experiment other applications of technology which includes:

Crowd-sourcing of content that encourage participation and contribution by public and bring awareness before the happening of events.

IOT shopfront that integrates sensors to collect traffic data and customer profile at a location. Its frontage can also be used as billboards for advertisement, as showcases for products and as screen for online shops.

[b] *Electrical and Mechanical Services Department, Government of the HKSAR, Hong Kong SAR, whleung@emsd.gov.hk*
[c] *Electrical and Mechanical Services Department, Government of the HKSAR, Hong Kong SAR, dlau@emsd.gov.hk*

ABSTRACT

Buildings use about 40% of global energy and they emit approximately one third of global greenhouse gas. In Hong Kong, buildings account for more than 60% of the total annual energy consumption and about 90% of the total electricity consumption. In this connection, building sustainability is a crucial element for meeting the needs of contemporary end users without damaging the prospects of future generations nor increasing environmental burdens to the neighbours.

The Electrical and Mechanical Services Department Headquarters Building (EMSD HQs) situated in Kowloon Bay was formerly an air cargo terminal building in the ex-international airport at Kai Tak. The EMSD HQs successfully exhibited an excellent showcase of sustainable development through renovating the old cargo terminal into an office building and workshop, thus minimizing the generation of construction and demolition wastes.

As a pioneer in advocating environmental responsiveness, the Electrical and Mechanical Services Department (EMSD) always takes a proactive approach in promoting energy efficiency and sustainability. Since moving in the new headquarters in 2005, we have been implementing continuous enhancements to our indoor and outdoor facilities and environment in various aspects to making EMSD HQs greener, not just to meet the changes in operational need but also to enhance sustainability for the sake of our staff, our neighbours and the public at large. These enhancements include many advanced technologies leading to energy and water conservation as well as waste reduction, and are verified using the BEAM Plus environmental assessment tools.

This paper will briefly introduce various sustainable features applied in the green transformation of EMSD HQs, the good practices adopted in operation and management, and the experience gained in the building integration with the community.

Keywords: sustainable neighbourhood, green building management, transformation

1. INTRODUCTION

Being an international metropolitan, Hong Kong is characterized by many high rise buildings to render the spaces needed for our work, living, recreation and commercial activities. Buildings in Hong Kong impact a significant portion of our carbon footprint and account for more than 60% of the total annual energy consumption and about 90% of the total annual electricity consumption]. To combat climate change, the reduction of our buildings' carbon footprint is top of our agenda with aspiration towards a vision of developing to a low carbon city.

In around year 2000, the EMSD of the Hong Kong Special Administrative Region (HKSAR) in collaboration with the Architectural Services Department saw the opportunity to give the former Hong Kong Air Cargo Terminal 2 Building (HKACT2) built in early nineties a new life by converting it into the EMSD HQs.

Similar to many existing buildings which are 30+ years old in Hong Kong, energy efficiency of the HKACT2 was not a foremost consideration at that time when it was built. There were tremendous rooms and potentials to improve energy efficiency performance of the building by application of state of the art energy efficient building designs and technologies.

In 2004, the HKACT2 undertook a complete conversion with a sustainable design and construction approach which was fundamentally different from the traditional approach by demolishing the old structure for construction of new building. This approach could save capital construction cost, and the most important of all, avoid generating

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

unnecessary demolition and construction waste while conserving the embodied energy within the existing building elements.

2. SUSTAINABLE FEATURES

The EMSD HQs, with a total gross floor area of approximate 81,800 square meters, was designed to make full use of the existing concrete structure as far as possible resulting in a saving of HK$600 million in construction cost. By retaining most of the existing concrete and steel structure of the old building, the volume of construction waste reduced was estimated to amount to a four-storey building of the size of a football pitch.

Year 1991
Former Air Cargo Terminal Building

Year 2005
EMSD Headquarters Building

Figure 1: Photos of Former Air Cargo Terminal Building and EMSD Headquarters Building

The refurbishment works were completed in November 2004 and the building was equipped with a number of sustainable features for enhancing energy efficiency and promoted use of renewable energy. Examples of these features are highlighted as follows:

2.1. Building envelope

The building facade is fitted with sun shading architectural fins at the southeast elevation to minimize direct sunlight penetration into the building in the summer and with double-glazing to minimize heat transmission from outside. In addition to the sunshades and double-glazing, green roofs on the second and seventh floors provide thermal insulation to the building as well as pleasant outdoor spaces where staff can interact and relax. A low overall thermal transfer performance of the building envelope is achieved.

2.2. Thermal comfort

As electricity expensed by air-conditioning system shares about half of the total building electricity consumption of a general office building, high efficiency water-cooled chillers using ammonia as refrigerant have been adopted in the EMSD HQs. The coefficient of performance (COP) of the chillers at full load is 5.7 which was about 10% above the requirements in the Code of Practices for Energy Efficiency of Air Conditioning Installations published in 2005. Besides, ammonia is a zero ozone depletion refrigerant and helps minimize global warming effect.

During “off-peak” period of electricity demand, “slurry ice” which is a good thermal storage medium was produced and stored in five ice storage tanks. During peak period of electricity demand, the slurry ice is used to absorb cooling load and hence reducing the maximum loading demand of electrical installation.

The advantage of having high headroom from the old air cargo building enables the use of displacement ventilation via raised floors to supply the conditioned air to offices, instead of using the conventional supply and return air at ceiling level. In workshop areas, natural cross ventilation is achieved by constructing new openings on blank concrete walls with booster fans installed to improve air circulation during sultry days.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.3. Natural lighting and interior lighting

The use of natural lighting in office areas and main lobby reduces reliance on artificial lightings. Apart from conventional manual lighting switches, smart controls such as occupancy sensors or photo sensors have been applied to the lighting systems at peripheral areas to minimize energy consumption.

For office areas, task lighting coupled with occupancy sensors enables a lower background illumination level and hence a lower lighting energy consumption. In addition, sun pipes installed to harvest direct daylight from roof to 7/F corridor can further reduce the energy consumption of interior lighting.

2.4. Renewable energy

The rooftop solar photovoltaic system installed on roof of the EMSD HQs consists of over 2,300 photovoltaic panels with a maximum installed capacity of 350kW, which was the largest photovoltaic panel system at that time. These panels are grid connected with the electricity power distribution network and can generate electricity from direct sunlight to meet about 3% of the total building electricity demand.

2.5. Water recycling

Grey water such as wastewater from showers, washbasins and kitchen areas of the EMSD HQs is collected, treated using membrane bio-reactor technology and stored in underground tanks for toilet flushing. The approximate saving of water is about 14,000 litres per day.

3. GREEN TRANSFORMATION

Since moving into the new EMSD HQs in 2005, we have been continuing our effort in implementing further enhancement to our facilities and environment, both indoor and outdoor, on a non-stop basis, not only to meet the change in operational needs, but also to enhance the sustainability and greenery of our building as well as the staff productivity and the well-being of our staff, visitors, neighbours and the community at large.

3.1. Thermal comfort enhancements

With advancement of technology, EMSD took the opportunity to pilot install a new water-cooled variable speed oil-free centrifugal compressor chiller in the EMSD HQs in 2008, which was the pioneer use in government at that time. The chiller operates with magnetic bearing technology that reduces energy loss, and is quieter and more energy efficient to run than traditional chillers. The variable speed oil-free chiller that achieves a good part load COP can partner with the original ammonia chillers to achieve the optimum chiller plant efficiency at all partial load conditions. In addition, an electromagnetic induction descale system was installed in 2012 to apply an electric field to prevent formation of scale in the condensing water circuit and hence maintaining the heat transfer efficiency at all times.

In sub-tropical climates like Hong Kong, solar heat gain through building envelope imposes significant cooling load to the air-conditioning systems. In order to reduce the solar heat penetrating through windows, window solar films are installed on the façade glazing of office areas at 6/F, 7/F and rooftop viewing gallery to further lower the heat transfer.

3.2. Lighting power consumption enhancements

As technology advances, LED lighting, photo-sensor lighting control and occupancy sensor lighting control have been widely adopted in refurbishments of the EMSD HQs whenever applicable. The lighting power density of renovated meeting rooms and toilets completed during the period between 2013 and 2015 is around 11W/m2 and 7W/m2 respectively, which outperforms the minimum requirements of the latest Code of Practice for Energy Efficiency of Building Services Installation 2015 Edition [3] by about 21% & 36% respectively. The existing fluorescent tubes are being replaced by LED lamps progressively to further lower the lighting power consumption of the EMSD HQs.

3.3. Renewables

To cope with the hot water demand of canteen and shower facilities of workshops and better use of solar energy, a solar water heating system with a total solar collector area of 60m2 was installed in 2007. The system brings us an annual saving of about 25,000kWh. A sun-tracker concentrated photovoltaic panel, a light shelve and solar powered street lights have also been installed to further promote utilization of solar energy. The enhancement will not come to a halt and there will be installation of solar-wind powered lighting at the piazza for completion in 2017.

3.4. Waste management

At present, most of Hong Kong's food waste is disposed of at landfills. Because of the limited landfill spaces in Hong Kong, such practice is not sustainable. In addition, it creates odor nuisance and generate landfill gases that require further mitigation measures. To reduce the pressure on landfill site, a food decomposer was installed to reduce the food waste from the canteen of the EMSD HQs. An average monthly waste of 500kg is collected for conversion as fertilizer used in landscape area.

In reducing water consumption, a pilot project proposed by staff for using condensate water collected from air handling units of air-conditioning system for toilet flushing was implemented starting from 2012. A rain water harvesting system was also installed in 2014 to collect rain water for irrigation.

Furthermore, we have pledged to reduce waste and recycle the recyclables generated by joining the "Waste Check Charter" launched by the Environmental Protection Department. Besides the hardware, we have implemented good environmental management system to sort and recycle the waste metal and waste oil from vehicle workshop.

3.5. Greenery

To improve the spatial quality of the building, external vertical greening of 200m2 was erected as feature walls in the piazza in 2011, while an indoor vertical green wall of 30m2 was installed at the ground floor main lobby in 2014. We are now planning further enhancement of the outdoor piazza for completion by 2019. Apart from enlarging the outdoor space for the community to enjoy, more external greening including lawn and vertical greening to enhance the environmental quality are in progress. This not only highlights the function of the space, but also enlivens these areas in midst of an industrial district with a contrast of pattern, colour and textures.

3.6. Building asset management by RFID and BIM

Since 2014, EMSD has pioneered the application of innovative Building Information Modelling (BIM) together with Radio-frequency Identification (RFID) technology which converts and organizes building design information into a 3-dimension digital model to improve the asset management (AM) of the EMSD HQs. With advanced mobile device technology, the estate management staff, and operation and maintenance staff can work more closely and effectively. The operation efficiency would be significantly improved by shortening the response time for fault diagnosis, clearance and service recovery.

3.7. Building energy consumption monitoring

The best measure to ensure the optimum system efficiency and reliability is to nip potential problems and faults in the bud. Apart from incorporating communication gateway between the Central Control and Monitoring System and Building Energy Management System for real time data communication, the EMSD HQs has been progressively adding different smart meters, such as chilled water flow meters in chilled water circuit and branch circuit power meters in electrical sub-circuits, to enhance the existing building energy management system in monitoring the energy performance of building services installations in more details. In addition, the enhancement of building energy management software, including a more powerful energy usage analyzing capability and the capability of issuing energy usage alert, is being implemented.

After the completion of the above enhancement in 2017, the real time energy performance of the EMSD HQs can be monitored closely and abnormal operating conditions can be identified at an earlier stage for necessary rectifications. With the enhanced building energy management system, the logged operation parameters and energy consumption records of different locations of the building can be analyzed in details and more energy efficient modes of operating set points as well as energy management opportunities can be identified by the operation and maintenance staff through the information network. The new building energy management system can also provide user-friendly dashboards for the building users to visualize their energy consumption, which facilitate the cultivation of energy saving behaviors of building users.

3.8. Green transport

In order to encourage green transport, bicycle parking spaces were set out within the site in 2013 for our staff to return to office by cycling. With the popularity of electric vehicles continues to grow, we also set up charging facilities for visiting electric vehicles in 2015.

4. INTEGRATION WITH COMMUNITY

A green building being a part of the community is simply not sustainable on its own. Connecting with community enables sustainability to be leveraged beyond the building's boundaries to reach out for the general public.

By the time the EMSD HQs was designed, a traffic impact assessment concluded that a footbridge across Kai Cheung Road would be required to cater for the increase in pedestrian traffic and enhance the interconnectivity of the EMSD HQs with neighbours. Hence, to enhance connectivity and walkability, a footbridge was then built with the full support from developer of the adjacent commercial complex and forming an important gateway for us to physically reach out to the neighbourhood community.

Coming in through the main entrance, an education path including exhibit features in piazza, exhibition gallery on ground floor and viewing gallery on roof, takes members of community on an exploratory journey and experience of energy efficiency, renewable energy and electrical and mechanical safety. Throughout the past decade, EMSD has been adding and updating exhibits of the education path to keep visitor's experience fresh, and the revamp of the education path is underway which will give visitors multi-sensory experience through dynamic, multimedia and interactive displays.

What keeps a building alive is its ability to continuously cope with the different needs of its occupants and visitors. EMSD constantly explores various new ways to enhance our amenities to make the EMSD HQs a greener environment for shared use with the community. Apart from enhancement of the hardware such as enhancing greenery, providing bicycle parking spaces, and widening pedestrian access in piazza, etc., EMSD has engaged a social enterprise to run a café at the main entrance hall in 2015. Through such initiative, EMSD can create opportunities for the underprivileged people, and also foster a caring culture in the community.

To make the EMSD HQs even greener, the air-conditioning system will be connected to the district cooling system (DCS), which is the first district-wide air-conditioning engineering system in Hong Kong, in mid 2017. By that time, the EMSD HQs building will become the first existing building to adopt DCS, and will set out an example for other existing buildings to follow. The DCS consumes approximately 20% less electricity as compared with traditional water-cooled air-conditioning system using fresh water cooling towers. Taking the advantage of energy efficient nature of the DCS, it is anticipated that this enhancement could generate a saving of 1.7 million kWh per year, which is equivalent to the annual electricity consumption for about 300 households. Furthermore, the local heat island effect from the existing cooling tower system can be reduced. After connecting to the DCS, there is a further opportunity to make good use of the existing air-conditioning plant room and ice storage area to convert them into new facilities as part of our sustainable development to make our piazza area more appealing, open, and accessible to people in the neighbourhood.

EMSD is fully committed to contribute to a greener community. In line with the Hong Kong Green Building Council's focus to enhance environmental performance of existing buildings, the EMSD HQs has become the first government building achieving the "Platinum" rating under the BEAM Plus Existing Buildings assessment [4] in 2016. The project of Transformation of EMSD HQs into a Green Building is also rated "Platinum" in the BEAM Plus Neighbourhood pilot assessment scheme in the same year.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

5. CONCLUSION

The transformation of EMSD HQs demonstrated that an old building could be rejuvenated to satisfy the needs of all occupants, visitors and neighbours in a sustainable manner. At different stages of a building cycle, various innovative concepts and elements to optimize the energy performance and sustainability of the building have been considered. The energy performance does not only comply with the minimum requirements including the Building Energy Code, but also aim at outperforming the bare minimum requirements to promote energy efficiency and sustainability. By continuous enhancement and integration with our community, the EMSD HQs is further transforming into a government model to the society in driving towards a low carbon city.

Shaping Energetic Neighbourhoods: A Dynamic Approach for a Future Proof Urban Energy Planning

Jürgen KNIES[a]

[a] *Jade University of Applied Sciences, Germany, juergen.knies@jade-hs.de*

ABSTRACT

The announced heat transition, with a huge impact on the reduction of the greenhouse gases, addresses especially cities. The simple question "Which technological solution of sustainable energy supply should be implemented at which place?" often leads to a confusion of local stakeholders caused by the wide range of possibilities. Besides technological and social challenges, facing the related question of the best location or area will be a key factor of a successful local implementation. The approach enables stakeholders to analyse cities spatially from the perspective of heat demand across planning borders like districts and real estates. The result shows areas of suitability for heat supply systems like LowEx - heating grids, typical district heating systems, or local heat generation, e.g. on block or building level. The shapes of this energy driven neighbourhoods are fuzzy. Due to the scenarios the dynamic spatial change of the suitability patterns can be used as a forecast system for urban planning activities.

Keywords: sustainable neighbourhood, spatial fuzziness, energy supply systems

1. MOTIVATION

The ongoing Energy Transition in Germany has come to a point where it becomes clear that the former focus on power generation is not sufficient to reach the climate protection goals. The enormous potential of greenhouse gas (GHG) reduction in the building sector is now on the political agenda [1] [2]. In 2050 the buildings in Germany shall be carbon-neutral [3]. Two different and also complementary approaches are suitable for this goal [4]:

- Fostering the refurbishment of existing buildings and developing energy standards for new buildings.
- Integration of renewable energy into the heat supply system and replacing fossil fuels.

The future energy system couples the different sectors e.g. heat, power, and logistics on a very local level and enables an exchange of energy between different actors within a neighbourhood [5]. Shaping the energy driven neighbourhood is a dynamic process and connects actors on various energy levels in space and time [6].

The presented approach is not suitable for detailed energy planning. Rather, it fills the gap between urban planning and the detailed planning by a fuzzy shaping of energy driven neighbourhoods [6]. It shall give a first overview for a spatial monitoring of potential heat supply systems based on heat demand data.

2. DATA AND APPROACHES

The approach presented in this contribution is tested in the city of Oldenburg (164.000 citizens) and in the smaller cities of Bramsche and Wallenhorst (36.000/ 23.000 citizens) in Lower Saxony (Germany), so it meets typical sizes of cities in Germany.

2.1 Data and subjects

Heat demand data are derived from models about the age and construction of buildings, the number of inhabitants, the usage within the building etc. So heat demand does not represent the heat consumption. Heat consumption depends on personal behaviour and certain structures, so the heat demand gives a more objective picture.

For the city of Oldenburg the commercial data of DBI GUT GmbH is used (ca. 53.000 points of heat demand data). Input data from 2011 to 2015 are used to model the heat demand. In some cases, the heat demand is revised because the local situation is different from the demand data, e.g. public facilities like schools, university etc. In this case concrete data of the municipality is used or the heat demand is recalculated [7] [8]. A high degree of uncertainty is given in the industrial sector, caused by unknown parameters like the amount of produced goods,

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

see also [9]. For the cities of Bramsche and Wallenhorst the data of the PlnA project ("Planungsportal für industrielle Abwärme", planning portal for industrial waste heat) is used (in total ca. 23.000 points) [10]. The county of Osnabrück is involved in the plausibility check.

In both cases the information about the single input data is lost caused by constraints like data protection and business secrecy. So the modelled data is the starting point of the analysis.

2.2 Scenarios of the future energy demand

Due to the data situation and constraints, the scenarios are not driven from the building stock in detail. Is it necessary to think from the GHG – reduction point of view, because the goals and requirements are set.

The meta-analysis on future heat demand in Germany [11] gives a good overview about different assumptions about the future energy demand:

- A reduction by 60% in residential buildings.
- A reduction by 20 to 30 % in the industry sector.

The reduction only by increasing of the efficiency is a critical point. The so called "Efficiency Base" is a constraint according to issues like preservation orders, physical conditions, distance regulations etc. [12]. Only integrating renewable energy sources into heat supply systems without building refurbishment is also not possible, because in reality there are often no adequate, realistic potentials. Both approaches together can meet the goal. Thamling et al. [12] define two scenarios:

- Renewable Heating (RH): Use of the realistic potential of renewable energy resources; coupling heat and power sector, moderate building refurbishment; reduction of heat demand by around 40 %.
- Efficiency (E): Ambitious refurbishment and building activities; reduction of heat demand by around 60 %.

According to the size and heat demand of the buildings, the degree of reduction differs around +/- 5% [13], so smaller buildings have a smaller reduction potential than larger buildings. The heat demand data points are divided into three portions with a third of the total sum of heat demand. So each building is assigned to one of this groups by its present heat demand. For this study the scenarios for dwelling houses, trade and services are defined in Table 1. Industrial buildings have a potential reduction of 20 % in 2050.

Year	2020		2030		2050	
Scenario	E	RH	E	RH	E	RH
Reduction on (spread (+/- 5%)	91% 86% 81%	94% 89% 84%	73% 68% 63%	82% 77% 72%	45% 40% 35%	65% 60% 55%

Table 1: Definition of the scenarios and the reduction of heat demand

This generalisation cannot take into account the individual situation of each building, and yet it allows a first picture of the future development. "A scenario is a story that describes a possible future. "([14]; p.8)

2.3 Heat supply classification

The heat supply in urban areas is grid related (gas grid, district heating, or even for heat pumps based on the power grid). The advantage of district heating systems is the flexibility regarding the energy sources [15]. The energy demand density according to the (pipe) line length is a good indicator for a suitable energy supply. The theoretical (pipe)line length for e.g. a district heating system is calculated by the length of the streets, based on OpenStreetMap data, plus the distance between the streets and the demand points per 100 x 100 m raster. The algorithm avoids parallel structure of potential pipelines by creating branches. A spatial smoothing filter takes the average length within the immediate neighbourhood into account to avoid illogical extrema. In combination with the sum of the demand within the raster it is possible to express the indicator as MWh/(m x a).

Limit / Ranges	Definition

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

< 0,5 MWh/(m x a)	Single Supply: Heating by fuel cells, air and geothermal heat pumps etc. No connection to a grid, limit for grants [16]
0,5 – 1,5 MWh/(m x a)	Cold/Warm Heating System: Seasonal operation management of a grid (summer: 30-40°C. heat pumps in the house for domestic water, solar thermal and power; winter: 70-90°C. by (decentralized) CHP; integration of industrial waste heat [17][18]. In Germany there are different definitions of low exergy - heating systems, so in this contribution it is focused on systems with the operational specification.
1,5 – 2,75 MWh/(m x a)	Classic District Heating: 70-90°C. by (decentralized) CHPs and supported by heat pumps (industrial heat pumps, solar thermal energy, etc.) [19]
> 2,75 MWh/(m x a)	Site / Block Supply: CHPs on site, direct connection to the gas grid, district heating in the sense of cellular grids

Table 2: Heat density ranges of heat supply systems

The efficiency of district heating systems and the related thresholds (Table 2) are not a static figure, the recent experiences with the integration of sources like solar thermal energy and industrial waste heat into the district heating systems [20] [21] is still in progress. So the suitability of different kinds of heat supply systems, based on the demand density, is not static, too, there is a smooth transition of thresholds.

The transition can be described by the concept of the fuzzy membership [22]. In this case a linear membership function is used. The function differs according to the range of the suitability. The current stage of the thresholds and functions are illustrated in Figure 1 and were derived from publications (Table 2). The definition of these is still in progress caused by the ongoing technological development.

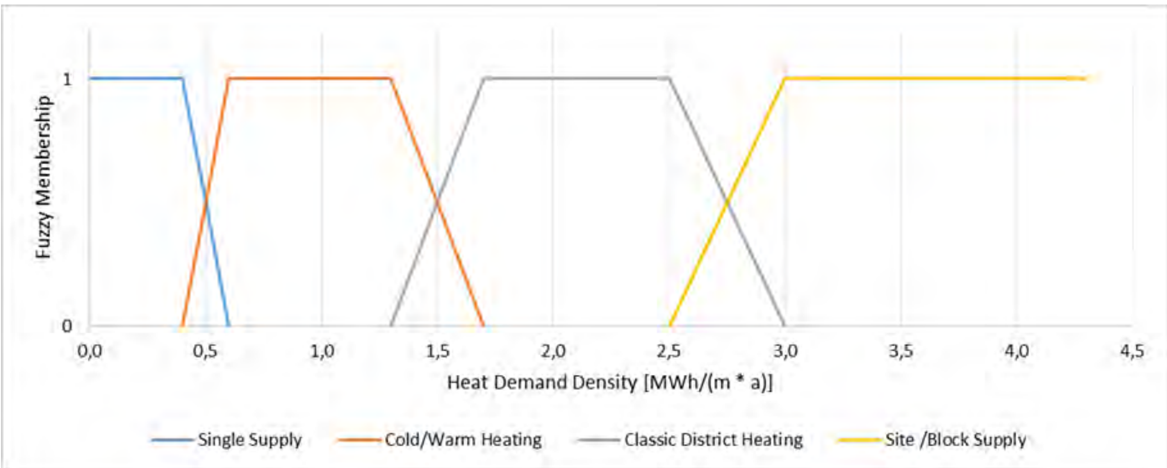

Figure 1: Fuzzy membership of heat supply systems

2.4 Spatial analysis

Based on the rasterized heat demand density and on the concept of the fuzzy membership, the spatial analysis determines the core areas of the different memberships by a supervised Hot Spot Analysis. Combining the Hot Spot Analysis with the scenarios the spots begin to move over space and time. Additionally, the spatial aggregation and combination of the fuzzy memberships enables a city-wide mapping of the leading heat supply system.

3. RESULTS

The analysis of the heat demand density differs in Oldenburg and in Bramsche/ Wallenhorst. The city of Oldenburg is more compact, while Bramsche/ Wallenhorst is more distributed with some sub-centres. An overview of the heat demand density is given in Figure 2.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

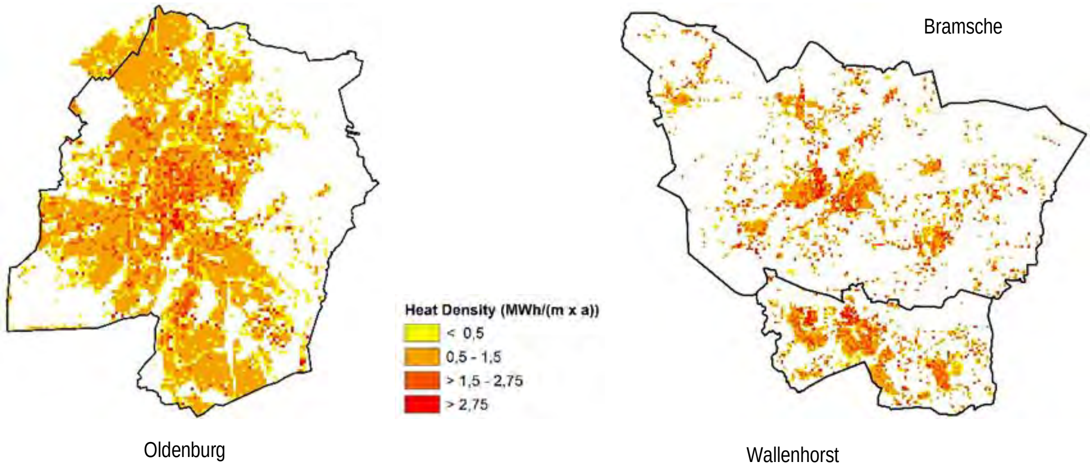

Figure 2: Heat demand density in Oldenburg and Bramsche/ Wallenhorst (Status Quo, unscaled)

The Hot Spot Analysis of the fuzzy suitability with regard to the different heat supply systems allows an overview of the suitability areas in space and time. These areas represent the core areas for the following energy planning in detail. In Figure 3 the Hot Spot Analysis shows the core areas of Cold/Warm Heating System for Oldenburg for both scenarios.

The core areas do not represent the whole settlement area of a city. By combining the fuzzy memberships it is possible to find out the leading heat supply system with a degree of the suitability (Figure 4). Of special interests are the indifferent zones (yellow cells). They are suitable for two different systems equally. So this areas could be very important for the coupling of systems (fuzzy transition). They also represent a smooth transition between the borders between the areas. The proportions of the indifferent areas between the Single Supply areas and the Cold/Warm Heating System areas differs in Oldenburg (14%) and Bramsche/ Wallenhorst (24%). This could be a hint of the patchiness and the more heterogeneous building structure in Bramsche/ Wallenhorst than in Oldenburg.

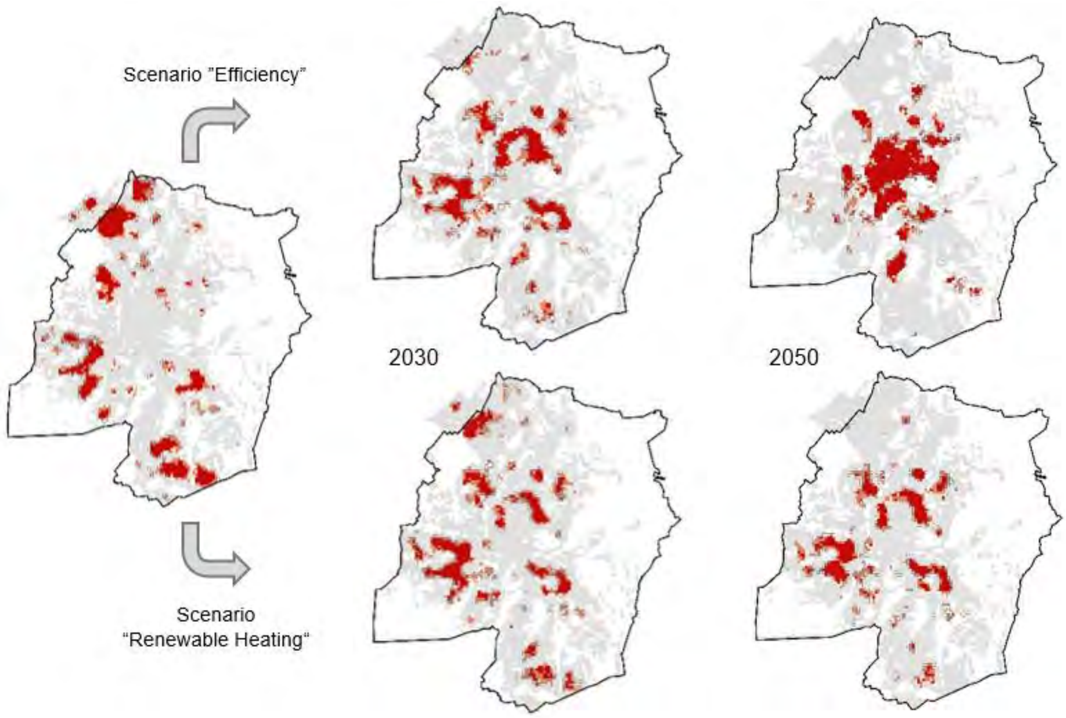

Figure 3: Hot spot analysis of the suitability of cold/ warm heating systems in space and time in Oldenburg (unscaled)

The scenario E leads to a huge area of Cold/Warm Heating Systems in the inner city, so the integration of renewable energy will be a challenge in 2050 there. The scenario RH shows more stable areas, so the areas are more secure for future investments. But then it is necessary to consider, how to bring the renewable (heat) energy amount into the inner city, e.g. industrial waste energy, deep geothermal plants, Power-to-Gas and/ or huge solar heating systems. Figure 4 shows the mapped combination of all suitability areas for both scenarios in 2050.

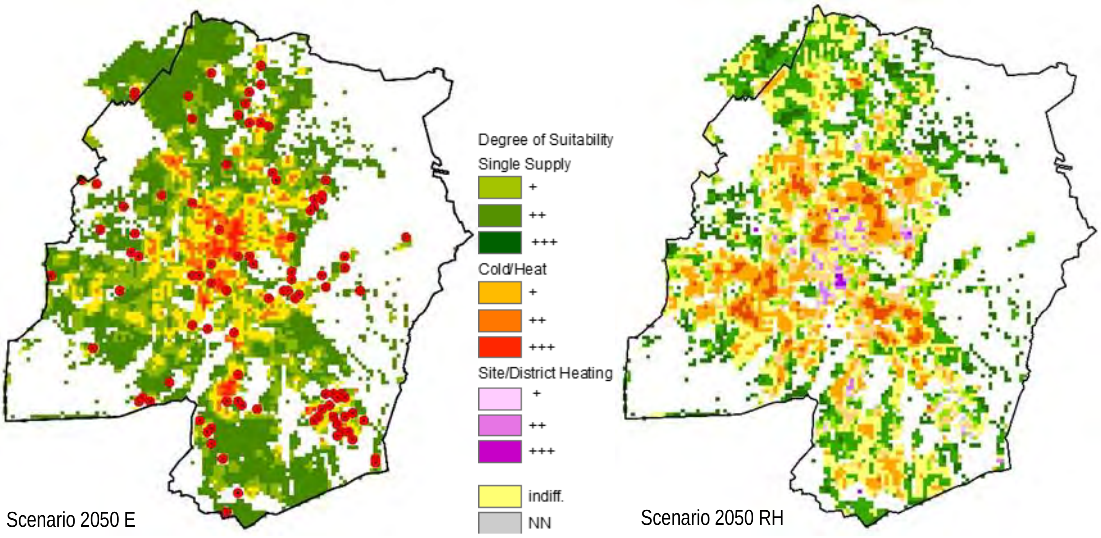

Figure 4: Spatial aggregation and assessment of the suitability in Oldenburg (unscaled)

In 2050 E there are still some sites with a punctual high demand, symbolized with red dots. The analysis of Bramsche/ Wallenhorst shows similar results, but the settlement structure leads to a different patchiness of the suitability areas.

4. CONCLUSION AND OUTLOOK

The presented approach shows, how to create a first idea of a potential local and future development. Now, urban renewal projects can take into account an overall strategy: "Look over the project-fence." The shaping of project areas and the following detailed planning on district level can use it as an orientation. Within energetic driven suitability areas it is possible to find adequate and future proof solutions.

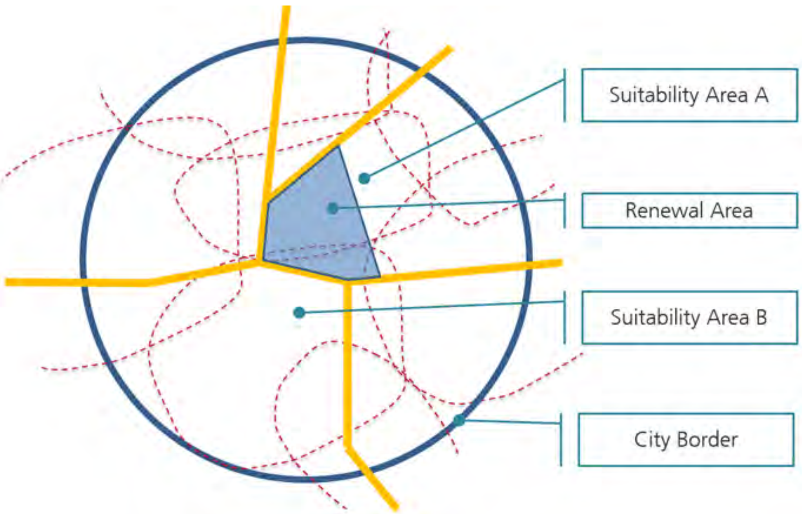

Figure 5: Look over the project-fence with suitability areas

The "Where" and "What" questions can be encircled now on a conceptual level. But the most important question is still open: Who drives the process and how can be brought the ideas of a long term energy planning into action? The approach may help to create a spatial understanding of the stakeholders for the future tasks.

ABSTRACT

The most effective way to realize sustainable lifestyle is not to install considerable amount of cutting-edge technologies, but it is more important to implement sustainable provisions that drive the behaviour change of stakeholders. Demonstration buildings that aim to drive the behaviour change of stakeholders would act as a role model of sustainability to influence everyone engaged with the building, including visitors, building operators, building owner and nearby communities, etc.

The Green Atrium, a 3-storey demonstration building, is built within a residential development in Yuen Long, Hong Kong, in a rural community where large amount of traditional farmlands are located. The Green Atrium is intended to establish the coexistence of commercial activities and environmental protection which are often irreconcilable. It provides a set of commercial facilities serving the visitors and the community—supermarket, restaurant, multi-purpose venue, exhibition venue and rooftop garden. To protect the environment, a total of 28 sustainable features are installed to achieve low carbon operation, as well as to maximize the lifetime of resources such as food and water by creating a circular economy.

There are 4 key objectives of The Green Atrium:

- A role model of future developments for low carbon operation and a prototype for innovative sustainable technologies.
- A showcase of holistic sustainable lifestyle to stakeholders through interactive engagement and implementation of sustainable design features.
- A coexistence model of commercial activities and environmental protection to establish a complementary linkage.
- A focal point to form a hub to promote sustainability, to educate the public, to organize community events, as well as to provide an organic market, given its location within close proximity of agricultural land, vernacular villages and country parks.

Keywords: Behaviour change, sustainability, low carbon, community, commercial, engagement

1. INTRODUCTION

Climate change and environmental depletion are two major ecological challenges facing by humanity. According to United Nations, "sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (WECD, 1987). It consists of three pillars, namely environment, social and economic, which require integration and balance of each area to achieve the ultimate goal of sustainable development. Sustainable development is being commonly applied in building construction to address ecological issues and green buildings are emerged as a result. Green buildings typically contains considerable amount of cutting-edge technologies in the building systems to reduce resource use and to enhance environmental quality of the building. However, this approach is often not effective in terms of sustainability due to the disconnection between building systems and the occupants, in which the social aspect is being neglected. To maximize the benefits of green building, the building shall become a driver for behaviour change of every stakeholder.

In response to become the next generation of sustainable building that preserve the environment and provide social benefits, The Green Atrium was commissioned to be designed in 2013 and completed in 2015. The purpose of The Green Atrium is to become a role model of sustainability and to set an example for future developments. It adopts an eco-living concept that engages the community with the building. The Green Atrium is intended to

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

establish the coexistence of commercial activities and environmental protection which are often irreconcilable. There are a total of 28 sustainable features installed to achieve low carbon operation and to maximize the lifetime of resources such as food and water by creating a circular economy. The Green Atrium is aimed to begin a revolution in sustainability by making positive impacts to the real estate industry, the construction industry and the community. The outlook of The Green Atrium and the eco-living concept is shown in Figure 1.

This paper discusses the detailed approach of sustainable design development and sustainable operation principles in The Green Atrium for driving behaviour change of stakeholders.

Figure 1: Outlook of The Green Atrium (Left) and eco-living concept (Right)

2. SUSTAINABLE DESIGN

The Green Atrium is an experimental building that offers commercial, educational and community spaces. Climate responsive design approach is adopted to facilitate the use of natural resources. The Green Atrium incorporates active and passive sustainable design considerations, which aims to provide a green hub to promote holistic lifestyle through interactive engagement and sustainable feature installations. Regenerative model is adopted to create a circular economy within the site, extending the life of resources by feeding waste from one system as the resource for another. A total of 28 key sustainable features are categorized to 5 fundamental elements: energy, air, water, food and waste. Each element creates its own cycle and interlink with each other to form a semi-self-sustained system. Furthermore, The Green Atrium is the first project to install the award winning ventilation device, the Air Induction Unit (AIU), providing an innovative and revolutionary experience to building users. The sustainable design features at The Green Atrium are shown in Figure 2.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

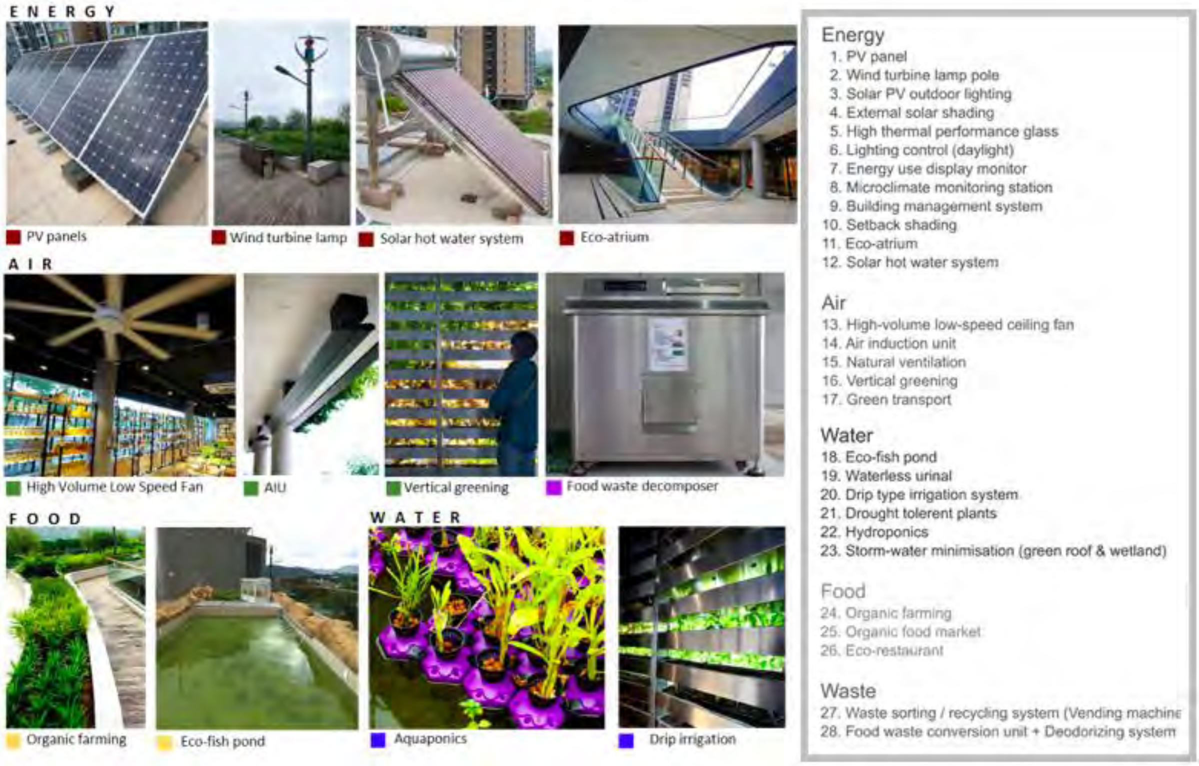

Figure 2: Sustainable features at The Green Atrium

2.1 Climate responsive design

Buildings account for a major portion of total energy use in Hong Kong, nearly 70% of overall energy were consumed by buildings in 2013 (EMSD, 2015). The Green Atrium has adopted both passive and active strategies for de-carbonization. Particularly, climate responsive design was employed from the early architectural planning stage. The architectural design is optimized to accommodate spatial functions and passive design features. The design begins with a bounding volume with maximum GFA of approximately 2,200m^2. The intermediate level is opened to create a fully shaded semi-outdoor space. An atrium is added to enable fresh air flowing across the building and removing accumulated hot air. The permeability and shallow floor plate depth enhance daylight penetration into the interior space. The microclimatic responsive façade reduces heat exposure on building surface and provides visual comfort for building users.

Furthermore, environmental simulations are carried out to optimize the climate responsive design in terms of natural ventilation, daylight and solar radiation. Starting from a conventional built form, daylight penetration and natural ventilation are inadequate and the facade is exposed to high level of solar radiation. The green wall at 2/F and the setback shading at 1/F effectively reduce the exposure of solar radiation. A large void is added in the middle of the building mass to enhance daylight penetration and natural ventilation through the building. Lastly, high performance XIR glass is installed at G/F shop front to reduce solar load while maintaining exceptional daylight performance for the commercial space. The climate responsive design process using environmental simulation is shown in Figure 3.

Climate responsive design is an effective approach to reduce building energy use and The Green Atrium is setting an example for this design approach.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

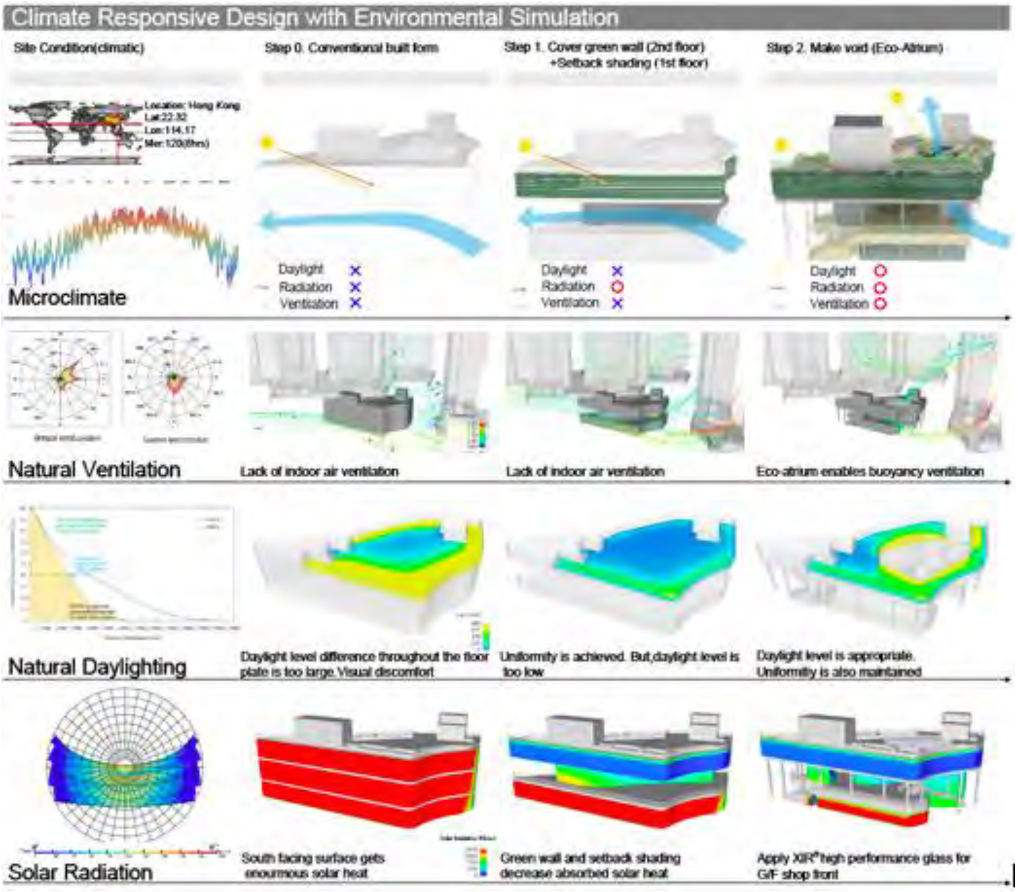

Figure 3: Environmental simulation process for optimizing climate responsive design

2.2 Circular economy

Circular economy is a system that aims to eliminate waste through restorative and regenerative by design (EMAF, 2013). In The Green Atrium, the design of the biological and mechanical systems are based on circular economy, where waste from one system is eliminated by feeding as the resource for another. For example, food waste from the restaurant is being converted into fertilizer and fish feed by the food waste decomposer for on-site farming and fish cultivation. The vegetable and fish crops from on-site farming and fish cultivation would be freshly served at the restaurant in The Green Atrium, thereby creating a closed loop of commodity supply. Another example is the aquaponics system at R/F. It mimics water filtration and recycling process in natural ecology, where the polluted water in fish pond with fish waste is being fed to the hydroponics as nutrient for plants. The in the hydroponics flows back to the fish pond after the toxic substances are removed by the plants. The food waste cycle and system provisions at The Green Atrium are shown in Figure 4.

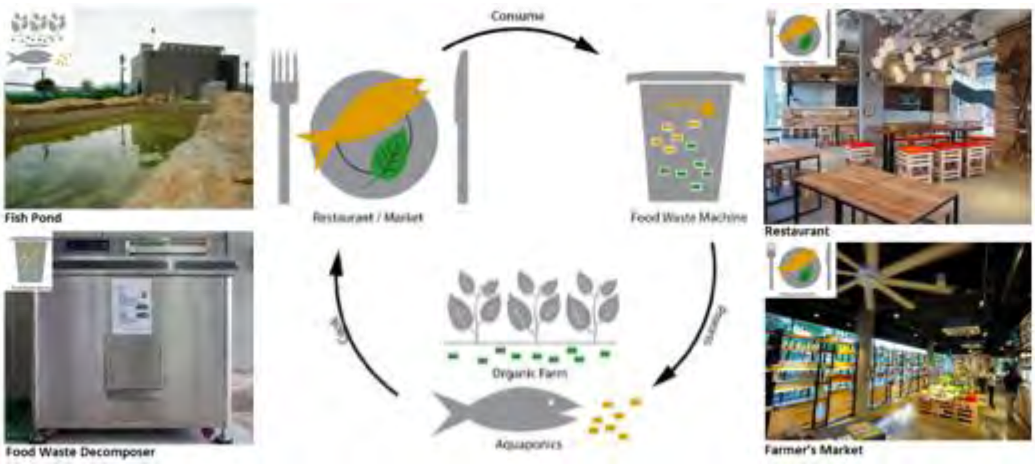

Figure 4: Food waste cycle and system provisions at The Green Atrium

2.3 Innovative technology

The Air Induction Unit (AIU) is a displacement ventilation device stimulating breeze-like moving air for enhanced comfort. It has a minimal and aesthetically pleasing blade-like design that operates using the principle of induction in aerodynamics. It is designed to enhance the thermal comfort by inducing a large volume of gentle air movement. The AIU aims to be an alternative to other means of mechanical ventilation such as industrial fan and ceiling fan.

The AIU is installed at the 1/F semi-outdoor space and it consumes about 30% less energy than using conventional fans. The AIU has no mechanical part exposed to its service environment. It is safer and easier to clean and maintain compared with conventional industrial fans, which lead to lower maintenance cost. The installation of the AIU at The Green Atrium is shown in Figure 5.

The benefits of the AIU is intended to be demonstrated at The Green Atrium. With wide-adoption, the AIU would revolutionize the industry and bring positive impact to the environment and the community.

Figure 5: Installation of AIU at The Green Atrium

3. SUSTAINABLE OPERATION

The operational phase is the longest phase during the lifecycle of a building. It is therefore important to ensure the building is being operated sustainably by taking environment, social and economic aspects into consideration. The sustainable operation at The Green Atrium forms a complementary linkage where commercial activities and environmental protection can co-exist and maintains a symbolic relationship that neither one can be neglected. The upper energy hub sustainably converts natural resources into energy for The Green Atrium, while commercial activities in the lower block provides economic support for the operation of The Green Atrium.

3.1 Post-occupancy evaluation

Previous study shows “over 80 percent of greenhouse gas emissions take place during the operational phase of buildings” (UNEP, 2009). For this reason, it is crucial to ensure the building would be operated in an efficient manner. After a building is designed and constructed, the systems often do not operate as specified during operation. Post-occupancy evaluation (POE) is an evaluation and feedback process that enables design verification and continuous improvement of building systems (HEFCE, 2006).

In The Green Atrium, sensors and meters are installed to monitor energy usage, water usage, renewable energy generation and microclimate of the development. A dashboard displays real-time data of building performance and local climate, allowing visitors and operators to easily view, monitor and evaluate the building performance. The measured data during first year operation shows the energy use of The Green Atrium is 70.8% more efficient in comparison to the energy use benchmark developed by Energy Efficiency Office of the Electrical and Mechanical Services Department for similar building type (EMSD, 2016). The detailed monthly energy consumption breakdown for various energy use and the POE equipment installed at The Green Atrium are shown in Figure 6.

The implementation of POE at The Green Atrium showcases the benefits towards sustainable building operation. It sets a new standard of building operation for future developments.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

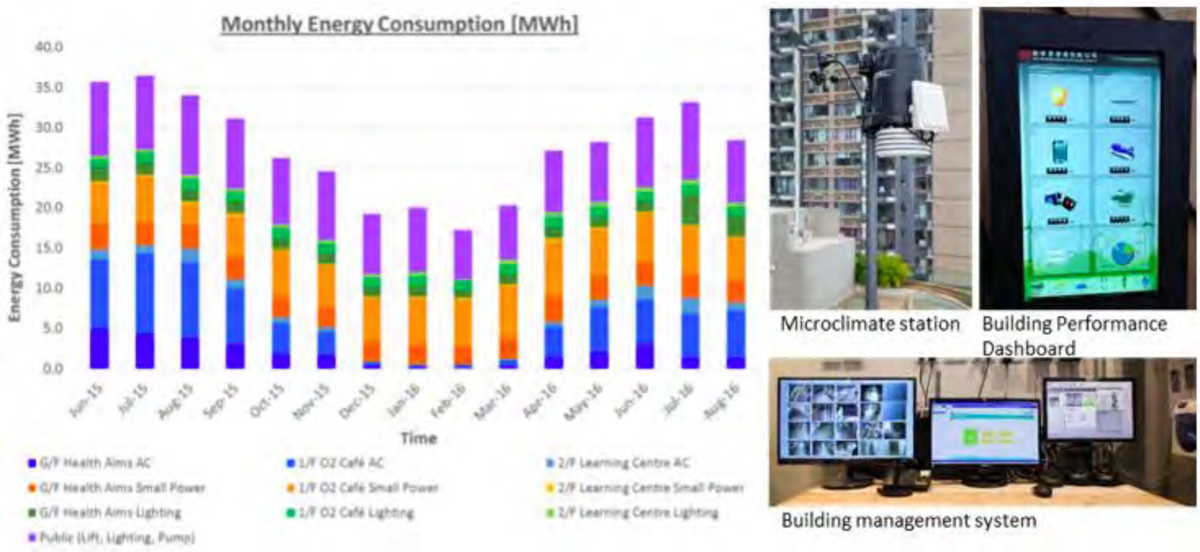

Figure 6: Monthly energy use breakdown from Jun-15 to Aug-16 (Left) and POE Equipment (Right)

3.2 Green community movement

Located within close proximity of agricultural land, vernacular villages and the Country Park in Yuen Long, The Green Atrium forms a focal station to promote sustainable technologies, green community events, as well as organic food production for the neighbourhood. To promote local farming and organic food products to the communities, The Green Atrium provides a venue to sell organic food products at the G/F market and a restaurant to introduce farm-to-table concept at 1/F restaurant. Themed events are organized at The Green Atrium and regular tour are hosted at the 2/F exhibition and R/F educational spaces, during which visitors could understand the relationship between lifestyle, health and sustainability. The schedule of accommodation of the building is summarised in Figure 7.

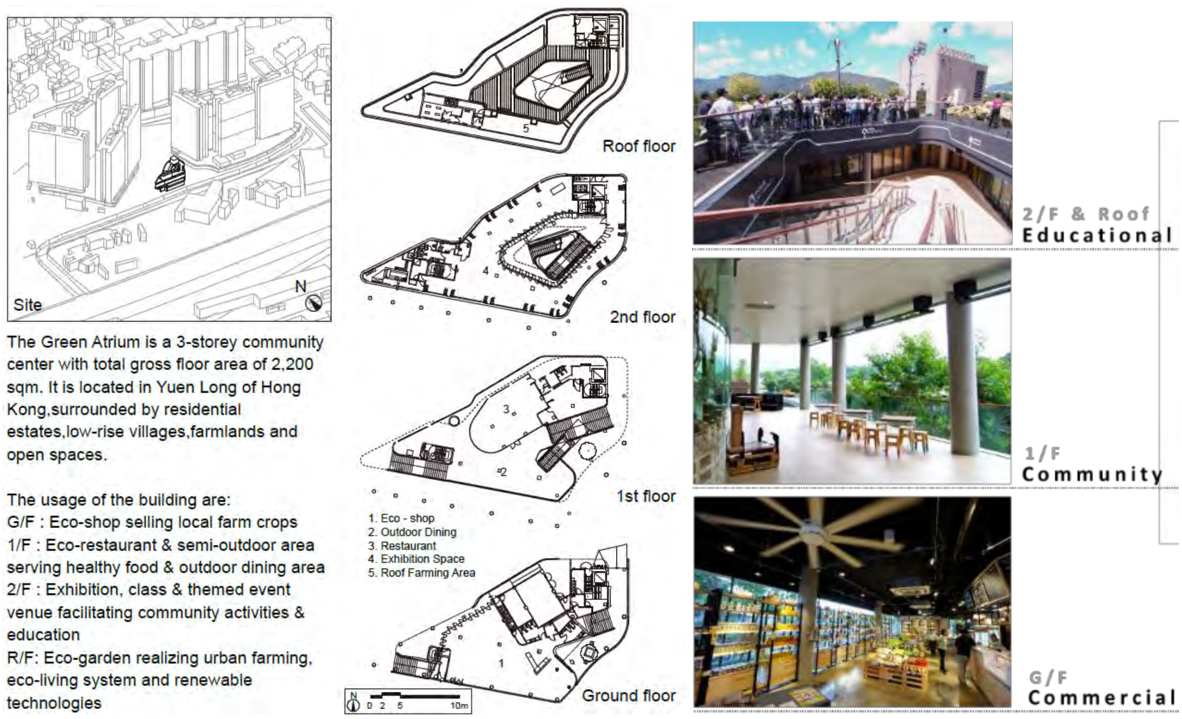

Figure 7: Spatial function breakdown of The Green Atrium

In addition to be a green hub for the community, The Green Atrium equips with infrastructures to facilitate sustainable operation in the neighbourhood. The adjacent residential development, Park Signature, is designed with large openings in the clubhouse for natural ventilation to reduce air-conditioning energy use when weather permits. The real-time local climatic data measured by the microclimate monitoring station at The Green Atrium provides useful information for the clubhouse operator to use natural ventilation according to the pre-determined thermal comfort criteria.

All in all, The Green Atrium is not only a sustainable building by itself, but it is also a facilitator to transform the local community into a sustainable neighbourhood.

4. CONCLUSIONS

The Green Atrium is a role model of sustainable building, it is aimed to bring benefits to all three dimensions of sustainability, including the social aspect which is often being neglected. Sustainable design concepts are incorporated from the beginning of the architectural planning stage with objectives to provide sustainable operation.

The Green Atrium provides an “experiential ground” allowing new sustainable concepts and prototypes to be put to test, review and improve. The concepts and technologies learnt would be useful for successful adaptation in future projects. New ideas are being implemented in The Green Atrium to push the forefront of sustainability. Climate responsive design, circular economy and AIU are adopted to revolutionize the building construction industry. POE infrastructures are installed to enable performance verification and continuous improvement. Lastly, commercial and educational facilities are provided for building social engagement and driving green movement in the community.

ABSTRACT

As mother nature, natural resources and heritages worldwide are threatened by the rapid pace of urban growth and development, The Chinese University of Hong Kong (CUHK) has demonstrated her commitment to develop a "Sustainable Green Campus" through intensive studies, engagements and design innovations.

The Library Extension project completed in 2012 featured a minimalist and sustainable design that cleverly integrated a love of nature with respect of history, and demonstrated how development needs were balanced with preservation concerns. The tough challenges of the project included the following aspects:

- Preserving CUHK's history, values and collective memories
- Design for quality learning environment
- Exploring opportunities for developing underground space
- Green Building design and efficacy
- User-oriented design and knowledge sharing

The project has explored various new frontiers and opened up opportunities for sustainable development. While the iconic University Mall and Garden dating back to the 1960s were preserved by the innovative design of a generous Learning Commons in the basement, the much loved swifts habitat on the existing Library building was successfully preserved through careful studies and measures. The project has obtained the highest HKBEAM Platinum rating for her sustainability and energy conscious design and was honoured with Green Building Award in 2014.

Keywords: library, green building design, sustainable neighbourhood ding

1. INTRODUCTION

The University Library Complex consisted of three independent buildings with little interactions with each other as the original 1970's main library, its 1980's annex, and the latest new extension were built decades apart. This project involved the construction of a new Extension and spatial re-organization of the two existing buildings;

merging together and transforming into a coherent whole where different learning activities could come together in the open and free planning spaces.

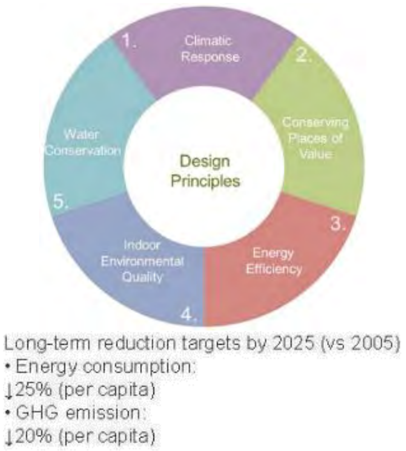
2. PRESERVING OUR HISTORY, VALUES AND COLLECTIVE MEMORY

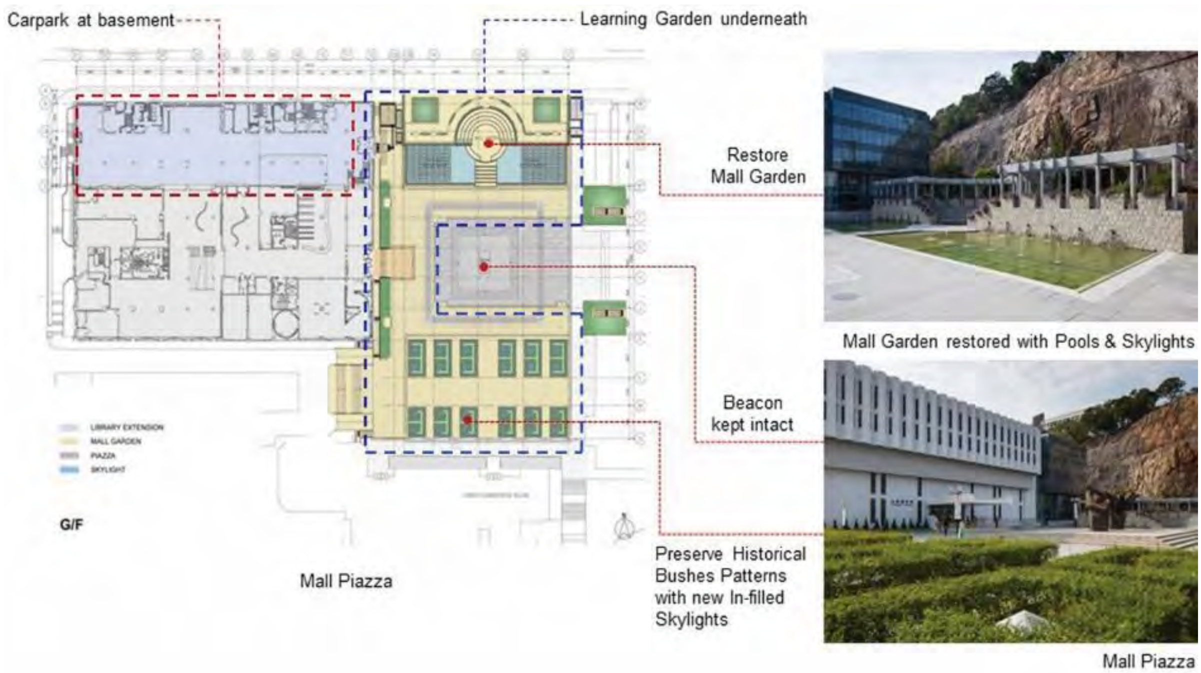
2.1. Embedment into the campus environment

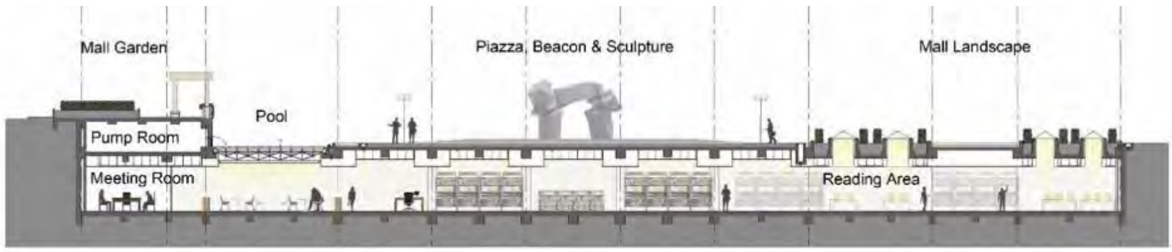
The project addressed the core values of CUHK's Campus Master Plan and Vision of "combining the tradition with modernity, and bringing China and the West together" and sustainability targets.

The new Extension annexed to the iconic University Library preserved the spatial quality and ambient of the University Mall with complimentary massing and height same as the adjacent buildings. The simple and unadorned design preserved the architectural integrity of the central axis of the University Mall and the adjacent landmarks, including the Roman-style garden 'Forum' and the 'Beacon' on which the sculpture 'Gate of Wisdom' stands.

The project featured a minimalist, sustainable, preservative and conservative design that integrated nature with respect to its history; a huge basement was developed under the 'Forum' and the 'Beacon' to minimize the visual impact.







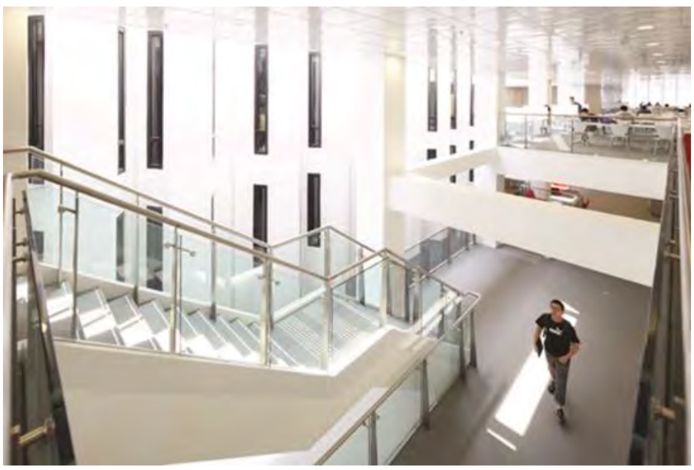
2.2. Preserving historical façade

Inside the Extension, the historical façade of the University Library was preserved to become a feature wall for the atrium space, lighting up by the skylight above, serving as a visual articulation of Meeting the Old and the New.

2.3. Preserving swift habitats

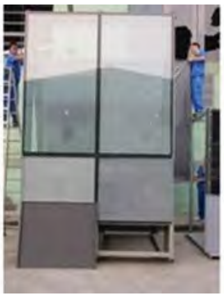
CUHK is home to the largest colony of house swifts in Hong Kong and the eaves of the University Library house over 500 house swifts. To minimise the impact on the house swifts due to the construction of new Extension, CUHK invited consultants to carry out ecological study and was suggested to incorporate bird-friendly glazing for the new Extension and to install artificial nests to allow birds' migration to the south façade of the University Library before the construction.

Bird-friendly façade with fritted pattern glass panels was adopted for the new Extension. Mock-up and tests were also conducted on site to ensure no unwittingly kamikaze performs on the external wall of new Extension.



Preservation of historical facade

Preservation of swifts habitat



Bird-friendly façade design with fritted glass pattern

3. ENVIRONMENTAL QUALITY

The project aimed at creating quality space conducive to the physical, psychological and emotional needs for learning and interactions.

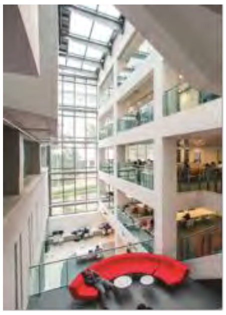
3.1. Transparency and daylight

External walls of the Extension with low-E double glazing reduced solar heat gain and maximized daylight penetration. It invited lovely nature environment into the study areas during daytime and displayed the indoor study life to the external campus at night.

3.2. Spatial connectivity

As part of the spatial reorganization for the entire Library complex, a central void with a new grand staircase platform, the 'Reading Garden', was inserted into the existing library. This physical connection not only opened up the interiors but also enhanced the inter-floor communication and interactions among students for an active learning environment. The existing skylight above further brought daylight into the renovated library floors for both environmental comfort and energy saving.

Reading Garden



Atrium

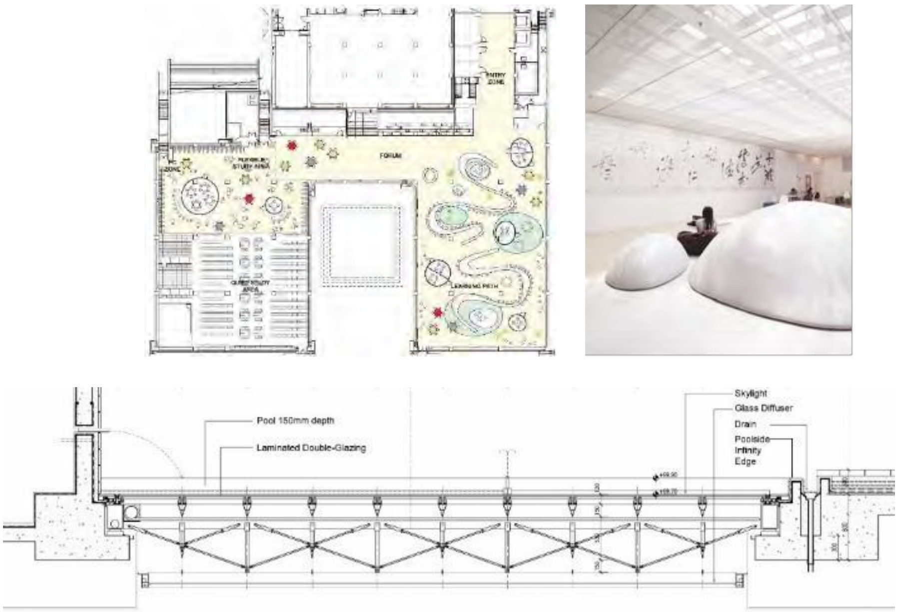
3.3. Acoustics

Double glazing façade panels provided effective acoustic insulation from the adjacent road traffic to create a quiet learning ambience. Variable air volume (VAV) A/C system was also adopted to minimize noise generation in the interiors. The noise level was mitigated effectively from 80dBA road traffic noise with busy school buses to 35dBA inside the library spaces.

4. INNOVATIVE DEVELOPMENT OF UNDERGROUND SPACE

With an innovative design, the extensive basement of about 4,500 sq.m. was designed into a colourful 'Learning Garden' which presented a new image for library interiors: spacious, cosy and bright. While chairs in vibrant colours and 'Bubble' shape workrooms were available for students having small group discussions or studying alone, the 'Learning Garden' opened up its interiors to glittering daylight and green surroundings above through an extensive glass ceiling of under-pool skylights. These innovative skylights consisted of a thin layer of water on top of laminated double glazing; the assembly provided desirable thermal insulation for the 'Learning Garden' below.

Inside the Learning Garden, one could find the long, sinuous, wavy, S-shaped table, the 'Learning Path', weaved students together through its curves and defined a series of study zones. This ambiguity between public and private, openness and enclosure, allowed for different modes of study and flexible use of spaces. Subtle variations in the height, width, and shape of the Learning Path provided a datum line for students to discover new ways of learning.



Learning garden and under-pool skylights

5. EFFICACY

The University Library Extension project was honoured with the FuturArc Green Leadership Award 2016. As highlighted in the 10th Anniversary Edition Vol. 48 of FuturArc magazine:

"To align with sustainability policy of The Chinese University of Hong Kong, many energy-efficient features have been adopted for the project. Rainwater and condensate water are collected to serve irrigation, cooling and flushing purposes. Adjacent buildings share a centralised chiller plant, hence reducing the peak electricity demand. To maximize energy savings, different types of sensors have been adopted: fresh airflow control via carbon dioxide sensors and heat pipes; car park ventilation control via nitrogen dioxide and carbon monoxide sensors; a highly efficient heat pump unit for dehumidification and space heating; and PVC panels to generate energy for landscape lights."

Façade area was reduced effectively by designing the new Extension as an attachment to the original University Library. Extensive basement construction of about 4,500 sq.m. also reduced materials consumption considerably versus conventional superstructure and building envelope construction.

With the objective to preserve the historical Mall Garden, every granite stone of the historical Mall Garden was surveyed, dismantled and reinstalled after the basement construction.

6. USER-ORIENTED DESIGN AND KNOWLEGDE SHARING

This project aimed to develop a people-oriented study space and to provide a healthy and comfortable study environment. Besides making good use of natural daylight and the surrounding greenery, the highly flexible design of the learning commons and its IT backbone further encouraged users to explore their own ways of study with unlimited possibilities. With the implementation of Green product and purchase policies, environmentally–friendly materials and finishes were used throughout the entire building; furthermore, interior lighting and air conditioning were optimized with building automation and sensor systems to achieve excellent indoor air quality and energy saving.

The Library Extension was well received by the users as well as the visiting public and scholars since her completion. It has provided CUHK with an excellence model for education and knowledge sharing in Green Building Design and Sustainability Development. Collaboration with the academia for case studies and data analysis on building performances was also in progress.

Users' feedback
University Librarian - Ms Louise Jones's Comments

"The Learning Garden at the University Library – a most wonderful innovation and a much welcome collaborative space for students and for the Library to make new offerings. It is allowing us to reconceptualize the Library."

FuturArc Green Leadership Award 2016 **juror's comments**

"A project must tell the story of where it is, of people and space … The entries display a good cross section of innovative and ecologically responsive designs that respond to different social, cultural and climatic contexts…articulate a genuine sense of sustainability, blending in neatly with its surrounding environment; harnessing the use of natural resources a topography..… achieving exquisite spatial qualities, fitness for purpose; and a comforting environment."

Green Building Award 2014 - Hong Kong Green Building Council Merit Award - New buildings category (completed buildings) **jury's cit**ation

"A comfortable environment with a natural appearance has been created for learning. Attention to the interface between indoors and outdoors may further enhance its humanistic quality."

ABSTRACT

China is facing an increasing challenge of aging population. United Nations projected that a third of Chinese population will be over 60 by 2050. The requirement for the state and private housing provision for the elderly is emerging due to the absence of children caring for their parents. A revolution in architectural design for the aging population is expected to deal with this unprecedented situation.

In addition, care homes have high energy requirements 24 hours a day and 7 days a week as well as high level comfort requirement. It is important to improve energy efficiency of care homes to tackle the overall fuel security and climate change as well as to reduce the running cost in order to reduce the finance burden in an aging society. However, their energy consumption profile and thermal requirements present both opportunities and challenges to energy positive design which can generate more energy than it consumes.

The paper aims to investigate the potential to deliver nearly zero-energy home design in cold climate in China with a system approach and innovative technologies which have been established in research and practice in the UK. A systems approach for energy positive care home design consists of four steps: 1) reducing internal heat loads, 2) using passive design strategies, 3) applying efficient HVAC systems and 4) integrated renewable energy supply and storage systems. Building simulation is used to optimise the design in each step in order to achieve the most practical design solution.

In this study, a typical care home in China is used to provide the geometry information, and building simulation will be carried out with local context and climate to evaluate the impact of different design steps and strategies. Furthermore, the impact of each design strategy on energy consumption will be discussed.

Keywords: nearly zero-energy care home design, building energy simulation, high performance building

1. INTRODUCTION

China's 13[th] Five-Year Plan (2016-20) aims to reduce overall energy use by 15% per unit of GDP and carbon emissions by 18% by 2020, compared to the 2015 level (Seligsohn, 2016). In addition, China is facing an increasing challenge of an aging population with a third of its population over 60 by 2050 (Denison and Ren, 2014) An urgent requirement for the state and private care home provision is emerging to replace the traditional model of children caring for their parents at home. Care homes have high energy consumption due to 24/7 operation and a high level comfort requirement. Therefore, it is important to improve the energy efficiency of care homes to tackle the overall fuel security and climate change, and to reduce running costs in order to reduce the financial burden in an aging society.

In order to deliver nearly zero-energy buildings and energy positive buildings, it is important to adopt a holistic systems approach. A systems approach is a sustainable design method that integrates across site planning, architectural design and building engineering, which can provide lower running costs and contribute to reducing the demand on the energy supply infrastructure. A holistic systems approach consists of four steps (Figure 1): 1) Reduce energy demand by using energy efficient lighting and equipment to reduce direct energy usage as well as the heat gains to the space; 2) Apply passive design strategies in relation to site planning, building form and building fabric, to utilize free energy (mainly solar and wind), and reduce heat gains in the cooling season and heat losses in heating season; 3) Use efficient HVAC systems to further reduce energy demand; 4) Integrate renewable energy supply and storage systems to decarbonise remaining energy requirements.

2. CURRENT STANDARD OF PUBLIC BUILDING DESIGN IN CHINA

The China Design Standard for Energy Efficiency in public buildings (GB50189-2014) developed by the Ministry of Construction is playing an important role in regulating the energy efficiency in commercial buildings in China (Hong et al., 2015). It aims to reduce energy consumption by 30% compared to the 2005 standard. GB50189-2014 provides prescriptive compliance pathway for new building construction and retrofits, covering design standards for building envelope, HVAC systems, lighting, plug loads, water and drainage systems, domestic hot water systems and renewable energy supply systems. All building sub-systems and components must fulfil the prescriptive efficiency requirements.

In relation to energy demand, the GB50189-2014 sets the maximum Lighting Power Density (LPD) for different room types. Table 1 compares the LPD requirements of different countries. The British and American standards are more generous in energy usage in lighting, while the Swiss best practice can provide good lighting condition with less LPD due advanced lighting technologies.

	GB 50189-2014	CIBSE	ASHERAE90.1-2013	SIA180
Lobby	9.0	10-20	11.5	5.6-8.3
Office	9.0	8-12	12	9.1-12.5
Ward room	5.0	9.0	6.7	2.9-4.5
Exam/ treatment	15.0	15.0	18.0	11.6-15.9
Dining/ lounge room	--	--	--	4.6-6.9
Kitchen	--	--	--	12.4-17.0
Circulation area	--	--	--	4.6-7.0

Table 1: LPD requirements of different countries (W/m^2)

Regarding passive design strategies, the GB50189-2014 for cold zone sets the minimum requirements for building fabric. Compared to the Building Code in the UK and US, these requirements are less stringent (Table 2). This reflects the relative poor market penetration of high performance envelope technologies in China, as well as the importance of developing such materials and technologies suitable for the building industry in China (Hong et al., 2015). In addition, the requirements for opaque components are related to shape co-efficient, while the standards for windows are related to Window to Wall Ratio (WWR) and the orientation of the windows.

		GB 50189-2014		Building Regulation Part L 2014		ASHERAE 90.1-2013
		Shape co-efficient<=0.3	0.3<Shape co-efficient<=0.4	Min.	Recipe	
External wall		0.50	0.45	0.35	0.26	0.291-0.513^
Roof		0.45	0.40	0.25	0.18	0.119-0.184^
Ground floor		0.50	0.45	0.25	0.22	1.263-1.765^
Floor		0.50	0.50	0.25	0.22	0.188-0.321^
Glazing	U-value	2.00-3.00*	1.80-3.00*	2.20	1.60	1.82-2.84^
	G-value	0.35-0.52*	0.42-0.588*	-	0.40	0.40
Party wall		1.0	1.0	-	-	-
Infiltration		-	-	10m³/h/m²	3m³/h/m²	-
Note		* The range depends on different WWRs from 0.2 to 0.7. G -values mainly applies for east, west and south windows. ^ The range depends on different construction types.				

Table 2: Fabric efficiency U-value (W/m²/K)

In relation to building service systems, the GB50189-2014 sets the minimum efficiency requirements of HVAC systems. The standard for efficiencies of HVAC systems in China is lower than the relevant standards in the UK and the US (Table 3).

		GB 50189-2014	Building Regulation Part L 2014	ASHERAE 90.1-2013
Chiller efficiency	Water cooled	4.1-5.8	4.5	4.69-6.29
	Air cooled/ evaporative	2.6-3.0		2.4-2.8
Unitary air conditioning	Water cooled	2.9-3.5		3.51-3.6
	Air cooled	2.4-2.75		2.78-3.81
Boiler		86-90%	91%	-
Specific Fan Power		0.27W/m³/h	1.8W/L/s	-

Table 3: HVAC systems efficiency (W/m²/K)

In relation to renewable energy supply and storage systems, the GB50189-2014 sets out guidelines for the use of solar power and ground source heat pumps. An evaluation of solar resource is required before the detailed design of a PV system. In addition, the minimum efficiency for heat pump units is defined. However, there is no mandatory requirement or guidance for the renewable energy storage systems.

The following section will introduce the process to investigate the energy performance of a typical care home in Beijing with this systems design approach.

3. RESEARCH METHODOLOGY

3.1 Research flow

This study was conducted in three steps: 1) Select a typical design of care home, located in Beijing; 2) Develop modelling frameworks for current practice, as well as for nearly zero-energy design, including parameters for internal gains, building fabric, HVAC systems and renewable energy supply and storage systems; 3) Conduct building energy simulations for (i) Current practice and (ii) Nearly zero-energy design (good and best practice). The simulation results of monthly and annual energy consumption were compared and discussed.

3.2 Typical care home design

There are two main categories of elderly accommodation in China: 1) Care centres which are staffed 24 hours a day with provision of care; 2) Residential development designed specifically for the elderly but without the level of medical care. This study focuses on the first categories.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

A typical good care home design in Beijing is selected (Figure 2). The building is 5 stories above the ground with a floor area of 2100m² for each floor. The floor to ceiling height is 3.3m. The shape coefficient is 0.195, while the WWR is 0.2/ 0.3. It has rooms for 2, 4 and 6 occupants with a capacity of 216. The design of the typical building has carefully considered the space for wheelchair access, good daylighting (all rooms facing south) and natural ventilation potential, as well as good vision.

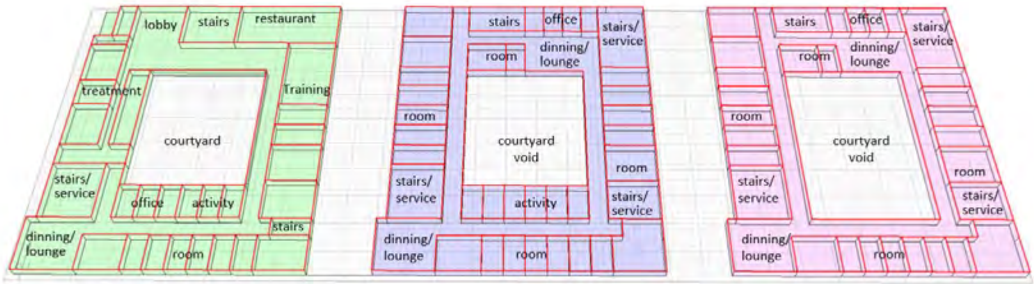

Figure 2: Typical care home design

3.3 Modelling frameworks

Building energy modeling is used to investigate the performance of the typical care home design. Heat Transfer in Buildings version 2 (HTB2), a dynamic building energy model developed at the Welsh School of Architecture since 1970s, has been used in this study. A series of extensive validation has been conducted, including the IEA Annex (Faber, 1980), IEA task 12 (Neymark et al., 2011) and the IEA BESTEST (IEA, 2006). Based on local climate data, building layout and construction details, shading masks, building services, and occupation profiles for people, equipment and lighting, HTB2 can simulate hourly and annual energy consumption and internal thermal conditions. In this study, the building services have been simplified by using an average efficiency and Coefficient of Performance (COP) for heating and cooling systems. The energy generated by PV systems has been calculated using an average PV efficiency.

3.3.1 Current practice

The main input data for current practice are based on the threshold of GB50189-2014 (Table 4). Various studies (Zapata-Lancaster and Tweed, 2014) have found that clients tend to comply to building regulation only.

Internal gains (W/m²)			Ventilation	Fabric efficiency U-value (W/m²/K)	
Rooms	Lighting	Plug load	Fresh air	External wall	0.50
Lobby	9.0	9.5	10L/s/person	Roof	0.45
Office	9.0	15.0	10L/s/person	Ground floor	0.50
Ward room	5.0	6.0	10L/s/person	Glazing	2.7
Exam/ treatment	15.0	30.0	10L/s/person		G=52%
Dinning/ lounge	6.9	3.0	10L/s/person	Systems	Boiler efficiency= 88% Cooling COP=3.2
Kitchen	15.9	50.0	30L/s/person		
Circulation area	7.0	0	10L/s/person		

Notes:
- The building is used 7 days a week, 24 hours a day.
- The designed room temperature used in the simulation is 21 (winter) to 26ºC (summer).
- The occupant's load is based on the design.
- An infiltration rate at 10m³/h/m² @50Pa is applied, based on the minimum requirement of British Building Regulation Part L 2A.

Table 4: Simulation input data for current practice

3.3.2 Nearly zero-energy design

As mentioned in the introduction section, a systems approach integrating four design steps can maximize the energy saving.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

First of all, energy efficient lighting systems and equipment should be used to reduce directly consume energy, as well as to decrease cooling load of air conditioning or ventilation systems by reducing heating gains during cooling season. An energy consumption labelling scheme has been developed in Europe to indicate the energy efficiency of appliances and lighting systems in terms of a set of energy efficiency classes from A+++ to G on the label (DEFRA, 2011).

Second, better efficiency of building fabric is required rather than fulfil the minimum requirements. New materials and technologies have entered the construction market, such as multi-layered glazing systems and structural insulated panel systems. For example, the benefits of a multi-layered glazing system with a lower U-value and a lower G-value are: 1) reduce annual heating and cooling consumption, 2) reduce peak loads to decrease capacity of service systems and 3) improve thermal comfort due to better internal glazing surface temperature.

Third, an all-air system can be suitable for care homes to improve indoor air quality, avoid the risk cause by high radiator surface temperature and lead to flexible furniture arrangement. Heating and cooling is provided through a Mechanical Ventilation and Heat Recovery (MVHR) system. It works by extracting heat from the outgoing air to warm incoming air in heating season via an air to air heat exchanger within the MVHR unit. The heat recovery rate of modern MVHR systems can reach 85%. In addition, a dark coloured Transpired Solar Collector (TSC) can be installed on the south and west facing wall in between windows on the upper floors. It is made of a layer of metal cladding with perforations, installed at several centimetres from a building wall to form a cavity (Croitoru et al., 2016). Figure 3 shows the working principles of a typical TSC. It can preheat the outdoor air supply prior to the MVHR in heating season, and the heated air in the cavity can be used to heat domestic hot water in cooling season.

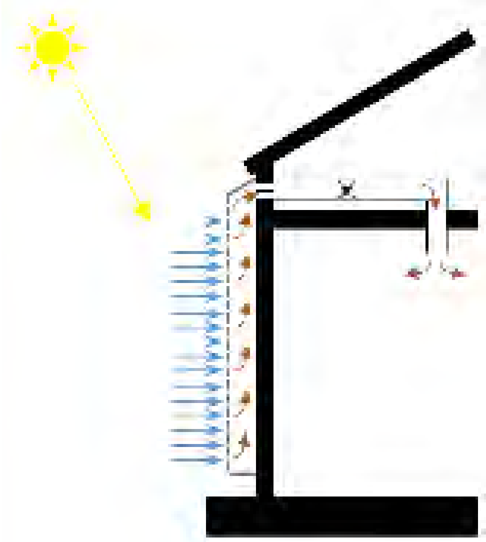

Figure 3: Transpired solar collector figure

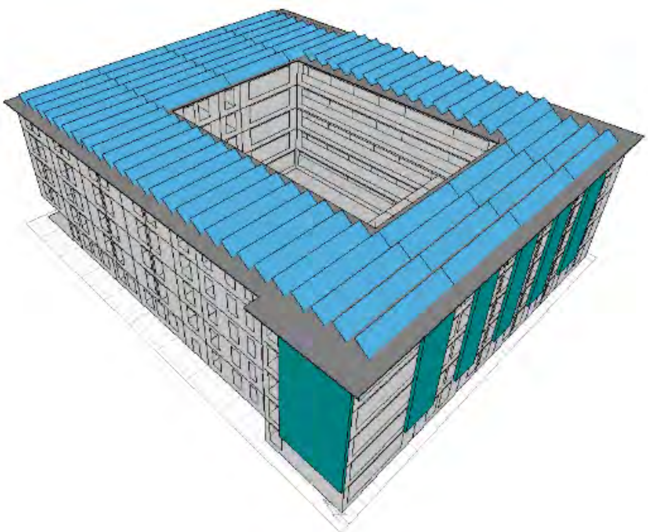

Figure 4: Near zero carbon care home design

Fourth, monocrystalline silicon PV panels (Mono-Si), which is currently the most efficient photovoltaic technology with the module efficiency of 17% can be installed on the roof to decarbonize the energy demand. If more energy generation than consumption, the PV system can be linked to a battery storage before connect it to the grid to reduce the pressure on the grid. Figure 4 shows the installation of PV panels on the roof (blue) and UTSC on the south and west facade from first floor to the top floor (green) on the typical care home building.

Data used in the building energy simulation for nearly zero-energy design is summarized in Table 5.

</table>

Table 5: Simulation input data for nearly zero-energy design

This next section will present the simulation results for both current practice and step by step nearly zero-energy design cases.

4. RESULTS AND DISCUSSION

Table 6 shows the monthly heat balance and energy demand of the simulated cases, as well as summarizes annual energy consumption of heating, cooling and lighting equipment. The current practice is the base case with the minimum requirements for building fabric and LPD required by GB50189-2014 for cold zone. The simulation results show that the main heat gain throughout the year is incidental gains (including heat gains from occupants, lighting and equipment) and solar gain. The incidental gain is around 7kWh/m² every month, while the solar gain ranges from 3.4 to 6.2kWh/m² in winter and summer months. The main heat loss is through ventilation (including fresh air requirement and infiltration) and fabric. The ventilation loss ranges from 12.1 to 14.9kWh/m², while the fabric loss ranges from 8.8 to 10.9kWh/m² through winter months. Due to large heat losses from ventilation and fabric, heating will be required from October to February. In addition, cooling will be required from March to August. The total heating and cooling demand is 45.0kWh/m² and 41.5 kWh/m² respectively. The total energy consumption for heating, cooling and lighting equipment is 121.8kWh/m².

With energy efficient lighting and equipment, the incidental gain decreases, which leads to an increase in heating demand, and a reduction in cooling demand. The overall energy consumption for heating, cooling and lighting equipment will be reduced by 11.6% to 107.6kWh/m² for the good practice case, while by 16.6% to 101.6 kWh/m² for the best practice case.

With improved building fabric, the solar gain to the space decreases by one third and two thirds due to the reduction of g-values for the good and best practice cases respectively. The ventilation and fabric loss is reduced due to the improvement of the air tightness and u-values. The overall energy consumption for heating, cooling and lighting equipment will be reduced by 26.3% compared to the base case to 89.8kWh/m² for the good practice case, while by 34.4% to 79.9kWh/m² for the best practice case.

With the application of TSCs and a MVHR system, the overall energy consumption for heating, cooling and lighting equipment will be reduced by 57.7% compared to the base case, to 51.6kWh/m² for the good practice case, while by 67.8% to 39.2kWh/m² for the best practice case.

Cases	Monthly heat balance (kWh/m²) Incidental, Solar, Ventilation, Fabric	Monthly energy demand (kWh/m²) Heating, Cooling, Lighting & Equipment	Annual energy consumption(kWh/m²)	
Base case: current practice			Heating	51.1
			Cooling	13.0
			Lighting equipment	57.7
			Total	121.8
Step 1: Reduced energy demand (good)			Heating	57.9
			Cooling	10.6
			Lighting equipment	39.1
			Total	107.6
Step 1: Reduced energy demand (best)			Heating	61.2
			Cooling	9.7
			Lighting equipment	30.7
			Total	101.6
Step 2: Passive design (good)			Heating	40.4
			Cooling	10.3
			Lighting equipment	39.1
			Total	89.8
Step 2: Passive design (best)			Heating	42.2
			Cooling	7.0
			Lighting equipment	30.7
			Total	79.9
Step 3: Efficient HVAC systems (good)			Heating	1.7
			Cooling	10.9
			Lighting equipment	39.1
			Total	51.7
Step 3: Efficient HVAC systems (best)			Heating	0.6
			Cooling	7.9
			Lighting equipment	30.7
			Total	39.2

Table 6: Monthly heat balance and energy demand for current practice, and cases with reduced energy demand, passive design and efficient HVAC systems

Figure 5 shows the solar access of the roof PV panels. Simulation results suggests that monthly energy generated by the PV panels is not sufficient to supply the total energy consumption (Figure 6). The overall energy generated by the roof PV system is 19.4kWh/ floor area/ year, which can meet 37.5% and 49.5% of the reduced energy consumption of the good and best practice cases respectively. Although zero energy target has not been achieved, this systems approach can reduce the total energy consumption of heating, cooling and lighting equipment can be reduced by 73.5% and 83.7% the good and best practice cases respectively.

5. CONCLUSION

The paper has introduced the application of a systems approach, combining reduced energy demand, passive design, efficient HVAC systems, and the use of renewable energy systems, to deliver a nearly zero-energy care home design in cold climate zone in China. The building energy simulations have investigated the energy performance of a standard care home building in Beijing in current condition, as well as with the application of the systems approach step by step. In addition, two levels of efficiencies for equipment and building fabric on the energy consumption have been explored. The simulation focuses on energy consumption of heating, cooling, lighting and equipment.

This study identified that the proposed systems approach can nearly eliminate the heating demand, while significantly reduce energy demand in cooling and lighting equipment. With good practice, the total energy consumption can be decrease to 42.3% of the current practice, while with the best practice, the total energy consumption can be reduced to 32.2% of the current practice. In relation to the current practice and availability of advanced technologies and materials, it is not necessary and unpractical to improve the efficiencies of lighting equipment and building fabric to the level of best practice. Practical efficiencies from the good practice can provide substantial energy saving. Furthermore, due to the ratio of roof to floor area, the roof PV system cannot fulfil the total energy consumption of the building, but there is the potential for using solar energy to meet most of the energy supply with the fast development of technologies in the near future. Under current circumstance, supply the remaining energy requirement with energy from grid generated with renewable sources can the option to achieve the zero carbon target.

ABSTRACT

The Ministry of education promoted the sustainable campus development and put into the transformation of the various objectives, in which the gymnasium ventilation type in primary schools usually adopt both natural ventilation and mechanical ventilation design. However due to architectural ontology design problems, the usage of indoor area and maintenance always caused bad indoor temperature and ventilation distribution problems.

This study is to investigate the influence of natural ventilation by different openings and type on the indoor flow in gymnasium, way of thinking about how to make use of natural phenomena, and indoor and outdoor temperature difference or outdoor wind pressure and so on to achieve ventilation, fresh outdoor air is introduced to solve the problem of the heat of the indoor temperature, to ensure the effect of indoor air quality. By reviewing the different opening positions in the gymnasium space, the principle of the natural wind is controlled by the size of the window, which is used to reduce the temperature in the room, and to increase the amount of ventilation. This study aimed at different window opening position, window opening type and window aperture size, as the research change, to collect the literature research on natural ventilation in hot humid climate regions at home and abroad, as a theoretical basis to study, Computational Fluid Dynamics is used to analyse the benefits of natural ventilation, to ensure the reliability and accuracy of the numerical simulation, the amount of the actual situation in the space simulation before test data, data results are compared with CFD numerical simulations, discussion on the effect of the subsequent analysis results on the natural ventilation, analysis and comparison of different ventilation types and specifications, finally unified whole research results, provide for follow-up research planning and project proposals with reference stadium ventilation.

Keywords: natural ventilation, indoor thermal environment, gymnasium, CFD numerical simulation

1. INTRODUCTION

The architectural design of Taiwanese campuses in the past focused on educational function and space rather than sustainable management. Since the campus is the main place where students spend most of their time during school days, the quality of the environment has constant effects on their health.

Based on the quality of air in current school gyms in Taiwan, this study aims to determine the ideal ventilation pattern for school gyms to correspond to the concept of sustainable health management. In general, an effective ventilation pattern can solve the issue of indoor heat with the effect of fresh air convection, enabling the outdoor fresh air to keep flowing to the inside of the building and the indoor hot air to keep ventilating outside, so that the heat and moisture indoors can be decreased, and the indoor air quality can be adjusted.

2. METHODOLOGY

With the adoption of Computational Fluid Dynamics (CFD) simulated and analyzed by computer, this study investigated the gyms in elementary schools to examine the correlation between the opening position of the air windows and the indoor air flow. To ensure the credibility and accuracy of the stimulation data, the in-situ measurement of the actual space condition was conducted prior to the simulation. The schools where the gyms were naturally ventilated were included as the subjects of the assessment.

2.1 Subjects selection

Through the Sustainable Campus and Smart Environment Construction and Efficiency Assessment Project in Taiwan, this study investigated in situ the schools across Taiwan that had been partially reconstructed and selected those which applied to reconstruct their gyms with natural ventilation design in vertical openings, to assess the efficiency of ventilation after the gym reconstruction. The information on the selected subjects is presented in Table 1.

2.2 Relevant variable setting for CFD spatial unit simulation

The unit dimensions of the simulation model in this study were length 40 m, width 20 m, height 8 m, and total area 800 m2. Considering that there is usually a stage in a school gym since it is sometimes used as an auditorium, the dimensions of the opening were set as the type of single opening for the spatial unit simulation in this study, shown as Figure 2.

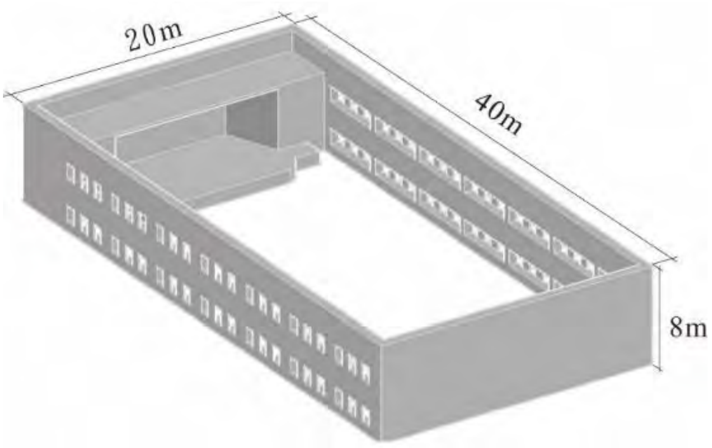

Figure 2: Model of spatial unit simulation

2.3 Opening type setting

The natural lighting surface of the simulation model in this study was 40m in length, and the net width between pillars was 450cm; therefore, the width of the window opening was 150cm. Given the different depths of the pillars on the edge of the building, the dimensions of the air windows are hard to unify; thus, it was unnecessary to modularize the dimensions of the air windows.

The subjects in this study were the elementary schools in Kaohsiung City; 34 of them have a gym on campus. After examining the types of gym openings, the results indicated that 32.4% of them belonged to Type 1, 5.9%

belonged to Type 2, 5.9% belonged to Type 3, 14.7% belonged to Type 4, 11.8% belonged to Type 5, 2.9% belonged to Type 6, 5.9% belonged to Type 7 and 20.6% belonged to Type 8. According to the eight main types of opening, the author of this study arranged the specifications and listed the information in Table 2.

Type 1	Ventilation Path
	Description	Normal windows on both the top and bottom layers.
Type 2	**Ventilation Path**
	
Description	Normal windows only on the bottom layer.
Type 3	**Ventilation Path**

3. RESULTS AND ANALYSIS OF CFD DATA SIMULATION

The percentage of average temperature and the assessment factors of indoor wind speed amenity were used respectively to discuss the influences of the sizes of one-layer or two-layer windows upon the indoor thermal and airflow environment. The items of the assessment include: analysis on the distribution of airflow fields and average temperatures, as well as assessment of the amenities and advantages/ disadvantages of different types of window openings.

3.1 Influence of one-layer windows on indoor natural ventilation of gyms

Comparing the average temperatures of Type 2, Type 3, Type 5 and Type 6, the results show that among the types of one-layer windows, French windows, whether on the top or the bottom, have a better performance concerning the thermal environment than normal windows do. Type 5, the one with French windows on the bottom layer, has the best performance. The results of average indoor temperature comparison are as follows: in Type 2, when opening normal windows on the bottom layer, the average indoor temperature is 30.3˚C; in Type 3, when opening normal windows on the top layer, the average indoor temperature is 0.1˚C lower than Type 2, equivalent to a 0.3% decrease; in Type 6, when opening French windows on the top layer, the average indoor temperature is 0.5˚C lower than Type 2, equivalent to a 1.5% decrease; in Type 5, when opening French windows on the bottom layer, the average indoor temperature is 0.7˚C lower than Type 2, equivalent to a 2.3% decrease. Figure 3 present the percentage comparisons of average temperature between one-layer normal windows and French windows.

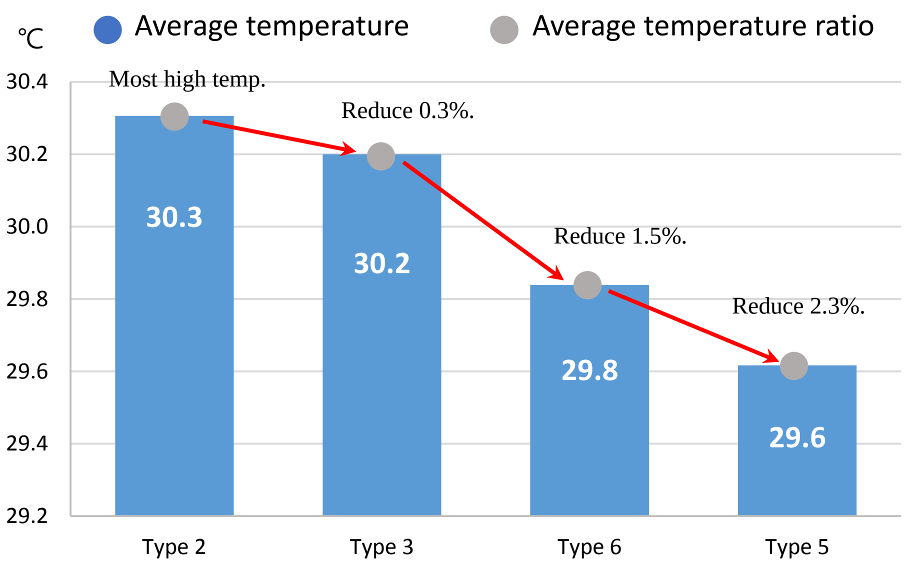

Figure 3: Model of spatial unit simulation

The data on the assessment of the indoor wind speed amenity is shown in Figure 4. The average wind speed values in Type 2, Type 3, Type 5 and Type 6 comply with the acceptable range of average wind speed amenity for indoor environment as defined in this study. To find the better influence pattern of indoor wind speed amenity in gyms, the author also examined the wind speed magnification to observe which of size windows has stronger influence on the indoor flow field inside the gym; the results show that larger windows have better performance on the speed of flow field.

In Type 3, when opening normal windows on the top layer, the average indoor wind speed is 0.13 m/s. In Type 6, when opening French windows on the top layer, the average indoor wind speed is 0.03 m/s higher than Type 3, equivalent to an increase of 1.3 times. In Type 2, when opening normal windows on the bottom layer, the average indoor wind speed is 0.19 m/s higher than Type 3, equivalent to an increase of 2.5 times. In Type 5, when opening French windows on the bottom layer, the average indoor wind speed is 0.26 m/s higher than Type 3, equivalent to a three-fold increase.

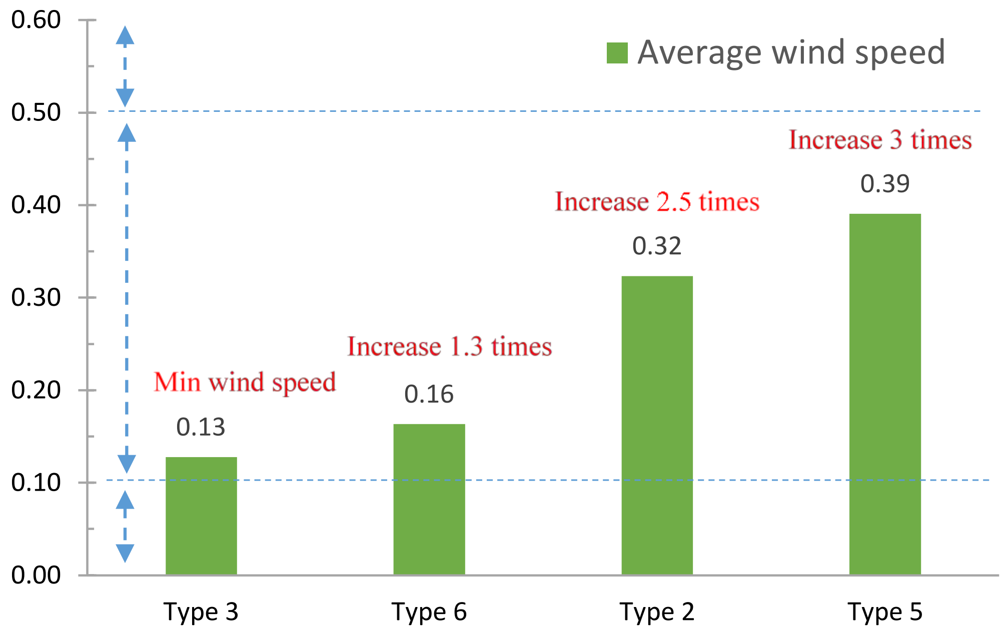

Figure 4: Comparisons of average indoor wind speed amenities among the types of one-layer windows

3.2 Influence of two-layer windows on indoor natural ventilation of gyms

Comparing the average temperature among Type 1, Type 4, Type 7 and Type 8, the results show that the two-layer windows, whether belonging to normal windows or French windows, have better performance on the thermal environment when both the windows on the top and the bottom layers are open. Two-layer windows effectively facilitate the airflow field through the effect of thermal buoyancy, and exchange the indoor airflow with the one outside through the effect of cross ventilation, thereby reducing the sultriness inside the gym. The results of average indoor temperature comparison are as follows: in Type 1, when normal windows are open both on the top and bottom, the average indoor temperature is 29.3˚C; in Type 7, when French windows on the top and normal windows on the bottom are open, the average indoor temperature is 0.1˚C lower than Type 1, equivalent to a decrease of 0.3%; in Type 4, when French windows are open both on the top and bottom, the average indoor temperature is 0.2˚C lower than Type 1, equivalent to a decrease of 0.7%; and in Type 8, when normal windows on the top and French windows on the bottom are open, the average indoor temperature is 0.2˚C lower than Type 1, equivalent to a decrease of 0.7%. Figure 5 presents the percentage comparisons of average temperature between two-layer normal windows and French windows.

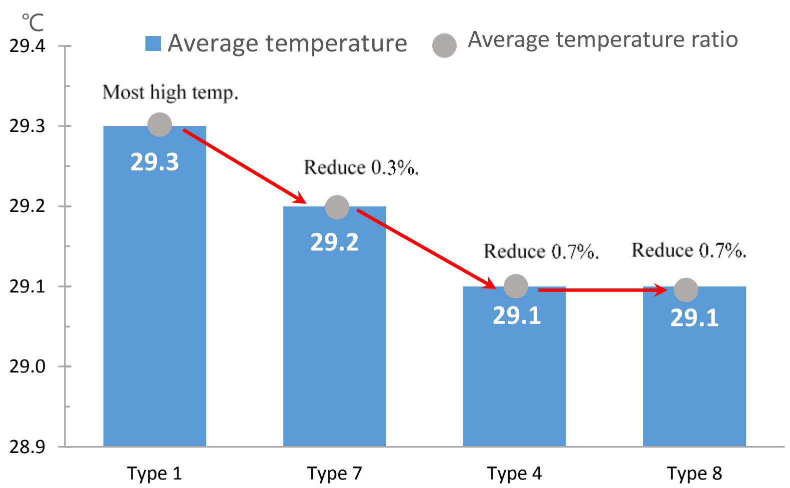

Figure 5: Comparison of average temperature of two-layer windows

The data on the assessment of the indoor wind speed amenity is shown in Figure 6. The average wind speed values in Type 1, Type 4, Type 7 and Type 8 comply with the acceptable range of average wind speed amenity for indoor environment as defined in this study. The author further assessed the other aspect of indoor wind speed amenity in gyms by comparing the wind speed magnification of the above mentioned Types to observe which size of windows has a stronger influence on the indoor flow field inside of the gym; the results show that all the Types of two-layer windows, whether French windows or normal windows, have fine performance on the speed of flow field when they are open.

In Type 7, when French windows on the top and normal windows on the bottom are open, the average indoor wind speed is 0.34 m/s. In Type 4, when French windows on both the top and the bottom are open, the average indoor wind speed is equal to Type 7, 0.34 m/s. In Type 1, when normal windows on both the top and the bottom are open, the average indoor wind speed is 0.01 m/s higher than Type 7, equivalent to an increase by 0.04 times. In Type 8, when normal windows on the top and French windows on the bottom are open, the average indoor wind speed is 0.03 m/s higher than Type 7, equivalent to an increase by 0.1 times.

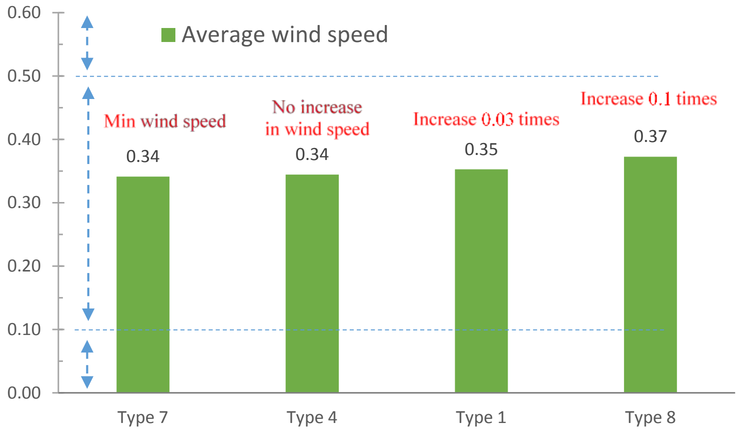

Figure 6: Comparison of average indoor wind speed amenities among the types of two-layer windows

4. CONCLUSION

4.1 Results of influence of one-layer window opening on indoor natural ventilation in gyms

According to the assessment results regarding the amenities of indoor wind speed and thermal environment, the ventilation performance of thermal buoyancy and wind action improves as the indoor heat source increases. When the deviation of the inlet wind speed is bigger, the airflow will facilitate more obvious improvement on the ventilation effect. In addition, the position of window opening can influence the speed of the indoor flow field. The author discovered that the bottom layer window openings in the gym cause a significantly greater speed of flow field than those on the top, and that bigger widows result in a better indoor thermal environment. After simulation, the study found that Type 5 has better performance on the speed of flow field and indoor thermal environment.

4.2 Results of influence of two-layer window opening on indoor natural ventilation in gyms

Two-layer windows effectively facilitate the airflow field through the effect of thermal buoyancy, and exchange the indoor airflow with the one outside through the effect of cross ventilation, thereby lowering the sultriness inside the gym. According to the assessment results regarding the amenities of indoor wind speed and thermal environment, the percentages of average indoor temperature indicate that opening the windows both on the top and the bottom can achieve the optimum performance regarding the gym's indoor thermal environment. Two-layer window pattern combines with thermal buoyancy and cross ventilation in the concept of natural ventilation for buildings, making the thermal environment correspond to the level of human comfort. Moreover, the dimensions of the two-layer windows have no significant correlation between the average indoor temperatures. In other words, whether using normal windows or French windows, two-lay windows have fine performance regarding the speed of flow field and thermal environment. Consequently, for the weather conditions in Taiwan, when adopting natural ventilation to improve the quality of indoor environment, the thermal buoyancy and wind action should be included in the consideration to improve the airflow circulation and efficiency.

Quantifying and Improving Environmental and Human Sustainability in Remote: Region Health Clinics, Australia

Steve BURROUGHS[a]

[a] *University of Canberra, Australia, drsteve@drsteveburroughs.com.au*

ABSTRACT

A sustainable building must address environmental sustainability aspects (E.g., energy use) as well as human sustainability (The well-being and productivity of its occupants). Climatic and socioeconomic conditions in remote regions of Australia mean that achieving such sustainability is challenging and costly, much more so than in urban areas. The standard industry response has been an increased reliance on the use of mechanical heating–cooling systems rather than passive design strategies aimed at reducing energy use and improving indoor environmental quality (IEQ) to maintain human well-being and productivity. These methods have come with a significant energy cost and pressure on the power supply system due to high peak loads. This trend is unsustainable as climate projections for remote regions indicate a continuing rise in the number of hot days in summer and cool nights in winter, increasing the demand for energy and associated infrastructure. The performance of health clinics in remote communities with respect to energy use and IEQ is unknown, meaning that these variables cannot be matched to the prevailing climatic conditions. This paper reports the establishment of a research project aimed at quantifying the environmental and human sustainability of remote-region health clinics, based on which strategic interventions and design modifications can be made. In the research, variables related to climate, energy consumption, and IEQ will be measured and monitored for eight clinics in different climatic zones. This will allow the levels and patterns of climatic variables, energy use, and IEQ, and the relationships between them, to be quantified. The findings will be used to inform best practices for improving the energy-use efficiency and IEQ of existing remote-region health clinics as well as informing design solutions for future buildings to optimize sustainability with respect to climate, environmental performance, and occupant well-being.

Keywords: remote health clinics, energy performance, human sustainability

1. INTRODUCTION AND BACKGROUND

Sustainable building practices have made significant advances in the last two decades (Kibert, 2016). However, a truly sustainable building addresses not only environmental impacts but also human sustainability and well-being. Environmental sustainability is the ability to maintain the qualities of the natural environment, including the processes involved in producing energy, as well as the impact of buildings and human activity on the environment. Human sustainability is in large part related to the quality of the built environment and involves specific strategies and methods implemented to enhancing the well-being and productivity of building occupants/ users (E.g., Yang et al., 2014).

Remote parts of Australia are defined based on the physical road distance to the nearest town or service centre. The officially defined "Remote Australia" covers 86% of the area of the entire country. In the 2006 census (Statistics Australia, 2006), Remote Australia was home to 470,000 people, including 2.5% of the Australian population overall, but 24% of Australia's Aboriginal and Torres Strait Islander population. The characteristics of Remote Australia differ from other parts of Australia, and these remote regions have common systemic properties as well as a history of persistent social and economic disadvantage manifest in poor health statistics and weak infrastructure. These systemic, remote-region characteristics when interfaced with changing climate and different energy futures result in impacts, vulnerabilities, and opportunities that differ from those that apply to coastal and urban regions of Australia (Maru et al., 2012). There are particular challenges faced by remote-region buildings and their occupants with respect to environmental and human sustainability compared with urban areas in Australia. These include generally harsher climates with greater temperature extremes and much higher electricity costs ($5/ kWh versus $0.2/ kWh).

Remote Australia is served by a network of health clinics and associated staff. These clinics provide a wide range of health services to local populations as well as training medical students and registrars. These healthcare facilities provide care for some of the most vulnerable members of Australian society. Hospitals and clinics serve

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

the needs of those who are ill or recovering, and need to generate conditions that are conducive to treatment and recovery by mitigating the spread of disease and improving occupant comfort, as well as allowing staff to work productively. Indoor environmental quality (IEQ) provides a critical foundation for meeting this target. However, it is an unfortunate fact that strategies to enhance human health and well-being have played a rather minimal role in the evolution of building standards and practices in remote communities. Further, there is a continuing imperative to reduce the environmental impact of buildings, particularly with respect to energy use, as well as to reduce operational costs. Therefore, it is imperative that human health and productivity, as well as environmental quality, take centre stage in building design, function, and operation so that buildings can perform better for both people and the environment. This can be achieved through a dedicated focus on evidence-based research and measurable performance of sustainability metrics.

The present paper reports a new project investigating the environmental efficiency and human sustainability of health clinics in remote regions of Australia. The project has been defined and is now in the initial stage of execution, with monitoring devices having been installed in one of eight selected clinics as of November 2016. Therefore, the purpose of the paper is to report the rationale for and development of the project, the methodology, and the anticipated outcomes. The project has been commissioned by the Department of Health (DoH) in Australia and is the first of its type in the country. The author is the Principal Investigator of the research team engaged in the research project. The results and findings of the research will provide an important baseline for measuring remote health clinic sustainability.

2. CLIMATE, HUMAN SUSTAINABILITY, AND ENVIRONMENTAL SUSTAINABILITY

Climatic conditions in the remote regions of Australia are acknowledged to be harsh, characterized, for example, by extreme temperatures, wide temperature variation, and high seasonal variation in rainfall. Such conditions pose difficulties for achieving environmentally efficient buildings (E.g., Isaacs, 2006) and for establishing high levels of IEQ for sustaining human comfort and well-being. These challenges are likely to become greater, given projections of climate change and energy requirements, as discussed below.

2.1 Climate

Since 1910, the Australian average annual temperature has increased by 1ºC, with most of this warming occurring since 1950. Furthermore, it is likely that average annual temperatures will continue to increase in the near future, and by 2030, temperatures are expected to rise by up to 1.8°C in some inland regions (Maru et al., 2012). There is a high level of uncertainty in the trend of projected rainfall, particularly in inland and northern Australia. Rainfall is likely to decrease in southern areas of Australia, especially in winter, and in southern and eastern areas in spring caused by the contraction in the rainfall belt towards higher latitudes (IPCC, 2007). Increases in evaporation are likely throughout Australia, which, combined with a general decline in precipitation in many parts, provides a strong indication that the Australian environment is generally becoming drier under enhanced greenhouse conditions (Frederiksen et al., 2011).

2.2 Energy needs and costs

Remote Australia is still highly dependent on fossil fuels for transport and for household and public service energy needs. For example, over 31 million litres of diesel fuel were used to generate electricity for major remote communities in NT in 2009, and demand was expected to increase by 25% over the subsequent three years (Maru et al., 2012). Household consumption of energy is rising, and the use of air-conditioning will increase with increasing temperatures in inland Australia, which will lead to even higher demand for energy to maintain current lifestyles and to address the changing requirements of an ageing population. Energy prices are likely to continue to rise as the cost of production of fossil fuel increases, and gas utilities (Which generate electricity using fossil fuels, including natural gas) will be obliged to purchase emissions permits under the Clean Energy Act 2011.

The cost of renewable energy sources affects uptake in Remote Australia. Barriers include pricing, perceptions, relatively immature technology, and the distance between energy sources and markets (Ellis and Peake, 1996; Harrison et al., 1996; Lloyd, 2001; Marinova and Balaguer, 2009). There are high costs of infrastructural development and maintenance associated with remote locations, and immediate economic returns on such

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

investments are rare. Areas with small populations are often unable to justify upfront and maintenance costs for renewable energy systems (McHenry, 2009).

3. RESEARCH OBJECTIVES AND METHODOLOGY

3.1 Research objectives

Climatic conditions impact significantly on a building's ability to provide the necessary conditions for occupant well-being as well as on its environmental efficiency, particularly its energy consumption. Climatic conditions have changed significantly over the last century, and predictions indicate that changes will continue to occur in the near and mid-term futures. In this respect, it should be noted that many existing DoH health clinics in Remote Australia are performing in climatic conditions that now differ from those applying when they were designed and built. Therefore, it is important that climatic and building performance data be available not only to assist in measuring and managing energy use and IEQ in existing health clinics, but also provide a base upon which future clinics can be planned, designed, constructed, and operated. Currently, DoH has no data regarding environmental sustainability (as measured through energy use) and human sustainability (As measured through IEQ) for its remote health clinics. Such data, when combined with climatic data, should be a valuable tool for developing strategic interventions in existing buildings and for indicating sustainable design solutions in new buildings.

This research involves the collection and analysis of data on the characteristics, occupant response, and environmental performance of DoH health clinics in regional/ remote areas with respect to environmental and human sustainability. The relevant metrics include those related to enhancing human well-being and productivity in remote clinics, as well as the energy consumed to sustain the functions and occupants of the buildings in a bid to maximize environmental efficiencies. As the first project of its kind, the research has the following objectives:

- To generate a baseline database of environmental sustainability and human well-being performance indicators and corresponding measurements for remote-region health clinics in Australia;
- To develop a body of knowledge based on the monitoring and measurement of environmental and human sustainability that will inform decision-making and strategic interventions in remote-region health clinics in Australia; and
- To provide an initial understanding of the key sustainable design and operational aspects when designing, operating, and maintaining remote-region health clinics in Australia.

The findings of the research should be able to be applied to increase, improve, or enhance the following DoH assets and areas of interest: (i) The environmental sustainability and IEQ of its remote-region health clinics; (ii) the well-being and productivity of its staff working in these areas; and (iii) the recovery and well-being of the local populations cared for in the clinics.

3.2 Methodology

This investigation uses a mixed-methods approach to obtain complementary results and evaluations offered by qualitative and quantitative methods. Research in Phase 1 of the project will use qualitative methods including site description, documentation analysis, and a questionnaire survey of building occupants (Medical staff). This will establish data about the current conditions and performance of existing clinic buildings, and how staff operate within them, including issues and constraints.

Phase 2 uses a more quantitative approach, with monitoring instrumentation being installed to continuously measure in-building energy, environmental, and IEQ data, including energy use, temperature, and air quality, as well as climatic data, for a 12-month period. The monitoring instruments will upload data continuously to a cloud-based system that is able to be entered via a portal online. Each clinic will be assessed across key sustainability metrics as described below, establishing a 12-month period of data that will demonstrate how the clinics operate. This will allow DoH to be able to define what "normal" is for a wide range of metrics as well as the variation. In addition, site-assessed IEQ variables will be measured and occupancy profiles established. These data will allow a range of indicators to be defined for the selected buildings.

The following data and information will be collected during the project:

- Monitored climatic variables over a 12-month period, including temperature, humidity, wind speed, and rainfall.
- Monitored IEQ metrics over a 12-month period, including volatile organic carbon concentrations, air speed/ flow, humidity, temperature, CO_2, CO, formaldehyde, amongst other gases and substances.
- Site-assessed IEQ variables including lighting levels, air exchange, ambient sound levels, particulate matter, and airborne microbials.
- An occupant satisfaction questionnaire will be conducted to augment the quantitative IEQ data and will seek information on aspects of IEQ, comfort, and human sustainability and productivity. The questionnaire will cover occupational profile, time–location data, time–activity data, building layout and furnishings, thermal comfort, air quality, lighting, acoustics, privacy and security, programmed spaces, energy-use patterns, and building sustainability features.
- Monitored energy consumption over a 12-month period, including totals and readings sub-monitored according to function and space within each clinic.
- Energy supply quality and variations over a 12-month period, including power outages (Brown- or black-outs), power supply (Grid, solar, other), and back-up.
- Building occupancy and operational profiles and variations over a 12-month period.
- An inventory of energy-consuming equipment in each clinic.
- Static built environment variables – building design and material characteristics, such as orientation, room layout, material types and properties, passive sustainability features, air systems and ventilation, and insulation.

This research will measure data for remote clinics over a period of 12 months at selected sites in different geographical regions in Australia. The sites for investigation will be based on selecting a range of clinics with respect to differing climatic conditions, building characteristics, and occupancy profiles. Identified sites will cover differing climatic conditions, including at the long-term, seasonal, and diurnal scales, so that the range of environmental constraints on variables such as energy use and IEQ can be considered. This will allow a more accurate characterization to be established of the variation in environmental and human sustainability aspects of remote clinics.

It is considered that eight sites are needed to cover the variation in climate and in other variables of interest such as occupancy and operational profiles, building characteristics, and IEQ variations. Currently, the first site has been identified, at Wanarn in Western Australia (Figure 1 and 2), whose health clinic was built in 2015. The health clinic has 18 rooms in total (For diagnosis, treatment, storage, and other purposes) and a floor area of around 230 m^2, and serves a population of around 2000 people in Wanarn and the surrounding area. Wanarn has a long-term average maximum temperature of 27.5°C and a mean monthly rainfall of 10–45 mm. Monitoring equipment has now been installed at the Wanarn clinic, and data collection and data portal establishment started in December 2016. Initial results for this clinic are expected to be available during the first and second quarters of 2017. Subsequently, during 2017 and 2018, further clinic locations in remote communities will be identified for investigation in the Northern Territory, South Australia, and Queensland.

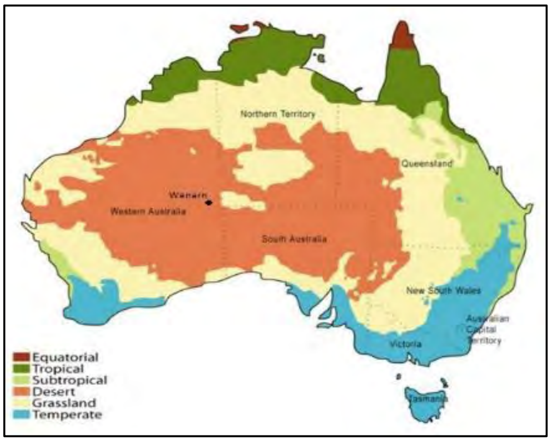

Figure 1: Political states and climatic zones of Australia, and the location of Wanarn. Remote Australia includes the equatorial, tropical, desert, and grassland zones

Figure 2: The Wanarn health clinic

3.3 Data analysis

Temporal variations in the monitored quantitative data will be analyzed, including at the diurnal and seasonal scales. This will indicate changing levels of building performance at various temporal scales, and highlight possible problems such as periods of inefficient energy use or of undesirably low IEQ. Quantified correlations between energy-use values, climate variables, staff well-being, and IEQ metrics will establish the relationships between these data, thereby highlighting where and/ or when interventions could be made to optimize the building systems. Site variables measuring occupancy, building design, and building operation and their relationship to the monitored data and survey results will allow additional inferences to be made regarding the levels of, and factors influencing, human and environmental sustainability, thereby suggesting scope for design adaptation and strategic interventions. Building information modelling (BIM) will be used with building energy modelling (BEM) to help explore the relationship between performance and design and to test and identify design improvements using the obtained data

Part of the data analysis effort will be aimed at energy load reduction, followed by the application of energy-efficient solutions to match reduced load profiles. Some emphasis will be placed on designing the building skin to minimise external loads. The data collected will be used as a baseline for energy modelling of different orientations for several Australian climatic zones. Hourly data profiles will demonstrate times and places where loads exceed the established threshold for building heating, ventilation, and air-conditioning (HVAC) systems. BIM/ BEM simulations will also be used to provide load profiles. For example, such modelling can indicate how long exterior shades would need to be deployed in order to minimise external energy gains. This information will enable a design path to be established for generating improved thermal performance and human comfort using mechanical and/ or passive systems.

4. ANTICIPATED OUTCOMES

The anticipated outcomes of the research include the following:

- Generate data that will allow sustainability gaps in existing remote clinics to be identified and solutions to be developed.
- Generate data that will assist in evaluating and prioritising the implementation of new strategies and techniques for achieving energy efficiency.
- Identify the levels of IEQ in remote clinics and develop cost-effective strategies for enhancing these levels.
- Generate results to form a basis for management and decision-making regarding staff well-being and human/ clinic productivity.
- Enhance the energy optimization of building features such as plug loads, lighting, and HVAC systems to reduce energy costs without compromising occupant well-being and productivity.

- Provide workable and reliable data that will inform and guide the planning, design, construction, operation, and maintenance of sustainable clinics in remote regions.
- Establish foundation metrics (Key performance indicators – KPIs) for future use, for benchmarking, and for measuring improvements.
- Guide and set performance standards for energy use and IEQ on a wider basis for health clinics, based on the measured data.
- Identify the utility of the environmental and IEQ data as inputs into evidence-based design via BIM software for generating new clinic concept designs for different climatic zones and occupancy/ operational profiles.

  The anticipated scope of the recommendations covers the following:
  - Identification of the KPIs that best demonstrate the performance of health clinics and the design and construction of these facilities.
  - The use of these KPIs as a basis for strategic interventions in the design, construction, operation, maintenance, and improvement of health clinics.
  - Strategic planning to assist in setting priorities focusing on energy reduction and human sustainability and in the design and construction of medical clinics.
  - Examination of cost-related issues in the final design of clinics.

ABSTRACT

Urbanization is an undeniable trend in modern world. By 2030, count of Mega-cities, residing more than 10 million people, is projected to leap by nearly 50% worldwide. More than half of current world population lives in urban areas and it is estimated to soar to 66% by 2050. Nearly 90% of the projected increase would be happening in Asia and Africa, concentrating in developing countries.

Rising concern requires balanced attention on sustainability, environmental and economical opportunity. In addition, the expanding and crowding urban context demand innovative and manageable solutions to address issues on housing, transportation, utilities, and other developmental priorities.

Sustainable planning on neighbourhood is to allocate socially vibrant, ecologically restorative and economically sound communities with integration of sustainable strategies and balance of Social, Environmental and Economic benefits. Successful cases become distinct fusion of balanced neighbourhood of people and environment, as well as laying sound foundation on reducing carbon footprint and associated environmental impacts in now and future. It is the most critical and cost-effective to address all sustainability issues at master-planning stage.

Adaptive and sustainable masterplanning provides tools to address these concerns and materials innovative solutions. Sustainable planning strategies are deployed to set-pace for a pleasant neighbourhood/district with prioritized endeavours on various aspects. Adaptive analyses are exercised to design practical and approachable solutions, which optimize sustainability and environmental performance. Inspiring ideas and innovative products create new dimension to tackle environmental and microclimatic issues.

Extensive experience in master-planning for sustainable neighbourhood, green building design, and conducting performance evaluation and carbon footprint evaluation has been successfully practised throughout the world, including USA, Asia, Mainland China, Hong Kong, Vietnam, etc. The authors have developed a systematic approach to address all global and local sustainability issues and develop an integrated sustainable solution, which benefit the Communities, Users and Developers.

Keywords: sustainable masterplanning, adaptive analyses, optimization & approach

1. INTRODUCTION

In year 2015, probably every people on Earth should have noticed the effect of Climate Change. It was one of the warmest years in record, with at least anomaly of 0.9OC or 1.62OF above annual average temperature, since 1880 (NOAA 2015). Climate change has been widely studied with evidences linking to various intensifying human activities, the leading one of those is Urbanization (Kalnay and Cai, 2003; Argüeso et al, 2014, Zhou et al, 2004).

1.1 Urbanization

World population is on track of continuous growth and urbanization has been growing in accelerated pace in recent decade. By year 2050, world population is projected as over 9.5 billion, out of which 70% will be living in urban areas, almost doubling the urban population 3.4 billion back in year 2009. This translates into addition of 2.5 billion urban occupants in absolute numbers (United Nations, 2014). Out of steep climb, more than 60% of the growth will be anticipated on Asian soil and close to 90 per cent of the total increase is forecasted altogether with Africa region.

In Asia, the percentage of urban population was around 16% in 1950, increased to 40% at present, and is projected to be 65% by 2050, making a progressive increase at a rate of 1% to 5% annually. Japan, Korea, Hong Kong, Singapore and Taiwan are leading developed economies in the region, and having high population portion of urban occupants, ranging from 82% (Korea), 93% (Japan), to 100% (Hong Kong and Singapore) currently (Cheng & Tong, in press 2017).

Most of the South East or South Asian countries are developing countries. Their population are climbing rapidly. Indonesia and the Philippines are about 50% urbanized, with projection up to 65%, whereas Thailand and Vietnam are estimated to rise from current ratio of 30 – 40% to 55% when reaching year 2050.

More and more infrastructure, buildings for housing and social supporting facilities such as schools and hospitals need to be in place to support the urban living. Moreover, mobility and transportation are associated issues, which would deepen complications on the situations. Without proper planning and governance in place, this could lead to social instability and many environmental problems.

1.2 What are anticipated?

Consuming society

Resources of the Earth is no doubt limited. Carry capacity to accommodate a rapidly growing population, which is moving towards “urban consumerism” would result in only unpleasant outcome on over-consumption on natural resources, forest, grassland, fisheries, energy fuels, etc.

East Asia economic development has outperformed its Western counterparts in recent years, which has resulted in the forming of more and more consumer societies there. Increasing in income has brought change in people. They have begun to exhibit a more “Western” lifestyle. The results of this change have manifested themselves in multiple ways. The most notable is that in 2009, China overtook the US as the World’s biggest energy consumer, according to the International Energy Agency. China consumed 2.3 billion tonnes of oil equivalent, 4% more than the US, although still remains the world’s largest consumer of energy per capita.

Quality of life

Space in denser urban environments with growing urban populations means that land for healthy and functional “green” space has to compete with development and “grey” city infrastructure. Whilst our city parks, squares, open spaces and streets support networks of green and blue infrastructure, there is a pressing need to maximise and seek out new spaces and surfaces in the city to support quality of life.

Urban environmental degradation

Human disturbance causes environmental degradation, earth’s natural resources are depleted and environment is compromised in the form of extinction of species, pollution in air, water and soil, and rapid growth in population. Environmental degradation is one of the largest threats that are being looked at in the world today. In city, the activities of urban living have intensified the process. This is particularly critical for the regional developing countries as the measures of control are not in place.

2. MATTERS TO BE ADDRESSED

2.1 Aesthetic quality

Apart from functional aspects of green infrastructure, the aesthetic qualities it can bring are significant. It provides an aesthetic that is potentially timeless owing to natural regeneration (Arup, 2016). Building envelopes have been covered with plants like ivy, wisteria and clematis for centuries, merely enriching the original architecture. This provides not only seasonal colours but also something that changes year after year. The psychological connotations of green infrastructure are multiple, as mentioned in the section on well-being. In addition, there are the psychological and physical interactions. A study showed that people with complex views of nature could accept more glare on their computer screens than those without.

2.2 Place-making

The most expensive property in cities such as New York and London surrounds exceptional green parks such as Central Park and Hyde Park for good reasons. Some of the most successful developments have created "destinations" rather than just a collection of buildings, by integrating green spaces in their developments. As urbanization increases, the number of people moving to cities will start to place strain on existing green infrastructure. Therefore, as space becomes rarer, desirable places will need to be created through new vertical and horizontal greening. Havens of peace can be created through new forms of green infrastructure. This is essential to create attractive places for people in cities to escape the 24-hour culture for short periods.

2.3 Air quality

Today, cities suffer from levels of air pollution, which have been shown to affect human health significantly. Large metropolitan cities like London and New York regularly exceed WHO limits for particulate matter. The WHO estimates that poor air quality led to seven million deaths in 2012; and Yale University's Environmental Performance Index has calculated that over 1.78 billion people have inhaled polluted air over the past decade (Cheng & Tong, in press 2017). Air quality is a key driver for public health, particularly in urban areas where the population is heavily exposed to poor air quality. Breathing polluted air has been shown to trigger or exacerbate health problems such as asthma, lung disease and a variety of other medical issues.

2.4 Urban heat

The concreting over of natural spaces and the use of low-reflective materials on buildings contribute to the urban heat island effect. This is caused both by the loss of natural spaces that benefit from adiabatic cooling and by the impact of certain materials commonly used in urban construction such as asphalt and concrete (Arup 2016). Countries such as Greece have painted their buildings white for centuries to avoid overheating. Vegetated roofs can offer similar benefits.

2.5 Energy

Rapid growth of urban population is positively related to the percentage of urban population as more and more people are moving from rural areas to city for livelihood and better quality of life (Cheng & Tong, in press 2017). It is also projected that global urban populace would consume approximately 3 or 4 of the world's energy by then (Kamal-Chaoui, 2009). Cities have enormous potential for capturing the energy they received, e.g. heat, wind or sunlight. A renewable energy mix for significant developed countries is no longer merely an option, but is now enshrined in law under climate reduction commitments.

3. HOLISTIC AND OPTIMIZED APPROACH

3.1 Passive design

Passive design is the first principle in sustainable design and should be adapted as well at planning level. Best practice of sustainable passive design could moderate outdoor comfort by enhancing environmental factors. Research (Givoni et al, 2003) had been conducted to identify the factors influential to outdoor thermal comfort perceived by human. Temperature, air movement speed, humidity and solar irradiation, as illustrated in Figure 1, were studied and correlated in the scientific equation to assess comfort level in a scale of 7 steps. Further research (Cheng et al, 2010) customized Givoni et al's research for sub-tropical climate.

The formula of Thermal Sensation (TS) is a collection of multiple factors:

$$\mathrm{TS} = 0.1185 \cdot \mathrm{Ta} - 0.6019 \cdot \mathrm{WS} + 0.0025 \cdot \mathrm{SR} + 0.1155 \cdot \mathrm{HR} - 4.77$$

Equation 1

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Where

TS – Thermal Sensation

Ta – Dry Bulb Air Temperature (OC)

WS – Wind Speed (m/s)

SR – Solar Radiation Intensity (W/m²)

HR – Absolute Humidify (g/kg air)

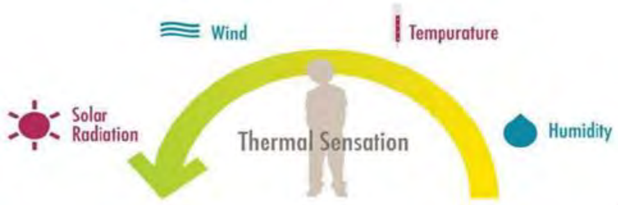

Figure 1: Illustration of thermal sensation and influencing factors

3.2 Urban wind micro-climate

As urban area gets intensified with building density, the more deteriorated situation of wind micro-climate would be in street canyons, especially on pedestrian level. By approaching passive design terminology at planning level, wind corridor is a key strategy to promote areal air movement and enhance pedestrian comfort, which subsequently bringing benefits to natural ventilation design at building design level. Optimized planning should consider to provision strategic street alignment towards prevailing wind to introduce wind corridor for hot season. Deep penetration of breeze into urban region would bring positive benefit to outdoor comfort, as shown in Figure 2. For winter season, especially to northern Asian regional which could reach to sub-zero Celsius temperature, passive planning design would be recommended to adopt staggered block arrangement with respect to incoming prevailing chilly wind for sheltering downstream built environment. Both the strategies tackling summer and winter season by moderating air movement speed to improve thermal sensation of outdoor space.

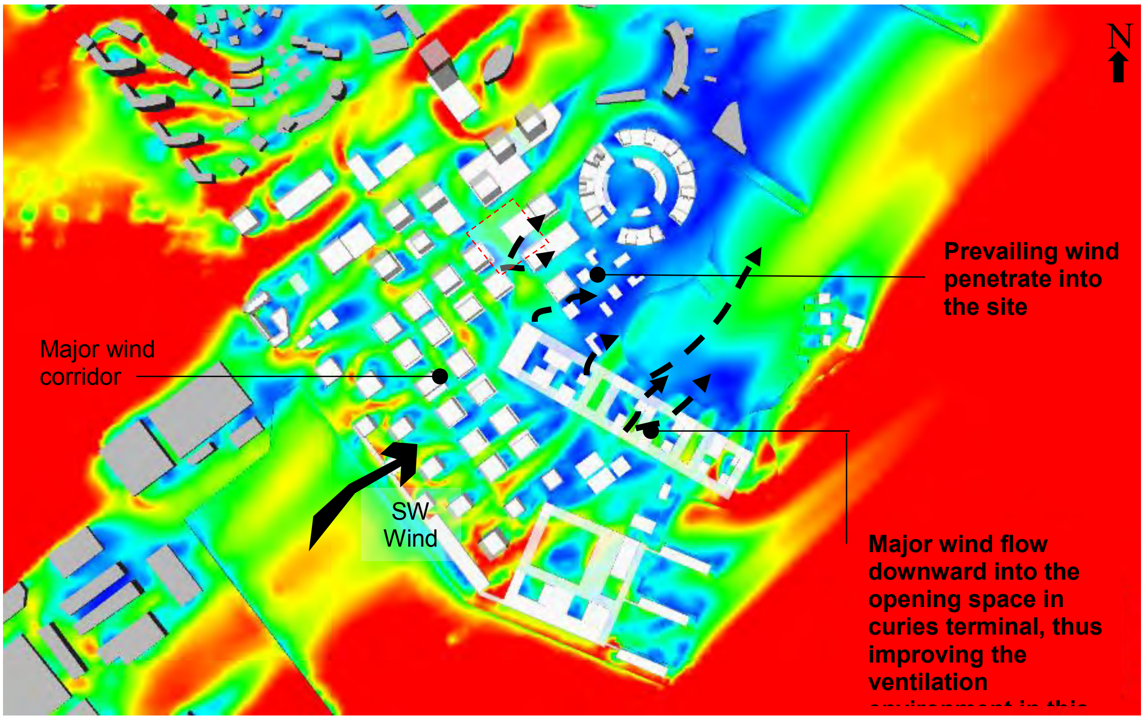

Figure 2: Summer wind microclimate performance simulation of design scheme for a masterplanning project in Shenzhen

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

In Singapore, Arup succeeded a project with "Environmental Filter" canopy that covers open space, linking up buildings and covering the podiums heritage and buildings. The integrated design of environmental canopy addresses sun, wind, light and rain holistically. As modified into semi-outdoor environment, this sustainable design achieves a tailored balance of promoted wind environment, solar irradiation control, rainfall screening, and air temperature moderation. Thermal comfort have been enhanced effectively with multi-dimensional adaptation of environmental factors, through studies of Built Environment Modelling (BEM) as shown in Figure 3.

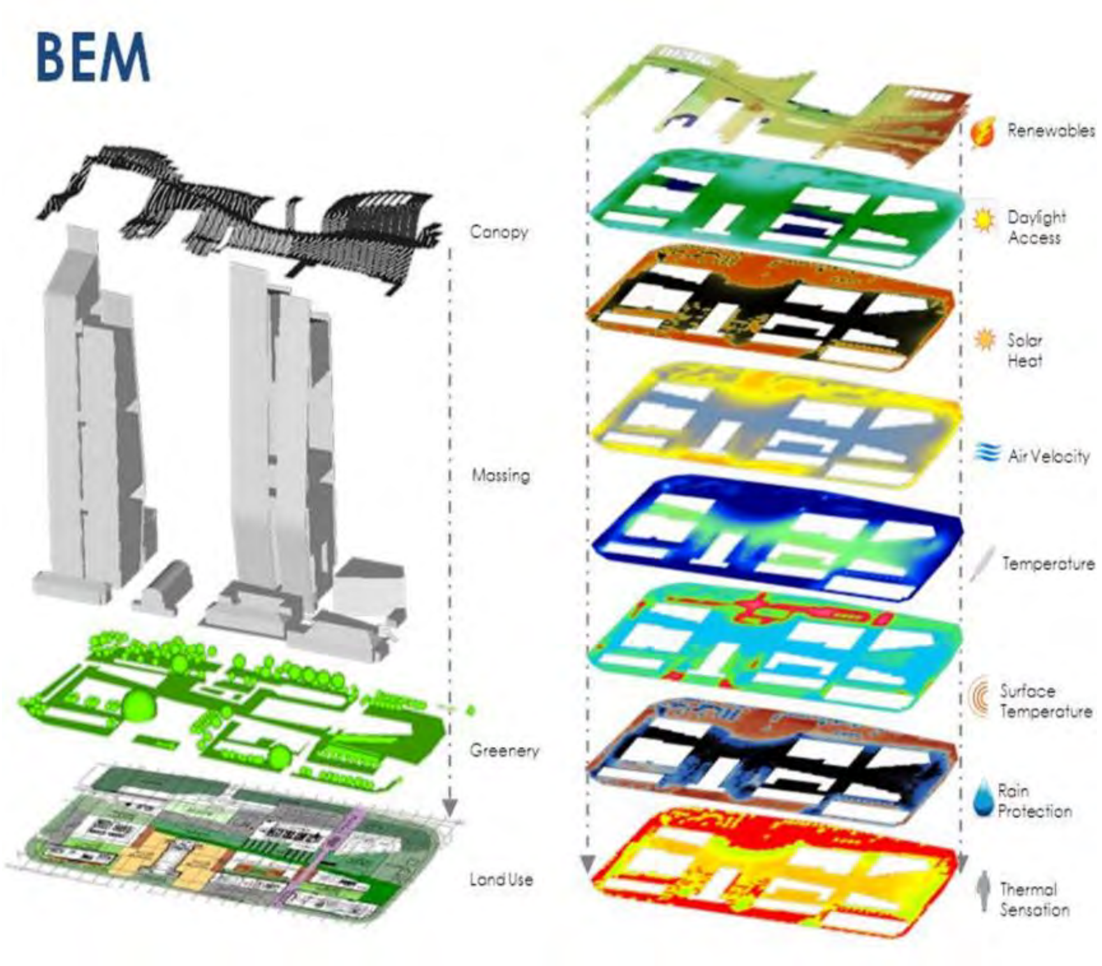

Figure 3: BEM study design optimization of semi-outdoor spatial design for enhanced outdoor thermal comfort

3.3 Urban heat island (UHI) effect

UHI describes an urban area whose temperature is considerably warmer than the surrounding suburbs and rural regions. Metropolitan hardscapes are the primary cause of this effect: concrete sidewalks, asphalt roadways, steel and glass façade, and other solid surfaces, which radiate rather than absorb heat (Arup, 2016). As global urban populations continue to rise, so too will energy consumption and poor air circulation, resulting in higher temperature for city residents. The United States Environmental Protection Agency advises that an urban area with a population exceeding 1 million may be 1 – 3°C hotter in the daytime and up to 12°C warmer in the evening than surrounding areas.

The idea is to improve heat island through city fabric design (Arup 2016). In the study on city level urban heat island effect, typical city grids were modelled with typical surroundings. To calculate the effect that vertical green façade would have on an urban scale would require a relative comparison for a city with and without green facades. The effect of the green facades would most likely be perceived in a reduction in air temperature over the urban landscape, typically referred to as UHI.

For the urban heat island (UHI) effect, it was found that there is a variety of city-associated parameters like the grid, solar radiation, canyon height-to-width ratio, thermal mass and the percentage of green space that influence the effect independent of green envelopes. Figure 4 illustrates indicative street canyon ratio of the 5 cities, Los Angeles, Berlin, London, Melbourne and Hong Kong, selected in study.

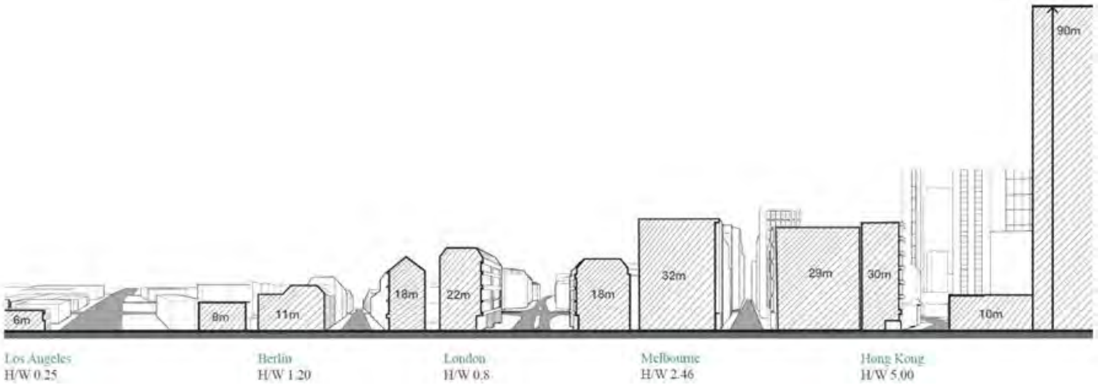

Figure 4. Canyon height-to-width ratio of 5 selected cities

Predicting the UHI effect was not the aim; instead, the change in air temperature to the urban atmosphere was calculated. It was found that vertical façades have the greatest impact on UHI in dense city topologies, as shown in Figure 5. Once the city is widespread (e.g. Los Angeles), most of the solar radiation will be absorbed on the streets instead of along the buildings. Similarly, once the cities are fairly green (e.g. Berlin), the relative benefit of adding vertical green facades makes a smaller difference.

Figure 5: Calculated maximum change in air temperature due to green facades in correlation with height-to-width ratio of street canyons

Green facades are most effective in reducing UHI in cities with a height-to-width (H/W) ratio greater than 2 – very dense urban city centres like Hong Kong or Melbourne fall into this category – peak temperature reductions of up to 10°C having been modelled. Green cities like Berlin experience limited benefit compared to denser cities with more concrete surfaces. Cities with wide streets and low-rise buildings like Los Angeles benefit more from greenery at street level.

3.4 Air pollution

Air Pollution is a complex mixture of gaseous, solid and liquid particles in the air. The list of airborne contaminants in urban spaces is extensive and includes some of the following: dust, pollen, factory emissions, soot, smoke, and motor vehicle exhaust.

Passive design mentioned in previous could improve pollution situation when prevailing wind could penetrate deep into tight urban built environment. However, pollutant accumulation could inevitably reach unhealthy level in claim wind days. Furthermore, busy road traffic in densely populated cities causes poor roadside air quality and it is a direct threat to public health. Due to the density of high-rise buildings, a common characteristic in cities is that many narrow street canyons are created. Street Canyon effect would result in accumulation of pollution is one of the major problems of modern cities. Citizens on pedestrian walkways due to long exposure are subjected to serious health problems. Most of these cities face challenges to achieve acceptable air quality level on the street. In Beijing during 2013, it was reported that 58 "very unhealthy" days that had an Air Quality Index (AQI) reading higher than 200.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

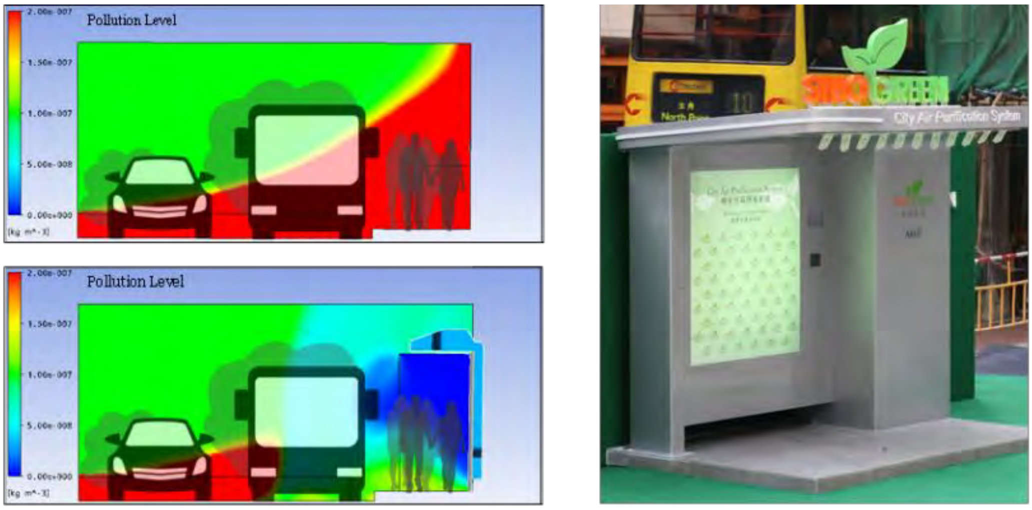

Figure 6: Design of City Air Purification System (CAPS) in a format of road side bus stop.

To serve immediate and pressing needs of curbing air pollution, active system should be considered. Arup and Sino Green have jointly developed a patent-pending design as shown in Figure 6, named the City Air Purification System (CAPS) (Cheng & Tong, in press 2017). The goal of this system is to provide a ventilation system that filters out pollutants and generates purified air for pedestrians in proximity to the system. A prototype, fabricated in the format of a bus stop, has been set up in one of the busiest city streets in Hong Kong. The prototype draws air current through inlet located at the bottom, then processes the airflow with bag filter which is effective in removing fine suspended particles (FSP or PM2.5) before discharging from overhead louver outlet. The discharged air stream is designed to form a wind barrier and provides better air quality “inside” the bus stop prototype. The improvement was measured up to 70% reduction of air pollutants.

3.5 Technological advancements

Advanced air mover

On top of adaptive and optimized passive design, advanced active engineering systems complete the puzzle of sustainable design. Active systems have been widely adopted to modify built environmental conditions. One of the most commonly seen applications is mist cooler, which is regular mitigation measure of evaporative cooling for dry climatic locations during hot season. However, such effective measure could become adverse action if put in place for hot and humid region. Another environmental parameter of thermal sensation, air movement speed, should be focused on to modify environmental conditions.

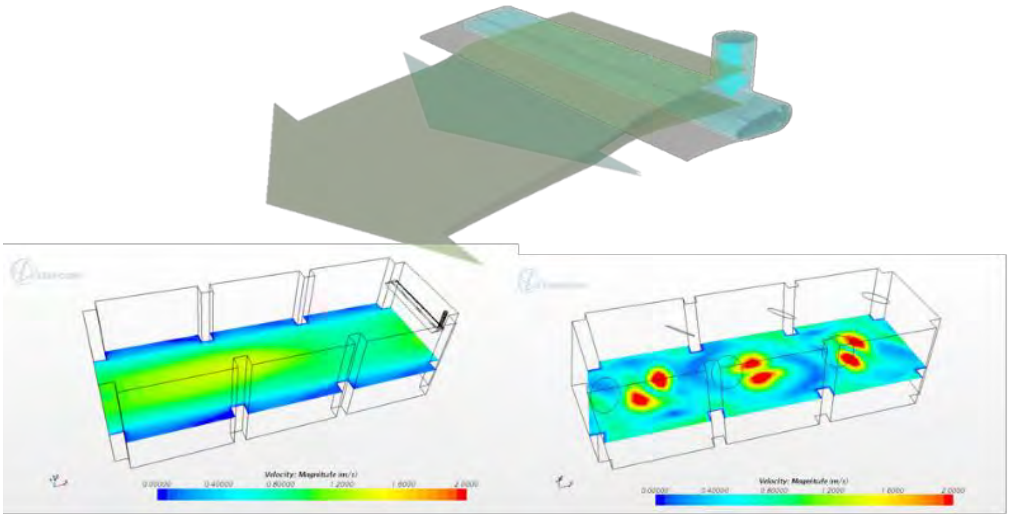

Figure 7: Design of Air Induction Unit (AIU) and study comparison of conventional swing-head fan and AIU on air movement distribution

Arup has conducted research and development on terminal device that could deliver the desired performance. Air Induction Unit (AIU) (Cheng & Tong, in press 2017), as shown in Figure 7, performs air movement similar to conventional fan, but in a much enhanced fashion. It improves ventilation with wide and even spread of air movement delivered in continuous and steady manner, instead of spot and intermittent bursts by swing-head fan. Furthermore, AIU holds merits of minimized electricity consumption and aesthetically harmonic with architectural appearance.

District energy

Conventional energy consumption is unidirectional in nature. Planning of new town provides opportunities to realize low and zero carbon vision at wider scale, which distributed district energy infrastructure is one of the good candidates. At present, utilities supply energy formats to consumption side with minimal feedback in return. This leads to inefficient use of resources as the consumption cannot be analysed and controlled. As shown in Figure 8, Micro-energy Grid (MEG) is a new approach (Kaushal and Basak, 2014; Marnay et al, 2008) which supplies major utility sources combined with a feedback loop and real-time control to reduce both peak demand and energy consumption. Electrical, heating, cooling and gas district networks are centrally managed and monitored via the Total Operation Centre (TOC). This facility acts as the brain of the network, collecting, analysing and managing real-time demand data in order to provide energy in the most efficient way possible.

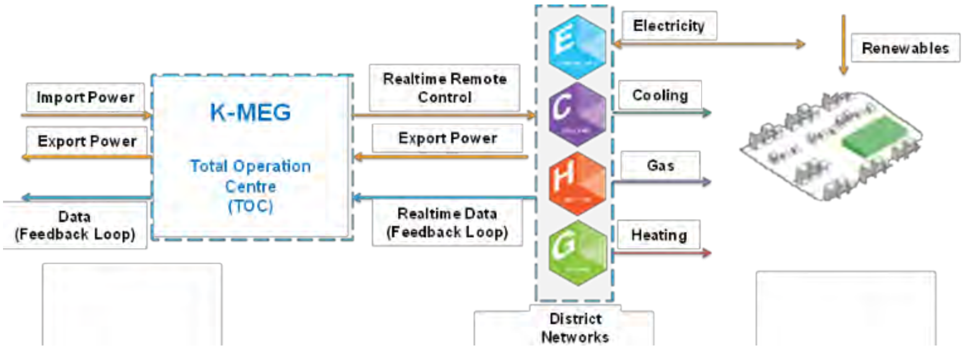

Figure 8: Schematic of Micro-energy Grid

Further improving overall system efficiency can be achieved by centralizing energy conservation systems. With better large-scale technologies becoming available and practical, higher systems efficiency at community level through increasing economies of scale by district energy systems. In addition to higher efficiency, centralised system also benefits by centralising maintenance; hence, maintenance can be managed more effectively through a single professional entity. Moreover, more prime space within buildings can be freed up for higher value functionalities. A successful District Cooling System (DCS) has to be planned and designed with the concept of enhanced system performance and economic. This is done by optimizing the design of chilled water production and the associated distribution network, therefore enhancing the energy efficiency and financial viability. DCS in Kai Tak Development, Hong Kong is one of the most recent experience. It has an energy saving potential up to 35% as compared to traditional building-level air-conditioning system, with better quality and reliability of services.

4. CONCLUSION

This paper presents the idea that rapidly rising on urbanization pushes additional resources pressure to the nature. Urban planning design could be one of the key approaches to demonstrate sustainability.

This is where buildings as a component of cities can make a vital contribution by fundamentally adopting nature-based design approaches. This can be through new ways of providing new development and important retrofitting and refurbishment of existing buildings in cities.

Passive design strategy approaches masterplanning with innovative ideas. Adaptive solutions with optimization addressing key issues of urban heat island and outdoor thermal comfort were presented. Study on street canyon relationship to urban heat island effect and potential mitigation measurement by green building envelope were demonstrated. In addition, technological advancements on active systems demonstrate various measures for enhancement built environment and address key issues due to intense urbanization by innovative system solutions.

Water Use of Thin-Layer Green Roof by Vertical-Flow Constructed Wetlands

PENG Jr-jie[a], CL CHENG[b]

[a] National Taiwan University of Science and Technology, Taiwan, af9864@cpami.gov.tw
[b] National Taiwan University of Science and Technology, Taiwan, ccl@mail.ntust.edu.tw

ABSTRACT

Thin-layer green roof is irrigated by tap water supply and supplemented with rainwater as the auxiliary water supply. There have been continuous researches carried out by many domestic and foreign experts and scholars, and there have been many cases proving the water saving benefit of replacing a portion of tap water. However, green roof is still regarded as a facility consuming water resource. In this study, the thin-layer green roof integrated with vertical flow constructed wetland purification effect has been established based on the perspectives of recycling, treatment, and reclamation of water in a building in order to replace the water source of tap water irrigation. The evaluation equation has been proposed for understanding the benefit of using reclaimed water to replacing tap water. In addition to meeting the need of its own irrigation system, it can also be used for the irrigation of other facilities or the water for flushing toilets in a building such that the water demand management of planting and cultivation can be simplified. The advantages of this study is that it can achieve the short cycle of building self-management and the concept of reduction of energy consumption due to the easy access of source of slight pollution generated by a building, which will lead to the benefit of positive sustainable operation.

Keywords: green roof, resource, short cycle

1. INTRODUCTION

The alternative option of creating green roofs (GR) setup involves providing a layer of soil media on top of the roof to improve thermal resistance of the roof and provide heat insulation. Water retained in the soil can also improve the average heat capacity of the soil and delay heat conductance into the interior spaces within the building. The layer of vegetation supported by the GR can also reduce direct exposure to sunlight and lower heat absorption of constructed and concrete surfaces. Evapotranspiration from the vegetative cover can also help modulate the temperature and humidity in the surrounding air. However, GR requires irrigation and therefore consumes water, increasing the demands for water resources of the building. The current approach is to integrate rainwater recycling systems as well as public water supplies. The Industrial Technology Research Institute (ITRI) of Taiwan has conducted water usage surveys with 600 public water users that include tourist hotels, integrated hospitals, key tourism areas, department stores, schools, and public agencies. Survey results show that with the exception of department stores, bathroom activities consumed the highest proportion of water in all other public water users. Large-scale implementation of effective on-site collection, treatment, and reuse of discharged water or sewage for other purposes will significantly reduce water consumption. Gray water recycling systems offer the advantage of improving the stability of water supply, but water treatment equipment tend to be very expensive. A new green landscaping system capable of simultaneously reducing water usage and improving wastewater recycling could be developed if ecological engineering technology capable of emulating the cleansing mechanisms and functions of natural wetlands could be developed and employed in thin-layer GR. This would transform the GR from a net consumer of water into a producer. This improved GR will retain the advantages of GR, while providing water purification functions. Gray water and harvested rainwater could be used in short-range resource recycling within buildings. For example, the water generated and collected by the system can be directed to water consuming amenities and facilities in vicinities for flushing toilets or fighting fires.

2. ESTABLISHING THE MODULAR SYSTEM

This study selected a site in Taiwan Taipei. The surrounding environment is relatively open and offers good ventilation. Building information modeling (BIM) and ECOTECT software simulation were used for the analysis.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The site has an ambient temperature range of 8 to 35oC and an indoor floor space of 49 square meters. Figure 1 shows simulated models and layout plan of the building.

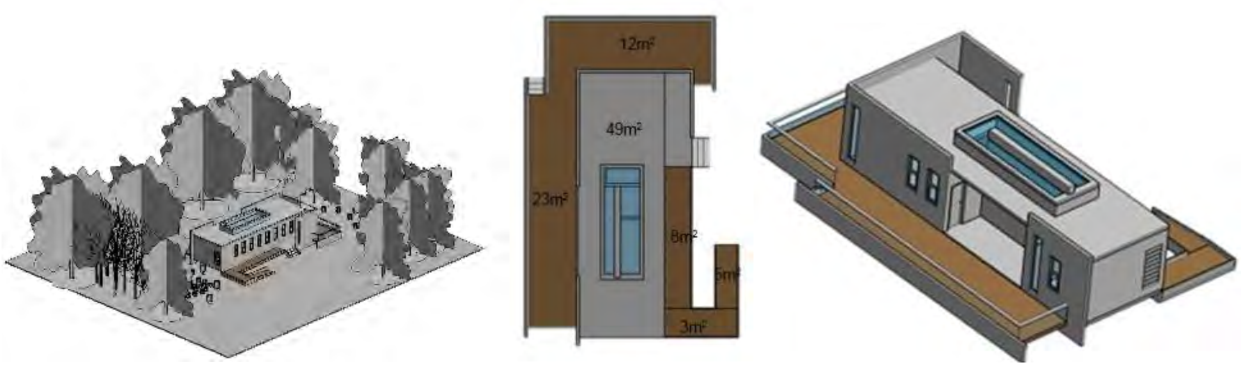

Figure 1: Layout plans and models used for the simulation

2.1. Roof parameter settings

The Technical Specifications for Heat Performance and Energy Saving Designs for Reinforced Building Envelopes stipulated by the Construction and Planning Agency of the Ministry of the Interior was used as a reference in order to estimate the heat transmission coefficient of the roof. The Detail function of the BIM was used to set formulas and parameters for the exposed rooftop (Table 2), general thin-layer GR (Table 3), and thin-layer GR with purification function (Table 4). Parameters include: thermal conductivity, thermal resistance, total thermal resistance, and coefficient of thermal transmittance (U-value). Coefficient of thermal transmittance is the inverse of total thermal resistance, while total thermal resistance is the sum total of thermal resistances of all materials. Thermal conductivity (unit: W/m.K) is also known as heat conductance and can be calculated using the formula of k = (Q/t) * L / (A*T), where k is thermal conductivity, Q is the amount of heat, t is time, L is the length, A is the area, and T is the temperature difference. This expression is used to measure the amount of heat vertically conducted through a material of unit area per unit time per unit temperature difference. Formula of coefficient of thermal transmittance is:

$$U_i = \frac{1}{R} = \frac{1}{\frac{1}{h_0} + \gamma_\alpha + \frac{1}{h_i} + \sum \frac{d_x}{k_x}}$$

Major construction components	Thickness, d (m)	Thermal conductivity, 1/k (m.k/w)	Thermal resistance r = d/k (m^2k/w)	Total thermal resistance R = **Σr** (m^2k/w)	Coefficient of thermal transmittance (w/m^2k)

Table 4: Settings for thin-layer GR with purification functions

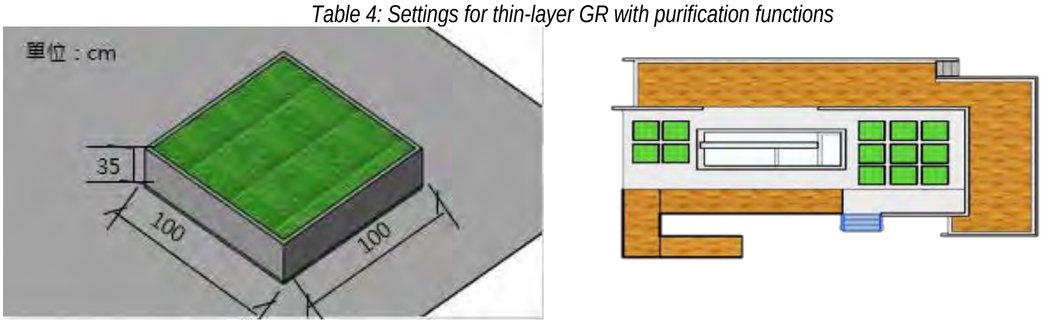

Figure 2: Configuration of the GR module

The thin-layer GR with water purification functions used in this study must consider roof loading, water source quality, and ease of operations in addition to basic requirements and irrigation of the plants growing on the GR. While setting the parameters, BIM was used to modularize the general thin-layer GR and the thin-layer GR with purification functions. These modules were then added to the site model. Due to the need to reserve areas for skylight openings as well as cabling and pipeline arrangements, a layout configuration with 13 thin- layer GR module units was used. (as shown in Figure 2)

Growth medium layer: 100 cm x 100 cm x 12 cm (Length x Width x Height). This layer was designed according to Article 17 that described the minimum active loading regulations described in the chapter of building construction of Building Technical Regulations. Lightweight medium and materials for easier retention and stable volume were selected instead of traditional growth medium. The mixture near the inlet would be composed of ∮5~10 mm vermiculite and ∮5~10 mm expanded clay aggregate. The middle section was filled with a mixture of ∮3~5 mm perlite, ∮1~4 mm maifan stone, and other sticky materials. To provide the plants with a good growing environment, the growth medium layer composes at least 30% of the total volume.

First filtration layer: 100 cm x 100 cm x 4 cm (L x W x H), composed of a mixture of diatomaceous earth and diatomite pressed into plates. Diatomaceous earth are extremely inert materials that offer good filtration and purification properties. The extremely tiny pores of the material allow the filtration of foreign materials, dust, and bacteria. Meanwhile, diatomite offers larger pores, strong water adsorption, and chemical stability. The first filtration layer lies between the soil-free medium and the drainage / water retention layers. This layer prevents the growth

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

medium from being discharged along with the water while preventing discharge pipes at the water retention layer from being clogged.

Drainage and water retention layer: 100 cm x 100 cm x 8 cm (L x W x H). This layer was constructed using recycled polypropylene that is comparable to PE, but offers better physical and mechanical performance in terms of tension and stress resistance. The drainage and retention layer functions as a plate for filtering out contaminants in the water which would then settle at the first filtration layer, preventing the tank from accumulating too much water, leading to deterioration of water quality while retaining enough water for plant use.

Second filtration layer 100 cm x 100 cm x 6 cm (L x W x H). This is composed of ceramic gravel (5), quartz sand, and a gravel layer (6). A discharge outlet was placed at the bottom of the tank to drain the retained water completely.

2.2. Indoor temperature testing

After the BIM models were built, they were then imported into the ECOTECT software to simulate the results for the general thin-layer GR as well as the thin-layer GR with purification functions. Simulation results were then illustrated on a chart for comparisons. The simulation conditions include natural ventilation and the environmental temperature of Taipei City at 12 PM (noon) on August 1st. The areas reviewed in the comparison were the master bedroom (A), living room (B), and toilet (C). (as shown in Figure 3)

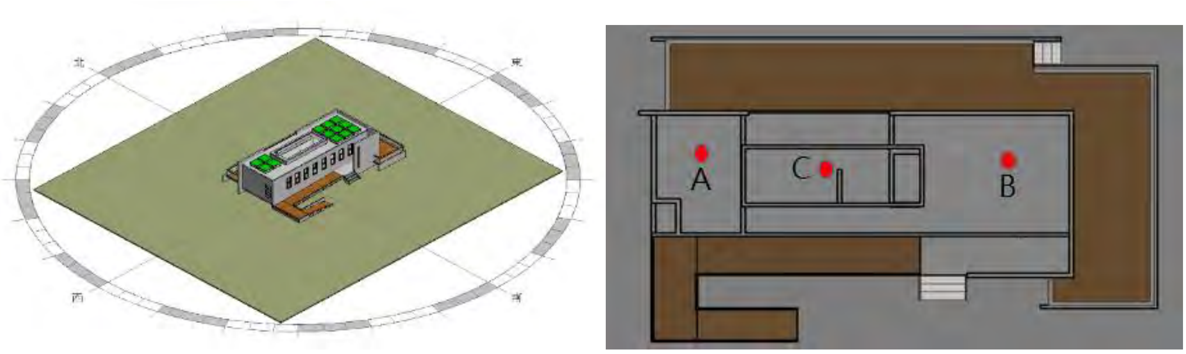

Figure 3: Testing area

2.3. Building a model for a thin-layer GR that employs vertical-flow constructed wetlands

A total of 3 water supply systems were designed for the thin-layer GR with purification functions in this study. The first uses harvested rainwater as the source of water. Gray water will be used if not enough rainfall was received, and public water will only be used if both rainwater and gray water were unable to meet water requirements. If gray water volume exceeds the designed capacity, the excessive quantities will be purified, recycled, and then diverted for irrigating other landscaping facilities or flushing toilets. A study of decision support and cloud operating system for the allocation of stormwater detention capacity published by the Architecture and Building Research Institute (ABRI) of the Ministry of the Interior in 2015 was used as the reference to investigate water cycling when employing vertical-flow constructed wetlands in thin-layer GR and to evaluate a number of different influent flow and hydraulic parameters for various thin-layer GR models. The design volume for water retention was assumed to be equal to the sum of water infiltration and water storage to deduce the related formulas shown in the following:

Design capacity of the GR ∀(m3). Design volume for water detention = Water infiltration + water storage:

$$\forall = \mathrm{Min}(A_6 ft, 0.42V)$$

A_6: Area of the GR (m^2)
f: Final infiltration rate of the soil at the site m/s
V: Volume of the GR (m^3)
t: Standard time delay for maximum rainfall (sec). Default value was set to 86,400 sec

Equation 1

Soil material	Sand	Silt	Clay	Highly plastic clay
Final infiltration rate, f	10^{-5}	10^{-6}	10^{-7}	10^{-7}

Table 5: Setting for the final infiltration rate of the soil at the site

The formula below was used to determine whether to activate or deactivate the gray water injection and calculate the GPV grey water injection rate (m^3/hr) into the GR once activated when the maximum GR design volume exceeds the hourly cumulative rainfall:

$$GPV = \forall max - (I/1000 \times A6)$$

I: Total rainfall (mm/hr)
∀max: Maximum roof volume (m^3)

Equation 2

The formula below was used to determine whether or not to activate or deactivate the rainwater replenishment system and calculate the GRV replenishment system irrigation rate (m^3/hr) once activated when the grey water hourly injection rate into the GR falls below a certain limit:

$$GRV = \forall max - GPV$$

Equation 3

Incoming runoff retention rate for the thin-layer GR that uses vertical-flow constructed wetland:

$$GRR = \frac{(GRV+GPV-V) \times S}{(GRV+GPV)} \times 100\% \ldots$$

GRR: Incoming runoff retention rate (%)
GRV: Volume of rainwater that passes through the thin-layer GR module per hour (m^3/hr)
GPV: Volume of gray water that passes through the thin-layer GR per hour (m^3/hr)
V: Runoff volume of the thin-layer GR per hour (m^3/hr)
S: Evaporation rate

Equation 4

Additional considerations must be made to calculate various hydraulic parameters at different influent volume, including the volumes of processed water or wastewater per unit time per unit area. The resulting formula can also be used as an expression for hydraulic loading. Hydraulic loading is an important design and operational parameter for the processing unit. A feasible range should be specified to assess the allowable purification performance of secondary treatment of domestic wastewater.

To calculate various hydraulic parameters at different influent volumes, the hydraulic retention time (HRT) and hydraulic loading of the thin-layer GR with vertical-flow constructed wetland should be calculated:

$$Vr = Gv \times n$$

Vr : Actual volume of the water containing layers (m^3)
Gv: Volume of the thin-layer GR module (m^3)
n: Porosity (ratio of pore volume to total volume of the materials, and ranges from 0 to 100%)

Equation 5

$$HRT = Vr/Q$$

HRT: Hydraulic retention time (hr)
Q: Inflow (m^3/hr)

Equation 6

$$HLR = Q/As$$

HLR: Hydraulic loading rate (hr)
As: Surface area of the thin-layer GR (m^2)

Equation 7

3. ANALYSIS

3.1. Heat island reduction of thin-layer GR with purification function

This study employed BIM tool of ECOTECT software to replace roof materials and simulate the resulting temperature distribution for further analysis. Simulation time for natural ventilation simulations were set without changing the air conditioning settings and scenarios. Daytime was selected for the simulation primarily to evaluate

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

conduction of solar heat and how it changes indoor temperatures. Thin-layer GR with purification functions was shown to achieve good thermal insulation effects and able to suppress increases in indoor temperatures as it utilized ceramic materials that offer better thermal resistance. Since the BIM system could only analyze average daytime temperatures, further research will be required to determine whether GR can help retain heat or reduce heat dissipation and other energy loss for indoor temperatures and environments during nighttime and provide designers with reference and information needed for effective data utilization.

3.2. Gray water efficiency in the thin-layer GR with purification function

BIM details showed that total water conservation volume would be 1.64 m3 for the 13 GR modules with purification functions after subtracting the water in the growth medium and plant structures. For Taipei City, the average rainfall in the month of June was 325.9 mm with an average hourly rainfall of 0.45 mm. This meant that 1,630 liters of gray water could be purified per hour to replace public water used for irrigation purposes. Hydraulic retention time (HRT) and hydraulic loading were found to be within the recommended design values stipulated for using constructed wetlands for secondary treatment of domestic wastewater. In other words, the system met the HRT and hydraulic loading requirements of decontamination processes using free water surface (FWS) and vertical-flow constructed wetlands. Water requirement management for vegetative cover grown on GR was made easier. The advantages was that water could be easily acquired from light polluted wastewater from the buildings as well as rainwater. Under the concept of short-range water recycling, these sources of water could also be used for other irrigation purposes, benefiting the environment with sustainable management. However, this study has yet to carry out in-depth investigation of variables of the thin-layer GR that include structural form, dimensions, materials, choice of aquatic plants, choice of lightweight growth medium, and climate changes and their relationships to gray water decontamination performance in the system. These investigations may be carried out in subsequent studies.

4. CONCLUSIONS

BIM was employed to investigate hydraulic conditions and parameters under different inflow volumes and thin-layer GR types, and to establish models for hydraulic retention time (HRT), hydraulic loading, and pollution loading models to understand and assess reasonable grey water recycling and usage models for irrigation and toilet flushing in the building. Lightly polluted wastewater discharged from building showers and sinks as well as rainwater could be adequately controlled and treated through this system. Once water quality reaches an acceptable standard, the treated water could be used for irrigating GR and other landscaping features or for flushing toilets. Water requirement management for vegetative cover grown on GR was also made more convenient. The advantages was that light polluted wastewater from the buildings as well as rainwater could be easily acquired. Under the concept of short-range water recycling, these sources of water could also be used for other irrigation purposes, providing positive sustainable management and benefiting the environment in the process.

ABSTRACT

With worldwide cities getting bigger and climate change threatening to bring more extreme weather, about half of China's cities are considered water scarce or severely water scarce by UN measures and another half fail to reach national standards for flood prevention. "Sponge cities" equivalent terms to Low-impact development (LID) used in North America and sustainable urban drainage systems (SUDS) in the UK, a re-imagination of the urban environment where almost every raindrop is captured, controlled and reused has been trendy in China. Instead of funneling rainwater away, a sponge city retains it for use. Some might be used to recharge depleted aquifers or irrigate gardens and urban farms. Some could replace the drinking water to flush toilets and clean homes.

A study recently being completed on "Sponge City" planning of Sino-Singapore Tianjin Eco-city is located in North China. The study aims to help the local government achieving the goals of storm water reduction and source runoff control. In this way, the Eco-city could retain, infiltrate and purify storm water, and fulfil the concept of "sponge city". Storm Water Management Model (SWMM) was selected to simulate runoff process and assess the effect of using different combinations of LID facilities. The model result shows that the LID measure can help control 80% of the annual total runoff under the design precipitation. In consideration of high salinity in Eco-city's water and soil, the recommended LID facilities include green roof with cistern, high level rain-parterre, ecological pond, pervious pavement and grass swale. Guideline of each kind of facility is provided as well for next stage detail design. The study demonstrates reverse-engineering a city to make it more spongey requires a mental shift back up by practical scientific solutions.

Keywords: low impact development, sponge city, sustainable neighbourhood

1. INTRODUCTION

High groundwater level and soil salinization are the main constraints for sponge city construction of Tianjin Eco-city and other Northern Chinese Cities. Considering the goal of improving water environment and restoring water ecology, and the constraints in Tianjin Eco-city, the overall sponge city construction strategy for Eco-city is determined as the combination of small-scale distributed measures and large-scale regional measures. It is a combination of pilot "sponge city" neighbourhood as well as a whole city development strategic vision.

Technically, this study is to build Low Impact Development (LID) hydrological model for Tianjin Eco-City by using the SWMM software. LID layout schemes are compared and optimized in combination with the hydrological status of Eco-city to determine the control indexes of LID rainwater system and resources utilization system. Best practical LID facilities and technologies for Tianjin Eco-city are recommended. It is an effort to experiment the relevant technology and to back up the mentally fundamental thinking and behaviours.

2. SIMULATION FOR ECO-CITY LID RAINFALL SYSTEM

The study area is to set as 150.58km^2 of Tianjin Eco-City including the original Central Eco-City Area, Binhai Tourism Area and Tianjin Marine Economic Area. Figure 1 shows the assessment area.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 1: The study area

2.1 Technical approach

The technical approach for the Eco-city LID model development is as followed:

- Define the sub-catchment of the research areas according to the rainwater systems, regional land use planning and road network;
- Set up the design targets (mainly for volume capture ratio of annual rainfall) according to the relevant national requirements on sponge city development;
- Determine the boundary conditions;
- Digitalise the inputs of SWMM model, including topography, soil, land use, slope, impervious rate, etc.;
- Primarily set the control indexes and combinations of different LID facilities, simulate and analyze whether design targets could be met;
- Adjust the control indexes to meet the design targets;
- Design the Best Management Practice (BMP) measures for process and end control, evaluate extra rainwater regulation and storage measures and carry out SWMM simulation;
- Determine the optimal "LID+BMP" combination measures and build up the index system for the Eco-city.

The defined sub-catchment and the major model parameters are shown in Figure 2 and Table 1.

Figure 2: Sub-catchment area of Eco-city

Module Parameters	Adjusted Value
Impervious rate (%imperv)	10~80
Manning coefficient in impervious area (N-imperv)	0.012
Manning coefficient in pervious area (N-perv)	0.032
Manning coefficient in pipelines (roughness)	0.013~0.015
Depression storage depth in impervious area (S-imperv)/mm	0.38
Depression storage depth in pervious area (S-perv)/mm	1.52
Maximum infiltration rate of Horton module (Max.Infil)/(mm/h)	75
Minimum infiltration rate of Horton module (Min.Infil)/(mm/h)	3.8
Decay coefficient of Horton module (α)	0.006

Table 1: Major hydrological parameters of Low Impact Development (LID) module

2.2 Hydrological computation

Design rainfall

According to Outdoor Drainage Design Guideline (GB50014-2006) (2014 edition), the Annual Maximum Value Method shall be adopted in the storm intensity formula for designing drainage system if the area has over 20 years of rainfall records; value of many years can be adopted if the area has less than 20 years of rainfall record.

The storm intensity formula adopted in Tianjin is as follow:

$$q = \frac{3841 \times (1 + 0.85 \lg P)}{(t + 17)^{0.85}} (L/S.ha)$$

Where, q = Designed storm intensity (l/s•ha); P = Recurrence period (year); t = rainfall duration (min).

Overall objectives

The control volume capture ratio of annual rainfall shall be no less than 80%, corresponding to 30.4 mm of design rainfall for Tianjin. The pollution control indexes of rainwater runoff shall be calculated based on Suspended Solid (SS) and Chemical Oxygen Demand (COD). The total annual removal rate of SS shall be more than or equal to 30%, and the total annual removal rate of COD shall be more than or equal to 20%.

Rainfall type selection

As stated above, the control volume capture ratio of annual rainfall shall be no less than 80%. According to the storm intensity formula for Tianjin city area, the corresponding rainfall type is obtained for the Eco-city by using the Chicago Method.

The model also simulates the storm of single-peak long-duration rains for 2-year and 30-year recurrence period by Chicago Method:

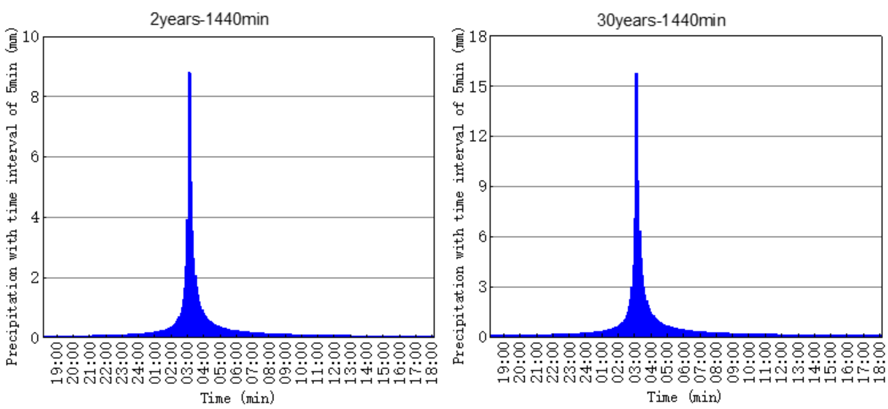

Figure 3: Rainfall process of 2-year and 30-year long-duration rain types in Eco-city

2.3 Model results

The simulation analysis were carried out on tradition practices of drainage system (without LID) and sponge city building schemes (with LID) in ECO-CITY, mainly including designed rainfall analysis, general analysis and runoff process analysis.

Design rainfall analysis

The total runoff process of the design rainfall type based on 80% control volume capture ratio of annual rainfall (30.4mm of design rainfall) is shown below:

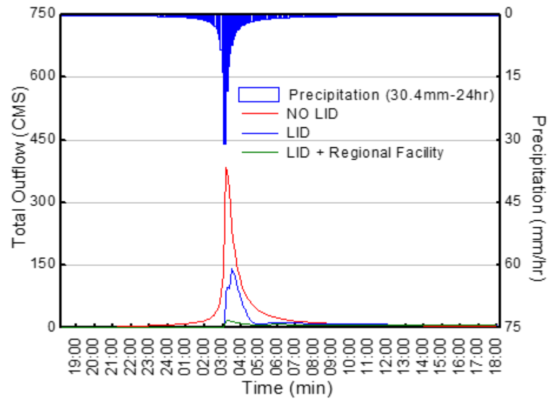

Figure 4: Outflow comparison of Eco-City system with/ without LID

As shown in the above figure, for 30.4 mm rainfall during 24 hours, the outflow could be controlled after adding LID facilities and regional facilities in the planning area. The result meets the requirements of Technical Guidelines for Sponge City Building (Trial version) for 80% control volume capture ratio of annual rainfall.

General analysis

The comparison for total outflow under 2-year and 30-year recurrence period is shown below:

Total Outflow (10 thousand m^3)	2years-24hr	30years-24hr
NO LID	650	1251
LID	504	1084
LID + Region Facility	250	931
Runoff Reduction Rate	61.5%	25.6%

Table 2: Comparison for total outflow under different recurrence period

Results show that the sponge city building scheme can reduce the total outflow. However, with the rainfall intensity increases, the storage volume of LID facility tends to be fully utilized and cannot store more runoff. Thus, the LID facility is more effective during regular rainfall than during heavy rainfall.

Comparison results of peak runoff values under different recurrence period are shown in Table 3. Results show that the sponge city building scheme can effectively reduce the peak value in the project area, and can also help controlling flood risks in the Eco-city.

Peak Value (m^3/s)	2years-24hr	30years-24hr
NO LID	1768	3800
LID	1355	3468
LID + Region Facility	580	925
Runoff Peak Value Reduction Rate	67.2%	75.7%

Table 3: Comparison for peak flow under different recurrence period

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Runoff process analysis

Runoff processes for 24-h rainfall under 2-year and 30-year recurrence period in the project area are analysed. The results are shown as below:

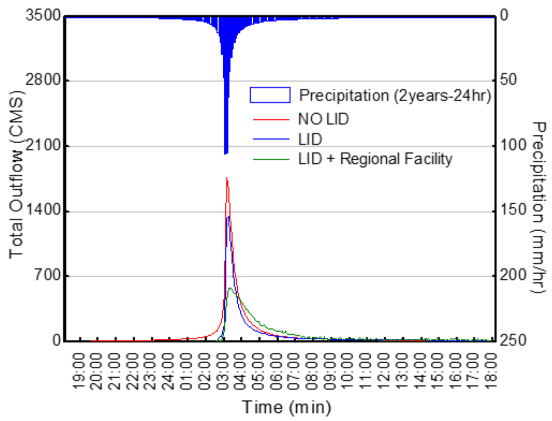

Figure 5: Outflow comparisons for 2-year long-duration rain type with/ without LID

As shown in Figure 5, under 24h rainfall of 2-year recurrence period, the systemic outflow peak value is significantly reduced by 67.2%, and the total runoff amount is also significantly reduced by 61.5% after adding LID and regional facilities in the project area.

As shown in Figure 6, under 24h rainfall of 30-year recurrence period, the runoff peak is significantly reduced by 75.7% after adding LID and regional facilities in the planning area. And the total runoff reduction rate is 25.6.

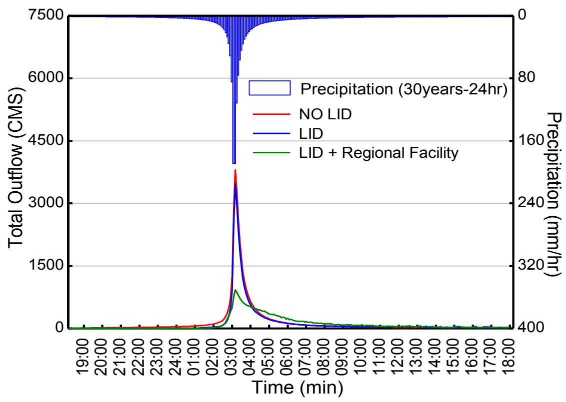

Figure 6: Flow comparison for 30-year long-duration rain type with/ without LID

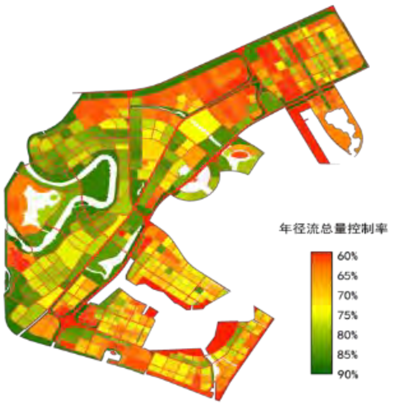
3. CONTROL SCHEME FOR LID RAINWATER SYSTEM AND RESOURCE UTILIZATION

3.1. Applicable LID facilities in Tianjin Eco-city

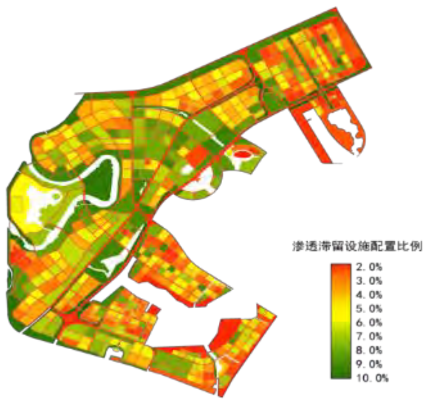
Considering the major water issues and restriction factors in Tianjin Eco-city, the combination construction of the small-scale distributed measures and large-scale regional measures is recommended as the general strategy for sponge city building in Eco-city. Small-scale distributed measures include green roof, rainwater barrel, high-level rainwater parterre, ecological pond, pervious pavement, grass swale, rainwater garden (rainwater storage) and etc; Large-scale regional measures include regional treatment and storage, green storage/reservation (constructed wetland, wet pond, etc.).

3.2. Control quota distribution of LID measures of Eco-city

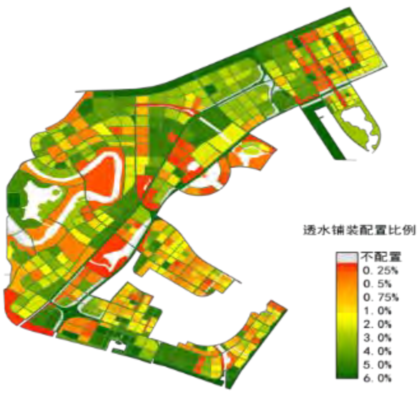
According to calculation of the above-mentioned LID models, the control quota distribution of LID measures of various land types of Tianjin Eco-City can be acquired. Figure 8 shows plan figures for LID measure distribution of different land types of Tianjin Eco-City.



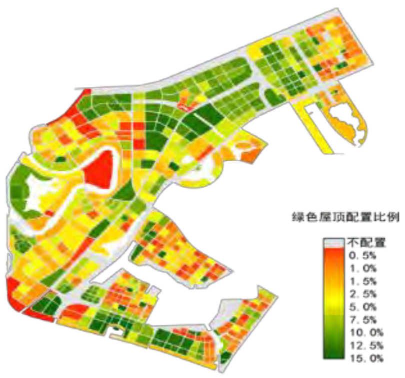
Annual Runoff Volumes Control Rate of Land Parcels



Infiltration Retention Facilities Configuration Ratio



Pervious Pavement Configuration Ratio



Green Roofs Configuration ratio

Figure 8: Control quota for different land use type

4. CONCLUSION
