
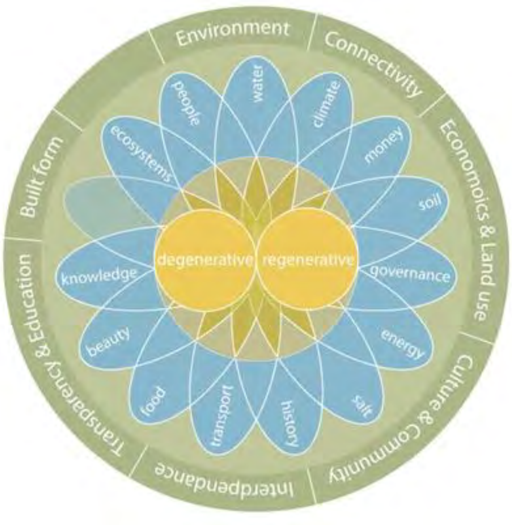

Figure 1: Visual representation of the LENSES framework

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Beyond its visual representation and ability to organise thoughts and information, LENSES focuses on systems thinking, allowing regenerative outcomes to emerge. Stakeholders develop their own lens during the initial workshops and then use the resulting model to guide the design charrette. LENSES has been used to drive regenerative outcomes in multiple projects (including for town planning, building design, education, personal growth, organisational development and others). However, there is limited information about how participating stakeholders perceive LENSES and judge its effectiveness. The next section describes the research method used to evaluate this aspect.

2.2 Overall research strategy

The authors have led and organised a series of workshops with key stakeholders of the project in order to facilitate regenerative thinking from the early stages of design. The results of the each workshop were carried forward to the next as depicted in Figure 2. The workshops are described in more detail in Section 2.3.

As shown in Figure 2, this paper focuses on the evaluation of the workshops facilitated using the LENSES framework. This evaluation was conducted through an online survey (described in Section 2.4) and additional interviews with stakeholders. The survey and interviews are designed to extract as much information as possible on the effectiveness of the LENSES framework and how different it is from business as usual. Only the survey results are analysed in this paper due to a lack of space.

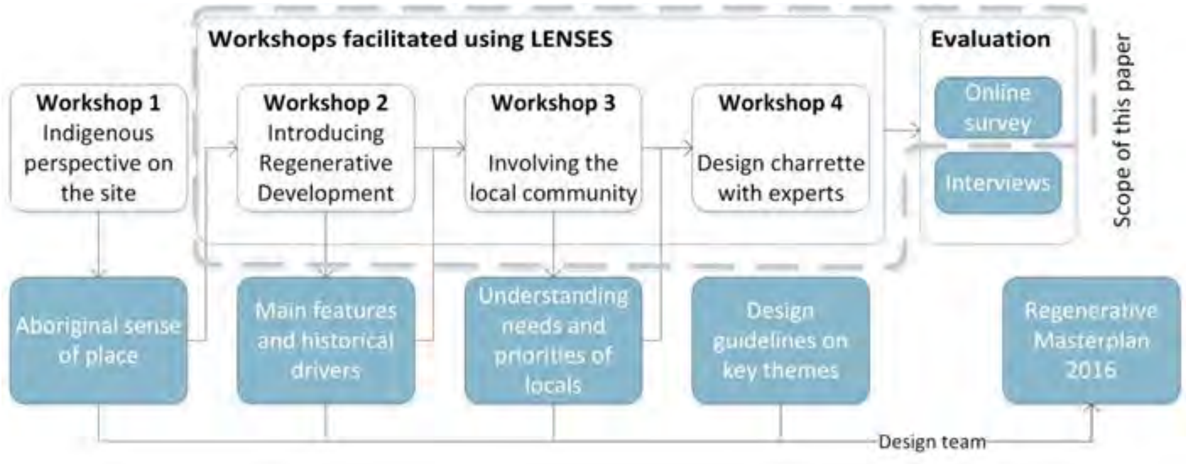

Figure 2: Overall process of the project and scope of this paper

2.3 Project timeline and workshops description

Table 1 is a summary of the process used to integrate regenerative development principles in the design process. Based on the LENSES framework it was critical to first understand the story of place and the context of the project in order to identify the principles that the project would be designed to. This context included a timeline of the site with inputs from the local community, government, and Indigenous participants. The following step was to determine the flows that brought this site to life, and identify potential flows that can create resilience and adaptive capacities for social and ecological systems. The resulting LENSES artefact was then used to inform the two days charrette workshop. The outcomes of all of these were fed into the final design process, the resulting master plan and details for implementation.

WS/ event	Aim	Stakeholders	Activities	Outputs
2015 – Prework – at the site around the room table	Identify the principles of the project	land owners	Used the Vitality lens Discuss shift from degenerative to regenerative design; and foundation lens develop an initial understanding of regen. development principles	Key principles: Interdependence Stewardship Respecting limits Partnership Transparency and education
2016 Jan –	Team formation	group of researchers	Shares the potential of the project for a research grant from Carlton Connect.	Received grant
2016 Feb WS1 – at the UoX	Cultural Awareness Training	The initial design team	Team taken through Indigenous history and design; and, the way to be sensitive and effective communicators to the Indigenous community.	Deeper understanding of inclusion and potential, we also started using the Indigenous timeline as basis for the history of place activities.
2016 Feb WS2 at the UoX	LENSES and Regen training	The initial design team	Three hours introduction to regeneration (Vitality) and the LENSES process, and started the Flows Analysis through a history timeline activity (Flows)	Shared understanding of the potential of the site and the regenerative design process
2016 Feb site visit	Site familiarisation	design team and researchers	A whole day visit of the site – visited 4 areas of the site and collected drone footage	Ability to connect to the issues of the site, input into the flows lens
2016 March WS3 onsite	Community input and site visit	Community – with wine and cheese – around 20 participants	site visit, followed by a two-and-a-half-hour workshop around: "What is important to the community?"	Ability to connect to the issues of the site, input into the flows lens
2016 March WS3 at the local council	Community and government input	Community, government and design team – 12 participants	Repetition of the above with an additional three hours workshop: "What are the critical flows and relationships we need to develop to ensure the place has the potential to thrive?	Ability to connect to the issues of the site, input into the flows lens – this finalised the principles, and flows lenses
2016 April/May – design several	Integrate regen thinking into the design	Design team	Develop design concepts and finalizing principles and flows	Initial design ideas
2016 April WS4 at UoX - 2 days	Design concepts for the project	40 industry and research experts	Developed regen. ideas integrated across building, infrastructure, ecosystem, water, land, governance, community & innovation.	Participants identified opportunities and gaps in the knowledge to further inform the research agenda

2.4 Survey description

In order to evaluate LENSES an online survey was conducted with the stakeholders that attended the workshops. The survey consisted of ten questions (see Appendix A for the entire survey):

- 2 questions regarding the role of the stakeholders and their attendance;
- 3 Likert-scale (7 options) questions on personal gain from the workshops, the project's benefit from the workshops and the stakeholder's understanding of regenerative development;
- 4 open-ended questions that cover personal gain, defining regenerative development, the benefits of LENSES and the potential improvement to the facilitation process with LENSES: and
- 1 Likert-scale (5 options) with 9 sub-questions evaluating the performance of LENSES on a range of indicators.

The survey was opened to participants from the end of Workshop 4 (12/04/2016) and closed on the 31/05/2016. Participants were encouraged to participate and were reminded twice by email. Although, participation in the survey was facultative, 28 responses were collected out of 40 stakeholders involved in the workshops (most of whom were present during the design charrette or workshop 4). The resulting response rate of 28/40 = 70% is relatively high. However, the sample size is not statistically significant and this is further discussed in Section 4. All survey questions were approved by an Ethics committee and all participants were informed of the project, data collection and survey participation through a plain language statement distributed during the workshops as well as face-to-face explanations.

3. RESULTS

The 28 responses received for the survey included 3 architects (11%), 7 engineers (25%), 6 scientists (21%), 2 community members (7%) and 10 other (36%), which mostly included consultants (4/10) and academics (3/10). The large majority of respondents participated in Workshop 4 (86%) and some participated in Workshop 2. Regarding personal gains (Q3 and Q4), 61% responded that the workshop was useful (5/7 on the Likert scale) followed by 25% responding that it was essential (6/7 on the Likert scale). The average was 5.1/7 with a standard deviation of 0.96, revealing that respondents felt they benefited personally from attending the workshop(s).

The free comments revolved mostly around the interdisciplinary nature of Workshop 4 and the positive exposure to LENSES. The respondents felt that the project gained useful (5/7 on the Likert scale) to essential (6/7 on the Likert scale) value from the workshops (Q5). On average, they rated the added value 5.5/7 with a standard deviation of 0.79. This shows that most participants valued the inputs of LENSES.

Most respondents felt that they understood regenerative development in Q6 (14% a little (4/7), 39% enough (5/7) and ~46% a lot (6/7)). When asked about defining regenerative development (Q7), some of the most recurring words used included environment (11 responses), positive (8 responses), system (7 responses) and human (5 responses). Overall, respondents were seemingly satisfied with the performance of LENSES.

Answers to Q8 (see Figure 3) present averages ranging from 3 to 4 (over 5) across the different aspects evaluated. The lowest average score was attributed to the capacity of future proofing the development while the highest score was linked to its support for cross disciplinary collaboration. When asked about the benefits of using LENSES (Q9), a strong focus was made on its ability to discuss the topic broadly, providing a more “holistic approach” (Respondents 10 and 22). The most used words by the respondents included, different (7), flows (5), thinking (5), understanding (4) and relationships (4), highlighting some of the key features of regenerative development (see Section 1). The major limitation of the process and what could be improved in the view of most respondents (Q10) was the amount of time provided to better understand the LENSES framework. This is highlighted by the word time appearing in 10 different responses.

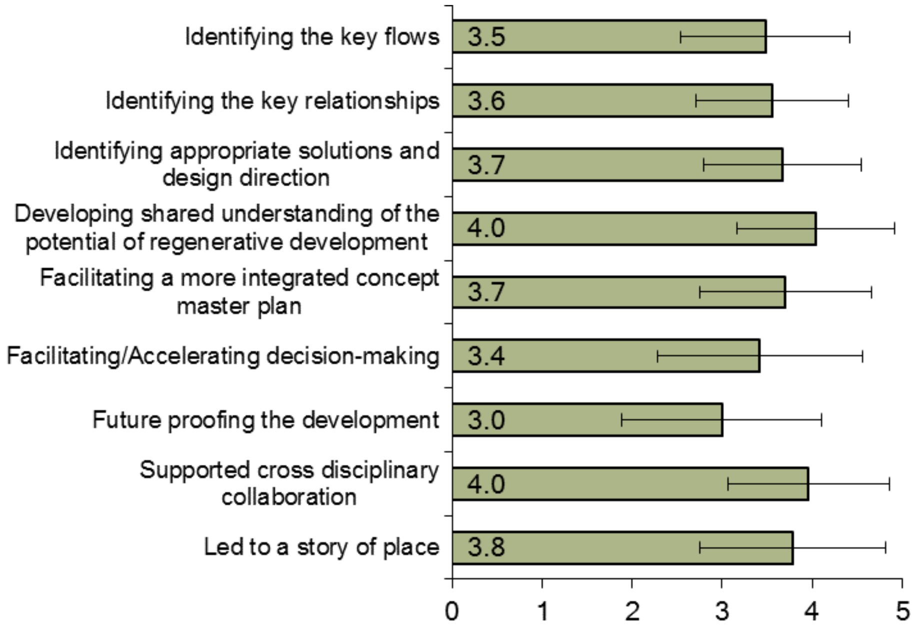

Figure 1: Answers to question 8 of the survey on a scale from 1 to 5, can you score how well you felt the following parts of the workshop, including the LENSES framework worked?

4. DISCUSSION AND CONCLUSION

Designing a community such as Seacombe West regeneratively requires systems thinking and designing with the express intention of creating benefit for those systems. The results shown above illustrate the ability of those in the project to think beyond their disciplinary silos, as it was noted by one of the stakeholders in the interviews: “The lenses process I believe is probably quite an interesting way of trying to focus people who have specific expertise … onto [common] topics, and … breaking down communication barriers…”. One of the reasons this was achieved was the ability to have a shared understanding of the project. This ability to have a common story, a common purpose to a project has been shown to be critical in the success of complex projects where the aim is to produce results beyond common practice (Mang and Haggard, 2016, Hes and du Plessis, 2015).

Interestingly the survey results show that participants wanted more time, to resolve and refine ideas and create concrete opportunities. Yet for most projects the time spent on this activity would not be seen as productive. This is where looking at projects across their design, development, construction and handover is critical. The work of Reed and the 7 group (2009), has shown that integrated project design, where more emphasis is put on the initial holistic concept design, and includes all stakeholders, results in projects that are completed faster with less cost than comparative projects.

It is interesting that the participants score the LENSES framework lowest on its ability to future proof the project. This may be a reflection of the project being at such a preliminary stage and/or the low lying nature of the project and therefore uncertainty around its ability to thrive through sea level rise. It may also be related to the lack of time spent debriefing the project around next steps and how the guidelines would feed into the design, development and construction aspects. Theoretically the process the project went through should help improve the resilience of the site to future changes as an interdisciplinary body of experts was present. Further assessment of the built project is required to evaluate the effectiveness of LENSES in resulting in adaptive design outcomes.

To conclude this research shows that the LENSES framework seems to be assessed favourably by workshop participants and that it strongly supports interdisciplinary systems thinking. Whether this project will indeed lead to increased vitality, viability and ability to adapt will need to be seen over time. The results of the design stage and the comparison of the resulting master plan to that of the original master plan of 2003, discussed in a previous paper suggest that the potential is there (Hes, Stephan, Moosavi, 2016; Plaut et al. 2016) and highlighted by stakeholder comments such as: “So it [LENSES] really helps us look at not only just the building of the development, but all the other aspects such as the environment and the social outcomes and how the whole development will operate into the future. And so it gives a much deeper and fuller understanding of the project”.

APPENDIX A: Online survey questions

This appendix presents the questions of the online survey. A description of the three Likert-scales used is given first in Table A.1.

Likert Scale 5		Likert Scale 7a		Likert Scale 7b	
1.	Not at all	1.	Waste of time	1.	Totally confused
2.	A little	2.	None	2.	A little confused
3.	Fairly	3.	A little	3.	Barely
4.	Significantly	4.	Some interest	4.	A little
5.	Very much	5.	Useful	5.	Enough
		6.	Essential	6.	A lot
		7.	This changes everything	7.	Everything I need to know

Table A.1: Likert scales used in the online survey

The questions are given below in bold and the answer format between hyphens afterwards. Not that LS refers to Likert Scale and FA refers to Free Answer.

- What is your role? (select from: Architect, Engineer, Scientist, Commnunity Member, Indigenous Representative, Government Member, Other (specify)
- Which workshops did you participate in? (select one or more from workshops 2-4)
- How much value do you feel YOU gained personally from attending this/these workshop(s)? (LS 7a)
- What did you gain from attending? (Free answer)
- How much value do you feel the PROJECT gained from this/these workshop(s)? (LS 7a)
- How well do you think you understand regenerative development? (LS 7b)
- In your own words what do you think regenerative development is? (FA)
- On a scale from 1 to 5, can you score how well you felt the following parts of the workshop, including the LENSES framework worked? (LS 5)
  - Identifying the key flows
  - Identifying the key relationships
  - Identifying appropriate solutions and design directions
  - Developing shared understanding of the potential of regenerative development
  - Facilitating a more integrated concept master plan
  - Facilitating/Accelerating decision-making
  - Future proofing the development

Gamification as a Means to User Involvement in Decision-Making Processes for Sustainable Buildings

Hanne Tine Ring HANSEN[a], Mary-ann KNUDSTRUP[b], Stine Skøtt PEDERSEN[c]

[c] *Søren Jensen, Denmark, ssp@sj.dk*

ABSTRACT

User ownership, actors' and stakeholders' lack of knowledge is often identified as critical success parameters and barriers when evaluating how well sustainable buildings perform. Recognising that it is impossible to drive sustainable development without the people who pay for sustainable buildings, and the people who run and use these buildings, the development of a dialogue and prioritisation tool was funded by the Danish Ministry of Immigration, Integration and Housing. This paper presents the tool development process that is a result of a participatory research and development process where the tool was developed by a multidisciplinary group of stakeholders and actors from the Danish building and housing industry. The paper presents how gamification can be used to make complex and academic issues of sustainability available to decision-makers in housing organisations who are typically people from all walks of life.

Design thinking was used as method to develop a tool that focuses on how to make sustainable strategy development accessible to non-specialists during those critical stages of building design processes when goals and prioritisations are set. The tool is based on an open and editable platform and it will be available to the public in the early Summer of 2017. The paper presents how design thinking is used as an engaging research and development methodology, as well as, an introduction to the dialogue and prioritisation tool's content and format.

Keywords: community empowerment, affordable housing, decision making process

1. INTRODUCTION

In August 2013, an open two-stage architectural design competition was launched under the title 'Future Sustainable Public Housing'. The project owners, selected by the Danish Ministry of City, Housing and Rural Districts, were the two Danish housing organisations, 'Lejerbo' and 'AL2Bolig'. The Danish version of the DGNB system [2] was described in the competition material and the project owners hired a DGNB consultant to initiate a pre-certification of the competition projects that were selected for participation in stage two of the competition. During this process the DGNB tool was introduced to the project managers from Lejerbo and AL2Bolig and the residential decision-making construction committee at AL2Bolig. During this process it became apparent that the DGNB system was too academic and complex to enable easy communication with decision-makers in the housing organisation. Because of this, the director of AL2Bolig initiated the idea to develop a dialogue and prioritisation tool for user-involvement on sustainability strategy development for social housing. In late 2015, The Danish Ministry of Immigration, Integration and Housing decided to fund the tools' development.

1.1 Decision-making in Danish housing organisations

The social housing organisations in Denmark depend on subsidies for renovation from "Landsbyggefonden", governmental subsidies for new constructions, as well as, municipal planners who determine where housing projects are to be built and how they are financed. Because of the public subsidies, and the fact that the tenants carry most of the investment in new buildings, Danish housing organisations are based on residential democracy where the residents elect their peers as members of the board and different committees. The residential democracy is supplemented by professional staff consisting of a director, a communication department, tenant management, technical staff and facility managers. How the residential boards and committees are involved in decision-making on building projects vary a great deal depending on the housing organisations. In some organisations the residential democracy is greatly involved in the decision-making processes. This means that in some cases residents with very different educational background will have a great impact on the sustainability strategies for building projects thus making it necessary to communicate with the residential democrats about complex and highly specialised knowledge.

1.2 Project organisation

The project was organised as follows: A work group was established that refers to the Danish Ministry of Immigration, Integration and Housing. An advisory board and a test group were established as advisors to the work group. The work group consists of two building design engineers, a social housing expert and the following representatives from two housing organisations: a director, a technical chief and a communication team leader. One of the members in the work group is the project owner who refers to the Danish Ministry of Immigration, Integration and Housing. The advisory board is interdisciplinary with representatives from the work group and the following roles: Architect, engineer, technical chief and project managers from housing organisations, contractors, municipal plan chief, residential democrat and technical reviewer from the Danish Green Building Council. The test groups consist of project managers from five different housing organisations and a group of residential democrats with very different background and skills who were elected by their peers for decision-making on building projects in their respective housing organisations. The purpose of the multidisciplinary workgroup and advisory board was to ensure that all relevant actors from the building industry could contribute with their experiences and ideas in the tool development process whilst the selection of people for the test group focused on ensuring that projects managers and residential democrats from very different housing organisations would test the tool. This was chosen to ensure that the tool is applicable by housing organisations with very diverse backgrounds.

2. TOOL DEVELOPMENT METHODOLOGY

2.1 Design thinking as a methodical approach

Design Thinking was used to facilitate the development of the dialogue and prioritisation tool. The term Design Thinking (DT) is often used as a way of describing how designers think. David Kelly, IDEO, is amongst the pioneers behind the notion of Design Thinking in business development projects. IDEO explains DT like this: "Design thinking is a human-centered approach to innovation that draws from the designer's toolkit to integrate the needs of people, the possibilities of technology, and the requirements for business success." (Brown, September 20th 2016). Prior to the launch of the term design thinking researchers like Professor Bryan Lawson, Sheffield University, and the laid Professor Donald Schön, Massachusetts Institute of Technology, were some of the main authorities in the field of how designers think. The referenced paper by Hansen and Knudstrup (2008) concluded that designers and engineers traditionally approached problem solving in different ways where the designer reframed the design problem continually throughout their process whilst engineers tended to stick with the original problem and test different hypotheses for how to solve the problem. Today DT is a commonly used term that is applied to many disciplines including engineering and the disciplinary boundaries between architectural design and engineering have therefore diminished. When developing the dialogue and prioritisation tool a model of design thinking, developed by the Danish Design School in Kolding, was utilised. The model shown in Figure 2 was chosen because it builds on the theories behind design thinking and visualises when open and closed modes are utilised in the project and product development.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.2 The tool development process

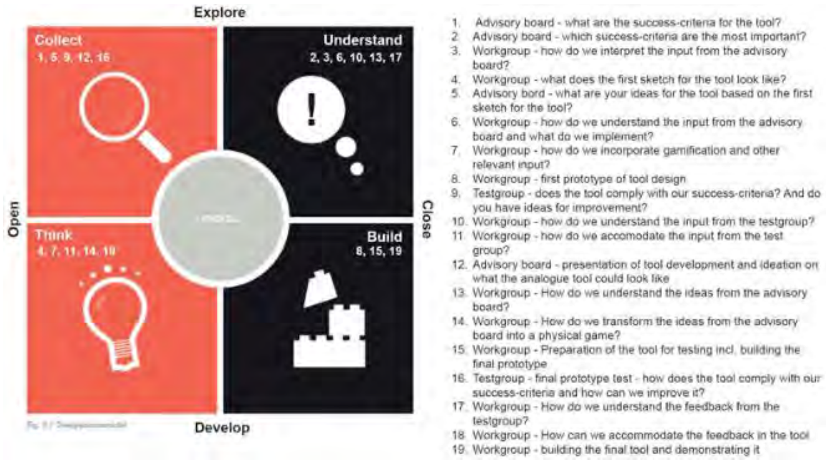

Figure 1: The tool development process mapped via numbers added to the "Design Process Model" from the Danish Design School in Kolding

The dialogue and prioritisation tool development occurred in four phases with a total of 19 activities where each phase included open and closed modes in the Design Process Model from the Danish Design School in Kolding. These activities are added as a new layer with numbers in the Design Process Model (please refer to Figure 1).

3. THE NEW DIALOGUE AND PRIORITISATION TOOL

The idea of basing the dialogue and prioritisation tool on gamification originates from a meeting with the advisory board where some of the advisory board members explained how using the DGNB system on projects had resulted in a sense of competing with oneself and how this increased the project actors' engagement and commitment to increase the features of sustainability in their projects. The reasoning behind the decision to gamify the dialogue and prioritisation process was that 1) Physical interaction with objects will make the decision-making process more engaging and 2) Visualisation of qualitative performance at an early stage is an important driver that makes stakeholders compete with themselves. Gamification was therefore selected as a means of using the DGNB system to turn sustainability into measurable parameters thus quantifying and visualising the decision-making effect on social, economic and environmental sustainability. Gamification is thus in this instance defined as an interactive strategic decision-making process where the results of qualitative decisions are quantified and visualised as a driver for a better dialogue about sustainability and hopefully more holistic sustainability strategies [10]. The element of gamification in the tool is therefore essentially the situation where the decision-makers gain increased insight into sustainability aspects of building design and compete with themselves to improve the project performance.

To ensure that the actors focus on strategic decisions rather than immersing themselves into specific solutions the tool contains two components; 1) A digital tool programmed in Microsoft Office Excel for project managers in housing associations and 2) A dialogue tool number of physical dialogue and prioritisation cards that are to be used at a workshop with different actors from the housing organisations. Physical objects in the form of different coloured Centricubes are assigned to each corresponding coloured dialogue and prioritisation card. The number of Centricubes roughly corresponds with the influence that the specific dialogue card has on the environmental, social, economic, technical or process quality in the DGNB system. The purpose of these objects is to visualise how the conclusions of the decision-making process affect the project's sustainability.

Figure 2 shows a picture of the new analogue dialogue and prioritisation tool used in the prototype test in November and December 2016. The dialogue board and the questions on the cards are under revision after the prototype test but the essential elements of the tool described in this paper will be preserved.

Figure 2: The new developed analogue dialogue and prioritisation tool used in the prototype test.

3.1 Tool content

As mentioned in the previous paragraph, the tool consists of two components, a digital platform for the project manager and an analogue platform to be used by the project manager in dialogue with the residential democrats in the housing organisation.

The approach taken to sustainability in the tool is the Danish version of the DGNB system. The challenge one faces when trying to use the DGNB system in communication with non-specialists is that the system is perceived as very academic – i.e. very theoretical and abstract – and very unapproachable by non-specialists. This makes sense seen in the light that one needs to have at least 2 years of practical experience prior to completing the training to become a DGNB consultant. It is however a significant barrier when it comes to ensuring ownership and engagement with non-specialists in the decision-making process. Because of this the DGNB system has been transcribed into the themes listed in Table 1.

Quality	Themes
Environmental quality (green colour)	Materials, Energy, Water, Biodiversity, Pollution management
Economic quality (blue)	Life cycle costs, Flexibility, Durability and robust solutions
Social quality (orange)	Quality of outdoor areas, Indoor climate, User control, Accessibility, Safety and security, Cyclist facilities, Architectural quality, Functionality and planning
Technical quality(yellow)	Fire management, Building envelope quality, Cleaning and maintenance
Process quality (purple)	Project planning, Integrated design process, Integrated concepts, Responsible contractors, O&M material handover, Construction site operation, Onsite measurements, Commissioning

Table 1: List of DGNB themes referring to the different colourers in the tool

Communication with the residential democrats is based on these themes and a number of topics related to each of these themes. Examples of topics related to the theme Materials are: design for disassembly, environmental impact of materials, embedded toxins and responsible procurement. For each of these topics there is a short explanatory text that describes 1) What this topic has to do with sustainability and 2) Which type of value it adds to the projects social, environmental and economic sustainability. Each topic has at least one question that the residential democrats are asked to discuss and prioritise on a scale of three levels of importance. Depending on their answers the actors will place the Centricubes belonging to the specific dialogue card in one of two fields at the dialogue board 'prioritised' and 'not prioritised'. The purpose of this exercise is to visualise how different types of sustainability is weighted by the dialogue partners as well as an identification of the remaining potential to improve the project's sustainability. The project manager will mark the selected answer for each question in a table that he/ she has printed from the digital tool in case the dialogue partners wish to change their minds and change the project's prioritisation of a specific topic.

After the workshop the answers to each question is transferred to the digital tool and translated into a series of graphs that show how the project is expected to perform against the DGNB system. It is also possible for the project manager to add his or her own weighting to each theme if they do not wish to adhere to the weighting of the themes in the DGNB system e.g. if they have chosen to disregard some of the themes in their project. Once the dialogue process has been completed the dialogue tool translates the questions and answers for each topic back into the DGNB system's structure as part of the preparation of the tender material. This is done to ensure easy communication with DGNB specialists that have to reply to the upcoming tender.

3.2 Tool application

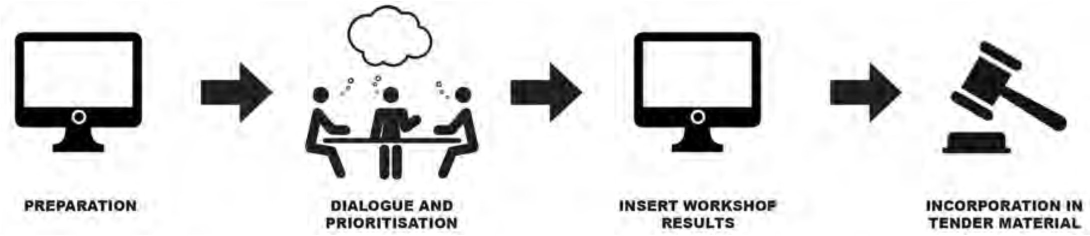

Figure 3: Overview of the tool application process.

The tool is applied in the following manner:

- The project manager fills out a form with background data and contextual questions about the project's preconditions including which actors he wishes to include in the dialogue process.
- Based on his or her answers the list of themes are sorted by the digital tool and for each of the themes listed by the tool the project manager selects which actor or group of actors to include in the decision making process for each theme.
- Based on step 2: The tool divides the topics, questions and answers for each theme into separate sheets in the tool. This is where the project manager will insert the results of the analogue dialogue process.
- Based on step 3: The project manager divides his/her dialogue cards into piles for each actor or group of actors that he/she wants to involve in the decision-making process. He/she also divides the number of Centricubes into piles and brings these with the rest of the dialogue tool to a meeting or a workshop with these actors.
- At the workshop each card is prioritised on a scale of three levels that define the importance of the card's topic. Each card has a colour that tells the dialogue partners whether the topic has to do with social, environmental, economic, technical or process quality. The project manager can also choose to bring the coloured Centricubes that correspond to the weights of each card and use these to build an image of how the selected strategy performs for each of the 5 qualities in the DGNB system. If this is included in the dialogue process the actors will receive instant feedback on how their choices influence the future sustainability of their project. The type of sustainability is marked via the coloured Centricubes thus visualising how different types of sustainability is weighted in the strategy.
- After the workshop the project manager inserts the conclusions from the dialogue process into the digital tool and the tool provides him/her with input for the tender material and a series of graphs of the project performance at this very early stage of the design process.
- After the project tender has been completed the prioritisation can be revised in collaboration with the residential democrats if they need to find areas to save money or if the winning tender has improved the project's sustainability.

4. CONCLUSION

This paper presents the development and content of a tool developed for early actor involvement in decision making processes related to sustainable building design. The tool development was based on a combination of design thinking and gamification. The preliminary tool was tested in August 2016 with positive feedback and great suggestions for improvement by project managers in residential housing organisations. A second round of testing was completed with residential democrats and their project managers in November and December 2016. The feedback from this test was very positive and the work group got some interesting input on what was difficult to understand and ideas for how to improve the tool.

The conclusion of the prototype tests was that a) Using analogue elements such as dialogue cards and Centricubes in the dialogue with residential democrats increases their understanding of sustainability and their engagement in the decision-making process, b) Physical activity increases the actors' remembrance, c) Gamification is interesting because it makes actors reflect on how to improve the performance of their decisions towards the project's sustainability profile and d) the final tool needs to find a balance between abstract ideas and specific solutions that ensures that the discussion does not focus too much on specific solutions and give an illustrative information over the prioritisation in the project exemplified in the numbers of coloured Centricubes referring to the 5 DGNB themes.

After the final testing in November and December 2016 the tool will be finalised. The final version of the tool is expected to be released in May 2016 and the final tool will be ready for presentation at the WSBE17 conference.

Design Thinking has proven itself as a valuable method for the tool development. Without the conscious and strategic use of open and closed modes the final tool would not have ended out as well as it did if the work group had designed it without the input from the advisory board and the test group.

ACKNOWLEDGEMENT

The following people have contributed to the tool development either as part of the work group (WG), the advisory board (AB) or the test group (TG): Ole Nielsen (WG) and Jesper Toft-Nielsen (TG) , Boligselskabet Sct. Accelerating HKIA's Carbon Footprint Reduction through Multi-stakeholder Engagement and its Potential for Multi-tenant Facilities

Mike KILBURN[a], Stephen CHAN[b]

[a] Airport Authority Hong Kong, Hong Kong SAR, mike.kilburn@hkairport.com
[b] Airport Authority Hong Kong, Hong Kong SAR, stephen.chan@hkairport.com

ABSTRACT

With a team of 1,500 staff, Airport Authority Hong Kong (AAHK) is responsible for the operation and development of Hong Kong International Airport (HKIA) while the majority of the airport's operation is outsourced to its business partners (BPs), such as airlines, caterers and cargo handlers, who collectively employ 73,000 staff (AAHK, 2016a).

In order to accelerate environmental footprint reductions at HKIA, AAHK has adopted a strategy of moving beyond its direct sphere of control to proactively engage with its BPs and other stakeholders to address specific environmental issues. In 2008, AAHK launched the HKIA Carbon Reduction Programme which provides the framework that enables AAHK to work collaboratively with BPs from a range of sectors to measure, reduce and report carbon emissions through a series of initiatives. This collaboration enables a greater pool of emissions to be addressed as the BPs account for some 60% of airport emissions (AAHK, 2015). In 2010, AAHK, together with 40 BPs, pledged to reduce the airport-wide carbon intensity by 25% from 2008 levels by 2015. This multi-stakeholder approach has proven successful in reducing the carbon footprint of HKIA, and is also suitable for implementation by other operators of multi-tenant facilities such as shopping malls, universities or industrial parks seeking to reduce carbon across the whole facility. This paper describes how the multi-stakeholder approach was adopted at HKIA in achieving the 25% carbon reduction target and the potential of its application to accelerate carbon footprint reduction in other multi-tenant facilities.

Keywords: HKIA Carbon Reduction Programme, carbon footprint reduction, stakeholder engagement

1. INTRODUCTION

Airport Authority Hong Kong (AAHK)'s HKIA Carbon Reduction Programme is the core carbon reduction initiative for Hong Kong International Airport (HKIA). Airport operators typically report only on the emissions under their direct control, but under this voluntary multi-year programme AAHK provides a framework that enables it to work collaboratively with over 40 business partners (BPs) to measure, reduce and report carbon emissions across the whole airport. This multi-stakeholder approach, which has won several carbon management and reporting awards, is also suitable for implementation by other operators of multi-tenant facilities (such as industrial parks, shopping centres or universities) seeking to take a lead in reducing carbon across the whole facility. AAHK continues to develop the Programme and proactively shares its methodology with interested parties in Hong Kong and the global aviation community.

The foundation of this Programme is the pledge made in 2010 by AAHK and 40 BPs to reduce airport-wide carbon intensity at HKIA by 25% by 2015 based on 2008 levels (AAHK, 2010). This was the first airport-wide carbon reduction target made by any airport operator (AAHK, 2010). As at end 2015, AAHK and its BPs together achieved a reduction of 25.6%.

Figure 1: The HKIA carbon reduction pledge ceremony

2. PROJECT SUMMARY

2.1 Scope and sources of airport carbon emissions

Carbon emissions are categorised into three different scopes according to Hong Kong Government's guidelines for carbon auditing (EPD & EMSD, 2010). Examples of the main airport and airport-related emission sources in each scope are summarized below:

Scope 1: Direct emissions from sources and removals by sinks

- Emergency power generators
- Vehicle fleet including ground support equipment (GSE)
- Hydrofluorocarbons (HFCs) and perfluorocarbons (PFCs) emissions for refrigeration / air-conditioning

Scope 2: Energy indirect emissions

- Emissions from electricity/ Towngas generation

Scope 3: Other indirect emissions

- Methane gas generation at landfill in Hong Kong due to disposal of paper waste

2.2 Overview of carbon reduction programme

To reduce the airport's carbon emissions, AAHK started the airport-wide HKIA Carbon Reduction Programme in 2008. The key milestones of the programme are summarised in Figure 2.

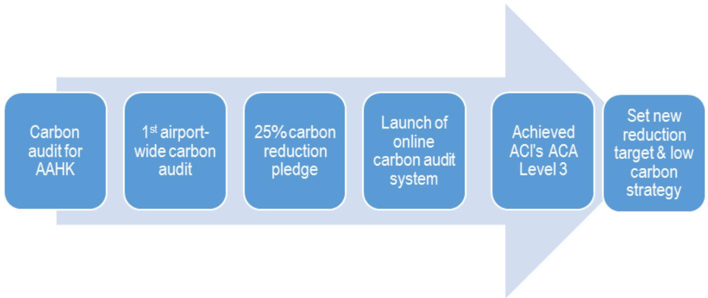

Figure 2: HKIA's carbon management roadmap

In 2008, following the release of the Hong Kong Government's guidelines for carbon auditing, AAHK conducted the first carbon audit of its own buildings and facilities at HKIA.

This was then followed by an airport-wide carbon audit in conjunction with AAHK's BPs in 2009. This audit laid the foundation for AAHK to develop and formalise the airport-wide HKIA carbon reduction programme.

In 2010, AAHK, together with some 40 BPs, pledged to reduce carbon intensity by 25% by 2015, based on 2008 levels.

In 2011, AAHK developed and launched a proprietary online carbon audit system (CAS) that provides an advanced carbon monitoring and reporting platform for AAHK and its BPs (AAHK, 2015a).

HKIA's efforts in carbon management and reduction were recognized in March 2013 when it was awarded the 'Optimisation' level in Airports Council International's Airport Carbon Accreditation (ACI's ACA) programme. This is the second-highest level of accreditation, and HKIA was the first airport in the Asia-Pacific region to achieve this standard (AAHK, 2013). AAHK successfully renewed the accreditation in the subsequent years, and has extended the airport-wide Carbon Reduction Programme to cover 46 BPs at HKIA (AAHK, 2015b).

In 2015 – 2016, AAHK worked with its BPs to develop a new airport-wide carbon reduction target for 2016 – 2020 and the associated strategies to achieve carbon reduction.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.3 Reduction in airport-wide carbon emissions

AAHK understands that the carbon emission sources at HKIA which are under its direct responsibility, and hence the extent of reduction, are limited. In fact, AAHK accounts for approximately 40% of the airport-wide carbon emissions while the BPs account for the remaining 60% (Figure 3).

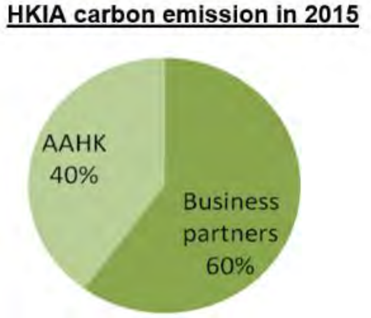

Figure 3: AAHK's BPs account for some 60% of emissions at HKIA

Through engaging and collaborating with BPs, AAHK has been able to accelerate the rate of airport-wide carbon reduction. With the concerted efforts made by the airport community, the airport-wide carbon intensity was reduced by 25.6% in 2015. Figure 4 illustrates HKIA's carbon emission reduction performance between 2008 and 2015 in both intensity and absolute reduction. It should be noted that between 2008 and 2015, the throughput has increased from 48.6 million passengers and 3.6 million tonnes of cargo (AAHK, 2009) to 68.5 million passengers and 4.4 million tonnes of cargo respectively (AAHK, 2016b), representing a growth of 41% and 22% respectively during this period.

Note:
1. A fixed grid emission factor for 2008 was used throughout to enable year-to-year comparison.
2. Excludes emissions from companies joining the programme after 2010.

Figure 4: HKIA carbon emission reduction performance between 2008 and 2015

The number of BPs joining the programme grew from 40 in 2010 to 46 in 2015 as a result of AAHK's continuous engagement approach, which has led to enhanced awareness of carbon management amongst the airport community. The exceptionally high rate of participation also demonstrated the success of the Programme and its contribution in spreading the message of carbon reduction.

Looking forward, AAHK will extend the Programme to cover tenants and other Hong Kong-based airlines. By recruiting more BPs to the Programme, the footprint of emission that can be reduced is further increased.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. KEY SUCCESS FACTORS

The success and achievements of the HKIA Carbon Reduction Programme are attributable to the following factors. These factors are not specific to airport environment, and are also applicable to carbon reduction initiatives in other multi-tenant buildings.

3.1 Flexibility in adoption of carbon reduction solutions

The BPs include a wide range of organizations from sectors including airlines, airline caterers, government departments, cargo handlers and ground services providers.

Given the diversity of their business nature, it is not possible to find a "one-size-fit-all" solution for all BPs. Rather than dictating what the BPs should do to reduce carbon emissions, AAHK encourages the BPs to devise their own measures based on their business nature, resources and level of expertise, but plays an important role in facilitating the sharing of best practices.

In this way, each of the 46 participating BPs have the flexibility to determine the most effective solutions for its own situation, but can also benefit by learning from the best practice of other participants. The flexibility of this model makes it also suitable for other multi-tenant facilities such as shopping malls, logistics centres, industrial parks or multi-tenant office buildings.

3.2 Public commitment from senior management

The 25% carbon reduction pledge set in 2010 was the world's first airport-wide carbon reduction pledge (AAHK, 2010). The pledge, supported by the Hong Kong Government at ministerial level, AAHK's senior management, the BPs and environmental non-governmental organisations (NGOs), set a carbon intensity reduction target for 40 BPs and demonstrated the commitment of the whole airport community. This public commitment served as a compelling driver for the successful and continuous implementation of the HKIA Carbon Reduction Programme.

3.3 Demonstrating the business case for reduction measures

AAHK acts as a pioneer within the airport community, leading by example through investing in the adoption of innovative reduction measures, and proactively explaining the associated benefits and business case. For example, AAHK's replacement of 100,000 traditional lights with LEDs successfully demonstrated that the savings in maintenance cost and reductions in operational disruption exceeded the greater capital cost of the LEDs and the new fixtures (AAHK, 2015).

AAHK also highlighted the work of BPs to demonstrate the business case of other innovative carbon saving solutions such as solar-powered staircases. The operational and environmental benefits included reduced labour costs and fewer incidents of damage to aircraft in addition to the savings in fuel and associated carbon emission.

3.4 Airport-wide carbon reporting platform

AAHK invested over US$70,000 to develop an online CAS to calculate and monitor HKIA's airport-wide carbon emissions. The CAS is made available to all 46 participating BPs at no cost, enabling them to enter all data relevant to carbon emissions, and to calculate and analyze their carbon performance on a single unified platform. The system automatically calculates carbon emissions and generates various graphs to suit different analysis and reporting needs. BPs only have access to their own data. AA uses the aggregated data to monitor, review and report airport-wide carbon reduction performance.

3.5 Capacity building

To ensure BPs are equipped with the necessary knowledge, AAHK has organised over 30 carbon workshops, sharing and training sessions. AAHK has also trained 5 internal staff as certified carbon auditors to conduct free carbon audits for participating BPs every year, which also provide another opportunity for AAHK to understand BPs' needs and to provide assistance accordingly.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4. SETTING A NEW CARBON REDUCTION TARGET

Following the completion of the 2010 - 2015 pledge, in 2015 AAHK began the process for setting a new airport-wide reduction target for 2016 – 2020. This process involves benchmarking the carbon targets set by other hub airports, comprehensive engagement with the BPs and internal departments to identify energy efficiency and other carbon reduction measures, as well as developing a framework for stronger airport-wide collaboration in pursuit of the new targets. The outline of the target-setting process is presented in Figure 5.

4.1 Engagement with BPs

With over 60% of HKIA's emission coming from the BPs, it is important that BPs' views are taken into account in setting the target. Their views have been consolidated through various stages in the target-setting process.

A survey was conducted to identify suitable carbon reduction measures reflecting the fact that the BPs have different business natures and different reduction opportunities. This survey was also important to understand the key hurdles to implementing low carbon measures, so that support measures could be tailored to suit the BPs' needs. Based on the feedback from BPs, an initial target range and the associated support measures were prepared for consultation. Consultation sessions were conducted to introduce the targets to BPs. Following the consultation, their views were collected in a survey. These showed BPs agreed to the support measures and identified a consensus around the level of target to be set.

To demonstrate the airport's commitment, a public ceremony will be held in November 2016 at which AAHK and the participating BPs will jointly pledge to achieve the new target, in the presence of senior government officials, environmental NGOs and the media.

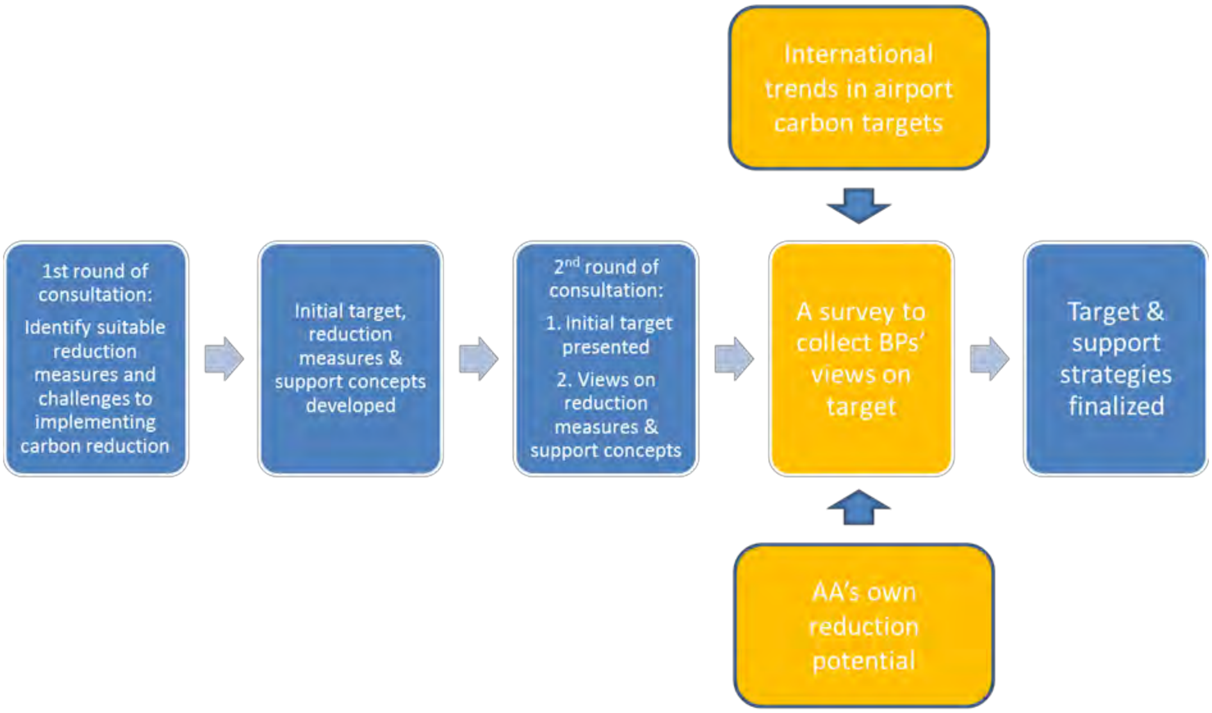

Figure 5: Process for setting the new airport-wide carbon reduction target for 2016 - 2020

4.2 Support Strategies for BPs

As the Carbon Reduction Programme matures, the reduction opportunities available to HKIA will shift away from 'low hanging fruit' energy saving opportunities to more complex technologies and projects, with potentially greater capital requirements, longer lead times and longer payback periods that need to be justified by a sound business case. Having considered the feedback from BPs, AAHK is considering to implement the following measures to encourage reductions from BPs:

- Roundtable discussion with BPs' senior management;
- A technical working group to share technical knowledge of carbon reduction technologies;
- A benchmarking scheme to enable BPs to compare their carbon reduction performance; and
- A carbon reduction award scheme to encourage best practices.

5. CONCLUSION

The HKIA Carbon Reduction Programme has demonstrated its value as a tool for accelerating carbon reductions across the airport. The Programme could also serve as a template for other multi-tenant buildings or facilities to effectively manage and accelerate the reduction of their carbon footprints through innovation and collaboration with their BPs and tenants. This approach is supported by a proven business case based on cost, operational and reputational benefits and the flexibility for different individual tenants and franchisees to determine their own best approach for carbon reduction.

[d] *sol·id·ar planungswerkstatt, Germany, dalkowski@solidar-pw.de*

ABSTRACT

PLENAR is a design guide for structuring of basic principles of building design for the preparation and implementation of an integrated design process. Without this process ambitious projects won´t succeed. Main focus is the support of a common, interdisciplinary understanding of planning philosophy regarding energy efficiency and sustainability, among all partners involved in a building project.

PLENAR consists of three main goals which include

- Communication among actors involved by well-structured discussion formats
- Qualification of participants and project goals by interdisciplinary approaches
- Documentation of results in suitable formats for decision making and QA

For facilitating these goals PLENAR provides correlating application modules

- Evaluation: Using the matrix, correlations of relevant criteria can be evaluated individually by participants, the next step is to compare and assess the result.
- Information: A database provides generic information on criteria and their correlations with a focus on energy efficiency and sustainability.
- Analysis: The individual assessments of the relevant correlations made by the participants are discussed to derive the main goals for the specific project.

The structure of Goals and Modules creates an interrelated network which will enhance an interdisciplinary understanding among all actors involved and will foster a target-oriented integrated design process during early design stages.

This contribution presents the tools current state of development and advertises the support of planners as well as interested customers and companies to promote progress towards a professional, web-based tool.

Keywords: integrated design process, sustainable building, energy efficiency, design guidance

1. BACKGROUND – OBJECTIVE - POTENTIALS

The complexity of design processes increases continually. The potential of influence on energy performance, comfort and cost efficiency, as the most essential characteristics of sustainable building design, lies in early design stages. Hence, already in state of demand planning certain conditions have to be settled to define a requirement profile with an entire space allocation plan and holistic project goals.

Therefore, it is necessary that a common understanding of planning philosophy regarding energy efficient and sustainable building is set from the very beginning among all project partners. The early and constructive examination of the most important criteria and their correlations as well as their impact on sustainability quickly leads to this common planning understanding and guarantees a higher quality of the entire planning process. PLENAR can be used and adapted by all design teams for their individual project.

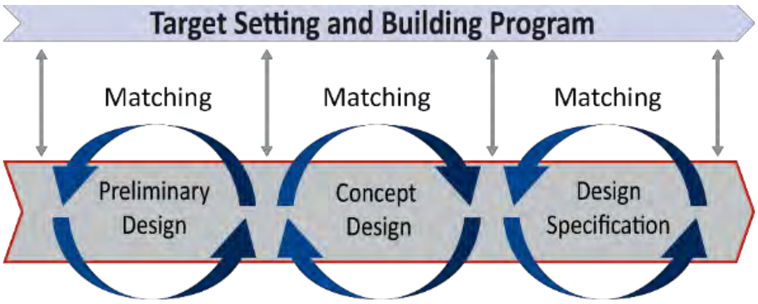

Figure 1: Optimization by Iteration loops during an integrated design process

The planning aid PLENAR enables in a short period of time

- An improvement of transdisciplinary understanding on energy and sustainability-oriented relations for all project partners: client, architect, professional planners, user, facility manager and others
- The development of an individual project master as a baseline for the specific project requirement profile and the structuring of the projects integrated design process by selecting and adapting the type and number of relevant criteria
- The development of a project roadmap for the further approaches in the integral design process with concepts to iterations in individual planning stages to optimize the entire planning and implementation process
- The documentation of results as a requirement profile for target agreements and performance specifications as a to-do-list for planners
- The documentation for the building certification as a verification and optimisation for planning objectives when applying assessment systems

2. APPROACH

The design guidance is based on extensive experience of comprehensive project support focussing integrated building design, energy efficiency and sustainability. All correlations (Figure 2) are assessed individually concerning their degree of influence on energy efficiency and sustainability by each actor.

Example: Correlation no. 21 represents the relation between building mass distribution (criteria no. 2) und flexibility (criteria no. 6). The assessment of the actors is determined and compared to a reference (master). Significant deviations to this master, but also among actors, allow a structured discussion. By this way misunderstanding among participants and information gaps can thereby be eliminated. Moreover, the actors will get insight to their role during an integrated design process.

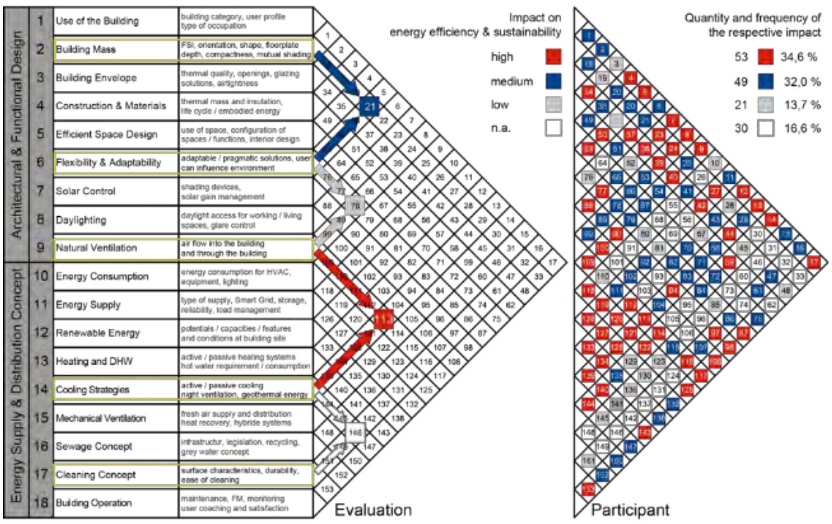

Figure 2: The correlation matrix for an individual application for planning actors

All planning participants, such as architects, energy planners, client and other experts evaluate 153 correlations resulting from 18 criteria, e.g. for office buildings, according to their individual assessment and experience. If possible, all correlations are to be assessed completely with regard to their impact on energy efficiency and sustainability and to be determined in the matrix according to the evaluation level (high, moderate, low or not applicable).

Hence, in the early planning stage each member of the interdisciplinary team has to deal with the same questions. This means, all project participants gain an extensive insight into the planning complexity and, above all, beyond the boundaries of their own planning discipline.

2.1 Evaluation of the individual knowledge

The results are analysed on the basis of the assessments made by the actors, i.e. they will be compared among each another and mirrored to a (master-) reference matrix provided by the design guidance PLENAR. This process gives an overview of the individual knowledge of all actors involved (Figure 3).

With a professional supported and moderated discussion, the different perspectives of the actors can be brought to a common level. Thus, individual expertise is exchanged and expanded for each participant. In the first iteration of the discussion process only the assessments with substantial deviations (deviation of 3 levels) are considered. In a second loop the deviations of level 2 can be discussed on demand as well.

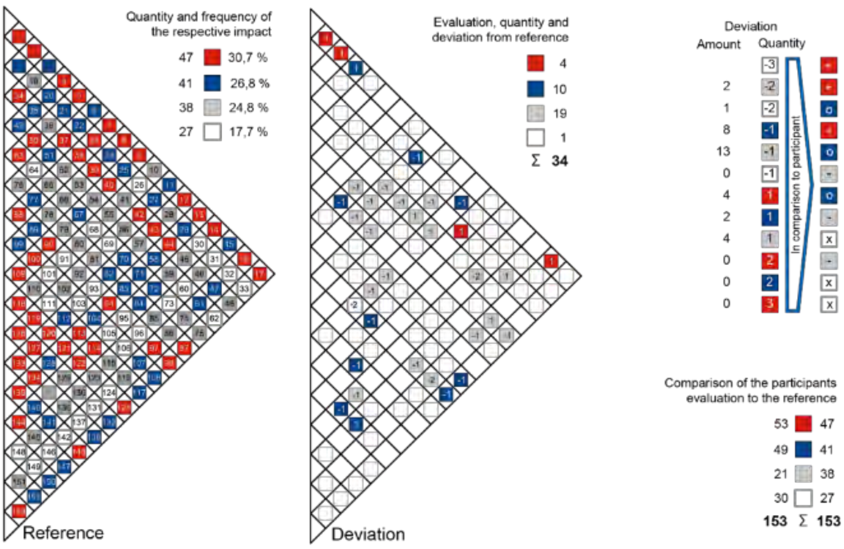

Figure 3: The individual correlation matrix is compared to a reference matrix (master) and evaluated

PLENAR is applicable on different levels. Information level 1 (see Figure 4) gives a rough description of the related criterion and its specification and a recommendation for the planning to its user. This level is the basis for evaluating the correlations of individual assessments regarding their respective relevance and the degree of their influence on energy efficiency and sustainability.

Information level 2 describes a variety of information about the potentials of the respective criteria, requirements, risks, standards and guidelines, concepts and examples, such as generally formulated sheets for the requirement and performance specifications (see Figure 5). In a discussion, this additional information provides well-founded information to qualify and simplify the planning process.

2.2 Information about the correlations (Level 1)

The database provides supportive generic information for the interdisciplinary discussion of the actor's assessments. This is done for all 18 criteria. If the correlation between two criteria has a high impact on energy efficiency and sustainability (e.g. correlation 113 marked in red), corresponding relevant information is provided as well (see Figure 4).

This information can also be adapted and documented according to the respective project specific requirements of the construction project. In this way you fulfil the prerequisites for compiling a performance specification sheet for further planning steps.

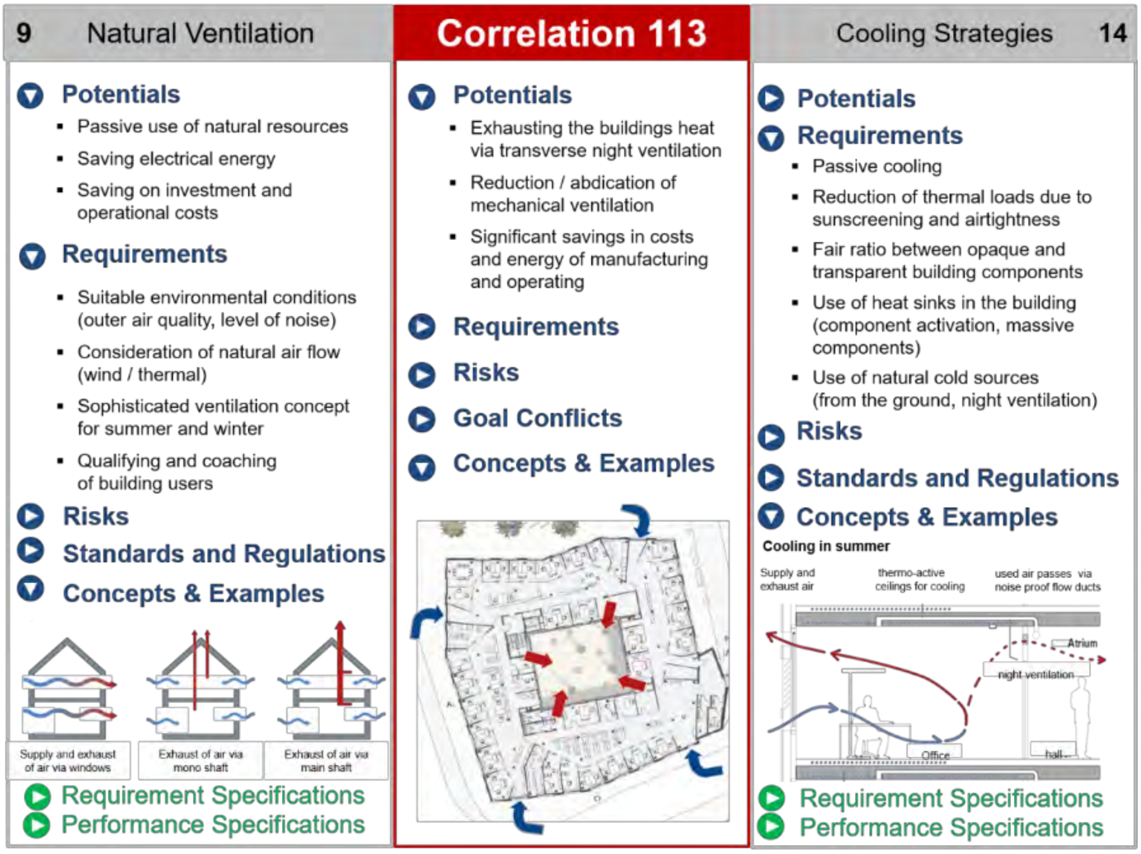

Figure 4: Correlation example 113: Natural ventilation versus cooling strategies

Information: As a communication basis a database provides information on all criteria provided and relevant correlations of high, moderate and low impact. In the discussion different levels of knowledge of the individual actors are balanced and the database is expanded continuously by the feedback of each project implementation. This is true for all building type applications.

Communicate contents and attitudes. Deviations of assessments will be analysed and interpreted in comparison to the chosen reference (generic master, individual project matrix, individual actor’s assessment). Important deviations are preferably discussed in a kick-off workshop.

2.3 Profile of requirements and implementation concept (Level 2)

For sustainable design, the requirements profile must be defined with clear project targets and subsequently a complete building program, which is then to be transferred into a performance specification sheet and implementation concept. The starting point and guideline are the confirmed project targets resulting from and addressed in the sustainable building certification system.

The example in Figure 5 shows requirements for a qualified ventilation concept: air quality, user acceptance, low energy demand, low operating costs and noise distribution. The performance specification sheet instructs the relevant measures to be implemented.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 5: Requirement specs define requests - Performance specs determine related steps for a successful realisation

Qualify: The professional exchange for the assessment of correlations and the relevance for the certain project qualifies both the actors and the entire planning process. As a target agreement, elaborated content and results are documented in a requirement specification sheet as well as in the performance specification sheet based on it.

Document the integrated design process. With the help of PLENAR, all results of the assessment, the discussion and the specification of the connections for the optimisation of energy efficiency and sustainability can be structured and documented bindingly, for all subsequent planning steps.

2.4 Analysis of effective conclusions

The respective interrelation of tasks, targets, issues and target conflicts, requirements and desires as well as their backgrounds and effects can be analyzed in a subsequent context analysis (Figure 6) in order to develop solutions. In further planning progress design-related specifications are defined and updated or re-defined especially for the current project. As a directive for the objective implementation they are then documented in a comprehensive performance specification manual serving as an instruction book as well.

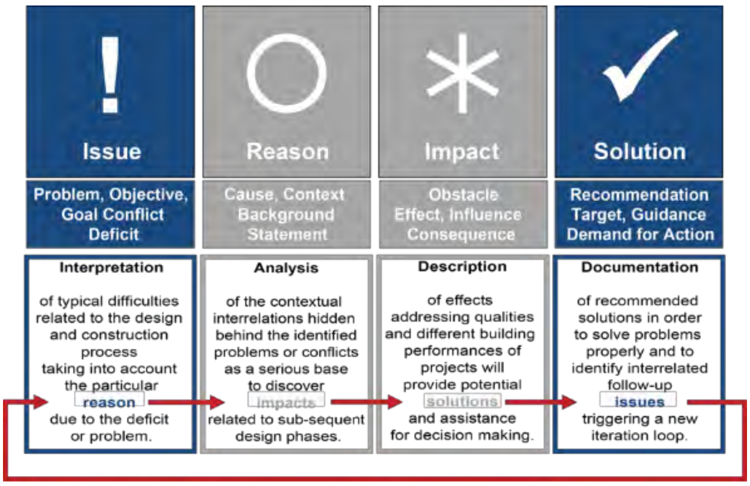

Figure 6: The context analysis is a method for the holistic analysis of correlations in the context of tasks and solutions of all kinds, in order to create a solid basis for the decision-making process

By using the method of context analysis, tasks, issues, goal conflicts and deficits or problems can be identified in a dialogue with all planning actors. Their backgrounds should be described as well as the respective effects, for example on comfort or operating costs, can be identified systematically. Only this kind of view on the entire context will give the opportunity to deal with questions in a comprehensive way.

For example, solution approaches of the context analysis will also be developed resulting from contradictions and problems with review of the requirement and performance specification sheets or with deviating in goal statements during design progress.

Thereby this method is an important instrument for the elaboration of decision papers and also, based on comprehensive consideration, an element for the integrated planning and implementation process.

3. FUTURE PROSPECTS

In order to provide the tool for planning teams in all kinds of projects, it is to be developed as a web-based application. for individual adaption. As a result, it gives an important contribution to the improvement of the interdisciplinary planning and building culture towards integrated design, energy efficiency and sustainability. In addition to the use of PLENAR as a design guidance in building projects, it is also suitable for (interdisciplinary) teaching at universities as well as for further education and training through the academies of architects and engineers chambers.

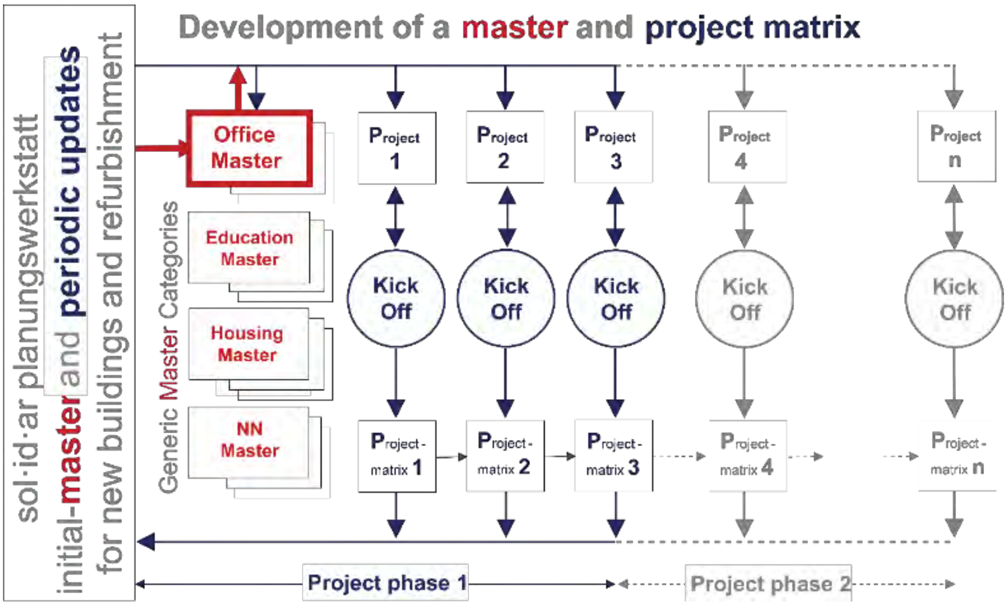

Figure 7: Development of master and project matrix: By applying PLENAR in different projects with different building categories, different masters for different building uses will be created

Moreover, it is also reasonable to use the tool to educate sustainability coordinators and auditors of sustainable building certification systems such as DGNB and BNB in Germany, LEED, BREEAM, etc.

The development for professional applications will provide so-called masters for building categories like office building, housing, education buildings, etc. for both new buildings and refurbishment (Figure 7). Thus, PLENAR qualifies itself frequently by the implementation into design processes and feedback from application practice.

Responsive Design – The Innovative Approach to Create Sustainable Neighbourhoods and Cities

Mary CHAN[a]

[a] *Dennis Lau & Ng Chun Man Architects and Engineers (HK) Ltd, Hong Kong SAR, mc@dln.com.hk*

ABSTRACT

Green building certifications worldwide have mostly been focusing on building performance in terms of efficiency and savings in the use of energy and water, or the enhancement to the environment such as reduction in CO2 emission, heat island effect, rainwater runoff or better indoor environmental quality as well as green material use.

Neighbourhoods and cities now face greater challenges of sustainability beyond efficiency and high performance. Unsustainable situations have led to disastrous consequences which have caused the loss of lives, destroying communities, neighbourhoods and cities.

From the wildfires in Alberta, Canada, to the sudden blast of underground pipes in Taiwan, earthquake and tsunami in Japan that triggered the failure of nuclear power plants, hurricane Katrina that swept through New Orleans, or simply the collapse of buildings and structures due to poor construction or lack of maintenance, time and again, none of the affected communities, neighbourhoods or cities were prepared to face the devastating consequence of disaster that shocked and destroyed them.

Are such catastrophes really unavoidable? While humans cannot control the natural environment, we can surely manage the man-made environment which we have created ourselves to minimize the magnitude of effects caused by unexpected events. With better planning, design and management, we should aim to avoid disasters from happening in the first place. Sustainability of neighbourhoods and cities is achievable and needs to be addressed as a matter of utmost urgency.

Using case studies, this paper will look into examples of neighbourhoods and cities in various countries where sustainability can be achieved through the use of responsive design as the innovative approach to create sustainable neighbourhoods and cities, helping them to avoid the devastating consequence of disasters.

Keywords: climatic responsive architecture, sustainable neighbourhood, sustainable cities

1. INTRODUCTION

Green building certifications worldwide have mostly been focusing on building performance in terms of efficiency and savings in the use of energy and water, or the enhancement to the environment such as reduction in CO2 emission, heat island effect, rainwater runoff or better indoor environmental quality as well as green material use.

Neighbourhoods and cities now face greater challenges of sustainability beyond efficiency and high performance. Unsustainable situations have led to disastrous consequences which have caused the loss of lives, destroying communities, neighbourhoods and cities.

From the wildfires in Alberta, Canada, to the sudden blast of underground pipes in Taiwan, earthquake and tsunami in Japan that triggered the failure of nuclear power plants, hurricane Katrina that swept through New Orleans, or simply the collapse of buildings and structures due to poor construction or lack of maintenance, time and again, none of the affected communities, neighbourhoods or cities were prepared to face the devastating consequence of disaster that shocked and destroyed them.

Using case studies, this paper will look into examples of neighbourhoods and cities in various countries where sustainability can be achieved through the use of responsive design as the innovative approach to create sustainable neighbourhoods and cities, helping them to avoid the devastating consequence of disasters.

The current state of disaster management seems to suffer from one or all of the following:

- Insufficient investment to design for safety
- Reactive rather than responsive approach
- More attention on post-disaster management instead of pre-disaster management

2. WILDFIRE IN ALBERTA, CANADA

2.1 Spread and action – the reactive approach

Wildfire broke out in Ford McMurray, Alberta, Canada on May 1, 2016. When first discovered, the size of the wildfire is 2 hectares. Due to the dry weather and wind, it spread quickly and was soon uncontrollable.

By 10 May 2016, the wildfire had reached 200,000 hectares. Emergency registry by Red Cross had been setup and 32,000 household were affected. 90,000 persons had registered with the Red Cross by then. The Government of Alberta was also offering a relief fund of 1250 Canadian Dollars per person with 500 Canadian Dollars for dependents, for people who were affected by the wildfire but asked those that are not really in need not to apply for the relief fund.

If all 90,000 persons registered at Red Cross's emergency registry applied for the relief fund offered by Government of Alberta, it would have cost millions of dollars in relief fund.

This is only a small fraction of the loss caused by the wildfire. Many people who were evacuated were faced with the grim consequence of the wildfire in multiple folds. Many of them lost their home. Many lost their jobs which were dependent upon the oil industry that had to shut down due to the wildfire. The financial loss due to the wildfire was mounting. It was also devastating to all the people affected.

The Forestry Department has on-going routine effort to manage wildfire all along with on-going fire management teams. Their routine effort includes the removal of dry grass by burning them off. They have cut down trees to reduce fuel size available. They have also put up fire status maps and update of wildfire status all available to the public on their website. Last but not the least, they have listed all the common causes of wildfire and provided advice on the actions necessary to avoid causing wildfire which include naked campfire and the use of OHV (Off Highway Vehicles). In spite of all the precautions and warnings taken, wildfires continue to break out, often becoming uncontrollable as they spread with the help of favourable dry weather, heat and wind.

On Mother's Day 2016, it was reported in the news that 2 persons died during the evacuation. In her televised report, the Alberta's Premier Rachel Notley was tearful when she talked about the devastating situation on Mother's Day, a happy occasion which had turned into a gloomy one due to the wildfire. Premier Rachel Notley proclaimed that the city contained hazardous material, water was not drinkable, 2,400 structures were destroyed.

How fast and how big the wildfire spread:

	Status	Area affected	Growth
May 1, 2016 4pm	Wildfire first discovered	2 hectares	Initial size of fire = 1x
May 2, 2016 12am	8 hours from start	60 hectares	30x
May 5, 2016	5th day	85,000 hectares	42,500x
May 6, 2016	6th day	100,000 hectares	50,000x
May 9, 2016	9th day	200,000 hectares	100,000x
May 10, 2016	10th day	229,000 hectares	114,500x
May 15, 2016	15th day	251,000 hectares	125,500x
May 26, 2016	26th day	566,188 hectares in Alberta and about 3,200 hectares in Saskatchewan Total: 569,388 hectares	284,694x
June 10, 2016	41st day	589,995 hectares	

The Fort McMurray Wildfire as of May 10, 2016 had grown to be the most costly wildfire. Insurance cost for rebuilding was estimated to be 9 billion Canadian dollars.

2.2 Responsive design – the proactive approach

According to Chad Morrison, Alberta province's senior wildfire official, the wildfire would not pose any danger to the Suncor oil sands facilities which were located 30 km away from the wildfire. These sites were resilient to forest fire because they were cleared and free of vegetation. He also mentioned that all the oil sand facilities in the area were surrounded by wide firebreaks and were protected by their own highly trained fire crews. Nevertheless, Suncor and Syncrude had evacuated their facilities as a precautionary measure.

If we compare a forest to a building compound, we need to look at prevention and the provision of automatic detection systems and automatic fire fighting systems so that the fire can be detected at early stage before the fire size grow into uncontrollable size.

When fire size is about 2 hectares in the case of Ford McMurray, the fire-fighters already could not control the fire. So, it can be suggested that to control the growth of wildfire, fire size should be less than 2 hectares.

In a super tall building or a building with a very large footprint, the building will be divided into compartments of a certain size to make any breakout of fire more manageable. There will be automatic smoke detectors and automatic sprinkler systems which will ensure early detection of fire and early activation of the automatic sprinkler system to control the fire.

It is highly possible to place similar fire detection and fire-fighting systems in the forest as well. If forest can be covered by automatic smoke detectors and automatic sprinklers, then any wildfire will be detected earlier when the fire size is smaller, and with automatic sprinkler triggered, the water from the sprinkler will make the fire diminish or reduce in size. At the very least, it will help to reduce the chance of the fire spreading to a much bigger area and becoming uncontrollable with the rapid growth of the fire.

The grid for laying the automatic sprinkler system shall be more than one hectare. The closer the grid, the higher will be the chance of containment of the fire. One would immediately think about how costly this will be and will dismiss the practicality of implementation.

While the provision of automatic detection and sprinkler systems is not cheap, it makes sense when we compare this to the extreme high cost of restoration when big wildfire such as the one in Ford McMurray occurs.

Comparing to a large scale residential development such as Double Cove in Hong Kong where the total site area is about 5 hectares with over 2 hectares of greenery, we note that the greenery area of Double Cove is about the original size of the wildfire that broke out in Fort Murray, Canada. The Double Cove project , being a normal construction project , has an emergency vehicular access roads complete with street fire hydrants allow fire-fighters to reach each and every one of the twenty-one blocks of residential towers within this neighbourhood development. Each tower is also complete with standard fire fighting installations including smoke detectors, fire alarms, automatic sprinklers, fire services water tanks. Each floor is a fire compartment separated from the next floor with smoke lobbies, doors and walls of required fire rating.

Where there are people living or working in close proximity of forests, we should no longer consider the forest as undisturbed nature. Learning from the examples such as the oil sand facilities Suncor and Syncrude in Fort Murray area or the large scale residential development such as Double Cove in Hong Kong, we should adopt more preventive fire fighting design and management in the construction near the forest. In the case of large forest areas such as those in Canada, more investment in fire detection system and fire fighting system in the forests is a necessary investment which will help to save lives, save the forest, save jobs, avoid the trauma and even higher cost of post wildfire rebuilding of structures and communities.

Installation of automatic sprinklers is not a totally new invention. People have used automatic sprinklers to water their garden lawns at their homes or to water the extensive area of golf courses or man-made park areas. If such sprinklers were modified to form part of a fire-fighting installation for the forest, the wildfire will not be out of control as what have happened in the wildfire at Fort Murray in Canada. Smoke detectors in the forest can be connected to a fire control management centre so that wildfire will be detected when the size of wildfire is still small. Wildfire prevention and management should take advantage of modern day technology to adopt a more proactive approach in the design, planning, monitoring and management of forests similar to new building construction projects.

3. TSUNAMI IN JAPAN

The earthquake and tsunami in Japan that happened in March of 2011 caused the melt down of the Fukushima Daiichi Nuclear Power Plant operated by the Tokyo Electric Power Company (Tepco). While earthquake and tsunami is a natural disaster that cannot be avoided, the tsunami in the melt down of the Fukushima Daiichi Nuclear Power Plant is a disaster that could have been prevented.

It was noted that the Onagawa Nuclear Power Plant operated by the Tohoku Electric Power Supply (Tohoku Electric) near the Fukushima Daiichi Nuclear Power Plant was also affected by the tsunami. However, a report from the International Atomic Energy Agency mission found that the Onagawa Nuclear Power Plant had shut down safely and was unremarkably undamaged, even though it had experienced very high levels of ground motion.

Location wise, the Onagawa plant is located 123 kilometres away from the epicentre of the earthquake which is 60 kilometres closer to the epicentre of the earthquake as compared to the Fukushima Daiichi Nuclear Power Plant. Seismic intensity experienced by both nuclear power plants was similar. The tsunami at Onagawa was 14.3 metres high while the tsunami at Fukushima Daiichi was 13.1 meters high.

Given the same nature of the plant experiencing similar natural disaster of earthquake and tsunami, the result is very different.

Prior to the plant’s construction, Tohoku Electric conducted surveys and simulations to predict tsunami levels. Their initial prediction was tsunami height of 3 metres based on historical average tsunami levels in that region. Based on this prediction, Tohoku Electric constructed their Onagawa nuclear plant at 14.7 metres which is about 5 times the historical average tsunami levels. As more research was carried out, the tsunami levels increased and Tohoku Electric conducted periodic check-up based on such new research results.

Fukushima Daiichi plant however was built at a lower elevation of 10 metres. Tepco had removed 25 metres from the 35 metres natural seawall at the Fukushima Daiichi plant site in order to enhance easy transportation of equipment and to save construction cost.

It was noted that the original construction of the Fukushima Daiichi plant was based on existing seismological information which was shown to be underestimated by later research. While Tohoku Electric learned from the past earthquakes and tsunamis and continuously improve its counter measures, Tepco’s approach was different. According to the Nuclear Accident Independent Investigation Commission (NAIIC)’s report that Tepco “resorted to delaying tactics, such as presenting alternative scientific studies and lobbying”.

In terms of emergency response, Tohoku Electric established an emergency response centre at the Onagawa plant and at the company headquarters immediately after the earthquake. “Thorough the disaster, headquarters supported the plant operators minute by minute. Supervisors and chief engineers were dispatched to the main control rooms of the damaged reactors to make decision, and information was sent in a timely manner to all levels of the response team.”

The safety culture in Tohoku Electric at the Onagawa plant is observed to be very proactive and more transparent as compared to Tepco at the Fukushima Daiichi plant. “After the disaster, Hasuike Tooru, the former president of Tepco, described how management decided to lengthen the expected lifetime of power plants, even if there were safety consequence.

It is noted that the Fukushima Daiichi plant melt down can be prevented if it had adopted better safety approach in the planning and construction. If it had not removed 25 metres of the natural seawall of the Fukushima Daiichi plant site and the plant was built at a much higher elevation, the power plant could have been more resilient to the tsunami and like the Onagawa plant, the melt down of the Fukushima Daiichi nuclear plant may have been prevented.

4. FLOOD

In LEED for Neighbourhood Development 2009, the Green Building Certification for neighbourhood development of the US Green Building Council, under the Smart Location and Linkage (SLL) category - Prerequisite 5 Floodplain Avoidance, there are several options for floodplain avoidance as summarised below:

Option 1. Sites without Floodplains

The best strategy was to avoid locating the neighbourhood development within a 100-year high- or moderate-risk floodplain or to locate it entirely outside any floodplain subject to 1% or greater chance of flooding in any given year.

Option 2. Infill or previously Developed Sites with Floodplains

It requires the neighbourhood development to comply with National Flood Insurance Program (NFIP) requirements for any portions of the site that lie within a 100-year high- or moderate-risk floodplain. If the project includes construction of any critical facility, such as hospital, water and sewage treatment facility, emergency operation centre, emergency shelters or fire or police station, the critical facility must be designed and built to be protected and operable during a 500-year flood event.

Option 3. All other sites with Floodplains:

Requirements are similar to Option 2.

It is noted that there are two different standards adopted:

- Critical facilities which are considered to be important enough to remain operable after the flood are required to be located above floodwater levels representing 0.2% annual chance (500-year) flood.
- Other buildings and facilities that are not defined as being critical are subject to a much lower standard and are only required to be located above floodwater levels representing 1% annual chance (100-year) flood.

Based on such double standard, all the homes for people are not considered as critical. This really means that in order to seek a place that is safer, people must evacuate from their homes and move to emergency shelters or hospitals.

In the devastating flood that was brought by hurricane Katrina to New Orleans in the United States in August 2005, we can see how homes were destroyed and many people had evacuated from their homes. Even though they sought refuge at emergency centres, their living conditions were undesirable and often just as devastating. There were deaths reported and the city of New Orleans was mostly destroyed. The post disaster reconstruction of the city was extremely costly.

In August 2016, the Federal Emergency Management Agency (FEMA) finally proposed regulations that would require companies and homeowners using federal funds on construction projects in flood-prone areas to build on higher ground based on the following three options:

- Build 2 feet above the 100-year floodplain level for standard projects, or
- Build 3 feet above the 100-year floodplain level for “critical action” projects such as hospital or nursing homes;
- Build to the 500-year floodplain.
- Use the best available scientific models which combine flood records with other factors e.g. sea-level rise data.

It is noted that there were concerns from business groups and politicians that this new regulation will result in higher cost for builders and the cost of recovery for areas which have suffered flooding will be more expensive. This point of view emphasizes cost saving rather than the importance of investment for design for safety in the first place.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Although FEMA's proposed regulations only applies to companies and homeowners using federal funds on construction projects in flood-prone areas, such regulations should also be applied to those projects not using federal funds so that such higher standard for design for safety can be adopted for all buildings.

5. CONCLUSION

Apart from natural disasters, there have been many other disasters that resulted in loss of life, loss of properties, destruction of neighbourhoods and cities.

From the gas explosion of underground gas pipes in Kaohsiung in 2014 in Taiwan to the collapse of buildings and roads due to poor construction or lack of proper monitoring or maintenance, there are man-made disasters that could have been prevented by proper design and planning.

Responsive design that takes into consideration of the worst case scenario shall be in place from day one. There shall be no excuse to lower the standard to save initial cost of construction or operation. Any compromise in the initial stage may lead to even higher costs for post disaster rebuilding of the neighbourhood and cities that are affected. In addition to the cost of reconstruction, the cost of people's life is priceless.

Responsive design is design that can respond to the situation in the best possible way. It takes innovating thinking to adopt strategies that are preventive and should exceed the conventional thinking of how neighbourhoods and cities are built, maintained and operated in order to make our neighbourhoods and cities truly sustainable.

ABSTRACT

Neighbourhood planning which dates back to the closing decades of the nineteenth century has metamorphosed under various movements in an attempt to evolve places that are socially responsive, economically viable, and environmentally friendly. With the constraints of rapid urbanization, climate change, financial instability coupled with significant demographic and social changes, the ability of the contemporary approaches to neighbourhood planning have been questioned, as to if it can lead to delivery of sustainable settlements. In addition, the potential of a single-specialist profession thinking as the 'messiah' to resolve the dynamic urban problems has been challenged. This paper proposes how placemaking, which promotes citizens' involvement and engagement in the plans and polices that shape the places where they live through an inclusive, collaborative, and design-led initiatives can provide a basis of a suitable approach for sustainable neighbourhood planning. The paper examines the nature of contemporary approaches in neighbourhood planning in the context of both developed and developing nations. While some degree of progress have been recorded by applying some of these initiatives across the various context, findings show that there is an urgent need to respond to the obvious shortcomings associated with the sectoral and individual attempts to tackle the problems that confronts the 21st century neighbourhoods. In proposing the transdisciplinary and collaborative placemaking approach, its salient key features and processes are highlighted in this paper and how it could be the game changer in delivering sustainable neighbourhoods. The paper concludes with recommendations on how collaborative placemaking can further be enhanced in practice, academia, and in policy making.

Keywords: collaborative placemaking, neighbourhood, sustainable

1. INTRODUCTION

The neighbourhood can be regarded as the building block of a city with a potential to determine the sustainability of that particular nation as it has been well established that the battle for sustainable urban planning will be won or lost in the city (Komeily & Srinivasan, 2015). This submission clearly justifies the attention that the neighbourhood scale of spatial development deserves as the planning unit of urban centres (Rohe, 2009). While the campaign for sustainable urban planning has continued to take the central stage in academia, practice, and policy making (Berardi, 2011), of necessity is the need to examine how it can best be delivered at the neighbourhood level. Since the beginning of the 20th century till date, there have been several approaches adopted to evolve sustainable settlements- an endeavour that has resulted to the emergence of various movements. However, taking an unbiased view to assess the state of neighbourhoods in both developed and developing country context, the ideal neighbourhood suggested by Roberts (2009:128) where people 'can live, work, prosper, and enjoy good quality of life now and in the future' is still a challenge to the 21st planning.

Aside from the generic sustainability issues like environmental degradation, global warming, and social inequality among others, various countries of the world are seeking for ways to abate their peculiar sustainability challenges. Developed countries like the USA are battling urban sprawl and high car dependency; UK is trying to reduce energy demand and consumption (Edwards, 2014) while developing countries like Nigeria for example is confronted with urban slum, inadequate amenities and infrastructures, waste control and management, and insecurity. The aim of this paper therefore is to conceptualize sustainable neighbourhood through collaborative placemaking. The objectives to be pursued are: (i) to examine sustainable neighbourhood planning; (ii) to examine the contemporary approaches to neighbourhood planning in different context and their shortcomings in order to justify a need for a paradigm shift; (iii) to introduce the concept and key issues of collaborative placemaking; (iv) to examine the nexus between collaborative placemaking and sustainable neighbourhood planning.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Although there have been series of studies carried out independently on sustainable neighbourhoods (Barton et al., 2010; Barton, 2000; Wheeler, 2013) and placemaking (Arefi, 2014; Parlemo and Ponzini, 2015), there is no evidence in literature of a study that to establish a correlation between sustainable urban neighbourhood planning and collaborative placemaking. This is therefore a fundamental gap in research which this paper attempts to address. How can a sustainable neighbourhood be conceptualised through collaborative placemaking is the main research question of this study.

2. WHAT IS A SUSTAINABLE NEIGHBOURHOOD?

A neighbourhood is a local unit within which people are personally acquainted with each other by reason of residential proximity (Lynch, 1981). While the term neighbourhood could be subjective in terms of its size, it should typically refer to an area that can be traversed by foot with some distinct and unifying social, architectural, historical, and economic features (Wheeler, 2013). Although, 'neighbourhood' and 'community' are often used interchangeably in literature, the former refers to the fabric (such as streets, buildings, facilities, and green spaces) while the later refers to the people in the neighbourhood (Barton et al., 2010). A sustainable neighbourhood according to Roberts (2009) is the spatial manifestation of sustainability principles. A sustainable neighbourhood should be compact, supports pedestrian movement, and mixed-use in design in which many daily living activity can be carried out within the shortest possible distance through interconnected networks of streets (Charter for the New Urbanism, 2015). A sustainable community according to the ODPM (2004) must address the issues of good governance; transport and connectivity; services; environmental; economy; housing and built environment (figure 1).

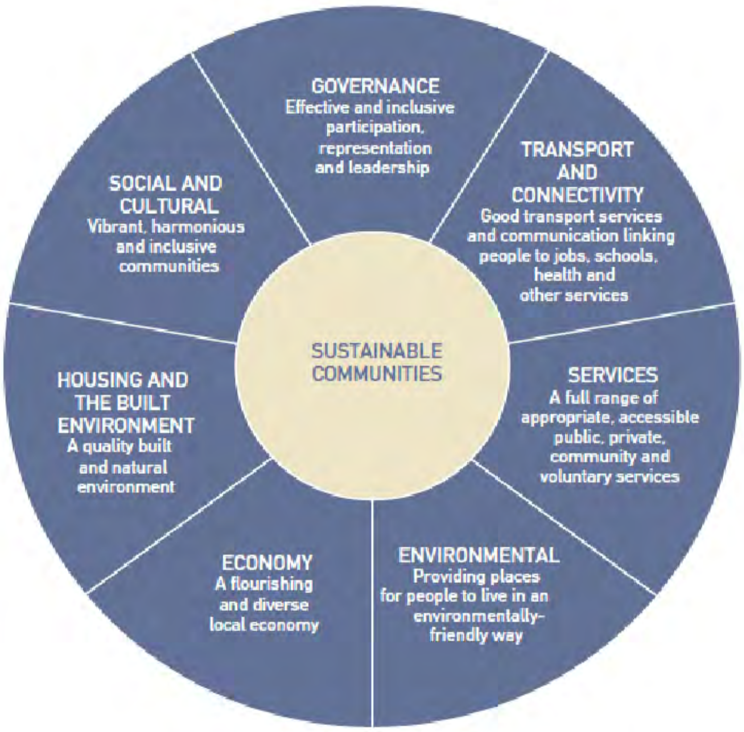

Figure 1: A sustainable community (Source: Egan Review, 2004)

3. CONTEMPORARY APPROACHES TO NEIGHBOURHOOD PLANNING AND THE NEED FOR A PARADIGM SHIFT

Although the neighbourhood planning predates the concept of sustainability, the campaign for sustainable urban planning at the local level (chapter 28 of Agenda 21) led to renewed interest in developing new initiatives and paradigms to address sustainability issues at the neighbourhood scale of spatial development (Farr, 2008; Rohe, 2009). Prior to this time in history, attempts have been made to create liveable, environment-friendly, and prosperous places through the neighbourhood planning model. The sustainable neighbourhood planning is therefore an extension of urban planning and design trends of the early 20th century works of Ebenezer Howard's Garden city; the Neighbourhood unit of Clarence Perry; the modernism movement initiated by Le Corbusier and

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Frank Lloyd Wright; the neo-traditional (new urbanism) movement of the likes of Andres Duany, Elizabeth Plater-Zyberk, Peter Calthorpe; the eco-urbanism; and the latest being the smart growth movement (an advancement to the neo-traditional movement).

Contemporary approaches to enhance sustainable neighbourhood planning are traceable to several initiatives from the academia, practitioners and policy makers in various parts of the world. In the developed countries, the 21st century heralded the development of Neighbourhood Sustainability Assessment Frameworks through which a master plan can be evaluated against an array of Sustainability criteria and indicators (Al Waer and Kirk, 2015). Sustainability Assessment is carried in order to evolve a better scheme of development (Gibson et al., 2005) by integrating a wide range of assessment practices that are concerned with long-term impacts of development (Al Waer and Kirk, 2015). Examples of these frameworks include BREEAM communities in UK; LEED for Neighbourhood development in USA; CASBEE in Japan; and Green STAR Communities in Australia among others. Coupled with these assessment frameworks was the development of the Neighbourhood Quality Assessment Tools which can be used to assess the quality of neighbourhoods (Nickelson et al., 2013). Several governments agenda like the 'Towards an urban renaissance' (a report by the UK Urban Task Force) of 1999; The Planning Advice Note (PAN, 83 prepared by the Scottish government in 2008); and the Plan 2030 of the Abu Dhabi Planning Council are also worth mentioning.

While Neighbourhood Sustainability Assessment frameworks and Quality Assessment Tools are yet to evolve in most developing countries (Berardi, 2013), the existing planning laws are outdated and as a result have failed to meet the present urbanization demands and challenges. What is observable in these countries is the adoption of urban neighbourhood regeneration which is the reconstruction and upgrading of deteriorating neighbourhoods. It is a deliberate effort to effect a change in an urban environment by large scale adjustment of existing area to meet the present and future requirements for urban living and working. However, not much progress have been recorded with these initiatives as expected in both developed and developing countries context due to the persistent urban problems that are obvious. Consequently, the ability of the contemporary approaches to neighbourhood planning in the 21st century has been questioned. The Neighbourhood Sustainability Assessment framework for instance has been questioned on the basis of the following uncertainties:

- The involvement stakeholders in its development (Brandon and Lombardi, 2011; Sala et al., 2015)
- The consideration of existing statutory and legal planning framework (Berardi, 2011)
- Adoption of a holistic approach of sustainability issues and how balanced it is in its choice of indicators (Srinivasan and Komeily, 2015);
- Whether it can be adopted for use in another context (Joss et al., 2015).

While the urban regeneration programme has helped in revitalizing the urban neighbourhoods in developing countries by evolving new houses, apartments, offices, shops, schools, the approach has been criticized as it most often result to break-up of communal relationship; congestion of the nearest neighbourhood due to migration of displaced residents; and the upsetting existing economic systems and opportunities. These identified limitations of the contemporary approaches to neighbourhood planning in both developed and developing countries context call for a paradigm shift in the planning and delivery of the 21st century neighbourhoods.

4. PLACEMAKING

4.1 Basic concepts and key aspects

Placemaking is a collaborative process of shaping a community's public realm with a goal to maximize shared value through creative pattern of use and emphasis on the physical, cultural, and social identities that defines a place (Project for Public Space, 2016). Making better places is not new as the earlier works of Jane Jacobs in The death and life of great American cities (1961); William H Whyte in The social life of small urban spaces (1980) and Kevin Lynch in The Image of the City (1960) attest to this. In recent times, the works of Jan Gehl in Cities for people (2010), How to study public life (2013), Public space, public life (1996); and Herbert Girardet in Cities People Planet (2010), while advocating for placemaking provide practical guidelines for creating liveable, healthy, and safe places. Placemaking according to Arefi (2014) can triggered by needs, opportunities, or by assets as shown in figure 2 and explained:

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

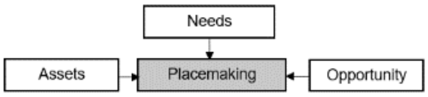

Figure 2: Placemaking paradigms(Source: Adapted after Arefi (2014))

While the placemaking stimulated by the forces of needs and opportunity have been criticised for being a top-down approach, with dependency on government resources and the sovereignty of expert knowledge over local knowledge, asset-based placemaking creates an atmosphere of synergy and interaction within which experts and non-experts can have a common ground for the planning of long term needs (Arefi, 2014). This is collaborative placemaking as shown in figure 3:

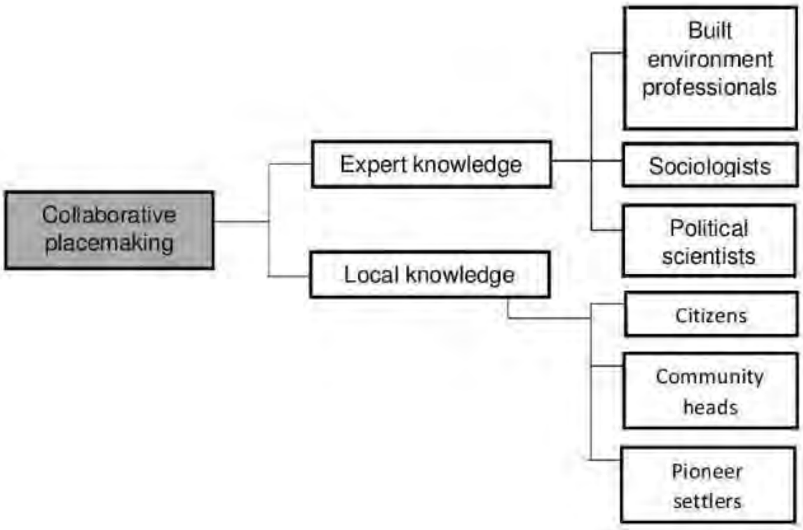

Figure 3: The Collaborative Placemaking (Source: Adapted after Arefi (2014))

4.2 Process of collaborative placemaking (From space to place)

Making better places is a universal activity as people consciously and unconsciously try to shape the places where they live with or without professionals. Schneekloth and Shibley (1995) however argued that professionals can contribute to this unconscious process in a deliberate way in the following three stages: (i) creating a dialogic; (ii) dialectical work of confirmation and interrogation; and (iii) framing action. (Figure 4)

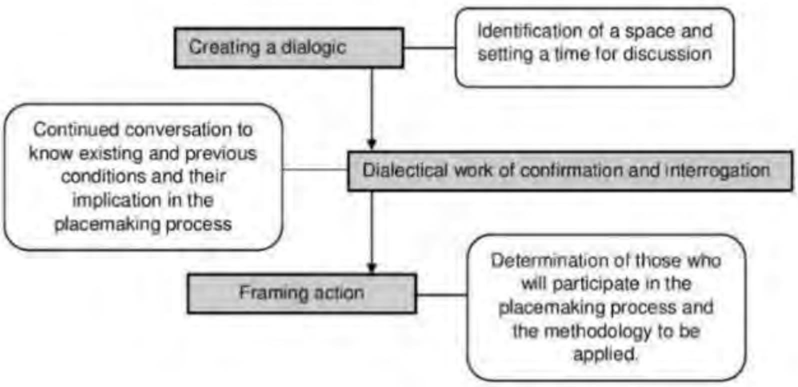

Figure 4: The placemaking process (Source: Adapted after Schneekloth and Shibley (1995))

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

5. DISCUSSON

The previous sections of this paper provided the theoretical understanding of sustainable neighbourhood planning and collaborative placemaking. This section attempts to establish the nexus between both concepts by examining the question of how well does collaborative placemaking address principle of sustainable neighbourhood planning.

5.1 Needs and assets in sustainable neighbourhood planning

Sustainable neighbourhood planning is driven by the needs which vary from one particular context to another. In neighbourhood planning, there is need to consider the existing assets in terms of physical and social capital and how it be identified, leveraged, and managed. It has been argued that what makes a neighbourhood sustainable is determined by how it has been able to explore its local assets (Gibson et al., 2005).

5.2 Sustainable neighbourhood planning as a long term vision

While progress can be monitored intermittently, the sustainability of a neighbourhood can only be assessed on a long term scale. This can be justified on the basis that sustainability considers both the present and future generations (intergenerational and intragenerational equities). Placemaking is termed to be a 'work-in-progress'. Plans do evolve and change (as a result of monitoring in the placemaking process) into a more sophisticated and complex one (Arefi, 2014). It is this possibility whereby plans can be reviewed and monitored as a result of the environmental, social, and economic challenges that sustainable settlements evolves.

5.3 Social learning and knowledge sharing

In recent times, attaining sustainable neighbourhoods has gone beyond environmental concerns, as the issue of governance in terms of public participation and engagement have well been advocated for (Brandon and Lombardi, 2011). One of the key objectives of sustainable communities' skills and knowledge agenda is to transform the closed disciplinary and professional territories and boundaries into open institution landscape (Roberts, 2009). Equitable and sustainable development can be encouraged through placemaking that engages all users (Project for Public Spaces, 2016).That is, an opportunity where social learning and knowledge sharing can be enhanced through the synergy of both local and expert knowledge. This can be actualized through charrette, workshops, and focus groups among others. Also, attempts by an architect to enhance architecture of place will only result to mere artistic statement without consulting and engaging with the local community in evolving solutions.

5.4 Security, local economy, health, and public realm

Undoubtedly, security, local economy, and public realm are key criteria to be considered in assessing the sustainability of a neighbourhood. Placemaking in its process advocates for mixed-used development, walkable neighbourhoods which enhance safety through easy surveillance in the neighbourhood as against the concepts of gated communities and disconnected neighbourhoods noticeable in most developing countries. Collaborative placemaking also has the potential to drive local economy through innovation, usage of local construction materials and workforce while also advocating for business ownership and retail sales centres. In addition, collaborative placemaking prioritise the community needs by ensuring that the neighbourhood planning enhances the physical, mental, and social health of individuals and the entire community (Project for Public Spaces, 2016)

6. CONCLUSIONS

This paper attempted to conceptualize a sustainable neighbourhood through collaborative placemaking. The limitations of the contemporary approaches to neighbourhood planning in both the developed and developing countries were discussed which justified the need for a paradigm shift. The placemaking approach that enhances citizens' engagement in the planning and delivery of the places where they live as against the expert-led contemporary approach was introduced. How this concept could lead to a sustainable neighbourhood was explained in this paper. In order to enhance collaborative placemaking as a solution for 21st century neighbourhood planning challenges, there is need to make its outcomes and delivery clearly visible so as to be well appreciated and recognised. A review of professional ethics and practices is also important by advocating for a behavioural change. Professionals should learn to imbibe the ethics of engaging with local knowledge and non-experts who by their local experience will contribute significantly to their planning and design decisions.

ABSTRACT

The fundamental shift of design thinking towards embracing co-evolutionary and partnered relationship between socio-cultural and ecological systems is critical in combating climate change. Immediate radical reduction of anthropogenic greenhouse gas emissions is demanded to keep the global average temperature rise within 2 degree Celsius. Meanwhile, drastic enhancement of building energy efficiency further exhausts technologies, which means exceeding potential planetary boundaries for the long run. However, meaningful actions are delayed firstly due to the long-standing disparity of the perceptions and standards towards “good” and “green” design. Secondly, externalization of sustainable designs consideration during the design process is a common practice among practitioners. The built environment of today remains impactful in decades to come, which unequivocally represents the window of time where effective changes are still possible to avert catastrophic climate consequences. Therefore, we are here to explore an effective and integrative instrument that bridges the gaps within the local practice that is imperative to the juncture in meeting our obligation towards global climate change.

This paper examines the fundamentals of sustainability, drawing on an interdisciplinary body of literature relating to, inter alia, ecological and regenerative design principles as well as established integral theories. We would explore and introduce the conceptual model of integral sustainable design framework in transcending awareness and the know-how of architecture practitioners. Through the guiding principles devised to enable vigorous engagement with the implications and consequences of design decision in facing the 21st century environmental challenge, this framework ultimately celebrates the gift of creative capacities for the richness of architecture making in the era of transition.

Keywords: regenerative design, ecological design, climate change

1. INTRODUCTION: CHALLENGES OF OUR ARCHITECTURAL PRACTICE

Integral Sustainability Design is an emerging term originating from the theory of ecological and regenerative design (Wackernagel et al. 2002; Mang & Reed 2012; Moffatt & Kohler 2008). The concept of integration challenges whether the current practice of sustainable development is indeed sustainable (DeKay 2012; Raco 2005; Whitmarsh 2012). If we refer sustainability as the ability to re-establish cooperation between human and nature for mutual beneficial development, it would be a great depart from the regenerative definition in the Brundtland Report (Sadler-Smith, 2015; WCED, 1987). The key difference between the two paradigms resides in two substantially different goals (Conte & Monno 2012; Fraser et al. 2006; Kwok & Grondzik 2007). In the first scenario, sustainable development is targeting at reducing the natural resource depletion and the environmental impacts while maintaining the current architectural practice (Conte & Monno 2016; Chen et al. 2015). As for the latter, regenerative design reverses the current trend of consumption in the ecological-system indispensable for the human race existence (Mang & Reed 2012; DeKay 2012). The built environment is the most significant field of action because it represents the socio-cultural identity at the local, regional and global level (Conte & Monno 2016; Bond 1999). In the meanwhile, the shift of value in designing the built environment can better utilize resources and minimize impacts within the ecological boundary of the planet.

In this essay, we would first identify the limitations of the traditional building centric design process. The perception of “green” design is stereotypical and often technological charged (Holden et al. 2014; Chen et al. 2015). It represents implementation of macro-level policies, plans and programmes (Baresel et al. 2006; Iwaro & Mwasha 2013). Sustainability assessments become the only instrument to determine the building performance (Howard et al. 2008; Poveda & Young 2014). The documentation process is complex and commonly externalized. Certification highly relies on the top-down command weighting each criterions by cost-effectiveness (Fraser et al. 2006; Moffatt

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

& Kohler 2008; Conte & Monno 2012). Therefore, we would explore different ways of design thinking for fundamental shift in values, not as substitute, but as complement to the current rating system (Dorst 2001; Conte & Monno 2012). The theory of ecological and regenerative design offers an alternative inter-disciplinary perspective on design (Wackernagel et. Al. 2002; Moffatt & Kohler 2008; Hosey 2012). It proposes frameworks that are open and heuristic for innovation. Through simple guiding rules in a socio-ecological perspective, integral designs inducted from the regenerative values and facilitate massive-small change from the bottom-up (Fraser et al. 2006; DeKay 2012). With the early adoption of eco-centric world view, we conclude that integral design would no longer be externalised as a particular sustainable check box (Poveda 2014; Wright & Alajimi 2016). Embedding qualitative reflection process in the current architectural practice, integral sustainable design would be integral design simply.

2. LIMITATION ON TRADITIONAL DESIGN PROCESS

2.1 Disparity between "Good" and "Green" design

Architectural practices, as a knowledge-based profession, are challenged to reconfigure their traditional design process. Established firms' architectural knowledge is rooted in the social channels, systemic filters, and individual strategies (Henderson et. al. 1990; Blizzard 2012; Board et. al. 2015). As a result, the discovery process and the creation of new information take time. The cooperation often is tempted to modify the existing system rather than incurring the substantial friction required to build new sets of design method from scratch (Poveda 2014; Geels 2011). According to Dorst (2012), the challenge of dealing with open and complex problems, like Climate Change, leads to particular interest to create "frames". Design organizations deal with frames in their field of practice as part of collective consciousness called "design thinking" (McHarg 1969; Raco 2005). The term implies deliberate strategies tackling complex challenge by coming up with an intervention (what) which is induced from the framework of its working principle (how) and "value". In other words, the strategy involves developing a specific "frame" by applying principles that generate values (Dorst & Cross 2001; Dorst 2011). In the context of Climate Change, we attempt to develop a design framework with guiding principles that cultivate the value in securing a sustainable future.

The economic benefits of "green" buildings fall into four areas according to Yudelson (2008). Firstly, decreasing the electricity consumption which is the dominant energy source for buildings would reduce the operating cost (Yudelson 2008; Poveda 2014). Secondly, comprehensive functional testing of energy systems before occupancy could minimize the maintenance cost (Yudelson 2008; Sadler-Smith 2015). Furthermore, energy efficiency can significantly increase the building value cost (Yudelson 2008; Chen et. Al. 2015). Lastly, the tax benefit offered by the local authorities is the primary incentive for the implementation of "green" strategy cost (Yudelson 2008; Sullivan 2012). However, designers are confused when energy efficiency is equivalent to "good" design and compliance to the rating scheme is "green". Paraphrasing Horsey's (2012) quote during Peter Eisenman's interview, "green" design and sustainability are irrelevant to architecture. "Green" design has a reputation of all substances and no style (McHarg 1969; Horsey 2012). The stereotype of sustainability as exclusively technical and ugly comes from the polarized values of "aesthetics" versus "environment". In the current debate on "green" design, the iconic buildings by "Starchitect" represent unsustainable development on one end; environmental and sustainable rating system (ESRS) present a particular vision on "sustainability" on the other end (Yudelson 2008). It is a common practice for project managers to divide the job between designers and environmental experts in creating aesthetically-pleasing building while externalizing sustainable tasks in complying certification criterions (Mang & Reed 2012; Iwaro & Mwasha 2013). The selection of categories of water and energy consumption, greenhouse gas emissions and waste reduction are independent to the design process.

2.2 Complex rules and self-perpetuating process of externalization

The primary framework of the current practice of "green" design is indeed grounded in the environmental and sustainability rating system. The evaluation methods translated into assessment system is the common tool for communication among the actors in the building industry (Henderson & Clark 1990; Holden et. Al. 2014). In the sustainable urban development process, ESRS is a benchmark to measure the rate of sustainability in buildings, neighbourhoods and cities (Iwaro & Mwasha 2013; Poveda & Young 2014). However, the inherent limitation in ESRS is beyond aesthetic. It leads to a self-perpetuating process of externalization. Fundamentally, the location of a project renders majority of pilot sustainability project uncertified (Holden et. al. 2014; Wright & Alajmi 2016). On the contrary, achieving "energy efficiency in buildings" and "reduced water use" would be rewarded comparatively fewer points, although these strategies contribute to the sustainability of the project by itself without requiring occupants to change their behaviour (Reed 2009; Hosey 2012). Furthermore, the subjectivity in weighting the importance of the criteria is ambiguous. It is difficult to determine which strategy would have higher contribution. Lastly, the incompatibility between ESRS and the unique local conditions impeded adoption aligning with the local sustainability development goals (Garde 2009; Board 2015). The role of rating system is questionable when the ESRS is irrelevant to local contexts.

The voluntary approach encourages developers to attain certification with minimal changes. Thus, the cost-effectiveness becomes the determining factor of final implementation. Unfortunately, projects that do not meet the prerequisite of the ESRS are often overlooked even if the design retains a higher regenerative value in comparison to a certified project (Howard et. al. 2008; Garde 2009). Nevertheless, the complex rules underlined and exhaustive documentation work in ESRS led to externalization of the sustainability design (Iwaro & Mwasha 2013; Conte 2016). As a result, ESRS is usually outsourced to the environmental consultants, while designers are blind-sided in the process. This defeats the purpose of ESRS as a tool to inform, design and educate (Kwok & Grondzik 2007; Reed 2009; Sullivan 2012). We argue that building can sustainably behave without a large content of advanced eco-technologies (Mang & Reed 2012; Conte & Monno 2016). Therefore, we are motivated to set-up some proactive guiding principles to address the limitations in the building-centric assessment where sustainability is achieved at its minimal standards of performance.

2.3 Top-down command control

The current unilateral approach to developing, adopting, and implementing ESRS originates from the top-down command control tradition (Fraser et. al.2006; Moffatt & Kohler 2008; Wilnaz & Daly 2016). In the building industry, authoritative decision-making structure can implement programmes efficiently; However organizations fail to include participation of the end-users (Holden et. al. 2014; Wright & Alajmi 2016). On the contrary, decentralization of decision and political controls is often perceived as creating conflicts between stakeholders (Raco 2005). It is a common practice to develop environmental management plan by hiring trained experts (Holden et. al. 2014). However, the failure of top-down implementation is due to the disparity between detailed local knowledge of the individuals and the community support composed mainly of the practitioners and architects (Howard 2008; DeKay 2012). Adopting Dorst's (2011) principle of design thinking, the assessment is the intervention (what) while the rating system defines the working principle (how) for decision making. In a reflective research conducted by Garde (2009), the qualitative findings suggest that the majority of respondents, who are developers, designers and consultants, find the rating system useful for informing sustainable design. From the respondents' observation, the certifications mainly generate publicity and give them marketing advantage (Garde 2009). ESRS also streamlines the project approval process because the local officials recognize the appraisal as bench-marking (Garde 2009). However, this way of sustainable development is only targeting at reducing the natural resource depletion and the environmental impacts while maintaining the current architectural practice (Moffatt & Kohler 2008; Mang & Reed 2012). In the neoliberal paradigm, sustainability is viewed as re-establishing the cooperation between human and nature for mutual beneficial development (Sadler-Smith, 2015; WCED, 1987). Therefore, we argue that the convention "check-list" approach is not embodying the regenerative value of sustainability and the top-down governance structure needs to evolve.

3. INTEGRAL DESIGN CONCEPTUAL FRAMEWORK

3.1 Theory of integral, ecological and regenerative design

The structure of integral design conceptual framework in the built environment is found on the socio-ecological system (SES) perspective. Moffatt and Kohler (2008) described SES as multiple-related metabolisms that interact with one another at different time scales. The tension between the nature and built environment becomes a dynamic attribute that changes within the historical context (Wackernagel 2002; Moffatt & Kohler 2008). The integral theory set up a common framework by combining the flow-based models, resource-conservation-based models and top-down and bottom-up model (Fraser et. al.2006; Moffatt & Kohler 2008; Wilnaz & Daly 2016). Different from the quantitative assessment ESRS as a retrofit in the traditional design process, ecological models encourage adaptive and resilience design in building from the start (Reed 2009; Hosey 2012). The regenerative management is a co-evolution of the social-ecological system for the long term. SES incorporates the ecological concept of time with the history of nature and human culture (Wackernagel 2002; Moffatt & Kohler 2008). This life-cycle orientated design methodology addresses two major deficiencies of the building industry of today (Moffatt & Kohler 2008; Conte & Monno 2012). Firstly, the negligence of the spatial characteristic of the environment disconnects with the physical flows. SES attempts to integrate the morphological and physiological process within the analytical methods and design decision-making process to negate this phenomenon (Moffatt & Kohler 2008; Conte & Monno 2012). Secondly, majority of the ESRS evaluation method is temporal which disregards the economic discounting of the built environment in the ecosphere (Moffatt & Kohler 2008; Conte & Monno 2016). The incapability of forecasting and back-casting scenarios renders most sustainable development irrelevant. The simplistic concept of time is the biggest hurdle to effectively develop applicable concept to our built environment (Moffatt & Kohler 2008). Therefore, regenerative designs incorporate the time factor in SES which takes sustainable development further by reversing the current trend of exhaustive consumption in the built environment.

Regenerative design relies on a developmental process that enhances the value of the whole and takes the system to the next level. Furthermore, integration would evoke a set of higher orders and develop the capacities for pursing the goals context (Wackernagel 2002; Moffatt & Kohler 2008). Integral design conceptual framework departs from the traditional design process above where value is a two-dimensional combination of an intervention (what) and its working principle (how). The theory of ecological and regenerative design is a dynamic three dimensional process (Mang & Reed 2012; DeKay 2012). On the left vertex of the triangle in Figure 2, aligning human development efforts with the creative efforts of nature is the key to achieve sustainability. Meanwhile, co-creative partnership between people and the planet is activated by the aims and aspirations on the right (Mang & Reed 2012). The complementing relationship between the alignment and activation would eventually achieve regenerative action.

3.2 Fundamental shift of values from bottom-up

A collective balance ought to strike between the need to build climate resilience rapidly and to encourage inclusion of marginalised voices in order to change the way we design. Climate science agencies should be able to contribute in decision-making, planning and implementation (Geels 2011; Whitmarsh 2012). The process of engaging people in designing is a great opportunity for values cultivation, community empowerment and education (Kwok & Grondzik 2007; Reed 2009; Sullivan 2012). The shift in design methodology is not necessarily initiated from a bottom-up level, but the local stakeholders would be allowed to drive the design process (Fraser et. al. 2006). As a result, public protocols would be an integration of collective simple rules and bureaucratic complex regulations. Meanwhile, regenerative designs would germinate from both grassroots emergent solutions and sophisticated place-making process. Ultimately, the top-down governance would take on an empowering role in initiating leadership from the bottom-up. In order to achieve regenerative action (value) which aims at reversing the current trend of consumption in the ecological-system indispensable for the human race existence (Mang & Reed 2012; DeKay 2012), we create a design frame under the qualitative reflection process (how). Adopting Dorst's (2011) principle again on design thinking in Figure1, the integral design palette in Figure 3 is the intervention (what) we are introducing to the (frame) integral design framework (Dorst & Corss, 2011; Dorst 2011). The goal of this tool is to stimulate the alignment and activation process in Figure 2 which would eventually lead to holistic design (Mang & Reed 2012). Under the integral design framework, design palette is a device based on the shifted eco-centric values and sustainability guiding principles. It provides an open and holistic platform for designers to frame the condition and character of a space (Fraser et. al. 2006; Moffatt & Kohler 2008; Suzuki 2010). Taking into account of the time factor, designers can back-cast the precedence and invent their own steps along the way in searching for a proper design solution.

3.3 Integral design palette for qualitative reflection process

The integral design palette in Figure 3 is divided into six segments in a circular format radiating from the pillars of sustainable development, social, economic and environment. Recognizing the three sectors are in transition and bridged into one another and introduce additional subsections as socio-economic, socio-environment and eco-economic respectively (Wackernagel et al. 2002; Mang & Reed 2012; Moffatt & Kohler 2008). Adopting the top-down and bottom-up model, governance is used as the unifying subject in balancing the power of the three (Fraser et al. 2006; Moffatt & Kohler 2008; Conte & Monno 2012). This is to ensure clarity in linking the main cause of implementation to suggested design responses. Different aspects of design strategies are organized in radial line according to the six categories mentioned above. The sub-division element is assigned with potential design responses from five different colour-coded sections in the middle rings of the palette, corresponding to the design elements. They are categorized under low-impact high efficiency, health productivity & well-being, safety & resilience, community & innovation and informational technology (Iwaro & Mwasha 2013; Poveda & Young 2014). The outermost ring refers to the topic of interest in the design archive that relates to a specific sustainability issue. At the beginning of the design process, designers can navigate each section from the centre-out to explore synergistic relationship of sustainability attributes and forecast the potential benefits or impacts of their decision-making. The palette is emergent and mature over time with the gain of design knowledge.

Spatial representations of natural systems were introduced to the design and preliminary planning process in the early 1970s following the publication of Design with Nature by McHarg (1969). However, the prescriptive tool is obsolete to the contemporary design-making. Nevertheless, Moffatt and Kohler (2008) argue that integrating spatial specific information at the beginning of the design is vital to inform professionals on the long-term effects of their designs and management decisions. The combination of this integral design palette (what) and the qualitative reflective process (how) define in the working principle for sustainable design and complement to the building-centric ESRS to achieve holistic design (Dorst & Cross 2001; Dorst 2011). Therefore, integral design palette is a critical analytical tool to inform the key ecological functions which are sensitive factors to the built environments and their relation to the local resources (Reed 2009; Hosey 2012). The simple guiding rules of integral design palette would encourage early adoption of eco-centric worldview. Under this integral design framework, sustainability would no longer be externalised as a particular check box. Embedding qualitative reflection process in the current architectural practice, integral sustainable design would be integral design simply.

4. CONCLUSION

Integral Sustainability Design challenges the current practice of sustainable development, not as a substitute, but as a complement to the current design thinking (Dorst 2001; Conte & Monno 2012). At the beginning, established firms' architectural knowledge is rooted in the social channels, systemic filters, and individual strategies (Henderson et. al. 1990; Blizzard 2012; Board et. al. 2015). Thus, the translation of evaluation methods into environmental and sustainability rating systems is an effective tool for communication among the actors in the built industry with minimal adoption to a new design paradigm (Henderson & Clark 1990; Holden et. al. 2014). However, the inherent limitation in ESRS leads to a self-perpetuating process of externalization. Hence, ecological models respond to such deficiency and encourage adaptive and resilience design in building from the start. Different from the quantitative assessment as a retrofit in the traditional design process, regenerative design stimulates evolution in governance structure and change the way we design from bottom-up (Moffatt & Kohler 2008; Conte & Monno 2016). Moreover, integration strikes between the need to build climate resilience rapidly and encouraging inclusion of marginalised voices. In this regard, the socio-ecological system perspective sets the ground work to establish integral design palette as a tool to inform professionals on the long-term effects of their design and management decisions (Wackernagel et al. 2002; Mang & Reed 2012; Moffatt & Kohler 2008). As a result, the fundamental shift in values and design thinking would embed qualitative reflection process in the architectural practice. Therefore, this integral design framework is critical to cultivate the value of securing a sustainable future.

ABSTRACT

While we are excited in pursuing a sustainable environment through advanced technologies design, our consciousness to bring people closer to nature for a healthier habitat less dependent on energy consumption fades.

In this paper, we use the Ko Shan Theatre New Wing as a case study to explore how environmental sustainable design can escalate the social and cultural aspiration of a public venue that benefits both the general community as well as the district neighbourhood.

A theatre in a park

The challenge starts off with the finding of an environmental design solution to dissolve a 30m high theatre bulk, which houses 600-seats and supported with numerous amenities, into the tranquil park treasured by the neighbourhood as a precious communal backyard to their tiny dwellings in the old district. By preserving the mature trees – the old and faithful “companions” of park users – located in front of the site and carefully positioning the building masses according to the approaching view vista, the architect well integrates the building into its environmentally sensitive context.

A new sustainable living experience

Well-being of the park users has never been neglected when we were responding to the functional need of a new theatre. Values are added to the park through introducing a “green trail” around the building envelope from ground level to the “moon lawn” on the auditorium roof. Instead of simply strolling at ground level, park users can now “hike up the building” and enjoy panoramic scenes of the district. This trail together with the roof garden increases the site greenery coverage by 300 per cent.

A park in a theatre

Located on a site originally occupied by just four tennis courts, the theatre’s design adopted an innovative space-creation approach for its interiors. By wrapping the theatre foyer around the auditorium with a transparent building facade, the park’s scenery is “borrowed” into the interior and let the foyer bathed in natural daylight and greenery of the park.

Cultural and economic sustainability

The Old and New Wings aim to create a cultural heritage hub for Cantonese Opera, sustain and promote this traditional arts form. Bringing this mission to life involved the intensive engagement of various stakeholders in the performing arts – from actors to stage technicians and maintenance operators. The input of these stakeholders helped shape the design brief and the design process to ensure that the facilities can be well received by the public, allow flexibility to meet the changing needs throughout its building lifespan and become a value-added cultural venue to the city of Hong Kong.

Keywords: well-being, green trail, social and cultural sustainability

1. SUSTAINABILITY IS NOT JUST ABOUT TECHNOLOGICAL INNOVATION, IT IS MORE FOR THE HUMAN WELLNESS

Sustainable design that attracts public's attention is often through the display of its advanced technological innovations in its capability in energy/ water saving and energy renewability. Building systems efficiency performance is becoming the sole yardstick to measure the successfulness of a building sustainability design. While this engineering-based approach to sustainability does encourage people to waste less and recycle more, our consumption-based lifestyle has not altered much.

In this relentless pursuit of innovative design technologies, our design should facilitate people to interact more with the natural environment and to enjoy more the outdoor living habitat for a healthier lifestyle. After all, it is always more economical in capital and long-term running and maintenance costs when the building occupancies depend less on mechanical installations.

2. CLOSER LIVING RELATIONSHIP WITH THE NATURAL ENVIRONMENT TRANSFORMS OUR BEHAVIOUR FOR A SUSTAINABLE LIVING

This paper will look at the design of the Ko Shan Theatre New Wing (the "New Wing"), the first theatre built in Hong Kong to service the needs of the art of Cantonese Opera. It will act as a case study, looking at the transformation of an otherwise typical inward-looking theatre design into an environmentally, socially and culturally sustainable architecture project.

The focus of its sustainable design is more than benchmarking its energy efficiency with an engineering yardstick but to let the architecture socially respond to the park-users expectation for a "humble" design that sits quietly in the park context and environmentally blend in with the greeneries and avoid obstruction to the ventilation paths around the park. In fact, the design also aims to add values to the theatre-goers for them to experience the park's green context even inside the foyer areas. By introducing a new "green" trail up onto the roof of the auditorium, the design adds a new vertical dimension to the park-users for jogging or strolling up to the rooftop moon lawn.

We aim to transform the public behaviour by taking visitors out of an introverted air-conditioned space to outreach the nature and to enjoy fresh air and gentle breezes even here, deep inside the fabric of the city.

By allowing the users to organically experience the park's natural environment, the design helps facilitate a truly sustainable lifestyle and transform to a healthier living behaviour for the well-being of our future generations.

3. A DESIGN DILEMMA OF CELEBRATING CULTURAL HERITAGE WITH A GRAND DESIGN VERSUS CONCEALING THE BULK WITHIN A TRANQUIL PARK ENVIRONMENT

Parks in Hong Kong, regardless of whether they are located in the countryside or the urban area, are precious community resources. For the densely populated residential district of To Kwa Wan, Ko Shan Road Park has always been an irreplaceable breathing space– a "backyard" garden and a "communal clubhouse" for people living in the tiny dwellings in the district.

Built in the 1980s as an amenity facility in the Ko Shan Road Park, Ko Shan Theatre (or the "Old Wing") gradually became a popular Cantonese Opera performance venue for Hong Kong. Over the past decade, there were increasing calls from the cultural groups and general public to foster this traditional performing arts form. Eventually, the government confirmed that it would build a new wing next to the existing Ko Shan Theatre as a commitment to preserve this intangible cultural heritage and to promote the venue as a cultural and tourism asset of Hong Kong.

Performing arts groups as well as district council have eagerly anticipating this new theatre and expecting it to provide advanced theatrical installations and various ancillary services that the Old Wing cannot support. These include a fly tower for the stage, properly-sized dressing rooms, rehearsal rooms, singing practice rooms, an exhibition gallery, a souvenir shop, a tea house, a VIP lounge and more. However, only a tiny site of 4,000 sq. m., previously occupied by just four tennis courts, is available for the annex. After all, the tranquil park environment, strict zoning height restriction, high bedrock ground condition and presence of mature trees around the site have imposed unprecedented challenges to the design team to come up with a feasible design, not to mention a sustainable design solution.

This assignment was not only a design challenge, it also posed a design dilemma to the architect: whether to take this as a rare opportunity to design a landmark building which celebrates this piece of intangible cultural heritage for Hong Kong, or to design a building that rests humbly within the tranquil "backyard" which the local residence treasures so deeply.

Our desire to create sustainable, people-centric designs along with our commitment to design excellence led us to our final decision: we would attempt to address both sides of the dilemma by delivering on the expectations of stakeholders and theatre-goers for a landmark theatre, and give park users an enhanced leisure garden experience which would blend in with the park environment.

Essentially, we decided to create "A THEATRE IN A PARK" through the seamless integration of the theatre building with the park, and "A PARK IN A THEATRE", whereby the park environment blends into the theatre's interior.

4. A THEATRE IN THE PARK: A CONVERGENCE WITH THE PARK ENVIRONMENT

Trees are vital to a park environment. They soften the hard edges of any structure within the park and create an atmosphere of leisure and relaxation. Old mature trees in parks are often considered by park users as their old faithful companions and commonly become the landmark and remembrance in the community.

Despite the already-small site, we sacrificed the precious buildable footprint by setting the building's perimeter back and adopting a curvilinear shape for the auditorium and foyer space to preserve most of the existing mature trees in-situ in front of the site and thrive hard to keep them in healthy condition throughout the construction period. These mature trees now embrace the building and serve as a visual screen for the building bulk behind, preserving the sound of wind through the tree leaves and birdsong high in the tree branches.

Our green design approach has not stopped at tree preservation. We create accessible green terraces at various levels of the building and we link them up to form a green trail that culminates at the moon lawn on the roof of the auditorium. This trail is an innovative extension of the park: a new, elevated exercise ground which gives park users a fresh experience and the moon lawn provides a spacious open roof garden where morning exercise classes can be held and events can be celebrated on festive days. This trail together with the roof garden has contributed to the park beyond the design brief requirements and figuratively has increased the site greenery coverage by 300 per cent.

Shared "green" space is also created at ground level – a naturally ventilated entrance foyer covered with a skylight. It is a cosy semi-outdoor plaza where people can meet before show time or gather as a pre-function area extended from the air-conditioned main foyer during intermissions. On non-performance days, it is used as an extended park amenity – a grand trellis that provides shelter for ad-hoc park activities in hot or rainy days. This is truly a people and space connector where the park and the theatre meet and a place where both park users and theatre-goers can utilise at different times of the day.

5. A DESIGN FOCUSING ON ENVIRONMENTALLY PASSIVE APPROACH

In addition to creating "green spaces", sustainable building design should also start with a passive environmental approach, using strategic orientation and positioning of the building mass to minimize solar heat gain, while encouraging the use of natural daylight and ventilation into interior space to lower building's energy consumption. The following "green passive" design approaches are adopted in the New Wing:

5.1 Building massing disposition and orientation

The building is oriented so that the main foyer faces east and south, drawing natural daylight into the common circulation space in the morning. The tower portion of the complex is treated with a solid surface façade and positioned on the west of the building composition shading the lower auditorium portion and the roof garden during the afternoon. With the rock slope behind the site lending its assistance, the building heat gain originating from the low-angle setting western sun is greatly reduced.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

5.2 Building profile to optimize urban air ventilation

The stepped building profile follows the prevailing wind direction from east to west. Despite being the tallest part of the theatre – at almost 30m above ground – the tower portion is situated at the rear of the site close to the cut slope and merges well with the site topography and creates no adverse effects on the district's ventilation corridor.

The curvilinear building form of the auditorium block which faces towards the windward side also allows air to flow easily through the park and around the building perimeter and avoids creating undesirable wind gusts which could affect park users.

5.3 Solar reflectivity of the building envelope

White-washed walls are adopted for the tower's large vertical wall surfaces providing effective solar reflectivity and reducing solar heat absorption through the building envelope. This plain wall surfaces are easy and economical to maintain.

These passive sustainable strategies and the creation of shared "green spaces" help this new comer to be perceived as a park companion that accomplishes the cultural characteristic of the Ko Shan Road Park than an invader depriving the space and green resources of the Park. Such positive social interaction with the neighbourhood and the users gives an equal weight to the importance of environmental sustainability for a civic building.

6. A PARK IN THE THEATRE: AN INTEGRATED BUILDING ENVELOPE FOR A SUSTAINABLE INTERIOR SPACE

Besides being a Park companion, the park's greenery is welcomed into the theatre foyer through full-height glazing. External views of the park are "borrowed' into the interior through window frames or gate openings and reveals like a row of traditional Chinese landscape paintings through the window segments, a technique often used in traditional Chinese landscape design.

The following elements amplified this design:

6.1 Building facade

Through a high-performance glazing system which uses low U-value insulated glass units (1.5W/m^2/K), the entire theatre foyer can be bathed comfortably in natural daylight, incurring neither high thermal transmission nor high cooling load demand. The overall thermal transfer value of the building envelope is only 17.17W/m^2 –51 per cent lower than the baseline standard for a local office building.

The glazing panels of the full-height curtain wall are electrically operated and work with the main foyer's free cooling mode ventilation system under favourable weather conditions, minimising the air conditioning system's power consumption.

External sun-shading fins, which detach from the glazing panels to form an external shading "skin" for the envelope, serve as an effective solar shield, minimising direct solar impact on the east- and south-facing glass façades. A maintenance gap is reserved between the glass façade and the fins to ensure easy access for cleaning and repair work.

6.2 Rooftop thermal insulation

The urban heat island effect is mitigated by incorporating green roof system at multiple levels of the building. The greenery acts as an insulation layer, reducing heat gain through the building envelope and providing extra protection to the roofing system from direct radiation attack. This also reduces the temperature of the local area and the energy consumption of the air-conditioning system operating in the space below.

6.3 High greenery coverage

The total planting area covers 34.6 per cent of the site. More importantly, majority of these landscaped areas are not only designed for visual pleasant, these green terraces are also accessible and can be integrated with the adjoining rooms to form an expandable function area.

6.4 Acoustic insulation

Acoustic separation is achieved in a number of ways: through sound barrier ceiling, isolation partitioning and floating slab. The isolation elements are suspended by isolation hangers or spring fixing with neoprene separators, allowing the room interiors to be isolated from building structure.

Such design integration of the interior atmosphere with the exterior park environment reinforces its companionship of its natural setting in the park and the traditional Chinese cultural arts form through its close spatial interaction with the Nature.

7. CULTURAL AND ECONOMIC SUSTAINABILITY

Sustainability should be interpreted multi-disciplinarily. Environmentally, a low-carbon building enables the building operations to be economical and friendly to our earthly environment.

In the design process, the architect has always been conscious on its social sustainability aspect of the development and fully engaged its design with the environment to let it be a companion of the park setting and its neighbourhood.

Besides, intensive engagement and partnering workshops (20 nos.) with stakeholders from various disciplines and consultation meetings at district level (10 nos. of District Council meetings) as well as professional level (50 nos. of Cantonese Opera Advisory Committee Meetings) were conducted.

The aim is to ensure that the facilities can be economically sustainable as a well-received arts venue by the performers and the audiences and can accommodate flexibility to meet the changing needs throughout its building lifespan. After all, the project can gradually become a value-added cultural venue to the city of Hong Kong.

8. CONCLUSION

The heart of the design approach to the Ko Shan Theatre New Wing involved a re-evaluation of the basics of sustainable design: instead of focusing solely on technology-based sustainability innovation, we sought to create a design that well integrates with the green environment, encouraging all users – theatre-goers as well as park users – to reach out and embrace nature.

In a wider sense, our search to achieve building sustainability should not be limited to economic and environmental sustainability, but should also incorporate intangible social and human values which service the well-being of our future generations to achieve cultural sustainability.

Session 7.13: Place-making – Practices Review

From Icon to Community: Repositioning the Image of the Modern Mega-Towe

Bryant LU[a], Guymo WONG[b]

[a] Ronald Lu & Partners, Hong Kong SAR, bryantlu@rlphk.com
[b] Ronald Lu & Partners, Hong Kong SAR, guymowong@rlphk.com

ABSTRACT

Historically, mega-towers were frequently labelled “egocentric displays of power”, becoming iconic symbols of a city or an individual.

In today’s age of global hyper-urbanization, mega tall towers are, for the first time in history, becoming more than just iconic power symbols. Mega-towers address a real urbanization problem: they create more building space with less land. New generation mega-towers have evolved from being independent structures into complex mini-cities with integrated underground transportation systems and pedestrian connections. Their underground and above-grade connections to infrastructure are often more challenging to design and build than the towers themselves. Given this complex and highly dynamic design environment, the existing mega-tower delivery model is no longer fit for purpose; a new, more efficient model must be explored.

This paper compares two mega-towers: Tianjin CTF Finance Centre (530m) in Tianjin, China and Wuhan CTF Finance Centre (648m) in Wuhan, China; discusses the design and build challenges involved in both towers, and proposes a procurement methodology which will usher in a new era for mega-tower delivery.

“Come, let us build ourselves a city, with a tower that reaches to the heavens, so that we may make a name for ourselves; otherwise we will be scattered over the face of the whole earth.”

– Genesis 11: 4, The Bible

Since the dawn of humankind, towers constructed by human hands have served one overriding purpose: to express power. Towers have been variously depicted as a challenge from humanity to the gods, a demonstration of local or personal prestige and even, to put it bluntly – as the ultimate phallic symbol.

Often a product of boom times in wealthy cities and nations, the primary function of these early icons was to be just that: an icon, designed to represent the high status or a person, city or nation, or to fuel the ego of a developer or a government and broadcast that image to the world. But as the world changed and societies evolved, many of these original icons have now fallen and become monuments to forgotten people.

The world in the 21st century is a very different place, but the echo of this original, egotistical purpose still lingers when one considers many of the tall buildings in cities across the planet. For many people, towers still represent power. However, today’s mega-towers are challenging this idea and a dramatic shift is beginning.

These new towers are still iconic – but they act as symbols of something entirely different – the strength of a community and the vitality of a neighbourhood. This paper will examine the evolution of the modern mega-tower as well as the tower’s significance to the wider world and the local community. A specific example, Wuhan CTF Finance Centre in China, will be examined in detail.

1. FROM ERECTION TO ICON

The first modern skyscrapers to be built, let us call them Generation One, were located in Chicago in the 1880s – the Montauk Block and the Home Insurance Building – both ten storeys tall. Designed to house offices and make businesses more efficient, these towers were part of society’s response to rising land values sparked by an influx of people into cities, and the corresponding increase in the urban population and fall in the availability of land.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

These buildings also served as a training ground for architects and engineers as they developed the Commercial style of architecture – steel-framed edifices which steadily grew higher, stronger and bolder over the next 50 years. Despite their prominence in Chicago, New York and the US Midwest, and the fact that they paid testament to the obvious skill of their designers and builders; these buildings were ultimately just places of work – destinations serving only themselves.

Then came Generation Two, the first example of which was the mighty Empire State Building built in 1931. At 443m this magnificent super-tall building became – and has remained – an icon of a nation and its people. One reason for its wide popularity was a new and crucially different design feature – a public observation deck on the 102nd floor, giving the public a never-before-seen 360-degree view of Manhattan.

This provision was the first nod to the potential "community service" these towers could provide: a public space located at the top of a city. This space immediately captured the imagination and the hearts of the public – cementing its place in popular culture and inspiring stories, books and films, notably An Affair to Remember and Sleepless in Seattle. This excitement and enthrallment illustrates the latent potential power lurking within tall buildings – the notion that towers can provide a community with something that "belongs" to them.

Through the years, towers have risen higher and higher, with breakthroughs in engineering and technology allowing super-tall towers and mega-towers to become ever more complex, beautiful, lofty and iconic. Yet still, their function within the city has remained relatively static – they are a place to do business and the focal point of a city's skyline, sometimes even defining a city; but still they remain disconnected from the community around them.

In spite of this fact, super-tall towers and mega-towers are widely considered by developers, planners and governments to be the primary generator of urban development and renewal. Thanks to advancements in material science, wind analysis modelling and vertical transportation mechanics, not to mention pressing demand, high-density urban development and growth can be promoted and sustained, and more and more skyscrapers are being built.

This is particularly the case in Asia, the fastest-growing region on Earth. With rapidly-rising urban populations and precious little space, mega-towers are the seemingly perfect solution to all problems.

2. THE VERTICAL CITY PARADOX: FUNCTIONAL BUT DISCONNECTED

Today's mega-towers are mostly Generation Three – the next evolutionary step of Generation Two towers. These mega-tall super-towers often invoke the concept of the "vertical city" – where multiple uses are contained within a single building, providing the building's occupants with many of the conveniences one would find in a mature, developed urban neighbourhood. Generation Three skyscrapers contain an impressive diversity of facilities organized around a comprehensive vertical.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

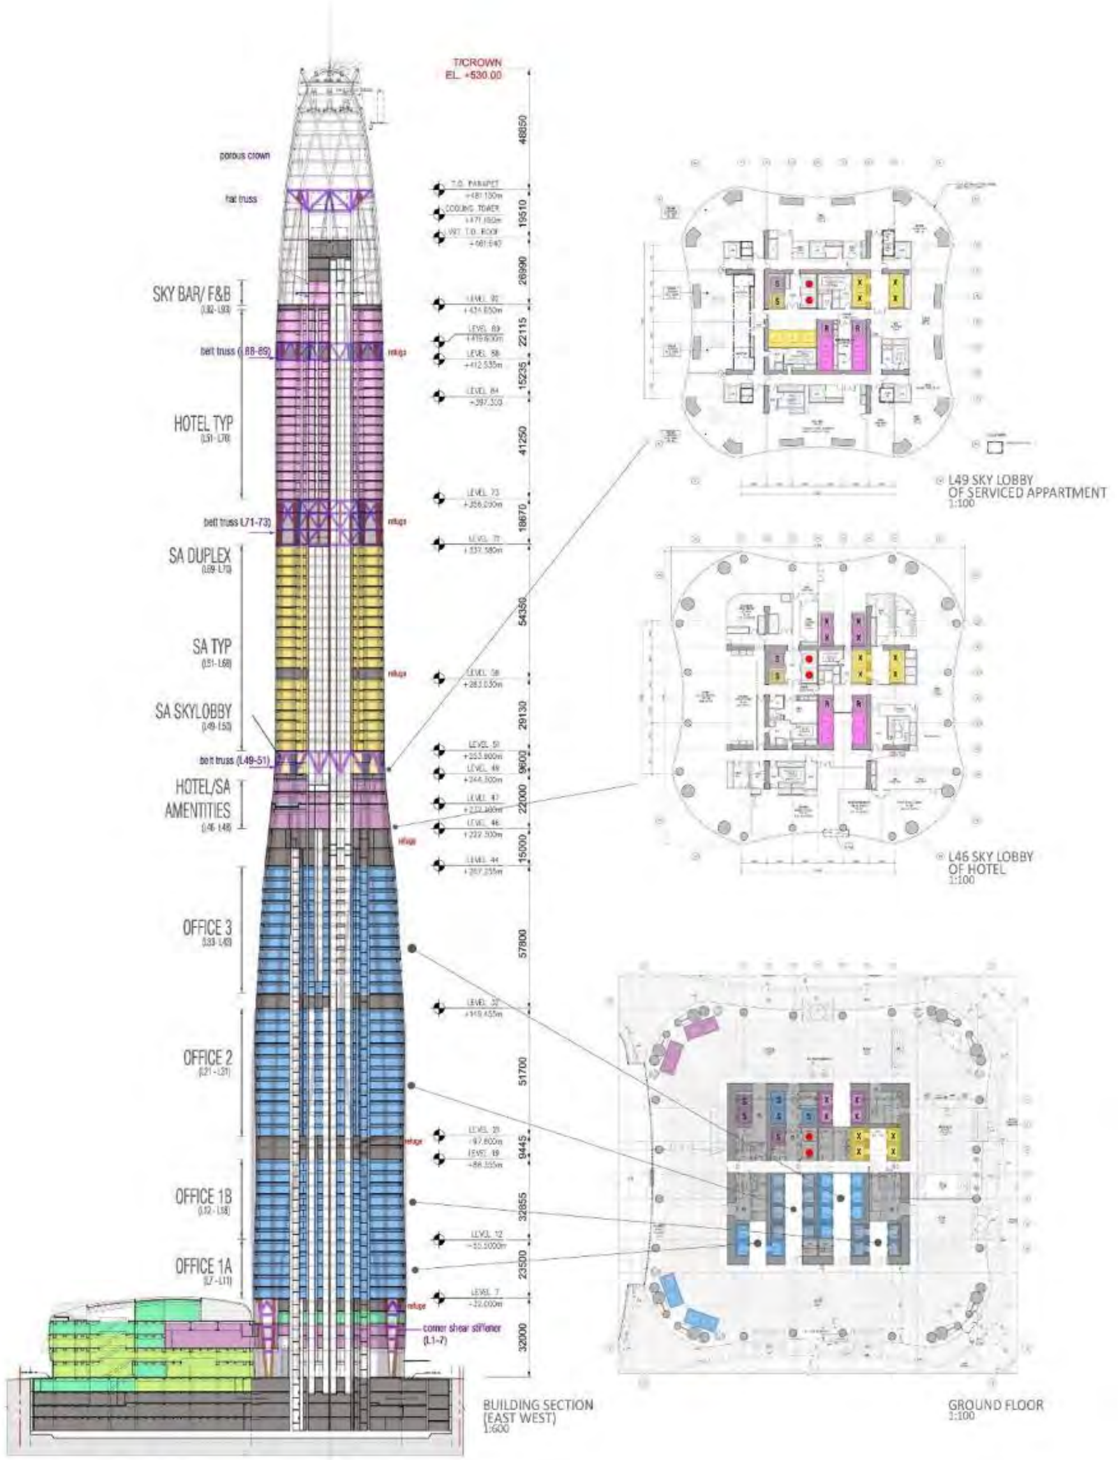

Figure 1: Tianjin CTF Finance Centre: Section showing a stratified vertical city

One example is the Tianjin CTF Finance Centre mega-tower, situated in the newly-developed Teda urban area in Tianjin's Binhai New Town. Rising to 530m, Tianjin CTF Finance Centre is a standalone mega-tower surrounded by institutional, commercial and retail buildings, but its design is fully confined within the site boundary, with the exception of one underground pedestrian connection to an adjacent metro station.

Figure 2: Tianjin CTF Finance Centre: A carved-out city block in a low-rise neighbourhood

With a total gross floor area of 389,900 m^2, this tower is the vertical city personified. Its 99 floors are stratified into different zones, including a 23 storey ultra-luxury hotel; 21 floors of serviced apartments; 34 office floors; five storeys of lobby and clubhouse facilities at the lower floors connecting to a five-storey retail arcade and hotel public facility podium; and four basement levels which house car parking spaces, a mechanical plant and a back-of-house area.

Figure 3: Tianjin CTF finance centre: An icon in the community

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Impressively demonstrating the integration of facilities, form and structure, Tianjin CTF Finance Centre is inarguably an icon for the city, as are so many Generation Three towers. But while remarkably efficient and self contained, these towers are still more about themselves than the surrounding area. Their zones are well-defined, but often have limited connectivity with each other; there is a distinct lack of accessible and good quality public space; and most crucially – these towers lack a connection to the wider community. They are still disconnected islands floating in an urban sea.

3. FROM ICON TO COMMUNITY GENERATOR – CREATING CONNECTIONS

As the most populous country on Earth, China is the ultimate "people-oriented" place. The unprecedented rural to urban migration occurring in modern China is leading to rapid, hyper-density urbanization as the country's cities rapidly run out of space to house new arrivals. This current growth model is unsustainable and, as we have seen repeatedly in other countries, leads to massive society-wide problems – traffic congestion, pollution and declining quality of life.

People can only truly thrive in functioning, living, connected communities. The designers of newest generation of mega-towers, "Generation Four" if you like, have begun to realize this and are acting accordingly. Generation Four towers create solutions to these hyper-density related problems by providing the missing piece of the puzzle: creating flourishing, sustainable mini-cities with multiple robust connections to the surrounding environment.

Wuhan CTF Finance Centre mega-tower, currently under development, is an example of a Generation Four tower. Located on a vast site, with most of its area consisting entirely of public green space, Wuhan CTF Finance Centre is first and foremost a people-oriented development which emphasizes community and connectivity. The development is highly connected to the rest of the city via an underground "root" system – road, rail and pedestrian connections – which firmly "plug the project in" to the rest of the city.

Figure 4: Wuhan CTF Finance Centre: Visually connecting and physically integrating with the community

4. DESIGNING A NEW GENERATION OF MEGA-TOWER

Wuhan CTF Finance Centre is situated in an urban renewal area of Wuhan, the capital city of Hubei Province. Wuhan, historically known as "two waters and three towns", is widely known as being the traditional transportation hub of Central China. The site sits next to a flood prevention dam on the Yangtze River in a key, centralised position in a newly-planned CBD area.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 5: Wuhan CTF Finance Centre: Genius loci with three-dimensional pedestrian links with the community

Looking at the site from above, it is immediately obvious that the Wuhan CTF Finance Centre project is not the typical "carved-out plot" commonly seen in earlier generations of mega-towers; it is much more a node with multiple connections to the surrounding area. It is a high-density development with a plot ratio of eight, much higher than the more typical 2.5 or 3 common in Generation Three towers. The plans allow for the release of a startling 53,000m^2 of land for the construction of a city park, while increasing the supply of office space by 80 per cent when compared to similar projects.

Wuhan CTF Finance Centre's design stresses its connection to the urban and community environment on every level, and in doing so, the design demonstrates the project's commitment to providing public space. The project will accommodate a total gross floor area of 532,000 m^2, configured as a vertical city, with office, retail and residential functions. An additional 200,000 m^2 will be provided for car parking spaces and back-of-house functions at the basement levels. The offices will be housed in the 648m high, 118-storey mega-tower with a total floor area of 327,000m^2 floor for lease or sale. The remainder of the development will include four 90m residential towers located at the four corners of the site, and a 100,000 m^2 four-level retail podium which will connect to the office and residential components of the project.

5. KEY CHALLENGES AND STRATEGIES ADOPTED

This template is used to provide you with the formatting specifications needed for preparing electronic versions of your papers. All margins, page numbers, column widths, line spacing and font styles are prescribed, please do not alter them.

5.1 Connecting a significant business and retail hub to different communities

The planning and design of Wuhan CTF Finance Centre involved much more than the rather linear concept of "creating a magnet" to draw in the working population of the new CBD. This project casts its net to a much wider demographic: connection to the cross-river rail and underground road network will provide rapid and convenient transportation links for members of the university and the high-tech research community living and working in the nearby Wuchang district, allowing them to mingle with business people working in the tower.

The retail portion of the development is also being positioned as a family and children's mall – the planned children's education and learning facilities will extend the value of the development to yet another demographic and bring life into the tower outside of office hours.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

These unique links will connect the surrounding residential neighbourhoods and the main city with a less congested, greener and more vibrant urban space – a place which does not exist in the current city fabric – providing the entire city with new green space.

5.2 Providing a safe and enjoyable venue for community interaction

The at-grade level of both the project and the park sites encourages the unrestricted flow of pedestrians and designated urban spaces for where the public, shoppers, members of the university and business communities and more can interact. Most of the external vehicular traffic will be at the underground level, which will reduce the amount of traffic-related air pollution in the at-grade portion of the development. The above-grade tree bridge network also allows convenient pedestrian movement between the functional, recreational and transportation portions of the site.

The numerous open spaces give the circulating pedestrians various opportunities for relaxation and other activities. The city park provides not only a large green space, but also a large stage for different activities like art exhibitions, sports events and a vibrant public space for children and adults alike.

5.3 Controlling the design and maintaining the future built environment

Your submission must provide the details of the work to readers. It should be clearly divided into sections, with heading/ sub-headings, so that readers can follow the logical development of work. Using headings is a great way to organise the paper and to increase its readability, so make sure to format them correctly.

From the start, it was essential that the developer proactively controlled the urban design rights of the surrounding area, in order to maintain the desired overall environment and set a baseline for the planning and integration of activities for different communities. One strategy which provides these safeguards is to take up the design of the city park and its pedestrian connections with the the project.

During the project's initial land sale deal, the developer also bought another 25,000m^2 of retail GFA under the city park site – this will allows direct below-grade connections to the development. To ensure that the functionality of the development and the connected areas is truly harmonious into the future, the demarcation of maintenance responsibilities in connected by non-project site areas must be carefully considered, otherwise this harmonious concept could rapidly unravel.

5.4 Bringing a mega-tower office project to life beyond office working hours

Most CBD and mega-tower projects across the world face a common problem – the notion of the vacated city – or "dead city" – after office hours and on non-working days. To allow effective, continuous and constant use of the area, regional retail and residential elements were planned into the project. These discrete elements will allow different communities to enjoy various activities around the clock, providing multiple uses for this public space which can be enjoyed at different times of day.

6. CONNECTING WITH EACH OTHER

Merging "work", "play" and "live" destinations is not a particularly innovative concept these days. Wuhan CTF Finance Centre's uniqueness lies in its connectivity, which will feature:

- A metro/ tram transportation hub, including three metro/ tram lines at the basement level, street level and above-grade viaduct levels;
- Six pedestrian connection points to adjacent developments at the basement level, including to retail facilities which will be provided in an adjacent future development;
- Six pedestrian connection points with current and future metro and rail lines;
- Two pedestrian links to the city park to the east at two levels;
- Six pedestrian connection points which will connect to future commercial developments, the city park, the cultural centre to the north and the current promenade park;
- Connections to public and cultural facilities in the vicinity;
- Public loop roads at the above-grade and basement levels.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 6: Wuhan CTF Finance Centre: underground vehicular loop road with community parking at B2&3

Connectivity does not strictly mean "transportation"; the concept also involves the creation of connections between people. Wuhan CTF Finance Centre seeks to create a space that the surrounding community can enjoy around the clock, through the provision of public open space and numerous services and facilities. Business clubhouses and office rest lounges will be located throughout the building; retail facilities will feature family- or child-based themes to help stimulate interest and attract people to the property; and the development will be well connected to green spaces. Residential facilities will also provide private open green spaces at the deck level and exclusive clubhouse facilities for residents.

Given the project's proximity and accessibility to the major commercial, residential and educational areas of Wuhan and its strong pedestrian, road and rail transport links, this project has the potential and the capacity to attract people into the neighbourhood – creating a community and providing Wuhan citizens with unprecedented opportunities for fun, leisure and learning.

The tower itself has been designed specifically to define and draw people to the area, rather act as an outright display of power. Its enormous height will make it a natural icon – this is unavoidable – but an icon which serves rather than displays. Wuhan CTF Finance Centre will serve as a nexus for new development and a place where people can gather and connect with one another.

The tower's structure consists of a central concrete core with corner setbacks at various levels which echo the shuttle lift stacking, and perimeter moment frames comprised of composite columns, belt trusses and perimeter spandrel beams. The tower's structure will be fully integrated with a versatile energy-efficient façade system which will be put through stringent wind load analyses, with the aim of minimizing the materials used for the structure.

Figure 7: Wuhan CTF Finance Centre: A "mega-hub" for work, live and play

While emphasizing the tower's verticality, a curvilinear spline will begin at the base of the tower and wrap around the building's envelope all the way to its top. The primary purpose of the spline is to mitigate the wind loads exerted on the surface of the tower, but it will also provide a certain important aesthetic. The overall image of the tower will be of a flower about to blossom – symbolising the bright future which lies ahead for Wuhan.

The green space created by this project also makes it unique. The city parks and large waterfront park balance the impact of the development, both visually and environmentally. The green areas within and outside Wuhan CTF Finance Centre site are seamlessly connected – creating a long, unbroken space where nature and people intermingle.

Figure 8: Wuhan CTF Finance Centre: A city park integrating urban design with the city fabric

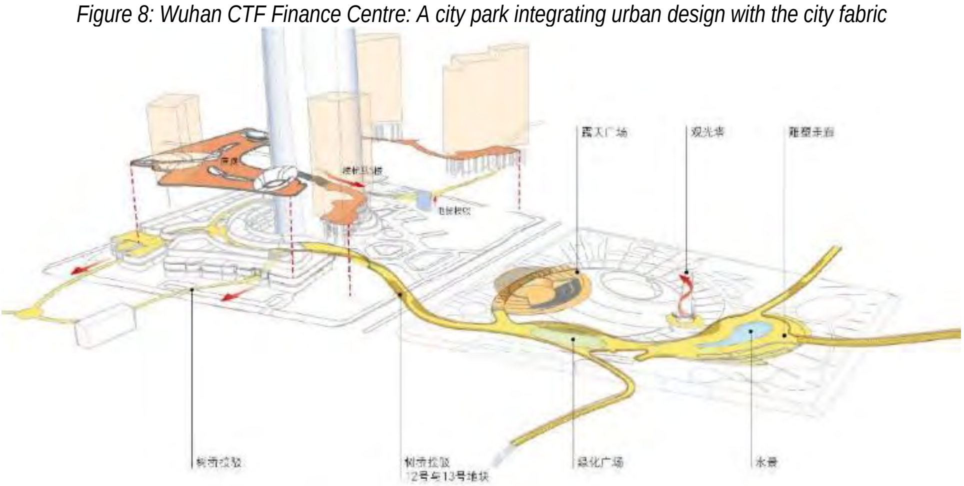

Figure 9: Wuhan CTF Finance Centre: the Centre is linked with the surrounding neighbourhood via a landscaped bridge and an underground arcade

7. DRIVING THE FUTURE

Creating these new mega-towers requires another kind of community – a vast cooperative network of people working together to shepherd a project from the design stages through to final completion. Whereas standalone mega-towers require a large project team, they are focused on completing the tower only. Connected Generation Four towers are fantastically complex undertakings requiring highly specialized knowledge, skills and experience. In the case of Wuhan CTF Finance Centre, planning the connections to the surrounding environment – the "spaghetti under the surface" – was actually more complex than planning the tower itself.

In Asia, particularly in China, executing a project of this scale requires a dedicated team with deep experience – not only architecture and design experience, but cultural experience as well. Such teams need to be able to coordinate, liaise, negotiate and enter into dialogue with a wide array of people and companies – from government departments to transportation engineers to contractors and beyond – all in the specific and unique context of modern-day China.

With Wuhan CTF Finance Centre, a number of specific challenges were encountered. While unique to the project, firms seeking to undertake these projects in the future should be aware that these types of challenges will certainly reoccur in other mega-tower projects in China. These include:

- Multi-disciplinary design challenges which occur during the design, development and implementation stages. These can include the need to create large amounts of specialized building materials, which can rapidly escalate costs.
-
- The need for large teams of consultants and specialists. While necessary, these teams must be unified by a unified, strong leadership team.
-
- Exceptionally complex designs involving enormous amounts of information. Potential solutions involve the use of Building Information Modelling to resolve potential design clashes, and factory-fabricated products to decrease construction times.
-
- Numerous logistical barriers and other hurdles exist in terms of obtaining the various necessary statutory approvals from government bodies. Flexible schedules need to be utilized and keen attention paid to the time lag between design approval and statutory approval.

Firms operating in China must seek solutions to these and other issues quickly, as over the next five years, 71 per cent of the world's completed super-tall and mega-towers will be located in China.

8. CONCLUSION

The world has come a long way since the first tall buildings scraped the sky over Chicago. In most parts of the world, the "good old days" of a building being a symbol of power and pride are gone forever. Today, self-contained, standalone towers are becoming an anachronism, with their importance to the cities of today in rapid decline.

This is not to say that mega-towers are irrelevant. Far from it – in Asia especially, they have a vital important role to play in the urban environment. The mega-towers of the future – Generation Four and whatever comes next – will still be icons that embrace and celebrate the achievement of creating incredible buildings, but they will also, more importantly, celebrate their connection to the neighbourhood, embrace the public and generate living, thriving communities.

Do We Design Our Cities?

Eugenio Maria FONTAN YANES[a], Jorge BENEITEZ[b]

[a] *Enzyme Apd, Hong Kong SAR, e.fontan@weareenzyme.com*
[b] *Enzyme Apd, Hong Kong SAR, j.beneitez@weareenzyme.com*

ABSTRACT

Architecture and Cities are a manifestation of our relation with space and nature. It is not just a mechanism of making money and profit.

The Quality and Environmental Performance of a building is determined by its very first Design.

Nowadays we have tools at our disposal that allow us to Optimize Time, Resources, Cost, Energy consumption during construction and life cycle, etc. We know passive techniques that optimize sustainable performance. Why we don't implement these techniques in our Design?

A Smart Design Process is the one that integrates all this considerations within the space we want to live in.

How to project our city? Right now the spaces we live in are the result of different disciplines poorly connected and not coordinated. The design of a city is a single process, it is the design of different parts and aspects of the same thing. We need to think in an integrated way when designing buildings and cities from the very beginning. A building doesn't become sustainable when adding a solar panel and a city doesn't improve just adding trees..

How we achieve it? Every architectural design of any scale, from interior renovation to mix use or master planning, should propose Technical and Environmental "objectives" related with the conceptual ideas of the project.

All aspects would afterwards be coordinated with specific consultants of each discipline such structure, MEP systems, energy performance, facility management, etc. Such coordination and development would involve the Design Team and every consultant as a cooperating Team Work.

Tools that allow the integration of works in a collaborative way such Building Information Modelling and other tools that analyse performance of the building should be implemented at the beginning of the project, should be part of the Design process.

We can Design the cities we live in.

Keywords: design process, climatic responsive architecture, sustainability

1. INTRODUCTION: ABOUT OUR CITIES

When starting to design an architectural project at University they used to tell us that understanding the environment was the most important step of the whole process. It was the way to understand the right questions and give the appropriate answers. It doesn't matter the scale of a project, the environment and time that we live are claiming for accurate answers for specific problems.

Good design is often not about giving a good answer but more about formulating the right questions. Our city is the result of how do we give answer to all questions. How do we answer to social demands, private space, economical revenue, regulation, connectivity inside the city, relationship of the urban fabric with the surrounding environment.. How do we design our cities?

2. THE DESIGN PROCESS

2.1 About the design process

Let's first of all define the process of developing a project till it becomes real. We are going to call this whole process "the design process". To agree in a very simple way of understanding how a project becomes real we divide this process in three stages: Design Stage, Design Development and Final result or Outcome.

We can generally call the beginning of any project the early Design stage. The moment in which we start thinking and proposing our intentions, necessities, expectations, principles and constraints.

After this first little step the design needs to go through a long process to become reality which is the development of the initial design. The result and outcome of a project will then depend on that process and the initial design. We need to ask the right questions to get the right answers.

A smart design process is the one that enhance all our intentions and allow the final result to be what we expected. A bad design process is the one that worsens the intentions and principles of the design and creates a worse outcome.

A smart design process is also the first sustainable strategy, is how we optimize resources for the creation of a new project.

2.2 The early design: Making the right questions

Before start designing we need to have a clear vision of the ideas, constraints, benefits, etc.., that will influence our design.

Government bodies establish constraints and regulations to ensure minimum requirements for every project. Some regulations are there at the first place to protect the users from greedy developers that build poorly in order to maximise benefits. Economical considerations are also very important. We must ensure that the investment on a project must create some revenues, so developers also will keep on investing on the community.

The environmental considerations are not yet a must in every project but we must make them become a valuable asset of our design. Regulation bodies have the capability of making environmental strategies mandatory.

What about the social and private space quality?

We need to understands which are the questions so we can design the proper answers. The challenge of designers is to give answer to these questions to make them complement each other without making sacrifice and satisfying all demands that involve the project, "Yes is more" (Bjarke Ingels. 2009)

2.3 The Design development: Multidisciplinary challenge.

Through the process to become reality our design is going to have to adapt to different demands. The design development is done by different teams during the process. It is always a multidisciplinary task.

Apart from the Architect in the case of a building we have structural consultants, fire consultants, MEP (Mechanical, Electrical and plumbing), landscape, etc.. How do we coordinate all these disciplines in between them? Are we using the right tools and platforms for this purpose?

The sustainable considerations of our design will be rather optimized or ruined. How are we ensuring that the development is making them to become real at the end?

The building process will also determine the result. Was that phase also taken in consideration while defining our design? Sometimes this process change extremely the original design. The more we have in consideration this development at the early design stage of a project the less it will be affected negatively in the future.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.4 The Outcome

What is the outcome that we have? How the process affected the design principles? Does it fits all our demands and constraints? How is the performance of our project once is real?

Sometimes a non appropriate design can be the responsible for poor development. A poor early design can be the cause of a bad development and a bad result.

Inefficient coordination can be as well the responsible of over cost and delays during construction process. It can ruin most of the strategies implemented on the early design stage.

3. THE CURRENT SCENARIO (PROCESS A)

3.1 The process A

How is the current design process that we commonly see in our cities? Let's have a look to the case of Hong Kong as an example of a common process that happens in a lot of cities around the globe.

3.2 Analysis of current design stage

Which are the main ideas, constraints, benefits, etc.., that are influencing our design decisions?

There are different voices calling for different answers. Clients/ developers usually search for economical answers and investment return. Regulation bodies like BD (Building Department) search for standard and performance requirements. But Regulation Bodies could also request environmental and social solutions. How can designers give answers to the right questions if governments or developers are not asking for them?

Hong Kong is well known for the use of huge amount of energy for balancing the energy gain of our buildings. Developers are not interested in improving the quality of their projects so the energy performance is more efficient.

Sometimes seems that the design of Hong Kong projects is just a result of bad coordinated questions and aggressive economical considerations ignoring environmental and social aspects.

3.3 A Multidisciplinary development

When developing the project all different disciplines need to evolve with it and need to be coordinated so the information is appropriately shared. How good or bad is this coordination happening in a city like Hong Kong?

After design is signed off by a client very often the project starts to gain detail while approaching the GBP (General Building Plans) submission (BD). For achieving the level of development that the GBP submission requires disciplines should be developed in parallel. It is very common that the coordination is poor and not well organized and this means that the information that teams are using is not updated and basically not the same. For instance, platforms like BIM (Building Information Modelling) which is a great coordination tool, are poorly implemented in Hong Kong projects right now causing a huge amount of mistakes and over costs.

All this overlapping of a bad coordination and errors lead to over costs and delays during the execution of the project. Fixing errors on site can lead to major design changes as well.

At this stage of the process if considerations regarding energy performance or sustainable strategies were not taken at the design stage it is quite late to implement them now.

3.4 Analysis of our outcome.

After the whole development of the project does it looks or performs as the early design intended? Was the design we proposed at the beginning the appropriate answer to our intentions, constraints, etc.? Did we asked the right questions?

How is the performance of our project now that has been completed?

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Which is the feedback of the final users? Did we designed our city after all? Or the project has become the result of bad coordinated process after inappropriate design premises?

As a conclusion we can see that the early design doesn't take in consideration the right questions and a poor coordinated development lead to a bad outcome full of errors and over costs.

4. SMART DEVELOPMENT (PROCESS B)

4.1 The process B

We need the best design to evolve through an efficient and smart process to get the best result. Basically we need to understand the potential and weaknesses of the process A. Let's define a smart design process.

4.2 About Smart Design

As we proposed before, first we need to identify and ask the right questions to design the right answers.

Government bodies have the authority to demand sustainable and social goals. Without this support designers have a little power of decision on these matters. Designers have just the option to show how these strategies do not have to be more expensive or to prejudice other project aspects. But the regulatory bodies have a crucial role here.

Following these goals a sustainable construction methodology should be implemented at the design stage.

Passive energetic saving strategies should be part of the concept design as methodologies to increase the energetic performance without increasing costs.

Quality for social and private space. Space in Hong Kong is expensive. But small spaces can have quality as well. We need to propose more quality social spaces for the city. Which is the design strategy for Hong Kong?

The early design needs to have in consideration the development. If the design has in consideration the realistic constraints of the different disciplines that will develop the project then the result will match the expectation of the early design in a more effective way.

The conclusion is that we need to understand and coordinate the right questions to give the right answers when doing a design.

4.3 Appropriate Development

An appropriate development requires an effective coordination. The coordination of information and documentation is crucial for the project development.

We need to implement the right collaboration platforms to avoid errors during the process. BIM platform is a methodology that allows interdisciplinary coordination during the development of a project. It is also very efficient in terms of documentation production. Authorities should ask for the implementation of this methodology in Hong Kong projects and designers have the responsibility of implementing in their projects as well.

Keep track on the environmental strategies implemented on the design stage. Some features of BIM platform, and several different softwares, are the evaluation energy performance. Implementation of energy evaluation methods to maintain the environmental and energetic goals of the design should be mandatory.

Hierarchy in the process of communication and responsibility during the process is also very important to avoid misunderstandings on the process. Also regarding the establishment of common goals and objectives, leadership and managing expectations among the teams is crucial for an efficient development.

Only by using these principles we will save over costs, problems fixing on site and major design changes.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4.4 Benefits

The final result will benefit from an appropriate development and a smart design. The outcome will match the goals of our early design thanks to an appropriate design process. Only in this way our cities will benefit from our projects and we will actually design our cities.

5. IMPLEMENTATION: FROM A TO B

5.1 Improving the Design

Identify right questions and coordinate them properly. Coordinate all demands.

Social demands for public spaces need to be asked by the regulation bodies.

Minimum quality for both public and private spaces shall be demanded by government.

Sustainable construction methodologies shall be part of the main design intentions and supervised by regulatory bodies.

Passive energetic design strategies should be implemented as part of the design and supervised by regulatory bodies.

The development needs to be taken in consideration at this stage. A multidisciplinary team can design having in consideration the development.

5.2 How a development becomes smart?

Implement collaborative working platforms such as BIM for the development of projects for better coordination of documentation in between teams.

Implement energy evaluation techniques and require them as mandatory by regulatory bodies for a better achievement of sustainable strategies on the design

Implement communication tools that allow all teams to be coordinated and establish a clear hierarchy of communication through teams.

5.3 Outcome B: key benefits and conclusion

Result will match the design intentions and goals. Over cost due to errors during works development on site will be highly reduce.

Better environmental and social spaces for the city.

Have an efficient process is the first sustainable efficient strategy: to optimize resources, time and money without losing quality.

Design our city is a collective responsibility that needs to be assumed by the regulatory bodies. Designers can propose important improvements in their projects that the city will benefit from. Little strategies implemented in small projects can make a huge change together.

In this paper the questions have a higher importance than answers. The answers need to be provided by every designer. There is not such a correct answer but an appropriate question. Environmental and social questions are always left to a second position compare to those that ask for economical benefits.

We can design our cities but the right questions needs to be done and the smart process needs to be implemented.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Sustainable Residential Building Developments Towards Neighbourhood Level: **From A Hong Kong Private Developer's Perspective**

Kevin NG[a], Edward CHAN[b]

[a] *Henderson Land Development Co. Ltd., Hong Kong SAR, kevin.ng@hld.com*
[b] *Henderson Land Development Co. Ltd., Hong Kong SAR, edward.cw.chan@hld.com*

ABSTRACT

Hong Kong, as a high-rise high-density metropolitan city, Hongkongese living in tiny residential units and surrounded by other tall buildings is not uncommon. Scarce supply of land in Hong Kong leading to many of new residential developments are either re-developed inside a small site in old district or large scale housing estate developments in new districts or nearby new MTR stations.

Spatial and regulatory related planning constraints are primary concerns for private developers to review whether the new development is financially viable. Financially sustainable business operation is crucial for the continuous housing development by the private sector. However, social, environmental and financially sustainability are not mutually exclusive.

New residential buildings in old districts are usually be developed as a single tower, which is playing an important role in the urban renewal of Hong Kong. Housing estate development considers the environmental sustainability to a broader level. The development itself may not be able to form a self-sustained community. Hence, the elements leading to sustainability shall be extended from housing estate to district level. Environmental considerations and interactions with the neighbourhood are the crucial parameters driving a genuine sustainable design, construction and operation of a new residential development.

The approaches and success factors of sustainable urban renewal and large scale residential estate development are exemplified by some recent projects which have been accredited by both local and national green building assessment schemes. Signature urban renewal development project and a large scale residential development project obtained with LEED Neighbourhood Development were also be introduced so as to explain how sustainable residential development is extended from the conventional building level towards neighbourhood level.

Keywords: sustainable residential development, neighbourhood development, private developer

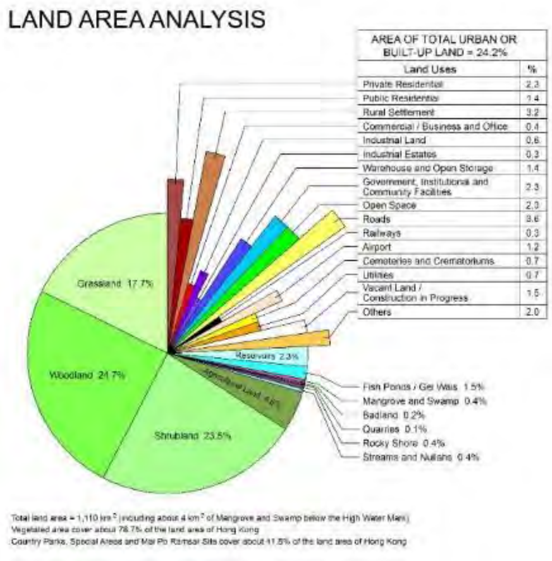
6. INTRODUCTION

1.1 Private housing in Hong Kong

Hong Kong, as a high-rise high-density metropolitan city, Hongkongese living in tiny residential units and surrounded by other tall buildings is not uncommon. Hong Kong's natural terrain is characterised by rugged uplands flanked by steep slopes. A layer of soft, weathered rock covers the bedrock in most places, slope debris mantles the natural hillsides, and alluvium fills many of the valleys. Most of the flat land being developed are reclaimed land and scattered throughout Hong Kong Island, Kowloon peninsula and new towns of New Territories.

Up to the end of 2015, the population of Hong Kong was 7,324,300. However, most of the lands in Hong Kong are undeveloped, whilst the built-up land accounts for only 24.2% of the total land area in Hong Kong (1,105.7km^2 in 2015), in which only 3.7% of the total land areas in Hong Kong being used for private and public residential usages. Hence, each person in Hong Kong can occupy equivalent to around 5.6 square metres of land. Scarce supply of land in Hong Kong leading to many of new residential developments are either re-developed in a small site in old district or large scale housing estate developments in new districts or nearby new MTR stations.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk



Private sector housing is playing an important role in Hong Kong. At the end of March 2015, private residential stock amounted to about 1.5 million housing units, in which the amount is larger than that of public rental housing (789,300 units) and government subsidized sale flats (398,600 units) up to March 2016. Hence, the visions and approaches of sustainable residential building developments are influential to the overall living environment from the residential unit interior level to the community and neighbourhood levels.

1.2 Sustainable residential development: Private developer's perspective

From the private development perspective, the planning, design and construction of each new development project is for the people and for the future. Well maintained building can be used for decades or even to hundred years. Hence, each well-planned sustainable development shall take account various building lifecycle factors. New development also aims to improve the built environment in the vicinity, such as daylight access, air ventilation, noise, hygiene, comfort and safety of its urban neighbours.

New residential buildings in old districts are usually be developed as a single tower, which is playing an important role in the urban renewal of Hong Kong. Housing estate development considers the environmental sustainability to a broader level. The development itself may not be able to form a self-sustained community. Hence, the elements leading to sustainability shall be extended from housing estate to district level. Environmental considerations and interactions with the neighbourhood are the parameters driving a genuine sustainable design, construction and operation of a new residential development.

From the private developer perspective, developer can be dedicated to the role as a corporate citizen. Developer shall consider and act on the social, economic and environmental impacts of the business and contribute to community. Spatial and regulatory related planning constraints are primary concerns for private developers to review whether the new development is financially viable. Financially sustainable business operation is crucial for the continuous housing development by the private sector. This is particularly important for developer's continuous investment of land and old building acquisition, design and construction of good quality building projects, as well as leading the industry ahead to improved liveability, healthy environment and well-being. In each building development, social, environmental and financially sustainability are not mutually exclusive.

No matter people are living in the old districts or new towns, various sustainable factors are influencing the residents and communities. On the environmental aspect, residents are concerning the energy and water consumption, air ventilation, health and safety factors inside their residential units. Besides, residents are also looking for environmentally-friendly common areas, such as the circulation lobbies, club house, podium and ground level open space, as well as the supporting facilities inside the site. People's expectation has already extended from the tiny space to the shared common areas in the past decades. Nowadays, as a corporate citizen, each building development shall extend the planning and design notions to the community level, which aims to hand-in-hand with the neighbours and share the benefits achieved from social and environmental sustainability.

7. SUSTAINABLE URBAN RENEWAL PROTOTYPE: THE GLOUCESTER

2.1 Development parameters

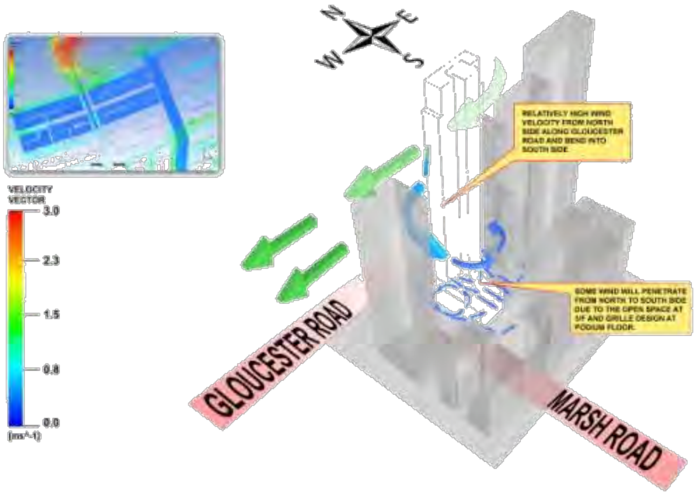
Situated in the old downtown area – Wan Chai, with high density and busy traffic, The Gloucester is a typical "urban renewal" residential project in Hong Kong. The Gloucester is a 34-storey 177-units residential tower sitting on a 3-storey carpark podium, with an aquarium-style indoor heated skypool on top floor as the building's iconic feature over Victoria Harbour. The site constraints were turned into opportunities in creating a vibrant city life with comfort and convenience. The greatest challenge of design was to create an enjoyable yet environmentally-friendly living space within the old urban district.

2.2 Sustainable design considerations

The tower is enveloped with prefabricated façade with low-e tinted Insulating Glazing Units (IGU) to optimize the natural daylight, acoustic and thermal performance and to command a panoramic view over Victoria Harbour. It provides the residents with a host of recreational amenities and a podium garden articulated with vertical/ horizontal greenery at a green ratio over 30%.

The predominantly north-south facing building layout offers low heat transmissions to the interiors from the unfavourable east and west sides, appropriate window-floor ratios for natural daylight and a wide variety of flat layouts. Careful consideration is given to façade lighting design of indirect LED lights, striking a good balance between architectural elegance, and light pollution to neighbourhood. Energy efficient equipment, water saving and rainwater recycling are widely used in residential units. Waste sorting facilities and food waste composting facilities help to reduce loads to public landfill.

Porous podium façade and landscaped podium garden diverted natural wind from the harbour side to the narrow streets behind the site such that the micro-climate of the neighbourhood is highly improved. Indoor air quality monitoring in public area and effective natural ventilation shape a healthy living environment. Besides, the extended building separation of The Gloucester and the sister development Mira Moon Hotel improved the daylight access to the adjacent residential buildings substantially.



8. SUSTAINABLE LARGE-SCALE RESIDENTIAL DEVELOPMENT: DOUBLE COVE

3.1 Development parameters

Double Cove is located on a unique twin-cove peninsula which offers sweeping views across Tolo Harbour. The development comprising 21 residential towers, and offering tranquil living environment for over 3,500 households, with flat mix ranging from unit in 50m^2 to 320m^2. In addition, there will be 25,000m^2 of commercial and club house facilities as well as car parking with electric vehicle chargers, cycling track and jogging path around the site perimeter. Ample green space (>50% of site area) is available in the development.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The residential towers all lie along the perimeter of the development in a stepped layout from south to north, creating a larger sense of space and view for residents. Walkways, cycle paths and sitting-out areas are also available to encourage exercise within the community and promoting social cohesiveness.

New urbanism and sustainable buildings are the principles which must be collectively considered in order to attain such a quality standard. Connectivity or walkability is one of the key features. Double Cove provides a 24-hour covered footpath on the podium level allowing residents and public to move freely to the MTR Station and the Public Transport Terminus.

Double Cove residential development was awarded a Grand prize in Quality Building Award (Multiple Buildings Category) in 2016 and certified in September 2015 as Hong Kong's first LEED-Neighbourhood Development, demonstrating sustainable certification being applied beyond just the green building blocks.

3.2 Driving for green lifestyle: **'Extended Home" with** enjoyable spaces b**eyond the "Flat"**

The vision of Double Cove is to set a New Benchmark for large-scale residential development in Hong Kong. The main focus of Double Cove development is on creating a high quality development set within beautifully landscaped park and gardens. This does not only give the development its unique sense of place, but it also creates a backdrop to the distinctively designed towers.

The idea of 'Living in a Park' by Architect, Lord Richard Rogers, became the main theme of the development and formed the key driver in many aspects of the design which echoed with the vision of the development - "Driving for Green Lifestyle".

Enhance low carbon living

Provision of electric vehicle parking spaces in public parking spaces, residential carpark and garden units with self-contained parking spaces with 32A medium speed charging facility encourages use of electric vehicles. Communal bicycle rental is available to encourage cycling as a sustainable means of transportation. A public twenty-four hours walkway with direct access to the MTR/ public transportation connecting to each residential tower and nearby developments encourage healthy and low carbon lifestyle.

Creating a comfortable and healthy environment

- Minimize view obstruction by creating view corridors for the neighbours.
- Enhance air quality through computational studies and creating optimal building separations.
- Ample planting and water features to reduce urban heat island effect.
- Air quality monitoring, hybrid ventilation and north-facing skylight in shopping arcade shaped an innovative and healthy pubic environment.

Promoting health and well being

- Communal bicycle rental service with electronic parking/ rental facilities encourage eco-transportation inside the site and connect into the nearby public cycling tracks.
- Extensive cycling track within the site 1,360m, connecting to other districts.
- Extensive jogging path within the development 2,302m, connecting outside.
- Energy efficient equipment, water saving and rainwater recycling are widely used.
- Waste sorting facilities and food waste composting facilities help to reduce loads to public landfill.

3.3 From "Green Building" to "Green Neighbourhood"

Site planning: Nature and cityscape consideration

The masterplan concept is a response to the site and the neighbourhood, in particular to views of the harbour and the natural surroundings. The central park creates a major 'Green Lung' within the development and also visual relieve for the surrounding development. The towers are mainly arranged in pairs in two curvilinear 'wings', enclosing the park. This arrangement creates a series of view and ventilation corridors through the site. The elevated towers with air ventilated lowest two-stories, descending in height towards Tolo Harbour, create a cityscape which is more in-keeping with the natural surroundings.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Making the sustainable living community a reality

The development was planned and achieved with LEED Neighbourhood Development (ND) elements. Double Cove was designed as a compact development and close to neighbourhood, and developed with optimized development ratio that suit the usage needs and improved environment. Healthier community was featured with comfortable living residential units and walkable street network, together with bicycle track and storage. Sustainable design was also supported by computational heat island analysis (first done for a residential project in Hong Kong) to review the heat island mitigation for the site and the nearby community.

Individual green building was designed to encourage low carbon living style by means of achieving over 10% of energy saving accordance with ASHRAE 90.1-2007, reducing potable water for irrigation by 50% and reducing potable for sewer conveyance by 20%. The site was designed to promote natural habitat together with long term conservation plan. Environmentally consciousness was achieved by extensive deployment of greenery. About 50% of the site area is designated as “green area” which includes preserving existing woodland and creating woodland extension plus green roofs, green walls, water features and landscaped amenities.

Enhance air ventilation in and around communities

Voluntary district-wide Air Ventilation Assessment (AVA) was conducted for the development site and the district, though not statutorily required. Besides, micro-climate, outdoor thermal comfort and natural ventilation under mid-season and summer wind conditions in and around the development using computational fluid dynamic simulations were conducted to assist the site planning and building design, so as to achieve optimized micro-climate performance both within the site and the neighbours.

3.4 Landscape design and management

Landscape planning, design concept and surrounding environment

Total landscaped area, including woodlands, green roofs, green walls, sky gardens, water features and landscaped amenities constituted around 50% of total site area. 8,800m^2 existing woodland; 16,000m^2 recreated woodland extension; 26,000m^2 green roof, green wall, water feature, landscaped amenities; 2779 trees to be planted (756 nos. on grade, 1274 nos. on podium, 749 nos. native species) on grade.

Various types of landscape and associated features being deployed in the development, such as reserved existing woodland and creation of woodland extension, well planned tree protection measures, soundscape integrated landscape design, green roof on shopping arcade, vertical greening scattered inside the development, bio-climatic eco-garden with various local and well adapted plant species, large landscaped amenity area contains recreational and cultural elements, distributed water features and greenery to create passive cooling and breezeway, as well as unique green hedge fence wall. Before the commencement of construction, archaeological investigations were carried out by archaeologists to ensure that the priceless antiques can be well protected and handed over to Antiquities and Monuments Office (AMO).

ABSTRACT

77 Hoi Bun Road is a new grade A office-cum-retail development situated in the rezoned business district of the Kowloon Bay Action Area in Kwun Tong, Hong Kong, with a total GFA of approximately 82,000m2. The project aims to become part of the green driving forces that are transforming the current Kwun Tong industrial district into a new dynamic and vibrant CBD2, which is in line with the Hong Kong Government's visionary initiatives for the Kowloon East areas as set out in its Policy Address in 2011-2012: a smart city that thrives on the use of data and advanced technologies, a sustainable green community with low carbon footprint, and high connectivity to public transport nodes by means of walking.

The project team adopts many innovative design ideas to enhance the building performances in terms of sustainability, social benefits to the community as well as health considerations. From building orientation and massing, envelope design, landscaping throughout the inside and outside of the building, people's circulation, diverse functional programme, innovative technologies, to the pursuit of work-life balance and community engagement, the project exemplifies an integrated design approach involving rigorous exchange of professional expertise with seamless coordination among various design disciplines which lead to many constructive dialogues with the client to achieve a high performance office and retail architecture. As a result, the project will become an iconic landmark in the CBD2 when it is completed in 2019. Unique green features in the building includes varying width of solar responsive shading devices optimized by computer simulation technique, sky garden with fitness equipment for the office community, air induction unit (AIU), naturally ventilated carbon filters, solar de-humidification system, to name just a few.

The proposed development has been registered with the world-wide recognized sustainable framework like LEED and BEAM Plus for the highest Platinum rating. The project will also be one of the few pioneers in Hong Kong to address the health and wellness issues of the building users, which will be assessed to achieve a WELL Certification by the International WELL Building Institute in USA, the leading healthy building label in the world.

Keywords: high-performance building, community empowerment, climatic responsive architecture

1. INTRODUCTION

In the Policy Address 2011-2012, the Chief Executive announced that the Hong Kong Government would transform Kowloon East (KE) into another attractive Central Business District (also known as CBD2) to sustain economic development (The Government of the Hong Kong Special Administrative Region, 2011). To expedite the plan, the Hong Kong Government was considering relocating the existing government facilities in the two action areas of KE. One of them is known as Kowloon Bay Action Area (KBAA) (The Government of the Hong Kong Special Administrative Region, 2013).

To achieve the envisaged commercial and office hub in the district, KBAA has been planned based on a number of guiding principles including: (a) to cater for territorial needs and generate public benefits; (b) to make efficient use of land resources; (c) to promote smart city and green neighbourhood; (d) to deliver quality urban design and integrate with surrounding urban context with place-making strategy; (e) to enhance pedestrian network; and (f) to ensure implementability (Development Bureau, 2016).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Despite the grand vision of the HK Government, the polluted air, heat and noise generated from surrounding industrial buildings and busy road networks cannot be totally mitigated at the moment.

Given the above vision and challenges, the proposed development aspires to create a pleasant and desirable environment for the future users, which addresses air quality and acoustics, whilst holding the vision that the building will act as a "green lung" and "pedestrian hub" to its immediate environment. Apart from environmental sustainability, the building design framework is further extended to address the issues of green community and people's health and wellness, aiming at linking people, building and community together.

1.1 Integrated design approach

The proposed Commercial Development at 77 Hoi Bun Road will provide approximately 82,000m2 of office and retail floor areas to the new CBD2, comprised of 17 levels of Grade A offices, 3 levels of retail podium, 3 levels of basement carpark, a roof garden and a podium sky garden to be shared by the office community and retail customers.

At the project commencement stage, sustainability workshops were held between the client and all the consultants together with the future facilities manager to align the expectations of different parties to set up clear and achievable goals for the new development. These early engagement exercises provided an open forum to the team to have open dialogues to thoroughly understand the strengths and weaknesses of every possible design solution from different perspectives, and only the best options acceptable by everyone were then adopted in the final designs.

2. LOW CARBON, GREEN COMMUNITY

2.1 Pedestrian hub and landscape design

Being the first commercial development in KBAA and situated at the crossroad between KBAA and the waterfront, and between Ngau Tau Kok MTR (Mass Transit Railway System in HK) Station and Kai Tak, 77 Hoi Bun Road would become a busy pedestrian hub in the future CBD2 of KE. Potential footbridge linking the public terrace to the upcoming Action Area provides a flexible connection in the pedestrian network, an essential component that enhances pedestrian connectivity in KE.

To further enhance the walkability for the neighbourhood and enrich the pedestrian experience, building setbacks, public spaces, green walls and extensive landscaping are utilised to create transition areas between the heavily trafficked road and the development. Lush landscaping in these areas serve as an effective "air purifiers" and "sound barriers" to filter air pollution, noises and excessive solar heat gain, ensuring desirable outdoor open spaces and indoor environment.

Feature green walls at pedestrian level improve streetscape and provide visual focuses for pedestrians approaching from both the Action Area and waterfront facing the Victoria Harbour and the new Cruise Terminal. Other outdoor greenery, building setback and canopies at various locations are also utilised to create a pleasant pedestrian zone around the building. Special attention has been given to the design of these transition areas between outdoors and indoors to ensure good air quality, comfortable and green surrounding can be experienced by the pedestrians as they approach the building, whilst desirable indoor environment quality (IEQ) with good thermal comfort and healthy building environment are provided once inside the building – an "Urban Oasis" amidst the currently harsh industrial setting surrounding the site.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

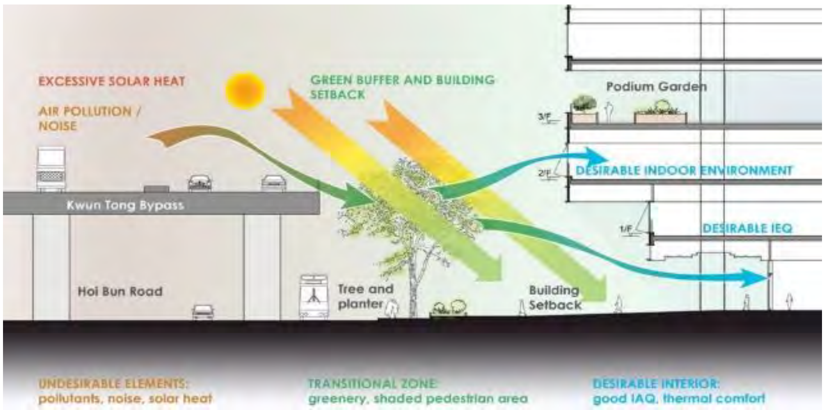

Figure 99: Concept of transition area

2.2 Spaces for green community

A wide range of communal areas and green spaces have been distributed throughout the building to form part of the green community. Well integrated into the building form, the harmonious spatial quality of these areas create a well-balanced interior and exterior. Building users or people from the community can freely encounter nature at various locations; allowing for spontaneous interactions with the sustainable facilities that will enrich the daily experience.

Once inside, biophilia accesses to urban greenery, health and active transportation feature heavily. Making up 30% of the site area, gardens are interspersed at G/F event plaza, terraces on 1/F, 2/F, 11/F, 21/F, while the roof and 3/F podium are largely dedicated to greening.

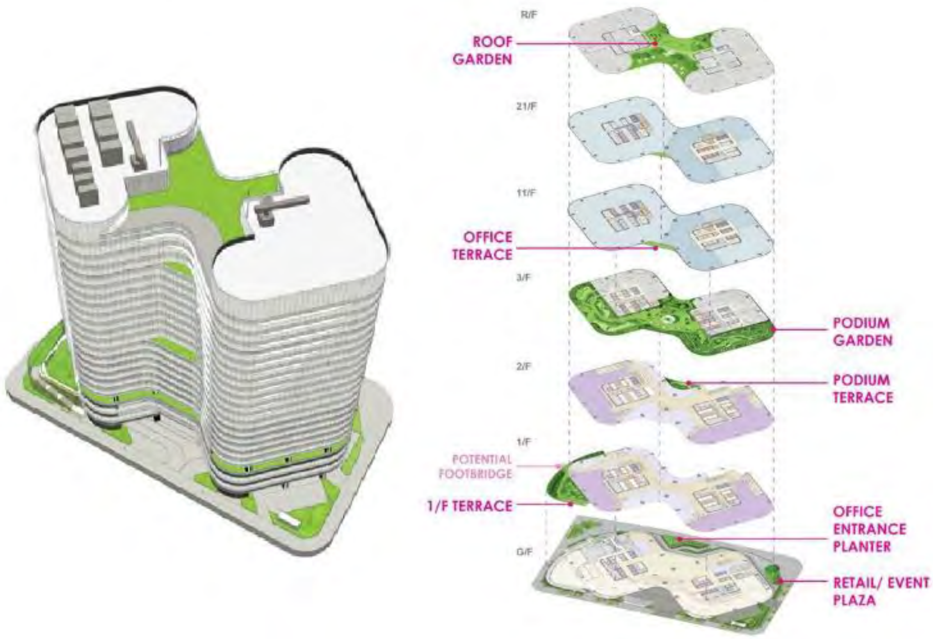

Figure 2: Communal area and green spaces

3. HEALTHY DESIGN

Sustainability is a major trend in the building industry. It can be reflected from the international sustainability building rating systems such as BREEAM in UK, LEED in US, BEAM Plus in Hong Kong, CGBL in China, etc. The systems usually focus on the environmental related issues such as climate change, energy and carbon reduction, pollution, water conservation, etc. However, there is critique that these systems cannot fully address the human health issue in buildings (Wargo, 2010). To respond to the challenge, the project team introduced numerous initiatives to

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

encourage a healthy environment and life style through the building design. These address concepts of air, water, nourishment, light, fitness, comfort and mind (International WELL Building Institute, 2015).

3.1 Cleaner air

Adjacent to the Kwun Tong Bypass and heavy vehicle traffic, outdoor air quality is a concern. EPD's Indoor Air Quality Certification Scheme and WELL Air Quality Standards were used to guide the filtration system design. As a start, the primary air handling units (PAUs) are placed on the opposite side of the Bypass, and elevated from the traffic through their placement on 3/F and R/F. Prior to occupancy, flush out and filter replacement will be carried out. In operation, carbon and MERV13 filters in the PAUs target the removal of nitrogen dioxide and small particulates such as PM2.5, while duct ionisers and MERV13 filters primarily treat volatile organic compound (VOCs), formaldehyde and particulates in the recirculated air of the air handling units. Fan coil units in common areas will have the capacity to install carbon filters in the future. Low-emitting materials will be used in the paints, coatings, adhesives, flooring, insulation, furniture and furnishing of the interior to minimise VOCs and formaldehyde.

The innovative Air Induction Units (AIU), carbon filter and pollutant-reducing plants are proposed to enhance the outdoor air quality by serving as an air curtain in the occupied zones of the 3/F podium garden

3.2 Occupant comfort

Enhanced fresh air provision, humidity control through adopting the solar dehumidification, good acoustics and glareless type light fixture improves the indoor comfort of the office spaces. Positive pressure sensors ensure that main entrances are kept cool and free from pollutants. To improve thermal comfort of outdoor areas, especially during hot summer days, AIUs enhance the thermal comfort in the podium gardens, while fans will serve the drop-off waiting area.

3.3 A work life balance approach – energising garden

To promote work-life balance in the future community in the building, easy access to the exercise facilities can motivate more people to take up the health habit. Therefore, an energising garden is designed on the 3/F Sky Garden, where outdoor recreational facilities are provided to allow people to do physical exercise, or to take breaks away from their work environment.

The Sky Garden is divided into passive and active zones, where diverse activities from yoga, stretching, relaxation, cycling and jogging can occur. To raise public awareness on sustainability and attract more people to do exercise, kinetic bicycles will be provided and the jogging track will be paved with tiles equipped with electricity generator. For every step, electricity will be generated and recorded for the achievement made. Further, cycling amenities like basement bicycle parking and showers can encourage cycling for reducing transport energy to the transport nodes or the nearby Kwun Tong promenade.

3.4 Healthy staircase

To encourage the use of staircase, an accessible stairs is provided with signage, enhanced lighting and artwork to encourage occupants to take the stairs instead of vertical transportation, minimising energy consumption.

4. SUSTAINABLE DESIGN

4.1 Passive design – solar responsive shading devices

High-rise, high density are the characteristics of Hong Kong built environment (Ng, 2009). The building solar heat gain can be affected by both self-shading effect due to the built-form and the shading effect by the external surrounding buildings. Owing to the complex and dynamic interaction between buildings and the sun position, there is no quick tool to calculate the facade solar heat gain.

However, thanks to the state-of-the-art computer modelling technique, the solar heat gain can now be visualised as shown in Figure 3. Variation due to the shading effects was observed on the facade. Based on the analysis, the envelope was classified into 3 different zones in which depths of the horizontal overhangs are determined with reference to the respective solar heat gain. Excessive solar heat gain is thus mitigated through the optimisation of

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

shading. Combined with high performance glass, the building design targets to achieve Overall Thermal Transfer Value (OTTV) of about 18W/m2, significantly lower than the code requirement of 24W/m2.

Figure3: Computer modelling and visualisation of building solar heat gain

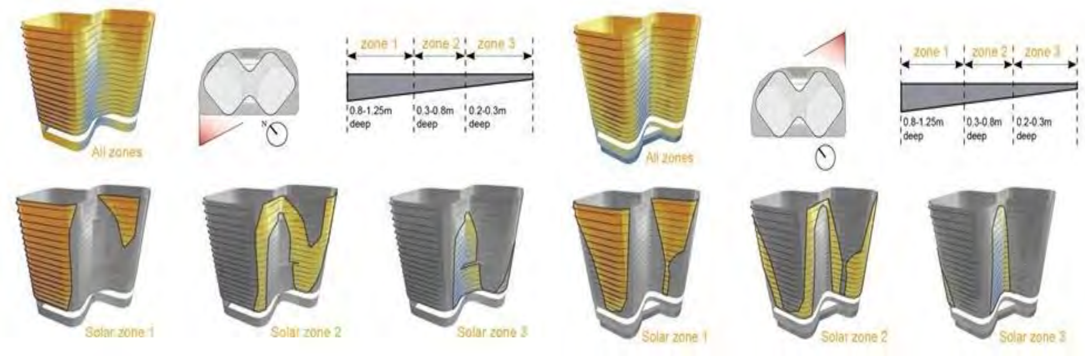

Figure4: Illustration of solar shadings in different zones

4.2 Active and renewable system design

The HVAC systems have incorporated a dehumidification system integrated with solar hot water panel specifically designed for Hong Kong context where it is humid for most of the year. The desiccant system can absorb the water moisture in the air and then regenerated using solar hot water. The renewable energy generated is equivalent to 2% of annual building consumption. Other implemented carbon reduction measures include variable speed drive chillers, heat recovery system, LED lighting for office spaces, regenerative unit for lifts, etc. Compared to the Baseline of Building Energy Code (BEC) 2012, the project building targets to reduce energy use by 33.4%. The detailed breakdown of energy reduction is illustrated in Figure 5

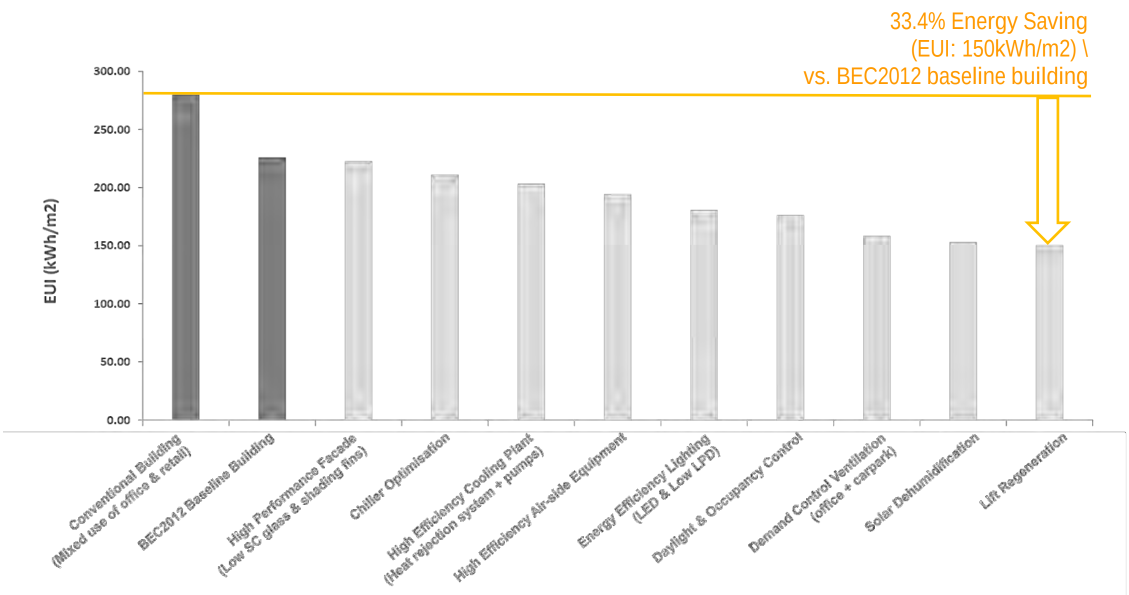

Figure5: Energy reduction breakdown

4.3 Operational performance

A detailed measurement and verification plan, testing and commissioning requirements, as well as having an independent commissioning agent will ensure the sustainable operations are maintained. Intelligent BMS allows 24x7 real-time monitoring of electricity and water meters and the data recorded is converted into meaningful information for performance display in the office entrance lobby. They communicate to staff and visitors how the building is performing, provide sustainability information and tips in a simple, real-time and interactive manner. Other information like health diet, exercise and community activities update will also be shared to raise users' health awareness.

Furthermore, to echo the smart vision of the district, mobile apps will also be developed for users' access to a world of real-time parking information, e-queuing for restaurant, shop recommendations and more.

4.4 Water saving

Since the greenery accounts for more than 30% of the site area, the water demand for irrigation will be huge. Thus, to utilise water resources wisely and effectively, rainwater recycling system is proposed to reduce the potable water use for irrigation make-up. Rainwater is collected on roof and ground floor under the pervious paving. After treatment in the plant, the rainwater will be stored in the tank for irrigation use. Cooling tower bleed-off for flushing and water efficient sanitary fittings further mitigates potable water use.

5. CONCLUSIONS

This paper introduced the design methodology and implemented sustainable design features for the project. Through the integrated design process, the team has identified the major challenges and formulated the design framework based on environmental sustainability, green community and human health.

Last but not least, the proposed development has been registered with the world-wide recognized sustainable framework like LEED and BEAM Plus for the highest Platinum rating, for recognition of the tremendous efforts by client in conjunction with the consultants to contribute to the environment. The development will also be one of the pioneering projects in Hong Kong to address the health and wellness issues of the building users, and it will be assessed under WELL Building Standard, a performance-based system for measuring, certifying and monitoring criteria for the built environment that would affect the well-being and health of the building users. The WELL Certification is offered by the International WELL Building Institute in USA, a leading healthy building label in the world.

Sustainable Workplaces in High Density Urban Areas

Ryusuke KOJIO[a]

[a] *TAKENAKA CORPORATION, Japan, kojio@takenaka.eu*
[a] *TAKENAKA EUROPE GMBH, Germany, kojio@takenaka.eu*

ABSTRACT

Recently in Japan various methods of green design, construction and operation of buildings have been developed. This paper introduces two recent award-winning projects, which demonstrates how careful consideration and refined design and construction techniques can achieve a sustainable urban environment. The projects are both multifunctional buildings with vast office floor areas, yet they both offer a comfortable landscape of workplace environment through “utilizing natural sources” and “encouraging human communication”.

Supertall Compact City: Abeno Harukas

Abeno Harukas is a super tall building with 60 above ground floors and five basement floors and, at a height of 300m, is the tallest building in Japan. Completed in 2014, ‘Supertall Compact City’ integrates the huge activities of sprawling cities into one supertall building. The following three elements are key to attracting people and further to generate conditions in which people get together: three-dimensional routes affording various choices, networks of ‘Eco-voids’, and three-dimensional networks of greenery.

100X100m: A pioneering eco-friendly model - Meiji Yasuda Life Insurance Building

This integrated office facility combines the main office of a life insurance company with lodging for trainees. Completed in 2011, the office spaces are divided into four large and small sections with floors on staggered levels interconnected around a continuous spiral core at 1.2-meter intervals. An atrium measuring 35-by-35 meters in the centre of the building, contains a light court of 17-by-17 meters, which attracts abundant light and outdoor air creating an environment in which people can communicate with nature as they work.

In order to create “architecture for sustainable society” it is extremely important to offer a rich and varied living/working space and quality environment not just reducing environmental burdens. This idea applies not only to major projects but also smaller size buildings.

Keywords: high-performance building, energy saving, nature

1. INTRODUCTION

The workplace environment in Japan in recent years has advanced to a different stage. From focusing on efficiency or functionality of closed work spaces, it has now become essential to create ‘collaboration space of open organization’ rather than ‘divisional cooperation of closed organization’. (Konno et al., 2012)

The two projects (Image 1 and 2) introduced here are both multifunctional buildings with significant office floors areas, yet they also provide a comfortable landscape of an open workplace environment simply by means of “utilizing natural sources” and “encouraging human communication”.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Image 1: Abeno Harukas Image

Image 2: Meiji Yasuda Life Insurance New Toyocho Building

2. ABENO HARUKAS: SUPERTALL COMPACT CITY – 300 M HEIGHT

Situated in Osaka, heavily dense urban area, Abeno Harukas was planned and realized as a super tall building with 60 aboveground floors and five basement floors, covering a total floor area of 306,000m^2. At a height of 300m above the ground, it is the tallest building in Japan, and was completed and opened in 2014. (See Figure 1)

2.1 Environmental design

High-level CO_2 reduction targets were established to achieve a low carbon emission building (See Figure 2,3), and the architects and engineers worked to achieve these targets especially by means of multiuse function of the building as well as utilizing natural sources and its height.

Utilizing multi-functionality

The load levelling of heat source demand by multi-functionality of the building use, and the energy recovery from utilizing heat interchange and height of the building greatly increases the energy efficiency of the entire building.

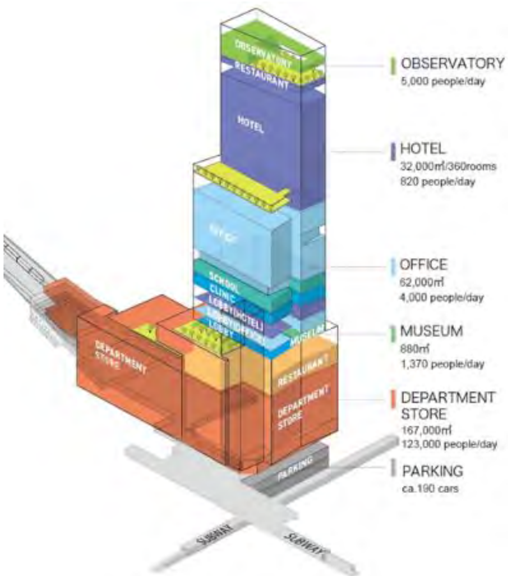

Figure 1: Building composition

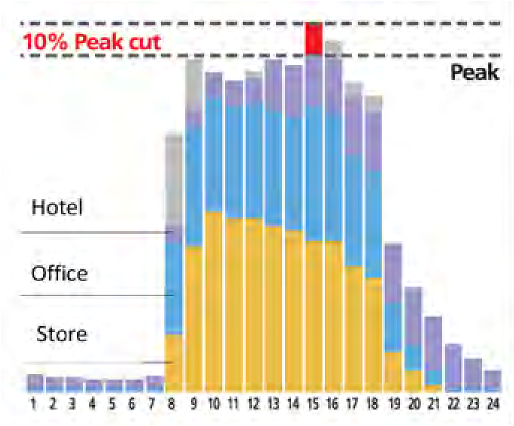

Figure 2: Peak cut

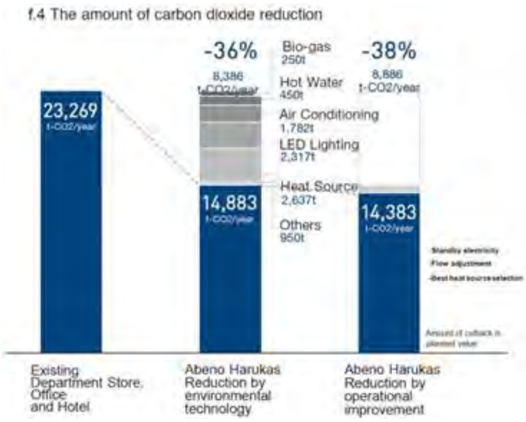

Figure 3: CO_2 reduction

"eco-voids"

The building is exposed to the outdoor air and natural light by making use of "eco-voids", which stimulate sensitivity and creativity of the office staff, while they simultaneously reduce environmental burdens with "passive technology" which decreases energy required for lighting and air conditioning. (See Image 3 and Figure 4.)

Image 3: Eco-voids

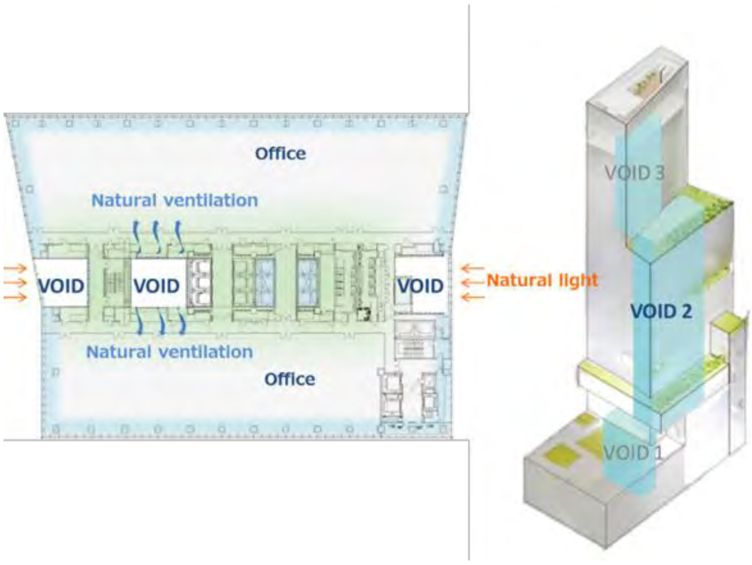

Figure 4: Eco-voids and Effects

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.2 Three-dimensional sky gardens x voids x trajectories

The shuttle elevators (6 times 60 passengers units) installed in the corner of the building convey large numbers of people to the three lobbies located high above in the air (Air Junction), creating vertical circulation that provides an extension to urban transport. Trajectories further branch off from the lobby floors, establishing a complex network of multifaceted spaces. These selectable trajectories incorporate the city's dynamism. (See Figures 5, 6)

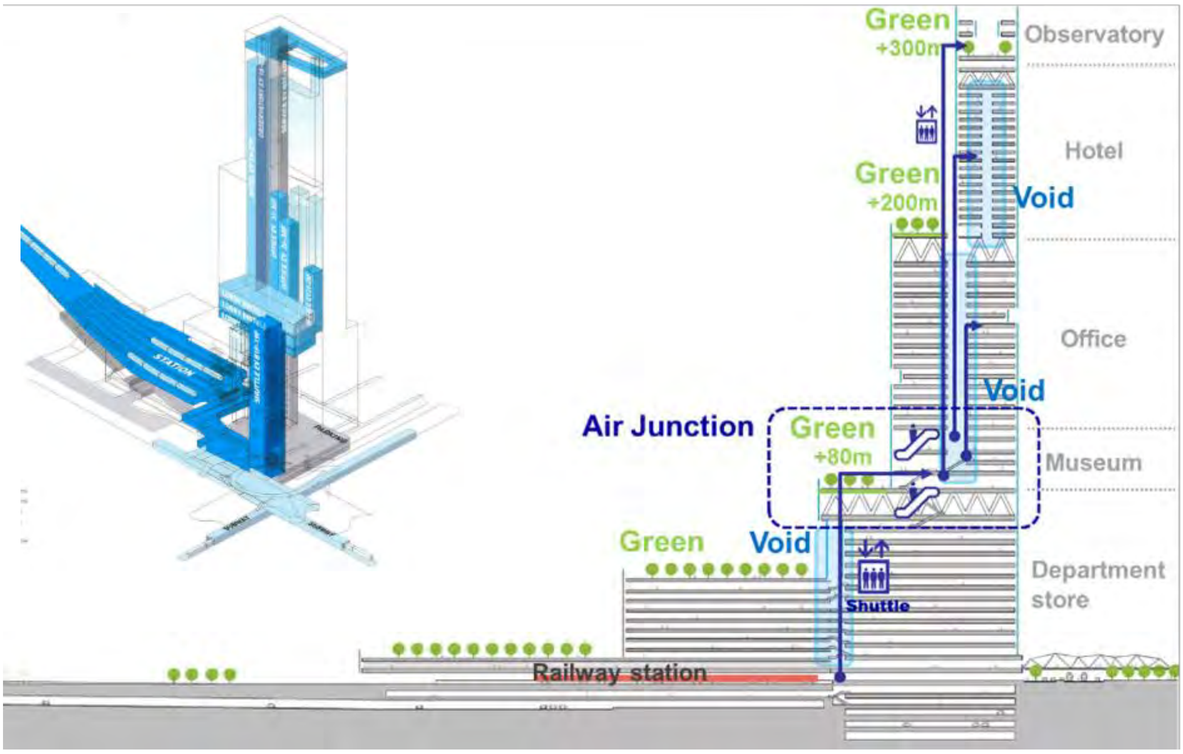

Figure 6: Green – voids – trajectories

The floors of the building are set back further and further the higher they are, making it possible to create several roof gardens. People can find their own spots within these roof gardens and the surrounding green spaces, each spending time in their own way. (See Images 4, 5.)

Figure 5: Supertall trajectory

Image 4: 58th floor Observation deck

Image 5: 16th floor Sky garden

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. MEIJI YASUDA LIFE INSURANCE NEW TOYOCHO BUILDING

A pioneering environmentally friendly model office building: 100X100m office

In the eastern part of Tokyo, the integrated office facility combines the home office of a life insurance company with lodging for trainees. The office spaces are divided into four large and small sections with floors on staggered levels interconnected around a continuous spiral core at 1.2-meter intervals. It was completed in 2011. (See Image 6.)

Image 6: Front façade

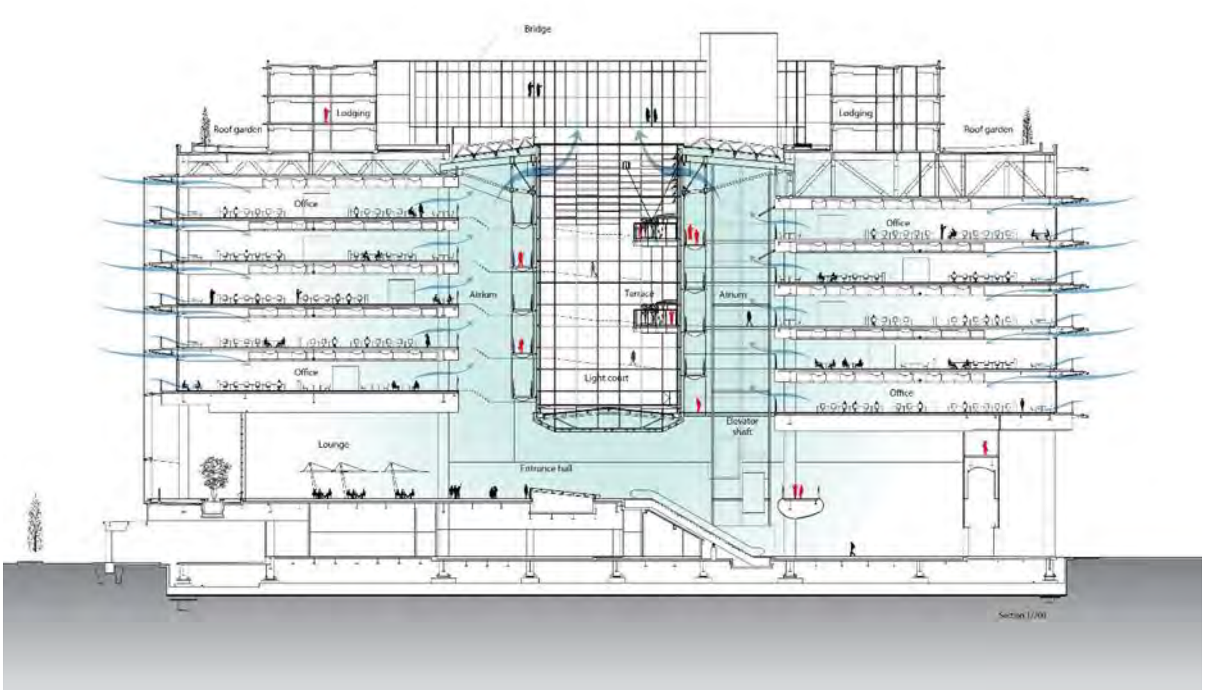

Figure 7: Section

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.1 Communication with nature

Atrium and light court

An atrium measuring 35-by-35 meters in the centre of the building with the office floors arranged around it contains a light court of 17-by-17 meters in its centre that draws in abundant light and outdoor air creating an environment in which people can communicate with nature as they work. (See Figure 7)

Natural ventilation

Natural ventilation is provided through outdoor air intakes controlled by dampers on the balconies around the outside perimeter of the building and by windows that can be closed or opened at will. Fresh outdoor air passing through the office spaces is discharged from the centre of the upper section of the atrium and solar chimneys. The atrium serves as an environmental facility combining architectural and equipment planning in pursuit of a comprehensive reduction of CO_2 emissions.

3.2 Spiral office configuration

A low-rise planar configuration with 100-by-100-meter floors was chosen to enable flexible responses to office reorganizations and increases/ decreases in numbers of staff as well as changes in department layouts without hindering intervening floors. (Figure 8, 10)

The office portion of the building is divided into two large and two small column-free areas comprising continuous floors arranged in a spiral formation on staggered levels 1.2 meters apart. As the images below show, the seamless work places can be clearly seen. (See Images 7, 8, 9, 10, 11)

3.3 CO_2 reduction

CO_2 emission from the entire building (office, training, conference area): 53% reduction from the average level of office buildings in Tokyo. (Figure 9)

Image 11: Flying slopes

4. PRACTICES ON PROJECTS IN SMALLER SCALE

Smaller scale workplaces present different challenges for our organization, however we have been able to find ways to provide “Sustainable works” to the society in many regions. In Germany, for example, despite having to comply with the stringent legal requirements there, we suggest, plan and realize some greener solutions.

“Communication and collaboration” is almost always a key factor in enriching an office environment, and atria, courtyards, voids, terraces and the like are considered to achieve the most beneficial way to support this. While providing a space for get-together, environmental effects of the space are always carefully devised, to take account of factors such as daylight, natural ventilations etc. (See Figures 11, 12)

Figure 11: Natural ventilation simulation

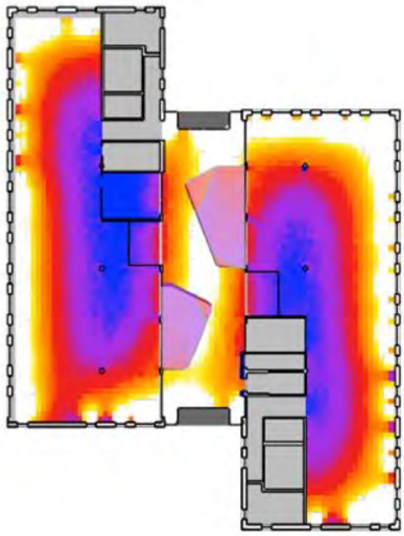

Figure 12: Natural light simulation

5. SUSTAINABLE ARCHITECTURE: THE BEST PRACTICES

“Sustainable architecture” should have been originally “architecture that was designed for a sustainable society, and the best practice for sustainable architecture must be architecture that predicts new architectural possibilities [2]” (Kodama, 2003), whereby it is quite important to have rich and quality living/working space, not just reducing the burden on the environment. The following two main issues are to be always emphasized in our works: the creation of a highly efficient and high-quality workplace, and the reduction of the environmental loads utilizing all the blessings of nature.

“Living in harmony with nature” would be always what we want to realize when planning and building …, just like Japanese traditional-style buildings. So our aim to design is ‘Modesty to live with nature’.

Estate Revitalization Scheme Ping Shek Estate: Pilot Project Completed

WONG Man-lung[a], LAM Ho-yin[b]

[a] *Hong Kong Housing Department, Government of the HKSAR, Hong Kong SAR, ml.wong@housingauthority.gov.hk*
[b] *Hong Kong Housing Department, Government of the HKSAR, Hong Kong SAR, ricky.lam@housingauthority.gov.hk*

ABSTRACT

Ping Shek Estate is a public rental housing estate owned by the Hong Kong Housing Authority (HKHA). It has been built over 40 years ago and was completed in 1971. HKHA decided to implement the Estate Revitalization Scheme in 2010 to rejuvenate the estate. According to the four core values of the HKHA, namely, caring, customer-focused, creative and committed, the estate facilities and environment were brought up to current standards.

Through the Scheme, traditional characteristics of the Estate were preserved and facilities renewed. The main improvement works included the provision of new lifts and escalators to enhance barrier-free access, a covered performance stage for special festive and community events, and covered walkways connecting main activity pockets, tactile guide-paths, and other activity zones so that the estate could provide a better living environment for tenants of all ages.

The main purpose of this project is to “preserve and enhance”. Hence no tree was felled during construction but more greeneries were introduced. Building-integrated photovoltaic (BIPV) panels were installed to generate electricity for solar lightings. Natural lighting was used in a Well Being Centre and automatic irrigation system was used at green roof; and all these served to save electricity as well as reduce carbon emission.

With the change of population profile and living habits of residents, vacant market stalls were changed into a “Well Being Centre” for community use and surplus car parks were converted into a “Shopping Lane” with four new shops added.

The project demonstrates how a carefully planned and implemented revitalization project can help to transform our built environment to suit the changing needs of people and community. The project was successfully completed in 2014. It also received the Finalist Award in the Green Building Award 2014.

Keywords: sustainable neighbourhood, energy saving, green economics

1. BACKGROUND

Ping Shek Estate is a public rental housing (PRH) estate owned by the Hong Kong Housing Authority (HKHA). Once situated in a remote locality, Ping Shek Estate is now conveniently accessible by the Mass Transit Railway (MTR) and other means of public transport. Built in the 1970s, the Estate is now housing about 12,000 people in 4,574 domestic flats. About ⅓ of the tenants living in the estate are over 60 years old, and there are around 930 elderly households.

The estate area is about 54,000 m2, with 7 domestic blocks surrounded by generous open space. Five of the domestic blocks are 28 storey high with lift service for even floors above the 5th floor and the two 8 storey low blocks are with no lift service. A large central podium with a one-storey carpark underneath extends as the lowest floor of the two low blocks. Ping Shek Estate has an ample supply of car parking spaces as well as 6,700m2 of retail areas and comprises a restaurant low block, ground floor shopping arcades and a cluster of market shop stalls.

Over the years, a number of maintenance and improvement works e.g. concrete repairing, re-roofing etc. have been implemented through the Housing Department (HKHA's executive arm) to maintain the estates' original designed functionality. But for an estate of 40 years old, due to changes in the population profile, tenants' activity patterns and developments in the vicinity over the years, the original estate design and provisions have become outdated. Some of the provisions and amenities have to be brought closer to current standard to meet the tenants' needs. After assessing that the Estate can stand structurally safe and are economically viable to be retained for another 15 years, HKHA had decided to implement an Estate Revitalization Scheme (ERS) for the Estate.

2. REVITALIZATION CONSIDERATIONS

Ping Shek Estate's mature community, convenient location, relatively spacious layout, and possibilities to optimize the commercial facilities are among the unique characteristics which present an opportunity for the HKHA to consider a revitalization project taking into account the views of tenants and their activity pattern.

2.1. Putting people first

Ping Shek Estate did not have a prominent main entrance, and the estate as a whole lacked an identity. Tenants commonly remarked that the estate blocks, retail shops and estate amenities appeared somewhat outmoded. Both pedestrian and vehicular traffic near the Choi Hung MTR exit at Clear Water Bay Road were heavy where they criss-cross the estate road.

As old age sets in, living in building blocks without lift service and moving around the estate with different platform levels would, for some ⅓ of Ping Shek Estate's population, not as effortless as before. Elderly tenants characteristically would spend more of their time hangout out in the estate common areas enjoying each other's company: here in Ping Shek Estate gathering outdoor for morning Tai Chi, playing chess or chatting with neighbours in the shade of trees, and taking grand children to the playground are daily routines for the elderly. Ping Shek Estate has pockets of recreation ground scattered in the open space, but they were designed many years ago modeled on a much different estate population profile. Our aim is to provide a better living environment to meet the needs of our tenants.

2.2. Scope of work

The ERS brought the estate provisions and amenities closer to more recently completed estates as far as practicable and enhanced tenants' living environment through an optimum scope of work that is cost-effective, befit tenants' activity pattern and not causing unnecessary nuisance to tenants –

- Gave the entire estate a facelift and an identity through creating visual interest and functional landmarks;
- Provided barrier-free access and improved connectivity within the estate;
- Converted existing public areas to quality communal space and enhanced greening;
- Adapted under-utilized retail premises and carpark to better uses to optimize their commercial potential and enhanced the estate amenities;
- Improved common areas inside domestic blocks including ground floor lift lobby and corridors at typical floors;
- Enhanced home safety paying particular attention to the special needs of elderly and physically impaired tenants; and
- Saved resources through use of renewable energy.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. DESIGN SCHEME

3.1. Estate common areas

The passage connecting the Choi Hung MTR station abutting Clear Water Bay Road was modified as the estate main entrance serving as a visual and functional landmark for Ping Shek Estate, with a lift and escalators added to facilitate access. Most of the vehicular traffic was diverted away from this part of the estate road and traffic calming features were installed to ensure safe pedestrian crossing. The overall design of the entrance area was given a decorative touch of "stones" to echo the estate name (Ping Shek Estate 坪石邨) and create a visual landmark.

A portion of the carpark next to the new estate main entrance was converted into a shopping lane of small grab-and-go shops. The new shops realized the retail potential brought by the pedestrian traffic from the estate main entrance, and the atmosphere of a vibrant shopping lane in turn enhanced the ambience of this area.

A weather-protected network of pedestrian walkways running through the entire estate provided unobstructed access to all blocks from the estate entrances. The works involved the addition of about 500m long covered walkway of lightweight structure and modification to the existing walkways to align the design. The walkways were formed into activity pockets at suitable locations, e.g. pavilions, chess or bird-cage corners, shaded seating areas and lead to walking trails, Tai Chi garden etc. Community play areas were designed to integrate rather than segregate activities of the elderly and the kids, where fitness equipment for the elderly was placed close to or intermingled with children's play equipment. Other estate amenities such as ball courts, lighting and furniture were also refurbished based on current standard.

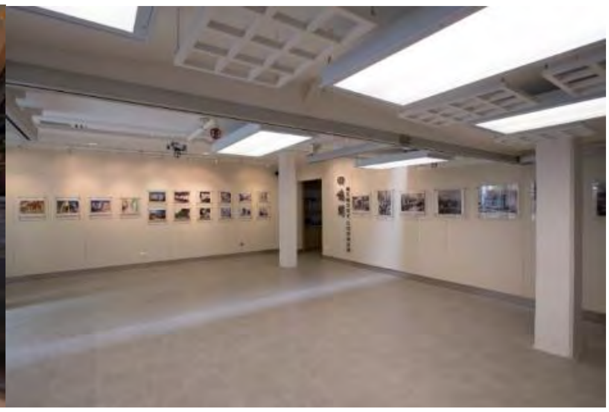
From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The spacious podium square occupies a central position in the estate. As it is effectively the roof structure of the carpark underneath, possibilities of planting trees or major alteration works were excluded. The relatively dull paving was replaced with finishes of a more-lively pattern and planters, and flower beds or landmark icon were put there to turn the area into a visually interest focal point. For the square to double as a central event plaza, a covered stage for festive and community functions was also added.

A new lift tower was added to the restaurant block. The covered area under restaurant was brightened up with better lighting and fitted with seating / chess tables, and ample room was left to accommodate group activities as this is a popular morning exercise area.

The shopping provisions were reviewed to meet the tenants' needs. The shopping arcade was given a refreshed look through aligning the shop front design while preserving the characteristics of the old shops. The market stalls were refurbished with the awnings replaced by an orderly canopy design.

Commercial premises of low retail value were put to better communal use. A few of the long-standing vacant market stall were converted to a small multi-purpose hall, serving primarily a memory corner of the estate and a meeting place for tenants, and can be readily used as a "well-being centre" for charitable organizations to provide regular health services for the elderly, or turned into a study room for youngsters during examination time.



The roof of the market stall visually had been in a rather run-down state, and turning it into a green roof substantially improved the views of the domestic flats facing the market stalls; the greening project was also extended to the roof of the two low blocks. In addition, automatic irrigation system was installed at the green roof. This would reduce future operation cost for the green roof. A communal farm was provided at a suitable location in the estate open area. The greening ratio of Ping Shek Estate as a whole had risen from the existing 21% to some 23%.

Building-integrated photovoltaic (BIPV) panels were installed on top of new covered walkway. In addition to solar bollards, use of natural lighting in the Well Being Centre and automatic irrigation system at green roof, all served to save electricity as well as reduced carbon emission.

3.2. Block common areas

Another new lift tower was added to each of the two low blocks, and lift modernization works were carried out to the five high blocks.

The external facades of the blocks were redecorated with a new colour scheme that had given a different accent colour to each of the seven blocks according to the block names.

The ground floor lift lobbies were given a facelift, with seating benches provided to turn it into comfortable waiting areas. Tiling panels with accent colour were added to the lobby wall to create visual interest. Existing metal louvers were modified to make full use of day-lighting and lighting design was enhanced. False-ceiling was installed to hide unsightly pipeworks and the randomly fixed electric fans were replaced by ceiling fans to improve ventilation. Besides these, the security counter, letter boxes and notice boards were replaced based on current standard.

In response to tenants' feedback, canopies at the corridor ends of each floor to the high blocks were installed to reduce rain penetration. The paving and lighting design were modified to brighten up the internal courtyards of the high blocks. Corridor lighting was progressively replaced with energy efficient light fittings.

3.3. Domestic flats

The domestic flats were further enhanced in the following areas-

- Laundry racks were installed to replace bamboo pole holders;
- Grab rails were fixed inside bathrooms for elderly tenants;
- Ramps were added at flat entrance for wheelchair users;
- Modifications works were carried out to particular flats according to the specific needs of elderly tenants or tenants who are physical impaired.

4. COMMUNITY HEARTWARE

Our society is devoting more attention and resources to green and healthy living, enhancing home comfort and enabling elderly persons to be integrated with young generation to strengthen community bonding. The Ping Shek Estate revitalization project is not just about improving the building fabric, it is also about bringing vivacity to the estate and instilling a caring neighbourhood, which is only possible if the communal services are enriched to dove-tail the improved living environment and meet the diversified needs of tenants of all ages.

Ping Shek Estate has a range of communal facilities: schools, kindergartens, new immigrant social services centres, a nursery, a neighborhood elderly centre and a popular youth centre operated. As the project was taken forward, we had enlisted the support of various government departments and non-government organizations in identifying further opportunities to provide multi-faceted communal support services of Ping Shek Estate's tenants e.g. bring in mobile Chinese medical and care services etc. content

5. PUTTING IDEAS INTO ACTION

It is recognized that the estate involves sitting tenants and many of Ping Shek Estate's tenants have in fact grown up and grown old with the estate. The revitalization project would be bringing changes to their living environment and how to put ideas into action was a real challenge.

A strong project team involving the Client (HKHA), Housing Department's staff in the Estate Management, Building Works, Structural Engineering, Building Services Engineering Sections, and consultant teams was formed to implement the project. Other stakeholders including the estates Estate Management Advisory Committee (EMAC) members, Focus Group members, Legislative Council members, District Council Members and some Non-government Organizations were all invited to participate actively throughout the project implementation.

Continuous communication and coordination among project team and various stakeholders through Partnering Workshops, monthly Project Coordination meeting, bi-weekly Consultants Meeting, bi-monthly EMAC meetings, quarterly Focus Group Meetings, ad-hoc meeting and even use of WhatsApp to resolve problems and keep all parties well-informed of the work progress so that everyone could make timely feedback and preparation. Special emphasis had been placed on planning the timing and phasing of works so as to minimize disturbance to local residents according to their living habits.

The overall project costs about HK$280.85M and the estate was expected to sustain for more than another 15 years. Instead of total redevelopment, the revitalization scheme saved a vast amount of energy, material, cost and time that could be involved in the demolition and re-provision of a new estate. The facilities were successfully upgraded to suit the aging population and maintain the residents' living quality, which could eliminate any resources required for relocation, saved society's resources and contributed to the continual of social sustainability.

The project started in 2010 and completed in 2014. The project proved to be very successful. It was completed on time and within budget. Throughout the project, various stakeholders including residents, commercial tenants, Legislative Council members, District Council members and EMAC members gave very positive feedback on the management and to the new facilities and outlook of the estate.

The Study of Pavement Reconstruction Corresponding to Microclimate Cooling Efficiency in Elementary School Campus

ABSTRACT

In today's environment, the main reasons of "heat island effect" are causing by the architectural design techniques or design on the pavement. The imperfect building and the pavement in the environment will generate heat retention effect. Specific elementary school campus is chosen for integrated environmental assessment. The environmental improvement projects and the pavement design are taken into consideration at the stage of campus planning and design. These are all the factors affecting the campus microclimate. For the school with partial constructions, the renovation projects are categorized and the scientific method is adopted for collecting the data. The benefit assessment of the overall environmental factors can be used as decision-making for the future campus improvement. The goal of campus environmental quality and sustainable development will be achieved thought these effective campus design techniques.

The impact of environmental benefit assessment is carried out by practical measurement and numerical analysis. Stationary and mobile meteorological stations have been taken to analysis surface heat flux distribution of the case. The campus transform will lead to quality increased of the environment and also affect the situation of indoor living comfort. According to the preliminary results, the effective items of reconstruction projects have great influence on campus temperature. The campus microclimate modes are discussed and integrated accordingly. The analytics results are built up with the understanding of variations between the reconstruction items and campus micro-environment. Eventually, the actions will be implemented to the following cases need to be improved and strengthened in a timely manner.

Keywords: micro-climate, pavement heat flux, campus reconstruction

1. RESEARCH BACKGROUND AND LITERATURE REVIEW

In addition to the provision of a design concept for future, educational and model teaching space, a sustainable campus responds to the concept of a thermal and wind environment on campus in terms of architecture environment change. Its level of change is tied to the strength of the campus' temperature adjustment mechanism. Thus, this study aims to analyze the performance of the "pavement heat flux" for an integrated environmental evaluation that incorporates campus selection. With the analysis of variance before and after the architecture change, this study further analyzes changes made to the urban campus environment responding to the requirement for sustainability.

According to the results of relevant studies that surveyed campus users about their perception regarding the sustainable development of campus, "a healthy environment" is the first evaluation indicator set. This indicated that academic and research institutions believe the pursuit of "environmental sustainability" should be built on the basis of protecting "human health."

The Ministry of Education of the Republic of China (2003) defined a "green campus" and "sustainable campus" as reflecting a school that is equipped with environmental awareness and implementation capabilities of rebuilding technologies for green buildings and ecological campus environment meeting the principles of sustainability, ecology, environmental protection and health. Chiang & Su (2004) explained two key factors required to realize the building of ideal, sustainable campuses as proposed below by the MOE:

“An ecological campus environment:” This refers to a campus focusing on ecology and co-existing with ecology to ensure biodiversity, an ecological and cultivation environment of native plants, clean indoors and outdoors environment, and the cycle of sustainable environment.

“Green building technology:” This concept focuses on the protection of a green environment incorporating the design of health-protecting buildings and the development of new energy sources. For example, the overall design shall emphasize ambient sound, lighting, heat, air, water and other composite issues to improve the features of structure and equipment.

During the promotion process, various studies discussed indoor environmental quality to address a sustainable campus and the vitalization and reutilization of campus space, but sustainability has always been ignored. Partial rebuilding, construction, and evaluation after construction of a sustainable campus can be defined and qualified. Thus, this study especially uses the selected campus environment to evaluate and analyze changes before and after rebuilding and the impact of construction in order to understand the campus environment improvement items, and the sources and variances of micro-environmental factors that exert impacts.

2. RESEARCH METHOD

2.1. The school sample

A school with a permeable pavement rebuilding project was initially inquired for a questionnaire survey to investigate coordination made before and after by the school. After the school agreed, actual measurement and analysis were carried out. The analytical results were then provided for the building of sustainable campuses in other schools. the logical development of work. Using headings is a great way to organise the paper and to increase its readability, so make sure to format them correctly.

<table>

<tr><td>17,233</td><td>16,569</td><td>96.1%</td><td>3,188</td><td>18.5</td><td>815</td><td>25.6</td></tr>
<tr><td colspan="4">Before Rebuilding</td><td colspan="3">After Rebuilding</td></tr>
<tr><td colspan="4"></td><td colspan="3"></td></tr>
</table>

Table 1. Basic information on elementary school

2.2. Measurement intervals

Expected sampling values shall be derived during both day time and night time in order to analyze the variances of micro-climate at different times. Thus, the sampling of micro-climate environmental factors was set at 8:00-10:30 am, 12:00-14:30 pm, and 18:00-20:30 pm. At each interval, we finished collecting the sampling data within three

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

hours to reduce variances caused by time delay. As shown in previous studies on heat islands, the variance of development of a micro-climate shall be comprehensively evaluated. Basic climate variance of topography is caused by radiation flux and changes, especially when it is a clear cloudless day. In short, clear skies are good for the development of heat islands. As a result, this study conducted in situ measurements on clear-sky days.

2.3. Determination of measurement points

The area for actual measurement was the improved area for achieving a sustainable campus; in order to ascertain the distribution of comprehensive environmental factors, a checked coordinate system was used to divide the base into several arrays. According to the scale of area, a distance between 10-25 meters was set and the coordinate location was positioned with a GPS to ensure accuracy of measurement sites. During measurement, if an accurate point cannot be found, a new sampling point will be set within a distance of ten meters. Sampling points outside the distance are removed and recorded, as shown in Figure. 1.

Figure 1: Determination of measurement points

2.4. Measurement method

A mobile direct reading device is used for outdoor mobile monitoring. Sampling sites were selected at the center of road to avoid the shielding effect of buildings. When sampling, a sensor shall be kept at the distance 2 m higher from the ground and 50 cm above a human head to reduce the reflection impact of heat radiation. Measurements of in situ micro-climate factors were carried out by a group of two persons, as shown in Figure 2.

When measuring, climate conditions shall include low wind speed and less and lower clouds (measurements were stopped on rainy days). In order to understand the variance of high and low temperature in this area, measurements were carried out during both day time and night time. When measuring temperature, humidity, wind speed and wind direction, due to the use of a direct reading device, we needed to consider the issue of higher sensitivity. Records were not kept until readings on the device became stable; at the same time, photos of the skies and surrounding environment were also taken. While recording values, we conducted steps such as cross-examination and error corrections for conditions at that time, and sampling items to minimize error values. Environmental features at that time were recorded in detail for the acquisition of comprehensive data for the compiling and analysis of a micro-climate map, as shown in Diagram 3. A small weather watch station was installed on the roof of a campus building; the central point of the measurement area was designated as the sampling point for monitoring temperature, humidity, solar radiation and sunlight intensity. Please see Figure 3.

Figure. 2: In-situ measurement photo

Figure 3: A small weather watch station

3. MEASUREMENT RESULTS

3.1. Measurement results of the campus

In the rebuilding of campus environment, the main influential items include landscape, educational meaning, and the thermal environment on campus. Environmental rebuilding levels are tied to the adjustment mechanism of campus temperature control. Consequently, this study integrates factors of “pavement heat flux” to present a comprehensive environmental evaluation of the selected campus. Additionally, with variance comparison before and after rebuilding, we analyzed environmental sustainability that responds to the urban campus environment changes. Through the use of a database on actual measurements, an analysis was conducted for deriving the initial values. A contour map was then compiled with a Surfer software algorithm for each physical and environmental factor. Background information plus overlay analysis of the environmental map show the distribution of environmental factors in the area to allow us to understand how “pavement heat flux” was distributed before and after campus rebuilding. Diagrams 5 to 16 present the tests and measurements of the campus environment.

Temperature Contour Map 08:00						
Reduced Temperature Effect	Before Rebuilding			After Rebuilding		
	Current	atmospheric temperature	Abs-ratio	Current	atmospheric temperature	Abs-ratio

0.8˚C	29.1˚C	31.2˚C	1.007	28.3˚C	31.3˚C	1.010
Temperature Contour Map 13:00						
Reduced Temperature Effect	Before Rebuilding			After Rebuilding		
	Current	atmospheric temperature	Abs-ratio	Current	atmospheric temperature	Abs-ratio
-1.7˚C	28.7˚C	34.6˚C	1.020	30.4˚C	34˚C	1.012
Temperature Contour Map 17:00						
Reduced Temperature Effect	Before Rebuilding			After Rebuilding		
	Current	atmospheric temperature	Abs-ratio	Current	atmospheric temperature	Abs-ratio
1˚C	28.4˚C	31.6˚C	1.011	27.4˚C	32˚C	1.015

Table 2: Contour map of micro-climate in elementary school before and after rebuilding

3.2. Analysis of environmental factors

Analytical results of data collected from Pucian Elementary School: The square at the front gate and the hard court in the middle of campus buildings are found to have higher temperature in the morning due to the larger area of hard pavement with quick heat absorption. The building layout on campus also leads to the difficulty to achieve proper ventilation. The rebuilt area replaced some hard pavement surface with rocks, but the area was limited to the botanic garden, which features high temperature and humidity. The comparison of pavement rebuilding shows the temperature was decreased by 0.8˚C.

During noon time, the area at the center of the buildings has the highest temperature where wind from outside cannot reach. The rebuilt area and plants in the southeast side of the campus had low temperature and high humidity. The reduced temperature effect is poor. The monitoring comparison identifies the decrease of temperature by -1.7˚C.

According to the night time temperature trend, the large area of the sports field directly receives sunlight, and the red soil on the top absorbs heat and then releases heat during the night time. So, the temperature of the sports field is higher. Heat dissipation causes reduced humidity of the hard pavement in the courtyard. The grassland at the rebuilt area is not impacted by the hard pavement, but due to the distribution of more plants in this area, humidity here is higher than in the other areas on campus. The average measured temperature is about 27˚C with 1˚C reduction.

4. DISCUSSION AND SUGGESTIONS

This study incorporates the partial rebuilding program of sustainable campus promoted by the MOE. For partial rebuilding of campus environment of elementary schools, we selected a school that rebuilt its permeable pavement for a comprehensive environmental evaluation. Through tests and monitoring of regional micro-environments, we are able to understand the impact of sustainable campus building. We conducted the comprehensive analysis of pros and cons before and after rebuilding, and found a direct impact of the variance of partial improved construction on the thermal and wind campus environment. Through the initial value analysis of the actual measurement database, the effective contribution of permeable pavement for the temperature trend has been identified as the regional dissipation factor among campus buildings to effectively reduce the regional heat island effect. Overall, an understanding of pavement heat flux" distribution can be facilitated. In the end, the analytical results can be provided for the reference of other partial campus rebuilding designs.

The sampling time of this study for the impact and effectiveness evaluation before rebuilding was between October and early December; data after rebuilding were also collected during the spring (around March) for a comparison. When necessary, we will provide data collected in the summer time to make the study more comprehensive.

ABSTRACT

Kai Tak Development (KTD) is a major harbourfront development at the heart of Hong Kong adopting sustainable development and environmentally-friendly concepts. Its land use and development planning have gone through extensive public engagement exercises leading to a blueprint for the vision being "A distinguished, vibrant, attractive and people-oriented community by Victoria Harbour". KTD is also the catalyst for re-energising the surrounding older districts and creating a new Central Business District for Hong Kong.

With the implementation timeframe spanning over a decade, KTD has already witnessed the completion of its first package of public works projects starting from 2013. These projects include bio-remediation at the Kai Tak Approach Channel and Kwun Tong Typhoon Shelter together with associated drainage works which have notably improved the water quality and mitigated the odour issues associated with the water bodies. Additional footbridges and revamp of existing pedestrian subways have enhanced the walking experience and connectivity between KTD and its neighbourhood. New buildings at KTD comprising the Trade and Industry Tower, Energizing Kowloon East Office building, schools and sewage pumping stations have met the Building Environmental Assessment Method Plus, or BEAM Plus, green building ratings. Kwun Tong Promenade and Runway Park Phase 1 at the former runway tip have become favourable rendezvous for the public to enjoy the waterfront. In addition, continual efforts are maintained with a view to promoting sustainable built environment through application of District Cooling System, development of extensive green web with signature open spaces, revitalisation of heritage discovery, and opening up harbourfront area for public enjoyment. This paper attempts to elucidate how KTD is planned and implemented in the quest for sustainability being the impetus of Hong Kong's economic growth.

Keywords: Kai Tak development, public engagement, sustainability

1. INTRODUCTION

The transformation of Kai Tak from a former airport to Hong Kong's single largest urban development of about 323 hectares has opened a new opportunity to showcase Hong Kong's "World City" qualities. Under the planning vision for Kai Tak Development (KTD), Kai Tak is intended to be a "distinguished, vibrant, attractive and people-oriented community by the Victoria Harbour." It also bears a strategic role in stimulating the regeneration of older districts in its vicinity. The location of Kai Tak is shown in Appendix A.

In recent years, increasing attention is being paid to enhancing the urban design aspects of strategic projects in Hong Kong. With its array of projects of different nature and its prominent harbourfront location, KTD has exceptional potential to be developed into a high-quality community. A holistic implementation approach has been adopted with emphasis on sustainability and quality urban design under a focused brand, instead of the conventional project-by-project approach driven primarily by functional considerations, to ensure that Hong Kong is further developed on a par with other competing cities around the world.

2. PLANNING WITH THE COMMUNITY

Kai Tak is located in southeast Kowloon with the former runway projecting over 2 kilometres (km) into the harbour. On 6 July 1998, the former Kai Tak Airport retired after 77-year of service as Hong Kong's gateway to the world. Being the largest available site at the harbourfront, Kai Tak offers a good opportunity to create a quality living environment in the urban area, and its interplay with the Victoria Harbour will cultivate a unique sense of place. Given its size and prominent location by the Victoria Harbour, the scope of redevelopment and planning intention for KTD had been the subject of a decade-long public deliberation.

To take heed of public aspirations to protect the Victoria Harbour as natural heritage of Hong Kong, the Government conducted an extensive public engagement exercise between 2004 and 2006. After three rounds of large-scale

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

public participation, general consensus was reached on the development scheme for KTD based on the principle of "zero reclamation". Details of the scheme were eventually incorporated into the Kai Tak Outline Zoning Plan (OZP) approved under the statutory planning process in November 2007.

In terms of built development, KTD is intended under the approved OZP to provide about 2.9 million square metres (m2) and 2.3 million m2 of domestic and non-domestic gross floor area respectively. It will accommodate an estimated total population of about 130,000 with population intake starting from 2013. The broad land uses under the approved Kai Tak OZP is summarised in Table 1 and shown in Appendix B.

Uses	Approximate Area and Percentage	
	Area (Hectares)	Percentage (%)
Commercial	14.00	4.33
Comprehensive Development Area	9.62	2.98
Residential	34.69	10.74
Government, Institution or Community	37.85	11.71
Open Space and Amenity Area	102.89	31.84
Other Specified Uses	54.21	16.77
Major Road etc.	69.94	21.63
Total Area	323.20	100.00

Table1: Schedule of land uses and areas

3. EVOLUTION AND SYNERGY WITH SURROUNDING DISTRICTS

Adjacent to Kai Tak are several built-up districts including Kowloon City, Wong Tai Sin and Kwun Tong within Kowloon East. All of them are mature urban development areas mainly for residential and industrial use with a wide range of community and recreational facilities. Following the economic restructuring in recent decades and Government's policy initiatives to hasten the redevelopment/conversion process, the Kowloon Bay and Kwun Tong areas within Kowloon East has been gradually transformed into a distinct office node with a critical mass of offices further to the traditional "Central Business District" in Central. Under the current strategic planning, the office clusters and government node in Kai Tak will create noticeable synergy with the office belt transformed from the former industrial areas in Kowloon Bay and Kwun Tong, and provide an excellent opportunity for their evolution into a modern and premier business district in Kowloon East.

4. KEY URBAN DESIGN FEATURES

4.1. distinguished and attractive urban form

KTD is mainly surrounded by major trunk roads generating heavy traffic noise. In this regard, land uses with non-noise sensitive receivers, such as commercial and government, institution/community sites are located along the periphery of KTD, providing a shield to the inner residential sites. In principle, residential, office, retail and hotel developments are planned to mix with the sports and leisure activity nodes to ensure sustainable development and minimize cross-district traffic. The "podium-free" design concept has been adopted to enhance air ventilation, visual penetration and street level activities. Also, residential developments of suitable density are laid out in parcels with an average size of about 1 hectare each to create more intimately scaled urban street blocks.

4.2. A comprehensive green web

KTD seeks to improve the quality of living for the local population and cultivate a sense of belonging. Serving as a green web for sustainable development, KTD is characterized by a continuum of interconnected green spaces within KTD and its adjoining districts, and an extensive framework of tree and shrub planting. About 100 hectares of the land, which is about one third of the Kai Tak area, will be developed into green area and open space. This includes the 24-hectare Metro Park on former runway to become the prominent harbourfront park in Hong Kong. Other signature open spaces within KTD include the Station Square, Sung Wong Toi Park and Runway Park.

Moreover, KTD with about 11 km of continuous waterfront promenade will open up the harbour for public enjoyment. The scale of the promenade, occupying almost one-seventh of the waterfront of the Victoria Harbour, offers endless opportunities in the landscape design, with direct interface with the Kai Tak Cruise Terminal, Metro Park, Kai Tak Sport Park and a variety of other developments.

4.3. Connecting the neighbourhood

KTD is bounded by existing major road infrastructures such as the Prince Edward Road East and Kwun Tong Bypass. In addition, as a legacy of the former airport where security considerations took priority over pedestrian accessibility, there are limited connections with the surrounding districts. Through redevelopment of the former airport site, pedestrian circulations through an integrated network of open space, at-grade connections, footbridges and subways have been designed to maximize accessibility and mobility within KTD and further enhance connectivity with the surrounding districts and accessibility to the waterfront. A total of 25 numbers of new and enhanced connection points (Appendix C) will be provided between KTD and surrounding districts. For those existing pedestrian links subject to enhancement, thematic designs such as aviation history, street scene and etc., are adopted to highlight the culture and heritage of particular localities and to strengthen their function as welcoming entrances to KTD.

4.4. Preserving the heritage

KTD is dedicated to embracing not only its aviation history of being an ex-airport site but also the cultural and socio-economical significance of the neighbourhood districts in the development of Hong Kong. In this connection, the Kai Tak OZP was amended in 2012 to cater for the in-situ preservation of the remnants of Lung Tsun Stone Bridge (the Bridge) which was unearthed after the Kai Tak OZP had been formulated and approved in 2007. The historical significance of the Bridge remnants is attributable to its function as a pier for Qing Dynasty officials and garrison deployed at the Kowloon Walled City arriving on marine transport from 1875 until 1910s. Land parcels adjoining the preservation corridor were also rezoned to Comprehensive Development Areas for which the future developers would be mandated to submit master layout plans to demonstrate the relationship of their proposed developments with the preservation corridor.

Several signature open spaces (Appendix D) are also intended to preserve the unique “heritage” of Kai Tak as far as possible. With a nod to the aviation history of Hong Kong, part of the original Kai Tak Runway is retained and integrated into the planning of the parks. Substantial steel works with rustic finishes are used in the Kwun Tong Promenade to acknowledge the cargo handling area once established thereat. The drainage channel serving as a major flood relief path passing through the ex-airport site will be revamped to form the adorable Kai Tak River with extensive riverside hard and soft landscaping works. To date, the Kwun Tong Promenade and Runway Park Phase 1 have been completed and open for public enjoyment.

5. SUSTAINABLE INFRASTRUCTURES Environmentally friendly transport

The sustainable railway transport is planned as the backbone of public transport service for KTD (Appendix E). In this regard, the main developments in KTD are located in the former north apron area which will be served by the Shatin-to-Central Link (SCL) railway where two of its stations will be situated within Kai Tak. Subject to further study and consultation, an Environmentally Friendly Linkage System (EFLS) linking up the SCL stations and different areas/activity nodes of KTD is reserved in the OZP. As an essential component of the integrated multi-modal linkage system, the proposed EFLS would provide efficient intra-district connectivity services within Kowloon East, especially for those areas not served by the existing or planned MTR networks, and facilitate inter-district travelling through interchanges with the existing MTR Kwun Tong Line.

The section of the strategic Route 6 passing through KTD is planned in the form of depressed road or tunnel to significantly reduce noise, air and visual impact to the developments in the vicinity. In addition, local roads within KTD are all non-through roads (Appendix F) that can minimise the amount of through traffic and hence the traffic and environmental impacts.

5.2. Breeze through the grid

To promote natural ventilation in Kai Tak and to allow wind to penetrate the existing built-up areas in the hinterland, the new development area in KTD is laid out in a grid with breezeways (Appendix G) to capture the prevailing wind from the southeast. The development sites are divided in a manner to avoid wall effect. The space between the residential neighbourhoods will be mainly pedestrian streets with a width of 10 metres (m) to allow better air circulation and improve the townscape. Where necessary, set back of building lines from the site boundaries and building separation will be mandated to improve townscape and air circulation. These requirements are incorporated into the Kai Tak OZP for statutory control and under conditions of land lease and Government land allocations for mandatory enforcement.

5.3. High efficiency cooling

The District Cooling System (DCS) (Appendix H) is one of the major infrastructure facilities in support of the sustainable and environmentally-friendly development at Kai Tak. To promote energy efficiency and conservation, the Government is constructing a first-of-its-kind DCS in KTD to serve a planned total of about 1.73 million m2 of non-domestic air-conditioned gross floor areas. The DCS is an energy-efficient air-conditioning system, consuming 35% and 20% less electricity as compared with traditional air-cooled air-conditioning systems and individual water-cooled air-conditioning systems using cooling towers respectively.

Implementation of the DCS in KTD will bring about significant environmental benefits. Due to better energy efficiency, the maximum annual saving in electricity consumption upon completion of the entire DCS project is estimated to be 85 million kilowatt-hour, with a corresponding reduction of 59 500 tonnes of carbon dioxide emission per annum. Apart from energy saving, as chiller plants and the associated electrical equipment will no longer be necessary, each individual user building subscribing to the district cooling services will gain further benefits such as reduction in total building cost by about 5-10%, more flexible building designs and a more adaptable air-conditioning system to the varying demand.

5.4. Sustainable waterways

Given the considerable length of a continuous harbourfront, Kai Tak should be a suitable location for the provision of water-land interface to facilitate waterborne activities within particularly the two adjoining water bodies, namely the Kai Tak Approach Channel (KTAC) and the Kwun Tong Typhoon Shelter (KTTS), embayed by the former runway and the adjoining breakwaters. Nevertheless, poor water circulation within these two water bodies and continuous inflow of polluted water for decades due to expedient connections had caused water pollution and contaminated sediments deposited at the seabed, resulting in odour nuisance and other environmental problems. Upon the implementation of KTD, a 3-pronged approach has been adopted to mitigate the environmental problems by means of rectifying the expedient connections in the hinterland, bioremediation treatment of the contaminated sediments, and creation of a 600 m opening at the former runway to enhance tidal flushing effect within KTAC and KTTS.

Bioremediation treatment (Appendix I) is a cost-effective engineering solution to tackle the contaminated sediments. Basically, dredging was limited to localized pollution hotspots, followed by injection of calcium nitrate solution as an oxidant into the seabed to accelerate degrading the odorous substances into mainly odourless and harmless gases, thus reducing the offensive smells and improving the water quality. As a result, the burden on the reception sites for disposal of dredged materials can be substantially reduced. Recent field monitoring results indicates that the water quality within KTAC and KTTS has been improving significantly since the completion of the rectification of expedient connections and bioremediation treatment. There is more to be done. In lieu of the originally proposal to create a 600 m opening at the former runway which would result in the generation of huge construction waste, a recent study on other possible sustainable alternatives has revealed that further interception of the inflow at the immediate upstream of KTAC and creation of mechanical flushing by means of pumping seawater from the KTAC into the harbour side of the runway could achieve similar environmental performance as the originally proposed 600 m opening. Further development and design of this alternative inception and pumping scheme are underway.

6. GREEN BUILDING DESIGN

In Hong Kong, more than half of the total annual energy use is in the form of electricity consumption, with buildings accounting for about 90% of the city's electricity use. Promoting green buildings and enhancing building energy saving are priority considerations of KTD. Employment of low carbon and sustainable design is a mandatory requirement in all government and private buildings projects in Kai Tak, which is required to achieve at least Gold ratings under the Hong Kong Building Environmental Assessment Method (BEAM) Plus.

6.1. Government, Institute and Community (G/IC) building projects

As the first completed government offices building in Kai Tak, the Trade and Industry (TI) Tower project located at former north apron is set for demonstration purpose. Emphasis of the project has been placed on greening and energy conservation. With the energy efficient features and renewable energy technologies adopted in the building, the total electricity consumption of the building is anticipated to be approximately 25% less than normal office building. Major sustainable features in the project include double glazing and sunshades, integrated photovoltaic panels and photovoltaic panel, solar hot water system, solar chimney system, daylight sun-tube, solar tracking optic fibre light pipe and anidolic light pipe, lift regenerative power, automatic refuse storage system, drip irrigation system, water saving sanitary devices, use of material with recycled contents as well as adaptive and modular design for office area. In addition, the rectangular office tower is articulated with vertical greening. A "green ribbon" is formed through a series of vertical terraces on the façade as it extends up to the office tower and the roof garden. By achieving credits in various sustainable aspects, the TI Tower has achieved provisional Platinum rating under BEAM Plus as well as Platinum level under LEED® accreditation.

The Kai Tak Cruise Terminal Building at the tip of former runway is an iconic, highly functional and efficient terminal. The 42-m wide span column-free layout of the terminal building allows for maximum flexibility in the utilization of space, which can be configured in various layouts during non-peak season, optimizing the usage of the building. Design of the Cruise Terminal Building adopts a sustainable construction approach incorporating a large number of precast components and post-tensioning structures that extend beyond low energy consumption to the overall long term sustainability performance of the building. The project has also achieved provisional Platinum rating under BEAM Plus. Appendix J shows the overview of the major green buildings mentioned above.

The temporary building structure accommodating the Energizing Kowloon East Office (EKEO) is also a champion of sustainability by using a raft of integrated green building technologies and features, lean construction methods and low embodied energy materials to become Hong Kong's first low carbon temporary office. It revitalises a piece of unattractive land on a site under the Kwun Tong Bypass. This innovative and green EKEO building is the first temporary office building which is given final Platinum rating under BEAM Plus.

Through building disposition to bring in natural lighting and enhance ventilation while reducing heat gain, adoption of various green features and energy saving measures, many other G/IC buildings include Kowloon City No. 1 and No. 2 Sewage Pumping Stations have accredited with the final Platinum rating, Kai Tak Fire Station and Kai Tak Nullah No. 1 and No. 2 Desilting Compounds with the provisional Platinum rating, and Po Leung Kuk Stanley Ho Sau Nan Primary School and S.K.H. Holy Cross Primary School with the provisional Gold rating under BEAM Plus.

6.2. Residential and commercial building projects

In 2015, new greening clauses were formulated for incorporation into land sale conditions to mandate the requirement for private residential and commercial building projects within Kai Tak to secure provisional Gold rating or above under BEAM Plus as well as to provide smart water meter systems, electric vehicle charging facilities and additional greenery. To take further steps in building Kai Tak into a more sustainable and liveable community, there are also mandatory requirements on provision of real-time parking information in commercial car parks at appropriate sites.

In 2016, "De Novo" was completed as the first residential building project within Kai Tak, with provisional Platinum rating granted under BEAM Plus for its sustainable building design. This project is also renowned for being a pilot Flat-for-Flat scheme introduced under the prevailing Urban Renewal Strategy as an alternative choice to compensate domestic owner-occupiers affected by the Urban Renewal Authority's redevelopment projects. It has been an exemplar demonstrating the application of green building design concepts in private development projects.

7. CONCLUSION

With its unique background and history as a well-known former international airport of Hong Kong, Kai Tak is in no doubt a huge, highly diversified and complex redevelopment project with various challenges. Built on its blueprint formulated by accommodating public aspirations through extensive community engagement programmes, KTD showcases the success in consensus building for a mega size development project. Given the holistic implementation approach, which has been supported by orchestrated development with measures focusing on environmentally friendly infrastructure, green buildings and heritage conservation, KTD is now on the move to realise its planning vision through shaping a distinguished, vibrant, attractive and people-oriented community by the Victoria Harbour.

ABSTRACT

Historic buildings are notoriously difficult to adapt to suit contemporary requirements. Users retain modern expectations for functionality and comfort, whilst conservationists impose restrictions on adapting these buildings to suit these demands. Meanwhile, building professionals aspire to design sustainable interior environments for the occupants.

In this study, we assess the design of rooms in the Presidential Palace of San Anton in Malta, a historic building that currently serves diverse functions, including residential and administrative. This 17th century palace epitomises the climatic challenges for achieving functionality and comfort for occupants of heritage buildings in the Mediterranean and similar climates.

Although many of the rooms in the palace contain original fixtures and fittings, a significant proportion of its furnishings and window treatments are reproductions with no historic value. The latter could be substituted with aesthetically sympathetic solutions that would improve the functionality and comfort of these spaces.

In this paper, the results of a survey to establish how the internal layout of the rooms in the palace, their furnishings (furniture, appliances, and other movable articles including lighting and floor rugs), doors, windows and window treatments work for the occupants in their current design, is presented. Recommendations for improving the sustainability of these spaces are made.

Keywords: design process, energy saving, comfort and functionality

1. INTRODUCTION

It has been emphasised that public buildings should serve as role models in the shift towards eco-refurbishment, thus incentivising the market (Economidou et al., 2011). The Presidential Palace of San Anton would offer an excellent means of leading the eco-refurbishment of heritage buildings by example in Malta.

The primary residence and main office base of the President of Malta, San Anton Palace (SnAP) incorporates a variety of uses and an architectural configuration characteristic of palace heritage building typology. It was, therefore, selected as a case study for this research. The large-scale seventeenth century palace is a complex multi-functional building, catering to residential, administrative, office and service uses simultaneously. The diversity of this working palace must merge harmoniously with the need to maintain the highest standards of heritage protection. It therefore presents a challenging case study, albeit comparable in its characteristics and layout to other buildings classified within the same typology.

2. CONTEXT

2.1. Occupant comfort and behavior

Users' actions to improve internal comfort conditions account for a significant percentage of energy used in buildings (Yang et al., 2014). The drive to improve energy efficiency is, therefore, often paired with the objective of improving occupant comfort: unfortunately, green design does not necessarily equate to comfortable design. Paul and Taylor (2008) provided an indication of this through a study that examined the comfort and satisfaction perspectives of users of one green and two conventional buildings. Their research found no link between green design and comfort. This result was supported by a post-occupancy survey carried out by Hedge and Dorsey (2013), which identified issues regarding perceived health and performance in one of the two LEED Platinum buildings studied. Whilst the building was energy efficient and sustainable, there were concerns regarding variability in air temperature, freshness, and quality.

There is clear merit in ensuring appropriate occupant comfort. The advantages include better user satisfaction and productivity (Wagner et al., 2007). It has also been shown that both greenness as well as comfort influence property value (Zhao et al., 2015). These factors result in financial spin-offs, which validate addressing energy efficiency and occupant comfort on an economic level alone. Moreover, a relationship has been recognised between user health and building parameters, including physical comfort conditions (McMullen, 2007). The inherent characteristics of a building, therefore, translate into the occupants' perception of comfort by generating an indoor climate that directly impacts users. Another aspect comprises the occupants' initiative in taking action to increase their comfort levels. Occupant behaviour plays a pivotal role in reducing building energy use (Ben and Steemers, 2014).

Research has highlighted the impact of occupant behaviours, such as interactions with lighting, apertures and appliances, on adaptability and energy use (Yan et al., 2015). Therefore, low energy consumption in buildings cannot be guaranteed through technology alone: rather, it should be supported by the appropriate interaction of occupants with the building (Hong et al., 2015).

2.2. Heritage building assessment

Heritage buildings present particular challenges that may be addressed in-part through retrofit decisions derived from socio-technical and behavioural data (Chiu et al., 2014). Addressing occupant behaviour holistically is crucial in developing successful eco-refurbishment strategies, since this provides the highest energy saving potential of all retrofit solutions in protected housing (Ben and Steemers, 2014). However, not only is there a dearth of information in the literature on occupant interactions with heritage buildings, but the impact of users is difficult to identify accurately for various reasons, including behavioural diversity (Yu et al., 2011).

Design variables relating to physical building parameters such as position and size of windows, surface treatments and building layout, have been flagged as having an effect on energy performance (Yasa et al., 2014). These factors may be best identified through a comprehensive building survey. Users' perception of comfort, as well as their expectations and satisfaction, may be gauged through interviews with building occupants. The retrofit of heritage buildings should, therefore, include detailed architectural assessment, as well as occupant consultation.

3. METHODOLOGY

3.1. Building survey

A detailed field investigation was conducted to obtain an understanding of the: Architectonic qualities of SnAP, and the vernacular techniques utilised in its planning and construction; as well as Factors that impact on the internal environment.

The architectural survey of the case study provided a record of all elements influencing its energy profile, both directly and indirectly, including: Internal height; Lighting strategies; Apertures; HVAC systems; Floor, walls and ceiling surface materials; Passive environmental design features, such as courtyards and loggias; Room orientation and use; and Basement levels. This data was collated for the entire palace, except for the private quarters.

3.2. Interviews with palace occupants

The scope of the survey was to investigate and establish occupants' perception of comfort, functionality, satisfaction and expectation in the context of the building's existing use framework. The information gathered from participants was critical in exploring the impact of occupancy behaviour on energy demand.

A pilot schedule was developed based on an awareness of appropriate practice and published data. The interview design introduced participants to relevant factors before they were asked to formulate a general perception of comfort and functionality. The survey comprised 4 sections with a total of 21 both closed and open-ended questions. The first section provided a background of the respondent's roles and experience at SnAP, thereby contextualising the responses to subsequent questions. This included recollection of changes to the building. The next section assessed the following criteria for each room used by the respondent: frequency of use; tasks performed; actual room use; frequency of occupants' movement; number of occupants; general perception of the occupant's comfort. Section 3 provided detailed insight into the interior design in terms of room layout, furnishings, doors, windows and fenestration systems. The final section explored the participants' general perception of comfort and functionality at SnAP.

Once trialling of the pilot schedule was completed, a cross-section of the staff and residents at the palace were contacted to take part in the survey. All those invited agreed to participate, constituting a representative sample of the different user groups of SnAP. The respondents comprised approximately 30% of the population, and provided feedback on a varied range of rooms. Prior to conducting the interview, an introductory statement was provided to participants. The brief outlined the research and emphasised the importance of the respondent's contribution. It also defined terminology, ensuring a consistent understanding amongst participants. The interview was recorded and transcribed, thereby collating shared data into an effective and structured framework.

In order to contextualise the information compiled (particularly with regards to ratings) the air temperature, relative humidity (RH) and MET office readings were recorded on interview days in order to frame the comfort levels discussed by the respondents. MET office readings were taken from the Malta International Airport station, located approximately 6.7km away from SnAP. The air temperature and RH were measured using a portable data logger of accuracy +/- 0.1°C and ±3%, and resolution 0.1°C and 0.1%, respectively which took readings every 5 minutes.

4. RESULTS AND DISCUSSION Building survey

The internal height (i.e.: distance from finished floor level to the underside of the ceiling slab) has been found to have particular relevance when assessing natural ventilation and airflow (Li et al., 2013). As expected, most rooms were found to have high ceilings, characteristic of this building typology. Although this passive design technique was introduced to promote comfort levels, the large volumes created tend to make the rooms harder to heat or cool through artificial means, thereby exacerbating energy use.

A diverse mix of bulbs was identified, comprising a combination of tungsten filaments (70%), compact fluorescents (29%) and LEDs (less than 1%). Despite an on-going conversion to energy-saving bulbs, little effort has been made to address the lighting strategy. Consequently, poor lighting conditions have been flagged in a number of rooms. Notably, the lighting strategies in some of the office spaces have not been designed to meet the particular needs of the users: for example, light fittings are not placed such that desks are well-lit. The solution lies in the installation of a system that provides appropriate lighting levels at minimal energy demand, complemented by a layout that maximises natural lighting. It is recommended that the lighting layout should be designed with consideration of the furniture layout and the positioning of windows, and should incorporate energy-saving fittings/blubs.

Apertures mainly comprised timber frames with single glazing, complemented by louvered shutters. This aesthetic is original to the building design, and must be retained in conformity with architectural heritage preservation legislation. Apertures generally do not feature large areas of glazing, and external louvered shutters provide shading as necessary. The traditional timber louvered shutters are in fact an important passive design mechanism that, if used appropriately and as intended, may improve internal climatic conditions considerably. On the other hand, the single glazing timber window type is rarely conducive to a well-sealed building envelope.

For the purposes of this survey, an HVAC system was defined as any system used to artificially heat or cool a room, including air-conditioning units, ceiling/floor fans and fireplaces. Most rooms in the palace feature air-conditioning units and/or ceiling/floor fans. The overwhelming majority of air-conditioning units were on when the rooms were assessed, even if the rooms were not occupied.

Flooring finishes range from original flagstones (39%) and marble tiles (8%), to parquet (5%) and fitted carpeting (19%). In order to mitigate over-heating, the latter two were not included in the original building design. They have, presumably, been installed for aesthetic purposes but are generally unsuitable for the local climate.

A number of passive environmental design features were identified through the architectural assessment of the case study. These included: Central courtyards; Loggias; Flat roofs having traditional structural configuration with

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

insulating properties; Thick double-skinned external masonry walls with rubble-filled cavity; Use of inherent building materials and finishes which promote natural cooling (such as flagstone flooring); Well-positioned windows and doors (both external and internal); Louvered apertures; and Surrounding indigenous trees and vegetation. The cumulative impact of these on energy efficiency has not been established to-date.

Room-uses (i.e.: predominant use of a room) were classified into predefined categories including: state room, office, multi-purpose (where use varies frequently, for instance from a guest room to an office), guest room (temporary residence), private quarters (permanent residential rooms including ancillary facilities), service room (including kitchen, pantry, locker room), security room, workshop, chapel, storage, garage, toilet, lift, passage and loggia. Secondary uses were identified through interviews with building occupants. The room-use survey proved crucial in developing an understanding of the mixed-use nature of SnAP, which directly impacts energy use and comfort concerns. It highlights the various groups of building occupants, as well as their distinct behavioural patterns and comfort requirements.

The building survey clearly demonstrates that the palace presents a highly complex environment for a number of reasons. Firstly, the multi-functional nature of SnAP demands that a variety of uses and users interface harmoniously. This is compounded by the secondary uses of a number of rooms. Moreover, an extensive diversity of room parameters has been identified. Finally, the building also features a number of passive design strategies, the impact of which has not yet been evaluated. These facets should be addressed in an integrated manner and at varying levels: A master plan of uses at a macro-scale should be consolidated with, for instance, a detailed lighting strategy at micro-scale.

4.2. Interviews with palace occupants

Although participants could recall only recent changes, and more specifically changes affecting them directly, the great majority had an awareness of changes to the structure and/or layout of SnAP. This clearly indicates a high level of activity in this context. The foremost modifications mentioned included room restoration or redecoration, and shifts in room use, predominately related to office space. The fragmented redistribution recalled by participants implies that a holistic room-use strategy at SnAP is lacking.

It was established that a number of rooms are multi-functional in nature, having both a primary and secondary use. Moreover, it was found that higher-ranking management personnel tend to move around the palace quite frequently, utilising several rooms for meetings and events. The lack of designated meeting spaces was emphasised as a concern.

An analysis of the use criteria highlighted shared offices as having a high number of users and footfall levels. Most office users spent 8 hours or more in the rooms per day. This suggests that these spaces greatly merit a strategy for an interior design layout promoting comfort and functionality for occupants.

A number of issues relating to poor comfort levels were identified: in particular, a lack of natural light and ventilation, and uncomfortable levels of temperature and humidity were reported. The results clearly indicate that in order to improve comfort, occupants resorted to routinely using artificial lighting and air-conditioning, and also endeavoured to open doors and windows for ventilation whenever possible. These findings correlate well with the literature study, which identified a strong link between occupant comfort and behaviour, and energy use.

The majority of respondents felt that the room layout was not appropriate to function (64%) and nor did it maximise comfort (75%). Results indicate that the rooms cannot suitably meet the demands imposed, both in terms of number of users, as well as technological requirements. Participants were not satisfied (68%) with the furnishings of the rooms citing, amongst others, poor lighting (both natural and artificial) and insufficient storage space. Although most occupants did move furnishings (82%) in order to improve functionality, there was concern regarding the possibility of damaging items of value, both heritage and financial. Moreover, it was found that 47% of users preferred to move themselves to another space to improve comfort, rather than move the furnishings. This was generally related to improving light, ventilation, temperature and acoustic conditions in order to temporarily alleviate discomfort, and is a clear indication that the room layout is not appropriate to its use.

Windows have been rated as the preferred adaptive interactivity (Barlow and Fiala, 2007). Despite the express wish of users to do so, in a number of cases, it was not easy, practical or possible to open/close windows, shutters

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

and curtains. Reasons for this included the physical attributes, security or privacy, and the juxtaposition of conflicting uses. It may be argued that opening windows when the outside temperature is greater than that inside may negatively affect the comfort levels of the internal environment. However, the inability to use apertures excludes the possibility of night purging, and of allowing natural ventilation as necessary.

This restriction has induced occupants to resort to alternative means of ameliorating the internal environment, as evidenced by the high dependence on the use of air-conditioners. Rather than taking action to discourage this practice, there is a concerted move towards installing new units, and replacing ceiling fans.

Approximately 53% of participants open windows and doors for ventilation, and of these the majority (67%) also resorted to HVACs for cooling. The reasons given for not opening apertures were generally due to factors beyond the participant's control (pollution, impractical, privacy, security, no windows). Where possible, occupants always opened or closed shutter/blinds/curtains for comfort (86%) and functionality (93%). However, it was found that artificial light was also being used extensively. Good quality lighting is pertinent to providing a comfortable environment for occupants. It is, therefore, critical that the lighting strategies are custom-designed to address the unique conditions of each room use and layout.

The overarching perception of comfort at SnAP was negative. Participants clearly felt that the palace did not effectively meet the functional demands emanating from the present uses. Satisfactory light and temperature levels were the major cause for concern. This is acutely aggravated by frequent and piecemeal changes at the palace. Despite the appreciation for the building's heritage value, users generally felt awkward about the presence of valuable artefacts and furniture in the space they occupy.

5. CONCLUSION

Energy use in buildings is not solely a technical issue but, rather, one with a social dimension, and feedback from occupants regarding behaviour and comfort is a vital building block in green retrofits. In designing a strategy for improving building performance, it is important to establish the expectations and requirements of users, as well as their perceptions of, and interactions, with the existing building layout and fabric. The approach taken is, therefore, well validated by the wider literature.

Preliminary observations indicate that steps could be taken to naturally improve indoor comfort levels, and facilitate energy-conscious behaviours. Appositely, frequent and fragmented changes are being executed in an effort to better accommodate existing and new uses. It is therefore being recommended that any sustainable strategy should incorporate a Change Control Mechanism underlined by a Standard Operating Procedure, which flags specific indicators to be addressed.

The methodology adopted throughout this study aimed at being as inclusive as possible, thus imparting three major benefits. Firstly, it was designed to engage occupants in the eco-refurbishment process at an early stage, such that they feel empowered and cooperate in bringing about positive change. Secondly, it motivated them to respond correctly during the interviews. Thirdly, a positive climate, supporting future behavioural change, is created as part of this process.

The results of the interviews strongly highlight a negative user perception of comfort and functionality of this particular heritage building interior, and the resultant behaviour of occupants aims at improving their environment. Simple measures designed by our predecessors to provide a comfortable indoor environment are no longer used, and have been replaced with an ever-growing dependence on active mechanisms. This highlights the importance of re-visiting the passive design features inherent to the original building design, and developing a strategy for maximising their potential through a sustainable building interior.

Café des Visions: How to Anticipate and Consolidate Urban Negotiation through Art; a Practice-based Artistic Research

Anna GRABER[a]

[a] *Café des Visions, Switzerland, annagraber@swissonline.ch*

ABSTRACT

The Art in Public Spheres project *Café des Visions* establishes forums at unconventional locations in the public sphere to test new ways of discussing and working out together how public spaces shall be designed and used.

The goal is to link ideas and spaces by gathering implicit knowledge from people on the street by using their everyday experience in public spaces as expertise and to make this knowledge artistically visible in a way that allows it to be put at the disposal of creators and users of public spaces while at the same time challenging and blurring their traditional roles. Or with the words of the French sociologist Henry Lefebvre: 'City consumers shall become city producers.'

The artistic intervention *Café des Visions* serves as a nomadic research station transforming urban non-places into mobile village squares. Wishes for the restructuring of a specific public space are gathered there by interviewing guests at the café. The guests are invited to draw their wishes on the ground with white water-soluble paint. This gesture of inscribing the site with requests directly connects idea and space.

Café des Visions treats the constructed and the lived cities as if they were white spots on maps of ancient explorers. Data is gathered from drawings and logbooks, by semi-structured interviews and photographic investigation as well as by documenting the collected wishes. After the Café's intervention, the data is qualitatively analysed. The results are drawn typographically and published as city mappings on which wishes superimpose the grid of houses and streets.

The outcomes show everyday knowledge closely linked to the actual discourse in urban sociology or public space/public life studies. The artistic intervention provides knowledge created by open thinking, which is the starting point of any creative process and can serve as a first step in city development processes.

Keywords: sustainable neighbourhood, participatory city planning, urban negotiation, art contribution

1. INTRODUCTION

Public spheres reflect the value systems of an urban society. Anyone observing an urban space is confronted with a built environment and with people who move in it. The architecture of the buildings, the design of the street furniture, the available free space, the design of green areas as well as dealing with mobility determine who is welcome to stay, how everyone moves and how everyone treats each other. It shows how much weight an individual voice is given in the ongoing process of the negotiation of needs. Today as well as in the future, the greatest challenge to urban societies is to integrate interests and needs of different players and to tackle the related negotiation process so that social resources are freed and existential problems can be addressed.

In German-speaking countries the structural substance of the city centres and the organisation of the space date from the Middle Ages. The city foundations at that time were based on two premises: first, the freedom of the market and, secondly, a democratic society, which formed an antithesis to the feudally organised country. Cities were thus from the outset places of trade. The behaviour of people in public spaces is therefore the behaviour of customers in the marketplace. In contrast to this, public spheres served to shape public opinion in order to counterbalance the government's decisions. Coffee houses in the 18th century were meeting points where news circulated and where the social class of citizens discussed and became a political class. These bourgeois public spheres disappeared as the incremental coalition of business and politics took over public spheres. The public and the private mingled in favour of a permanent relationship of bargain and sale. The political stratum of citizens becomes reduced to a class of customers. The market overgrows democracy. This fact manifests itself in the design of public spaces as well. They are reduced to transit zones that connect places of consumption.

Modern architecture has solved the hygienic problems of medieval towns and restructured the space. This development culminated in the Fordist separation of living and working. Individual traffic was needed to overcome the distances between industrial and residential areas. The streets were widened and pedestrians confined to narrow channels between monotonous, oversized facades and overwhelming traffic. Public places are designed multifunctionally: they are asphalted, greened and sparsely furnished with a few benches positioned in a way that individuals or couples can sit side by side to enjoy the view. This setting inhibits communication. On the whole, these sites are not perceived as alive and are therefore avoided. Spontaneous contact does not occur.

2. RESEARCH TOPIC AND GOALS

From these discussions the following research question results:

What kind of city life should be designed to trigger a civic and sustainable development? How can art contribute to urban negotiation?

Three hypotheses lead to the research approach:

- People on the street own an expertise for the use of public spaces that consists of their everyday experience. This knowledge is often implicit.
- The implicit knowledge about public spaces is a source for the negotiation process within urban planning as well as for creating new forms of using public space.
- Collecting the implicit knowledge and making it artistically visible allows it to be put at the disposal of creators and users of public spaces to discuss, challenge and blur their traditional roles.

The goal is to build bridges between bottom-up and top-down planning to find resources and innovation potential for designing, building and living cities.

3. METHODOLOGY

The research is structured into two steps. The first one is planned around the question how the perception and the concept of public spheres can be changed by the means of art. Three types of experiments will be conducted:

- Collecting wishes: People on the street are asked about their wishes for a specific public place in order to tap into their implicit knowledge; their wishes are collected, discussed and artistically transformed into city mappings.
- Interventions in public spaces; they help develop and test new ways of interaction and cultural life.
- A cultural translation of transit zones will produce public spaces portraits.

The second step will trigger new ways of collaboration for designing public spheres. The experiment will consist of creating transdisciplinary forums to work out a charter of the values of public spaces and to initiate projects where unconventional collaborations are tested to build bridges between top-down planning and bottom-up projects.

This paper focuses on the first step and will describe an intervention and a collection of wishes with the art in public spheres project Café des Visions in the city of Zug, Switzerland, and Vienna, Austria.

3.1 Café des Visions: an artistic intervention as research station

As a mobile village square, Café des Visions moves from place to place by means of a bike trailer and questions its respective locations about their potential as social spaces. Designed as a coffee lounge, the Café invites passers-by to relax, at the same time serving as a forum where ideas can be developed and discussed.

What‘s your wish for this place in particular?

How should it be designed?

What should take place here?

What do you think would this place need to make it different from others, so that you would like to spend time here?

Café des Visions is also a city studio and a city laboratory, a place where wishes and visions take shape. The media and materials required for this process are available at the bar. At the Café, guests are invited to express their wishes and/or sketch them out. Wishes, desires, requests and visions are produced and collected by painting them on the ground with white water-soluble paint, transforming the place into a participatory installation, the spatial tattoo. This gesture of inscribing the site with requests directly connects idea and space and makes this relation artistically visible. On the project website www.cafe-des-visions.ch, the ideas are collected virtually and can be discussed and further developed.

The Café is made out of stackable lounge chairs and tables, which fit into a bicycle trailer that serves as a bar. Café des Visions travels from one place that has potential for change to the next that seems to need transformation. When set up, it occupies real space and simultaneously, by means of collecting visions, constitutes an ideal space. In this way, it takes the question of how space should be designed and used to where people actually are and where changes are taking place.

Café des Visions treats the constructed and the lived cities as if they were white spots on maps of ancient developers. Information is gathered by observing, collecting and drawing. After the Café' s intervention on each particular site, the data is qualitatively and quantitatively analysed. The results are published as a map of the city, typographically designed with the collected information being placed exactly where it was gathered in the grid of the city, thus mapping the neighbourhoods and the wishes located in them.

3.2 Combining idea and space

Café des Visions is focusing on two different types of public spaces:

- Neuralgic points: neuralgic points are places of transit people pass by unconsciously in the centre of a city, accepting them to be either vast or hostile, traversing them as quickly as possible although the geographical location and the design of these spaces indicate that – in early days or in the concept of the public architecture – they were meant to be a place where people rest or meet.
- Urban wastelands: urban wastelands are open spaces between two areal utilisations, for example the Stadionbrache Hardturm in Zurich, which are made publicly accessible but were not constructed as such or have no infrastructure to invite people to stay or initiate activities.

Both kinds of spaces are chosen by the methods of observation, photographic investigation, interviews with interested parties and reading literature on the history of the specific place. *Café des Visions* understands its respective location as a constructed and social space that is constantly changing because of the presence of people at a specific time. It asks the visitors about their personal view of the place, their emotional ties to it and their knowledge of its history, which it puts in relationship to the already established known history of the place. People are considered to be experts on the spaces they pass every day. The collected knowledge is an everyday knowledge, the collected social potential shows innovation that is rooted in everyday life – a portrait-collage of the 'genius loci'.

3.3 Artistic methods

Within the different phases of the project, Café des Visions works with various methods borrowed from ethnography and urban sociology that have been adapted to the artistic process. These strategies form a framework allowing the Café des Visions to reach people in a holistic way.

The unexpected presence of the participatory installation invites passers-by to come closer and take a seat. The seats were developed with sculptural techniques and the installation serves the objectives of city-sculpturing and space-tattooing. In this way, it speaks to people in a language that goes beyond the verbal.

Appropriation and production of space by Henry Lefebvre

The French professor of sociology (1901–1991) postulated a 'differential space' 4 as an objective for dissident urban development, which means that an urban situation is based on the coexistence of differences that have a potential for productive exchange. Appropriation and production of space are strategies to transform the 'abstract space' of profit orientation into a differential space. The mobile elements of the Café des Visions allow a quick

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

appropriation of public spaces. Every visitor helps to expand the appropriation and produces a temporary social space. Appropriation and production of space are also used to create an atmosphere that facilitates passers-by and citizens to get into a dialogue to collect information.

Collecting information: Information is gathered by observing, interviewing, drawing sketches and collecting oddities and finds in a metaphorical botanic specimen container: photographic investigation, documentation of the actions in the Café and of the collection of wishes, sketches, diary/logbook. Research in archives and precise description.

Observing: participant observation, a data collection method for qualitative research (ethnology), applied to the process of choosing a space as well as to being on tour with the Café des Visions.

Interviewing: semi-structured interviews (based on Flicks's concept of qualitative social research 5 applied to choosing a space as well as to being on tour with the Café des Visions.

Counting, classifying, evaluating: The collected wishes are discussed and arranged from different points of view, which results in texts and graphics (methods borrowed from 'Public Space/Public Life Studies', Jan Gehl, Birgit Svarre 6.

Mapping: the painted wishes are typographically assembled on a map of the city and laid exactly onto the edificial structures of the respective urban district. The mapping is inspired by the psychogeography of Guy Debord 7.

3.4 Framework for the experiment

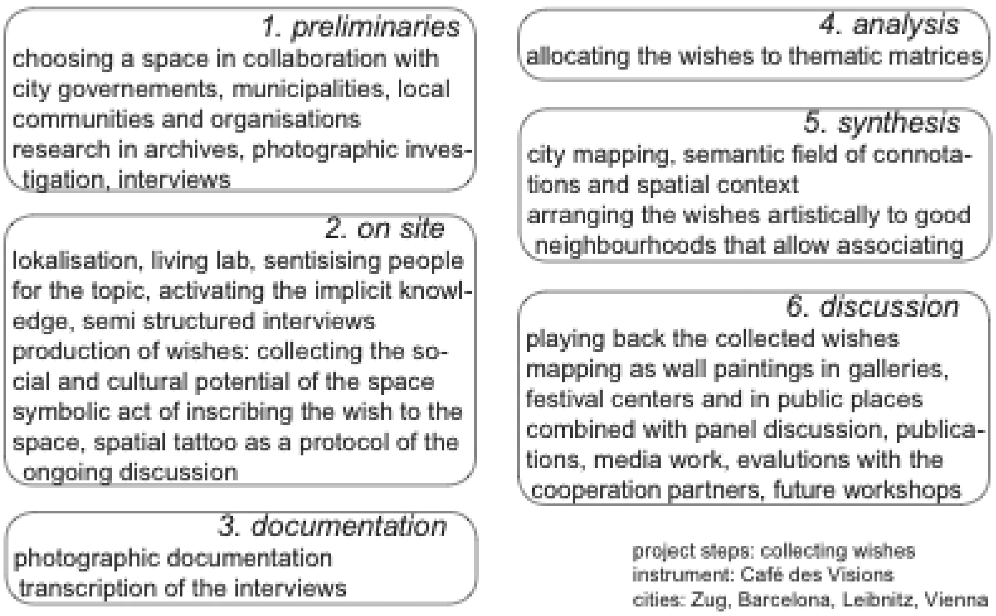

Figure 1

4. OUTPUTS AND OUTCOMES

Since 2012, *Café des Visions* has been travelling to various cities in Europe. Two examples may show the variety of the discussions resulting from these trips. The first one is from a roundtrip to twelve locations in the city of Zug, Switzerland. The conceptual design of the greater area mapping was made in collaboration with the city development department and with the department for culture. The results were published on a forum within public space, on a panel discussion and as publication.

Surrounded by mountains, Zug is a picturesque city at the lakeside. The city centre dates back to the Middle Ages and is surrounded by modern architectural ensembles. Selected pieces of dialogue show the quality of the statements made by passers-by.

The second example is from the Seestadt Aspern in Vienna, Austria, a smart city, which is going to be constructed within the next twenty years as one of the most ambitious projects of actual city planning in Europe. Here, the debate about the site was established by the act of painting the wishes voiced by passers-by onto the ground. The intervention was planned with the committee of the festival urbanize! and with the district management at Seestadt Aspern. The results were shown as a wall painting at the festival centre combined with a panel discussion and played back via the district management to the participating people at Seestadt Aspern.

4.1 Dialogues and a spontaneous forum in the city of Zug

On 21 June 2014, *Café des Visions* was a guest in the urban district of Herti, situated at the eastern city boundary. Compared to Zug's rich villa districts, this neighbourhood is multinational and its inhabitants belong to the lower middle class. The *Café* was set up in the backyard of a shopping centre built in the seventies; there is a fountain with artwork, benches and trees, and the square is flanked by a fast-food restaurant, a parish, a home for the aged and the entrance to the shopping centre.

A passer-by who is already a grandfather reported how the former 'Allmend' (a common green space) was rezoned for urbanisation on the condition that a social mix should be ensured in the resulting settlements by constructing subsidized housing, cooperatives and condominiums. He spoke of the vision of that former generation and expressed his wish that the place become a village square where strangers could mix with locals. Later on, a passer-by read this wish on the ground and said: 'This idea with the stranger is not working, they meet here smoking hashish.'

'They planned everything correctly. There are trees, water and seating. And yet the place does not live', analysed an architect doing his weekend shopping. Finally, she wished for boxes of wild roses by the walls of the parish centre.

A group of children suggested a waterslide from the church roof to the fountain, a water fight once a week, a football field with goals, in short, space for activity and motion. Later, the children began to drum on the lounge chairs and evoked the desire for a music garden, a sound game area with logs for instruments and people spontaneously playing music together.

A former landlady wanted room to talk, talk, talk. An artist suggested pimping the bare walls. Others wanted a party on the weekend, more people, more seating, more shade or a finer surface for wheelchairs.

'Zug has other problems: overpriced homes', said a man waiting in the café lounge for his wife to bring his dinner, 'nobody cares about the design of public spaces. Certainly not the politicians.' This statement made two adjacent groups arrange their chairs in a circle and discuss till dark what issues were pending in Zug, among the participants: Zug's city developer Regula Kaiser.

The contexts indicated in these talks can also be found in the discourse of urban sociology, psychology and philosophy.

The idea of the music garden was created by open thinking. After Mihaly Csíkszentmihályi, fluid thinking is at the beginning of each creative process – in everyday life just as much as in the 'great creativity' he examined and which leads to relevant inventions in all scientific fields.

The encounter with the unknown is one of the topics of urban sociology. 'The urban city is a place where different lifestyles, beliefs and cultures can co-exist and at the same time occur in a productive dialogue with each other', writes Walter Siebel. Thus, the confrontation with the stranger is important for Siebel. Through his differentness, the foreigner questions cultural certainties. Even if city residents do not approve of his otherness or feel even repelled by it, they develop a resigned tolerance towards it since they are constantly confronted with it In cities that represent interfaces of different cultures, Csíkszentmihályi found a great innovation potential.

Figure 2: Café des Visions, collecting wishes at Zug 2014, photo Anna Graber

Finally, the little spontaneous Forum has roots in the Greek agora as a place of debate where no one was allowed to be brought to justice for a divergent opinion. The philosopher and sociologist Jürgen Habermas described as early as in 1962 the disappearance of the bourgeois public sphere in the sense of a democratic critical counterweight to government and economy.

For the place at Herti 42 wishes were made. They can be classified into the following categories: architecture, design and infrastructure 12, socio-environment 14, nature 8 and culture 8.

For each place, the Café des Visions is stationed, two types of recommendations are deduced:

- wishes that initiate a change from a non-place to a place: shadow, more benches, movable seating that allows eye contact during a conversation, a well as meeting point like in an ancient village, a pitch or anything that triggers physic activity,
- wishes that show the special potential of a place: roses in troughs made of wood hanging on the scraggy concrete walls from the parish would give atmosphere to the place or art, that pimps up the concrete walls. More people at the weekend were wished and also to let the young generation more organize their own projects as a possible solution. A music garden would make the place unique. People could meet by playing music, jamming, experimenting or listening.

In the end of the café's journey the city-mapping is drawn. It is meant to show a vision for possible development, not in the sense of a list of assessment criteria but in the sense of a mapped potential, where wished are positioned "in good neighbourhood" to allow an associative reading of the city and to find new possibilities for combinations with every reading. (c.f. annex)

Zug has a tradition of reflecting and debating the issues of city development. People easily joined the discussion with verbal statements. The painting served as a summary of their discussions for the next people to come. On the whole journey 383 wishes have been collected. They can be classified into the following categories: architecture, design and infrastructure 122, socio-environment 118, nature 79 and culture 64. The design of the public spaces cannot match to the level of the discussions.

4.2 A spatial tattoo as ongoing dialogue at the Seestadt Aspern, Vienna

What do people who live in a city that is still being built wish for? In Vienna, a smart city that will eventually house 20,000 inhabitants is being constructed over the next twenty years. The best planners, like Johannes Thovat, who made the masterplan, or Gehl Architects, who designed the concept for the public spaces, are involved to create a completely sustainable city. By now, 6400 people live in the quarter already finished. The city will grow around it in the form of a spiral.

In October 2015, Café des Visions spent four days on the Hannah Arendt Platz, a public square planned to become central to the whole city once it will be finished. It is situated between the main square and the school and is divided into different zones: a smooth green hill that constitutes an area for playing and relaxing, an open plaza with some trees and benches meant to become a multifunctional zone e. g. for markets, and a third zone furnished with long tables and benches.

Asked about his wishes for the new Hannah Arendt Platz, a man answered: 'What should I wish for, we have everything here.' The dialog on the space started by children and as the adults joined in pointed out fundamental questions of marketing monopoly, of how city life can grow in a place without a history, of the responsibility of architects. People wish for a city life as they know it from their previous place of residence. The zone for appropriation that is part of the concept of the public space is not yet understood by the residents and is seen as sandy spots that should be greened.

At the Seestadt Aspern, people were attracted by the installation of the Café des Visions and came looking for something to happen in the vacant space. The act of painting wishes onto the ground initiated individual processes of reflecting the perception of public spheres. The spatial tattoo reflected a first discussion on the relation between individuals or groups and the development of the space. It emerged step by step with every painted wish. In this way, the mapping is like a record of this collective process and shows the specific conditions of these city pioneers. In total, 187 wishes were made. They can be classified into the following categories: architecture, design and infrastructure 81, nature 45, socio-environment 36 and culture 25.

Architecture, design and infrastructure: a noticeably great number of persons, 23, wished for more shops, stalls with take-away food and vegetable markets. They mentioned the monopoly held by one multiple shop, which is also one of the investors for the first ten years, and a fringe area of ten kilometres which prevents even a kiosk at the lakeside. They also want to have small cafés and bars, i. e. a Café Cardamom or a student bar that would bring young people to the Seestadt.

A bigger group of wishes challenged and questioned the architecture: that human dimensions should be respected, which means constructing no higher than a tree, they asked for more innovation in architecture, individually designed houses instead of copy-paste architecture, the construction of cities by respecting the needs of all demographic groups, for 'closing the door to keep out the wind' (not increasing the wind's speed by constructing small channels between high rises), for an evaluation of the buildings after a period of five years involving the inhabitants. 17 wishes concerned playgrounds and sports, 15 wishes were about safety in traffic: less cars or no cars at all, decrease in speed on the street in front of the school, a speed limit of 30 km/h, a play street, safe biking especially for families, car sharing. The Seestadt Aspern already has a mobility concept stipulating that car traffic must not exceed 20% of total traffic. The need for innovative handling of car traffic is immense.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 3: Café collecting wishes at Seestadt Aspern Vienna 2015, photo Anna Graber des Visions

Nature: in other cities, the wishes concerning nature are always mentioned first and constitute the biggest group. At the Seestadt, the main issue in this category was public green space instead of asphalt and concrete: walking on natural ground, trees to give shade, wild flowers with rich blossoms that attract insects and butterflies. A little girl painted a bee – in the whole area, not one insect was to be seen. The areas around the trees should be greened with grass and wild flowers or with plants in big pots. Water, a pond and a fountain for kids to play were mentioned. A young mother wished to have a farm with animals like cows and pigs.

Socio-environment: in this category, the main concern was creating urbanity: the space should be appropriated, city life should grow. It should be the people who write the history of the place, the uniting pioneer-spirit should be preserved. Other statements included: the city life of a small town, facelook, encounters of the heart, public disputes and controversy, there is few to negotiate, prevention of a ghetto, transparent communication, to be asked and included in the development process.

Culture: city life shall be initiated by culture, identity, i.e. an artwork, a connection to the history of the place, to the former airport (where great pilots are said to have been able to pick up a handkerchief from the runway out of the flying plane) shall be established, a lighthouse, a room for concerts as a meeting point, the possibility of making music everywhere in the city, an open stage with concerts every noon with a diversified program, a radio station, windflowers, poetry, fairy dust. Many wishes and paintings showed a great desire to express oneself openly in the city and in contact with others.

The way people used *Café des Visions* as a space for encounter and discussions showed how little they are involved in the planning of the new city.

5. CONCLUSION

From the above-mentioned social demands of users, demands on the design of public spaces can be derived. The simplicity of some wishes just show, that the basic needs are not met yet. People want to be invited to linger. The most frequently mentioned wishes at the Café are easily met and not expensive: green that gives the place its atmosphere, shade and comfortable seating. Places that beckon also promote communication. This requires movable seating that allows eye contact during a conversation and a flexible group size to speak at a pleasant distance.

A music garden is an example of an unconventional idea that has the potential to give a place a unique atmosphere. It would become unique and different from others and give passers-by a real choice as to where they wish to spend their time.

The moribund public described by Habermas needs new meeting points that are suitable and not commercially oriented. If there is no gap between customers and service providers, humans meet at eye-level. The responsibility for the place is then shared by everyone.

Therefore, *Café des Visions* recommends that every neighbourhood should have a village square that is planned and constructed by the inhabitants. How this can be achieved is shown at Park Fiction, a public park on the riverbank of the Elbe in Hamburg. With the support of the two artists Christoph Schäfer and Cathy Skene, the neighbourhood fought against the planned building complex and created, by means of an artistic production of wishes a park with unique elements like a flying carpet made of grass surrounded by an Alhambra mosaic – the person who made this wish thought the Alhambra to be the most beautiful place in the world. The park was constructed by a collaboration of specialists and ten years after the inauguration it is still maintained by the neighbourhood.

An artistic collection of wishes with its discussions on the street involves people, that wouldn't take part at conventional participatory meetings. It directly connects ideas and spaces. With the artistic method of open thinking an important step of a planning process for a public space can be made accessible to many people, it can build a bridge between professional planners and users in advance and provide a base for an ongoing collaboration. It brings back the imaginary to planning and to public spaces and it makes the creation of city live to an oeuvre in the sense of Henry Lefebvre.

Track 11: Sustainable Neighbourhoods: Applications and Case Studies

Session 5.8: Sustainable Neighbourhoods - Case Study Review (1)

Learning from The Lessons of Transit-Oriented Development to Improve Urban Planning in China

Frederic Daniel DU VERLE[a], Becky PY LOO[b]

[a] *Archimedialab, Germany / Mainland China, f.du.verle@gmail.com*
[b] *The University of Hong Kong, Hong Kong S.A.R, bpyloo@hku.hk*

ABSTRACT

A holistic evaluation of the built environment's sustainability should not be limited to common efficiency criteria such as construction standards or energy consumption. It should also consider the sustainability of its direct and indirect impacts of people. Transit oriented-development (TOD) neighbourhood's built environment has proved to contribute to more sustainable transportation, but Loo and du Verle (2016) push beyond the realm of transportation to consider the potentially sustainable benefits of TOD for city planning. Practical experience and studies in China show that despite China's efforts to turn to a more sustainable society, its urban development faces many challenges. Cities and towns still mainly follow a grid-pattern road network and wide multiple-lane vehicular roads. Planners and policymakers have little flexibility for interventions, leaving room for private developers to develop super-sized blocks as "typical" development that is far beyond the actual density or energy-saving expectations for sustainable development.

This work explores the possibility of transferring the TOD's built environment characteristics and approach to non-TOD Chinese neighbourhoods (as major transit stops may not be implemented or found everywhere) in order to improve their sustainability not only through promoting walking and more sustainable travel options but also by improving the quality of the overall built environment. The neighbourhood-scale approach helps to integrate policies and design guidelines for a more sustainable environment while preserving the interests of stakeholders. A fully integrated sustainable approach should be established through a highly collaborative planning platform involving every actor, from government to stakeholders, and guided by clear quantitative reference systems.

Keywords: transit-oriented development, built-environment, China

1. TOD OPPORTUNITIES BEYOND SUSTAINABLE TRANSPORTATION

Transit-oriented development (TOD) has been seen as an efficient policy to address modern urban planning's issues through the promotion of sustainable urban transportation aiming to reduce greenhouse gas (GHG) emissions to a certain level by a certain date, or as low as possible by fighting electricity and transport fuel, identified as the main cause of carbon emission (Brown, Sothworth and Sarzynski, 2008). This application of TOD does not offer a fully sustainable solution to transportation challenges around the world. By focusing mainly on carbon reduction targets, the social and economic aspects that composed the sustainable approach are often neglected (Loo and Chow, 2006; Preston and O'Connor, 2008).

A life cycle approach brings a more comprehensive sustainability by not only tackling down the effect but also looking at the causes for a change of development forms and behaviour. Applied to TOD, a life cycle approach would mean to use principles that can reduce indirectly the need of transportation but also offer a full range of alternatives in addition to the mass transit around which the neighbourhood is organised. The United Nation [U.N.] (2014) identified five (5) main principles to improve sustainability of neighbourhoods: 1 – "adequate space for street and an efficient street network", 2 – "high density", 3 – "mixed land use", 4 – "social mix" and 5 – "limited land-use specialisation". These principles are applied in a TOD through the management of the three (3) core dimensions of its built environment (density, diversity, and design).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Chinese urbanisation is facing important challenge that has urged for a more sustainable change. Many Eco-Cities projects have been developed in China in the past decades, but for those that are implemented, they often results in failure for different reasons such as lack of policy support and coordination between the different parties. Eco-cities are often based on a pilling up of new technologies aiming for at zero-emission target that is complicate to reach when applied at different local contexts. Most of the time, planning results into a standard form of development that creates super-sized blocks (of 500 to 800 metres long on each side) that are far from being sustainable. The use of green technologies only is not enough to create a sustainable environment. On the other hand, Loo and du Verle (2016) have highlighted the potential of TOD's principles beyond the realm of transportation by identifying different types of TOD neighbourhoods from a same city. In this paper, we are going deeper and explore the possibility to transfer TOD's 3D characteristics into a non-TOD neighbourhood to see whether sustainability can be increased without the presence of transit stations.

2. TRANSIT-ORIENTED DEVELOPMENT PRINCIPLES AND VALUE

TOD policy is a tool to create a healthier community development model with a stronger economy while reducing the carbon footprint and greenhouse gases (GHG) emissions by being centred around a quality public transport station in order to offer a more sustainable alternative form of transportation; this is achieved by creating a mix of housing, retail and/ or commercial development and amenities, which are all integrated into a walkable neighbourhood to create opportunity and feasibility of trips through better accessibility (Handy, 2002, Cervero, 2009, Loo, 2009, Loutzenheiser, 1997). To ensure its good implementation TOD's built environment is commonly defined by the 3Ds as core elements to support its sustainability (Cervero and Kockelman, 1997). In addition to the direct benefit related to the increase of public transport usage, TOD generates a lot of indirect co-benefits, such as helping to have fewer cars in the streets that affect different aspects of the development, e.g. its liveability, quality of life, social equity, and many others (Cutts et al, 2009; de Nezelle et al, 2011; Litman, 2006). Many of those co-benefits, and many more, can be directly associated with the 3Ds of the TOD (Loo and du Verle, 2016). Some studies, following more closely the principles of the UN, add two (2) more dimensions to bring the core characteristics of the built environment to 5Ds, by considering the distance to transit and destination access. However, in their study, Loo and Du Verle (2016) found that variables defining these additional dimensions could also be classified in one of the original 3Ds. Hence, destination access or accessibility is often explained by the variables measuring the number of intersections, the different types of public transport and the number of lines available, or the number of exits to a transit station. These same variables can also respectively be classified as part of the density, diversity or design dimension. In view to avoid any redundancy of variables or misclassification the use of the 3Ds was preferred over the 5Ds.

Many good lessons of TOD can be found to create a better environment in a neighbourhood where a transit station has been built or to support the ridership of the mass transit. To ensure the success of a TOD its mass transit has to be made successful through policy development and organisation of its surrounding built environment to justify the existence of a transit station. Those successful examples show how after changes in the built environment (densification, increase of the different activities, new design connecting to the mass transit, etc.), the new neighbourhood together with efficient mass transit system make possible the creation of a more sustainable environment. Beside projects such as the redevelopment around the BART stations in the San Francisco Bay area (National Research Council [U.S.], 1980), Hong Kong is a good example, with many successful TOD neighbourhoods, where the built environment's characteristics are carefully considered and integrated to mass transit station planning with programme strategies such as the Rail-cum-Property model of the MTR Corporation (Cervero & Murakami). The 3Ds play an important role in the sustainability of those new neighbourhoods. However, those examples are always centred on neighbourhoods including a mass transit stations. Yet, when often in new development or new neighbourhood, there may not be a lack of sustainability, there is no immediate possibility to integrate it with a mass transit system.

3. TRANSFERRING/ APPLYNG TRANSIT-ORIENTED DEVELOPMENT PRINCIPLES IN NON-TRANSIT-ORIENTED DEVELOPMENT AREAS

3.1. The three dimensions (3Ds)

The 3Ds bring valuable co-benefits for a more sustainable development; they also are the core characteristics of the built environment that help to identify TOD into different categories. To apply TOD principles in a non-TOD area the 3Ds characteristics have to be transferred to that area. TOD has been categorized into different types defined by the nature of their functions identified through the characteristics of their built environment and, on their integration to the mass transit system. However, 3Ds variables cannot be independently analyzed directly from non-TOD neighbourhood as the classifications of the TOD-neighbourhood show that they are the result of complex association of different variables coming from each dimension and not only from one of them. In a development where there is no transit-station neighbourhoods that can be used as reference to identify the different neighbourhoods, key centres are identified. In non-TOD areas, those ‘centres’ are a development pole with key functions (i.e. economic pole, educational pole, administrative and institutional pole, etc.) that structure the development. The non-TOD centres (or neighbourhoods) can be compared to TOD categories by the nature of their functions for the application of TOD principles.

3.2. Relevancy of local context

Loo and du Verle (2016), highlight the importance of using the district-level analysis for TOD, as even within a same given city, it is not a homogenous group, especially when even in a dense city all residents are not within a walking distance (defined as 500 metres) of a transport station. Often, study of TOD and its transportation system use the regional or city scale to analyse the stock of the different transportation systems and how they work together into a coherent network. In this study the analysis is not looking at the transportation aspect of TOD but rather at the built environment that is best understood at the neighbourhood scale. Moreover, a local context helps to clarify the identification of the neighbourhood and the possible interventions of the government.

3.3. Methods

The authors explore how it is possible to apply TOD principles through the transfer of its built environment’s 3Ds characteristics, to neighbourhoods without transit stations in view to see if that can increase their sustainability. In previous research five (5) types of TOD have been identified in Hong Kong (Loo and du Verle 2016). These five types of TOD were identified through a principal component analysis that reorganized the variables of each 3Ds into factors that describe the different type of TOD neighbourhoods. Among the 20 collected variables classified into one of the three dimensions (density, diversity, or design) by Loo and du Verle (2016), most of them consider sustainable principles listed by the UN (accessibility, social mix, etc.). The variables used were the following for the density dimensions: 01 – Population density, 02 – Employment density, 03 – Residential development intensity, 04 – Commercial development intensity, 05 – Mixed commercial-residential development intensity, and 06 – Overall development intensity. For the diversity dimensions the variables used were: 01 – Comprehensive development, 02 – Diversity of land uses, 03 – Household size, 04 – Diversity of housing types, 05 – Levels of other public transit services, 06 – Convenience of other public transit, and 07 – Income. Finally, for the design dimension the variables identified were: 01 – Road connectivity, 02 – Road density, 03 – Open space, 04 – Covered walkway (to the mass-transit station), 05 – Expressways (in the neighbourhood), 06 – Exit system (of the mass-transit station), and 07 – Retail (within the mass-transit station)

The nature of each TOD-neighbourhood is compared to the nature of non-TOD neighbourhoods from the case study to find the most relevant categories to be matched together for the transfer of the 3Ds from one into the other. TOD categories that are mostly defined by their mass transit station or their integration to the station (e.g. Station-type TOD and integrated-type TOD) are automatically discarded. Once the different types of TOD are selected, their 3Ds variables are listed to be extracted and analysed from the non-TOD neighbourhoods. Once again, variables that are directly connected to the mass transit station are not applicable in the case of a non-TOD neighbourhood and are discarded. The case study is a masterplan for a new development in China from the professional experience of one of the author, which aimed to reach Eco-City standards. This case study has been chosen, even though it is not yet totally built or occupied by any resident, because of the knowledge of its planning details, creation process involving different parties, and reduced gap between the context of the two case studies.

4. RESULTS OF A CASE STUDY IN CHINA

4.1 Presentation of the case study

The masterplan follows the “eco2city” approach developed by The World Bank and based on a “Life Cycle Approach” to create a resilient local economy supported by strong ecological integration. This approach is a guide for the use of powerful sustainable tools and planning process, such as the important "Charrette" (an advanced type of workshop) for a comprehensive collaborative platform for every party to be integrated into a more successful planning (Roggema et al., 2014). The study case is a 5 km² university town at the entrance of a 100 km² new town to be developed on the newly reclaimed land on the East coast of the Nantong municipality, in Jiangsu. The was developed and organised between strong centres of activity, to support its own development until it can be later fully integrated to the rest of the city. The major roads crossing the site are one of the most important consideration, they connect the inhabitants of the future new town to the regional road and to the potential future train station. The new planning has also to integrate existing built or under construction infrastructures from a previous government's plan. Various factors restrained the modification of the plot size. Therefore, the planning focused on increasing the sustainability of the development from within the super-sized block by planning for the use of local resources for constructions and greening, the integration of the plot to the road and the use of new technologies as some of the solutions to improve the sustainability.

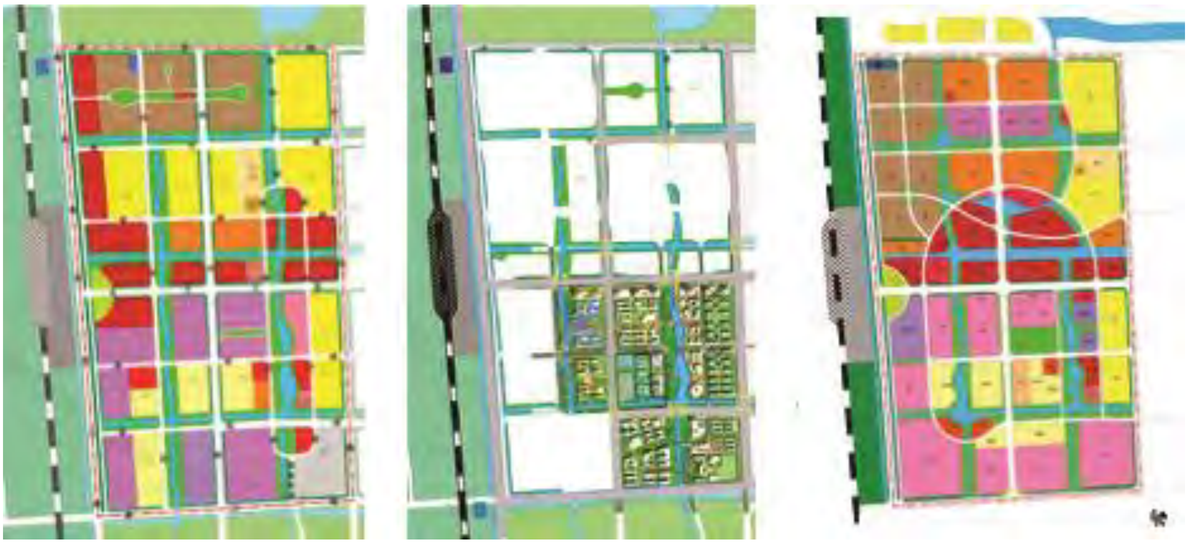

Figure 1: Nantong's masterplans - From left to right: original land use plan, existing or under-construction plan, company's final land use proposal

In this case study, six (6) types of neighbourhoods are classified into centres based on the nature of their functions and, none of them can be classified as TOD because of the absence of certainty of a mass transit station within or close to the neighbourhoods. The different centres identified are "matched" with TOD neighbourhood following the description of their nature as it is presented in Table 1, which helps to select the relevant TOD-neighbourhoods for comparison.

TOD neighbourhoods types	Nantong's centres types
CBD-type	- Business incubator and retails centre - Commercial and retails centre
Balanced-Type	- Living centre
Residential-Type	- Residential centre
N.A.	- Factory and production centre
N.A.	- University centre

Table 1: List of the different types of neighbourhoods found in the projects compared with corresponding types of neighbourhoods identified from the different categories of TOD.

The 3Ds' variables available in the case study are listed in Table 2, with the type of TOD in which they are found. Some variables were discarded because of the lack of data or simply because they were directly related to the transit station (e.g. number of station exits). Two categories of centre ("factory and productions centre", and the "university centre") cannot be represented by any type of identified TOD-neighbourhoods. The variables selected showed the importance of the physical aspect of the built environment in this analysis, especially because the project is also too recent to integrate complete and valid socio-economic variables. Interestingly, a similar number of variables for each dimensions (density, diversity and design) have been selected which, help to provide a more comprehensive and balanced study of the 3Ds, when other research may focus on one (or two) particular dimension and neglect the others.

Original 3Ds variables	Indicators	TOD-Type
(Density-1) Population density	Number of residents / land area	Residential-Type
(Density-2) Commercial development intensity	GFA of commercial use / land (ground) area for this use (m2 per km2)	CBD-type
(Density-3) Overall development intensity	Total GFA / total land (ground) area (m2 per km2)	CBD-type
(Diversity-1) of land uses	Simpsons Index of land uses (Loo and Lam,)	Balanced-Type
(Diversity-2) Levels of other public transit services	Total number of bus lines* / land area (km per km2)	CBD-type
(Design-1) Road connectivity	Number of road junctions / total area	CBD-type
(Design-2) Road density	Road length / total area (m per km2)	CBD-type, Balanced-Type
(Design-3) Open space	Share of built open space / land area	Balanced-Type

Table 2: List of remaining 3Ds' variables of selected TOD categories transferrable to non-TOD neighbourhoods

Due to the early planning stage of the study case not enough data is available to measure many variables that defined some of the type of TOD neighbourhoods identified. The few remaining available variables measuring the "residential-type" and "balanced-type" neighbourhoods are too reductive and have a too high value on the Skewness test. All the remaining variables that can be collected and retained from the study case are corresponding to the CBD-type. The variables compared to the characteristics of the centres identified during the planning process of the case study suggest that the CBD-type neighbourhood is more easily transferable in early planning stage to a non-TOD neighbourhood for the improvement of its sustainability. The variables explaining the CBD-type of neighbourhood highlight the importance of increasing road and transport connectivity through higher number of junctions, road length density, number of public transport lines, all in a denser development within the boundaries of the neighbourhoods or centre. This means that such accessibility must be implemented within the super-sized block of Chinese new planning projects. Therefore, an important work about accessibility and design integration to its surroundings must be done on these super-sized blocks. Despite the limitations of the study case and lack of data available, these preliminary findings highlight important points in the planning strategy that requires the collaboration of the different parties involved in the planning process.

4.2 Discussion about the dynamics of three parties involved in planning in China

Eco-city projects in China are often failing because of the lack of coordination between the three parties of a project, which are 1 – the (local and central) government; 2 – the stakeholders; and 3 – the planners.

Since 2012 the central government in China has shown its involvement for the development of Eco-City for triggering the country's shift toward a more sustainable development (Yu, 2014). However, even supported by an elaborate assessment system, the policies applied remain limited and continue to promote a traditional development model by being based on the same economic development policy since the 1980's and with mostly only incentive actions which are often ignored by local governments (Yu, 2014; Li, Zhang and Li, 2011). Local governments are subjected to a lot of pressure from higher levels to increase regional GDP, also used for the evaluation of the local government and senior leader, and to manage the region with a limited revenue coming mostly from land leasing and the tax system (Yu, 2014). Therefore, cities by growing faster become more complex with more levels of governance that require delegation of power. This context generates important conflicts for policy development of a city, resulting in a major challenge to create a real coordination, transparency and accountability of Chinese cities development (Hald, 2009).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Meanwhile, a "marketized" planning is being developed with the increasing involvement and influence of stakeholders set free by the lack of regulation and weak control capacity of the municipality for planning. In practice, it is easy to observe that developers often impose their own schemes of development, aiming for a minimum cost and quick financial return, to a government struggling to reach its economic development goal. They strengthen the standard development model by increasing the comfort and luxury but with a total lack of basic sustainable approach. Life span or energy savings become strange concepts and distant from the local population that can no longer understand the need or the advantages of a more sustainable approach (Yu, 2014).

Government's planners have a really "engineering approach" to support this whole process of "marketized" planning, offering more flexibility to developers. This results in a fragmented planning, organised into super-sized blocks that each independent developer builds following its own strategy. The main challenge of private firms is to integrate their projects to the rest of the development. Therefore, planners should focus on the development of collaborative platform to 1 – to increase population awareness toward sustainable planning, 2 – show to the government alternative economic and framed planning development and, 3 – involve stakeholders for ensuring their investment into the project and reassuring them about its profitability. The case study presented here is the results of such collaborative approach, allowing full participation of all the parties, trying to reach a certain level of sustainability of the projects despite compromises.

5. LESSONS LEARNT AND FUTURE DIRECTION

In this paper, we investigated the recognition of TOD's value beyond transport impacts to increase the sustainability of new development. In this first approach, it seems that one particular type of TOD would be more appropriate to use for the transfer of its built environment characteristics in a non-TOD neighbourhood. If it is confirmed that will be a great opportunity to increase quality of life and other sustainable dimensions of a neighbourhood through the co-benefits of the TOD's 3Ds (Cutts et al, 2009; de Nezelle et al, 2011; Litman, 2006).

However, in China, new development projects, though aiming at a more sustainable approach, are in too many aspects following the super-sized block planning model. This contradiction is often forced by a marketized planning that is required to ensure the continuity of any projects in the Chinese context. Until the super-sized block with unique land use is abolished, a clear effort of collaboration between the different planning parties of a project is required to create a better integration and coordination. Meanwhile, statutory planning guidelines should be implemented to support the increase of sustainability through the transfer of built environment characteristics using the various TOD-neighbourhoods identified as reference guidelines into comparable non-TOD neighbourhood. This new scheme, rather than drastically undo the super-sized block, should regulate them from inside by considering them as small neighbourhoods (the size of which being almost comparable to small TOD neighbourhoods). These guidelines should aim at the regulation of each super-sized block following the benchmark of a corresponding type of TOD-neighbourhood based on the nature of their functions for increasing their standards following principles such as the level of accessibility through design guidelines prescribing the number of public roads and intersection to be built within the super-sized block, or how to integrate it to its surroundings and the main roads. A more effective political structure, avoiding internal competition, is needed to support these development and implementation policies. Municipal governments, policy-makers and the population need to recognise the co-benefits of TOD's built environment, to ensure its application through a clear local statutory planning guidelines, supported by a reliable and quantifiable sustainable planning evaluation system that establish normative standards. Such standards already exist in architecture such as the LEED program (in USA), or the DGNB (German Sustainable Building Council) that include urban planning criteria (e.g. type of land use of the site – criterion #15) in Germany. Until such guideline are implemented, "Charrette" has been proved to efficiently integrate all the parties within a project, and despite the need for compromise, it can ensure its full realisation for a potential better success.

ABSTRACT

Found in 1963, The Chinese University of Hong Kong (CUHK) has developed from a student population of about 3,000 to 28,000 in 2016. In the course of development, the Campus Master Plan (CMP) has provided an exemplary sustainable framework to balance the growth of the University in achieving teaching and research excellence under her unique college system and campus environment. The CMP consists of six key planning precepts:

- Making a sustainable campus
- Places for education and research activities
- Enhancing college life
- A pedestrian friendly campus
- Conserving places of value
- A landscape of vital importance

Keywords: green campus, master plan, sustainable neighbourhood

1. INTRODUCTION

The mission and vision of CUHK:

- To assist in the preservation, creation, application and dissemination of knowledge by teaching, research and public service in a comprehensive range of disciplines, thereby serving the needs and enhancing the well-being of the citizens of Hong Kong, China as a whole, and the wider world community; and
- To be acknowledged locally, nationally and internationally as a first-class comprehensive research university whose bilingual and multicultural dimensions of student education, scholarly output and contribution to the community consistently meet standards of excellence.

Found in 1963, CUHK with a suburban campus of about 137 hectares has developed from a student population of some 3,000 to a population of about 28,000 in 2016. Following the initial development plan by W. Szeto & Partners, a master planning process is being carried out in response to the strategic objectives to address the increased student population and the changing requirements of the academic disciplines.

The CUHK Campus Master Plan (CMP) is an exemplary framework to balance the growth of the University in achieving teaching excellence and research achievements via CUHK's unique college system and campus environment. In the process, consultations and engagements are conducted with the stakeholders to gather their aspirations and feedbacks.

2. CUHK CAMPUS MASTER PLAN

The vision of the Campus Master Plan (CMP) is to enable the University to be an exemplar of sustainable development by balancing the enhancement of its campus environment with the conservation of its natural heritage. The CMP is conceived as a living and continually developing document and it consists of six key planning precepts as detailed in the following sections:

2.1 Making a sustainable campus

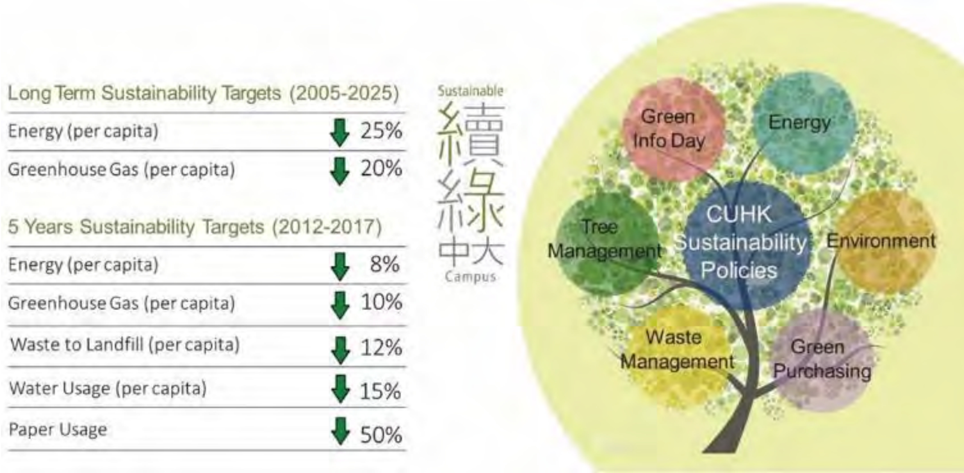
The University pledges its commitment to continuously improve the environmental quality of the campus, putting the principles of sustainable design at the heart of campus development, and has been acclaimed for her innovations and efforts, e.g. Green Building design excellence, measures for recycling, uses of renewable energy, energy conservation, wastes management, tree and ecology preservation, and carbon audit on existing buildings, etc.

Reporting to the Campus Planning Committee chaired by the Vice-Chancellor, the University's dedicated offices such as the Campus Development Office, Campus Planning and Sustainability Office, and Estates Management

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Office collaborate to carry out the campus planning, building and infrastructure construction, sustainability education and operations including energy audit and incentive schemes, etc. Green Building design principles are implemented to ensure that the built environments are friendly, inclusive and sustainable.

With the concerted effort and the implementation of the Energy Saving and Conservation Plans, the University has reduced energy and general waste progressively in the past years.



The University has adopted many initiatives in reducing the overall carbon emission. Weiyuan Lake 未圓湖, a genius Loci for Chung Chi College at the foothill, is used as a storage tank of natural rainfall. It helps to regulate the micro-climatic of the surrounding built environment and reduce the energy used for cooling. It is also home to over 200 plant species including over a third of all tree species in Hong Kong. After purification and sedimentation, the grey water from this alternate source is used for irrigation, street cleaning, A/C cooling and contributes about 27% of the daily water consumption of the University. In the reduction of energy and water consumption, other initiatives such as installation of daylight/ motion sensors to control lighting & AC, energy efficient LED lighting fittings, roof gardens, electric vehicles & charging points, wind turbines for street lighting, district cooling/water-cooled chiller system, solar water panel & photo-voltaic panels in student hostels, water-saving fixtures and reuse of used water collected are also adopted.

2.2 Places for education and research activities

The CMP develops the concept of clustered and zoned development for disciplinary teaching and research activities with a view to strengthening connectivity between the existing and new facilities. While the academic facilities are zoned in proximity clusters to encourage social interaction and academic collaboration, dedicated landscape features, open spaces and vertical transportation devices were planned in parallel to enrich the Walking Campus experience. This enables the efficient use of resources, convenience of access and optimizes the land use.

In designing these facilities consideration such as natural day lighting, visual comfort, indoor environment quality, thermal comfort, acoustics, natural ventilation are implemented such as window wall/ skylight to maximise natural day lighting, roof greening for enjoyment, acoustic windows, etc.

2.3 Enhancing college life

Of all Hong Kong universities, CUHK is the only one that offers a college experience. College programmes and activities complement the formal curricula by delivering whole-person education and pastoral care. The college system also encourages intimate interaction among teachers, students and alumni.

CUHK was established in 1963 as a University with a federal constitution. To the constituent colleges of Chung Chi, New Asia, United and Shaw, Morningside, S.H.Ho, C.W.Chu, Wu Yee Sun and Lee Woo Sing have recently been added, bringing up the total number of colleges to nine. The spatial organization of the University and the colleges is expressed in terms of their facilities as well as the clustering and scale of buildings in association with the planning of open space and circulation spines.

While CUHK's administration and academic facilities are mostly located in the Central Campus along the axis of the University Mall, the colleges are planned in a satellite pattern, maintaining their identities with different culture, architectural expressions and building clusters. Scale of the colleges ranges from 300 to over 3,000 students. Apart from the hostel blocks, the college complexes provide a variety of indoor and outdoor amenities, activities and gathering spaces. In the design and operation of these facilities, Green Building and 'Eco-Habitat' design principles are adopted to encourage whole-person development and interactions outside the classrooms.

College life is a vital part of student wellbeing and education in CUHK; dedicated programmes are conducted in Colleges to cultivate environmental awareness of the students and to achieve a green and energy conscious living style. In some new hostel blocks, 'Smart meter on Progressive rate Scale for Top-up' are installed for students to keep track of their electricity consumption for bedroom A/C, fridge, fan or heater, etc.

Campaigns in Colleges such as 'Love Food Hate Waste @ CUHK' guided students to reduce their Leftover Meal 剩宴 to more than 20% per year and trained more than 50 student ambassadors (有衣食達人) in the practice of 'Green Living'. 'Green Student Societies' are organized and 'Year-End Hostel Check-out Scheme' also recycles more than 10,000kg of clothes, paper glass, household ware, etc. from 34 hostels.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.4 A pedestrian friendly campus

The CUHK campus was found on a hilly terrain with a level difference measuring over 150m from the Mass Transit Railway along Tolo Harbour to the mountain top where two founding colleges and their iconic water towers are located. While vertical circulation poses a major challenge on campus, the CMP plans to reinforce the major pedestrian spines and connect the various campus terrains by creating a complete and desirable network through link bridges, covered walkways, grand steps and communal gathering spaces. This walkway infrastructure is further assisted by lifts and escalators in new buildings built along the major circulation routes.

2.5 Conserving places of value

The CMP recommends the establishment of a methodology for identifying places with unique values that should be conserved; and assess the implication of any intervention to a 'Place with Culture Significance'. This helps to enhance and extend the identity of the University while maintaining coherence in the campus environment.

2.6 A landscape of vital importance

The CMP promotes a green and humanistic framework to promote the enjoyment of the landscape and visual amenity of the surroundings by creating a comprehensive open space network within the campus. The Landscape Strategy Plan recommends the treatment of different types of landscape zones, identifies new nature trails within the campus to enhance the greenery and to supplement hard landscape works.

Under the steering of the Campus Development Office and Campus Landscaping Enhancement Committee, a new round of Campus Landscape Master Plan studies is being carried out with consultants to review the landscape opportunities and constraints, and to refine the strategy and plan for sustainable development.

3. SUSTAINABILITY ACHIEVEMENTS AND AWARDS

4. NEW CHALLENGES AHEAD

Universities are complex organizations with multiple roles and functions. They are not institutions of higher learning where knowledge is created, disseminated and exchanged; but also communities both consuming and supplying services from and to industry, corporations and professions. At the same time, the increasing mobility of students, rising interflow of the world populations, advancement in information and communication technologies, enhanced human connectivity have shifted the traditional geographical boundaries of industries and transformed the higher education landscape globally.

For CUHK to stay competitive, face new challenges and excel, we shall require a world-class environment that supports the academic endeavours in the information age through strategic allocation of human, financial and physical resources. Our goals are to foster a sustainable campus with professional design and management of our facilities and infrastructure to support the University's strategic developments.

CUHK has lately received the Green Building Award 2016 (Merit Award in Green Building Leadership Category) from the Hong Kong Green Building Council in recognition of her commitments in sustainable campus planning and Green Building design. To meet the tough challenges ahead, some key strategies for continuous research and development are as follows:

- Enhance campus infrastructure and facilities to support new university initiatives;
- Build and maintain a green and sustainable campus to meet challenges in Hong Kong and globally in the post-COP21 era;
- Use space more efficiently to promote social and academic exchanges and to meet new teaching and research needs;
- Strengthen IT infrastructure and governance for e-learning, effective data sharing and management;
- Promote green living for the university community; and
- Pursue advancements in sustainability planning and design through knowledge transfer, research and development.

ABSTRACT

The expansion of Tai Po Water Treatment Works (WTW) forms part of the overall strategy to enhance the resilience of water supply in Hong Kong. The project involves uprating the existing water treatment facilities and constructing additional components in order to increase the output capacity of the WTW from 400 Million Litres per Day (MLD) to 800 MLD. Tai Po WTW incorporates sustainable features in the existing and new water treatment facilities, particularly in the aspects of water management and energy efficiency.

Alternative water sources (such as rainwater, grey water and used sample water, etc.) will be exploited to minimize use of potable water in the WTW. Rainwater and sampling water from the water treatment process will be collected for use in landscape irrigation, toilet flushing and cooling tower in the WTW. A life cycle cost analysis has been conducted to confirm the economic viability of using the alternative water sources.

The water treatment process and delivery of fresh water produced from the WTW to the customers is electricity-consuming. Tai Po WTW is designed to provide a gravity flow conveyance system in the treatment process in order to minimize energy use. High efficiency pumps are used for conveying fresh water to service reservoirs and service water for dosing chemicals in the treatment process. A water energy model has been made to compare the energy intensity of Tai Po WTW against the benchmarks established by the Electric Power Research Institute (EPRI) and the Water Research Foundation (WRF) regarding the energy consumption in the production of fresh water from municipal water treatment works. The comparison shows that the energy performance of Tai Po WTW is on a par with the best performing water treatment works in the world.

Keywords: Tai Po water treatment works, energy, water management

1. INTRODUCTION

Tai Po water treatment works (WTW) and Sha Tin WTW are two major WTWs in Hong Kong, of which the total treated water output serves over 3 million people. As Sha Tin WTW has been in service since the 1960s, Water Supplies Department (WSD) plans to carry out in-situ reprovisioning of Sha Tin WTW. To maintain reliable water supply in the territory during the partial shutdown of Sha Tin WTW for reprovisioning, it is necessary to carry out the Tai Po WTW Expansion Project to increase its treatment capacity from 400 million liters per day (MLD) to 800 MLD . Upon completion of the expansion works, with the increased treated water output capacity, Tai Po WTW can take up part of the existing load of Sha Tin WTW for supplying fresh water to significant parts of Kowloon, Central and Western districts of Hong Kong Island (see Figure 1). This will pave the way for the in-situ reprovisioning of the Sha Tin WTW. Over the long term, the expansion will allow a more balanced distribution of treatment capacity territory-wide and enhance the reliability and flexibility of the water supply in Hong Kong. In addition, WSD targets to improve the treated water quality of the expansion treatment facilities by using ozone to achieve 4-log inactivation (i.e. 99.99% inactivation) of cryptosporidium and giardia.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 1: Supply zone of Tai Po WTWContent

Apart from meeting the water supply objectives mentioned above, since sustainable development is gaining greater awareness and of interest to the people of Hong Kong, WSD aims to set a good example to the community by incorporating various sustainable features in the existing and new water treatment facilities of Tai Po WTW under the expansion project, particularly in the aspects of water management and energy efficiency.

2. WATER MANAGEMENT

2.1 Introduction

Water is one of the most treasurable resources. Therefore, as the government department responsible for the water supply in Hong Kong, WSD attributes significance to water management in the Tai Po WTW Expansion Project.

In Tai Po WTW, a considerable quantity of sludge (i.e. the residual removed from the raw water during the treatment process) is generated every day. The sludge still has high water content. To minimize the loss/ wastage of water, the sludge is designed to undergo further treatment so as to collect the water in the sludge and return it to the inlet for re-treatment.

Furthermore, WSD carried out a comprehensive study on the feasibility to use alternative water sources for the non-potable applications including landscape irrigation, toilet flushing and cooling systems in Tai Po WTW. Some possible alternative water sources in Tai Po WTW include (a) raw water or partially treated raw water, (b) rainwater, (c) ground water and (d) used sample water. The study revealed that rainwater and used sample water were two alternative water sources which were technically and economic viable for non-potable applications. More details regarding the alternative water sources are discussed in paragraphs 2.2 – 2.7 below.

2.2 Rainwater

A rainwater harvesting system will be installed in Tai Po WTW. There are many design considerations for the rainwater harvesting system. For example, the harvesting areas must be restricted to clean surfaces, like building roofs, to ensure that only relatively simple treatment are required for harvesting rainwater. In addition, the quantity of rainwater harvested will depend on the harvesting area and the seasonal variation of rainfall. Too small a system may not be cost-effective while too large a system may incur high maintenance cost and become a wastage during the dry season. The system should therefore be designed to an optimized capacity with thorough consideration of the site constraints, rainfall variation and cost.

2.3 Used sample water

For monitoring the quality of the treated water against the required standards, sample water will be taken from various locations of the treatment process for analysis. Excess or uncontaminated sample water will return back to the treatment process. Sample water which is highly contaminated after analysis will be disposed of, while slightly contaminated sample water will be used for non-potable applications. A schematic diagram showing of the conveyance and collection arrangement of the sample water is shown in Figure 2 below.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

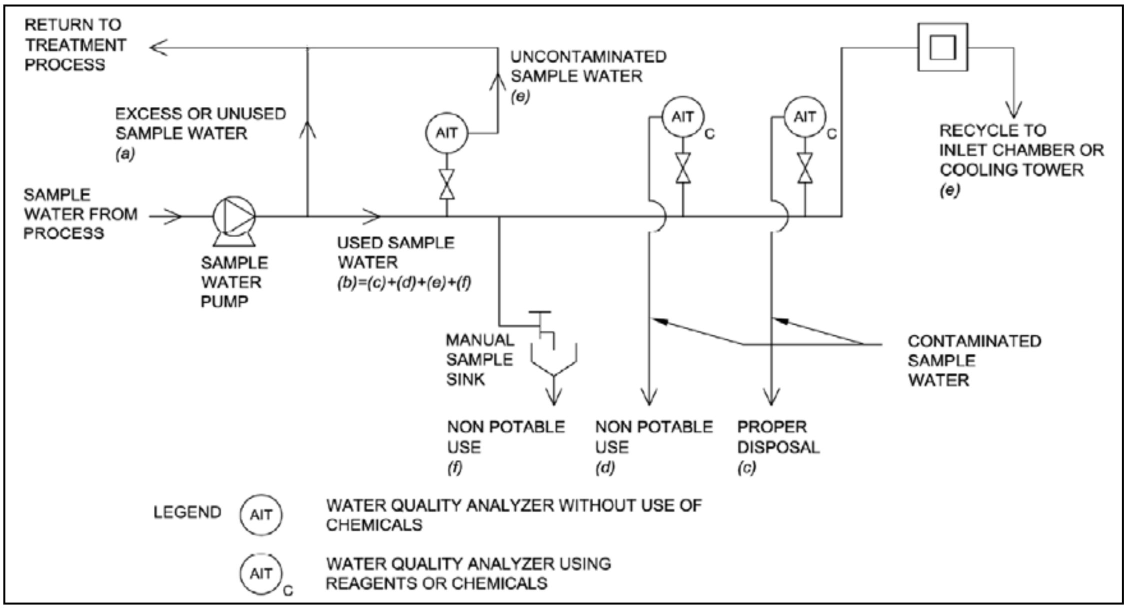

Figure 100: Conveyance and collection arrangement of sample water

2.4 Water use for irrigation

The total proposed landscaping area in Tai Po WTW is about 10,000 square metres (m^2). The estimated total daily water demand for irrigation of the landscaping area is about 75 cubic metres (m^3).

With reference to the rainfall statistics from the Hong Kong Observatory between year 1980 and 2010, the irrigation water requirement is determined based on the following assumed annual rainfall pattern:

- About 40 percentage (%) of the days in a year with rainfall exceeding 7.5 millimetres (mm) (i.e. heavy rainy days);
- About 15% with no rainfall (i.e. no rain days); and
- About 45% with average rainfall of 3.1 mm (i.e. moderate rainy days).

In heavy rainy days, no further irrigation to the planters is required. In no rain days, no rainwater can be harvested and used sample water will be used for irrigation. In moderate rainy days, the rainwater harvesting system will collect rainwater for irrigation. Due to the limitation of the sizes of the storage tanks, only 10.5 m3 rainwater can be harvested. The deficiency will be provided by used sample water.

For landscape irrigation application in Hong Kong, the quality of irrigation water must meet the public health requirements. These requirements impose limits on: biological oxygen demand, suspended solids, e.coli, pH and also residual chlorine. E. coli levels need to be kept at non-detectable level, with a total chlorine residual to minimize health risks due to usage with proximity to human contact and aerosols that can be inhaled. Therefore, a small water treatment package is provided to treat the harvested rainwater and used sample water before being used in irrigation. The package is comprised of strainer, storage tank, UV sterilizer, chlorinator, sand filter and irrigation pump and pressure tank unit.

2.5 Water use for cooling

Water for cooling system is another non-potable application in Tai Po WTW. There are cooling towers in the Administration Building and Ozone Generation Building (OGB). Sample water from clarity bowls will be conveyed to the cooling tower at the Administration Building. Harvested rainwater and used sample water collected from various treatment process buildings will also be conveyed to the cooling tower at the OGB. The estimated quantity of water reused in these cooling towers is around 75 m^3 per day.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.6 Water use for flushing

Both harvested rainwater and used sample water will be used for flushing purpose in Tai Po WTW. Compared with irrigation and cooling, the quantity used for flushing is relatively small.

2.7 Life-cycle cost analysis

A preliminary life-cycle cost analysis has been carried out to determine the cost effectiveness of rainwater harvesting and reuse of used sample water. The total annual water saving of the rainwater harvesting and used sample water recycling systems is about 47,000 m3 and the estimated payback period is around 20 years.

3. ENERGY EFFICIENCY

3.1 Energy efficient features

Generally, one of the major energy consumptions in WTW is pumping energy. To minimize the pumping energy, a gravity flow conveyance system for the treatment process should be adopted as far as possible. Tai Po WTW is located within a limited footprint on a hill. A multi-level configuration approach for the treatment process is adopted to maximize land utilization. The multi-level configuration approach is to stack a number of treatment units on top of each other (see Figure 3), which poses additional difficulty on the design of the treatment process. With the endeavour of the WSD project team, a one through gravity flow conveyance system with only one pumping station at the end is provided in Tai Po WTW. The pumping station pumps the treated water from Tai Po WTW to service reservoirs located in Kowloon.

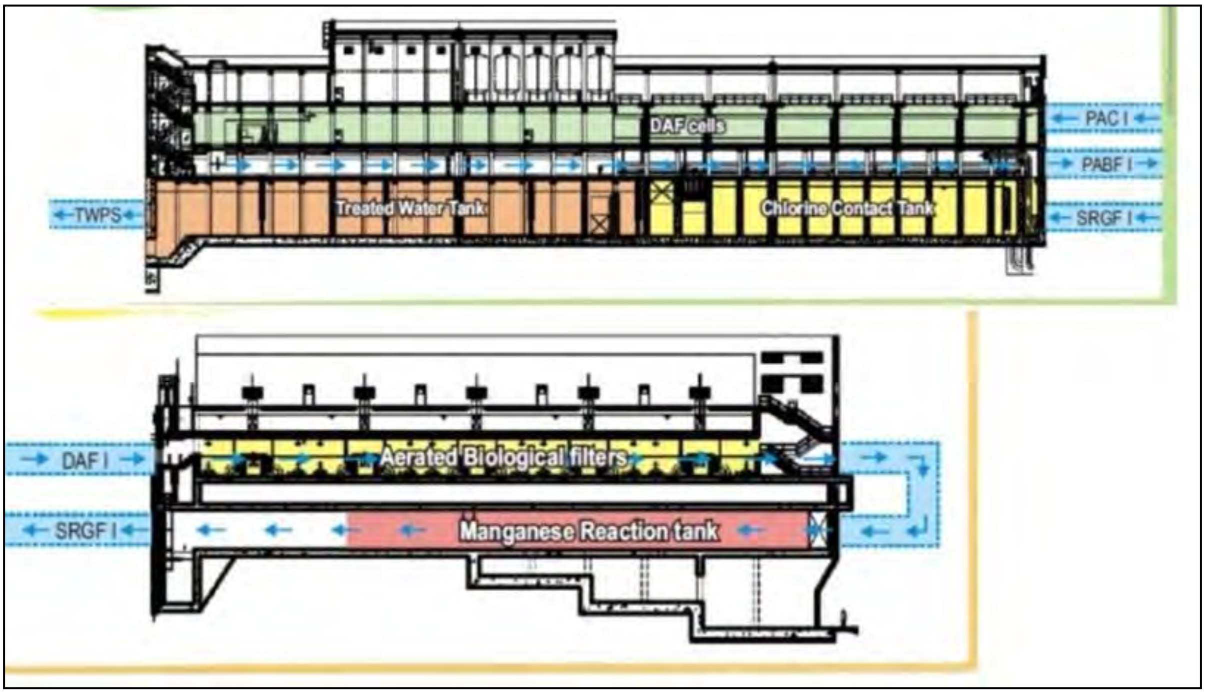

Figure 3: Multi-level configuration approach

The hydraulic profile for Stream II is illustrated in the schematic drawing attached in Appendix A. The high level at the inlet chamber is about 107.30 metres above Principal Datum (mPD) and the low level at the suction culvert of the treated water pumping station is down to 94.80 mPD. In addition, pumps with high efficiency will be adopted in the treated water pumping station of Tai Po WTW. A special coating instead of the standard epoxy coating will be applied to the internal surface of the treated water pumps to further improve the efficiency.

Other energy saving features in Tai Po WTW include:

- Light Emitting Diodes (LED) lighting will be used in the new buildings in Stream II to replace the existing lighting in Stream I progressively.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Variable Speed Pumps will be adopted for different types of pumps in the treatment process, such as backwash pumps, filtrate transfer pumps, sludge thickener feed pumps, etc;
- Security and area lighting will be modified to achieve zone control and dimming control;
- Building and Energy Management System will be installed to control and monitor the building services; and
- Photovoltaic panels will be installed on the roof of the new buildings to generate electricity for use in the WTW.

3.2 Water energy model

To determine whether the operation of Tai Po WTW is energy efficient and what improvement can be made, the project team conducted a benchmarking exercise to compare the energy consumption of Tai Po WTW with other water treatment works around the world.

The Final Report on Electricity Use and Management in the Municipal Water Supply and Waste Industries (The EPRI Report 2013) [1] published in 2013 by the Electric Power Research Institute (EPRI) and the Water Research Foundation (WERF) provides a benchmark for comparison with the performance of Tai Po WTW. In 1996, a joint study was carried out by the EPRI and WERF. The results published describe the link between water and energy; how electricity is used in the water/wastewater industries and how the facilities are managed efficiently. In 2013, the report was updated to take into account new treatment process options using a bottom up approach in determining the Energy Intensity (EI) values (in kWh/million gallons/day) for various water supply unit processes. The EPRI Report 2013 used engineering judgement and was cross-checked with actual water/wastewater treatment plant data in the United States. The EPRI Report 2013 highly recommended that any water treatment plant could be benchmarked against a database of known values, thus providing a valid comparison.

The EI values of various unit process of Tai Po WTW operated at 800MLD (i.e. both Stream I and II are under operation) is determined by projecting the actual operation data of the existing Stream I as well as making reference to the technical information of the proposed equipment used in Stream II. A comparison is made with the data in the EPRI Report 2013. A summary of comparison is shown in Table 1.

	EI values of Stream I & II of Tai Po WTW based on flow at 800MLD		EPRI Report 2013 EI values at 800MLD	
Treated Water Pumping	63,049	43.5%	168,126	55.1%
Processes	69,593	47.9%	98,498	32.3%
Building Services	12,471	8.6%	38,174	12.6%
Total	145,113	100%	304,798	100%

Table 1: EI values of Stream I + II of Tai Po WTW vs. the EPRI Report 2013 data

Using the EPRI Report 2013 data as a baseline, Tai Po WTW appears to be more energy efficient. When the expansion project is completed and Stream II is put into service, actual EI measurements will be carried out to verify the above results.

4. CONCLUSION

With the above-mentioned water management and energy efficient features and other environmental enhancement works in the Tai Po WTW expansion project, WSD will apply for assessment under the Building Environmental Assessment Method (BEAM) Plus aiming at accreditation to achieve the gold or above rating in the planning, design, construction, commissioning, management, operation and maintenance of buildings of the WTW.

WSD anticipates that Tai Po WTW can serve as a good example for promoting sustainable infrastructure development.

ABSTRACT

The ample sunlight in Pingtung County is advantageous for the development of its photovoltaic industry. Pingtung County Government, in recent years, has proactively developed green energy, including efforts to promote the Aqua Solar Farm program, the installation of photovoltaic systems on rooftops of public buildings and schools, green architecture, etc. What's more, the government established Taiwan's first and only floating solar power station on a detention pond in early 2016. As of the present time, a total renewable energy generating capacity of 125 MW has been installed in Pingtung County, and an annual growth of 50 MW is expected.

In addition, an intelligent green and energy efficiency industry cluster is forming in the Pingtung Export Processing Zone, which coupled with the Liukuaicuo Industrial Park to be established in the near future, will position Pingtung as Southern Taiwan's stronghold for the development of this industry. In light of this, the "Intelligent Green and Energy Efficiency Industry Guidance Project" was initiated to further strengthen the soft power of local industries. To assist Pingtung-based businesses with industrial transformation and development, this Project focuses on four approaches: 1. value-added application and promotion of green and energy efficiency technologies; 2. joint development and promotion of technologies and services; 3. establishing an innovative system for the application of intelligent green and energy efficiency technologies, and providing guidance on the system; and 4. designing intelligent green and energy efficient products and providing guidance for innovative services, in the hope of boosting the development of local green and energy efficiency industry, and in turn facilitating the formation of local industry clusters and R&D alliances.

Keywords: energy use, energy saving, green industry

1. INTRODUCTION

In recent years, global warming has had a significant impact on climate patterns. In light of this problem, countries around the world have actively invested in the expansion and promotion of the green energy industry, bringing huge business opportunities for its respective sectors. Due to its limited natural resources, a significant portion of Taiwan's energy supply is reliant on imports from other countries. In addition, faced with the decommissioning of its Maanshan Nuclear Power Plant in 2025, the possibility of a gap in Taiwan's energy supply chain has become a challenge which is confronting both the central and local governments. In 2009, Typhoon Morakot inflicted severe damage upon Pingtung by flooding nearly 1,075 hectares of aquaculture facilities and leaving several townships and villages without electricity for as long as two months. Pingtung County Government implemented the "Aqua Solar Farm Program" (Figure 1) to provide guidance for the upgrading and transformation of the fish farming industry, which has been relying on groundwater for lengthy periods. Pingtung County Government also established the "Guangtsai Wetland" green energy demonstration zone in Pingtung's Linbian Township, hoping to nurture the development of green energy-related industries such as photovoltaic power, marsh gas, wind power, biomass energy, and fuel cells. In addition to the Guangtsai Wetland green energy demonstration zone, the government also established Taiwan's first floating solar power station on a detention pond in 2016 at Jiadong Township's Dawuding Pumping Station (Figure 2). The government continues to push for the establishment of related facilities.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 1: Aqua solar farm program facilities

Figure 2: Taiwan's first floating solar power station

Furthermore, Pingtung County Government plans to establish the "Pingtung County Liukuaicuo Industrial Park", and has selected a property consisting of 19.75 hectares located to the south side of the Pingtung Export Processing Zone founded by the Ministry of Economic Affairs. Through the development of this industrial park, it is hoped that companies related to renewable energy will be attracted to set up offices in the park. By collaborating with the Pingtung Export Processing Zone, a green energy supply chain is expected to be built, thereby forming a cluster effect for the industry.

2. PINGTUNG'S STRATEGY FOR DEVELOPING ITS GREEN ENERGY INDUSTRY

Pingtung possesses many natural advantages for developing its green energy industry. The county is exposed to abundant sunlight throughout the year, reaching as many as 2,400 hours in terms of sunshine duration – ranking it second in Taiwan in 2015. The powerful katabatic winds which blow from October to April provide a source for generating wind power. Pingtung County also boasts the second longest coastline among all the counties in Taiwan, being adjacent to major bodies of water such as the Pacific Ocean, the Bashi Channel, and the Taiwan Strait. The strong Kuroshio Current is also a possible source for ocean current energy. In addition to the aforementioned natural resources available within its environment, one of the biggest advantages Pingtung County has for developing a renewable energy industry is its solid foundation in agriculture – the abundance of kitchen waste and manure from farm animals facilitates the development of marsh gas power and biomass energy utilization.

Figure 3: Pingtung county government establishes the green energy project office

Actively complying with the central government's green energy policies, the Pingtung County Government established the Green Energy Project Office (Figure 3) to manage the achievements and results obtained from the implementation of green energy projects by county government agencies. It establishes a platform for communication and coordination, creating a single-window system to accept inquiries, provide investment for green energy industries, offer services for the installation of green energy facilities, and assist in overcoming administrative obstacles. The project office has set a goal of installing 58.5 megawatts (MW) of renewable energy facilities in 2016-2017, as well as creating 234 employment opportunities, and 300 millions output value per year. We seek to promote renewable energy diversity.

In addition to establishing the Green Energy Project Office to actively promote renewable energy policies, the Pingtung County Government drafted the "Pingtung County Self-governing Ordinance on Green Buildings" in 2016, seeking to promote the installation of solar panels on townhouse communities and apartment buildings. Apart from publicly-owned buildings and schools, the ordinance requires that publicly-owned factories and new buildings intended for public use must abide by green building regulations. Furthermore, the number of pig farmers in Pingtung County comprise one-fourth of Taiwan's total population. To avoid the pollution of water bodies and air by the large volume of animal waste created daily, Pingtung County Government has recently been working on utilizing the marsh gas produced from the wastewater discharged from pig farms to generate power.

Based on the above, the types of renewable energy promoted by Pingtung County Government include solar power, marsh gas power, and ocean current power. The location for the placement of solar panels includes poultry houses, farm facilities, green buildings, publicly-owned buildings, and schools; the primary location of marsh gas production are livestock farms; and for ocean current power generation, the electricity-generating equipment will be placed in the sea in the vicinity of Eluanbi Lighthouse – along the path of the Kuroshio Current. The following table contains information on the types of renewal energy generators, locations for deployment, and objectives regarding Pingtung's green energy policies:

Type of Renewable Energy	Location	Installation Objective for 2016 (MW)	Completed as of Sept. 19, 2016	
			MW	(%)
Solar Power	Poultry Houses	30	8.7	29%
	Other Farm Facilities	20	6.85	34.25%
	Green Buildings, Publicly-owned Buildings, Schools	5	8.234	164.68%
	Detention Ponds,	1	0.5	50%
Marsh Gas Power	Livestock Farms	1	0.015	1.5%
Ocean Current Power	Sea near Eluanbi Lighthouse	1.5	0	0%
	Total	58.5	24.389	41.69%

Table 1: Green energy project office renewal energy equipment type, deployment location, and objective

3. GREEN ENERGY PROMOTIONAL PLAN AND CONTENTS

Through a short-term 4-year plan running from 2016 to 2020, Pingtung County Government is investing effort in the promotion of solar power, marsh gas power, and ocean current power. Each year, it sets the objective of installing renewable energy generation equipment with a combined capacity of 50 MW. Some of the proactive measures include: (1) Coordinating with the green energy policies of central government agencies by establishing the Green Energy Project Office to determine the county's vision, goals, and strategies for relevant green energy projects; (2) Drafting the division of duties and responsibilities regarding affairs related to the promotion of green energy policies for agencies and institutions affiliated with Pingtung County Government in order to duly supervise the promotion carried out by the affiliates; (3) Constructing a platform for communication and coordination, as well as the management and tracking of annual objective achievement rates; (4) Establishing a single-window system to accept inquiries, provide investment services for green energy industries, offer services for the installation of green energy facilities, and assist in overcoming administrative obstacles; (5) Handling affairs such as researching

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

and providing suggestions on regulations related to green energy, industry technology, along with market surveys, assessment, and analysis; (6) Formulating regulations governing subsidies and incentives for promotions related to green energy projects; (7) Drafting memorandums and proposals for promoting green energy policies to secure funds and subsidies from the central government; (8) Organizing promotional campaigns and investment seminars related to green energy projects.

In the long run, Pingtung County Government seeks not only to develop new energy sources, but also to promote energy conservation. In the future, it will continue to implement policies such as solar power, ocean current power, stream current power, marsh gas power, and wind power. It will also assist in the development of different kinds of green energy technology, integrating different fields to achieve the most effective results through synergy. The promotion of energy conservation policies will also start with Pingtung County Government. This involves the planning of energy measures in line with local characteristics, seeking to gradually change the electricity-use habits of county residents, thereby establishing a trend for energy conservation. The government also encourages the decommissioning and replacement of high energy-consumption equipment to reduce the load on Pingtung County in the coming years. Hopefully, by working in coordination with measures on both the supply and demand side, the county is expected to achieve its vision of a 2025 carbon-emission-free Pingtung.

4. CONCLUSION

In recent years, through approaches such as strengthening microgrids, generating electricity using marsh gas, and the Aqua Solar Farm Program, Pingtung County Government is gradually implementing its objective of promoting green energy. In the future, it will continue to boost the volume of green electricity by continuing to develop diversified renewable energy sources such as aqua solar farms and marsh gas power generation. By introducing the development of composite energy-generation – ocean current power and stream current power generation – which coexists with agriculture and aquaculture, Pingtung County Government seeks to become home to sustainable green energy development in the future.

ABSTRACT

Since the establishment of the Palestinian National Authority in 1994 on parts of the West Bank and Gaza, considerable developmental efforts have been observed. New neighbourhoods have evolved in order to cope with lifting the zoning restrictions put previously for decades by the Israeli occupation authorities, overcome the shortage in dwelling stock, and satisfy the demand for providing residential space for citizens and hundreds of thousands of Palestinian returnees from abroad. In the emerging State of Palestine, there are considerable limitations of land that could be used for development, scarcity of energy, water, and material resources, in addition the environmental pollution, persistent economic challenges, and new lifestyle trends. These factors need to be considered in planning and developing of the neighbourhoods. This paper aims to identify the strategic framework that will guide the efforts that will assist in achieving the goal of having sustainable neighbourhoods in Palestine. Sample regional and international sustainable neighbourhood planning and development efforts have been investigated. Strategic planning approaches have been utilized as related to neighbourhood development in Palestine, where SWOT analysis has been conducted to derive the strengths and weaknesses, as well the opportunities and threats, in order to lay the foundation to identify the most important issues that should be tackled in the strategic framework. Moreover, the focus group approach has been adopted and case study has been conducted in order to evaluate the ability of the stakeholders to set policies, plan, design, and implement sustainable neighbourhoods. Consequently, the strategic goals and objectives and the strategic framework highlighting the strategies and actions that need to be implemented over the medium term, whether related to setting policies, regulations, planning guidelines, and design standards, are set, where responsibilities have been proposed. The resulting strategic planning framework would guide the efforts to realize sustainable neighbourhoods in Palestine.

Keywords: sustainable neighbourhood, strategic planning, palestine

1. INTRODUCTION

The neighbourhood is a basic planning entity in modern residential planning theories. However, the literature demonstrates different approaches that tackle the application of sustainability to neighbourhoods. The Egan Review (Office of the Deputy Prime Minister, 2004) highlights sustainable communities as those which “meet the diverse needs of existing and future residents, their children and other users, contribute to a high quality of life and provide opportunity and choice. They achieve this in ways that make effective use of natural resources, enhance the environment, promote social cohesion and inclusion and strengthen economic prosperity”.

In the recent years, there has been increasing interest in sustainable communities. In its proposed new strategy of sustainable neighbourhood planning, UN-Habitat (2014) has suggested five principles to be considered to achieve sustainable neighbourhood. These include adequate space for streets and an efficient street network, high density, mixed land-use, social mix, and limited land-use specialization.

Numerous studies have been published addressing sustainable communities, sustainable development, and sustainable neighbourhoods. These have illustrated the concepts, policies, and applications of sustainability in developed and developing countries. Research has been published illustrating regional experience in this context as well. However, the concept of sustainable communities and its application to the neighbourhoods in Palestine is relatively new.

The Palestinian Higher Green Building Council (PHGBC) was established in 2010. It aims to encourage green and sustainable architecture and building in Palestine by introducing the main green building design strategies through their published guidelines (Palestinian Higher Green Building Council, 2013) and capacity building programs.

2. NEIGHBOURHOOD DEVELOPMENT IN PALESTINE

The establishment of the Palestinian National Authority (PNA) on parts of the West Bank and Gaza in 1994 had led to massive developmental efforts by the Palestinians in order to deal with the challenges inherited due to 27 years of Israeli occupation. The Palestine Liberation Organization (1994) has prepared the first Palestinian Developmental Plan for the period 1994-2000. The plan gave priority to correct the distortions caused by the occupation, especially in the infrastructure and the housing sectors. The Ministry of Public Works and Housing, established after the formation of the PNA, has the primary responsible of the management and implementation of national infrastructure and publicly supported or managed housing.

The Palestinian Housing Council (PHC) was formed in Jerusalem in 1991, slightly before the establishment of the PNA, as a non-profit organization, dedicated to help alleviating the shortage of housing and contribute to the development of the housing sector, by providing long-term loans for housing projects. However, the private sector and individual investors have been leading most of the residential development in Palestine. Official statistics indicate that about 60% of the households own their housing units, which they obtain mainly through their savings, and secondarily though loans from banks (Palestinian Central Bureau of Statistics, 2009). Based on the estimates for 2015, about 548,100 Palestinian households are in need of housing over the next decade. It is expected that the cumulative deficit at the end of 2019 will reach about 294,000 housing units (Abu Obaid, 2013).

New housing projects have evolved in order to cope with lifting the zoning restrictions put previously for decades by the Israeli occupation authorities, overcome the shortage in dwelling stock, and satisfy the demand for providing residential space for citizens and hundreds of thousands of Palestinian returnees from abroad.

During the last decade, a new trend in housing projects evolved, where neighbourhood-based residential developments start to spread rapidly compared with individual developers building-based developments. In 2006, the first new town in Palestine was established, Rawabi, as an initiative to build a new population centre for Palestinians and as a courageous economic initiative that integrates international best practices for urban master planning, sustainable environmental policy, regionally-suited architecture, and state-of-the-art infrastructure for residents, enterprises, and visitors.

In 2009, Al Etihad neighbourhood near Ramallah was inaugurated as the first integrated neighbourhood in Palestine. After that tens of new neighbourhoods in the suburbs of major Palestinian cities are observed, especially in central area of the West Bank of Ramallah-Al Bireh-Beituniya, including Al Reehan neighbourhood.

3. RESEARCH MOTIVATION AND OBJECTIVES

In the emerging State of Palestine, there are considerable limitations of land that could be used for development, scarcity of energy, water, and material resources, in addition the prevailing environmental pollution, persistent economic challenges, and new lifestyle trends. These factors need to be considered in planning and developing of the sustainable neighbourhoods. It has to be stated that there was recently a study conducted on the process of neighbourhood strategic planning in Palestine, but did not address the sustainability concerns (Fares, 2014).

This paper aims to formulate the strategic framework that will guide the efforts that will assist in achieving the goal of having sustainable neighbourhoods in Palestine. The neighbourhood level is highlighted as numerous developments on such level have been observed during the past few years, and where a number of developers have been considering aspects of sustainable neighbourhoods. The neighbourhood is the unit where the impacts towards sustainable development can be easily realized, compared with consideration of citywide or individual building sustainable development.

The objectives of this paper include the following:

- Analyse and understand the sustainable neighbourhood developmental related issues, especially on the local level.
- Identify sustainable neighbourhood domains and actors in the Palestinian context.
- Formulate a national strategic plan framework for sustainable neighbourhoods.
- Propose relevant recommendations to start implementing the proposed framework.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4. METHODOLOGICAL APPROACH

Strategic planning approaches are utilized in this research as related to neighbourhood development in Palestine. Strategic analysis is conducted first to derive the strengths and weaknesses, as well the opportunities and threats, in order to lay the foundation to identify the key issues that need to be tackled in the strategic framework. In such framework, the goals and objectives to achieve sustainable neighbourhood are formulated based on the analysis outcome, and consequently, strategies and actions are defined.

The followed tools include conducting relevant meetings with focus groups and the developer representatives in a selected newly developed neighbourhood case study in order to evaluate the current conditions and the potentials and threats as related to being a sustainable neighbourhood. Moreover, the approach includes conducting interviews with key stakeholders to understand their viewpoints and assess their ability to set and implement policies, regulations, plans and actions, and execute sustainable neighbourhoods. Figure 1 shows the research methodology.

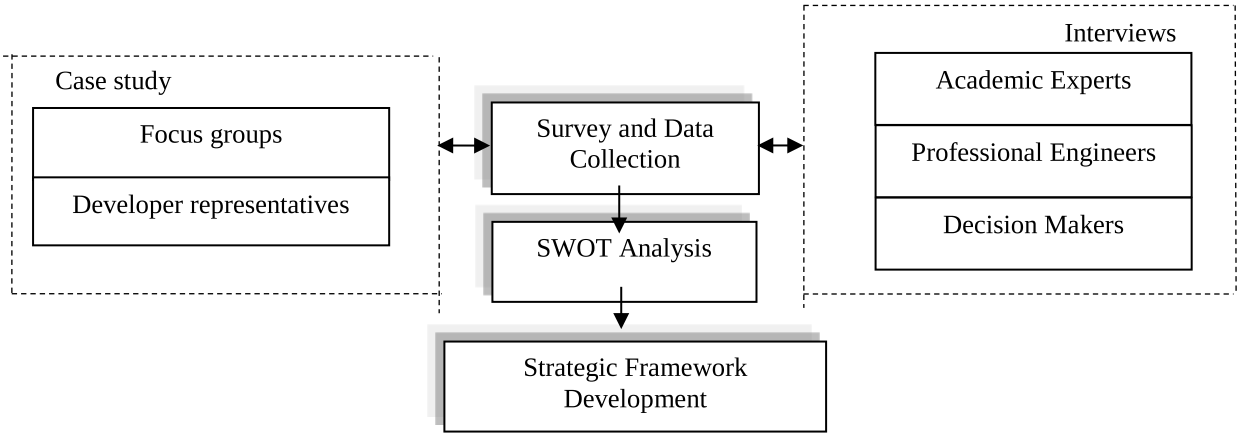

Figure 101: Illustration of research methodology

5. CASE STUDY SETTINGS

For this research, Al Reehan Neighbourhood has been selected as the case study, which is one of the new neighbourhoods where the developer has attempted to adopt and implement sustainability concepts and practices. It is located about 7 km north of the city of Ramallah, at the heart of the West Bank, on a land with area of 250,000 m^2. It has been developed for the past six years by Palestine Investment Fund (PIF), which is the sovereign development fund for the State of Palestine. It includes about 1800 housing units, with a variety of apartments' spaces ranging from 100-260 m^2 to fit the requirements and capabilities of the various Palestinian income and social groups. It has been designed to accommodate about 8,000 people.

In order to ensure an integrated community, the neighbourhood has been designed to accommodate the key services and facilities needed by the population such as a commercial centre, a school, a kindergarten, a mosque, a park, and a playground. In addition, its unique location has attracted investors to build the largest private specialized hospital in Palestine. Table 1 illustrates the sustainability issues and some of their elements that Al Reehan Neighbourhood has adopted.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Sustainability issues	Sustainable elements	Category	Description
Environ-mental sustainability	Water	Clean water	Potable new network of 8520m length.
		Waste water	Collection system constructed and a waste water treatment plant installed (closed container system based, with capacity of 500m³/day, located in the project lowest point, and minimum pumping system required). Treated water is not used till now in the project.
		Storm water	Special network, collection from streets and buildings' roofs. Collected water not used yet
	Renewable energy	Heated water	All units have solar system for hot water.
		Generating energy	PV system installed for commercial centre, covering 30% of its needs, with ability to be adjust its angle seasonally.
	Transport	Roads network	Different streets widths (14m, 16m, 20m). Internal cul-de-sac streets for social and environmental reasons. Paved pedestrians sidewalks, ability to add bike lanes.
		Public transport	Shuttle bus services exist between the neighbourhood and Ramallah city. No bus stations exist yet.
	Land	Land use	About 40% public space, 30% residential area (multi-storey buildings and villas); 30% green area.
		Materials	Reused the uprooted rocks from the site as gravels for roads and stones for building the residential units.
Economical sustainability	Water		Available system for using storm water and recycled water for irrigating the green areas.
	Energy		Using PV system, thermal insulation.
Social sustainability	People	Social fabric	Different residential unit areas for different family sizes, different social levels, different residential units (100-260m²) and types (villas and apartments). Strong relationship between residents.
		Public participation	Participation in all decisions related to the neighbourhood, strong loyalty to the neighbourhood.
Political sustainability	Land		Protecting the Palestinian land from confiscation by Israeli occupation.

Table 1: Sustainability issues and elements adopted in al reehan neighbourhood

6. STRATEGIC ANALYSIS

The strategic assessment is based on analytical diagnosis of both the internalities and externalities related to new neighbourhoods in Palestine. The analysis is derived from the outcome of the meetings with Al Reehan Neighbourhood case study developer and focus groups, and the interviews with key actors.

Three meetings were held with the relevant case study parties; a meeting was held with the developer representatives, and two other focus group meetings were held; one with a group of current residents, and the other with a group of prospect residents, who have registered to purchase residential units in the neighbourhood. Interviews were held with academic experts, professional engineers, decision makers, and developers.

SWOT analysis was conducted to guide the identification of the positives and negatives within the internal and external neighbourhood environment, in order to define the key issues, formulate the goals and objectives, and then determine strategies and key actions to ensure achieving sustainable neighbourhoods in Palestine. The analysis was conducted for each of the six domains of the sustainable neighbourhood separately, including energy, air, water, land, transport, and people. Analysis conducted for one example of these, energy, is presented hereafter. The findings of the research, combining the perspectives of developers, key actors, and current and prospect residents, in this regard are illustrated in Table 2.

Strengths	Weaknesses
• Use of solar system for hot water. • Use of solar panels in the commercial centre. • Proper location of the waste water treatment plant with no need for pumping. • The buildings are insulated. • Using a central system for gas utility.	• No use for solar energy in streets lighting. • No utilization of the roofs of the residential and public buildings to install solar panels. • Limited use of environmental friendly products in buildings that reduces energy consumption. • No proper awareness to use energy saving electrical devices.
Opportunities	**Threats**
• Electricity Sector Organizing Council incentives to encourage renewable energy initiatives. • Favourable environmental factors enabling potential utilization of renewable energy.	• High initial cost for establishing energy friendly systems. • Limited internal support and external fund devoted for sustainability-related development.

Table 2: SWOT analysis for Al reehan neighbourhood case study for the energy domain

7. STRATEGIC PLANNING FRAMEWORK

Based on the outcome of the analytical diagnosis of the related domains for sustainable neighbourhoods in Palestine, the strategic framework is formulated. This framework includes defining the strategic goals and objectives as well as the strategies and actions that need to be implemented over the short- and medium-term are set and presented. These include the strategies and actions related, among others, to setting policies, regulations, planning guidelines, and design standards.

Table 3 illustrates a summary of the goals, objectives, strategies and actions for sustainable neighbourhood defined for each of the considered domains.

The indicated strategic framework illustrate that specific strategies and actions have to be considered and implemented in order to achieve the aim of having sustainable neighbourhoods. To turn such strategies into actions, relevant organizations possess the ability and should have a leading role to lay the foundations towards sustainable neighbourhoods. Such organizations have the potential and the basis needed to lead the change through their organizational knowledge, intellectual capital, and capacity.

The research has laid the basis for a time- and budget-based action plan, in addition to a monitoring and evaluation plan with relevant Performance Indicators (PIs) for the base year and the coming five years to measure the progress towards achieving the goals and objectives stated in the strategic framework.

Goals	Objectives	Strategies	Actions
Clean air and healthy environment	1. Reduced emissions to least possible values 2. Improved quality of internal environ-ment	1. Reduction of pollution sources	• Develop the guidelines of the PHGBC for construction of buildings into regulations • Encourage active transportation (walkable and bike-enabling streets) and public transportation • Provide closed and separated containers for trash
		2. Encouraging green concepts	• Green open and plantable areas • Plant rain fed trees and fast growing trees • Increase public awareness on greening
		3. Achievement of better internal environment	• Design wide and deep windows • Adopt natural ventilation inside buildings • Implement thermal insulation in buildings
Efficient energy use	1. Reduced depend-ency on fossil energy 2. Improved efficiency use of energy	1. Increase the share of generated renewable energy	• Solicit government and external support of renewable energy projects, and the purchase of surplus produced energy with preferential prices • Use of photovoltaic panels in street lighting • Maximize utilization of efficient solar system in producing hot water • Support using smart energy-saving systems
		2. Decrease energy consumption	• Conduct public awareness on the efficient and sustainable energy and use of energy saving electrical devices and bulbs

Goals	Objectives	Strategies	Actions
			• Encourage the use of new efficient insulating techniques and materials in buildings
Integrated and cohesion community	1. Strengthen-ed social relations among residents 2. Easily reached vital needs	1. Encourage mixed social levels	• Provide various apartment sizes • Develop and support affordable housing • Provide residents with special needs, elderly and kids with proper facilities
		2. Encourage vital needs satisfac-tion for social infrastructure	• Provide public facilities like meeting space, playgrounds, parks, etc. • Provide on-site jobs for the neighbourhood residents • Activate residents committees
Sustainable transport system	1. Improved active transport 2. Reduced car depend-ency	1. Achievement of walkable streets and neighbourhoods	• Give priority access to pedestrians and cyclists over other vehicles across the neighbourhood • Provide daily needs in walkable distances • Providing neighbourhood public/recreational facilities
		2. Encouragement of public transportation	• Provide scheduled bus service • Subsidize public transport • Support provision of new buses
Efficient land use	1. Optimized use of land	1. Achieved mixed land use	• Provide different functions in the same area • Introduce regulations encouraging optimized land use • Provide interconnected safe and efficient streets
		2. Promotion of high density neighbourhoods	• Encourage multi-storey buildings • Encourage the provision of various apartments sizes
Sustainable water system	1. Efficient water use Achieved	1. Increase water harvesting and re-use practices	• Encourage building wells for rain water harvesting • Encourage use of treated water in irrigation • Implement systems to separate grey from black water
		2. Reduce water consumption	• Conduct public awareness campaigns on water conservation • Support using smart water supply/irrigation systems

Table 3: Goals, objectives, strategies and actions for sustainable neighbourhoods

8. CONCLUSIONS AND RECOMMENDATIONS

This study provides an overall framework that would guide the efforts to realize sustainable neighbourhoods which can be adopted in neighbourhood development in Palestine. Water, energy, air, people, land and transportation are the main domains that are considered in developing sustainable neighbourhoods. Using a case study, as well as interviews with key actors, an attempt is made to identify internal and external positive and negative impact factors, and facilitate the arrival of the proposed strategic planning framework for sustainable neighbourhoods.

It is recommended to adopt this framework after proper debate with the relevant key actors. All involved actors have to be engaged in the detailed strategy development and action plan implementation. First, the relevant ministries such as the Ministry of Public Works and Housing and Ministry of Local Government, the municipalities, and the semi-public institutions, such as the Palestinian Housing Council and the Palestinian Higher Green Building Council, have to exhibit a leading role in supporting sustainable neighbourhoods, through devising relevant policies, legislations, and regulations. Developers and investors should be pioneering in initiatives that will result in sustainable neighbourhoods. Professional societies, such as the Engineers Association, and technical experts need to conduct awareness campaigns and train engineers and planners, as well as developers, on various sustainable neighbourhoods' domains issues.

ABSTRACT

The core researcher area for this study is the basins of Gaoping River. This multidisciplinary research project coordinates the history, culture, industry, ecology and community to facilitate green living and sustainable autonomous management community network.

The aim is to renew the usage for air force military villages, adopt green architecture technology and green energy, water resource recycling as well as respond to climate change in hope of constructing a consummate and diversified ecological system for harmonious co-habitation between human and the nature.

The resources in the area can be classified in two streams. In ecological environment, there are around 50 species of birds, 31 species of fish in wetland habitation. In terms of humanities resources, the most important construction is an old iron bridge for steam train built in 1911. It was the longest iron bridge in Asia. The land connecting the iron bridge to the city includes the 44-hectare air force villages engraved with history memory of the bygone era. The main theme for this Oasis program is culture and its role as the ecological nodes between Kaohsiung City and Pingtung, an autonomous management community with a consummate environmental protection system.

The methodology for this research is based on trait analysis and value evaluation. The trait analyses are:

- Landscape trait analysis and evaluation
- Community vitality development and management
- Vision for lifestyle and ecology as well as action strategy

The value evaluation depends on professional platform and citizen participation.

The major results of the program to transform vision to an action strategy combining the public with the government are:

- A basin living circle to restore the dialogue between the river and community
- The trip to trace back the past and reconstruction of historical space and memory place
- Ecological restoration for the river basin and water resource network
- Sustainable resource development implemented by the adaptation of deep rooted action combining public facilities and neighborhood.

Keywords: inclusive eco-design, landscape, Gaoping River

1. INTRODUCTION

The program is part of "four-leaved clover vitality program" of Pingtung City proposed by Vision Integrated Platform Program of Pingtung County. The scope of the program is based on left bank of Gaoping River basin and Liukuaicuo as the core. In the area, there are living, ecological and productive complete life circle of water front wetland, military dependents' village, old iron bridge of Siadanshui River and industrial park. By complete planning, vital cultural landscape, financial evaluation of operation and residents' participation, it becomes "national" cultural park in the program to reinforce local characteristics and develop tourism mechanism, result in residents' resource sharing and carry out environmental and ecological sustainability.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

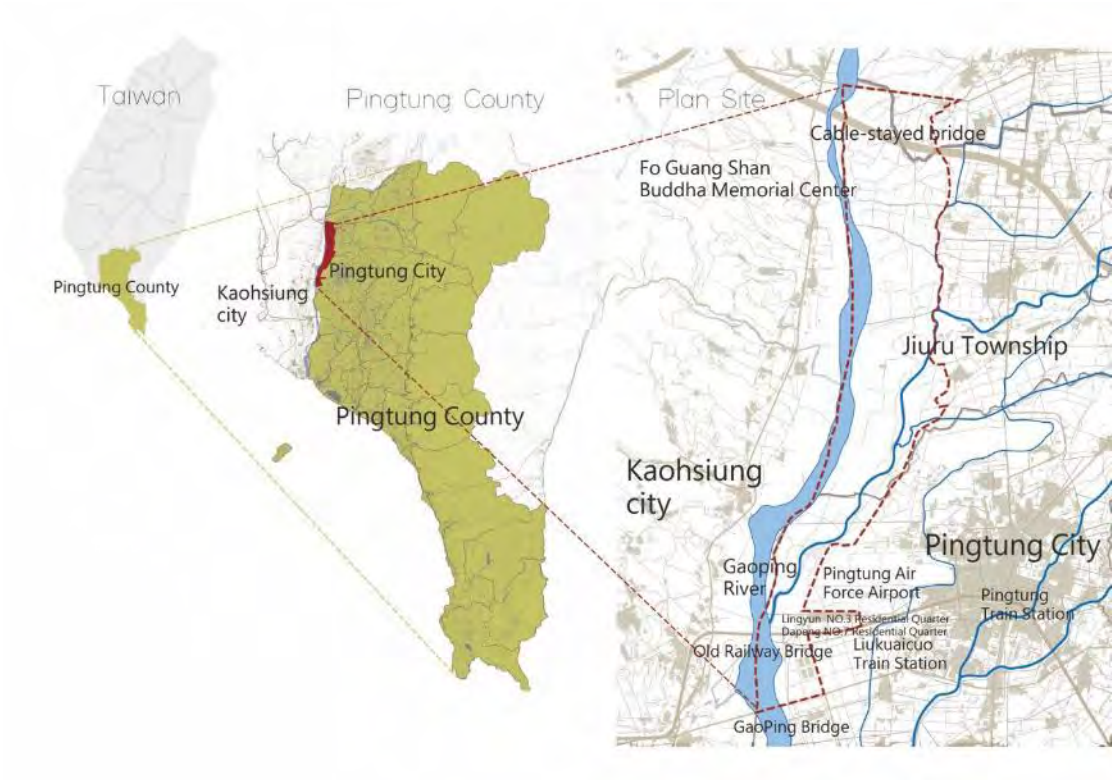

Figure 1: Scope of plan

Concept of program of cross-field integration is based on five items: connection, stability, highlight, preservation and development. We connect old iron bridge of Kaohsiung City on right bank of Gaoping River and Jiuqutang cultural and tourist path program and integrate rich natural and human ecology to establish cross-field human history, tourism and recreation and environmental education life circle of Pingtung and Kaohsiung. We stabilize basin network and precaution system and construct the theme of Gaoping River basin and human environment based water space to brighten, revive, vitalize and extend water bank network to the communities.

The program preserves human ecology and common historic memory of Gaoping River and coordinates history, humanity, tourism, recreational, historical and cultural landscape and environmental education place. It develops green industry, brand agriculture and welfare and by cross-field integration, it constructs new portal of Gaoping and new site of southern Taiwan planning to establish Gaoping River basin and green jade home.

Figure 2: Concept of program

The following sections propose the thematic and action programs of different phases. By analysis of historic background and current programs, we explore the steps of future execution, methods and expected result to carry out sustainable operation and local spirit.

2. REVIVAL OF BASIN HOME LIFE CIRCLE UPON DIALOGUE BETWEEN RIVER AND TOWN

The program includes Gaoping riverside park, Yun Peng community, Ta Wu Ying area, PIngtung Airport, Pingtung export processing zone, wetland, Siadanshui River old iron bridge and industrial park. It has diverse resources of rich ecology, humanity, history and industry. The integration of left bank of Gaoping River responds to the development of right bank and it enhances the development of the surrounding by total dimension.

According to the unofficial history, during the time when the iron bridge did not exist, people's life relied on water and frequently used water channel as important measure of transportation. They could thus approach the river and completely pictured the home in natural environment.

In the area of the program, in the past, the relationship between people's life and river was close. Nowadays, due to the issues such as river regulation and prevention of flood and wind disaster, protecting embankments are mostly applied to solve the problems and it separates people, life and water bank. Left and right banks of rivers become the routes for cars passing rapidly and they are distant from the land. Living landscape of basin of river gradually replaces infertile sands and farms of cultivation. Borders of the rivers are restricted by protecting embankments. It becomes difficult to reach the area beyond protecting embankments and the internal and external space of protecting embankments is rigid.

Action program of future basin life circle aims to create the benefits of infrastructure and support, vitalize the river area and reduce the distance from people and environment. Attraction is the priority. It constructs the river environment of ecology, production and life, reinforces the ecological diversity of river and river embankment in the surrounding and introduces the concept of super protecting embankment. Thus, river and people coexist. It is different from current situation in which people's production is only based on cultivation and breeding. The attraction and type of activity should respond to current culture and resources. How to connect the rivers with present life circle and coordinate the towns is the significant concern.

It also develops the construction and type of route with low impact on environment. For instance, protective coloration, green protecting embankment, multi-levels planting and ecological technique are applied to landscape protecting embankment design to effectively enhance biological diversity and the playfulness of recreational activities at river bank and protecting embankment. In addition, it introduces green energy based tourist shuttle bus, bike and creates ecology-friendly Green Park Way with low impact to result in positive education place. By route control, it restricts emission and pollution of waste gas, limits the vehicles and promotes green energy transportation. The previous measures will lower the original limit of protecting embankment, connect horizontal resources, maintain ecological environment and function as improvement of vertical lines.

Green Park Way can be the horizontal extension of tourist shuttle bus and bike path. The surrounding towns, resources of left and right banks, culture and industry respond to the nodes of different regions and the cross is at the vertical green protecting embankment. It enhances the association between internal and external space of protecting embankment and establish two-way dialogue. The program installs route guidance system, coordinates transportation and network system and connects mass transportation, p-bike of Pingtung, shuttle bus and parking lot as human-based network which breaks through the boundary between rivers and towns. Upon life, ecology and production, it triggers the development and process of the region.

The action program includes 5 phases: Step 1, future transportation plan and development plan investigation; Step 2, left bank basin and investigation on resource points of towns; Step 3, green park way network program – road reconstruction and extension of protecting embankment; Step 4, integration of related transportation and related measures; Step 5, preparation of infrastructure and support of community and integration of tourist resources. From basic investigation to installation of infrastructure, it creates basin home life circle upon dialogue between river and towns.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. TRIP TO TRACE BACK THE PAST AND RECONSTRUCTION OF HISTORICAL SPACE AND MEMORY PLACE

The Gaoping River was originally called “Siadanshui River”. In 1913, “Siadanshui River iron bridge” with the passing of train was above it and it was the significant construction. After the accomplishment of iron bridge, according to the Japanese official journal, it was “the first long bridge of Japan and it resembles the rainbow in the distance and it was the splendid construction in southern Taiwan”.

Nowadays, the Kaohsiung City Government, Pingtung County Government and local people all agree with the cultural and tourist value of old iron bridge of Gaoping River. Besides the planning of two bank wetland park to enhance ecological education and recreational function, it should connect two bank industrial resources and landscape characteristics by the circulation to recall the residents’ spatial memory, vitalize the old iron bridge of Gaoping River and regional economic development. In 2008, Pingtung County Government accomplished the reuse construction of the part of Pingtung of iron bridge and launched the passing.

As to the part of Kaohsiung of old iron bridge, Kaohsiung City Government finished “integrated planning of development and operation of Gaoping River old iron bridge cultural and tourist path industry” in 2012 and the program coordinates cultural landscape resource and horizontal alliance of local industry from perspective of resource integration of Gaoping River basin and introduces several plans to completely plan and construct the part of Kaohsiung.

In the future, the surrounding of the railway will be planned and changed. Because of the position change of taking off and descending, the construction limitation of the buildings around Pingtung Military Base on the left is liberated and it will enhance the related development. Air force military dependents’ villages around the airport and iron bridge include Lin Yun Three Village and Da Peng Seven Village. The area includes military dependents’ villages constructed after the war. The type of construction and arrangement reveal the significance of time and it is different from another area of Pingtung City. Sheng Li, Zhong Jen New Village are the colonial buildings of the Japanese Colonial Period. They can be the representatives of military dependents’ village of colonial style and after war in Pingtung area.

Currently, Ministry of National Defense intends to deal with idle land by sales and this program suggests vitalizing military dependents’ villages by land change and volume transfer. With population aging and great number of people moving out, it is one of the issues to remain the history and revive idle land in Gaoping area. Military dependents’ village is between Siadanshui River old iron bridge park and Pingtung City. The location is precious for the saturated town space. Although at present, there are mostly the broken buildings and damaged cultural landscape, we find the possibility of renewal and innovation.

In comparison to Pingtung Military Base on the left and military dependents’ village on the east, land of Taiwan Sugar Corporation is currently used for animal husbandry and agriculture. In the future, it will be constructed as green energy industrial park. Siadanshui River old iron bridge park will be an important entrance of the area. The cultural line connects the unchanged cultural land on left bank and future important development area.

The goal is to revive the time and structural aesthetics of the historic interests in order to reconstruct the natural gap of Siadanshui River old iron bridge. It is the connection between left and right banks. In addition, it provides diverse recreational life projects and completely associates construction and resources of left and right banks and it creates the opportunities for the young generation to return to the hometown and change of population and industrial structure. It is the future direction.

The action program includes five phases: Step 1, investigation on land ownership of air force military dependents’ village, Liu Kuai Tso farm of Taiwan Sugar Corporation and the surrounding of railway; Step 2, reuse of idle land; Step 3, evaluation of vitalization program and the following related measures; Step 4, human-based environment construction of railway; Step 5, connection program of left and right banks of old iron bridge; by action program with steps, it revives cultural and historic idle space and memory.

4. RIVER BASIN AND ECOLOGICAL REPOPULATION OF WATERWAY RESOURCE NETWORK

Water source of Gaoping River basin is rich and it is the main source for irrigation, drinking water and groundwater in Gaoping area. Current long-term problems of basin are the following: flying sand of riverbed during dry season, back-silting of river course or lower riverbed due to coyoting of sandstone. In addition, vegetables and fruit are cultivated on benchland, there is emission of breeding waste water, reduced number of migratory birds, low biological diversity, pollution of pig farms on left and right banks, industrial and family waste water, eutrophication of water and high quantity of ammonia and nitrogen. It indirectly influences quality of tap-water in Gaoping area.

In the future, in order to improve ecology of river basin and have balanced benefit between human-based use and natural ecology, this program will construct slope analysis on Gaoping River of the region. According to flow and direction of water, it classifies human interference space from high to low levels as criteria of spatial planning and propriety. Based on analytical result, public facilities in and out of river embankment, industrial model, space and type of road will coexist with river. It matches the diversity of Gaoping River and it will reach the balanced benefit between humanity and ecology.

The planning aims to avoid human activity based thoughts and attempts to revive natural ecology system of the bank of Gaoping River to "return to" the bank of Gaoping River and establish basic values upon river ecology. It follows the direction of flow as spatial planning of the bank, adopts low impact facility, permeable basal disc facility and low obstacle natural succession design. From perspective of natural environment, it uses the river land beyond protecting embankment.

Based on human interference level of activity space, in different sections of river, it establishes human interference space from high to low levels. Low-level human interference space: ecological reserve area and natural exploration park and it includes transition zone, bird watching area and wetland; medium level of human interference space: including mobile stores, camping area and space of outdoor activities in natural environment; high-level human interference space: compound space of large-scale activities and it avoids the idle space and when the land is not frequently used in ordinary days, the impact on the nature is low.

Besides recreational landscape space on the bank, for the concern of flood prevention, we should construct protecting embankment, river dam (cross-sectional structure) or river course dredging construction. In order to maintain diverse river course space, in the design of construction, we should pay attention to characteristics and flexibility of river. It avoids the border, provides natural habitat and leads to biological diversification.

According to concept of the action program, there are the following four steps: Step 1, investigation on water of Gaoping River and ecological resources; Step 2, Gaoping River slope analysis and propriety analysis of human activities; Step 3, basin ecological repopulation and recreational space design; Step 4, connection between surrounding water network and resources. Hence, this program creates sustainable Gaoping River basin of sustainable ecology.

5. ROOTING ACTION OF CONSTRUCTION TO CARRY OUT SUSTAINABLE DEVELOPMENT OF RESOURCES

The area of this program is based on profound history. After the first group of immigrants who arrived and cultivated the land, there were different types of groups, such as Minnan, Hakka and relatives of military. They were on the land with different beliefs and cultures and it results in unique and rich cultural landscape resources.

Great number of temples, old houses and old trees are the characteristics of the left bank area of Gaoping River (including Pingtung County, Pingtung City, Jiouru Township, Ligang Township, etc.). They are preserved completely with historical significance. The area is one of those with the richest historical resources in Taiwan. The famous one is the oldest Three Mountain Kings Temple which is located in the lane of Jiouru Township and it is the temple worshipped by Hakka people.

In recent years, Pingtung County implements village renewal program and the applications are based on local community development associations. There are also the items of agricultural transformation, village space reconstruction and manufacturing and promotion of agricultural products. It has successfully promoted several

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

communities and completely developed local characteristics. The well-known agricultural products include lemons and bananas. There are also local sales of farmers' associations and fairs, lemon cooperative, banana institute and agricultural experimental station for technical promotion and upgrading and the related measures such as industrial guidance.

Since the area is spatial and the resource network is loose, the development of the rich industrial and cultural resources is mostly based on single region and it lacks complete and cross-region program. Local characteristics are not highlighted and it is not favorable for tourism development. In addition, there are no connection among tourist sites, resource stations and network of routes and related measures. Local stores do not have interaction with the industrial circle. Community development cannot effectively enhance local environmental, cultural and industrial quality.

In the future, in order to fulfill sustainable development of local life circle, we must rely on complete coordination, use infrastructure and support, and carry out and execute sustainable resources. It requires total examination and integration to vitalize local historical space. By upgrading of public space quality and combination of transportation network, it reinforces the approachability of foreign tourists, strengthens effective use of local resources, constructs ecology-friendly recreational space and promotes green community. Based on local policy, it can implement green energy facilities and transform public and industrial space into demonstration points of new industry.

It also corresponds to infrastructure. By planning annual marketing activities, it enhances local reputation and further coordinates cultural, recreational and historical resources. It relies on packaging and promotion of cultural and innovative measures. With community participation, it fulfills local life, production and ecology to implement related sustainable guidance program from top to bottom, enhances local force and cultivates community independence to deal with negative effect caused by minority population structure to construct total sustainable circulation system of the area.

Based on the previous complete planning, it establishes the steps of action program, accomplishes it by phases, effectively coordinates the resources of different fields and sustainably operates and develops Pingtung area: Step 1, integrate industrial, cultural, historic, landscape and artistic resources of different communities; Step 2, community participation and implementation of activities from bottom to top; Step 3, construction of sustainable facilities; effective use of resources from top to bottom; Step 4, annual cross-field marketing; Step 5, implementation of sustainable guidance of life, ecology and production.

6. EXPECTED RESULT

Short-term benefits, integration of original open space, enhancement of use rate of idle space and spatial reconstruction: by establishment of human based system, it creates friendly interface of original open space. It integrates cultural and historic resources and natural resources to reinforce regional tourism effectiveness.

Long-term benefits: in recent years, regarding city-township development, Pingtung area has significantly upgraded landscape quality of the city. According to original location characteristic and industrial and economic conditions, it plans blueprint of future space and proposes function position and development strategy of individual regions. Thus, with global climatic change and competition of international cities, Pingtung area can still be a place for peaceful life and work.

This study aims to highlight left bank portal of Gaoping River and coordinates local resources and construction to expand the development benefit to the whole Pingtung area in order to carry out 2025 development program of Pingtung.

ABSTRACT

The HKSAR Government is taking the lead to implement a first-of-its-kind district cooling system (DCS) in Hong Kong at the Kai Tak development (KTD). KTD is a huge development project spanning a total area of over 320 hectares that covers the ex-airport and nearby areas. The planned total public and private non-domestic air-conditioned floor area in KTD amounts to about 1.73 million square metres which will require a large demand for air-conditioning of about 284 megawatt of refrigeration (MWr).

The DCS project is to construct a large scale centralized air-conditioning system. Chilled water is produced at the central chiller plant rooms and distributed to the consumer buildings in KTD through an underground chilled water pipe network. The project is implemented in three phases. The first two phases were completed and the final phase of the project is expected to be completed by 2022. The DCS at KTD has been put in operation since Feb 2013 to provide cooling services to the Kai Tak Cruise Terminal building.

DCS is the most energy efficient centralized air-conditioning system, consuming about 35% less electricity as compared to traditional air-cooled air-conditioning system, and is suitable for promoting building energy efficiency in new development areas. Upon completion of the project, the DCS at KTD is expected to achieve an annual saving of about 85 million kilowatt-hour in electricity consumption. Apart from energy saving, DCS will also help to mitigate the heat island effect in KTD by eliminating the heat rejection of separate air-conditioning system from individual buildings. Other benefits for individual consumers include reduction in upfront capital cost, more flexible building design, no noise and vibration arising from the operation of heat rejection equipment & chillers and a more adaptable air-conditioning system to the varying demand.

Keywords: DCS, KTD

1. INTRODUCTION

The HKSAR Government is taking the lead to implement a first-of-its-kind district cooling system (DCS) in Hong Kong at the Kai Tak development (KTD). KTD is a huge development project spanning a total area of over 320 hectares that covers the ex-airport and nearby areas. It comprises various types of buildings including commercial and office buildings, hospitals, hotels, schools, sport facilities and government buildings. The planned total public and private non-domestic air-conditioned floor area in KTD amounts to about 1.73 million square metres which will have a large demand for air-conditioning of about 284 megawatt of refrigeration (MWr).

Figure 1: The Kai Tak development (KTD)

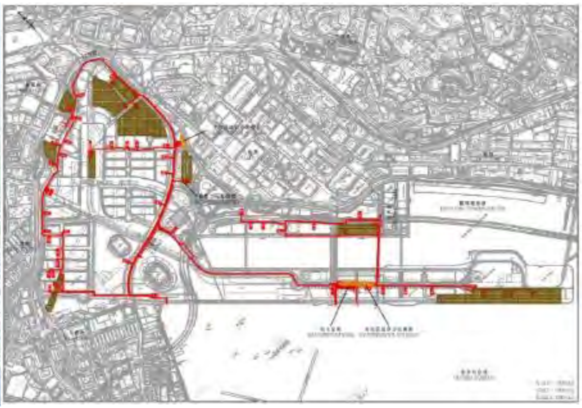

Figure 2: The DCS at the KTD

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2. CONFIGURATION OF DISTRICT COOLING SYSTEM

A DCS consists of a central chiller plant, an underground chilled water-pipe network, substations in consumer buildings and the seawater supply system for heat dissipation.

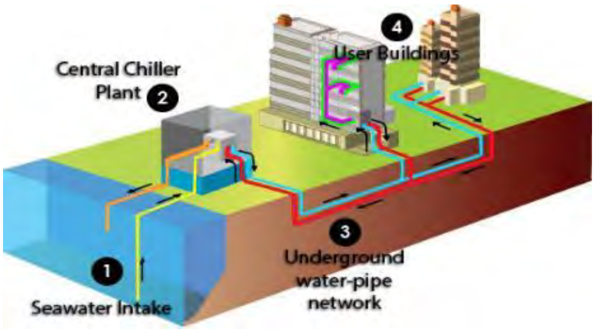

Figure 3: Configuration of DCS

3. THE DCS AT THE KAI TAK DEVELOPMENT

3.1 The DCS arrangement

The DCS project at the KTD is to construct a large scale centralized air-conditioning system which consists of two central chiller plants, namely the North Plant and the South Plant cum the seawater pump room, the underground chilled water distribution piping network, the seawater supply and discharge piping network. The cooling capacities of the North Plant and the South Plant would be 162MWr and 122MWr respectively. All plant rooms are mainly underground structures for the chiller plants and pipework installations. Chilled water is produced at the chilled water plant room and distributed to the user buildings in KTD through the underground chilled water pipes. The total length of the underground chilled water pipes is over 40 kilometers.

Figure 4: The North Plant located at Shing Kai Road

Figure 5: The South Plant located at the underground of Ex-runway of Kai Tak Airport.

3.2 A bank of chillers

Centralized chillers play an important role in an energy efficient and reliable air-conditioning system. Taking the North Plant as an example, upon completion of the whole DCS, there will be 14 nos. of chillers in total, ranging from 1.4MWr to 17.5MWr. With such combination of chillers, breakdown of any one chiller will not cause adverse effect to the operation of DCS, hence making it a more reliable system than traditional air-conditioning system. In addition, chillers with different cooling capacities could meet the varying cooling demand, thus making DCS more energy efficient than traditional air-conditioning system.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 6: The installed 1.4MWr and 4.3MWr Chillers at the basement floor of North Plant

Figure 7: The installed 17.5MWr Chiller at the basement floor of South Plant

3.3 Chilled water piping network

In order to increase the reliability of the DCS, the underground chilled water piping network is designed to be a 3-pipe system or in ring circuit forming a dual-feed supply. In a 3-pipe system, two of the pipes are duty supply or return pipes while the other pipe is a standby pipe. The standby pipe can be used as a supply or return pipe to maintain the district cooling services when one of the duty pipes is damaged or under maintenance. The dual-feed supply enhances the reliability of the system such that if the supply from one side of the network is not available, chilled water can still be supplied to the consumer substations from the other side.

Figure 8: 3-Pipe system of underground chilled water piping in Open Trench

3.4 DCS pipes protection

The DCS pipelines were constructed with open trench excavation or trenchless method. The trenchless method was adopted when there were prohibitively existing site constraints for constructing any open trench. In which, about 1km of DCS pipes were constructed by heading method or hand dug tunnel. Over 5km of DCS pipes were constructed by pipe jacking method with the use of Tunnel Boring Machines (TBMs). The largest TBM size used was 2,800mm in diameter which was the largest one ever used in pipe-jacking in Hong Kong. It was used to construct two nos. of 350m long subsea tunnels under the Kai Tak Approach Channel.

Figure 9: DCS pipes laying inside the underground tunnel

Figure 10: Two subsea tunnels (350m) constructed with TBM

The underground chilled water pipes are insulated with closed cell polyurethane insulation with 60kg/m^3 minimum density and 0.025W/ m℃ maximum initial thermal conductivity. The polyurethane insulation is able to withstand 300kPa minimum compressive strength. The heat loss in the piping network directly affects the energy efficiency of the DCS. To reduce the heat loss of chilled water in piping network, factory-prefabricated insulation with 65mm thick polyurethane is used and considered as optimum for the DCS pipes insulation. With this insulation, the estimated annual energy loss of chilled water distribution network can be limited to within 0.5% of the maximum cooling load.

Figure 11: Insulation of DCS Pipelines

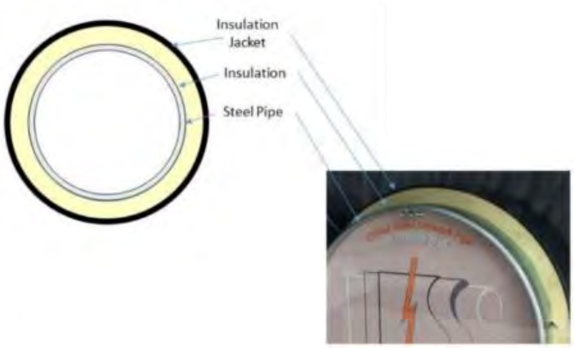

Figure 12: Cross-Section of Chilled Water Pipe

3.5 Consumer substation

The cooling energy required by each consumer building are transferred from the DCS to the individual building's central air-conditioning system via plate type heat exchangers installed inside the substation of the consumer buildings. The primary side of the heat exchanger is connected to the DCS distributing chilled water pipes and the secondary side is connected to the consumer's chilled water system. Under normal operating conditions, the designed chilled water supply and return temperatures of heat exchanger are shown below. It is desirable for both the DCS plant operator and the consumers to meet the designed temperatures in order to achieve energy efficient DCS plant operation and reliable chilled water supply to the consumers.

a. At the primary chilled water side of the heat exchanger, i.e. DCS side:

- Supply Temperature = 5°C
- Return Temperature = 13°C

b. At the secondary chilled water side of the heat exchanger, i.e. consumer side:

- Supply Temperature = 6°C
- Return Temperature = 14°C

Figure 13: The heat exchangers in DCS substation

Figure 14: The energy meter in consumer building

3.6 Energy management and monitoring

The system performances of DCS in KTD are monitored by an automatic computerised system, namely the District Cooling Instrumentation, Control and Communication Systems (DCICCS). DCICCS consists of the optical fibre network for data transmission and the automatic computerised monitoring system for central-control and remote-monitoring. The monitored data are transmitted through optical fibre network connected from all substations to the Control Rooms of North Plant and South Plant. In the Control Rooms, the DCS plant operator is able to carry out the remote-monitoring to get the real-time system performance from all substations and all chillers plants, such as the chilled water supply & return temperatures of all substations, the readings of energy meter of consumer buildings and the Coefficient of Performance of the whole DCS.

Figure 15: The control room in North Plant

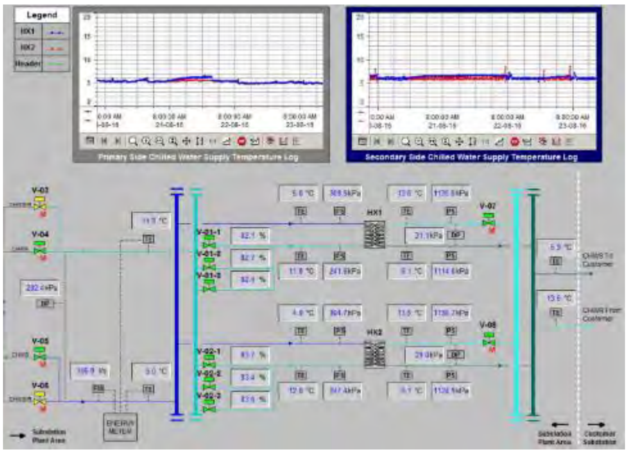

Figure 16: Remote monitoring the substation by CICCS

4. BENEFITS

DCS is the most energy efficient centralized air-conditioning system, consuming about 35% less electricity as compared to traditional air-cooled air-conditioning systems, and is suitable for promoting building energy efficiency in new development areas. Upon completion of the project, the DCS at the KTD is expected to achieve an annual saving of about 85 million kilowatt-hour in electricity consumption. DCS is also a more adaptable air-conditioning system to the varying demand as compared with individual air-conditioning systems. Each consumer building may adjust its contract cooling capacity, without carrying out extensive modification works for the building in question.

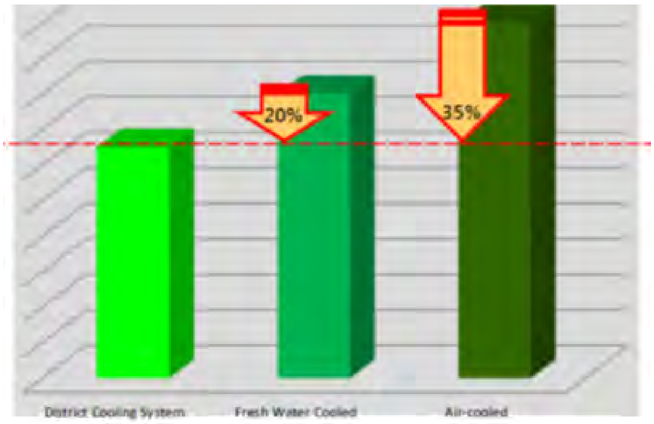

Figure 17: Most energy efficient centralized air-conditioning

Apart from energy saving, DCS will also help to mitigate the heat island effect in KTD as heat rejection no longer generates from separate air-conditioning systems of individual buildings. Also, the DCS can contribute to the vision of achieving low carbon economy.

Figure 18: Mitigate heat island effect

Figure 19: More flexible in building design

Other benefits for individual consumers include reduction in upfront capital cost for installing chiller plants at their buildings which account for about 5-10% of the building cost, more flexible building design as they do not need to install their own chillers and the associated electrical equipment as well as elimination of noise and vibration arising from the operation of heat rejection equipment and chillers.

5. IMPLEMENTATION OF DCS AT THE KAI TAK DEVELOPMENT

The project is implemented in three phases. The Phases I & II were completed and the Phase III is in progress. The DCS at KTD has been put into operation since February 2013. The whole project is expected to be completed by 2022.

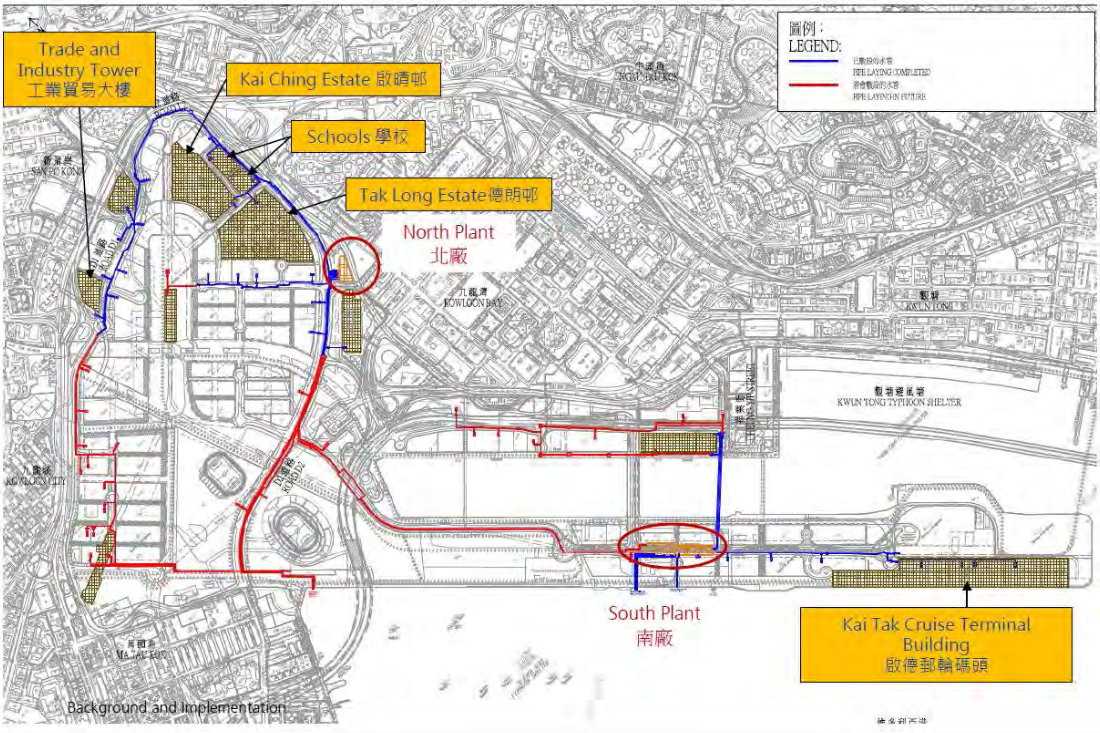

Figure 20: The consumers of DCS at KTD as at mid-2016

In mid-2016, the DCS at KTD is providing services to five consumers, namely the Kai Tak Cruise Terminal, Ching Long Shopping Centre (serving Kai Ching Estate and Tak Long Estate), the Trade and Industry Tower and two primary schools. Following the development of KTD, the number of consumers of DCS will be increased progressively in coming years. In 2017-2019, five more consumers will be connected to DCS, including the Shatin to Central Link (SCL) Kai Tak Station, the SCL To Kwa Wan Station, the Hong Kong Children’s Hospital, the Electrical and Mechanical Services Department Headquarters, and the Kowloon East Regional Headquarters and Operational Base cums Ngau Tau Kok Divisional Police Station.

6. THE DISTRICT COOLING SERVICES ORDINANCE AND THE CHARGING ARRANGEMENT & TARIFF LEVELS

The district cooling services charges have been set at a competitive level comparable to the cost of individual water-cooled air-conditioning systems using cooling towers, which is one of the most cost-effective air-conditioning systems available in the market. The charging arrangement intends to recover both the capital and operating costs from DCS consumers over the project life, which is estimated to be 30 years, as taxpayers should not subsidise such air-conditioning charges. To implement the charging arrangement, the District Cooling Services Bill was introduced to the Legislative Council (LegCo) on 15 October 2014 and the Bill was passed at the LegoCo meeting of 25 March 2015. The District Cooling Services Ordinance (Cap. 624) was gazetted on 27 March 2015. Under the District Cooling Services Ordinance, the district cooling services charges comprised: (a) the capacity charge (to cover the capital cost and the operation & maintenance costs of DCS; (b) the consumption charge (to cover the cost that vary with the actual consumption of district cooling services by the consumer); (c) the capacity overrun charge; and (d) the surcharges for unpaid charges. The capacity charge rate (tariff level in 2016/ 2017) effective from 1 April 2016 is HK$118.93 per kilowatt refrigeration. It is levied according to the contract cooling capacity agreed before provision of district cooling services. The consumption charge rate is HK$0.1941 per kilowatt-hour refrigeration. It is levied according to the actual cooling energy consumption of the building in a month.

7. CONCLUSION

DCS is the most energy efficient centralized air-conditioning system, and is suitable for promoting building energy efficiency in new development areas. It is expected that the whole project will be completed around 2022 and will achieve an estimated annual saving of 85 million kilowatt-hour (kWh) in electricity consumption. The DCS project commenced in early 2011 and the DCS at KTD has been providing services to consumer buildings since 2013. The construction of the remaining phase of the DCS project is in progress and will be completed along with the growing needs of air-conditioning of the new buildings which are coming up progressively.

ABSTRACT

Creating low-carbon, resilient cities and communities are major common issues worldwide. Community-wide decentralized and self-reliant energy network harmonized with centrally controlled grid energy such as power and gas is one of the effective measures to be further promoted.

In the past studies, in addition to energy benefit (EB) such as energy cost savings, non-energy benefits (NEBs) were evaluated into monetary value to show considerable cost-benefit ratio (B/C). But there is still large hurdle for implementing community-level decentralized self-reliant energy network caused by large initial investment and long-term pay-back period. To promote it in many communities, financial independence of the business scheme is necessary.

This study focuses on feasibility of a community-wide decentralized and self-reliant energy network in consideration of various co-benefits and proposes an original business scheme and feasibility evaluation process as follows;

- Public-private partnership business scheme
  This study proposes a PPP business scheme consisting of several key actors.
- Proper re-allocation of cost and co-benefits among stakeholders
  This study proposes re-allocation of cost and co-benefits (EB and NEB) among stakeholders in consideration of flows of payment and receipt through adjusting tariffs, taxes, subsidies between stakeholders.
- Target setting in terms of environmental, social and economic aspects
  Taking NEBs into account, SE-IRR (socio-environmental and economic internal rate of return) is originally defined and introduced for feasibility study.

A Case study is carried out to verify the proposed business scheme of community-wide decentralized and self-reliant energy network to an actual urban district in Tokyo including potential several redevelopment projects.

Keywords: community-wide energy utilization, distributed energy systems, co-benefits

1. INTRODUCTION

1.1 Expectations for a self-supporting decentralized energy network and problem of industrialization

For sustainable-city/ community development, worldwide efforts are exerted to achieve a substantially low level of carbonization. These efforts are also expected to contribute to other fields such as the activation of communities' economic activities and energy security. In IPCC's 5th report (April 2014), Adoption of the Paris Agreement (December 2015), these various benefits are taken up as "co-benefits".

Despite the considerable concern of municipalities and proposals from business enterprises, and so forth, however, in many countries, number of projects as self-supporting business are rare at present. This is partially because (1) The scope of business as well as business leaders are unclear, (2) The manner to judge investment decisions has

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

not been well-developed, and (3) There is no function to fairly allocate and coordinate costs/benefits among stakeholders.

While previous studies failed to cover the above-mentioned problem regarding business planning, this study focuses on the feasibility of a self-supporting decentralized energy network business, as Figure 1 shows an image, comprising community-wide public-private partnership entities, aiming to make a specific proposal to the following matters:

- Business entities responsible in terms of public benefit aspects and public-private partnership-type business schemes
- Method of allocating various benefits brought by the business to each stakeholder
- Performance index proving the feasibility as a sustainable business in the community

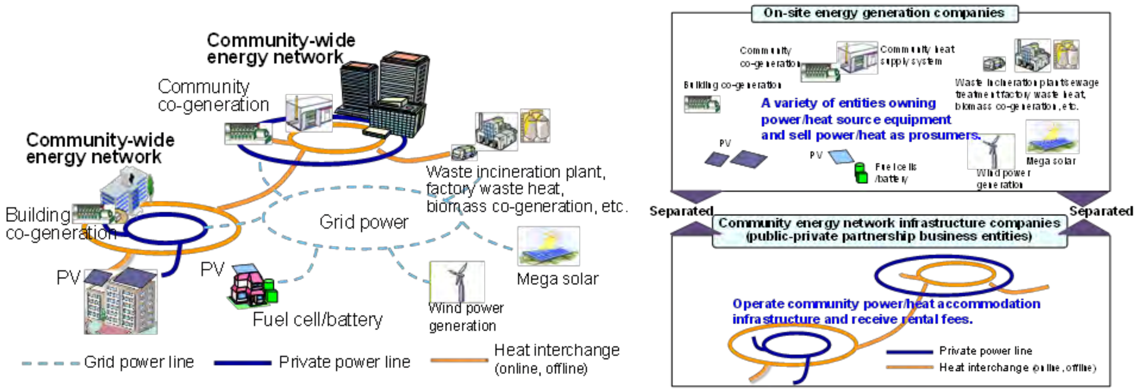

Figure1: Image of community-wide decentralized energy network and public-private separation concept

2. PROPOSED BUSINESS SCHEME

To enhance the independence of building- and block-level energy, consumers will probably have more on-site power/ heat sources allowing self-supporting operation.

On the other hand, when the separation of electric power production from its distributor, these power/ heat source owners may act as producers of more electric power/ heat than is self-consumed at ordinary times and allocate and sell them to adjacent buildings/ blocks will be paid for quicker returns on investments. In such cases, a mechanism of power/heat conveyance line networks being built as community infrastructure, with rental fees to be paid by users, is considered to be effective.

Hence, this study uniquely tries to suppose a public-private partnership business form embodied by two entities different in nature: one is mainly a private sector' "on-site energy generation companies" having a point of contact with end-use consumers as well as having and operating power/heat sources for production/ selling and the other is a "community energy network infrastructure company" serving the public good/interests and undertaking the ownership and management of infrastructure for power/ heat conveyance.

Figure 2 shows an overall image of the business scheme consisting of stakeholders of these business entities

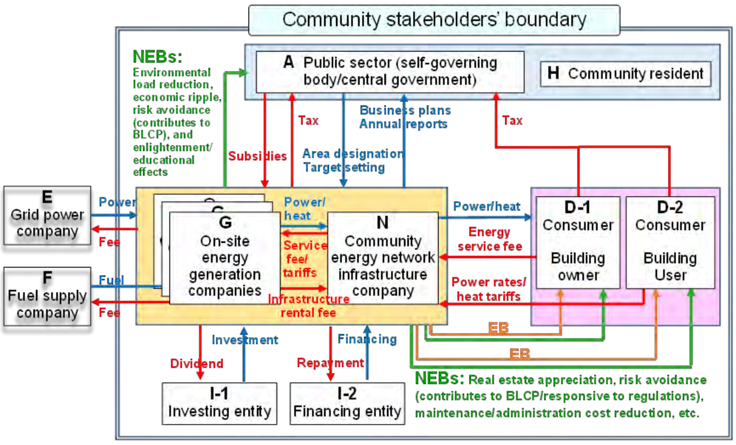

Figure 2: Shows an overall image of the business scheme consisting of stakeholders of these business entities

3. METHODOLOGY OF EVALUATING BUSINESS SCHEME

Figure 3 shows the flow of evaluating the business scheme. The flow is roughly divided into three steps as mentioned in the following 3.1. to 3.3.;

3.1 Verification of an overall community area

First, in accordance with the assumption of future building use composition and total floor areas for respective applications in targeted community areas, the case where these just satisfy the current standard for buildings is deemed to be BAU. Next, using a literature method, the maximum power load (kW) to be maintained for functioning as BLCP during disasters and other emergency times is calculated.

Based on the above, the quantity (kW) of co-generation to be adopted and the total length (m) of heat conduits/private power lines are determined for the estimation of costs required for adoption, with the following as a guide obtained through the introduction of a self-supporting decentralized energy network:

- CO_2 reduction rate of 20% or more of the BAU case
- Energy independence (power) of 100% or more
- Project B/C (= (EB + NEB)/C) is 1 or more.

3.2 Cost and co-benefit allocation to stakeholders

Policy for allocation of costs among stakeholders

The cost required for businesses is divided into facility improvement/ replacement investment and maintenance/ administrative/management expenses. Next, subsidy rates, and so forth, under ongoing subsidy programs of the central government and municipalities to assist ESCO business and low carbonization measures/policies are factored in to assume cost allocation among stakeholders. Figure 4 (left) images cost sharing policy in the case where the public sector helps with one-third of the facility improvement / replacement investment.

Policy for allocation of co-benefits among stakeholders

In case a community-level energy business is put into practice under the business scheme outlined in Figure 2, diverse co-benefits can be expected. Mizuishi et al. pointed out in their study the necessity to reallocate non-energy benefits (NEB) since they do not always belong fairly to stakeholders.

This study uniquely proposes to consider where the co-benefits brought by business intrinsically belong and, at the same time, allocates them among stakeholders in proportion to the above-mentioned ratio of cost sharing. Figure 4 (right) outlines the concept

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

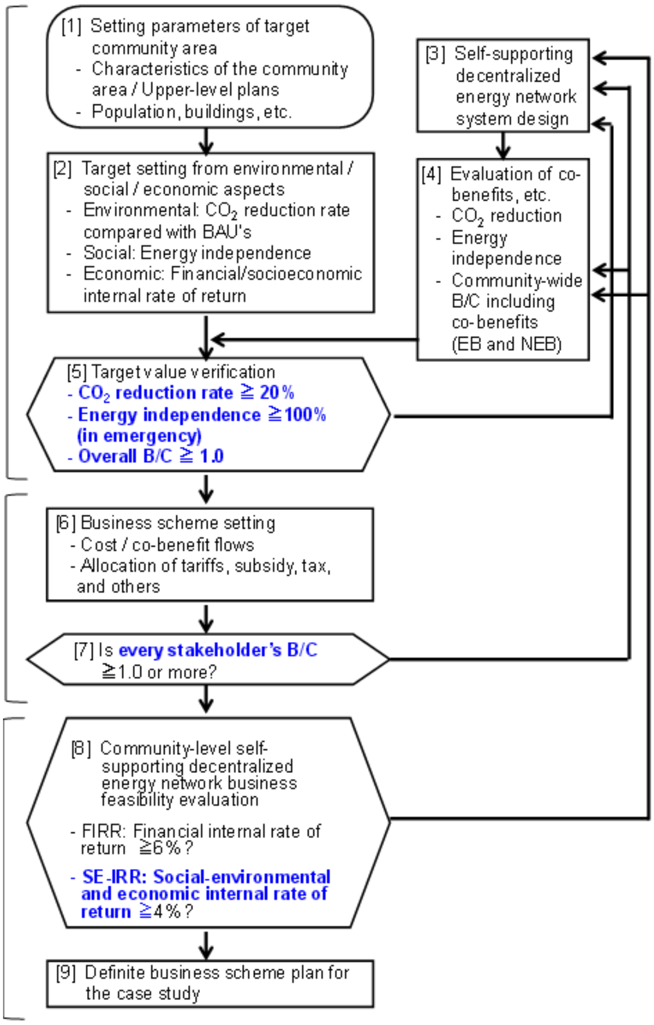

Figure 3: Flow of evaluating business scheme

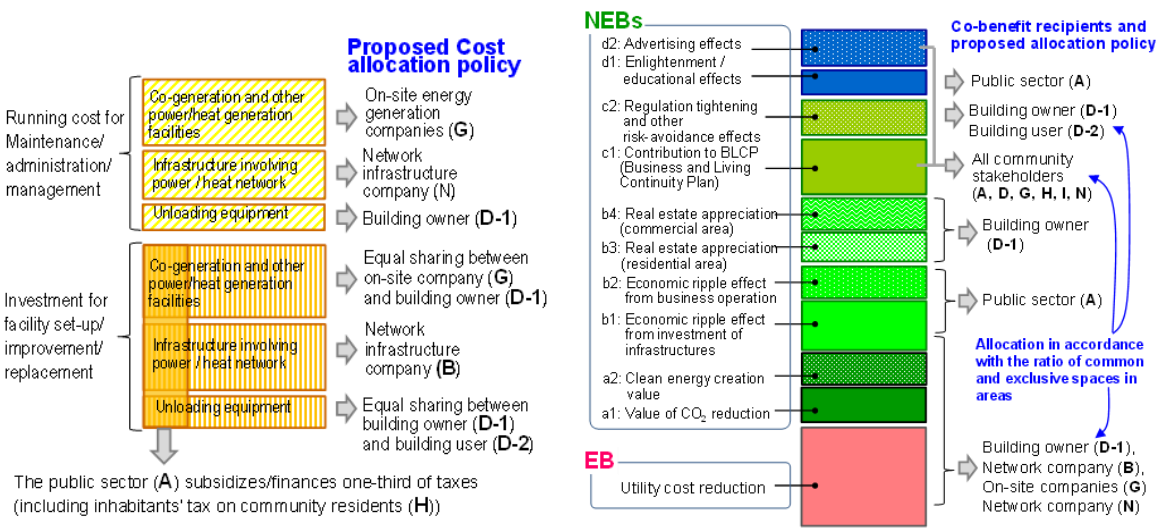

Figure 4: Policy of allocation of cost and co-benefits (EB and NEBs) among stakeholders

3.3 Evaluation of business entities' FIRR and SE-IRR

In order that the self-supporting decentralized energy system may be established as an independent business in the community concerned, it is necessary to prove that initial investments in business equipment for community-level co-generation and other businesses can be recovered by earnings through subsequent management. As an index to judge this, in addition to FIRR (financial internal rate of return) used in conventional business investment evaluation, this study, as mentioned below, uniquely proposes to newly define and use SE-IRR (social, environmental and economic internal rate of return), which takes into consideration the high-level contribution to public interests and takes co-benefits (EB and NEBs) into account.

SE-IRR defined r to establish;

$$\sum_{t=0}^{n} \frac{EB_t + NEB_t - C_t}{(1+r)^t} = 0$$

$$\left(\begin{array}{ll} n: & \text{Business period (in years)} \\ r: & \text{Discount rate} \\ EB_t: & \text{Amount of utility costs reduction enjoyed by business entities in FY t} \\ NEB_t: & \text{Indirect benefits enjoyed by business entities in FY t} \\ C_t: & \text{Costs of business entities in FY t corresponding to EBt/NEBt} \end{array} \right)$$

This study defines, as its own index, SE-IRR, which considers NEBs brought by the low carbonization measures of previous studies presented, as follows, to propose its use for community energy network infrastructure company (N) evaluation.

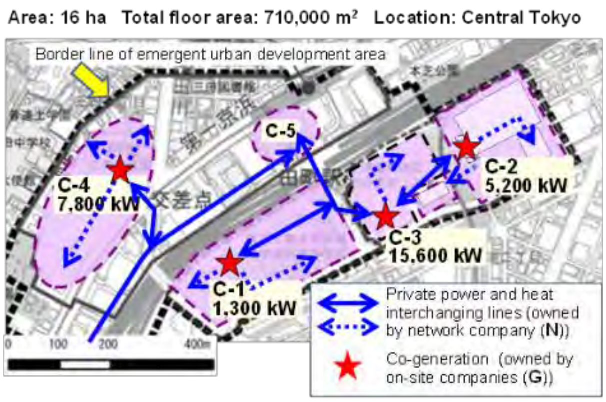
Concerning the target level of SE-IRR, Technical Guide to Cost/Benefit Analysis for Public Work Evaluation (General) (June 2009), published by the Japanese Ministry of Land, Infrastructure, Transport and Tourism (MLIT) proposes the concept of Economic Internal Rate of Return (EIRR) considering direct/indirect benefits in a variety of public works as well as advocates possibilities to judge the investment efficiency of a business by comparing it with the social discount rate and desires such as a rate of 4.0% to be used for both. Following this, this study considers 4.0% appropriate for SE-IRR very much serving the public good/interest in particular among community energy businesses.

4. CASE STUDY

4.1 Overview of the case study community area

Figure 5 describes the target community area of a case study. This area is one of the bases for strengthening international competitiveness in central Tokyo and is a block of about 16 hectares where urbanized areas are mixed with redevelopment counterparts around a railway station. Main points of the assumption in this case study are given below.

- Business operations targeting an estimated building gross floor area of 710 thousand square meters
- In each of C-2 to C-4 blocks, in which large-scale integrated development is expected, introduction of co-generation at every redevelopment project
- In each block, along with well-established plazas, decks, and others facilities, laying of private power lines and heat interchanging pipelines



Business Item	Key Assumption
Business period	30 years after start-up
Pre-business equipment servicing period	3 years
Equipment replacement timing/scale	After the lapse of useful life designated by law, 70% was replaced.
Unit power/heat price for consumers	Power: 14 yen/kWh, heat: 13 yen/kWh
Price increase rate	Fuel purchase cost – annual 1.0%, Business income – annual 0.5%
Disposal at the end of business period	Assumed book-value sale of remaining equipment

Figure 5: Overviews of the community area and key assumptions for the case study

4.2 Main results of the case study

Rate of CO_2 reduction

The CO_2 emissions reduction rate of the target community area as a whole can be expected to account for 28% of BAU.

Energy independence

Energy independence of the target block as a whole was examined for 2 types different emergency levels (several hours to one day and over one day to several days) and both were found to be over 100%.

Overall B/C

As shown in Figure 6, B/C of the entire business was 0.87 in the evaluation of EB alone, while B/C = 1.64 can be expected if co-benefits (EB and NEBs) are taken into account.

B/C evaluation for each of the stakeholders among which cost and co-benefits have been allocated

In compliance with the policy stated by Figure 4, cost and co-benefits (EB and NEBs) were reallocated through the flow adjustment of power rates, heat tariffs, subsidies, taxes, interest, and dividends among stakeholders as shown in Table 1, producing the result given in Figure 7. For every stakeholder, B/C exceeds 1.0 and the difference in B/C among stakeholders ranged between 1.4 and 3.9, or within 3 times. In addition to this, consumers (D-1), network companies (N), and on-site generating companies (G) may expect to recover shared costs only from EB. This is because, among co-benefits, the economic ripple/risk avoidance effect as NEBs returns mainly to the public sector (A) and, as its reward, costs accounting for one-third of initial investment were allocated. At this time, B/C of the public sector (A) is also 1.4, clearly highlighting the reasonability of cost sharing.

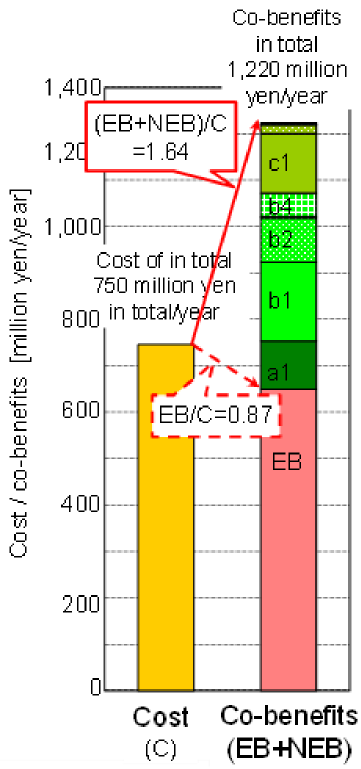


Figure 6: Overall B/C

Allocation policy items		Assumption
Public sector (A) and business operator (G and N)	Subsidies from the public sector	Subsidies to one-third of business operator (G and N) investment in equipment
	Rate of business operators' tax burden	40% including fixed asset/city planning and corporate taxes. Notwithstanding, 0% was assumed for business equipment of a network company (N) since it may probably be disposed of by the self-governing body.
consumer (D-1, D-2) and business operator (G and N)	Power rates/ heat price	Not to be coordinated. (Under an assumed contract for long-term connection, pay rate shall be deemed equal to BAU's.)
Financing (I-1, I-2) and business operator (G and N)	Interest	3% Notwithstanding, 1% is assumed for network companies (N) since they may enjoy long-term continual use by consumers (D-1 and D-2), debt guarantee from the public sector (A), and so forth.

Table 1: Proposed adjustment for re-allocation of co-benefits

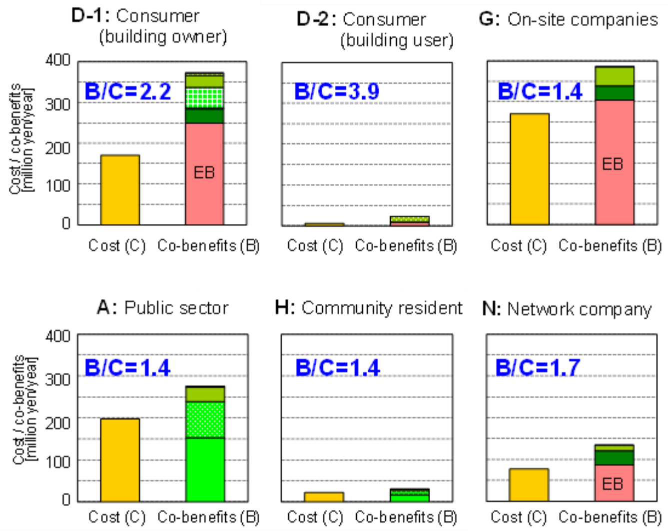

Figure7: Proposed allocation of cost and co-benefits among stakeholders

Evaluation of business entities' FIRR and SE-IRR

Figure 8 shows the profit/loss transition of business operators (G and N) during the business period to be used in FIRR and SE-IRR calculations.

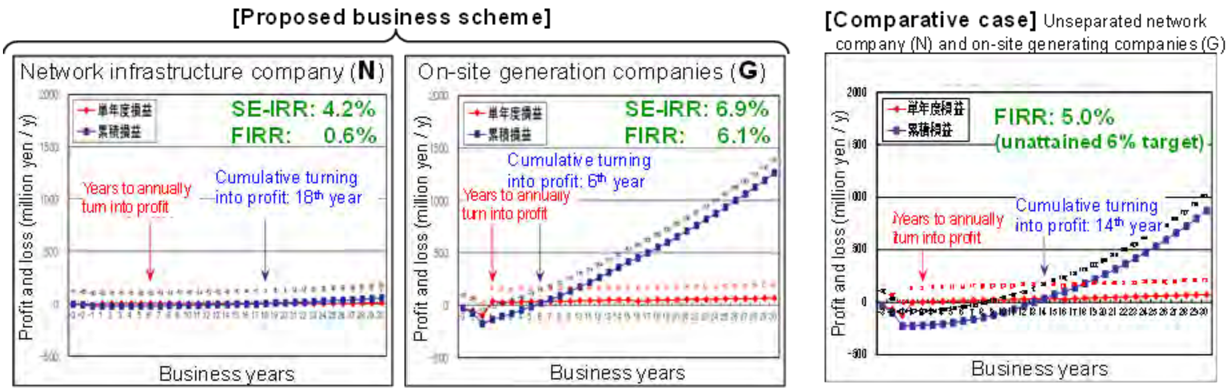

Figure 8: Financial performance of companies (G, N and unseparated case)

FIRR of on-site generation companies (G) was calculated at 6.1%, so the participation of a wide variety of private entities may be expected. On the other hand, network infrastructure companies (N) that totalled 4.2% in SE-IRR, satisfying the target value of 4% or more, may be judged to establish their business. Meanwhile, from Figure 8, the number of years to cumulatively realize a profit was found to be 6 for on-site generation companies (G) and 18 for network infrastructure company (N).

Figure 8 (right) shows a comparative case which constitutes both the network infrastructure company (N) and on-site generation companies (G) as one business entity. FIRR becomes 5.0%, lower than that of proposed case on-site generation companies (G) separated from the network infrastructure company (N) since it cannot be adjusted by consigned forwarding charges, and the number of years to cumulatively realize a profit becomes 14, indicating the difficulty to motivate private entities regarding the case.

5. CONCLUSION

Concerning how community-level independent decentralized energy network business can be established as a community's self-supporting project, this study proposed a business scheme considering co-benefits (EB and NEBs) as well as a series of evaluation methods and verified them through case studies.

ACKNOWLEDGEMENT

This paper is a part of the outcome of the academia, industry and government collaborative research "Energy Innovative Town" (led by Shuzo Murakami, President of the Institute of Building Environment and Energy Conservation) in the Japan Sustainable Building Consortium. The authors are greatly acknowledging the support of everyone involved.

Policy Framework and Instruments for Green Transformation in East Asia

Vincent CHENG[a]

[a] *Arup, Hong Kong SAR, vincent.cheng@arup.com*

ABSTRACT

The world has witnessed the largest global collaboration on combating global warming due to the excessive carbon emission associated with human activities. Many governments have made commitments on emission reduction and taken the necessary actions in addressing the problems. At government level, policies have been formulated to change the operations of industry, business and individuals to more sustainable manner. Developing low carbon society/ economy is becoming the prevailing initiative worldwide.

Asia has no exception on advocating this green movement. For those more developed East Asia economies such as Japan, Korea, Singapore, Hong Kong and Tai-wan, sustainable development is considered as the key national agenda not only for the sake of enhancing the environmental performance but also as the strategies on enhancing the social and economic benefits. Policies on directing the industry to the practice of sustainability are in place to increase the competitive advantages in global arena. Developing/ emerging countries, such as China take this agenda as the imperative for the survival of the nation on their process of urbanisation. Priority of policies has been channelled to the solutions/ strategies that can help resolving the environmental crisis.

In the quest for solutions, policy of the government plays the pivotal role, channelling the limited resources to address the most pressing issues. Implementation of policies, reflected by the adoption of appropriate instruments and institutional arrangements are critical to execute the policies. The success of the green movement will hinge on the prioritization of policies and its effective implementation. This paper develops a model to study the framework of sustainability policy on building sector that are prevailing in East Asian countries, highlighting the key agenda addressed and the effectiveness of these policies.

Keywords: policy and regulation, green transformation, urbanisation

1. INTRODUCTION

1.1 Rapid urbanization

Urbanization in the past few decades has accelerated the human activities for industrial and commercial productions that exacerbated the environmental problems. In Asia, regional urban economies (Japan, Korea, Taiwan, Singapore, Hong Kong and China to less extent) have developed through environmentally exploitive model in their urbanization process. As a result, many cities are now confronted with immense environmental challenges and some are facing multiple crises of liveability. Access to clean land, water and air are in jeopardy for cities in early urbanization stage. Environmental crises from air pollution and water contamination to waste generation are prevailing and affecting the daily life, in particular those poorest of the poor or society without society equity.

In parallel, cities are also facing adverse effects of climate change, which is escalating year by year, affecting everyone on earth. The risks of catastrophic natural disasters such as flooding, hurricanes or drought will hit severely those regional developing countries that are less prepared. The buildings, infrastructure and government and social supporting facilities are vulnerable to extreme weather. The cost for repairing the aftermaths is prohibitively high for those less affluent countries.

With more and more Asian developing countries undergoing their urbanization in faster pace, the outlooks of resolving environmental and climate change problems are not too promising. The world is facing more and unprecedented challenges in our history. It is imperative that we understand the problems and their root causes, and taking the actions in collaboration to resolve them.

1.2 Urban challenges in context

People move from rural areas to city in search of better livelihood and improved quality of living. City not only provides the basic necessities of shelter, food and water but also working opportunities to meet their enjoyment of urban consumption. Social security and communal supporting facilities can meet the needs on health care and education requirements. Yet, these expectations do not come naturally, and a worse-off situation is not uncommon in many cases in Asia, where people have to live in urban slum, suffering from the polluted environmental conditions of air, water and land. It has been argued that urban environmental challenges are the price for urbanization and had happened in all developed countries during their urbanization process. Some accept that these problems will only appear at the early stage of economic development and disappear when countries get richer. Yet such "develop first, clear up later" strategy may not be workable for the current developing countries of the region due to two reasons. Firstly the pace of urbanization is unprecedented and the environmental consequence could be too difficult to clean up later on. Secondly, compounded to the local environmental challenges is the global climate change. The combine effects could be disastrous.

Globally, there are little agreements on defining urban environmental challenges as different regions/ countries have different problems to face. Based on the scale and extent, urban challenges can be characterized in three types:

- Global climate change
- City-regional environmental challenge
- City-local liveability deterioration

Climate change is a newly emerging challenge. Asia and the Pacific in particular is the region most affected by natural disasters. Earthquakes, floodings and tsunamis are known threats. Global climate change makes the affected countries more vulnerable. The impact of disasters on urban areas of regional countries can be devastating. Urban agglomerations with high population density are experiencing high mortality levels in case of disaster.

Problems of urban environmental degradation affecting the daily life of city dwellers are equally daunting. Air and water qualify are threatening millions of people in the region, causing significant economic losses every year. Even the waste is becoming a key agenda for governments and policy makers.

In principle, enhancing the liveability is the interest and under the jurisdiction of city. It has the authority and incentive to make the city more appealing to its citizens. Yet, many developed cities in region are facing degradation in the built environment because of ineffective urban planning and poor management of urban facilities. Too many and too concentrated built-up areas causing heat build-up within the city and too little greenery to improve the quality of the ecological system.

These challenges have to be worked out from different levels and different stakeholders. Better urban practices and governance could help to reduce the burden if not eliminate the problems.

Scale	Challenges	Typical Issues	Causes
Global	Climate Change	CO_2 Emission, Global Warming; Extreme Weathers	Mass-consumption Lifestyles
City/ Regional	Environmental Degradation	Air, Water and Waster Pollutions; Energy and Resource Security	Rapid Urbanization
City/ Local	Liveability Deterioration	Urban Heat Island; Urban Form	Urban Planning

Table 1: Urban challenges

2. POLICY FRAMEWORK

In response to the urban challenges, there is always a case for reviewing the policies that affect buildings and construction in Asia. They are reviewed under the broad agenda of sustainability. These agenda include carbon emission, energy consumption, waste management and air quality, etc. In recent years, many governments have adopted the requirement for new regulations that a Regulatory Impact Assessment (RIA) should be undertaken. A

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

RIA consists, typically, of identification and clear statement of the purpose of the regulation, its risks, fairness and benefits which, if possible, should be valued. However, the main issue for the RIA is assessing the costs that are imposed on society and any other indirect effects. The review might adopt the principles of the RIA approach, but look retrospectively at the regulations in operation and not just at the proposals.

In 2004, HKSAR Government has conducted an exercise on establishing the policy framework of "Sustainable Construction". The objective is to find out the options on the effective policy framework to implement sustainable development. The framework developed out of the study, has looked into the issues from three perspectives to arrive at the policy options, namely the policy priorities, policy instruments and institution arrangements.

Policy priorities - a clear statement of its objectives, i.e. what it is that wants to achieve. Expressing objectives as "priorities" is important since not all the desired achievements are likely to be practicable within the foreseeable time-frame;

Policy instruments, which is used to achieve the priority policies;

Institutional arrangements, which are required to successfully identify and formulate the priorities for policy, specify the appropriate policy instruments and implement them; and in due course, undertake their view.

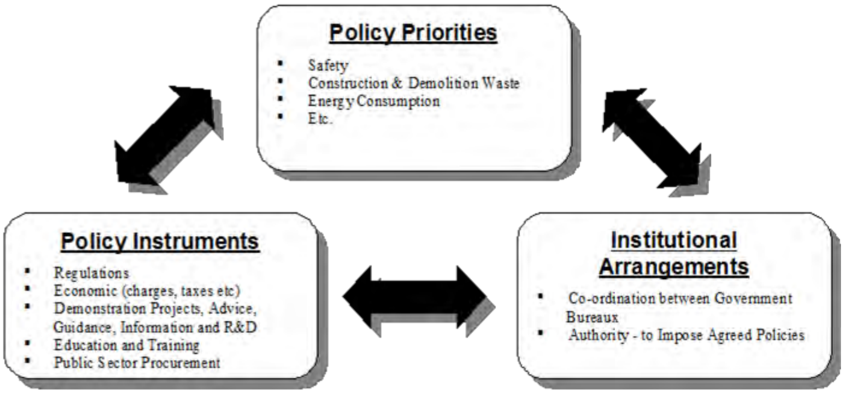

Figure 1: Policy framework for sustainable development

This framework provides a tool to study the policies on sustainable development systematically, on their rationale, implementation strategy and effectiveness across different countries. As many Asian countries share significant similarity on urban contexts and some on legal systems, they could provide valuable information for the policy makers when they conduct the RIA of their own.

3. POLICY PRIORITIES

In recent years, policy proposals are debated and pursued in some Asian countries without the existence of an overarching sustainability policy framework. Driven by more complex and complicated policy challenges, persistent problems, and conflicting interests, the desire for rooting policy-making in the available stock of knowledge and applying supporting techniques and procedures has grown. The issue for the governments, however, is how to ensure that the approaches are coordinated properly and implemented consistently with the sustainable development objectives. The developments of policy in Asian cities have shown some characteristic and share some similarities.

3.1 A moving target

Achieving sustainable development is a moving target. The key policy issues change with our understanding on the problem. The approach adopted by the EU on formulating the priority can be a good reference. This involves prioritizing a limited number of sustainable construction actions. Of course, EU priorities may well differ from Asian countries', although they are certainly relevant to the local circumstances. The EU established a high-level committee to review the possible areas for priority action and make appropriate decisions. To some extent, the Kyoto protocols and other international collaborations have fulfilled the role of information provider for the problems of the building and construction industry in this region, at least in large part. Regional and local forums were organized to discuss the policy issues on sustainable development and coordination for actions. There was no

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

shortage of information on the issues to be dealt with. Top items of the list are the climate change resilience, carbon emission reduction, environmental degradation, energy efficiency and renewable energy etc. The task outstanding is to prioritize them as a preliminary to taking the necessary actions.

Issues of Sustainable Development	China	Japan	Singapore	Hong Kong
Climate Change	Law on the Desert Prevention and Transformation (2001)	Act on Promotion of Global Warming Countermeasures (1998);		Resilient
Carbon Emission	Energy Conservation Law (2007)	Energy Conservation Law	Energy Law	Fuel-Mix; Energy Efficiency
Environmental	Environmental Protection Law (1989)	Basic Law of Environmental Pollution Control (1967); Basic Environmental Law (1993)	Environmental Protection and Management Act (1999); Environmental Pollution Control Act (1999)	
Liveability	Eco-City	Japan's Strategy for a Sustainable Society (2007)	Singapore Green Plan (1992); Sustainable Singapore Blueprint (2015)	Sustainable Building Design; Air Ventilation
Smart City	Renewable Energy Law (2005), ICT	Renewable Portfolio Standard (2003)	ICT	ICT
Others	Clean Product Promotion Law(2012); Government Procurement Law (2003)	Waste Management and public Cleansing Law (1970); Green Purchasing Law (2000)	Water Recycle	

Table 2: National plans and policy priorities on sustainable development of Asian countries

Issues on political environment also are affecting the priority of policy of a nation. For some democracies in Asian countries, the continuity of policy may have problems with the change in the administration. Technologies can also affect the priority. For instance, the commercialization of PV in the market and most recently the IoT technology are changing the landscape of sustainable development in Asia.

3.2 Prioritisation of policy issues

Globally, the policy objective of sustainable development is driven by the vision of a clean, healthy environment, and a strong economy. In recent years, the priorities of policy on sustainability of some developed Asian countries are extending from purely environmental issues such as air pollution, carbon emission and energy use to issues on society sustainability such as liveability, mobility and connectivity of people. The objective is to create communities that are more people-friendly as well as environmental friendly. This concept has expended the low-carbon development to sustainable development on encompassing the social and economic considerations, in additional to the environmental concerns. In the process of this green transformation, many regional megatrends have also driven the changes, including rapid urbanisation, economic integration, rising income and changing consumption pattern etc. These drivers of policy change have characterised the prioritisation of policy for sustainable development in the region. Some characteristics were observed on the regional leaders on their objectives in advocating sustainable developments:

- Regional integration – For regional leadership
- Top down national plan – For enhancing national competitiveness
- Green GDP – For addressing the environmental pressure
- Bottom up public engagement – For inclusive society and social equity
- Green consumption – For capacity building on green transformation

4. IMPLEMENTATION INSTRUMENTS

4.1 Leadership issues

The challenges for addressing the issues of sustainable developments, such as environmental problems, economic growth, poverty reduction, social development, equity and living standard are complex and inter-connected. Governments are better at institutionalising sustainability than any other sectors. And, if we are looking to achieve large scale transformation, the government sector is the obvious one to select. UNDP observed that active and effective governance requires institutions that are capable of delivering reliable and quality services by directing the talent, creativity and resources of people, business societies in shaping the changes we need. If public funds are required, the government can allocate and invest wisely, and manage public goods, including land and other natural resources equitably, for the benefit of all. Therefore, integrated policy and budget are critical to allocate resources to strategic national goals, rather than to individual ministries or departments.

Business clearly also has a critical role to play, and at its best demonstrates its capacity and will to advance the sustainability agenda. The private sector, however, cannot make the transition from a waste-based (resulting from our consumption behaviour) economy to a low-carbon economy without the rules of game to regulate/ facilitate the market that the economic life does not destroy the planet that provides us with food, air and water. The private sector can produce the goods and provide the services efficiently. Innovations and efficiency are what private sector is good at. Cross-sector partnering can only happen with the involvement of Government for the public-private partnership model.

4.2 Key policy initiatives and instrument applications

East Asia's dynamic economic performance has provided the opportunity for the green transformation. The regional economies have developed their own model of implementation arrangement, resulting in different extends of government/ private involvement. Key initiatives on policy initiatives and the corresponding instruments are found in Table 3.

Countries/ city	Instruments
Singapore (Liveability)	Sustainable Singapore Blueprint (2009) (2015) Green Mark Incentive Scheme (2015)
Japan (Energy Efficiency)	Feed-in-Tariff Scheme for Renewable Energy (2009) Tax for Climate Change Mitigation (2012) Low Carbon City Act (2012) Act on Energy Consumption Performance of Buildings (2016)
Korea (Green Growth)	Recycling Industry Promoting Loan (2012) Green Building Incentive Ordinance (2013) Renewable Energy Financing Programme (2015, 2016)
China (Eco-City)	Eco-city demonstration projects (2010) Feed-in-Tariff Scheme for Renewable Energy (2011) Green building direct subsidies (2012) Tax Rebate for Wind Energy Producers (2013)
Hong Kong (Green buildings)	HK-BEAM (1996) & BEAM Plus (2009) Energy Efficiency (Labelling of Products) Ordinance (2009) Buildings Energy Efficiency Ordinance (2013)

Table 3: Key policy and instruments for sustainable development in Asia

In particular, China decided to implement a "Green" GDP programme with the political shift in priority towards a more environmentally sustainable economic model. Effort has been turned to the building of sustainable (or low carbon) developments in China's urban transformation. With strong leadership and support from the Central Government, the policy of Green Urbanism in China is moving in the right direction, the principles of which are now being put into practice. Over 100 eco-cities are now being built in cities across China.

Bottom-up approach is also gaining more and more ground in developed economies across Asia in arriving at the creation of sustainability policies. These policies, in particular, those related to the environment of the local community, have to receive support from the local society itself. Enhancing the liveability of urban space is a good example. The bottom-up approach has also been widely introduced as a counterbalance to the national culture, and primarily aims at empowering the local population to participate in whatever development process may have conflicts. Regular and in-depth consultation with stakeholders is an important part of the process in arriving at new policy initiatives. Singapore and Hong Kong are examples that favour a bottom-up approach for formulating the strategies for sustainable development.

5. SUMMARY

Right governance is pivotal to the success of implementing sustainable development. At government level, a policy framework should be in place to direct the stakeholders. At the top of the framework, policy priority should be formulated. There are many drivers (external and internal ones) that are influencing the priority in Asia. Creating business or technology advantages for the countries for developed countries while those developing countries will have to focus on addressing the environmental challenges created by urbanization. The policy instruments should also be in place to implement the policy. Other than regulations, economic instruments are becoming popular to engage the key stakeholders.

On policy implementation, applying right instruments by the government is the key to success. At the early stage of green movement, regulations should be in place to control the business operation and individuals. When the green market is form, the government can consider apply economic instrument, which is proved to be effective on incentivizing the market. Some business, such as green building is now working effectively as market solution.

The institutional arrangement is also important. Normally, the government–led situation is common. There should be the right mechanism that link up the policy making process and the implementation of work. Private sector can also lead and in most case the support from the civic groups are also important.

ABSTRACT

Transitioning urban areas into sustainable communities is an important part of combating the current energy and emission challenges facing the world. The Norwegian municipality of Oslo has set ambitious energy and emission reduction goals for the coming decades. This analysis seeks to uncover how these goals are incorporated in the planning practice in the municipality.

Through in-depth semi-structured interviews with four energy planners employed in or related to this municipality's current urban development, this issue was explored. The data gathered from the interviews was analysed in relation to existing literature to reveal underlying problems, and what the potential benefits of a more integrated approach between the two planning agencies can yield.

Results from the interviews reveal that there are underlying challenges regarding system definitions, transformation of existing urban areas, making the right prioritizations, and indicate that integration between departments to reach common goals has potential for improvement. The urban planning department focuses mostly on other, non-energy related aspects of planning. From the data gathered it is clear that a stronger implementation of energy assessment in the urban planning practice can be beneficial for achieving the energy and emission reduction goals set by the municipality. New assessment methods and tools need to be developed and current tools should be stronger implemented in decision chains. Results are valuable for any government with similar challenges. As urban planning decisions will often have long-lasting implications this issue is pressing.

Keywords: energy use, policy and regulation, design process

1. INTRODUCTION

Cities all over the world are in the process of transitioning existing built areas into sustainable societies reducing local pollution and emissions that contribute to global warming, as set out in the Paris agreement. The goals set in this agreement, as well as the specific goals set by many local governments, are ambitious and require well-informed knowledge to identify measures that are most effective to support greenhouse gas mitigation.

The Norwegian municipality of Oslo has recently published its greenhouse gas (GHG) emission reduction goals (Oslo kommune, 2016). The overall goal is to achieve a reduction of GHG emissions of 95% by 2030 compared to 1990 levels. Achieving such an ambitious goal require dedicated integrated planning across sectors and scales, and a solid knowledge basis on which decisions can be made. The planning of cities consists on the one hand of professional objective assessments and calculations, while on the other hand there are political considerations that have to be taken into account. In energy planning, as in most areas, there is often a gap between the two. This paper seeks to identify current challenges of urban energy planning in Oslo municipality from the perspective of energy planners. Based on in-depth interviews with selected energy planners, as well as analyses of political documents and other literature, we present and discuss some of the challenges of reaching ambitious GHG emission goals.

1.1 Urban energy planning

Urban growth consists of different urban planning processes that include different aspects such as housing type and volume, traffic system, infrastructure, services, etc. The growth patterns are traditionally handled as several non-related sub-systems and processes, as opposed to a single system (Kuronen et al., 2010). Despite the high complexity of the energy sector, it can be studied in a meaningful way through an integrated assessment approach and a system-of-systems perspective (Agusdinata and DeLaurentis, 2008). Urban planning is, however, still treated as planning that considers only the spatial characteristics of a certain area (Kuronen et al., 2010), and energy planning is carried out only after the spatial plans are made. This practice is common despite that there is clear evidence of urban form affecting energy use (Weisz and Steinberger, 2010). An inter-organizational structure is argued by Korhonen (2004) to be an important element in successful urban planning, but is traditionally not part of the process, resulting in environmental management not being handled with a systems understanding. In a review paper (Keirstead et al., 2012), six approaches to urban energy system modeling were identified; technology design, building design, urban climate, system design, policy assessment, and integrated land-use and transportation. They conclude that “there is significant potential for urban energy systems modeling to move beyond single disciplinary approaches towards a sophisticated integrated perspective that more fully captures the theoretical intricacy of urban energy systems”.

1.2 Greenhouse gas accounting and system boundaries

Transitioning to zero-emission cities requires an increase in energy efficiency (reduction in consumption) and a shift to renewable energy sources, for all of the city’s activities. These activities include energy generation and energy use, as well as considering the import and export of goods that have associated emissions from their production and transportation. The energy consumption includes energy use for industry, transport, and buildings. Energy generation happens both within and outside of the municipalities’, and energy may therefore be imported or exported across the borders of the municipality, thus representing credit or debit in the CO_2-account of the municipality. The imported and exported goods are hard to account for and are therefore normally not taken into account in cities’ emissions accounting.

Renewable electricity from hydropower is abundant in Norway, and associated emissions from electricity production are small. Norway produces a surplus of electrical hydropower in a normal year. However, electricity is exported and imported with the European market and the actual electricity mix is, therefore, a more complex issue; what the marginal emissions are per kWh is a topic under discussion (Graabak et al., 2014). The municipality of Oslo has chosen not to allocate any emissions to the use of electricity from the grid. Within this definition, the used electricity is therefore not seen as a problem, but rather the remaining activities such as transportation, industry, waste generation and district heating plants. Still, the municipality has a focus on energy efficiency related to electricity use. The reason expressed for this is that it will “free up” electricity for other purposes such as electric vehicles and energy-intensive industries, as well as “be made available for export to other countries”. In addition, there are economic benefits of energy efficiency. Energy efficiency is in this way used as a proxy for reduction of greenhouse gas (GHG) emissions, but at the same time, there are by definition no emissions associated with it. The Climate- and Energy Strategy of Oslo is, therefore, twofold; an increase in energy efficiency and a reduction of direct emissions within the municipal borders. When assessing GHG emissions it is vital to set the system boundaries defining what to account for and what to exclude from the calculations. The system boundary definition will decide which actions will be taken to move towards the goals.

1.3 Political guidelines

The Climate- and Energy Strategy for Oslo municipality (Oslo kommune, 2016) was approved by the city council in June 2016. The overarching goal is a 50% reduction in GHG emission by 2020, and a 95% reduction by 2030, compared to 1990-levels. There are 16 target areas, whereof 10 are directly concerning emission reductions, and 4 are concerning the municipality’s governance towards emission reductions. The remaining two target areas encompass energy efficiency in buildings and water-based heating and cooling systems.

The Norwegian Planning and Building Act is the legal binding document for planning and building permits in Norway. In addition to this, there are national guidelines that supplement and elaborate on expectations from the national level to the local. The Norwegian Ministry of Local Government and Modernization have national guidelines on Integrated Residential-, Land-use-, and Transport planning released in 2014 (Ministry of Local Government and Modernisation, 2014). The guidelines seek to promote better resource efficiency and the development of sustainable cities and communities through compact urban development coupled with sustainable modes of transportation. Also, they state that the development of new residential areas should be evaluated together with the need for infrastructure. Similar goals are stated in the Climate- and Energy Strategy.

2. METHODS

The empirical basis of the paper is based on three in-depth semi-structured interviews. In one of the interviews there were two interviewees, and in the two remaining there was one, thus in total, four persons were interviewed. The informants were specifically selected based on their central roles in the energy planning and the Climate and Energy Strategy of Oslo municipality. The interviews took place in the offices of the informants or at the university and lasted approximately one and a half hours each. An interview guide was adapted for each interview. The interviews were recorded and transcribed. When analysing the interviews, a phenomenological approach was chosen, with a focus on the interpretation of the expressed statements in the context of the planning literature, the political goals and guidelines and the GHG emission accounting systems described in Section 1. The interviews were first read and highlighted, then, information was extracted, categorized, and compared. Finally, the findings from the interviews were analysed in the context of the issues outlined in Section 1.

3. RESULTS

The interviews revealed some challenges that were experienced by all informants as well as some that were pointed out by some interviewees. This section includes a synthesis of the content as expressed by the interviewees as well as descriptions of underlying challenges that were discovered.

3.1 Challenges in transforming existing built areas

The informants pointed out the special challenges of transforming existing areas. Different reasons were given to explain this; zoning restrictions; inhabitants' unwillingness to make changes, and long payback times for investments in the upgrade of buildings and energy infrastructure. They voiced the need for planning instruments for application in already existing areas, especially to tackle problems associated with the structure of ownership.

Oslo has a goal of densification, and to achieve a compact mixed-use urban environment. This goal was described as challenging to reach in some parts of the city due to active resistance from the people living in the area, which significantly slows the rate of densification. In these areas, there is strong resistance to building both taller than and close to existing houses.

3.2 Poor integration between energy planning and land-use planning

Although the integration between energy planning and land-use planning has been agreed upon and stated in documents, the integration has not been transferred into practice. However, the interviewees note that there is an increasing focus on this issue, but the practical implications are still very subtle. The integration mainly takes place in the form of interdisciplinary working groups and meetings. Still, the experience of some of the interviewees is that land-use planning is happening almost completely separate from energy planning. During land-use planning, all other concerns, such as the contractor's desire for profit, the municipality's concerns for good urban development, roads, and infrastructure, are prioritized. Energy planning is mainly done by the utility companies, and only after the zoning plans are set by the municipality.

Integrating transportation and land-use planning is considered very important, and to be the main tool available to the municipality for reducing transportation-related energy. On the other hand, the importance of focusing on energy efficiency of stationary energy use in land-use planning is questioned by some, but at the same time encouraged and wished for. Building close to public transportation hubs together with increased density and strict building energy codes are considered to be more important. On a stronger inter-organizational planning structure, opinions were mixed; both open to future reorganizations, and an emphasis on the need for dividing areas of responsibility.

3.3 Comparing the incomparable and the need for a common understanding of greenhouse gas emissions

A central problem mentioned by all interviewees was the challenge of comparing the incomparable. This can be synthesised in the following way: "We don't have the common underlying understanding and agreed upon framework for comparing different options in the right way". Since there are many variables affecting energy use, it was considered hard to assess impacts of different options. It was also expressed as a concern that there is not a common agreed upon framework for greenhouse gas emission accounting. This is related to the setting of system boundaries; that setting different boundaries will either lead to emissions not being counted, being counted differently, or that the emissions are shifted. It was voiced that this can put a specific energy solution in a negative light, disfavouring its use and that it might also lead to overall wrong prioritization on the municipal level.

There was no disagreement about the choice of not attributing any emissions to waste incineration in the district heating system. It was reasoned that the emissions are allocated to the waste sector which means that they are included elsewhere in the calculations. Also, it was argued that the waste handling system in Oslo was considered to be “particularly good”, and further improvements are planned. The heat from incineration is therefore considered to be waste heat. It was, however, pointed out by one interviewee that defining district heating as 100% renewable makes it hard for other options to compete, and in some cases, it might lead to a suboptimal solution being chosen.

Three informants described a concern that central energy solutions are disfavoured due to the way energy use in buildings is accounted. District heating solutions are said to be disfavoured in some cases because it is defined as delivered energy rather than primary energy, while delivered energy is what is taken into consideration in calculations. An example used was that local heat pump systems are often preferred over central heat pump systems due to the system boundary of delivered energy.

The fact that electricity had been defined by the municipality as having zero emissions was set forward as a more difficult topic. One of the interviewees particularly considered this to be a central problem, explaining that a consequence of such a definition is that there are no incentives for reducing electricity consumption to reduce emissions. There are two separate goals being promoted, one is energy efficiency and the other is emissions reduction. Although an underlying motivation for energy efficiency is the reduction of emissions, it is not counted as such by the municipalities. In this framework, they are incomparable, and improving one of them will not have any effect on the other. For instance, substantial subsidies are given for installing PV panels, when in fact, it is not helping the municipality to get any closer to the emission reduction goal. It was said that if the goal of improving energy efficiency is to reduce emissions, then the framework is not right. The interviewee argued that since the electricity from hydropower is part of the Nordic and European markets, a carbon component that is related to the actual electricity mix is needed. It was noted that the exact component related to a marginal use might not be possible to calculate, but there is a need for discussion of the principles on which this definition is made, which may lead to more well-informed incentives.

When being asked about what tools and assessment methods that could support a more holistic planning in the municipality, one of the interviewees expressed that, although such tools are welcomed and needed, there were doubts about the feasibility of creating them. Moreover, the belief in the benefits of such tools were limited. The opinion was that it is not hard to agree on the basic principles for an environmentally friendly city, such as mixed-use areas that have most services within 5-10 minutes of walking distance, placing housing close to public transport infrastructure, making electrical vehicles attractive, and strict building energy codes. Together, it was said, they will result in an energy efficient, climate-friendly city, and to calculate and quantify the effects can be demanding. Even if it is possible, it was questioned whether such calculations are necessary.

3.4 Prioritizations of actions made on insufficient basis

There was a concern that there is not a good basis on which important decisions on prioritization of resources are being made, expressed by one informant, saying that we are not doing enough cold, “cynical”, objective evaluations on what measures will be important in reaching the goals. It was stated that choices are too often made to promote spectacular, visible lighthouses and that there is too little focus on what actually has an effect. Examples of this included the willingness to support research and infrastructure for hydrogen, and the subsidies on PV panels; both of these measures not being coupled to the GHG emission reductions set by the municipality’s definition. It was reasoned that when the municipality is setting such bold goals, money should be more deliberately spent on reaching those goals.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4. DISCUSSION

The scope defined by the municipalities will have a big effect on the outcome of GHG emissions accounting, and can to a large extent determine where the focus is put on energy and emissions reductions. Since Oslo is not allocating any emissions to the electricity or waste incineration in district heating, there is a danger of not putting enough effort into reducing emissions from these sources, and thus encouraging consumption of these. Oslo municipality argues that they do focus on both energy efficiency in buildings, decreasing energy consumption from heating (mostly based on electricity and district heating), and on reducing emissions from the district heating facility. These goals are also clearly stated in their Climate- and Energy Strategy. This reveals that the municipality has a systems view on their sustainability approach that surpasses their emissions accounting. Nevertheless, a contradiction arises when two of the target areas by the municipality's definition are not related to GHG emission reduction, but rather on energy efficiency in buildings and water-based heating and cooling systems. Fossil fuels are being phased out from these two areas, which will soon render them emission free by this definition. We argue that there is an inconsistency in the municipality's reasoning, in that both electricity and waste incineration in district heating are considered to be emission-free, while at the same time energy use for heating and cooling in buildings is given high priority. It is possible that having two separate goals, achieving higher energy efficiency and reducing emissions, might not be the best way of mitigating climate change. By using a conversion factor between electricity demand and emissions, such as the ones described in Graabak et al. (2014), the GHG reduction potential of reduced energy use can be compared with other GHG reduction efforts to assure that each area receives the prioritization that will have the most effect on emission reduction. We should, therefore, have a scientific basis for the effect of these measures, and align our goals and actions thereafter.

When building district heating infrastructure based on the assumption that it is utilizing waste heat to recover energy, one should be careful that the infrastructure dependence on district heating does not make the municipality dependent on having a supply of waste beyond that which can be expected in the future. Especially since the municipality has a goal of reducing upstream waste, the future impacts of these two possibly conflicting efforts should be considered. An analogy can be drawn from research showing that there is a far greater benefit in reducing food waste than in recycling it for energy recovery (Hamilton et al., 2015).

In the interviews, it became clear that energy planning follows after land-use plans are developed. This is consistent with Kuronen et al. (2010) and signifies improvement potential in a stronger integration of the two sectors (Korhonen, 2004). Efforts in the municipality should thus be continued in this area. Stronger inter-organizational integration could also be considered, as argued by Korhonen (2004).

A concern was expressed in the interviews regarding the importance of achieving, and the feasibility of achieving, an integrated model for urban energy planning and land-use planning. Although the difficulties of isolating variables and creating such a model are documented in literature (Weisz and Steinberger, 2010), as described in Section 1, integrated assessment has proven successful despite the complexity of the energy sector (Agusdinata and DeLaurentis, 2008). While there is still a need for improvement of models, there is significant potential for urban energy systems modeling to move from single disciplinary approaches to a sophisticated integrated perspective (Keirstead et al., 2012). Quantifying to what extent different measures are successful can lead to the formation of more effective strategies.

The difficulty in transforming existing built areas is a barrier to reducing transport, renewing energy solutions, and altering urban form. There is thus a need for planning tools that reduce the challenges associated with this transformation.

We do not argue that cities should be planned only according to energy and emission reduction, but that a large fraction of the planning process can be done in this way, and that it is possible to make better quantitative integrated solutions than the ones used for the decisions taken today in the planning practice.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

5. CONCLUSION

From the interviews, it was found that there are some underlying challenges and areas of conflict that materialize as hindrances to reaching the goals set by the municipality. The energy planners find it hard to achieve the goal of a zero-emission city without a clear framework for evaluating alternatives and a holistic calculation tool for determining the effects of policy choices. There is thus the need for the development of such a tool and a scientific discussion on how to evaluate alternatives in a holistic way.

This research is part of a work to map the needs of municipalities in the transition to sustainable cities. The work will continue in other municipalities. Thereafter, based on the results we will develop methods and tools that will tackle the obstacles discovered.

ABSTRACT

This article reports on the development of the certification scheme Citylab Action. The process of development is described, design considerations for the scheme are accounted for, and results from a pilot study, in which twelve projects are testing the first part of the scheme, are provided. The scheme has been developed through an iterative process, involving more than 400 practitioners and experts. First a draft definition of sustainable urban development was formulated, based on an analysis of how urban development can contribute to national and international goals for sustainable development. The draft was then discussed in a series of workshops, after which the resulting comments and suggestions were used to develop the draft definition into a draft scheme. This resulted in the definition of 17 objectives for sustainable urban development. Moreover, ten effects were defined, clarifying what the scheme ultimately seeks to support.

The first version of the guide was released in October 2015. In essence, the guide defines what is important to consider when planning an urban development project. The guide was also complemented with a program for urban development projects, in which urban development projects that want to focus in sustainability can share knowledge and experiences. A pilot version of the program is running January to December 2016. The next step in developing the scheme is to follow up on the pilot, as well as to complement the scheme with indicators and criteria for certifying the planning process, as well as for ex-post evaluation of the performance of the urban development projects.

Keywords: sustainable neighbourhood, certification scheme, piloty-study

1. INTRODUCTION

Certification schemes for sustainable neighbourhoods work through establishing a number of criteria and related indicators, supporting specific processes (e.g. public consultation) and features (e.g. solar panels) as well as for ex-post performance evaluation (e.g. kWh/m^2 and year). Several studies have dug into these systems, identifying a few re-occurring challenges such as the balance between different dimensions or impact categories/spatiality of sustainability and the balance between mandatory and non-mandatory criteria

Since 2010 there has been an on-going discussion in the Swedish built environment sector about the need for a certification scheme for sustainable urban development, developed for the Swedish context. Within this discussion different international certification schemes were evaluated, showing that while certification schemes are seen as having clear benefits, they need to be complemented with a forum for learning and exchange. This article reports on the development of the certification scheme Citylab Action. The process of development is described, design considerations for the scheme are accounted for, and results from a pilot study, in which twelve projects are using the first part of the scheme, are provided.

2. DEVLOPING CITYLAB ACTION

2.1 Beta-testing BREEAM communities

To investigate whether BREEAM-C (BREEAM Communities) would be suitable for a Swedish context Sweden Green Building Council (SGBC) and the project “Nordic Built - Nordic Urban Development” arranged a series of beta-tests. The beta-tests were carried out in cooperation with 22 urban development projects in Sweden which tested themselves against the BREEAM-C’s manual to evaluate whether, and for what aspects, compliance with the certification scheme would lead to a more sustainable urban development or not. In order to collect the different views and opinions on BREEAM-C all beta tests were thoroughly documented. Moreover, a SWOT-analysis of using BREEAM-C in Sweden was carried out, the contact persons for each of the participating urban development project was interviewed [see 9] and a two-day concluding workshop was held when all beta-tests had been conducted. The concluding two-day workshop gathered partly the same persons as the interviews but also others that had been involved in the beta-tests. These evaluations together with the overall result from the beta-tests were the main basis when deciding whether to develop a Swedish certifications scheme or not. The results from the beta-tests, SWOT-analysis, interviews, and workshop pointed in two main directions. On the one hand, the participants recognised a number of positive effects of using a certification scheme. Certifying an urban development project is an opportunity to promote both the urban area being developed and the municipality as a whole, something that was seen as a way to attract both inhabitants and companies to the municipality. Using a certification scheme was also seen as providing a structure for integrating sustainability considerations into the development process. This involved both using the certification as a 'checklist' to make sure that all aspects are considered, but also using the certification scheme as an argument to implement actions which would be difficult to get realised otherwise. On the other hand, the respondents and workshop participants also raised some drawbacks of using BREEAM-C as a certification scheme in Sweden. BREEAM-C is based on a British context that in several ways do not correlate to the Swedish planning context resulting in a need for major adaptations. These differences include legislation, standards, praxis, the organisation of planning etc. An adaptation would also have needed to consider the differences in how different aspects of sustainability is handled in the two countries. Moreover, besides from commenting on the manual as such, several participants also voiced a need for a network for people working with sustainable urban development, to facilitate knowledge sharing between different actors and urban development project, something that BREEAM-C did not support. SGBC could thus conclude that while there was a clear recognised added value of a certification scheme, especially if it was complemented with a networking components, these values were of a general character and not related to BREEAM-C as such. Consequently, instead of adapting BREEAM-C to a Swedish context, SGBC decided to develop a new certification scheme.

2.2 Developing a new system – Guide, programme and certification

The creation of a new Swedish certification scheme started with the definition of draft core issues. These were based on the conclusions of the governmental investigation "The Delegation for Sustainable Cities" [12], national environmental objectives, the beta tests and other workshops from earlier in the project [10] [11] etc. The draft core issues were then discussed during ten open workshops in 2014-2015, lead by the research project Decode and co-organised with ten municipalities, involving about 400 people from government agencies, municipalities, developers, real estate companies, energy companies, consultants, architects, research institutes, universities, politicians etc. Using the core issues as starting point, the workshops focused on what to include in a certification scheme and transforming the core issue into concrete measures and desired outcomes.

After the workshops the draft core issues were handed to fifty experts on urban development for further development. SGBC's members (real-estate owners, municipalities, property developing companies, consultant companies etc…) were also involved through monthly web-meetings. Parallel projects working with sustainable urban development such as C/O City and Södertörnsmodellen also contributed to the development. The expert group handled all comments and suggestions. In June 2015 a demo version was released followed by a five-month referral process to which 18 of SGBCs member-organisations provided feedback. Additional input to the revision came from the UN Sustainable Development Goals (SDG) established in September 2015. In October 2015 the first version of Citylab Action's "Guide for Sustainable Urban Development" could be released. The Guide is not yet developed for certification but concentrates on what sustainability issues that are important and how to work with these issues to create a more sustainable urban development.

As concluded in the beta tests of BREEAM Communities, there was a need for something more, which a guide or a certification scheme could not fulfil: a need for knowledge sharing between different actors and urban development projects. The program Citylab Action was thus developed to support public and private stakeholders to develop their project specific sustainability programs and action plans. The aim of the program was also to facilitate a sharing of knowledge, experiences and ideas within the Swedish built environment sector.

3 INTRODUCING CITYLAB ACTION

3.1 The guide

The Guide is structured in three main parts: Desired Effects (Table 2) stipulate the intended outcome, and as such work as a definition of a sustainable city; the Sustainability Issues (Table 1) provide a concretization of what issues projects need to work with in order to realise the Desired Effects; and the Working Process (Table 2) which formulates aspects regarding management, participation and innovation throughout the project, which are fundamental to turn visions into reality.

Category	Issues		Issues elaborated
Spatial and integrated urban qualities	1	Built environment	Resource-efficient use of land to create a physically connected and socially integrated city.
	2	Cultural values	Preservation and use of existing cultural values and heritage.
	3	Functions	Diversity in design and functions (housing, service, culture, work-places).
	4	People	A good living environment with a minimized environmental footprint for residents, visitors and workers.
Proximity and accessibility to functions	5	Transport	Proximity and accessibility to urban functions and support sustainable transport (walking, biking, public transport, and delivery).
	6	ICT	Development and provision of information and communication technologies and data to support sustainability.
	7	Places	Access to safe and secure public and semi-public places in built and natural environments for people no matter ethnicity, gender, disabilities or age.
	8	Schools	Good indoor and outdoor environment in schools and preschools.
Air, light and soundscape	9	Air	Good air quality.
	10	Light	Good lighting conditions in support of orientation, road safety, security and aesthetics.
	11	Soundscape	Noise management so as to avoid negative health effects such as stress, hypertension, sleeping and concentration difficulties or general discomfort.
Multifunctional green areas and climate adaptation	12	Green areas	Multifunctional green areas and ecosystem services providing good quality of air, soundscape, and microclimate, supporting physical, psychological and social wellbeing.
	13	Climate adaptation	Increased robustness and decreased vulnerability for future extreme weather events, sea level rise and increase in temperature.
Sustainable resource use	14	Material flows	Low resource use and the establishment of circular flows of biological renewable and technical non-renewable resources.
	15	Products	Choice of products and materials that minimize emissions of hazardous substances to air, water and soil, and that creates possibilities for good working conditions.
	16	Water	A reliable and efficient water supply system, and a sustainable management of storm and sewage water.
	17	Energy	Minimized use of energy, coming from renewable energy sources with delimited impact on health and environment, and with close to zero GHG emissions.
	Synergies and conflicts		Conflicts between project targets and local, regional, national or international targets; Synergies and conflicts between project targets; Risk analysis for not reaching the targets; Identification of success factors

Table 1: Sustainability issues in Citylab action

Desired effects		Working process
1	Health and wellbeing	*Organisation*
2	Equality and social cohesion	Management, skills staffing and coordination of sustainability.
3	Participation and influence	
4	Safe living environment	*Collaboration*
5	Good livelihoods	Strategies, processes, tools and methods for coordination of the
6	Attractive city-life	different actors involved in the project.
7	Resource management	*Participation*
8	No negative climate impact	Strategies for participation of inhabitants and local actors, and for how
9	No negative environmental impact	to handle conflicts of interest.
		Innovation
10	Resilience and flexibility	Strategies to promote innovation.

Table 2: Desired effects and working process

Citylab Action's "Guide for sustainable urban development" looks quite different from other certification schemes. The Guide is not a "technical manual", stating how many points or what grade a certain action is worth or equal to and there are just a few issues that are formulated in quantitative terms. Instead the idea of the guide is to be a structure for the collaboration between the actors involved in an urban development project and support the process of transforming visions about sustainable urban development into concrete action. It should also be adaptable to different projects of different sizes and with different sustainability challenges. Indeed, this flexibility also brings about with challenges when it comes to certification, for which assessment criteria and indicators will need to be established.

3.2 The Program

As previously mentioned, one important part of the idea of Citylab Action is also to facilitate a sharing culture so that different actors within the Swedish built environment sector learn from each other's mistakes and successes. In order to do that a Program was developed, based on the Guide, to support urban development projects with sustainability ambitions. The Program builds on the pedagogical concepts of the flipped classroom and peer learning. During a 12-month period, participating projects meet at six two-day meetings. At every meeting one process theme and several sustainability issues from the Guide is discussed (see Table 3). Also, external experts are invited to speak and different exercises are arranged to make it possible to try new methods or to get new perspectives. The participating projects then starts their internal discussions about how they work with the issues and themes in their respectively projects and how to develop that work. After the meeting the work continues at home, where every project formulates their own targets, action plans and strategies to follow up the targets and actions. At the next meeting the participating projects presents their targets, action plan and strategies for follow-up for each other in so called peer-groups, letting individuals from the projects sit down and discuss the different projects' respective difficulties and share ideas for the development. At the sixth and final meeting the projects present their final results: a sustainability program for the project and a plan for implementation and follow-up.

	Meeting 1	Meeting 2	Meeting 3	Meeting 4	Meeting 5	Meeting 6
	2016:01	*2016:03*	*2016:05*	*2016:08*	*2016:10*	*2016:12*
	Uppsala	*Göteborg*	*Eskilstuna*	*Norrtälje*	*Helsingborg*	*Malmö*
Process theme	Organisation	Participation	Collaboration	Innovation	Implementation	
Sustainability Part 1	Conditions for sust. development	Place and connectivity	Mixed, heterogeneous city	Energy use and renew-able energy	Social life and sustainable behaviour	Presenting sustainability program
Issues	*1-17*	*1-4*	*3, 5-8*	*17*	*4, 7-8*	
Sustainability Part 2	Sustainable opportunities and life quality	Ecosystem services and green structures	Sustainable transport, mobility and ICT	Resource management	Sustainable quality of life	
Issues	*1-17*	*12-13*	*9-11*	*14-16*	*4, 7-8*	

Table 3: Structure and content of Citylab action programme

To promote the sharing culture of Citylab Action, only projects that have been participating in the Program can be certified. However, a project does not have to certify or try to certify according to Citylab Action to participate in the program.

4. PILOTING CITYLAB ACTION

In January 2016 a pilot-version of the program was launched. Twelve different urban development projects (Table 4) participate in six two-day meetings, running January to December 2016.

Participating projects	New development	Retrofitting with new development	Mostly housing	Mixed use	Mostly business	Municipality
Barkarbystaden TRE	x			x		Järfälla
Campus Albano	x			x		Stockholm
Drottning H		x	x			Helsingborg
Falsterbokanalen	x			x		Vellinge
Lommarstranden	x		x			Norrtälje
Masthuggskajen	x			x		Göteborg
Norrtälje Hamn	x			x		Norrtälje
Rosendal	x			x		Uppsala
Skeppsbron	x			x		Jönköping
Solna Business Park		x			x	Solna
Stadsläkning Lagersdal		x	x			Eskilstuna
Täby Park	x			x		Täby

Table: 4 Overview of projects participating in the pilot version of the program

At the time of writing this paper 4 out of 6 meetings have taken place, implying that all findings must be treated as preliminary. The findings presented here are mainly based on the evaluations that participants have been asked to fill in after each meeting. With a response rate of around 50 %, a vast majority (95 %) have found the program valuable and would recommend others to participate. All parts of the program; lectures, exercises, working within the project group, discussing issues in mixed groups; are popular with 85-98 % saying it was valuable for the project. Several of the contact persons for the participating projects have also expressed their satisfaction about the program, pointing to that it gives a needed structure to the sustainability work, that it gives the project an otherwise missing forum for discussions between the involved actors, and that it makes it possible to ensure that sustainability is integrated in the project and does not become "bolt on" project.

Since the Program is based on the Guide, the pilot version of the program is also a test of the first version of the Guide. The Guide has not yet been evaluated in any structured manner apart from that the participants in the Program has been encourage to give comments by post-it notes during the meetings as well as in a digital platform between the meetings. The comments have so far been focused on formulations of specific sentences, aspects missing among the issues and questions about what, more specifically, is meant with certain formulations.

Participants in the Program express that they find the Guide useful (also see [19]) as a checklist to ensure that they do not miss any important issues. The desired effects are here crucial and used at every meeting and by the projects back home to evaluate objectives and planned actions to see whether the project as a whole steer towards all desired effects or just some of them. Finding ways to optimise the actions to steer towards more than one of the desired effects at a time. One of the urban development projects even reorganised their organisation after the first meeting in the program. The new organisation was based on the recognition that to ensure that sustainability not becomes a special interest guarded by a certain group, it must be integrated into the entire organisation.

5. CONCLUDING DISCUSSION

Looking at the preliminary results of the evaluation of the pilot version of the Program, the participants seem satisfied with how the Guide and the Program helps them with formulating their own objectives, action plans and strategies for follow-up. Based on the evaluation we can also draw the preliminary conclusion that the Guide and the Program together seem to cater for the two key functions of a certification scheme requested by the participants in the beta-tests and workshops: a structure and a checklist for action, and a forum for sharing of knowledge, ideas and experiences. This shows that involving the target group early in the process of creating Citylab was important in order to create something that suited the needs of both private and public stakeholders.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Even though participants express a satisfaction of the Guide and the Program there are work left to do. First of all, the Guide needs to be developed with assessment criteria for both the planning phase and to evaluate ex post performance. Moreover there is a need to establish routines for continuous evaluation and development of the Guide and the Program in order to keep it up to date with how technology and society develop. Finally, given that it is the Program that is the most innovative part of Citylab Action, the knowledge sharing and learning aspect of the system would benefit from deeper theorizing.

The Break-Even Point: Impact of Urban Densities on Value Creation, Infrastructure Costs and Embodied Energy

Serge SALAT[a]

[a] *Urban Morphology and Complex Systems Institute, France, serge.salat@gmail.com*

ABSTRACT

This paper, based on the science of complex systems applied to cities, presents new findings on the impact of density on urban space economy: urban spatial expansion and value added creation *versus* additional urbanization costs. The paper proposes a new metric, the hierarchy coefficient in Pareto distributions, to describe the distribution of densities across urban space.

Based on case studies in London, Paris, New York, and a Chinese city, Zhengzhou, the paper reveals striking mathematical regularities, independent of the cities and their history, in the distribution of people, jobs, and energy densities within the urban space. This hidden order behind the apparent randomness of urban data points towards universality classes in the organization of cities. These findings have important policy implications for coordinating land use, transport, and economic policies in particular by determining a break-even point beyond which urban expansion costs more than the derived benefits.

Keywords: density, energy efficiency, agglomeration economies, complex urban systems

1. DECOUPLING

In economic and environmental fields, decoupling is becoming increasingly used in the context of economic production and environmental quality. When used in this way, it refers to the ability of an economy to grow without corresponding increases in environmental pressure. In many economies, increasing production (GDP) raises pressure on the environment. A "decoupled" economy is able to increase GDP growth while decreasing its negative impact on environment.

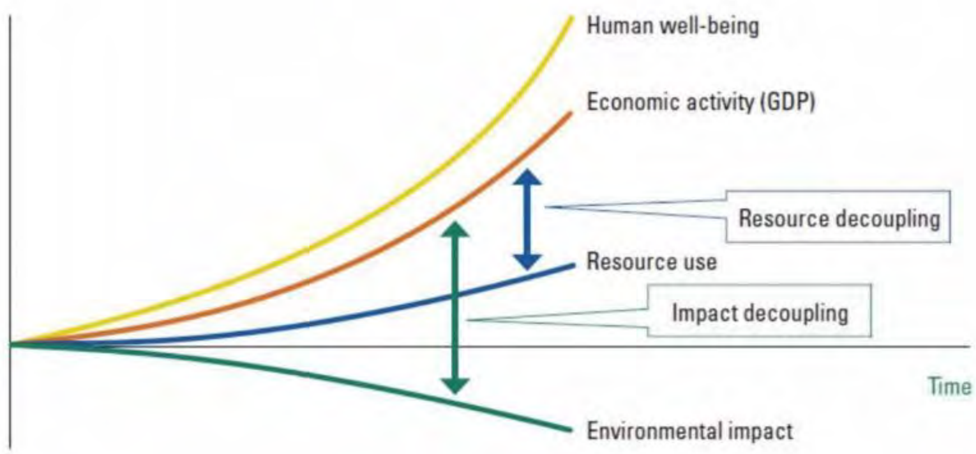

Figure 1: Decoupling human development and economic growth from escalating resource use and environmental degradation: resource decoupling: less resource use per unit of output; impact decoupling: less environmental impact per unit of output. source: International Resource Panel 2011.

This paper describes how shaping residential and economic densities at metropolitan scale is a powerful policy lever for decoupling.

2. THE SPIKY GEOGRAPHY OF URBAN PRODUCTIVITY

2.1 The 80/20 Rule in urban spatial economics

The 80/20 Rule is observed in many social and economic phenomena. Vilfredo Pareto was the first to see in the early 1900s that 80% of Italy's land was owned by only 20% of the population. More recently, Pareto's Law or Principle, known also as the 80/20 rule, has been turned into the Murphy’s Law of management: 80% of profits are produced by only 20% of employees; 80% of customer service problems are created by only 20% of consumers; 80% of decisions are made during 20% of meeting time; and so on. The 80/20 Rule describes the same phenomenon: in most cases four-firths of our efforts are largely irrelevant. The 80/20 Rule structures social networks: 80% of links on the Web point only to 15% of Webpages; 80% of citations go to only 38% of scientists; 80% of links in Hollywood are connected to 30% of actors.

The 80/20 Rule structures also the global economy. Today only 600 urban centers generate about 60 percent of global GDP. Among these, the top 10 cities with 2% of the world population generate about 11% of the world GDP. Only one city at the top of the global economy, Tokyo, generates about 20% of the top ten cities cumulated GDP. The 80/20 Rules structures also intra urban economic space. Within a city, 20% of the urban land produces 80% of the city's GDP. Inner London with 20% of Greater London area produces 70% of its GVA and concentrates 56% of all Greater London private sector jobs. This is due to strong agglomeration and localization economies.

2.2 Bumpy and spiky economic landscapes

Figure 2: Left: residential far in manhattan. source: urban morphology and complex systems institute.

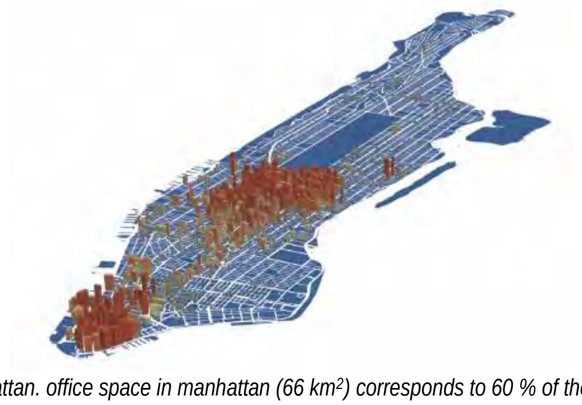

Figure 3: right: office far in manhattan. office space in manhattan (66 km²) corresponds to 60 % of the entire new york city office space while NYC spans 780 km² of emerged land with 8.5 million inhabitants. this office space is concentrated in only 6 km² of plots, which roughly correspond to 9 km² of urban land. source: urban morphology and complex systems institute.

Urban productivity results from a complex interaction of processes, including economies of scale and economies of agglomeration and localization induced by cost savings, location advantages, specialization premiums, and by the higher intensity of interactions between people and companies. Agglomeration forces translate into bumpy and spiky urban economic landscapes. In competitive cities, such as London and New York, one third of the jobs are agglomerated in about 1% of the metropolitan area creating intense knowledge spillovers, while the other two-thirds are clustered around transit stations. High densities of jobs increase productivity, competitiveness and job

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

creation: 29% of Inner London office space is concentrated in less than 1% of its area, in the City of London (450,000 jobs in 2.9 km^2 with a growth of 30% during the last decade); 60% of New York City office space is concentrated in 9 km^2 in Manhattan, that is in about 1% of NYC area. These extreme concentrations peak at 150,000 jobs/km^2 and are made livable by high quality public space like in London's Canary Wharf or in the project of Hudson Yards in Manhattan.

2.3 Pareto distributions: the hidden order of spiky economic landscapes

Within the high spike of wealth and economic might of Central London (309 km^2), the Square Mile of the City of London (2.9 km^2, 10% of Central London, 1% of Inner London, and less than 0.2% of Greater London) concentrates a disproportionate part of economic power in an extreme spike. The Square Mile of the City of London generates £45 billion in economic output in 2014, equivalent to 14% of London's output and 3% of the UK's total GDP. The cascade of spikes within spikes, The City of London spiking extremely high within the high spike of Inner London, points to a fundamental property of the 80/20 rule when applied to urban spatial economy: the rule applies at all scales; there is no characteristic scale; the rule is scale-free.

The new science of networks has shown that this scale free property is the intrinsic order to the number, size, and shape of the various attributes of networks (Barabasi 2014). And then in turn there is an intrinsic order of spaces and places that depend on urban networks. As summarized by Michael Batty, "in essence, the distribution of elements that compose the city - the hubs or nodes that sustain them - present us with highly skewed distributions, reflecting the essential economic processes of competition that drive a city's functions and determine its form and structure (Batty 2013)." These distributions usually describe large number of small objects and small number of large, following what are called scaling laws that, in turn, are usually configured as power laws, also called Pareto distributions in economy.

Power laws reflect processes that scale, that in some sense are self-similar, and this signature of a system's function implies that the system's subsystems, components, elements, are ordered hierarchically. These scaling processes generate urban growth and underpin the city's evolutionary architecture (Batty 2013), opening up our theory and model of urban economy to the world of complexity theory, to forms that associate a high level of order in their macro-structure with a high level of diversity and randomness in their details.

Figure 4: Inverse power laws: the hidden order of spiky economic landscapes. people, jobs, and economic densities, office space density, accessibility to jobs, rents, subway network centralities, and so on, across the urban space (Salat and Bourdic 2015) follow skewed distributions that are modeled by inverse power laws known in economy for a long time under the name of Pareto distributions. They comprise a few large and very large values (in green on the left) and a 'long tail' of small values on the right.

Figure 5: Left: The map of residential density in New York is aligned on the geography of transit accessibility to jobs. The higher the number of jobs a location has access, the more it is developed. Source: Urban Morphology and Complex Systems Institute.

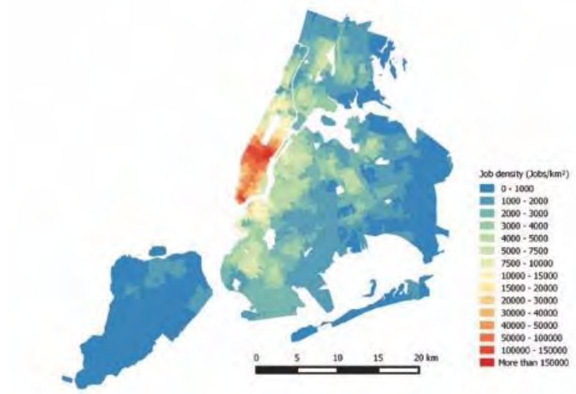

Figure 6: right: New York jobs are mainly concentrated in midtown and in lower manhattan with densities above 150, 000 jobs per km² in these 2 economic engines of New York. Source: Urban Morphology and Complex Systems Institute.

Densities in New York are articulated by power laws. Residential density in New York is extremely concentrated and aligned with the geography of transit accessibility to jobs, with a density above 18,000 people/km² on the densest 150 km².

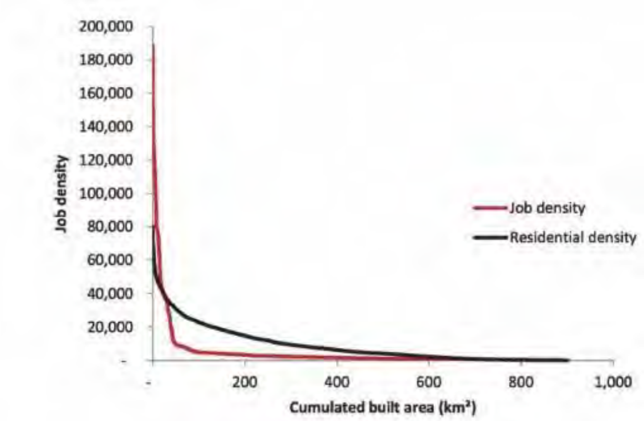

Figure 7: The jobs density distribution across New York urban space follows a power law of hierarchy exponent -1 (in a rank size analysis) while office density is even sharper in its spatial hierarchy with a hierarchy exponent -1.7. Residential densities are distributed more evenly than jobs with a hierarchy coefficient of - 0.74. Source: Urban Morphology and Complex Systems Institute.

New York and London as well as Paris have the same distribution of jobs densities – a power law with an exponent -1 – which points towards what is called a universality class in physics, that is a convergence of different phenomena towards the same geometric structure. In statistical mechanics, a universality class is a collection of mathematical models, which share a single scale invariant limit. While cities, such as Paris, London, and New York, may differ dramatically at small scales, their behavior will become increasingly similar as the limit scale is approached. In particular, asymptotic phenomena such as critical exponents will be the same for all cities in the class. Studies of cities as percolation systems with phase transition points may explain these universality classes in urban systems.

3. THE SPIKY LANDSCAPE OF URBAN ENERGY

The spiky economic landscape translates into very high energy density spikes. The geography of energy consumption in competitive cities is extremely uneven, and this is an important key to energy efficiency as the highest spikes of energy density are also the highest spikes of economic density. Like the urban economy, the urban energy is scaling according to Pareto distributions. Urban GDP and urban energy consumption/unit of urban land are highly concentrated in peaks in the cores of global cities while peripheries are less energy intensive but produce much less added value. The ratio of added value to energy inputs measures the different energy productivities across the urban space. The bumpy and spiky distribution of both energy consumption and value added per unit of land has important consequences for the choice of modes of decentralized energy supply, which varies between high energy intensity centers and low energy intensity peripheries.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.1 The hidden order of urban energy landscapes

New York City energy landscape presents a high level of variation at each scale, from NYC scale (780 km^2 of emerged land), to block scale, and to fiscal plot scale (200 m^2). It is a scale-free landscape with no characteristic average value for the energy use on a plot of land. These energy density variations of 100-fold within the same city matter and have strong impacts on the possible types of energy mix in each neighborhood. A power law orders the energy densities in New York. This is the signature of a scale free distribution of energy consumption across the urban space.

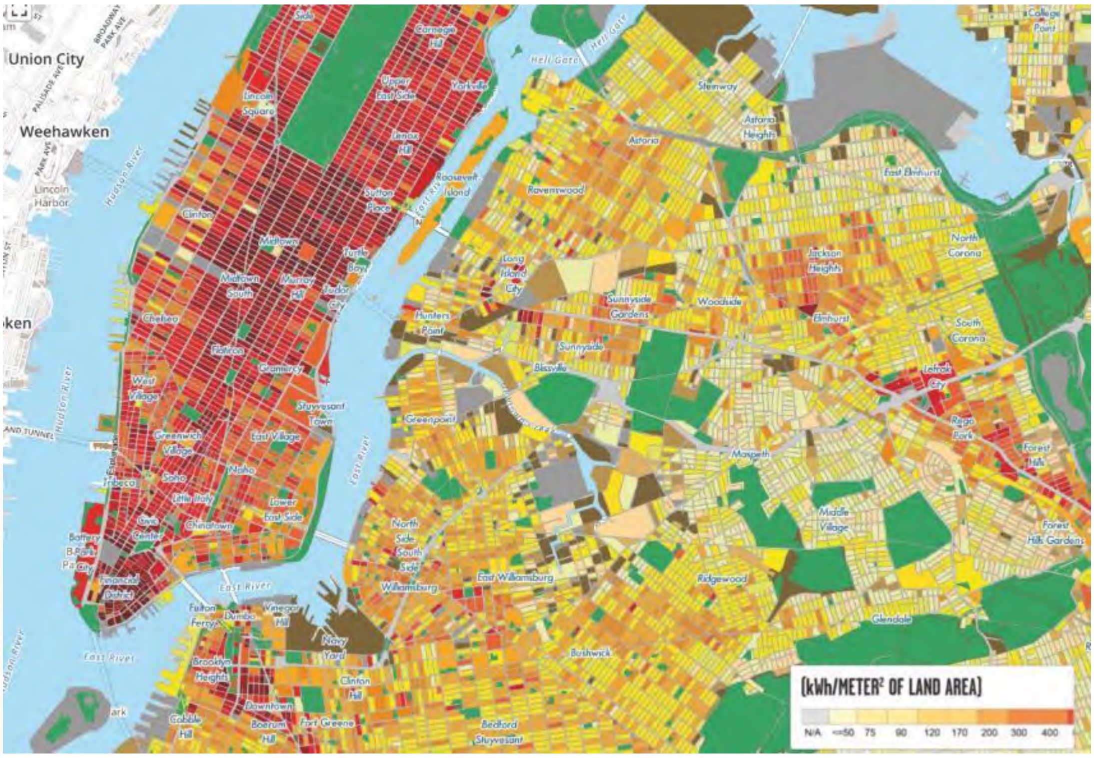

Figure 8: The map above represents an estimate of the total annual building energy consumption at the block level and at the tax lot level for New York City, and is expressed in kilowatt hours (kWh) per square meter of land area. A mathematical model based on statistics, not individual building data, was used to estimate the annual energy consumption values for buildings throughout the five boroughs.

Map created by Shaky Sherpa of Sustainable Engineering Lab (formerly Modi Research Group. Data Source: Spatial distribution of urban building energy consumption by end use B. Howard, L. Parshall, J. Thompson, S. Hammer, J. Dickinson, V. Modi

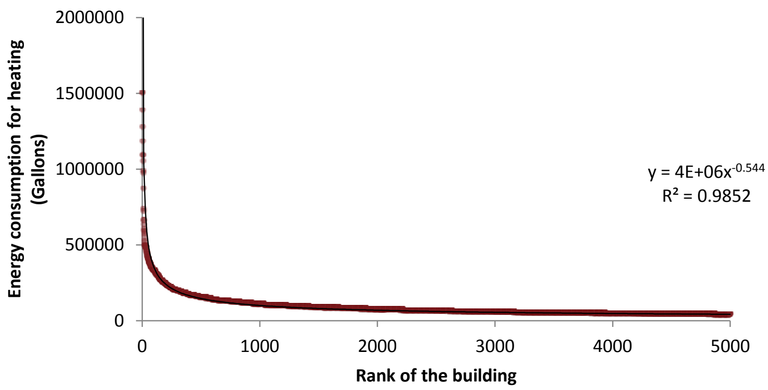

Figure 9: Heating energy by building in NYC. The energy consumption is ranked from the highest consuming large-scale office towers (on the left) to the long tail of residential houses (on the right). The distribution describes both the scale free structure of NYC urban fabric (here described by buildings) and the scale free structure of NYC building's energy consumption across the urban space. Source: Urban Morphology and Complex Systems Institute.

3.2 Spikes of economic density and energy correspond to higher energy efficiencies

As shown in the following maps, London's energy and economic landscapes reflect each other with peaks of high concentrations in the City of London and the Docklands (Canary Wharf).

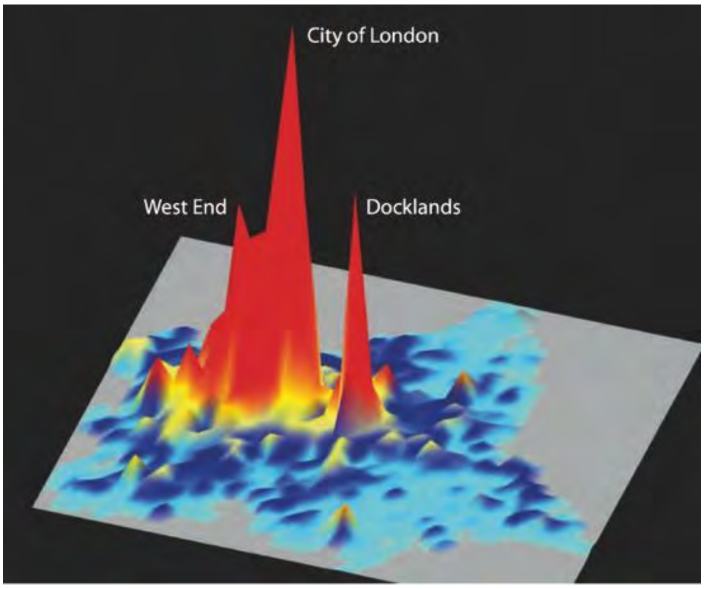

Figure 10: London energy landscape is characterized by a high spike of energy density (here electricity per unit of land) of more than 300 MW/km² in the city of London.

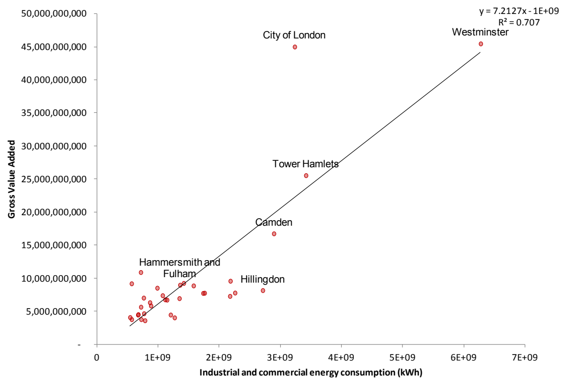

Figure 13: Right: GVA and industrial and commercial energy consumption in London boroughs. Source: Urban Morphology and Complex Systems Institute.

4. THE BREAK-EVEN POINT

In economics and business, specifically cost accounting, the break-even point (BEP) is the point at which cost or expenses and revenue are equal: there is no net loss or gain, and one has "broken even." Understanding the hierarchies in GDP creation across the urban space and the variations of costs of networks across urban space, allows determining a break-even point. There is a limit radius where further spatial expansion at low density produces less value added than it costs in infrastructures.

Our empirical research has shown that urban GDP is, like jobs densities, distributed according to a Pareto principle with 20% of urban land producing 80% of urban GDP while 80% of the urban land produces only 20% of the GDP. This is verified with the differences in GDP between Inner London and Outer London, and has been verified under the form on an inverse power law of exponent -1 in a detailed study of Zhengzhou in China and is more broadly confirmed by the universal power law with an exponent close to -1 that organizes the distribution of jobs densities in the urban space in Paris, London and New York. The Pareto structure of urban economic space derives from two combined self-reinforcing effects: the Pareto distribution ordering jobs distribution across the urban space, and the higher productivity per job in the left part of the Pareto curve because of strong agglomeration economies in this left part. Urban GDP follows a power law of exponent about - 1.

Networks lengths/km^2 and costs/km^2 decrease also with urban expansion because of their fractal nature but more smoothly (Batty and Longley1994, Salat et al. 2011, Salat and Bourdic 2015). They decrease at the power - 0.5 for subway systems, due to the core and spokes structure of these networks (Salat and Bourdic 2015), and more generally with a scaling exponent depending on the fractal nature of the specific network (Batty 2013).

Thus as GDP decreases more sharply than infrastructure costs with spatial expansion, beyond a certain radius, infrastructure lengths and costs (and embodied energy in infrastructures) become higher than additional economic output. As a result, urban land is less and less economically productive and more and more costly in terms of infrastructures, and embodied material and energy when moving away from the urban core. This pattern is captured in the following charts.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

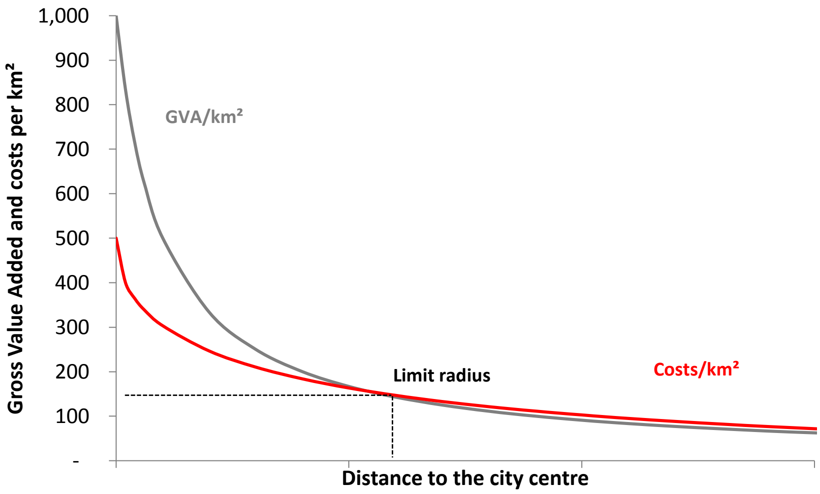

Figure 14: GVA/km² versus infrastructure costs/km² Source: Urban Morphology and Complex Systems Institute based on international benchmarks of infrastructure costs per km² linking urban density and pavement costs, water network costs, waste water network costs (Bourdic and Kamiya 2016, Müller et al. 2013).

The decrease in densities when moving away from the urban core induces also higher infrastructure costs per capita. The following chart describes the relationships between economic productivity (measured per capita) and infrastructure costs per capita.

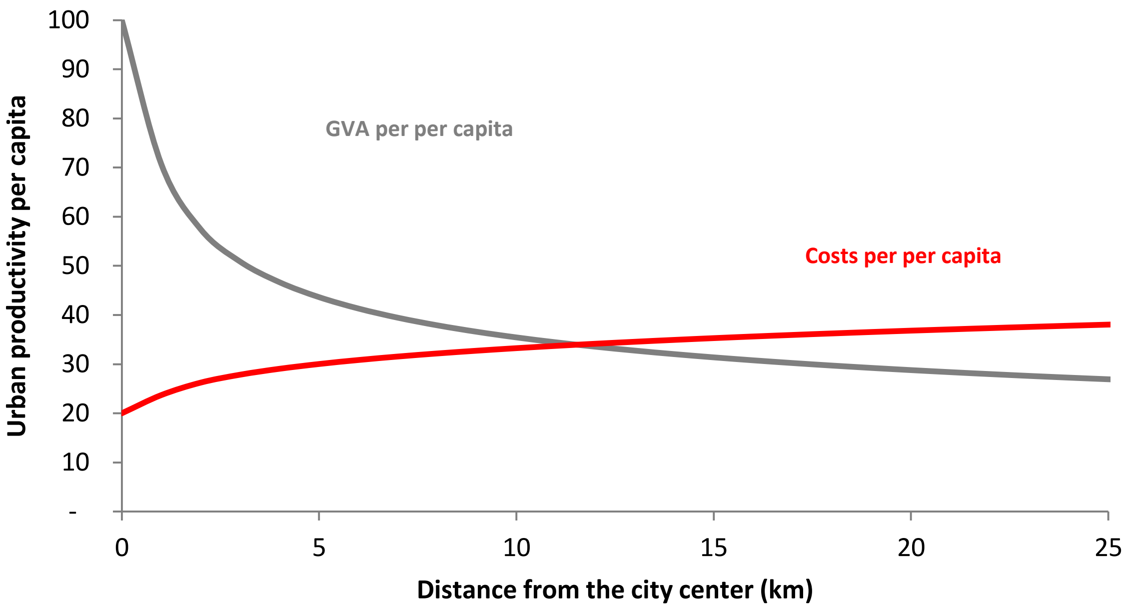

Figure 15: GVA and costs per capita across urban space. Source: Urban Morphology and Complex Systems Institute.

5. CONCLUSION

Sprawl is thus a highly inefficient pattern where costs become higher than economic benefits after a break-even point. Sprawl is central to our wasteful use of water, energy, and land. To move from sprawl toward more compact urban forms, urban connectivity and density must be intensified through changes in regulatory urban planning. Increasing densities around transit nodes will foster energy and resource productivity, decoupling urban economic growth from infrastructure costs and energy embodied in infrastructures.

ABSTRACT

This paper aims to address the need and barriers involved in the development for energy-efficient refurbishment at the district level and making conclusions about the need for improved processes. By district-level refurbishment, we mean concurrent renovation of several buildings in a same district/neighbourhood with the view to achieving cost savings, financial benefits and a more efficient use of Renewable Energy Sources (RES). Also, full optimization and performance of the nearly zero energy buildings (nZEBs) require aspects such as the consideration of load-matching and grid interaction. District-level refurbishment projects may enable a better understanding of these aspects. On the other hand there may also be significant barriers related to several factors such as legal issues regarding town planning and building permission practices; legal issues regarding practices, taxes and fees of energy generation; presence of several owners; simultaneous presence of several actors including energy companies; lack of actors able to initiate and integrate; lack of business models for profitable work in district-level projects; lack of experience in using collaborative delivery models; lack of tools for energy assessment at district level; lack of process descriptions for district-level refurbishment, and lack of design methods for optimization of grid interaction and load matching.

To understand these barriers, interviews in eight European countries were conducted. The results show that most of the questions addressed are relevant to at least to some extent. Different actors in various European regions emphasize somewhat different aspects. However, the most significant problem was found to be the involvement of many owners in district-level refurbishment projects with differing interests and their difficulty in forming an agreement. Related to this, the lack of actors who would initiate the project and motivate owners, and other stakeholders were also imperative. Besides, current legislation causes significant hindrances for refurbishment at the district level in many countries.

Keywords: sustainable neighbourhood, design process, energy saving

1. INTRODUCTION

Currently, nearly zero energy buildings (nZEB) methods and technologies are implemented in a single building and not yet at the district level. To fully optimize the nZEB performance, aspects such as grid interaction and load matching are necessary since peak loads and voltage deviances require a proper synchronization of electricity consumption and production. Optimizing nZEB requires demand-side management, electric storage capabilities, and also minimization of energy delivered to the building. The presence of an existing grid or grid connection is not mandatory since district level refurbishment projects can benefit by sharing renewable energy resources, such as biomass-based micro combined heat and power (mCHP), solar for hot water and heating, or geothermal energy. They can then take advantage of load matching at a building group level to fulfil the yearly energy balance (Salom et al. 2014; Sartori et al. 2012). The focus is already shifting from single buildings towards nZEB neighbourhoods/districts. As defined by (Marique & Reiter 2014) nZEB neighbourhood is where the annual energy consumption and transportation of inhabitants are balanced by renewable energy production on site.

The main prerequisite for local distribution system as pointed out by (Salom et al. 2011) is that the energy system should be designed according to the electricity demand of the grouped buildings while considering load variations between the buildings. Load marching indicators can inform designers, architects and engineers in comparing different design options which would make use of planned integrated technology (such as mCHP), sizing of storage devices, strategies of sizing storage devices factoring in the events such as grid breakdown, etc. With a step ahead, Ala-Juusela et. al proposed positive energy neighbourhoods, where '*the annual energy demand is lower than annual energy supply from local renewable energy sources*,' aiming to support even wider generation and distribution networks. Energy positive neighbourhoods can display key performance indicators including annual mismatch ratio, maximum hourly supply, maximum hourly deficit and a monthly ratio of peak hourly demand in comparison to lowest peak power demand (Ala-Juusela et al. 2015).

Significant risks and barriers for energy efficient districts renovations include insufficient support from residents, collapse of available infrastructure, failure of new technology, not too many examples to follow, principle-agent problems, negative externalities, financing, etc. (Ahvenniemi et al. 2013; Sepponen & Heimonen 2016). The primary motivation to understand the barriers affecting refurbishment of districts is to build upon solutions such as financing possibilities, new business models such as ESCO, customer-oriented renewable model, utility-oriented model, heat entrepreneurship model, on-bill financing model, energy leasing model, etc. to support energy-efficient refurbishment at a district level.

1.1 Objective

The purpose of this study was to identify barriers pertaining successful renovation of multiple buildings in districts/neighbourhoods in seven European countries. To understanding the complex relationships between stakeholders in reference to district refurbishment in various European countries, the following barriers were considered and assessed in (1) Legal issues regarding town planning and building permission practices; (2) Legal aspects regarding practices, taxes and fees of energy generation; (3) Presence of several owners; (4) Simultaneous presence of several actors including energy companies, designers and consultants; (5) Lack of players able to initiate and integrate; (6) Lack of business models for profitable work in district-level projects; (7) Lack of experience in using collaborative delivery models; (8) Lack of tools for energy assessment at district level; (9) Lack of process descriptions for district-level refurbishment and (10) Lack of design methods for optimization of grid interaction and load matching.

2. METHOD

Interviews were carried out in eight northern and middle European countries including Finland, Germany, The Netherlands, Slovenia, Lithuania, Latvia, Poland, and Austria. The aim of the interviews was to understand specific barriers preventing the district level refurbishment. We also intended to ascertain if there are significant differences or several similarities among different European countries. Such findings are further useful in the future for developing business models to attain benefits of energy-efficient refurbishment at a district level and to spike interest through collaboration among stakeholder groups in Europe.

The interviews were conducted as face-to-face meeting or teleconferences. The duration of the meeting lasted for about an hour. In total 67 stakeholders (interviewees) from the above countries participated one at a time. However, in Poland and Lithuania, the stakeholders were interviewed as a group. In those cases, the individual responses were also recorded. The number of participants per European country is presented in Table 1. The interviewees were asked to categorize themselves among eight categories based on the role of their company and their particular role in the enterprise, as categorized in Table 1 (A) Building owners with large building portfolios; (B) Designers and consultants actively engaged in district refurbishment projects; (C) Energy company; (D) Town planning and building permission authority; (E) Renewable energy technology service provider; (F) Contractors and developers engaged in district level refurbishment projects; and (G) Maintenance and building managers as illustrated in Figure 1. The interviewees were selected by the consortium teams part of ‘Mobilization of innovative design tools for the refurbishing of buildings at district level' (MODER) project which is present in each of the eight European countries except in Lithuania and Poland.

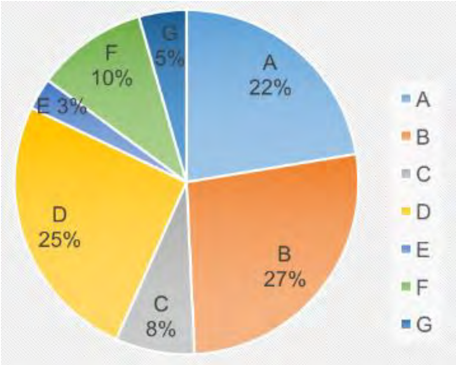

Figure 102: Percentage of respondents per category from all countries

The interviewees were provided with a set of barriers for assessing (as presented in Table 2) and the interviews were semi-structured to take advantage to document the experiences of interviews. They were also asked to determine the importance and validity of the claimed barrier on the scale of 1-5, where five was deemed very important and one as not relevant to their point of view. The list of presumed barriers is based on an extensive literature review which will be published in the future study and could not be included due to space limitation.

S.No.	Country name	No. of participants	Number of respondents per category (a.-g.)
1	Finland	23	5(A); 4(B); 3(C); 5(D); 2(E); 2(F) ; 2(G)
2	The Netherlands	6	2(A); 2 (B); 2(D)
3	Slovenia	13	2(A); 4(B); 2(C); 4(D);1(G)
4	Germany	4	2(A); 1(B); 1(D)
5	Lithuania	10	2(A); 4(B); 3(D); 1(F)
6	Poland	5	1(A); 1(B); 1(D); 2(F)
7	Austria	2	1(B); 1(D)
8	Latvia	4	1(A); 1(B); 2(F)

3. RESULTS

The cumulative results of all countries are presented in Figure 2 illustrating the importance of each barrier discussed in Table 2 and Figure 3 presents the standard deviation in the responses. This section will discuss each of the barriers selected as the most pertinent in each of the country.

The legal and institutional barriers associated with town planning and building permission process in Germany and Finland were found to be imperative. Typically, the planning processes are slow in Finland, because when a larger scale change is proposed which can influence the landscape of the site, local actors may oppose the change, which leads to further delays. The building approval process for multiple land plots at the same time is difficult to attain, but, municipalities, in general, were found to be supportive of energy efficient refurbishments. The Netherlands have strict laws protecting the rights of the tenant which are seen positively, at the same time it was found difficult for the building owner's/ housing associations to come to an agreement with the residents on needed refurbishments leading because it leads to increased rent. Similar legislation barrier was observed in Slovenia, at times 100% of the tenants/owners in a building are required to be in agreement on major renovations. Thus, we need to develop practical guidelines to support the large scale refurbishment process.

Legal and institutional barriers related to the practices, taxes, and fees on energy generation at a district level were seen as an obstacle in Finland, Germany, and the Netherlands. Most of the urban areas in Finland and Germany are connected to district heating, local energy generation in such scenario is not supported. In Finland taxation was seen as a barrier; when capacity is larger than 100kVA and the generation exceeds 800MWh. If even a part of the generated local electricity goes to national net the whole generation needs to be reported. The limit is so high that it causes no problems on building level but may decrease the profitability on district level refurbishment cases. Similar types of problems were described by the interviewees in Germany.

Legal issues on energy taxation and net metering in the Netherlands have been a significant barrier for energy generation via the photovoltaic installation of roofs which discourages the owners to share access production. The energy subsidies in the Netherland also vary from town to town each year. Increased administrative burden discourages owners to have collecting heating systems, which leads to each household having their gas boilers. The price of energy is rather low in Slovenia, leading to low interest in the implementation of renewable energy. The taxation and fees were not found to be a barrier in Lithuania and Latvia.

In general, the presence of several owners in refurbishment projects brings a lot of hindrances and barriers for smoothly proceeding processes because of different interests and financial possibilities in all countries. The availability of convincing information about the profitability of simultaneous refurbishment projects might help to solve the problem. Examples of successful projects with transparent results on costs and benefits are required.

However, the simultaneous presence of several actors was not seen as an important barrier if a leading body is presented. In the case of no one driving the process it becomes difficult from the administrative point of view for housing associations in all countries. An absence of facilitator at the district level in energy efficient refurbishment was found to be a barrier. For example, housing managers, building owner with large portfolios, ESCO companies, municipalities, etc. could play a role of an integrator or an activator for strong cases. This issue was not seen in Latvia, The Netherlands, and Austria, mostly the housing associations, lead such processes.

Lack of business models was seen as a critical barrier in Slovenia and the Netherlands, but not in Germany. The opinion on the presence of business models was rather divided among all other countries since it was seen as very case depended on. In some cases, business models work, and in some, they don't depend on the externalities of the project leading to differing opinions. Financial models should always be presented together with the technical refurbishment plans to private owners to guide the probability of investment in long term. Lack of procurement and delivery models was perceived differently by all interviews; again it's a process driven method which varies case by case. It was seen as an important barrier and not so important at the same time. In Slovenia, implementation of pilot projects was seen as a vital step to encourage district refurbishment project mainly due to the complex interaction between banks, owners, and municipalities.

Availability of energy performance assessment tools is crucial to foresee the energy saving potential to convince stakeholders to consider refurbishment as a profitable long-term investment. The better information a business model would have on energy conservation potential more are the chances of it being successfully implemented. There are tools available in most of the countries, but not all of them can handle a large amount of data on districts, also most of the time the data on the district level is not open to the public, which makes it more difficult to conduct the initial assessment. Some respondents expressed that these tools are not able to provide very accurate savings, of course, predictability can go only so far as the actual consumption also depends on the individual household practices.

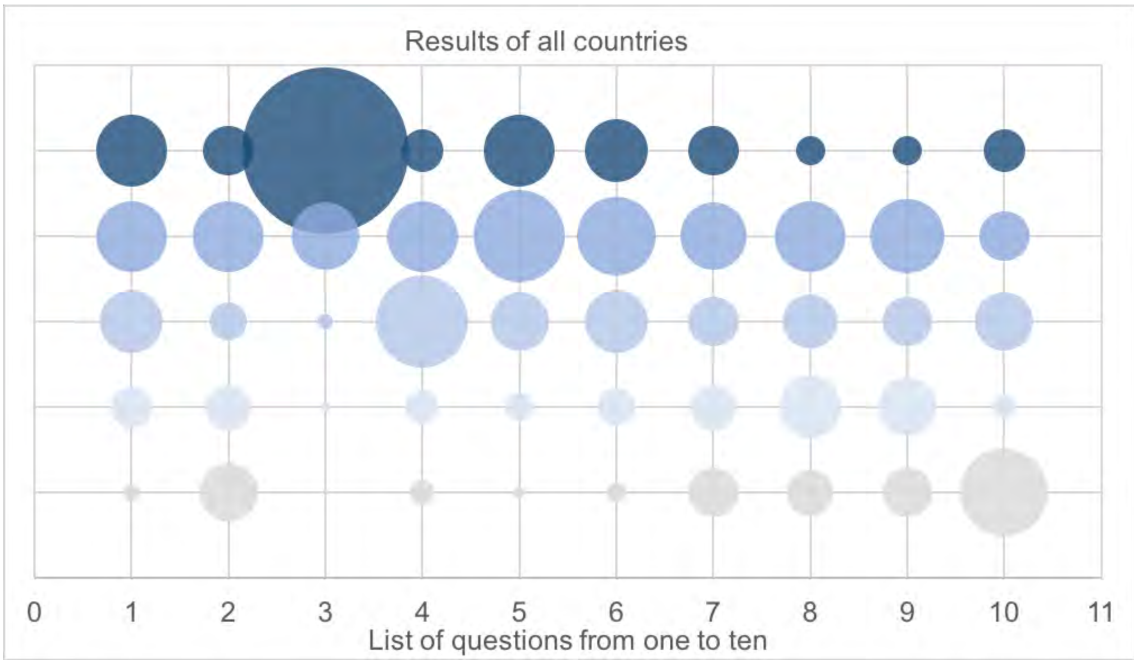

Figure 103: The size of the bubbles represents the number of answers and the colour gradient of grey to blue represents the scale from least important to most important

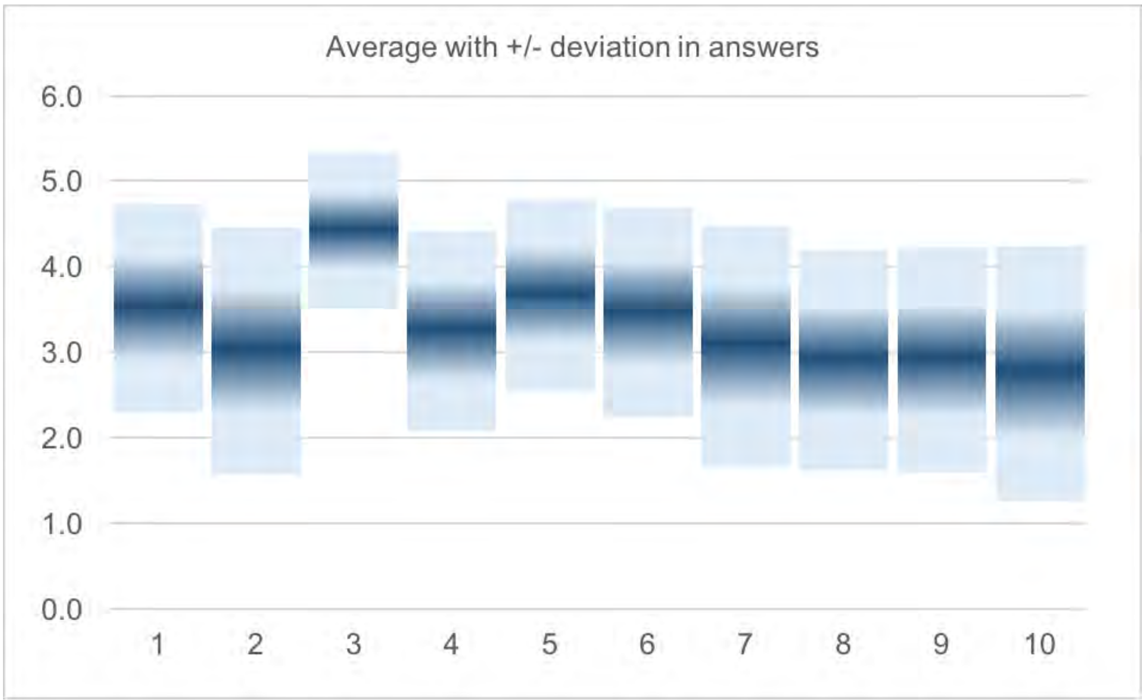

Figure 104: Deviation in interviewee responses

Designing process and methods for refurbishment at district level were seen as an obstacle but was not found to be a very significant barrier. Reason being that there are example projects in most of the countries, but at the same time analysis, legislation and license related issues are a single building oriented. Thus, in general, there is a lack of suitable models showing the comparison of energy savings between single building renovation versus collective buildings. On the other hand, design methods for the optimization of grid interactions and load matching are imperative from the technical perspective, but it was not observed as a barrier. It was noted that many interviewees were not familiar with problems which may occur in case set of buildings have their shared network. Thus, even though it was not observed as a barrier, prediction models for load matching are very much needed to evaluate the supply and demand including peak loads.

4. CONCLUSION

Interviews were conducted in eight European countries including Finland, Germany, The Netherlands, Slovenia, Lithuania, Latvia, Poland, and Austria. In total, 67 stakeholders were interviewed which included building owners with large portfolios, energy companies, designers, consultants, town planning and building permission authorities, renewable energy providers, contractors, developers and maintenance managers. Most of the interview were from Finland and least from Austria. The opinions of the interviewees were found to be very dissimilar because it was dependent on their experience on participation in district refurbishment projects and the role of their organization in those project.

The three most important barriers perceived by all interviews include presence and collective agreement of several owners to start district refurbishment projects, lack of activators or integrators and institutional and legal obstacles related to town planning and building permission practices. In Germany, barriers connected to regulations were not observed. In Poland, lack of energy assessment tools at district level was not seen necessary. For the Netherlands, agreement between the owners and lack of adaptable business models were considered as barriers. Slovenia and Lithuania somewhat had similar restrictions related to change in laws because of common ownership transition into distributed ownership.

It was noted that lack of assessment tools at district level was not found to be a significant barrier, but it is likely that the interviewees didn't have much experience in using any tool or being involved in the project which used such tools. We need more advanced district energy models which can predict the occupant behaviour also presented by (Yamaguchi et al. 2003). Pilot studies such as that of (Kilkiş 2014) have successfully demonstrated in matching the heating and cooling demand with waste heat/low-temperature energy resources leading to a reduction in high exergy resources. A second follow-up publication of this study will further explore the results of interviews in greater detail, along with business models to reduce the recognized barriers.

ACKNOWLEDGMENTS

The work presented in this document has been conducted in the context of Horizon 2020 programme of the European community project MODER (n° 680447). MODER is a 36-month project that started in September 2015 and is funded by the European Commission as well as by the industrial and research partners. Their support is gratefully appreciated. The partners in the project are SWECO (Finland), VTT Technical research centre of Finland Ltd (Finland), Fraunhofer Institute for Building Physics IBP (Germany), Siemens (Germany), REM PRO (Latvia), W/E (the Netherlands), Ertex Solar (Austria), ZRMK (Slovenia), Finnenergia (Finland), and LEAG (Slovenia). In addition to the authors of this paper, the interviewers and rapporteurs of interviews in different countries were as follows: Jaakko Ketomäki, Tarja Mäkeläinen, Mia Ala-Juusela, Marjana Šijanec Zavrl (rapporteur of the Slovenian interviews), Jyri Nieminen (Lithuania and Poland), Erik Alsema (The Nethrerlands), Ervins Palmbahs (Latvia), Dieter Moore (Austria) and Hans Ernhorn (Germany).

ABSTRACT

Existing district cooling projects display the potential to increase energy efficiency and reduce energy costs for cooling applications. The application of district cooling systems both is affected by and affects urban zoning, urban and architectural design and economic parameters. This paper analyses the status quo of planning and building regulation and urban policies as direct and indirect incentives for the application of district cooling systems (DCS). The paper aims at proposing strategies to facilitate the connection of more users to DCS in Singapore. We collect the planning and building regulations related to DCS in Singapore. Additionally, we retrieve more information from the video recordings of a discussion by experts on DCS in Singapore and China for first-hand experiences of the practice side. As a result, we will provide an assessment of the status quo of planning and building regulations and relevant urban policies concerning DCS in Singapore and suggest changes that may improve the efficiency of DCS and incentivize developers and proprietors to consider such system.

Keywords: district cooling, policy and regulation, building codes

1. INTRODUCTION

The global trend calls for serious and responsible actions on carbon emission reduction. Singapore has pledged to reduce CO_2 emissions by 36% in 2030 at COP21 (Ho 2015). The growing population and a potential increase in energy consumption also challenge this determination. District cooling systems (DCS) offer a solution for better energy performances as well as resilience-related, economic and environmental benefits (UNEP 2014). Research and application demonstrate multiple benefits of DCS with respect to architectural design, urban design and occupant comfort. These benefits include space saving, noise reduction and building program with complimentary temporal occupancy patterns.

Space savings in DCS refers to the space freed up by removing cooling facilities from the building rooftops and basements. It improves aesthetic and efficiency of the building and the city. Cooling towers on the rooftop can be replaced by sky gardens or terraces; chillers in the basement can be replaced by interconnected underground pedestrian tunnels. For example, the ship-like infinity pool floating over the three towers of Marina Bay Sands would not be realized without the district cooling systems. In addition, the removal of cooling facilities takes away the noises and the heat rejection into the urban environment especially street canyons.

DCS desires a stable consumption of the cold produced. Offices, for example, consume mainly in the daytime while residential buildings consume mainly at night. Thus, to maintain a stable and constant consumption pattern throughout the day, a mixed-use of various building programs with various types of occupancy, usage, time-of-the-day and weather conditions is beneficial (Tey 2010; Fonseca & Schlueter 2016).

Two of the main DCS providers in Singapore are Keppel DHCS and Singapore District Cooling (SDC). Keppel DHCS started operations in June 2000. Currently, it operates four cooling plants located at Changi Business Park, Biopolis One North, Woodlands Water Fab Park, and Mediapolis One North in Singapore. SDC, a subsidiary of the local electricity-utility started operations in May 2006 (Tey 2010). Currently, SDC operates two plants at the Marina Bay Business District. As part of a special urban policy for the development of the Marina Bay Business District, most buildings in the area are mandatorily required to connect to DCS (Zhuang 2016).

2. DIRECT AND INDIRECT INCENTIVES FOR DCS

A series of incentives have been adopted globally to promote energy efficiency in buildings and reduce their carbon emissions. Olubunmi, Xia & Skitmore (2016) categorized the incentives as internal incentives and external incentives. The internal incentives are human well-being related incentives, market demand-related incentives, gratifying incentives, altruistic incentives, and persuasion and inspirational incentives (Olubunmi, Xia & Skitmore 2016). These incentives highly rely on the developer's internal willingness to care about the human well-being and the green benefits. The external incentives include financial incentives and non-financial incentives. Financial and fiscal incentives are usually immediate financial remissions, like tax returns or fee waivers (Brilhante & Skinner 2015). Non-financial incentives include promotion and awareness incentives and economic incentives. Promotion and awareness incentives are services and assistances offered by the government as well as some pilot projects. Economic incentives concern peak pricing policies (Brilhante & Skinner 2015) and additional Gross Floor Area (GFA) (Shapiro 2011).

This paper focuses on the external incentives granted to the developers during the design and construction of buildings for connections to DCS. In Singapore, besides the incentives directly applied to the developers for the connections to DCS, there are also "hidden" benefits triggered by doing so. For example, DCS frees up the rooftop space, which can be used as public spaces or rooftop green. In Singapore, a green rooftop cannot only add economic and aesthetic values to the project but also raise the building height limit enforced by the Urban Redevelopment Authority (URA). We categorize the former as direct incentives and the latter as indirect incentives.

2.1 Direct incentives

The incentives directly applied for the adoption of district cooling systems are called direct incentives. Direct incentives usually come in the form of cash or tax rebate, discounted application fees, or additional allowance of gross floor area. Both Building Construction Authority (BCA) and URA have initiated several schemes of such direct incentives over the past decade to improve the energy performance and appearance of buildings in Singapore. These incentive schemes include the Green Mark Incentive Scheme by the BCA with cash incentives (BCA 2009) and the LUSH program 2.0 by the URA with extra gross floor area allowances (URA 2014). None of the existing incentive schemes in Singapore is focused on the adoption of district cooling systems.

2.2 Indirect incentives

Indirect incentives benefits are the result of the DCS's influence on various aspects of the building projects. Though there are no direct incentives, several building regulations and urban policies function as indirect incentives for the developers to decide to connect to the district cooling plants in Singapore.

Rooftop: As presented in Section 1, DCS's free up rooftop space in buildings can be used as public space or for rooftop greenery. In Singapore, a green rooftop can not only add economic and aesthetic values to the project but also lower the height restrictions enforced by URA. Roofscape is considered as one of the key urban design element (URA 2016a). URA grants bonus Gross Floor Area (GFA) for outdoor refreshment areas on landscaped rooftops of both new and existing commercial and mixed-use developments within the Orchard, the Downtown Core planning areas as well as parts of Singapore River (URA 2014). URA grants GFA exemption for rooftop pavilions when they are integrated into the rooftop landscape design occupying at least half of the rooftop space (URA 2014). For non-landed residential developments, rooftop landscapes meeting the criteria can be counted to meet the overall greenery provision and relieve the needs of spaces for on-ground greenery (URA 2016b).

Underground: When meeting certain criteria, URA grants GFA exemption for underground pedestrian links to rapid transit system stations (URA 2016c). Additionally, URA grants extra GFA allowances for activity-generating uses within the underground pedestrian links from Rapid Transit Systems (RTS) stations to existing development beyond the GFA allowed by the Master Plan. However, this additional GFA is not transferable and cannot be used to form future redevelopment of the site (URA 2001). The activity-generating uses include commercial uses like retail and eating outlet (URA 2016c).

Energy efficiency and noise control: DCS's have been proved in practice to increase the energy efficiency of buildings significantly (Tey 2010). Energy efficiency accounts for the majority of the points in the BCA Green Mark rating system (BCA 2013). The BCA Green Mark Scheme is a benchmarking scheme that evaluates environmental performance of building projects (BCA 2016). Additionally, points are also awarded for the performance of noise level (BCA 2013). Projects meeting the Green Mark criteria can be granted cash incentives and GFA incentives by BCA and URA (BCA 2009; URA 2009).

2.3 Voices from practices

This section outlines positions and experiences of developers and operators of district cooling systems in Singapore and China (Happle 2016). Participants include academic researchers and DCS providers.

Except for the mandatory cases, the main drivers for building owners/ developers to connect to a DCS are the increased freedom of building design and improved energy efficiency which allows to better meet the requirement of Green Mark ratings (Happle 2016). These aspects are both related to the building regulations and the urban policies discussed as indirect incentives in the previous section.

Residential building excluded from the mandatory connection: Although most of the building projects are mandatorily connected to DCS, residential buildings are exempted from this obligation. Unlike offices where cooling is needed on a daily basis, the occupancy pattern of residential buildings is more versatile. Personal living habits such as a short trip away from home can alter the cooling need. Also, the in-taking stations in the building take up GFA and the additional piping systems to distribute cold in the building generate costs. Additionally, the district cooling systems remove the air-conditioner ledge of the split-units, which doesn't count as GFA but is sellable. These are some of the reasons that undermine the economic profits potentially brought by the connections to district cooling systems.

Electricity tariff: To maintain a stable cooling need, various buildings with different occupancy pattern are needed. In Singapore, the electricity tariff defined by the Energy Market Authority fluctuates over the day. A cooling provider would thus rather generate and store cold during low tariffs and sell it out during peak time than generating all in the peak time as needed. Residential buildings have higher cooling demand during the night when there is the low tariff. This is another reason that the residential buildings are not preferred.

3. DISCUSSION

Interdependencies on different levels: When introducing a comparatively new technology to a new context, technical feasibility is usually the first issue to be tested and solved upon application. However, to keep the system operating in a much more complicated context, it requires many other issues to think about, like business, policy-making urban planning, urban design, building design, and operations. For example, since the mid-1990s, URA, Singapore Power and Dalkia have conducted feasibility studies to identify district cooling as an urban utility and its commercial viability for the Marina Bay Business District (Tey 2010). Afterward, in the urban planning process, the application of district cooling system requires establishing a link between the urban and energy aspects, e.g. density arrangements corresponding energy strategies (Cajot et al. 2016). In the building design process, it needs back-and-forth negotiations between the district cooling engineers and the architects for the building's connection to the network. However, beyond all these, an operational business model with a reasonable charging strategy is the one that keeps the system running. This model should give considerations to the benefits of all the related stakeholders, like the cooling provider, the customers, etc.

Policy matters: Building projects like Marina Bay Sands connect to DCS to free up the rooftop space from cooling towers for architectural design freedom, e.g., the rooftop infinity pool. More importantly, one of the reasons that the developers voluntarily choose to connect to district cooling plant is to meet the requirement of a higher Green Mark certification (Happle 2016). Policy matters. However, it is admitted that since there was no information from the developers' side, it is not sure that the other indirect incentives are effective. Except for cases with mandatory connection requirement, for the developers or the customers, decisions to connect to the district cooling plant are usually profit-driven. Thus, there are three directions that building regulations and urban policies could be adapted to incentivize more projects to join. One is to strategically introduce direct incentives of GFA or cash rebate. Another one is to increase the indirect incentives to make such "hidden incentives" more attractive and "visible". And finally, one is to tighten up the requirement of energy efficiency, noise control, green rooftop, and underground pedestrian networks to "force" the projects within the service radius to join.

Residential or not? As discussed in the introduction, it requires buildings with various occupancies, usage, and time-of-the-day to maintain a stable cooling demand pattern to the system. So far, all the district cooling plants in Singapore are located in business districts mainly with office buildings. Office buildings have high cooling demand mainly in the daytime of weekdays while residential buildings usually have intensive cooling demand at night and weekends. Thus, the cooling need of residential buildings can be considered complementary to that of office buildings. However, in Singapore, residential buildings are currently either excluded from the mandatory requirement of connection to DCS or not "embraced" by district cooling providers. Multiple economic reasons including the electricity tariff and the increased investment together with the versatile occupancy pattern mainly lead to this situation. Though economic issues are highly important in practices, mixed-use developments also offer urban qualities. Based on challenges like "eyes-on-the-street" of Jane Jacobs in the 1960s (Jacobs 1961) and experiences generated from projects like La Defense in Paris, business districts worldwide benefit from being mixed-use and all-day vibrant. To achieve such goal, residential buildings are indispensable. So, in the process of urban design within the service radius of a district cooling plant, residential buildings should not be excluded merely for the sake of the reasons discussed above. However, whether a residential building should be connected to the plant can be optional and on a case-by-case basis. Possible strategies of regulations and policies include bonus GFA or cash rebate and tariff discount to developers and DCS providers of residential buildings. In this way, the additional investment on the facilities for DCS connection can be fully or partially compensated by the bonus GFA

4. CONCLUSION AND OUTLOOK

This paper reviews the status quo of DCS applications and relevant building regulations and urban policies as direct and indirect incentives in Singapore. Experiences and voices from the practice side are valued and addressed. It is once more underlined that the application of district cooling system is multifaceted and more than merely a technical, a commercial or a policy issue. Exemplified for residential buildings, the interactions between aspects of energy systems and urban qualities become apparent. When introducing a comparatively new technology like district cooling system we can observe its influences on other aspects such as urban design issues of density deployment, building programs, etc. Urban design and district cooling systems should, therefore, work in synergy to increase the energy efficiency and urban quality. Last but not the least, policy matters. Building regulations and urban policies can work as direct or indirect incentives to promote voluntary connections. However, any adaptations of such regulations and policies should be carefully evaluated before coming into force.

Future studies on district cooling systems will include ideas, and experiences from all the stakeholders involved in the lifespan of a building project. This includes cooling providers, policy-makers, developers and district cooling customers.

The Exploration of Sustainable Neighbourhoods - A Case Study of Shenyang

LI Li-hong[a], WANG Zhuo[b]

[a] Shenyang Jianzhu University, Mainland China, lilihong022@126.com
[b] Shenyang Jianzhu University, Mainland China, 376308612@qq.com

ABSTRACT

Sustainable neighbourhoods have become more and more popular in the world recently, but they encounter numerous obstacles when developed in China, the obstacles are mainly as followed: policy system, legislation system, management mode and living concepts of residents and others. Firstly, sustainable neighbourhoods are interpreted in this paper, and the worldwide successful experience of sustainable neighbourhoods at the present stage is summarized. On this account, based on the specific circumstance of Shenyang, the sustainable neighbourhoods are designed from the aspect of how to strengthen the controlling by legal and policy system and technical architecture, how to build the target monitoring and feed respective interests, and how to innovate cooperation and safeguard mechanism, and so on. And the planning concept and control strategy of the sustainable neighbourhoods in Shenyang are built in this paper so as to promote the sound and fast development of sustainable neighbourhoods in Shenyang and even China.

Keywords: sustainable neighbourhoods, exploration, Shenyang, planning concept, control strategy

1. PREFACE

With the continuous improvement of people's living standard in our country and increasing awareness of environmental protection, residents have been putting more emphasis on the green, ecological and sustainable living environment, but there are barely Sustainable neighbourhoods of real sense in our country. Then, how to develop a sustainable neighbourhood of persistence, vitality, catering for the need of residents and benefiting posterity and other areas has become the right question which urgently to be solved. And this is also what this paper focuses on.

At the beginning of the solution, the sustainable neighbourhood must be comprehended all round and in depth. Given the potentially wide reverberations, there is hardly a clear definition of the sustainable neighbourhood. But represented by Bristol Accord, the understanding of sustainable neighbourhoods by research institutions and scholars at home and abroad can be summarized as the following eight key points (Evans 2011), as shown in the Figure 1.

Figure 1: Understanding on the connotation of the sustainable neighbourhood

In short, sustainable neighbourhoods emphasized on reducing the negative effect on resources and environment, creating a healthy and comfortable living environment, and the harmonious coexistence between human and nature.

2. THE DEVELOPMENT STATUS OF SUSTAINABLE NEIGHBOURHOODS AT HOME AND ABROAD

In 1898, the British scholar Howard put forward the idea of "garden city", he thought that there must be both good social economy environment and comfortable natural environment in human community, which is acknowledged as the bud of the conception of sustainable neighbourhoods in western society. Since 1987, when the World Commission on Environment and Development put forward the concept of sustainable development formally, the concept of sustainable neighbourhoods has gradually been transforming from the theoretical level to practical level, and ideas of sustainable development has been enjoy more and more popular support.

In 2009, the US Housing and Urban Development, Department of Transportation and the Environmental Protection Agency set up a joint cooperation group in support of the development of sustainable neighbourhoods from the policy and funding. By 2012, the group has received more than 7700 applications and been required for the amount of aid over 102 billion US dollars. There exists great potential and broad prospects for sustainable neighbourhoods.

Among the many sustainable neighbourhoods in the world, Hammarby Lake City, Stockholm Royal Seaport in Sweden and Sustainable Seattle in the United States have attracted worldwide attention because of their exploration on sustainable neighbourhoods from different perspectives.

2.1 Hammarby Lake City

Sweden has always been at the forefront of building sustainable neighbourhoods, and Hammarby Lake City has become the most representative example of sustainable neighbourhoods in Sweden because of its success in the applications of new technology. In the phases of planning and construction, Hammarby Lake City was designed in accordance with the circular metabolism proposed by Girard Heber, that is, all metabolites outputted from a city or an area (including waste water, rubbish, exhaust Etc.) must be re-used to produce energy, materials, or as a plant nutrient to re-enter the area. This is the so-called "Hammarby model". The model emphasizes the recycling of energy, waste and water, and reducing the generation of metabolites from the community, to achieve its planning target of "twice as good", which means reducing environmental impact in half compared to the early 1990s.

To this end, the managers developed the Hammarby environmental program, which contains nine categories as the energy, transportation, materials, water, land utilization, waste recycling, contaminated soil, lake restoration and noise (Jiao et al 2013), to achieve the planning objectives by controlling these indicators. And in the process of implementation, the Hammarby environmental program is continuously modified and improved in accordance with the views of developers and residents and other parties.

Up to now, although the Hammarby Lake City has not yet been fully completed, but the analysis of tracking indicators indicates that some of the project planning objectives have truly achieved, while in some respects, there are targets of serious failure (WÖrjan 2008). In this way, the construction of Stockholm Royal Seaport in Sweden is provided with valuable experience.

2.2 Stockholm Royal Seaport

Stockholm Royal Seaport began construction in 2010, and expected to be completed in 2025. It is positioned as a multi-purpose community which can effect the environment positively. Based on the reflection of the failure objectives in the Hammarby Lake City, Sweden made the following improvements on Stockholm Royal Seaport.

Stockholm Royal Seaport gave full play to the advantage that most of the land ownership is owned by the Stockholm Government. so when signing the land transfer contract, the government had clearly imposed restrictions on land developers on such indicators as building materials, building energy consumption, the proportion of renewable energy and so on (Fraker 2013). As a result, the government urged the establishment and implementation of the plan of Stockholm Royal Seaport effectively.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

For the better cooperation between the participants of the project, the government of Stockholm organized developers, builders, suppliers, consultants, technical consultants, etc. to hold several seminars for providing advice and suggestions for Stockholm Royal Seaport. More importantly, the government of Stockholm set up a policy-making committee to develop policies for different processes during the planning and development phase, and a follow-up control committees to control and amend planned targets of the project, and an action committee to urge the implementation of the plan (WÖrjan 2008). Through the approach of third-party supervision, the planning and construction of Stockholm Royal Seaport is carried out effectively.

2.3 Sustainable Seattle

Sustainable Seattle is one of the most influential sustainable neighbourhoods in the world dedicated to realizing urban communities with "long-term cultural and economic development, environmental health and vitality".

Sustainable Seattle is located in Seattle, United States, and developed by a civil community organization. The organization is dominated by voluntary residents, and focuses on instilling residents with the concept of the sustainable neighbourhood. In order to arouse the sense of identity and participation, the organization, through the studies of seminars and polls (Holden 2014), set up sustainability indicators of the community, including environmental, demographic, economic, cultural and social development, to guide and evaluate Sustainable Seattle.

Sustainable Seattle has penetrated the concept of "public participation" into the daily life of the residents. Residents established a fixed recycling center to promote things for things, increasing the economy and reducing the generation of garbage and environmental load. Residents travel also maximize the use of public transit or carpooling to reduce vehicle usage patterns. In addition, garbage charging system also prompted to reduce the production of non-reusable waste (Holden 2014), so that residents can implement a cost-effective attitude to life effectively.

Sustainable Seattle has been named "the World's Most Liveable City". From the international perspective, it is a model of best practice for sustainable neighbourhoods.

Based on empirical analysis of sustainable neighbourhoods abroad, these sustainable neighbourhoods are supported by not only the new technologies such as green building and renewable energy from the hardware level, but also a comprehensive, effective and cycling safeguard mechanisms of the life cycle of the project. In addition, the government has provided an effective impetus for these sustainable neighbourhoods in terms of policy, legal and technical standards systems to facilitate the achievement of objectives. Under this mechanism, the participants have cooperated with each other and have a clear responsibility to ensure the ecological benefits of sustainable neighbourhoods.

3. ANALYSIS OF THE CURRENT SITUATION OF SUSTAINABLE NEIGHBOURHOODS IN SHENYANG

The research on sustainable neighbourhoods started late in China, until the late 20th century, some scholars began to conduct some systematic studies. At the practical level, our country has made certain achievements in the hardware of sustainable neighbourhoods, that is, the relevant policies, standards and technical system of infrastructure construction. Taking green building for example, in January 2013, the National Development and Reform Commission jointly Ministry of Housing and Urban issued the "Green Building Action Plan", which clearly promote the building industrialization as one of the ten key tasks. Shenyang, as a national demonstration of construction industry modernization, its maturing technology of prefabricated construction, will contribute to sustainable neighbourhoods in Shenyang from the technical level. However, at the software level, compared with the management measures, ecological culture, etc. communities in Shenyang still have a wide gap.

From the macroscopic point of view, due to the lack of policy system, defects of legal system, backwardness of management mechanism, in addition with the contradictions between environmental goals and economic interests of each parties, there are still prominent constraints in the development of sustainable neighbourhoods in Shenyang.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

From a microscopic point of view, the current form of communities in Shenyang are mainly the property management led by real estate investor, including high homogeneity of apartments and villas, mixed communities and affordable housing districts, removal settlement area, etc. These communities differ in terms of infrastructure and management. What's worse, the awareness of environmental protection of the residents is generally weak, participation is relatively low, and the atmosphere of sustainable development in these communities is not strong.

These factors comprehensively lead to the embarrassment that there is hardly real sustainable neighbourhood in Shenyang. Therefore, solving the problems above, is an effective way to promote sustainable neighbourhood development in Shenyang. So, it is the key to explore an effective solution from the aspect of software. Only in this way, can Shenyang and even China achieve sound and rapid development of sustainable neighbourhoods.

4. SUGGESTIONS ON THE PLANNING OF SUSTAINABLE NEIGHBOURHOODS IN SHENYANG

For the planning and construction of sustainable neighbourhoods in Shenyang, there is many successful experiences can be learned from sustainable neighbourhoods abroad.

4.1 Strengthen the control of policy, legal and technical system

First of all, for the governments, there is a lack of the measures and efforts on land development and supervision. In the use of the overall statutory detailed planning to achieve the controlling of the project, the land transfer agreement is an effective policy tool. Taking Shenyang as an example, the government did not introduce a set of planning or standards of sustainable development. So for most of the projects, there is not such a program based on protecting the environment. At the same time, when signing the land transfer agreement, the government cannot constrain developers from the aspects as environmental and energy standards of the land, the control conditions of resource conservation and recycling and others. Under this circumstance, developers often tend to start from their own economic benefits, or applying technology superficial, or simply stacking a pile of technology, and energy conservation and recycling cannot be achieved from a global perspective.

In 2015, the "Several Policy Measures to Promote the Modernization of Construction Industry in Shenyang" was introduced by Shenyang Municipal Government, which proposing the new strategy of "Internet + modern building" for the first time, putting prefabricated residences as one of the conditions of land transfers, promulgating varieties of technology standards of prefabricated buildings and so on, in order to promote the development of prefabricated buildings from the policy provisions and technical standards.

But it should be noted that, when the government playing a guiding and restraint role, relevant laws and regulations and more scientific and applicable technical specifications should also be supported, which is the current lack for Shenyang. Following the national level of the legal system and macro-oriented policy, according to the natural, social, economic situation of Shenyang, the all-round, multi-level and three-dimensional regulations, target plans and technical specification systems can be established by Shenyang Municipal Government, so that it can provide a strong basis that promoting the development of sustainable neighbourhoods in Shenyang.

4.2 Constructing the target monitoring and feedback mechanism of the sustainable neighbourhood

What can be found from the successful experience of sustainable neighbourhoods abroad is that, the mechanisms for setting, monitoring, evaluating and improving goals of sustainable neighbourhoods is extremely important. Shenyang is lack of not only legal, policy and technical guidance, but also appropriate mechanisms. And, for Shenyang, there is no scientific planning process to develop environmental objectives before the project, no monitoring and feedback on the objectives during the project, no scientific evaluation and improvement of the objectives after the project, and the ecological benefits of sustainable neighbourhoods is out of the question. So, combining with the characteristics of Shenyang, establishing a comprehensive and scientific goal-tracking mechanism to control sustainable neighbourhoods throughout the lifecycle is particularly important.

Before the establishment of this mechanism, the status of Shenyang should be investigated. Something like potential energy, resource users and greenhouse gas emissions should be forecasted by scenario analysis, cost-benefit analysis, life cycle assessment, etc. On the basis of this, adding into the strategic guiding ideology, the overall target and strategy of sustainable development in Shenyang can be formulated. Considering the specific geographical environment, environmental technology and financial status of communities in Shenyang, the targeted targets can also be formulated.

At the same time, Multi-party monitoring platform that aiming at the implementation of the target in the whole life cycle of sustainable neighbourhoods ought to be established. The government acts as prosecutor to prosecute the implementation of policies, while others such as developers, contractors, suppliers, property management companies, etc. must appoint their clear responsibilities for Internal oversight and publicity. The monitoring platform can effectively solve the lack of feedback and defect of output deviation caused by unidirectional transmission of information. It is also possible to make real-time improvements to the target during the project, evaluate the objectives at the end of the project. So that the indicators, as well as the overall strategy of sustainable development of Shenyang can be adjusted timely. Using a cycle of planning, monitoring, evaluation and improvement, targets of the project are able to be revised constantly to maximize the sustainable eco-efficiency of sustainable neighbourhoods.

4.3 Balance the interests of all parties

The development of sustainable neighbourhoods requires the participation of all sectors, and interests of all parties should be coordinated to balance by the government. Participants should develop the planning programs jointly to avoid risk at the beginning to improve operability and success rate of sustainable neighbourhoods.

While, the most significant conflict is between environmental goals and economic interests. The promotion of environmental indicators means the increase of costs. Taking green building as an example, it is defined in “Several Policy Measures to Promote the Modernization of Construction Industry in Shenyang” that, in the administrative area, prefabricated building technology should be used in the real estate projects, and the overall prefabrication rate must be more than 30%. Based on a prefabricated building using prefabricated sandwich panel to reach 30% of the prefabrication rate, compared with a traditional cast-in-place concrete building, the costs of developers will increase by about RMB 160 yuan per square meter (Li et al 2015), which is contrary to its goal of pursuit of maximizing economic benefits.

So the direct financial compensation can be used by Shenyang municipal government to reduce the pressure on the developers. But for the current financial pressure in Shenyang, relevant policy measures should be more introduced to mobilize market compensation (Shen & Song 2012). Through financial support to the developers, their enthusiasm for sustainable neighbourhoods can be enhanced, and the quality of construction can also be improved.

4.4 Innovate the collaboration safeguard mechanism of sustainable neighbourhoods

After balancing the interests of all parties, in order to ensure the inherent continuation of sustainability of the project, the participation of residents in Shenyang into sustainable neighbourhoods ought to be changed as well. There is no right without obligation. From the planning stage, “resident participation system” should be advocated as the starting point of constructing the interests safeguard mechanism of sustainable neighbourhoods in Shenyang. Sustainable Seattle and other foreign successful experience shows that, public participation is the basic guarantee system for the development of sustainable neighbourhoods. The traditional "from top to bottom" development mechanism of sustainable neighbourhoods in Shenyang should be reversed. And the Innovative safeguard mechanism ought to be established, which is based on the “from bottom to top” development mechanism including the planning processes from the government to experts and management process participated by the residents. So that the “trinity” collaborative mechanism can be established (Cai 2005; Sun et al 2015), and its operating mechanism is shown in the Figure 2.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

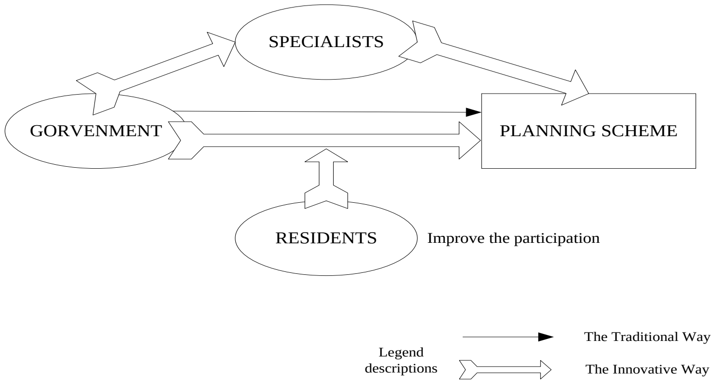

Figure 2: The "Trinity" collaborative mechanism of sustainable neighbourhoods in Shenyang

Under this collaborative mechanism, the construction of sustainable neighbourhoods in Shenyang should be based on the people-oriented technical measures such as perfect public transportation and ecological landscaping. Under the premise of ensuring the comfort of the residents` lives, boot mechanism should be more used to change the lifestyle of the residents. on the basis of energy cascade billing and garbage charges, economic incentives such as renewable energy power transactions should be increased as well, in order to enhance the concept of sustainable development like "from bottom to top" into residents` minds. This fundamental change is the focus of the sustainable development of sustainable neighbourhoods.

5. CONCLUSION

From the perspectives on controlling of the policy, legal and technical system, target monitoring and feedback mechanism, the interests of all parties, coordination mechanism and so on, the planning concept and control strategy of sustainable neighbourhoods in Shenyang is designed innovatively in this paper. Therefore, from the point of view of research, the theoretical and practical suggestions for the future development of sustainable neighbourhoods in Shenyang are provided in this paper.

However, due to the complexity of the implementation, the long-term of the development cycle, the large sums of uncontrollable factors and many other issues existing in the development of sustainable neighbourhoods in Shenyang, the viewpoints of this paper also need to be revised and perfected in practice. And there still need unremitting efforts of scholars to study on how to maximize the ecological benefits of sustainable neighbourhoods, and how can sustainable neighbourhoods exert more positive effects on the society, economy, ecology and other fields.

ABSTRACT

The green construction fence, green wall, can reduce the impact to the urban landscape cause by the construction site. However, keeping the plants survive usually consumes lots of water.

This study had surveyed 35 green walls in Taichung city, Taiwan. The result indicates that the two most used watering types are "delaminate watering by gravity with drilled PVC pipe", 62.8%, and "delaminate watering by drip irrigation system", 22.9%. And the plants were watered for 33.2 minutes, two times a day on average.

Base on the interview and field investigation, the average yield of water was 29.6 L/m^2-a day, which is 2.96 times to the references, thus the green wall was regarded as a hyper-water consuming structure. Therefore, this study aimed to assess which watering type is better and its' actual water consumption by doing an onsite experiment with an 1:1 scale green wall.

The watering type includes two parts: the watering system and the watering frequency. This study evaluated the appropriate watering frequency and water yield of two watering systems by measuring the soil humidity and observing how the plants grow or even died.

In conclusion, to keep the plant survive, the drip irrigation system is the better watering system for the green wall. The best watering frequency and the limit yield of water for each plant for the green wall in Taichung city is: (1) Shrub: 11.73 L/m^2, each 2 days; (2) Herbaceous plants: 8.93 L/m^2, each 2 days; (3) Succulent plants: 9.73 L/m^2, once a week; (4) Fern plants: 5.31 L/m^2, each 2 days.

When building a green construction fence, the drip irrigation system would be the better choice. And using appropriate watering frequency for different plants is also suggested. The green construction fence will have better benefit if built with water retention materials and water recycle system.

Keywords: green construction technology, watering type, water consuming

1. INTRODUCTION

The main function of the construction fence is to protect citizen from the possible risks and danger, however it also makes oppressive and cold images that impact the urban landscape. Therefore, the local government in Taiwan had promoted the decoration of construction fence by vertical greening for years. However, the green wall has few defects, such as (1) Choosing the unsuitable plants for the green wall; (2) Fail to create friendly walking environment for passengers; (3) Inappropriate management and maintenance; (4) Unsuitable water recycle system.

The related reference and early research mostly focus on the suitable plants choosing and the visual preference. According to Hong (2011), the yield of water using on the green wall is 7.58 L/m^2 per day, however it is only an estimated number. Therefore, this paper aimed to get precise water consumption of green wall and explore the feasible way to reduce the water consumption by field investigation and onsite experiment with an 1:1 scale model.

2. FIELD INVESTIGATION

In order to know construction detail of the green wall, such as the watering system, watering frequency, structure, materials and the choice of plants using, as a database for the onsite experiment, this study surveyed 35 cases of green wall in Taichung city, Taiwan.

2.1 The watering type

The watering type contains two parts: (1) The watering system; (2) The watering frequency. According to field investigation, the average area of the green wall is 78.5m^2, and the two most used watering system (Table 1) are" delaminate watering by gravity with drilled PVC pipe", 62.8%, and "delaminate watering by drip irrigation system", 22.9%. And the plants were watered for 33.2 minutes, two times a day on average.

The watering system	Delaminate watering by gravity with drilled PVC pipe	Delaminate watering by drip irrigation system	Spray from the top	Watering by manpower
Picture				
Ratio	62.8%	22.9%	5.7%	8.6%

Table 1: The watering system using on the green wall in Taichung City

2.2 The choice of plants

The field investigation result also indicated that the green wall usually uses 1~5 species of plants, and 54.29% green wall use 3 plant species (Figure 1). There are four plants most used in 35 cases (Figure 2): (1) Golden Dewdrop, 20.34%; (2) Spengeri Asparagus, 23.32%; (3) Rhoeo spathaceo, 13.56%; (4) Tuber Sword Fern, 13.71%.

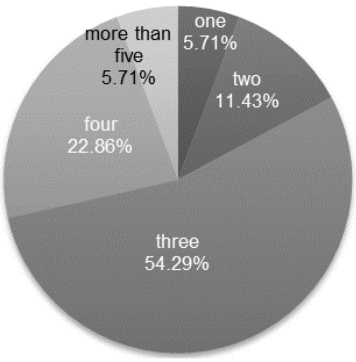

Figure 1: How many species using on green wall

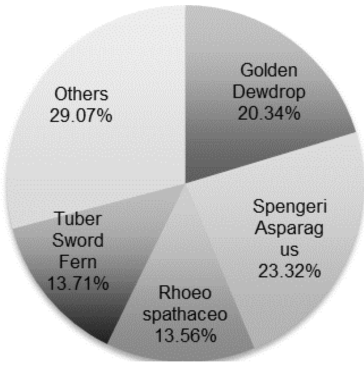

Figure 2: The using ratio of plants

2.3 The average yield of water used on green wall

This paper surveyed the watering type settings and structure details of green wall by interview and field investigation (Table 2) to figure out how much water did the construction site use on the green wall. And the average yield of water was 29.6L/m^2-a day for the 35 cases, which is 2.96 times to the references, thus the green wall was regarded as a hyper-water consuming structure.

Item	Description
Watering Frequency	Watering twice per day, mostly at 8 - 10 o'clock a.m. and 4 - 5 o'clock p.m.
Water Time	According to the timer settings, the water supply lasts 15 minutes, 30 minutes or 45 minutes each time

Quantity of Pump	Mostly using 1/2 or 1 hp motors, one set for 50m^2 on average, at most 3 sets
Pumping Efficiency	Referring to various manufacturers' catalogues, the motor pumping efficiency is influenced by the pipe diameter and pumping depth, the maximum yield is 20~50L/min, the average is 35 L/min

Table 2: The current condition of watering mode by field investigation

3. ONSITE EXPERIMENT

In order to know the suitable watering type for the green wall, this study built an 1:1 scale green wall to assess how much water was needed to keep the plants survive. The field investigation and the onsite experiment are all operated in Taichung City, Taiwan. Thus the climate is considered as a control variable, and the mean annual temp of Taichung City is 22.6°C, the mean annual rainfall is 1712.1mm, the mean annual RH is 79.8%, and the global radiation is 3.25 kWh/m^2-day. The onsite experiment is operated during September to December, 2013, and the experimental settings are described below.

3.1 Onsite experiment settings

The experimental site located at the southward terrace on the 8th floor of Jong Chin Building, Feng Chia University. Based on field investigation, this study set the experiment green wall as Figure 3 by using two different watering systems: (1) Delaminate watering by gravity with drilled PVC pipe; (2) Delaminate watering by drip irrigation system, and four different plants: (1) Golden Dewdrop, shrub; (2) Spengeri Asparagus, herbaceous plant; (3) Rhoeo spathaceo, succulent plant; (4) Tuber Sword Fern, fern plant.

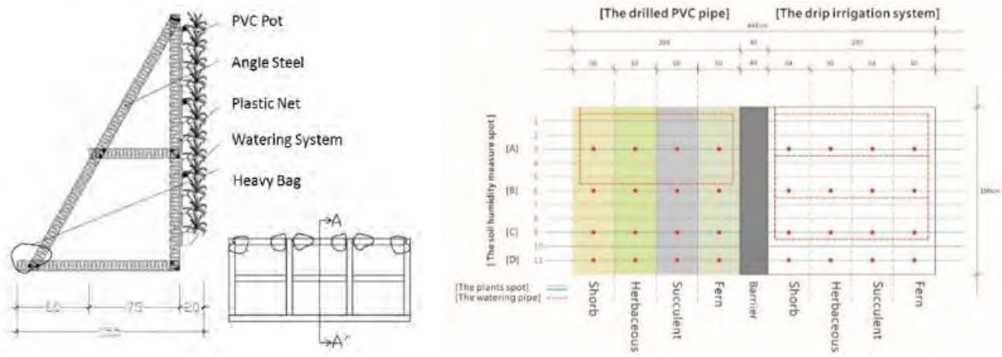

Figure 3: The experimental green wall structure and the watering system settings

Referred to the reference, this study appropriately reduced the watering frequency to watering everyday with 11.25 L/m^2 water. And researchers watered the green wall at 9:00am to prevent the heat hurts the plants. In this study, the watering frequency was the main control variable. If it rains, the experiment was restarted in two days after rain. The soil humidity should keep between 40~60% (M. X. GU, 2012) to assure the plants all grow well, so this paper used Rixen M-700 to measure the soil humidity as quantitative data.

3.2 The effects of different watering system

When using the same source and watering for the same time, the effects of watering system can be affected by" water pressure, the diameter of pipe, et al.", therefore this paper measured how much yield that the watering system watered the plants. Watering by drip irrigation system has better efficiency as Figure 4 shows, it can provide more water for the plants than watering by gravity with drilled PVC pipe when using the same source and watering for the same time.

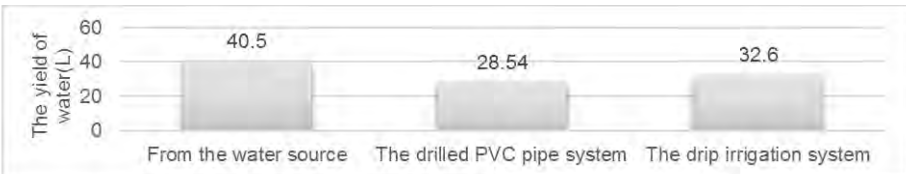

Figure 4: The provided water yields from the water source and different watering system

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

When watering the green wall everyday with 11.25 L/m², the average soil humidity of different watering system was almost the same. Which means the watering system doesn't have obvious efficiency difference in this watering frequency (Figure 5). Furthermore, when comparing the average soil humidity of different spots (Figure 6), the average soil humidity of all the D spots were higher than the other spots. That is because the water always runoff by gravity.

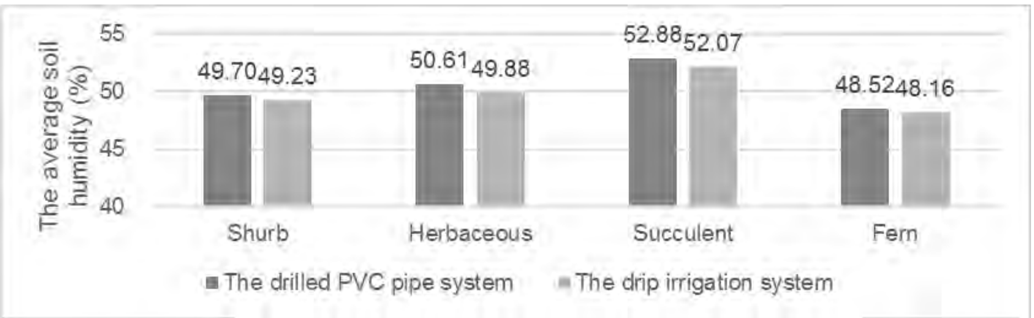

Figure 5: The average soil humidity of different plants when watering everyday

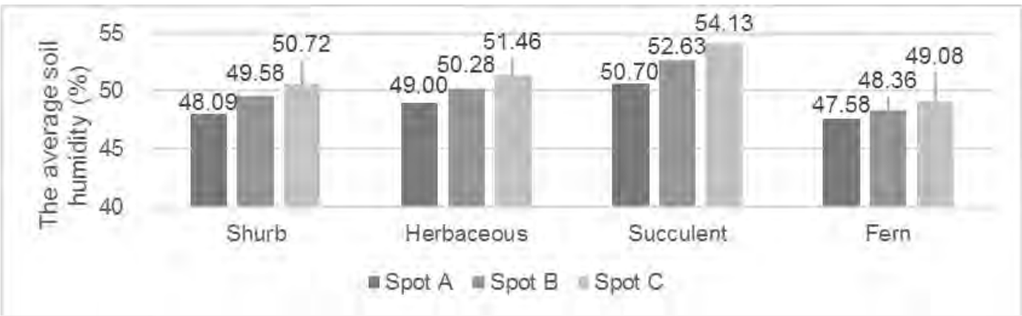

Figure 6: The average soil humidity of different spot when watering everyday

When the frequency was watering the green wall each 2 days with 11.25 L/m², the average soil humidity was still affected by gravity. However, when the frequency was watering the green wall every 3 days or 4 days (Figure 7) with 11.25 L/m², the average soil humidity of D spots by watering with the drilled PVC pipe were lower than the other spots, but the average soil humidity of d spot by watering with the drip irrigation system were still higher than the other spots. Overall, when using the same water source and watering for the same frequency, the drip irrigation system is better than the drilled PVC pipe.

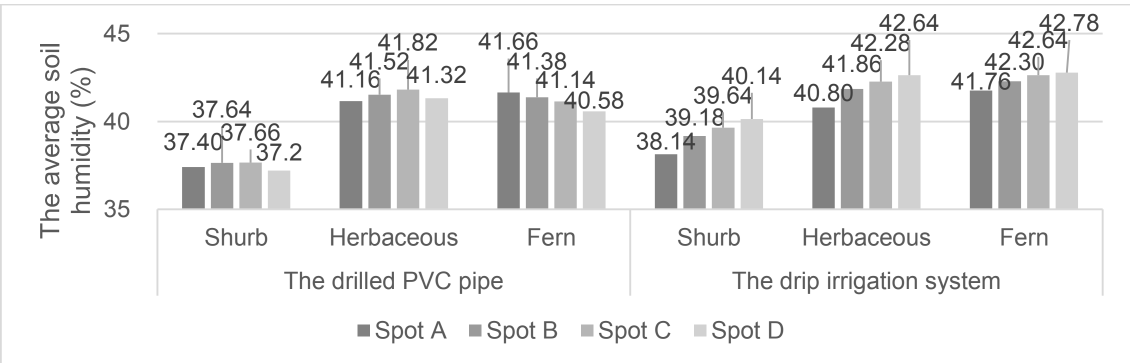

Figure 7: The average soil humidity of different spot when watering every 4 days

3.3 The suitable watering frequency

According to the measuring result, the maximum soil humidity was 54%. The soil humidity of shrub decreased 8% per day, and the shrub withered when the soil humidity went down to 33 - 36%. Therefore, the suitable water frequency for shrub was watering each (54-36)/8 = 2.51 days, that is the shrub should be watered each 2 days when using 11.25L/m² yield of water. By the same method, this paper discovered that the herbaceous plant and the fern plant should be watered every 3 days. Therefore, the suitable watering frequency is to watering the green wall each 2 days with 11.25L/m^2. In this frequency, only succulent plants could rot and die, but other plants all grow well without being withered or shrivelled.

3.4 The water consumption of different plants

This study collected the water which wasn't absorbed by the plants to know the suitable yield of water for each plants in different watering frequency. The single plant took 0.45m^2 on the green wall in the experiment, and the actual water yield for different plants in watering everyday could be calculate as Equation 1.

The water absorbed by the plants (L) / plant area (m^2) = water consumption (L/m^2)

Equation 1

The Rhoeo spathaceo is a kind of succulent plants, and it could rot then die when the soil humidity was higher than 45%. This study had replaced the dead items and changed the watering frequency, then figured out that the suitable watering frequency for it is watering once a week.

Overall, the suitable watering frequency and the water consumption for different plants are: (1) Shrub: 11.73 L/m^2, each 2 days; (2) Herbaceous plants: 8.93 L/m^2, each 2 days; (3) Fern plants: 5.31 L/m^2, each 2 days; (4) Succulent plants: 9.73 L/m^2, once a week.

3.5 The water conservation materials

To decrease the water consumption, the green wall should have suitable water recycle system and water conservation materials. As Figure 8 shows, there is about 50% water wasn't absorbed by the plants in watering every day or each two days. And the Figure 9 shows that when using water conservation materials, the water runoff on the ground had decreased from 52% to 28%.

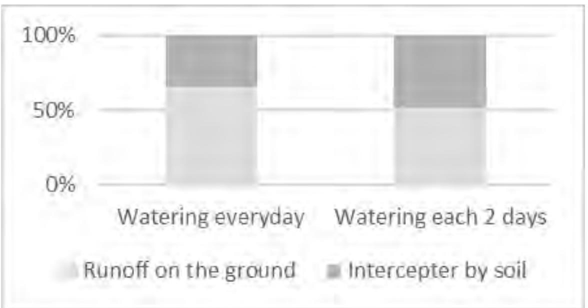

Figure 8: The runoff and absorbed water

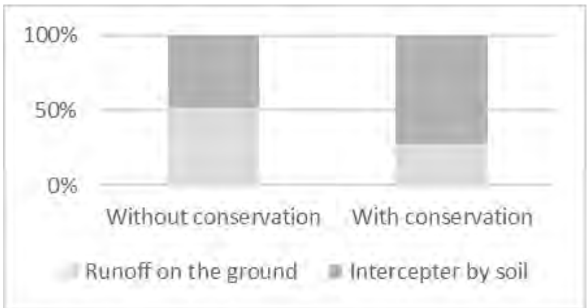

Figure 9: The conservation materials effect

4. CONCLUSION

The onsite experiment results indicate that to keep the plants survive, the drip irrigation system is the better watering system because it can provide more water when using the same water source and watering the same time.

There should be appropriate water conservation materials and irrigation water recovery mechanism for green wall. According to this experiment, if a green wall had no water conservation materials, over 50% water would runoff directly. When the green wall had water conservation materials, the runoff water could be reduced to below 30%. Therefore, if any water recycle system could be applied, the water consumption could be reduced effectively.

This paper figures out the green wall should take different watering frequency when using different plants. In order to take consideration to plant survival and reduce water consumption, the suitable watering frequency and the limit yield of water for each plant for the green wall in Taichung city are: (1) Shrub: 11.36 L/m^2, each 2 days; (2) Herbaceous plants: 8.93 L/m^2, each 2 days; (3) Fern plants: 5.31 L/m^2, each 2 days; (4) Succulent plants: 9.73 L/m^2, once a week.

ABSTRACT

A combined Life Cycle Assessment (LCA) and Life Cycle Costing (LCC) Study was undertaken to quantitatively measure the environmental impacts and cost implication of (1) an existing public housing block (50-year life); (2) an existing private sector residential block (50-year life) and (3) Integer Concept Tower (50-year and 75-year life) in 2003. The study measured the environmental impacts generated from the whole building life cycle stages including, raw material extraction, building material manufacturing, transportation, building operation, repair and maintenance, and disposal. However, the study did not quantitatively measure the environmental impact of on-site activities, except construction wastage. In 2013, Low Carbon Construction Plan was conducted for a new local public housing development in Hong Kong. The project develops the first low-carbon construction implementation plan for new housing development. The analysis included the entire 2.5-year construction period including (1) supply-chain; and (2) on-site construction. The project accounted and reported of the potential greenhouse gas emissions, possible offsets and removals for construction contract stage at the new public housing development in Hong Kong. This paper will report the findings and carbon reduction of the low-carbon construction measures and the implication of the life cycle carbon footprint of recent housing development in Hong Kong.

Keywords: climate change, green construction technology, life cycle assessment

1. INTRODUCTION

1.1 Life cycle assessment study in 2000s and the limitation on addressing public housing development in Hong Kong in 2010s

A combined Life Cycle Assessment (LCA) and Life Cycle Costing (LCC) Study quantitatively measured the life-cycle energy consumption, greenhouse gas emission, waste generation and cost implication of three 40-storey residential towers in Hong Kong - (1) an existing public housing block (50-year life); (2) an existing private sector residential block (50-year life) and (3) the Integer Concept Tower (50-year and 75-year life) in 2003 (Figure 1) (Amato, et al., 2003). One of the environmental indicators the study measured was the greenhouse gas emission generated from the whole building life-cycle including, raw material extraction, building material manufacturing, transportation, building operation, repair and maintenance, and disposal stage. Figure 2 shows the life-cycle greenhouse gas emission per construction floor area of the three 40-storey residential tower types. The building operation stage and repair and maintenance stage of the existing public housing block (50-year life) emitted 56% and 25% of the life-cycle greenhouse gas emissions, respectively. On the other hand, the building operation stage and the repair and maintenance stage of the existing private-sector residential block (50-year life) emitted 38% and 36% of the life-cycle greenhouse gas emissions, respectively. The result shows that the 50-year operational stage of existing public housing block emitted higher proportion of greenhouse gas emission (56%) than the existing private sector residential block (38%). It is because existing public housing block had a higher population density than private sector block in 2000s. The study concluded that energy efficiency, renewable energy generation, varying and improving how the housing to be run and maintained could greatly reduce the overall life-cycle environmental impacts and life cycle cost of the existing public housing block (Amato, et al., 2003).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 1: (1) Existing public housing block; (2) Existing private sector residential block and (3) The Integer Concept Tower (left to right) developed in 2000s in Hong Kong

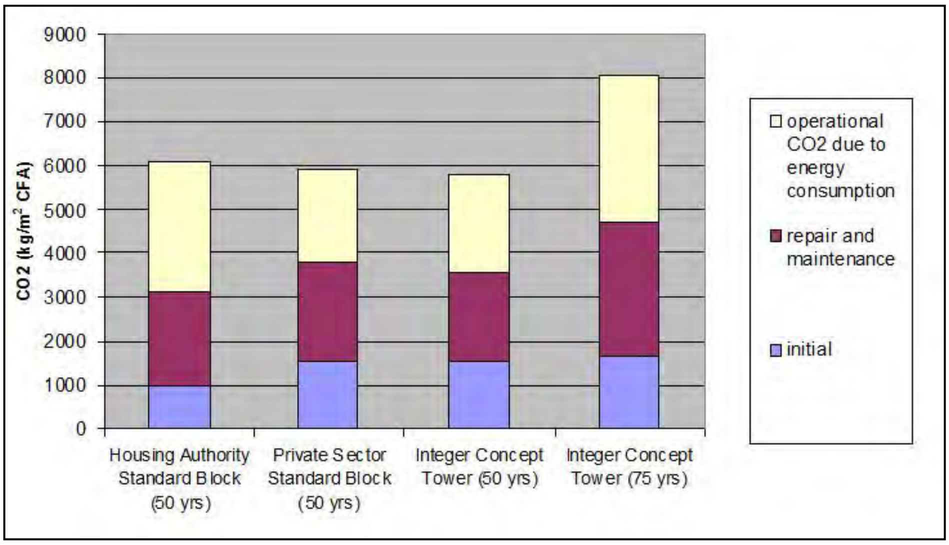

Figure 2: Life-cycle greenhouse gas emission per construction floor area of three residential tower types (Amato, et al., 2003)

In view of the conclusion of the above study, the newly-designed public housing blocks developed in 2010s incorporated numerous energy-efficient features and renewable energy system to reduce greenhouse gas emissions from the building operational stage. For instance, new public housing development completed in 2013 applied electronic ballast, T-5 fluorescent tubes and LED lighting on the lighting of the communal area. A two-level lighting control system was deployed in the lighting in the lift lobbies and corridors. The system could sustain a lower but acceptable level of lighting under normal conditions and could switch on the extra lighting when required. Those lighting control had reduced the energy consumption of lighting in communal area by 30% (Hong Kong Housing Authority, 2015). Renewable energy system in form of a photovoltaic system and lift with regenerative power generated 2% of energy consumption of the communal building services installation of the public housing block. Those energy efficiency measures reduce the carbon footprint of the building operation of newly-designed public housing developed in 2010s.

Figure 2: Two-level lighting control system (normal mode: 50 lux; triggered mode: 85 lux) (left); Roof photovoltaic system in a public housing development in 2010s (right)

In view of the construction stage, the previous life cycle study did not measure the greenhouse gas emission of on-site activities, except construction wastage. The construction contract period, including supply chain and site operation, can contribute a lot of the life-cycle greenhouse gas emissions of a public housing development.

1.2 Low carbon construction plan of public housing development

In 2013, Low Carbon Construction Plan was completed in a new local public housing development. The construction was commenced from 2010 and completed at 2013. The new public housing estate is comprised of 6 housing blocks of 35-40 storey residential buildings accommodating 5,204 units, car park, commercial centre, community youth service centre and elderly day centre.

This paper will report the findings and carbon reduction of the low-carbon construction measures and the implication of the life cycle carbon footprint of the new housing development in Hong Kong. Accounting covers the whole construction contract period, including:

- Supply Chain
  - Raw-material extraction,
  - Transportation from the extraction site to factory,
  - Building-material manufacturing in factory
  - Transportation from factory gate to the construction site; and
- Site Operation – construction activities in the local housing development

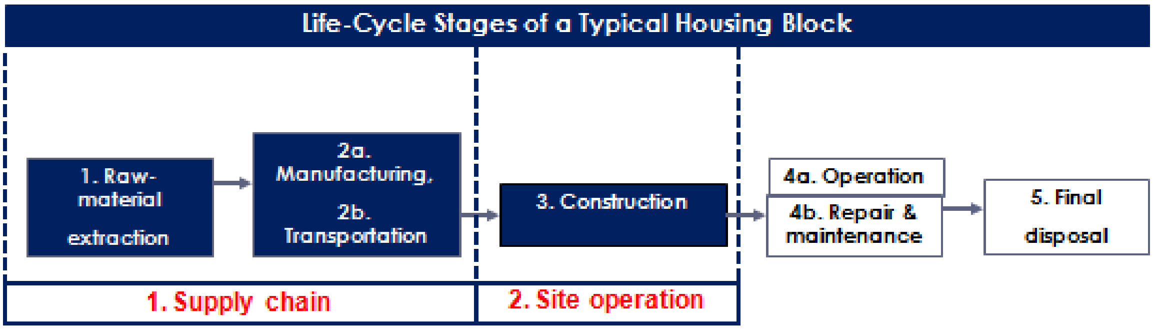

Figure 3: Life cycle stages in the construction contract period

2. ACCOUNTING METHODOLOGY AND RESULT OF CARBON REDUCTION

The accounting of greenhouse gas emission for the Low Carbon Construction Plan began in March 2011. The study took the below accounting methodology for the reduction of the low-carbon measures of the new local public housing development. Table 1 includes the low-carbon construction measures of the Low Carbon Construction Plan, their accounting methodology and their carbon reduction.

	Low Carbon Construction Measures	Accounting Methodology	Carbon Reduction
	• Volumetric Precast Bathroom (VPB) • Volumetric Precast Kitchen (VPK)	Life Cycle Assessment (Cradle to Site Stage) a. Raw-material extraction b. Transportation from extraction site to prefabrication factory c. Manufacturing of VPB/ VPK and precast elements at prefabrication factory	2854 tonne CO_2-e

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

	• Precast façade • Precast wall • Precast stair • Precast tie beam • Precast landing • Precast refuse chute • Precast beam and column for carpark	d. Transportation of VPB/ VPK and precast elements from prefabrication factory to construction site	4329 tonne CO_2-e
 ; 	• Semi-precast slab with fabric reinforcement	Life Cycle Assessment (Cradle to Site Stage) a. Raw-material extraction b. Transportation from extraction site to prefabrication factory c. Transportation of fabric reinforcement from Hong Kong to prefabrication factory d. Manufacturing of prefabrication elements at prefabrication factory e. Transportation from prefabrication factory to construction site	1400 tonne CO_2-e
	• Marine mud material into useful building element	The accounting measured the reduction of carbon footprint for transportation of the paving materials made in factory to site and the transportation of waste marine mud to public fill and the electricity consumption of convey belt and mixer.	487 tonne CO_2-e
	• Early electricity supply from grid	The accounting measured the reduction of carbon footprint between electricity from grid and from diesel generator during construction period.	1866 tonne CO_2-e
	• Recycling and waste sorting facilities on each block	The accounting measures the reduction of carbon footprint from recovery of materials from waste recycling and sorting. The waste recovered includes steel bar, concrete, plastic bottles, paper and aluminium cans.	2394 tonne CO_2-e
Reuse of concrete to produce temporary site drain 	• Volume of reused water and water saving	The accounting measures the reduction of carbon footprint from water reuse for vehicle washing facilities and dust control during construction period and water saving	3.8 tonne CO_2-e

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Waste sorting facilities			
	• Diesel bobcat\ forklift/ truck with biodiesel fuel (B5)	The accounting reports the carbon emission reduction due to the use of biodiesel B5 for replacement of normal diesel. Biodiesel was blended in the diesel. In Hong Kong, most of the biodiesel is sourced from the collected cooked oil from restaurant. In Hong Kong situation, biodiesel is more environmental friendly as it reuses waste cooked oil from restaurants.	0.5 tonne CO_2-e
	• Solar hot water system for staff showering	The accounting reports the reduction in carbon emission when using solar hot water system in addition to electrical water heater.	4.8 tonne CO_2-e
	• Food waste decomposer for staffs	The accounting reports the carbon reduction from food waste decomposer in compare to landfill decomposition. Food-waste-decomposer was adopted to convert the food waste into fertilizer which can be used in tree planting or donated to nearby school or communities.	0.4 tonne CO_2-e
	• Tree planting for hoarding greening	The accounting reports the carbon absorption from trees pre-planting on construction site.	2.2 tonne CO_2-e
	• Electric site car	The accounting reports the carbon reduction in carbon emissions when using electric car to replace petroleum site car as contract car.	2.2 tonne CO_2-e
	• Computer Document Management System	The accounting reports the carbon reduction in carbon emissions in paper saving.	0.9 tonne CO_2-e

Table 1: Low carbon construction measures of the low carbon construction plan and accounting methodology

3. CARBON REDUCTION FROM THE LOW CARBON CONSTRUCTION PLAN

Low Carbon Construction Plan reduces a total of 13,345 tonne CO_2-e for the construction contract period of the new public housing development which accommodates over 5,000 residential units. The total carbon reduction from Volumetric Precast Bathrooms, Volumetric Precast Kitchens, prefabrication elements and semi-precast slabs are 8,583 tonnes CO_2-e. Most of the carbon emission reduction result in carbon emission in raw-material extraction stage. It is because far less formwork and better quantity and quality control occur in prefabrication manufacturing in a factory environment. For instance, 12 sets of steel formwork were used during the whole production period to produce 4,910 numbers of Volumetric Precast Bathrooms, which is far less than the quantity of formwork required in in-situ construction. (Wong

& Tang, 2012) Some low-carbon construction measures are implemented in small scale. Examples are diesel bobcat\forklift\truck with biodiesel fuel (B5), electric site car, tree planting for hoarding greening and food waste decomposer for staffs. The carbon reduction can potentially be increased if all diesel fuels would be replaced with biodiesel (B5) and all site cars would be replaced by electric cars in the future project.

4. IMPLICATION TO THE LIFE CYCLE CARBON FOOTPRINTS GREENHOUSE GAS EMISSION OF HOUSING DEVELOPMENT

The new local public housing development adopts both low-carbon construction measures and energy-efficient features. The pioneer low-carbon construction approaches include Volumetric Precast Bathroom, Volumetric Precast Kitchen, various precast construction elements; semi-precast slab; marine mud building elements; early grid connection; recycling and waste sorting facilities; reused water and water saving; use of biodiesel; solar hot water for staff showering; food waste decomposer; hoarding greening and electric site car. The energy-efficient features include electronic ballast; T-5 fluorescent tubes; LED lighting; two-level lighting control system for lift lobbies and corridors; renewable energy system in form of a photovoltaic system and lift with regenerative power. Both low-carbon construction measures and energy-efficient features reduce the carbon footprint of both construction and building operation stages.

In consideration of the carbon emission from both supply chain, site operation and building operation, Figure 4 shows the comparison of the life cycle greenhouse gas emission per construction floor area of the public housing block of 2003 study and the new local housing development with Low Carbon Construction Plan completed in 2013.

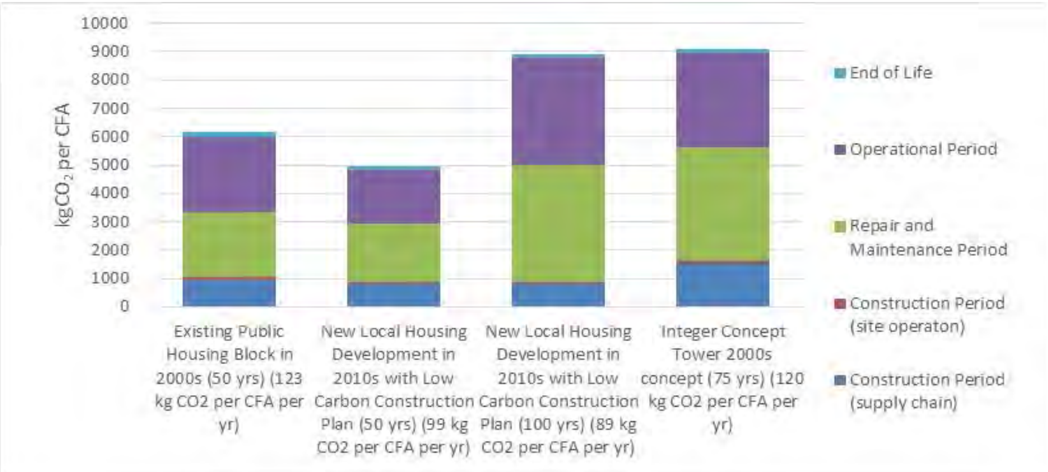

Figure 4: Life cycle greenhouse gas emission of the new local housing development with low-carbon construction plan and energy-efficient measures compared to existing public housing block and integer concept tower developed in 2000s

The life-cycle greenhouse gas emission of the new local housing development accounts both carbon reduction of Low Carbon Construction Plan, energy efficiency and renewable energy systems. The life-cycle greenhouse gas emission can be reduced by 19.4% under 50 years of operational life with Low Carbon Construction Plan, various energy efficiency and renewable energy systems. Low Carbon Construction Plan reduces 15.9% of the greenhouse gas emissions of construction contract stage while energy efficiency and renewable energy system reduce 29% of the greenhouse gas emissions of building operational stage. The operational life of new housing buildings could be at least 100 years according to recent research and development work (Mak, 2010). In consideration of the extended 100-year life, the indicator in form of life-cycle greenhouse gas emissions per construction floor area per year can be adopted to compare building with different operational life. The local housing development in 2010s with Low Carbon Construction Plan and energy efficiency measures with extended 100-year life can reduce life-cycle greenhouse gas emission to 89 kg per construction floor area per year while the life-cycle greenhouse gas emission of public housing block (50-year life) and Integer Concept Tower (75-year life) in 2003 study emitted 123 kg and 120kg per construction floor area per year. 28% and 26% greenhouse gas emission can be reduced from the Low Carbon Construction Plan and energy efficiency measures.

5. CONCLUSIONS

This paper takes into account the carbon reduction from the Low Carbon Construction Plan and the implication of the life-cycle carbon footprint of housing development in Hong Kong. Most of the carbon reduction come from prefabrication plan for the local public housing development. The carbon reduction can potentially be increased if the small-scale measures can apply in project-scale. Low Carbon Construction Plan reduces 15.9% of greenhouse gas emission of construction contract period. The study does not take into consideration the implication from varying and improving how the housing is run and maintained. The study does not take into consideration the life-cycle cost implication of the Low Carbon Construction Plan. Analysis can be made on the cost-effectiveness of various low-carbon construction measures. Guidelines can then be set up to direct the whole construction industry towards sustainable and low carbon construction in a cost-effective manner.

ACKNOWLEDGMENT

The study was supported by the China State Construction Engineering and Hong Kong Housing Authority. The support is gratefully acknowledged.

ABSTRACT

Every year, about 600,000 tonnes of incineration ash is produced in Singapore. The ash comprises bottom ash and fly ash. The bottom ash contains less leachable metals of concern and soluble salts and has a great potential for utilization. In 2008, Samwoh participated in a trial initiated by Land Transport Authority to evaluate the use of bottom ash in road construction. The study comprises laboratory tests and field trial to evaluate the properties of the bottom ash which was processed using a patented technology. The bottom ash was used for the construction of road base and subbase. The test results showed that the processed bottom ash meets all the relevant regulatory requirements.

Keywords: incineration bottom ash, road construction, road base and subbase.

1. INTRODUCTION

Singapore is a small city state with one of the highest population densities in the world. A key challenge is the limitation of land for waste disposal. One of the main strategies adopted by the government is to dispose the waste at waste-to-energy (incineration) plants to reduce waste volume by about 90%.

Every year, about 600,000 tonnes of incineration ash is produced (National Environment Agency, 2015). The ash comprises about 80-90% of bottom ash and 10-20% of fly ash. Incineration bottom ash (IBA) contains less leachable metals of concern and soluble salts and has a great potential for utilization. A key concern on the use of IBA is its potential leaching effect. The IBA has to be properly processed for safe applications. In 2008, Samwoh participated in a trial initiated by Land Transport Authority (LTA) to evaluate the use of IBA in road construction as part of LTA's Green Pavement initiative.

This paper presents the findings of a study which involves IBA processing, laboratory tests and construction of a field trial to evaluate the engineering and environmental properties of IBA. The ash was processed using a patented technology. Laboratory tests such as particle density, water absorption, maximum dry density, California bearing ratio, toxicity characteristic leaching test, dioxin and furan analyses were conducted to ascertain the quality of the processed IBA. Subsequently, a field trial was performed to determine the field performance of the ash which was used for the construction of road base and subbase. The test results are presented in this paper.

2. PROCESSING OF IBA

The processing of IBA involves ageing, screening to remove foreign materials such as unburned materials, ferrous and non-ferrous metals, crushing, sieving into the required size and chemical treatment using a patented process which is a commercially well-proven process to produce treated ash that meets regulatory leaching limits and be safely used in applications such as structural fill or road base.

The IBA was allowed to age for about 8 to 12 weeks from the time of arrival at the storage yard. Ageing allows swelling, hydration, carbonation, and oxidation aging reactions to occur. After the ageing process, the IBA was processed via the following processes:

- Preliminary screening to remove oversize and unburned materials
- Removal of ferrous and non-ferrous metals
- Crushing to break down the IBA into smaller particle size
- Sieving of IBA to the required size

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Chemical treatment
- Stockpile of the processed IBA at the storage area

After the IBA was processed, the ash was mixed with water and some additives using a pugmill mixer to enhance the bearing capacity of the IBA for base and subbase application.

3. LABORATORY TESTS

Laboratory tests were conducted on the processed IBA to determine its engineering and environmental properties. The results are described in the following sub-sections.

3.1 Engineering properties

The results for the engineering properties are shown in Table 1.

Properties	Results	Test Method
Particle density (oven dry)	1.62 Mg/m^3	SS 73:1974
Water absorption	22.5%	SS 73: 1974
Maximum dry density	1.48 Mg/m^3	BS 1377-4:1990
Optimum moisture content	24.9%	BS 1377-4:1990
California bearing ratio (soaked)	180%, 193%	BS 1377-4:1990
Plasticity index	8%	BS 1377-2:1990

Table 1: Engineering properties of processed IBA

From Table 1, the results showed that the processed IBA is relatively lightweight as compared to granite (conventional aggregate used for road construction in Singapore) which has a particle density of about 2.6 Mg/ m^3. The IBA is highly absorptive with water absorption of more than 20% and the optimum moisture content required for compaction is about 25%. In order to provide adequate bearing capacity for the base/ sub-base application, the processed IBA was treated with additives for strength enhancement. The CBR (soaked) showed more than 180% which meets the LTA specification requirement (LTA, 2010) of minimum 30% for subbase and the CBR is comparable to conventional graded granite aggregate base. As such, the processed IBA will provide good bearing capacity for subbase and road base applications.

3.2 Environmental properties

The environmental characteristics of the IBA samples were determined according to Toxicity Characteristic Leaching Procedure (US EPA Method 1311) and dioxin/ furan analyses (US EPA Method 1613). The tests were conducted on unprocessed and processed samples. The results are shown in Tables 2 and 3.

Table 3: Dioxin/ furan results (WHO-TEQ, pg/g)

Based on Table 2, no distinct changes were found in the results for the Toxicity Characteristic Leaching Procedure between the unprocessed and processed IBA. The results showed that all the unprocessed and processed IBA samples meet the regulatory requirements.

The test results for the dioxin/ furan analyses are shown in Table 3. They are expressed in terms of WHO toxic equivalent value (TEQ). The unprocessed IBA showed less than 200 pg TEQ/ g of dioxin/ furan and the processed IBA samples showed less than 50 pg TEQ/ g of dioxin/ furan. Based on regulatory requirements, the limit for dioxin/ furan contained in the IBA is 1000 pg TEQ/ g for road construction applications. The results showed that all the unprocessed and processed IBA samples meet the requirement.

4. FIELD TRIAL

Further to the laboratory tests, a field trial was constructed which comprises two test sections of 50m length each as shown in Figure 1. The processed IBA was used as a substitute for conventional materials approved by the LTA for the construction of road base and subbase. The assessment was conducted with respect to groundwater monitoring as well as pavement testing.

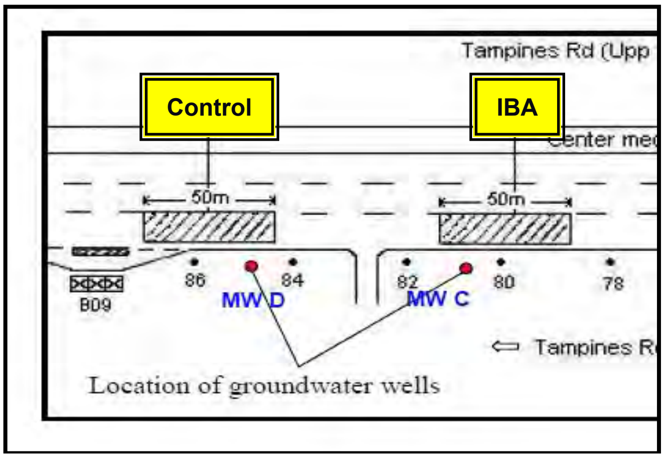

Figure 1: Location of test sections

4.1 Groundwater monitoring

Groundwater samples were collected from the groundwater wells, MW C and MW D as shown in Figure 1. A total of four groundwater tests were carried out over a period of 1 year, namely, before construction of the test sections and three times after construction. The tests conducted include conductivity, total organic carbon, total nitrogen, total phosphorus, total hardness, pH, heavy metals, dioxin and furan, as well as organic constituents.

Some of the results are shown in Table 4. In comparison with the results before construction, most of the results obtained after the construction showed a reduction in the concentration for each groundwater well. The results taken after the construction did not show any significant changes.

Type of Test	MW C				MW D			
	Before construction	After construction			Before construction	After construction		
	19/02/09	28/04/09	28/10/09	26/01/10	19/02/09	28/04/09	28/10/09	26/01/10
Conductivity (ms/cm)	17.5	7.37	6.42	9.24	11.1	1.16	1.19	1.00
Total organic carbon (mg/L)	52.6	30.7	26.6	26.7	20.1	6.6	6.2	5.8
Total nitrogen (mg/L)	34.8	29.5	34.9	37.8	29.8	5.2	5.3	8.1

Total phosphorus (mg/L)	0.11	0.03	0.06	N.D.	N.D.	0.04	0.06	0.03
Total hardness (mg/L)	2664	988	884	1217	1627	290	349	309
pH	-	-	6.9	6.9	-	-	6.7	6.7

Note: N.D. means "Not detected" where the result is less than the limit of reporting

Table 4: Groundwater test results

4.2 Pavement performance monitoring

The pavement performance condition was evaluated with respect to riding quality in terms of the International Riding Index (IRI) using a multi-laser profiler and structural strength using a deflectograph shown in Figure 2.

Figure 2: Left: laser profiler; right: deflectograph

The IRI is a roughness index that is widely used to express road roughness on a common internationally recognized scale. IRI is calculated from a mathematical function of the pavement longitudinal profile and is expressed as the average longitudinal road profile that represents the vertical response of a hypothetical quarter-car traveling at 80km/ h to the measured longitudinal road profile. The calculation has been documented in ASTM E1926. The test results are shown in Figure 3.

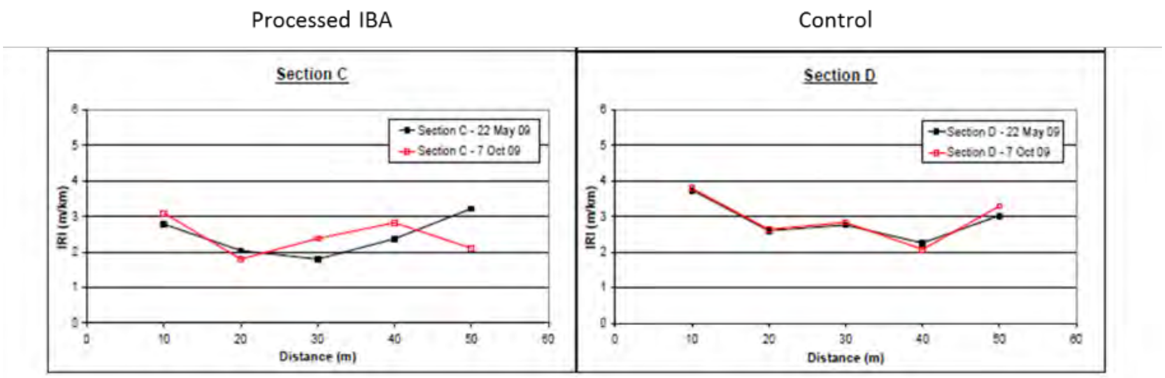

Figure 3: IRI results

The results showed that the IRI is less than 4m/ km which meets the LTA specification requirement (LTA, 2010). The two test sections showed similar performance in terms of riding quality.

The structural strength of the test sections was measured using a deflectograph which works on the principle that as a loaded wheel (of about 100kN) passes over the pavement, the pavement deflects and the size of the deflection is related to the strength of the pavement layers and subgrade. It is an automated deflection measuring system and a fully self-contained lorry-mounted system, whereby measurements of deflection are taken at approximately 4m intervals in both wheel-paths while the machine is in motion. The test results are shown in Figure 4.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

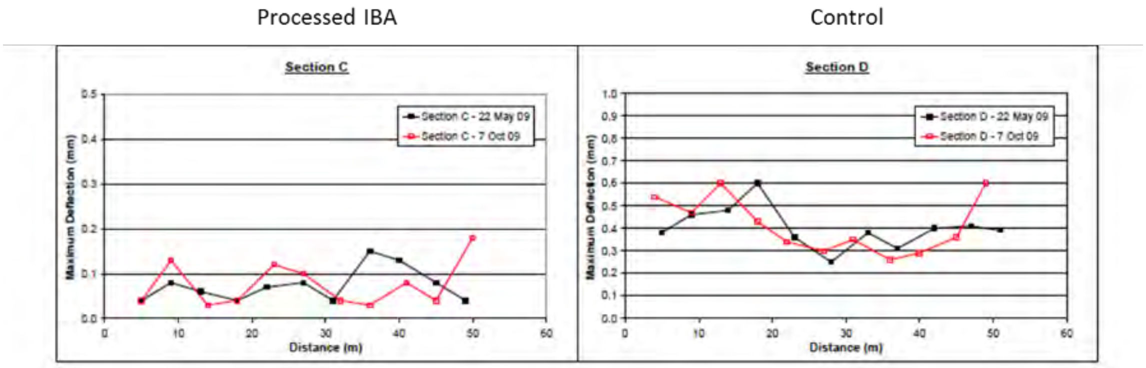

Figure 4: Deflection results

The results showed that the deflection measurements for the processed IBA are significantly lower as compared to the control section. This implied that the former showed higher structural strength as compared to the latter.

5. CONCLUSIONS

This paper presents the results of a study that was carried out to evaluate the use of processed IBA for the construction of road pavement. The key findings are summarized as follows:

- Laboratory tests –The processed IBA meet the regulatory requirements for Toxicity Characteristic Leaching Procedure and dioxin/ furan analyses. It also showed a high CBR which will provide good bearing capacity for road construction.
- Groundwater tests – The test results obtained after the construction of the test sections were generally better or comparable to the results before the construction. This implied that the processed IBA is safe for usage.
- Pavement performance tests - The test results showed that the test sections showed similar IRI and meet the LTA requirement of not more than 4m/ km. In the case of structural strength, the processed IBA showed higher structural strength as compared to the control section.

Based on these findings, it can be concluded that the processed IBA can provide a good substitute for conventional paving materials for road construction.

ABSTRACT

Efforts continue to embed sustainable construction within the built environment; however, little attention has been given to construction professionals' understanding of the relationship between the principles of sustainable construction and construction phases. With different professionals involved throughout the project life-cycle, achieving sustainable principles at different stages may be difficult. This emphasises the need to explore these professional's understandings of the relationships between sustainable construction and construction phases. This paper examines literature to establish this relationship as understood by construction professionals. Evidence is presented of a mutually inclusive relationship between the principles of sustainable construction and construction phases. This study highlights the limited understanding of the framework for describing these relationships.

Keywords: construction phases, sustainable construction, sustainable development

1. INTRODUCTION

Sustainable development (SD) has attracted the attention of policy makers, researchers, government and non-government organisations across the world. SD is 'development that meets the need of the present without compromising the ability of future generations to meet their own need' (WCED, 1987: 66). Numerous attempts at achieving SD have been discussed. In 2015, Agenda 2030 was signed to reinforce commitment to SD. Intensive efforts have been made in this regard and continue to be supported by several industries including the construction industry.

The construction industry has been criticised for those of its activities that conflict with SD principles (Pearce, 2005). Construction consumes 50% of natural resources (European Commission, 2001). Kibert (2012) identified resources as including land, materials, water, energy and ecosystems, stating that "the energy invested in building materials and construction is significant, amounting to 20 percent of the total life-cycle of the facility" (p. 4). This emphasises the need for resource efficiency and alternative construction approaches. Sustainable construction (SC) is seen as the industry's approach to achieve SD (Abidin, 2010, Hoffman and Henn, 2008). The Conseil International du Batiment (CIB) defined SC as "…creating and operating a healthy built environment based on resources efficiency and ecological principles" (Kibert, 2012: 8). Achieving sustainability in construction requires a holistic approach. Although construction phases are generally viewed as sequential, alternative sequences are possible. Several researchers (Ahadzie et al., 2006, Lim and Mohamed, 1999, Takim et al., 2003) have identified these phases as conception, planning, design, tender, construction and operation. The success of any construction project depends on them (Ahadzie et al., 2006).

Construction professionals' decisions are important in achieving SC. The principles of SC provide a decision making charter for them throughout the construction life-cycle (Kibert, 2012). Achieving SC principles may be challenged by their understanding and interpretation of these principles. Some view SC as a process or the management of a process/ system (Ogunmakinde et al., 2016a). Kibert (1994) opined that professionals treat SC principles in isolation. This compromises understandings of their interconnectivity. Some studies address the links between sustainable principles and their application in construction. This paper explores the relationship between construction phases and the principles of SC.

2. SUSTAINABLE DEVELOPMENT

The landmark SD definition by WCED deals with meeting peoples' present needs without compromising their future. Some have criticised this as being too basic (Oskamp, 2002) and several refined definitions have emerged. SD can be described as "enhancing quality of life and thus allowing people to live in a healthy environment and improved social, economic and environmental conditions for present and future generations" (Ortiz et al., 2009: 29). Most definitions emphasise the importance of striking a balance between environmental conservation, social equity and economic profitability. Decision making is central (Dernbach, 2003) and must include economic, social and environmental concerns to achieve SD (Emas, 2015).

2.1. Sustainability

Much has been written about sustainability. Newport et al. (2003) observed that it is not instinctively understood and well-communicated. Similarly, Arif et al. (2013) described it as a concept lacking an accepted definition and focus, resulting in numerous definitions and differing interpretations. Pearce (2005) defines sustainability as something that accommodates conventional financial concerns, as well as environmental and social effects (known as the 'triple bottom line'). Their integrations, interactions and relationships are emphasised elsewhere (Hutchins and Sutherland, 2008, Tam, 2008). Sustainability is all encompassing and requires concerted efforts from various spheres to provide comfort to all sentient beings.

2.2. Construction and construction phases

Construction is the art or manner of building something. It involves processes that use land, water, energy and materials. Du Plessis (2002: 4) described construction as 'the broad process/ mechanism for the realisation of human settlements and the creation of infrastructure that supports development'. It requires both skilled and unskilled labour in joining different components. Irurah (2001) identified four levels of construction as site activity, comprehensive project cycle, business of construction and human settlement creation. Site activities (the most common interpretation) lead to the actualisation of buildings while the project cycle includes feasibility, design, construction, operation, decommissioning, demolition/ deconstruction and disposal (Du Plessis, 2007). The process of construction consists of many sequential stages.

Construction phases are similar but dependent on size and scope. The timeframe for each phase varies as different activities are required in each phase. Table 1 categorises these as pre-construction, actual construction and post construction. Ahadzie et al. (2006), argues that the success of any construction project depends on these phases. Ankrah (2007) noted that the construction phase could determine a projects' success. It is important that construction professionals recognise the contribution of each phase in achieving results that are desired and sustainable.

Construction phases	Author (s)	Category
Briefing, Sketch plans, Working drawings, Site operations and Feedback	(Royal Institute of British Architects, 2013)	Pre-construction Actual construction Post construction
Planning/ Design, Schematic design, Design development, Construction documents, Bidding, and Construction	Infrastructure and Facilities Planning Section of Michigan State University, USA.	
Conception, Planning, Design, Tender, Construction, and Operations	(Ahadzie et al., 2006, Lim and Mohamed, 1999, Takim et al., 2003)	

Table 1: Construction phases

2.3. Sustainable construction

SC is generally used to describe pre-construction, construction, and post construction processes. Persson et al. (2008) listed these processes as preliminary design, detailed design, engineering, planning and procurement and the phases as operation, maintenance, refurbishment, reconstruction, demolition and recycling. Huovila and Koskela (1998) opined that SC is the building sector's response to the challenges of SD. Achieving sustainability in construction is challenging and SC remains a way industry meets present needs without compromises. SC addresses social, economic and environmental issues of buildings (Kibert, 2012) which suggests synergy with SD principles.

It is pertinent to note that resource efficiency, construction activities and construction phases are critical to SD. Ogunmakinde et al. (2016b) summarised SC as the effective management of all construction activities, resources and phases to create a safer built environment that meets present and future needs. Adopting SC involves integrating all the principles of SD into the construction activities of a project life-cycle, with every stakeholder being responsible for sustainable practices (Matar et al., 2008, Shen et al., 2008). Clients also play important roles by appointing professionals to practice SC (Abidin and Pasquire, 2007, Fadeyi et al., 2012). Construction professionals are responsible for providing sustainable buildings. Their understanding of SC informs their decisions which, in turn, affect the overall success (Abidin, 2010). Understanding decision-making processes and their relationships are pertinent when implementing SC (Rydin et al., 2007). Therefore, SC principles, construction phases and decisions by construction professionals alongside clients' requirements and government mechanisms are requisites of SD.

2.4. Sustainable construction principles

SC literature focuses on three main themes; resource efficiency, environmental protection, and waste minimisation. These encompass the overarching requirements of the construction industry in achieving SD. In 1994, the CIB articulated seven simplified principles of SC to include 'reduce resource consumption; reuse resources; use recyclables resources; protect nature; eliminate toxics; apply life-cycle costing; and focus on quality' (Kibert, 2012: 8). Hill and Bowen (1997) condensed these into social, economic, biophysical and technical principles. They are to be considered by construction professionals and other stakeholders throughout a project's life-cycle (Hill and Bowen, 1997, Matar et al., 2008). According to Kibert (2012), the principles inform stakeholders' decisions at each phase of design and construction. Al-Yami and Price (2006) emphasized the synergies and balances between the social, environmental, economic and political facets of construction in achieving SC. This depends on the interrelationship between SC principles, construction phases, and the resources required throughout a project's lifecycle (Kibert, 2012). Discovering how to integrate these areas is essential in solving built environment issues, highlighting the importance of SC to sustainable environments (Kibert, 1994).

3. METHODOLOGY

This study reviewed relevant academic literature relating to sustainable construction and construction phases. An electronic search of Google Scholar and other databases (including Scopus, Elsevier and Science direct) was conducted using keywords such as "construction phases", "sustainable construction", "green construction technology", "sustainable development", and "sustainable construction principles". These searches identified several publications (journals, conference papers and theses) and a selection was made based on their contents. Overall, the conceptual linkages between SC principles and construction phases were reviewed. The manner in which these links can be used to achieve SC were then developed as a framework and presented in Figure 1.

4. RELATIONSHIP BETWEEN CONSTRUCTION PHASES AND SUSTAINABLE CONSTRUCTION PRINCIPLES

SC principles have been identified in section 2.4 while construction phases include planning, development, design, construction, use and operation, maintenance, modification and deconstruction. Understanding their relationship is important when implementing SC principles. The application of SC principles at the corresponding phase(s) is core to SC. In view of this, construction phases have been categorised as pre-construction; actual construction and post construction.

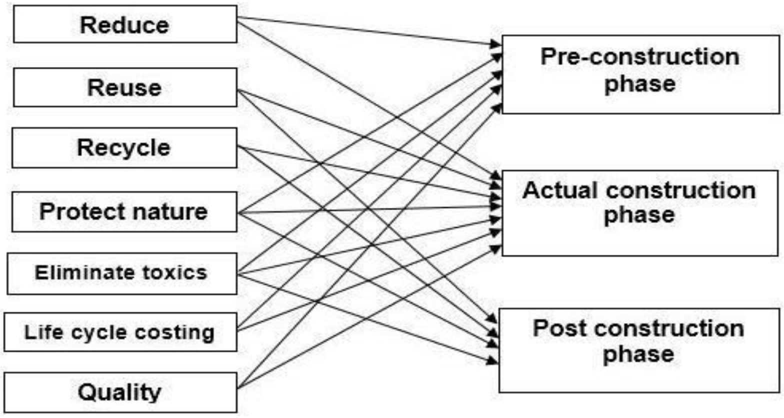

Figure 1: Framework for the relationship between SC principles and construction phases

The relationship between SC principles and construction phases is shown in Figure 1 and Table 2.

Reduce resource consumption (reduce): this principle addresses overconsumption, regarded as the main problem of sustainability (Kibert, 1994). It is aimed at decreasing resource and energy input in the consumption and production processes (Yong, 2007, Su et al., 2013). Several authors (Liu, 2012, Zhijun and Nailing, 2007, Su et al., 2013) emphasise material reduction, use of fewer resources and minimising the input of primary energy, particularly at the planning and design stages, to reduce waste and achieve efficient production and consumption. For SC, specification and use of durable materials with low maintenance requirements are vital at the pre-construction and actual construction stages.

Reuse resources (reuse): this is associated with processing and effective use of resources (Shi et al., 2006). Components used before are used again for the same purpose (European Union, 2008). Few processes are required for such reuse. Therefore, it has considerable environmental benefits including reduced energy consumption, fewer resources and less labour (Castellani et al., 2015). Reuse can revive local economies, reduce environmental impacts and create jobs (Castellani et al., 2015, Stahel, 2013). This should reduce dependency on virgin materials (Liu, 2012), lengthen a product's life span and minimise waste (Shi et al., 2006). Su et al. (2013) however stressed that frequent maintenance of reused products is necessary especially at the post-construction stage.

SC Principles	Construction Phase	Author(s) and year
Reduce	Pre-construction Actual construction	Yong (2007); Su et al. (2013); Shi et al. (2006); Liu (2012); Zhijun and Nailing (2007); Ghisellini et al. (2016); Damen (2012); European Union (2008).
Reuse	Actual construction Post construction	Shi et al. (2006); European Union (2008); Castellani et al. (2015); Stahel (2013); Liu (2012); Su et al. (2013).
Recycle	Actual construction Post construction	Duran et al. (2006); Moreno et al. (2014); European Union (2008); Van den Berg and Bakker (2015); Ghisellini et al. (2016); Murray et al. (2015); Shi et al. (2006); Su et al. (2013); Birat (2015);
Protect nature	Pre-construction Actual construction Post construction	Kibert (1994).
Eliminate toxics	Pre-construction Actual construction Post construction	Pacheco-Torgal and Jalali (2011); Liang and Ho (2007); Kibert (1994);
Life cycle costing	Pre-construction Actual construction	Fuller (2010); International Standard Organisation (2006); Sterner (2000); Ashworth and Hogg (2014); Clift (2003); Flanagan and Jewell (2008).
Quality	Pre-construction Actual construction	Arditi and Gunaydin (1997); Kibert (1994); Ashokkumar (2014).

Table 2: Relationship between SC principles and construction phases

Use recyclable resources (recycle): In the construction industry, recycling "takes place as long as construction and demolition wastes producers find it cheaper than landfilling and as long as users of construction aggregates find recycled aggregates cheaper and of similar quality than newly quarried aggregates" (Duran et al., 2006: 305). It requires considerable energy and does not include energy recovery (Moreno et al., 2014, European Union, 2008) and provides the last opportunity to recover the value of a material at the end of its life (Van den Berg and Bakker, 2015). This recovery operation (Ghisellini et al., 2016) may be applied to products or materials that cannot be reduced and reused. Murray et al. (2015) and Van den Berg and Bakker (2015) averred that recycling is mandatory and fundamental to achieving sustainability. It helps reduce the consumption of virgin materials (Shi et al., 2006, Su et al., 2013), and reduces wastes which include useable and potential materials (Birat, 2015). Thus materials could be recycled during actual construction or post construction based on the need and use of such material.

Protect nature: this principle is associated with protecting and preserving the natural environment and its ecological systems. Natural resources are extracted and manufactured into materials which are used for construction processes. These activities negatively affect the environment and ecosystems and can lead to resource depletion, pollution and destruction of flora and fauna. Protecting nature requires intelligent interventions (Kibert, 1994) and should be considered throughout the construction phases.

Eliminate toxics: use of non-toxic materials is as important as sustainable resource consumption is to SC (Pacheco-Torgal and Jalali, 2011). Air and water pollution in buildings results from materials releasing toxic fumes and contaminating water (Pacheco-Torgal and Jalali, 2011, Liang and Ho, 2007). Kibert (1994) emphasised the elimination of toxins in the interior and exterior of built environments as key to SD. Causes of toxicity include; use of some chemicals in paints, insecticides for wood, and asbestos. Liang and Ho (2007) studied the toxicity of building materials during a fire and found, for example, that polyethylene foam and polyurethane foam are highly toxic. They recommended that these materials be avoided due to their high toxicity and combustible nature. Liang and Ho (2007) noted a lack of awareness amongst design team members as one of the problems associated with the use of toxic materials. They recommended the specification of non-toxic materials during planning, design and construction stages. Therefore, elimination of toxins is appropriate at the pre-construction, construction and post construction stages.

Life cycle costing (LCC): this principle is aimed at determining the overall cost associated with a project over time including acquisition, installation, operation, maintenance, refurbishment and disposal costs (Fuller, 2010, International Standard Organisation, 2006). According to Sterner (2000), LCC is executed at the design phase to allow changes and comparison of different options. At the design phase, several decisions including material selection, cost parameters of the scheme, and functional elements are determined. Ashworth and Hogg (2014) argued that LCC is most effective during pre-construction. They asserted that design changes may easily be incorporated at the conceptual and preliminary design stages while Clift (2003) and Fuller (2010) advocated early consideration of LCC to obtain maximum benefit. However, it is important that precise information, estimates, and decisions are made at the design stage because of its impacts on projects LCC (Flanagan and Jewell, 2008). LCC ensures cost efficiency of projects by reducing cost overruns, material waste, and risks.

Quality: this principle is vital to the success of construction projects. It can be defined in terms of a building's aesthetic, functional and stability characteristics. Its purpose is to meet the requirements set by clients, design teams, constructors, and regulatory bodies (Arditi and Gunaydin, 1997). It recognises excellence in design and construction being an important element of SC (Kibert, 1994). Ashokkumar (2014) noted that quality project outcomes can be achieved at the design and construction phases. However, quality must be ensured throughout a project including its visible and non-visible portions. Poor quality construction may result in additional costs, delay, structural failure, injury, loss of resources, and even death. These reduce sustainability but good quality construction improves durability, economic viability, and resource efficiency whilst reducing maintenance.

5. CONCLUSION

This study has reviewed literature on SC and construction phases. It revealed seven SC principles including reduce, reuse, recycle, protect nature, eliminate toxics, lifecycle costing and quality. It also categorised construction phases into pre-construction, actual construction and post construction. The study developed a framework of the relationships between SC principles and construction phases. Although there is limited understanding of this relationship by construction professionals, the framework could improve their understanding and the implementation of SC principles. The paper also reveals the phase(s) where each principle could be applied for best effect. The relationship between SC principles and construction phases is mutually inclusive and critical in achieving SC. It is recommended that construction professionals first understand the context of sustainability, SC, SD and then familiarize themselves with the relationship between SC principles and construction phases. This will enhance their understanding and application of the principles in future construction projects.

ABSTRACT

Increasingly common building sustainability assessments include more and more the environmental, economic and socio-cultural performance in addition to the functional and technical ones. However, the influence of construction technologies and their technical building equipment as well as the way in which they vary depending on different energetic standards have not been described systematically in literature. For this reason, we evaluated the influence of these aspects and the impact on the environmental and economic performance of residential buildings.

The life cycle performance of 45 variants of a residential building was evaluated by applying the methodology of life cycle assessment (LCA) and life cycle costing (LCC) using quantitative assessment indicators proposed by the current European framework (EN 15643). The variants consist of four main construction types (brick, concrete, wood-chip concrete and prefab timber wood construction) in combination with different energetic standards (low to plus energy) and different technical building systems (pellets, heat pump, solar heating and photovoltaic). This led to a model that displays the existing technical variety in Europe.

The comprehensive results show a high optimization potential for the life cycle performance of buildings in general. However, the variation of the technical building equipment and energy standards lead to a higher improvement potential than the use of different construction techniques. Results also indicate that the use of a plus energy standard does not prove to be optimal in all cases.

Keywords: life-cycle assessment, embodied energy, building technologies

1. INTRODUCTION

The international energy agency (IEA) and the European Commission (EC) aim to achieve an 80% reduction of global emissions by 2050. In order to mitigate energy consumption in the building sector, several regulations and directives have been implemented on a European and country level. On a European level, specific measures to reduce energy demand have been introduced with the Energy Performance of Building Directive (EPBD) in 2002 and its recast in 2010. This EPBD, the Energy Efficiency Directive (EED) and the Renewable Energy Directive (RED) are designed as a package of measures that create the conditions for significant, long term improvements in the energy performance of buildings.

There is a clear trend of investing in the design of more energy-efficient buildings, and paying more attention to the embodied energy and related embodied impacts of such building concepts, taking the whole life cycle into consideration (e.g. the activities of IEX Annex 57). In the current literature on buildings LCA (e.g. [4], [5], [6]), a cross building related assessment of different energy standards and the influence of technical and/ or different construction materials can hardly be found [7], [8], [9]. The recently published European framework for the sustainability assessment provides a clear guideline on how to assess and report the environmental impacts in a transparent way. According to this framework, the building is to be assessed based on a functional and technical equivalent and the environmental assessment is to be based on the methods of Life Cycle Assessment (LCA,).

There is also no systematic description of the construction technologies and technical building equipment influence on the variation of different energetic standards (e.g. low energy, nearly zero energy or plus energy). For this reason, we evaluated the influence of these aspects and the impact on the environmental and economic performance in the case of a single-family house, which served as case study.

2. METHODOLOGY

The aim of the paper is to analyze the economic and environmental performance of the case study using Life Cycle Assessment (LCA) and Life Cycle Costing (LCC). These methods are used to quantify the difference in design options by using different construction materials, different energy systems and different energy standards. The whole variety of different combinations shows 45 scenarios, which were evaluated on their life cycle performance. The assessed scenarios consist of four main construction types (brick, concrete, wood-chip concrete and prefabricated timber wood construction) in combination with different energetic standards (low to plus energy) as well as different technical building systems (pellets, heat pump, solar heating and photovoltaic). The LCA and LCC analyses show which parts of the building are responsible for the main environmental and economic impacts.

2.1 Description of the case study

Different design options were created using a real single family house project [12], [13]. The case study is a two-storey building with a gross floor area of 220sqm (ground floor and first floor). This building design is the basis for all different scenarios. Within all the scenarios, the external dimensions and the cellar were kept the same- which is limited by the Austrian building code and therefore needs to stay the same. For these design targets, different construction materials and different insulation materials were used to model and calculate the energy demands according to Austrian standards. The energy demand of the different buildings has been calculated using certified energy performance software. For brick and wood chip concrete constructions, two scenarios, which do not need insulation materials to fulfil the low-energy standard, were additionally assessed. Table 1 shows the materials that were used to model the different building scenarios.

		Insulation type with symbol			
Construction material	Symb.	EPS	Rock wool insulation	Wood-fibre insulation	Without additional insulation
Bricks	B	E			1
Concrete	C	E			
Mantle block (wood-concrete)	M	E		W	1
Wood solid	Ws		R		
Wood-frame construction	Wf		R		

Table 21: Construction materials and insulation materials with codes

As a first step, different energy standards were defined from a heating demand perspective based on ÖNORM H 5055, according to which the different design options should be a "low-energy" building with a heating demand of about 40 [kWh/m²a] (code L and S) and a "passive-house" building with a heating demand of about 10 [kWh/m²a] (code P and E - see Table 2). These various technical systems for the different energy standards are shown in Table 2.

	Low-energy standard			Passive-house standard		
	40 [kWh/m²a] HWB_{ref}			10 [kWh/m²a] HWB_{ref}

Table 22: Technical systems

The heat pump, pellet boiler, solar thermal panels, single item wood furnace and photovoltaic (PV) in the scenarios were evaluated for the different energy standards (see Table 2). Additionally, a "sun-house" concept was analyzed. In this concept, solar thermal collectors provide at least 50 % of the heating energy needed.

The different construction and insulation materials were then combined with the technical systems in a scenarios matrix to a total scenario set of 45 variants. For the presentation of the results, codes for the different scenarios are used to identify the different measures. The first digit represents the construction material (code B, C, M, Ws, Wf; see Table 1), the second the energy standard (code L, S, P, E; see Table 2), the third the insulation type (code E, R, W, 1; see Table 1); and the fourth the technical system (code H, P, Si; see Table 2).

2.2 Environmental performance

The environmental performance calculations of the different scenarios are based on EN 15978 and ISO 14040. The scenarios have been assessed by the use of LCA for the whole life cycle, pictured in Table 3. The materials for the different construction techniques were quantified and modelled for modules A1 – A3. For the reference study period (RSP) of 100 years, the different replacement scenarios (module B4) were assessed based on an expert survey. Furthermore, the end of life stage (C3 – C4) was modelled on the basis of the expert survey (disposal, incineration, recycling, etc.) for the various materials.

The results from the energy simulation were used to quantify the operational impacts (B6) of the related energy use. For the life cycle impact assessment (LCIA), the ecoinvent database v2.2 and EPD (2013) model were used.

2.3 Economic performance

The economic performance is based on a detailed calculation of the initial construction costs according to ÖNORM B 1801-1 and 1801-2 [17], [18] for the same life cycle stages as pictured in Table 3, system boundaries, as used for the calculation of the environmental performance, but with a RSP of 50 years. Table 6 provides an overview of the relevant calculation parameters based on the Austrian sustainable building council (ÖGNI), which refers to the German DGNB/ BNB.

Electricity price	0,17 €/kWh
Pellets price	0,25 €/kg
Wood price	0,16 €/kg
Discount rate	5,5 %
Inflation rate	2,0 %
Escalation rate	4,0 %

Table 24: Calculation parameters for LCC

3 RESULTS AND DISCUSSION

3.1 Environmental performance

The environmental performance results are shown in Figure 2. Due to space constraints, only the GWP results are presented. Results for the non-renewable portion of Cumulative Energy Demand can be found in [20]. The different life cycle stages (A1-A3, B4, B6 and C3-4) are highlighted in different colors, to illustrate the difference between the phases. Negative environmental impacts are only pictured for the scenarios in plus-energy standard (Code x-E-x-x) due to the energy production onsite. The results also show the significant difference between the embodied and operational impacts in the different scenarios.

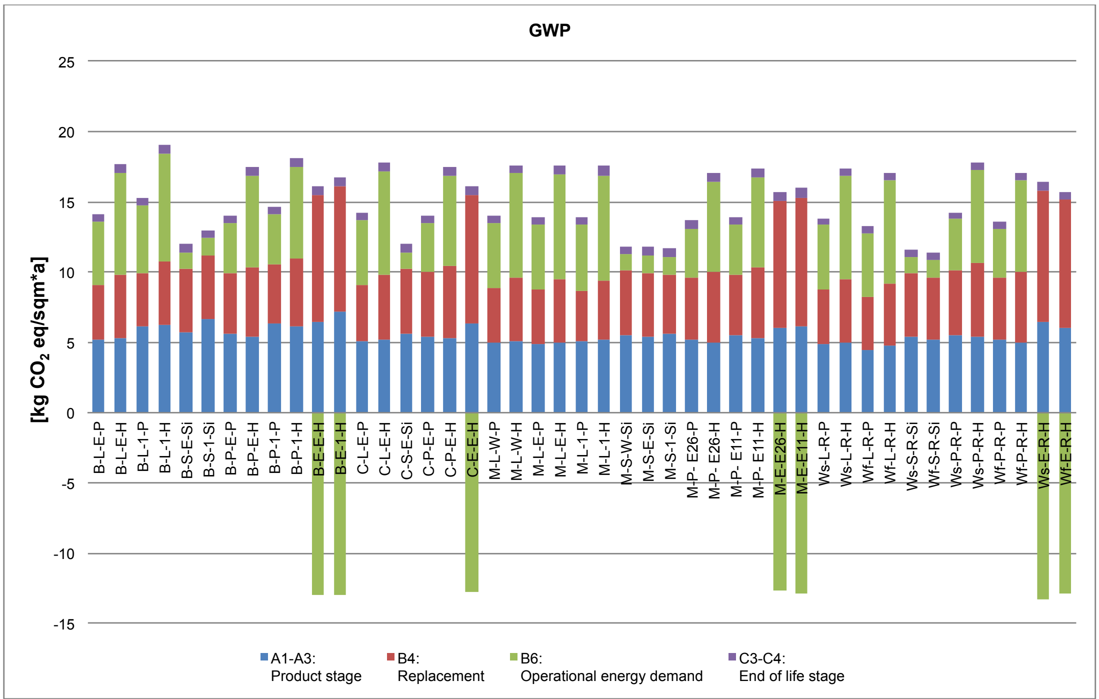

Figure 1: Global warming potential (kg CO2eq/m2a)

3.2 Technical system

The environmental performance results are quite spread out among the different energy systems (Figure 2). For these systems, the operational energy use (B6) dominates the environmental impacts and differs according to the chosen energy carrier. However, the assessed indicators do not suggest a clear preference for a single technical system, as some environmental indicators run counter. Particularly for the heat pump systems, ODP intensity is caused by the cooling refrigerants.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

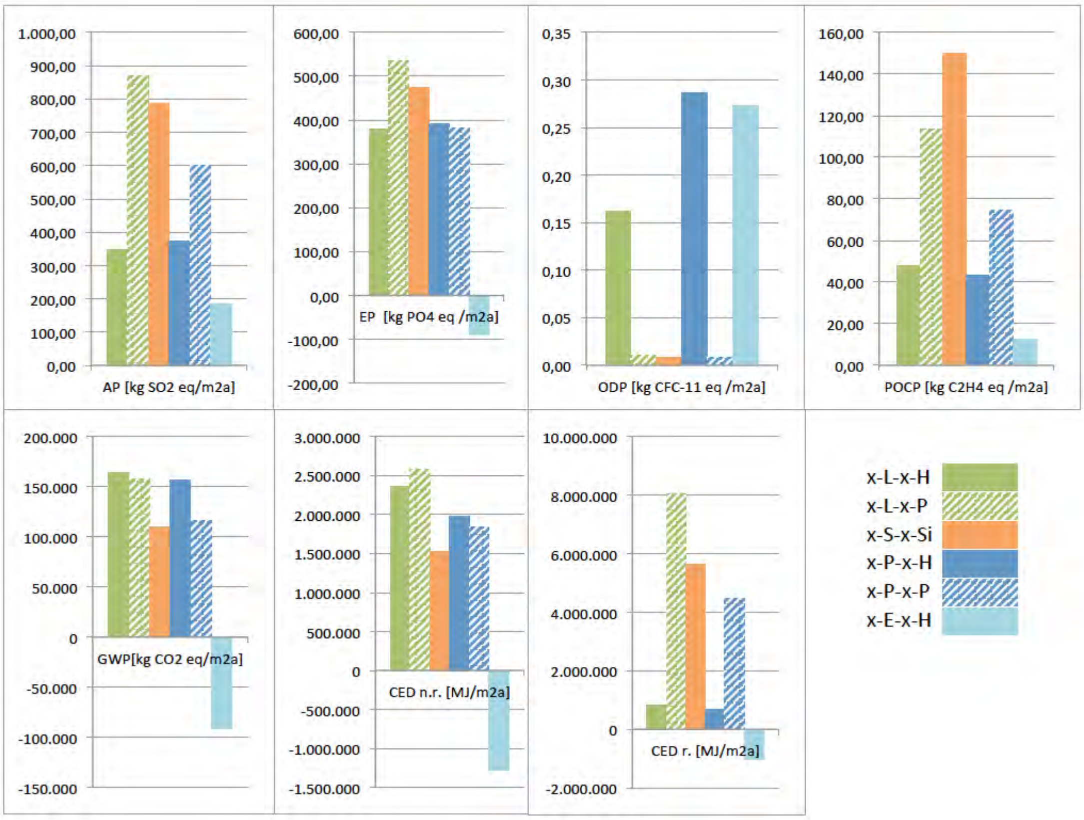

Figure 2: Results for the technical system over the whole life cycle

3.3 Economic performance

The economic performance results based on the LCC calculations are presented in Figure 3, which shows the total net present value per sqm. gross floor area.

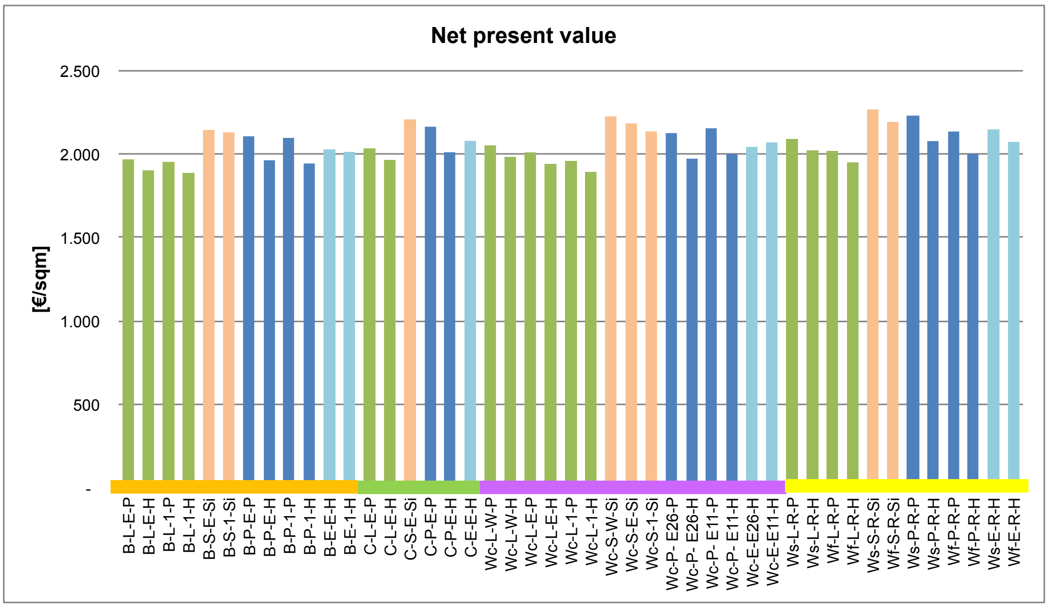

Figure 3: Net present value

Life cycle costs of the different construction techniques and technical systems are rather similar. However, the results also indicate that construction costs are very dominant when calculated based on a high discount rate (i.e. 5.5%) combined with low energy costs. Thus, according to these results, the additional investment and related replacement costs for better energy standards and energy performance hardly pays off over a life time of 50 years.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4 CONCLUSION

The comprehensive results show a high optimization potential for the life cycle performance of buildings in general. The findings indicate that the choice of different construction technologies and building materials does not lead to as high an improvement potential as the variation of the technical building equipment and the energy standard. However, in every case the results show an increasing importance of material related embodied impacts. Due to the current trend towards more and more energy efficient buildings, the role of materials within environmental assessments will increase dramatically and should therefore be researched more precisely.

In the plus energy buildings case, authors recommend evaluating the aspect of primary energy factors and LCA allocation rules for delivered and exported energy in detail, as the environmental performance results can change with different scenarios.

Regarding the sensitivity analysis of the environmental and economic performance results, authors do not agree with the functional unit defined as gross floor area, which is standardized for economic calculations. Results differ with highly insulated buildings due to the increase in wall thickness, so a more adequate functional unit is currently under assessment.

ACKNOWLEDGMENTS

The authors would like to thank the scientific committee of SBE16 Hamburg for awarding the contribution with an Outstanding paper award, which served as a basis for this contribution. Due to the page limit, we were only able to present a small excerpt of the work, which is based on the research project “Ökovergleiche”. Last but not least, the authors would like to thank all partners for their efforts.

A Peer-To-Peer Reviewing Framework for Selecting Construction Material Suppliers Using the Integration of Building Information Modelling and Web-Map Service

CHEN Po-han[a], NGUYEN Thanh-chuong[b]

[a] *National Taiwan University, Taiwan, pohanchen@ntu.edu.tw*
[b] *National Taiwan University, Taiwan, d00521034@ntu.edu.tw*

ABSTRACT

Selecting construction material suppliers is an important task in a construction project. The location of material is crucial to the supplier selection process because the transportation distance from the material extraction or manufacturing place to the project site significantly affect both transportation cost and material delivery time. Therefore, an accurate estimation of material's transportation distance is important. To support the supplier selection process, this paper presents a peer-to-peer reviewing framework for selecting construction material suppliers using the integration model of Building Information Modelling (BIM) and Web-Map Services (WMS). Using Autodesk Revit API and Google Maps API as the development tools, this research converts the integration model and the framework into a BIM-integrated plugin in Autodesk Revit. The plugins can help automate calculations, and provide a detailed plan of material cost and transportation. From that, the project manager can select a material supplier with the best price and reduce the risk of transportation delay.

Keywords: construction materials, suppliers selection, BIM, Web-Map Service

1. INTRODUCTION

1.1 The linear process of selecting construction materials and material suppliers

Traditionally, a construction material is often selected in the design stage by the designer. In later phases, the material is approved by the project manager or owner. The material supplier is selected in the bidding stage. A material supply plan is then provided by the chosen supplier. The process of material and supplier selection is linear, which can be illustrated in the following figure.

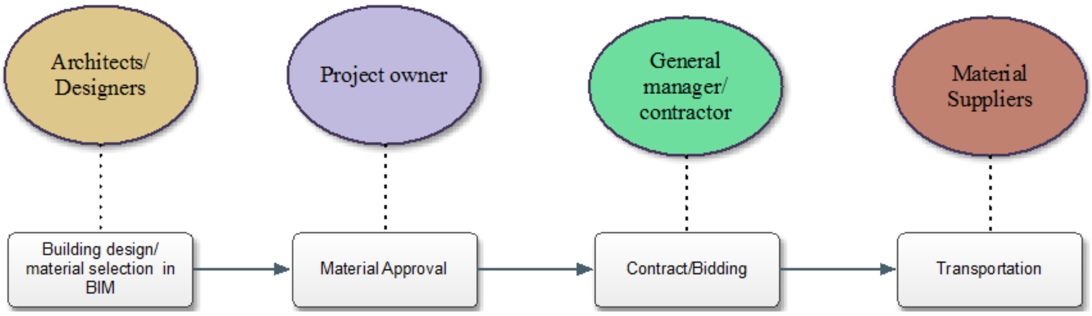

Figure 1: Traditional material and supplier selection process

There are some problems in this linear process. First, in the design stage, the designer and project owner choose the construction materials with less information of the materials availability, cost, and transportation plan when the suppliers are not selected. It means that if a material is not available, or its cost is higher than expected, the material selection process has to be restarted. Second, if the material transportation plan from the supplier doesn't match with one from the project manager, there is a possibility of project delays or conflicts.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

1.2 The importance of material location to project's cost and schedule

Construction materials contribute for a significant part of project cost: it is estimated that the cost of materials procurement can account for 60 - 65% percent total cost of a construction project. Therefore, the selection of material suppliers is important to the success of a project. Poor planning in material production and supply operations could result in problems in the project cost, schedule, and quality management.

There are many factors that affect the decision of selecting a material supplier. Some of the most important factors are the material cost and the plan of material supply chain. Ahmadian stated that transportation cost is considered as the dominant decision variable in the transportation planning of construction material. It is stated that transportation cost accounts for 10 - 20% total budget of a project. Material's location is the key factor to calculate transportation cost. The longer the distance from material to project site is, the higher cost, time and human works have to be spent for transporting the material. Therefore, material location is important in the decision of selecting the supplier.

Material location also affects the planning of material supply. Delay in construction material transportation, especially those in critical or near-critical activities can have significant impacts on the completion of a project. The longer transportation is, the longer time is spent on the transportation. However, the delivery time not only depends on the travel distance, it also depends on other factors such as transportation modes (vehicle availability and capacity, travel speed etc.). When the volume of material is tremendous, the management of material delivery schedule becomes more complicated and uncertain.

Construction material's location also affects the environmental impacts of the building. Construction transportation activities generate a large amount of or CO_2 emission. Those activities can have negative health and environmental consequences, generating water, air and noise pollutions. The use of regional materials, which are closed to project site, can reduce transportation activities and the associated pollution. It can also reduce vehicles activities, which put less stress on infrastructure development, and contribute to healthier local economy, as well as showcases the uses of the resources and specialties of the local region.

The importance of material location is reflected in some green building standards, such as in credit MRc5 of the LEED (Leadership in Energy and Environmental Design) standard by the U.S. Green Buildings council.

In conclusion, material transportation distance plays an important role in material cost and supply plan. Therefore, an accurate estimation of calculating the transportation distance is critical to the selection of material supplier.

1.3 Problems in calculating material transportation distance

Distance from project site to material location is the key to calculate transportation cost and time. However, there has been no effective method for this calculation. The traditional method is by personal experiences or calculating in paper maps, which takes time and very accurate. Another method by Wu to estimate the distance between material extraction place and project site by using Zip code. This method has low accuracy, because Zip code is used to present a region, not a particular place.

Another method of measuring the travel distance is by calculating the direct straight-line distance between two places, such as in the study of Irizarry (2013). The distance between point A and point B is calculated by the following formula:

$$\sigma_{AB} = \sqrt{(x_A - x_B)^2 + (y_A - y_B)^2}$$

However, this method of distance calculation has low level of accuracy. In the real situation the route between the suppliers and project sites are usually not straight. Therefore, the straight distance from supplier to project site are usually shorter than the real travel distance of transportation.

Therefore, to determining the travel route is crucial in material procurement planning. In other words, it is one important variable of the material supplier selection process. Finding a different approach in specifying transport distance is essential.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

1.4 Web-Map services

Web-Map Services (WMS) are the process of requesting map images from a map server with GIS databases through the web interface. Compared to traditional maps, WMS has many advantages: free and interactive (i.e., being able to zoom, pan, turn on/off layers, etc.) with easy access through a web browser. Using maps delivered by GIS system, WMS such as Google Maps can provide a route planner under "get directions". By analysing the geographic conditions and transportation mode, WMS can help specify the best available travel route for driving, public transit or walking….

2. LITERATURE REVIEW

Supplier selection is an interested topic to researchers and scholars. Safa et al. developed an integrated construction materials management (ICMM) model to support the supplier selection process. Ahmadian et al. identified several main factors that affect the transportation of material including: travelling distance, weight, dimension, mode of transportation, and terms of delivery. Among those factors, travelling distance and mode of transportation are two factors from the material suppliers that needed to be considered. Inadequate transportation capacity is also a cause of delay in material delivery.

3. RESEARCH OBJECTIVES

The study aims to develop a peer-to-peer reviewing framework for selecting construction material suppliers using the integration of Building Information Modelling and Web-map Service. The framework is based on the concept of Integrated Project Delivery. The reviewing framework using the plugins can help project owner and manager to choose the best supplier based on the following criteria:

- Total material cost (including based cost, transportation cost etc)
- Transportation plans
- Green Building compliance (LEED's regional material credit MRc5.2) of the material.

With the plugins, a detail and transparent plan of material cost and transportation is provided. From that, it can reduce the risk of redo and uncertainty in the material and supplier selection process.

4. METHODOLOGY

A framework of peer-to-peer reviewing framework for selecting construction material suppliers using the integration of BIM and WMS is developed. In the study, Microsoft C# programming language is used to develop the integration model of BIM-WMS as a Revit plugin to support the reviewing framework.

The research use Revit API (Application Programming Interface) to develop the model as a BIM plugin. For WMS services, Google API is selected as a development tool.

4.1 Integrated Material Selection (IMS) approach to support peer-to-peer reviewing framework

The BIM-WMS integrated tool is used in the design stage, it can help enable the process called "Integrated Material Selection" (IMP). Integrated Material Selection is based on the principle of Integrated Project Delivery (IPD). It requires the participations of designers, project owners, project managers, contractors, material suppliers and other stake holders from early stages of the project. The concept of integrated material selection using BIM-WMS model is illustrated in the following figure:

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

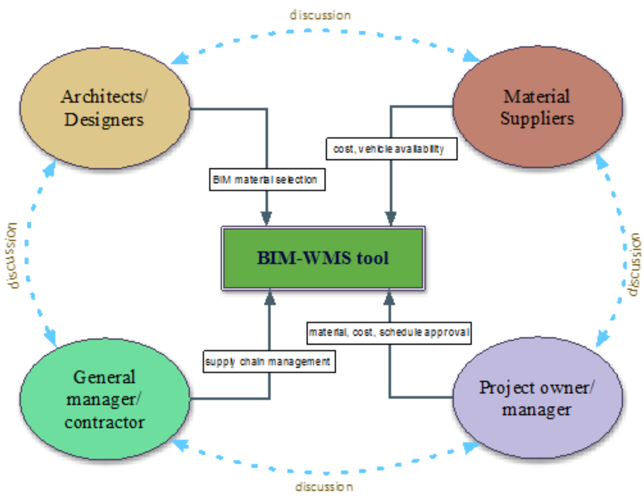

Figure 2: Integrated material selection approach using BIM-WMS tool

In contrast with the linear process of traditional material and supplier selection, in this study, all parties can use BIM-WMS tool to calculate the selection of material is done in early design stage.

4.2 BIM-WMS integration UI

Using Revit API and Google Maps API, the Autodesk Revit plugin of BIM-WMS integration is developed to support the framework.

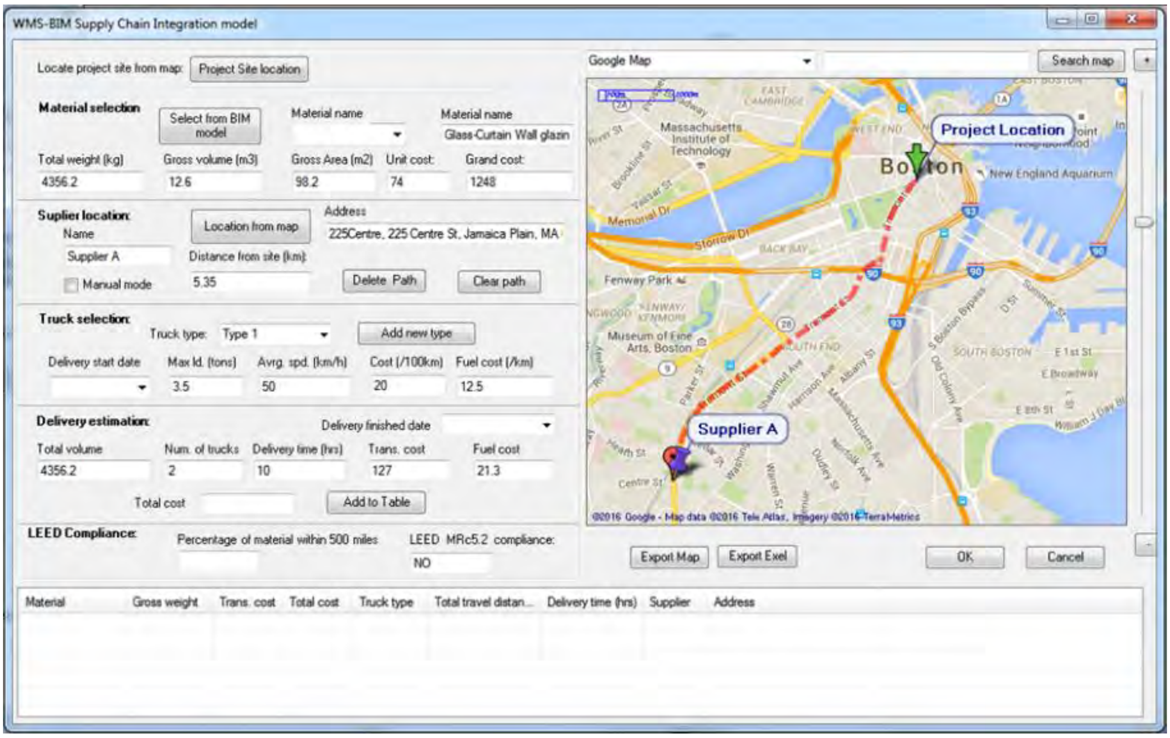

Figure 3: The Revit plugins user interface

By using Revit API to access BIM's material information and using Google Maps API to calculate travel distance from site to supplier's location, the plugins can help:

- Calculate material schedule (weight, volume etc.)
- Calculate material total cost (including based cost, transportation cost, fuel cost)
- Estimate transportation plan (delivery time, vehicle requirements etc…)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4.3 The peer-to-peer reviewing framework

The peer-to-peer reviewing framework can be illustrated in the following figure:

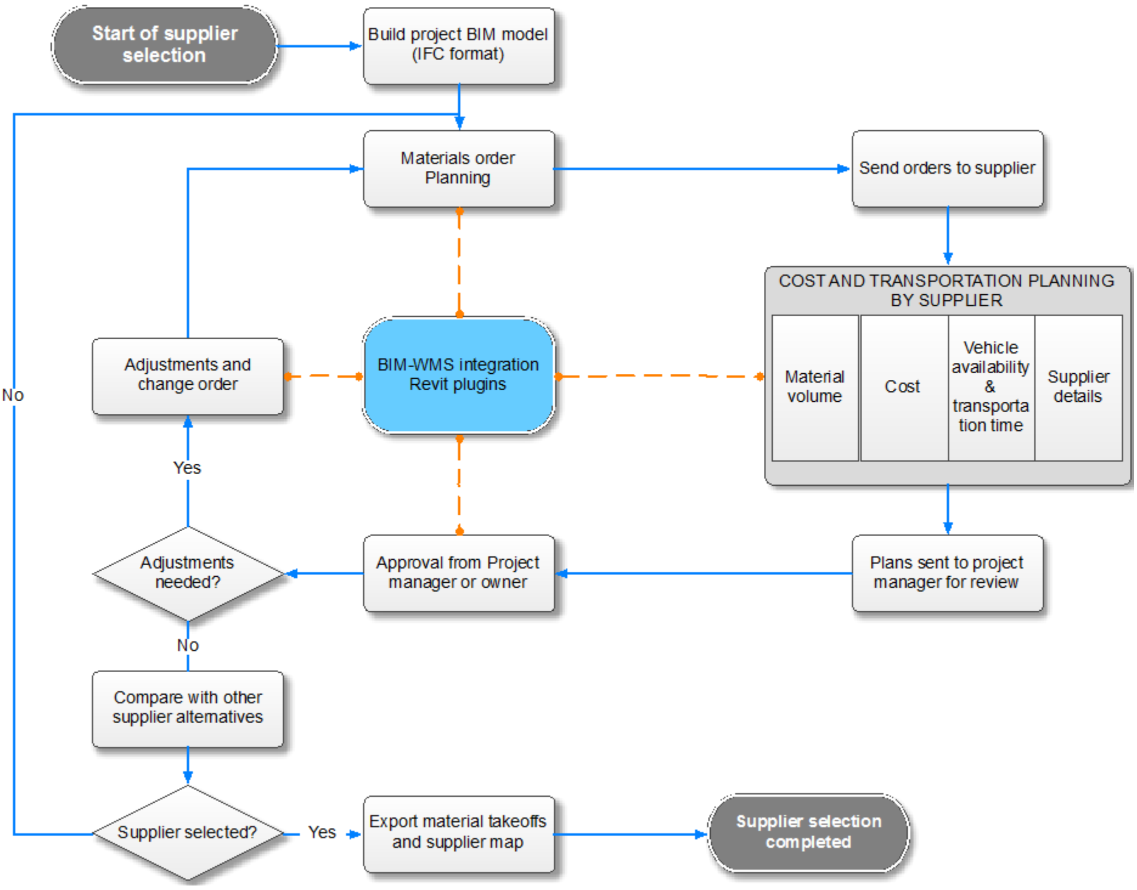

Figure 4: Framework of peer-to-peer reviewing for supplier selection process using the integration of BIM-WMS

From design stage, all stake holders can use the BIM-WMS plugin as a tool to estimate material cost and transportation plan:

- Architects build the BIM models with BIM tools and with considerations of aspects such as aesthetics, compatibility with other components etc.
- Project owners/managers use BIM-WMS tool to compare different options of materials, and approve on material type, cost and schedule.
- Various material suppliers provide different options of materials, with information about the location, availability, based cost, transportation of materials. This information can be used in BIM-WMS tool to help project designers, managers and contractors to select the most reasonable material for their project.
- General managers/ contractors can check information provided in BIM-WMS tool to verify about cost and supply chain management plan.

5. CONCLUSION

Selecting material suppliers are critical to the success of a construction project. The peer-to-peer reviewing framework can help reduce the risk of redo, cost overrun and delay in the construction project.

Because selecting material supplier is a complicated process which involves many factors, the proposed framework and system only address some of the most critical problems, such as the estimation of material transportation cost and time, and the integrated collaboration in the material selection process. In the supplier selection process, the proposed system should be used in combination with other techniques and methods to get the best results.

ABSTRACT

Sustainable development has been the focus of all major industries in the world, especially in the construction industry. As one of the sustainable construction modes, housing industrialization (HI) is now absorbing a growing number of attentions that lead the industry to go green. However, the implementation of HI in China is far from satisfactory due to its low economic efficiency. This paper attempts to improve the HI supply chain from a new perspective-transaction costs (TCs). First, it provides an objective understanding of status quo of HI in particular in China. Then, the study outlines the basis of TCs theories and supply chain management theory, compiling literature review of the application of TCs and supply chain management in other fields to states the feasibility of their application in HI area. A theoretical framework is developed to explain the relationships and overlaps among these three areas. Analysis of the state of research in application of TCs in HI supply chain management is expected to help optimized the governance structure of HI supply chain.

Keywords: housing industrialization (HI), supply chain management, transaction costs (TCs)

1. INTRODUCTION

Nowadays, the sustainable development has been the theme of the world. Building is a resource and labour intensive industry, where takes up 24% of raw materials consumption, and accounting for around 40% of primary energy consumption worldwide (Dong and Ng, 2015, IEA, 2014). It is vital for these aspects to be reformed in order to save energy and resources. There has been much work done in the past to look for optimal solutions to remedy these issues. One of such propositions is to apply industrialization in housing construction. Housing industrialization (HI) is a concept originated from manufacturing industry. As Egan (1998) highlighted, the construction sector necessitates a manufacturing process to be developed within its production which can lead to high performance. With the inspiration of the Egan report, the profile of HI has been increased and its implementation has been significantly expanded both in academia and industry. Many terminologies are associated with HI in the global construction industry. It is often referred to as: 'prefabrication', 'preassembly', 'modularization', and 'offsite fabrication' in the US (Song et al., 2005, Egan, 1998); 'off-site production' in the UK (Pan et al., 2012); 'off-site manufacturing' in Australia (Blismas and Wakefield, 2009); 'prefabrication' in Hong Kong (Jaillon, 2009) and Singapore (Park et al., 2011) and 'industrialized building' in Malaysia (Kamar et al., 2009). In this paper, HI is specifically defined as a business strategy that transforms the traditional construction process into a manufacturing and assembly process in order to reduce cost, time, and improve the quality of the product/ service. This is achieved by engaging people, embracing new technologies, and translating clients' needs into building requirements through new contractual working relationships across the whole supply chain (Nadim and Goulding, 2011).

Over last several decades, HI has been developed as one of the innovative approaches to overcome the traditional site-based construction drawbacks and being widely applied around the world. Today, Japan is the world's largest practitioner of industrialized construction with some companies producing over 70,000 manufactured homes a year (Arif et al., 2012). European countries, such as the UK, Ireland and Scotland, are experiencing a significant boom in industrialized houses. For instance, over 30% of the new homes built today in the UK are prefabricated; in Ireland and Scotland, industrialization rate is projected to rise to nearly 70% in a few years (Blismas and Wakefield, 2009). Leveraging lean management strategies, several Swedish construction companies start to transform their conventional site-based construction workflow into a lean-embedded off-site production and on-site assembly

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

workflow. Through these measures, the workforce, project design and delivery are envisioned to be benefited from continuous effectiveness and efficiency improvement of HI (Jansson, 2010).

With sustainable development becoming a profound global challenge, exploration has also been made in China to seek for sustainable development goals. The China' National Development and Reform Commission (NDRC), in collaboration with the China's Ministry of Housing and Urban-Rural Development (MHUD) published its Green Building Action Program (2013) with implementation of HI being one of the prominent themes (MOHURD, 2013). This program aims to reform the industrial practices through promoting the application of HI in major cities in China. Driven by the market and policy, HI is increasingly emphasized in China. Nevertheless, it was noted that China had not gained enough momentum to push HI forward due to an incomplete supply chain casing loads of environmental and social problems. HI develops rapid in recent years in China, few research has tried to improve the economic performance from a holistic view. To achieve high benefits and high efficiency within an innovative industry, it is essential that economic aspects are addressed throughout the whole supply chain (Blair et al., 2005). The theory of supply chain management, which takes a systemic view of the production activities of autonomous production units (subcontractors, suppliers in construction, etc.), can help seek for a holistic solution to improve HI (Mao et al., 2013).

Economic efficiency and supply chain management have, in recent years, become two of the most important performance-related issues within the construction industry. This study is an attempt to develop a combined framework, aiming to understand the current state of HI implementation and improve the economic performance of HI supply chain from a Transaction costs (TCs) perspective.

2. LITERATURE REVIEW

2.1 Transaction costs application in HI

The concept of TCs has a broad range of definitions and empirical evidences (Demsetz, 1968, Barzel, 1985, Allen, 1991, North, 1990). TCs refer generally to costs of trade beyond the materials cost of the product, such as the costs of searching for projects, estimating, project partners, negotiation, monitoring, regulatory approval and dealing with any deviations from contract conditions (Antinori and Sathaye, 2007, Li et al., 2015). In other words, TCs are costs beyond the direct costs (market price times volume) but incurred in making a trade (Antinori and Sathaye, 2007). In the theory of TCs, there are three key constructs that reflect the fundamental representation of it: assets specificity, uncertainty, and governance mechanism (Grover and Malhotra, 2003). In this study, we specifically refer to TCs in terms of risk, time delay, uncertainty, and information searching, setting up costs as well as learning costs. Compared with conventional construction, new procurement processes and extra tasks involved in HI require the support of new rules and institutions, and in turn, cause TCs, which are often invisible.

TCs has been around for nearly seven decades, and it has seen a wide application in various disciplines (Mundaca and Neij, 2006, Grover and Malhotra, 2003). Since HI is essentially a kind of innovative construction mode that combing the process of conventional construction into manufacturing, this study will first summary the TCs-relevant researches in manufacture and construction industry to learn experience (see Table 1).

Research fields	Key findings	Reference
Manufacture industry	Asset specificity is related to lower in-firm transaction costs.	Walker and Poppo (1991)
	Supplier-specific investments are negatively related to perceived buyer dependence. Transaction costs are positively related to collaboration propensity.	Sriram et al. (1992)
	Outsourcing alter the configuration and boundary of an organization and change the economic contribution that an organization makes to the economy.	McCarthy and Anagnostou (2004)
	Vertical integration by unconnected firms correlates with better economy performance.	Signorini et al. (2015)
Construction industry	Factors that affect TCs in construction projects are identified.	Qian (2012) Li et al. (2015)
	TCs to the public sector and the winning bidder vary between countries and sectors, and they are significantly higher in small projects.	Dudkin and Välilä (2005)
	Identifying factors that affect partnership performance using a TC framework.	Jobin (2008)
	Transaction costs in transport PPPs depend on the procurement mechanism used in each case.	Soliño and Gago de Santos (2010)

Table 1: Key studies applying TCs theory in manufacture and construction industry

From the perspective of TCs economics, well-designed institutional structures may lower TCs and provide net social benefits (Levine et al., 1995). Williamson (1985) believed that when the economic organizations have selected the appropriate governance structures, the transaction cost will low down; otherwise they need to pay for higher transaction fee, or even lead to transaction failure. The basic concepts of TCs theory applied to the manufacture industry broadly (Table 1) shows a high correlation with vertical integration in the organization, which is the core concept of supply chain management. Besides, some scholars believe that considerable opportunities within the manufacture industry for evaluating supply chain management issues from the TCs perspective (Grover and Malhotra, 2003). Therefore, TCs can also be applied as a new perspective to unearth the hidden rules in the HI industry to update its supply chain.

2.2 Supply chain management in the HI industry

Supply chain management has been introduced during the 1990s, which provides a clear statement that it is a question of a whole chain of organizations (Fredrik Olsson, 2000). According to Cooper et al. (1997), this study defines the supply chain management of HI crossing organizational borders as: Supply chain management of HI is the integration of business processes from original suppliers through end users that provides products, services and information that add value for housing customers.

The theory of supply chain management has been extensively researched and applied in the manufacturing industry. However, the application of it is comparatively new in construction field. Since 1990s, there has been an emerging number of people who have been interested in applying supply chain management theory in project organization. They characterized the deficiencies of it and proposed solutions in order to improve the coordination of the often many subcontractors and suppliers in the construction chain (Segerstedt and Olofsson, 2010). The benefits of supply chain in construction and barriers in its implementation, has been very well documented (Ahmed et al., 2002, Tiwari et al., 2014). It has been found that construction industrial chain management offers new approaches to reduce the costs and increase the reliability and the speed of facility construction.

It has been brought out that although supply chain management for an individual organization is an emerging field of research in the construction management discipline, less attention has been devoted to investigate the nature of the HI supply chains and their organizational economic performance (London and Kenley, 2001).

According to the concept of supply chain defined by Christopher (1999), this paper specifically defines HI supply chain as a set of organizations producing activities. It associated with the flow and transformation of HI from raw materials stage, through upstream and downstream linkages, producing value in the form of products and services in the hands of residents. Here we built a normalized supply chain of HI (Figure 1), which looks across the entire supply chain, rather than just at the next entity or level. It consists of numerous stakeholders, and there are some basic components of HI supply chain: (1) Nodes: they are all stakeholders in the HI industry, such as developer, contractor, supplier and government department. (2) Chain: each chain links several stakeholders and represents transaction behaviour among them. The chain in this study contains three kinds of flow: materials, information and capital. During operation process, this supply chain works in a loop state. The materials recycle plant plays as an important role to make this chain restart, which significantly improve the sustainability of HI.

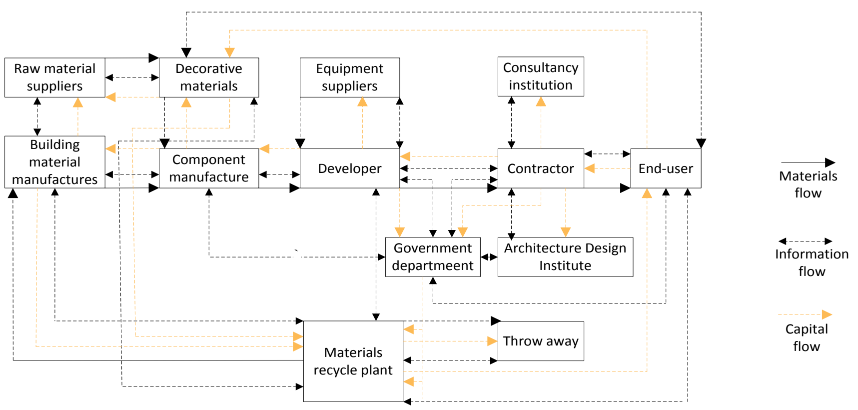

Figure 1: The normalised supply chain of HI (by the authors)

2.3 The framework to improve the HI supply chain using TCs

Under the theme of this programme, there are three major theories connected as the research basis, housing industrialization, transaction costs and supply chain management. The research question of this program is in the intersection among the three fields. Although this is quite a vacant field that is worth working on, studies on the supply chain of HI project from TCs perspective is still very limited. To fill this gap, we can first build the theoretical framework (Figure 2) using the overlap area between each two theories as the starting point.

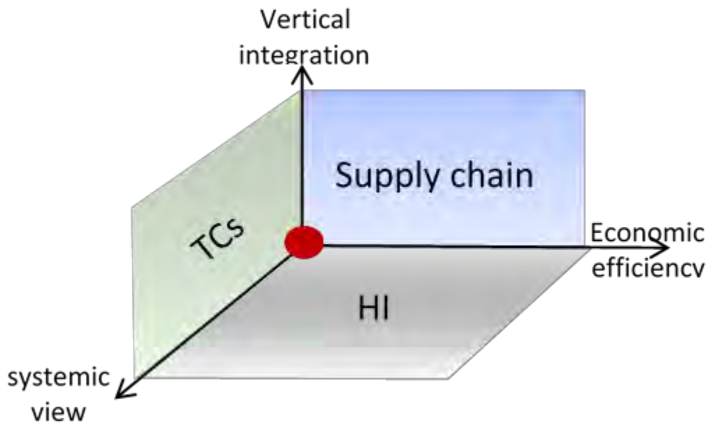

Figure 2: A theoretical framework combining HI, TCs and supply chain management

3. DISCUSSIONS

From Figure 2, we could find that there are common topics existing as the link between each two areas:

HI & supply chain management

HI is a research area that attracted loads of attention recent years. In the transforming period of China's construction industry from conventional construction to industrialization, a systemic view is needed. Supply chain, a vertical integration of constructors, end-users, the government and the market, which can provide a more objective view to achieve global optimization of HI (Mao et al., 2013).

TCs & supply chain management

Transaction costs are important because they affect the organization of economic activity or "vertical integration". Vertical integration, viewed as a continuum, is exactly the core of supply chain management (Hobbs, 1996). According to the TCs theory, one of the determinants of vertical integration is the nature and level of TCs. A change in the TCs arising from the exchange of a product may lead to a change in the management of that supply chain (Hobbs J E, 1996). Therefore, there is a correlation between TCs and supply chain management (Grover and Malhotra, 2003). Nevertheless, the combined application of TCs and supply chain in HI even the whole construction industry is very limited.

HI & TCs

Profits are the key motivation to maintain the operation of market, HI is no exception. Most researchers in this area prefer to study on the cost control to help enterprises boost profits in HI implementation. However, the actual cost of a construction project consists not only the production cost. There are also hidden costs, transaction costs(TCs), are often obscure, but they may affect the final decisions (Qian et al., 2015). The transaction paradigm has indeed received considerable attention by academics and has been applied to a variety of construction-related topics including project organization and governance. However, in the field of HI, only a few have given the attention to the importance in regards to the economic efficiency of HI projects. Most studies fail to systematically measure the TCs in the HI supply chain. Such knowledge gap is significant and it relates to the challenges faced by Chinese enterprises in producing more buildings, delivering higher quality, providing better affordability and improved economic efficiency.

4. CONCLUSIONS

TCs is chose in this paper as a new angle to understand and improve the supply chain of HI. It aims to summarize the literature of supply chain management in HI area from TCs perspective to propose a framework. The constructs of TCs and the feasibility of its application in both manufacture and construction industry is introduced. TCs is emphasised to evaluate HI supply chain integration mechanisms for the efficiency of the project economic performance. The results are expected to build a framework for scholars and managers who are working in HI field to rethink about the direction of this industry. This study also goes further exploring the key links where redundant TCs occurred on HI supply chain, which provides a guidance of HI supply chain optimization. The need to meet customers' needs and create value while organizing HI supply chain in high level will provide challenges and opportunities, so issues discussed here will remain on the agenda.

A Research Proposal to Improve the Environmental Performance of the Building Industry by Increasing the Innovation Activity of Small Contractors

Karen Jane MANLEY[a], Timothy ROSE[b]

[a] *Queensland University of Technology, Australia, k.manley@qut.edu.au*
[b] *Queensland University of Technology, Australia, tm.rose@qut.edu.au*

ABSTRACT

The World Building Council for Sustainable Development has singled out the building industry as an urgent problem where there are 'large and attractive opportunities' to reduce energy use at a lower cost and higher return than other sectors, given an appropriate investment in innovation (WBCSD, 2009, 1). Focus on the building industry is critical as it is the single largest contributor to climate change (UNEP, 2014, 16). It is the biggest consumer of energy amongst end-use sectors, and generates more greenhouse gas emissions than the transport sector (IPCC, 2014b, 47, IPCC, 2014a, 21-23).

A shift to more sustainable building is seen as an essential part of urban renewal focused on reduced environmental impacts. Such a shift will require significant innovation, yet the building industry is renowned as an innovation laggard, rated second-last amongst all 17 Australian industries (ABS 8158.0, 2014). An exciting opportunity for fast-tracking innovation leading to sustainable buildings has been discovered by the research team. Through this study, they will divert attention given to large firms and iconic projects, where change is ponderously slow and impacts are marginal, to small contractors where change can be adopted much more rapidly and where major impacts are much more likely. The role of small contractors is significant. In fact, 98.5% of all Australian contractors are small, employing less than 20 people; yet they generate nearly half of the industry's output and employ 62% of workers in the industry (ABS 8155.0, 2015, ABS 8165.0, 2015).

Small contractors provide the most efficient lever for improving the sustainability of buildings. Small contractors are ubiquitous specialist intermediaries in the building industry, linking product manufacturers and distributors with building owners and users. From an innovation system's perspective, the critical role of small contractors is clear; they hold a strategically important position within the industry and represent a focal point in the innovation system where the benefits of improved innovation activity to support environmental objectives would have strong multiplier effects. This role has not previously been examined in any depth, particularly with regard to environmental sustainability. The paper outlines a robust research proposal to address this gap in the literature.

Keywords: innovation, building contractors, environmental sustainability

1. INTRODUCTION

This paper presents a research proposal to investigate the research question 'How can the innovation activity of small contractors be increased to improve the environmental performance of the building industry?' This conceptual paper contributes to the global frontier of knowledge by (1) Presenting new theory optimised for investigation of built environment sustainability problems, addressing a long-standing gap in the literature concerning the operationalisation of the socio-technical systems approach to understanding sustainability transitions; and (2) Presenting a robust method of undertaking valid and reliable research in response to the aim of improving the environmental performance of the building industry, by increasing the innovation activity of small contractors. This aim has considerable significance given recent statistics concerning the built environment.

Research conducted by the United Nations Environment Program shows 'over a third of all CO_2 emissions come from building construction and operations, over a third of all energy and material resources is used to build and operate buildings, and over a third of total waste results from construction and demolition activities' (UNEP, 2011, 352). On the bright side, recent advances in know-how, technologies and policies are creating excellent opportunities for addressing unsustainable practices (IPCC, 2014b, 102). By marshalling the latest advances in innovative practices, this proposal offers a cost-effective approach for addressing globally escalating resource scarcity due to unsustainable use of the ecosystem. The study adopts the highly authoritative OECD definition of innovation as the implementation of a new or significantly improved product or process, including changes to marketing and organisational methods (2005). Innovation is widely considered to be a key driver of environmental improvement (UNEP, 2011).

This project will be a world-first in-depth study of the role of small contractors in facilitating environmental innovation in the building industry. The project employs Australia as a case study, where the role of small contractors is similar to that in other developed countries. In Australia, small contractors contribute nearly twice as much value in the building industry as either medium or large contractors (ABS 8155.0, 2015). Also, the building industry has the largest number of small firms amongst all Australian industries, who contribute the second-highest value to the Australian economy. The challenge is for small contractors in the building industry to deliver this prodigious output sustainably, requiring a significant investment in innovative practices.

Although small contractors represent a significant opportunity to address unsustainable building, they need policy assistance to animate and maximise their contribution. This is because small contractors have imperfect information about the climate challenge, the contribution they could make, and the benefits of innovation. The outputs provided by this proposed study are intended to address this information shortfall through a vigorous education campaign run with industry associations.

The key to unlocking the potential of small contractors lies in the need to develop new theory that captures emerging best practice in value-creation. The proposed project's practical benefits are completely predicated on the scientific significance of the theory work. A new Synthesised Theory of Service-Dominant Innovation will be developed by the research team to shape educational interventions that quantify the return on environmental innovation to small contractors, and (2) Map successful pathways towards achieving sustainable outcomes. This Synthesised Theory provides the vehicle to significantly improve innovation performance of the building industry and respond to Australia's environmental problems.

Using the new Synthesised Theory, the proposed study will pursue the following detailed objectives and outcomes to achieve its aim of improving the environmental performance of the building industry through increasing the innovation activity of small contractors:

Objective	Outcome
1. To advance social science by developing a Synthesised Theory of Service-Dominant Innovation for the building industry	*Advanced Social Science*
2. To improve the efficacy of Service-Dominant Logic by developing measurable items for new institutional and belief constructs	*Advanced Service Dominant Logic*
3. To refine and validate Synthesised Theory by conducting 20 case studies of firm-level environmental innovation by small contractors in the building industry	*Synthesised Theory*
4. To test the predictive power of the new Synthesised Theory by (a) Developing 10 Demonstration Booklets quantifying the firm-level benefits of sustainable building innovation, and showing the paths to success, and (b) Developing new Design Tools that encourage organisational change to improve innovation performance	*Demonstration Booklets and Design Tools*
5. To advance academic knowledge by publishing articles in leading journals such as *Research Policy*, conferences such as the Academy of Management meeting, and industry magazines such as *Business Review Weekly*	*Academic and Industry Publications*
6. To maximise the benefit of the Demonstration Booklets and Design Tools by vigorously promoting results through Capstone Symposia in the three most populated Australian states (NSW, Victoria, Queensland), organised with leading industry associations, such as the Master Builders Association	*Capstone Symposia*
7. To enhance knowledge diffusion with the building industry by producing content for industry magazines and advisories for industry associations.	*Magazine Content and Association Advisories*

Table 1: Objectives and outcomes

The study will address the: conceptual problem of improving the scope of services theory; empirical problem of reducing the impact of the building industry on climate change; management problem of the best way of driving environmental innovation; and policy problem of encouraging energy efficient building production.

2. LITERATURE REVIEW

Existing theoretical approaches to innovation have focused on the manufacturing industry. Unfortunately, learnings from the manufacturing sector do not readily apply to service-dominated contexts (Ordanini and Parasuraman, 2010), such as the building industry. The building industry is defined here as equivalent to Building Construction and Construction Services in Division E of the Australian and New Zealand Standard Industrial Classification (ANZSIC). These two subdivisions interpret the building industry by types of contractors, comprising main contractors and trade contractors providing general and specialised building services respectively, including: building, mechanical, air-conditioning, heating, fire, security, plumbing, electrical, carpentry, glazing, earthmoving, concreting, bricklaying, roofing, tiling, plastering, painting and decorating.

The issue of whether the building industry provides a service or a product is hotly debated in the construction management literature. The majority view is that contractors manage the production process – making them service providers – with material and equipment suppliers providing products (De Valence, 2011). The proposed research adopts this view, meaning a theory that addresses innovation in services is required to maximise the value of the empirical work. Emerging literature in the business management discipline focuses on the growing importance of service-dominant innovation and value co-creation within networked systems, where customers demand total solutions (Lusch et al., 2010). This service-dominant view suits the complexity of the building industry where production is service-intensive, project-based and delivered by multiple organisations.

Increasing emphasis on services in modern economies has given rise to Service-Dominant Logic (SDL) (Lusch et al., 2010) which is a conceptual framework that positions services as central to all innovation processes. SDL is gaining popularity because traditional approaches to understanding service innovation were based on product innovation theory, giving misleading results (Ordanini and Parasuraman, 2010). Product innovation theory rests on formalised R&D processes, which are often absent in service innovation, replaced by 'softer' creative processes. Existing literature on service innovation also fails to account for the complexities of the building industry context, because it is more focused on other industries such as tourism, health or telecommunications. The research team will develop a new Synthesised Theory of Service-Dominant Innovation drawing in-part on SDL, by combining fresh insights from business management and construction management disciplines to provide a new in-depth value-creation framework. The new Synthesised Theory aims to capture the drivers of 'grassroots' innovation which is increasingly argued to typify successful construction innovation (Loosemore, 2015). Consistent with SDL thinking, grassroots innovation relies on a capable motivated workforce capitalising on their day-to-day interactions with other firms and thinking across projects.

The proposed study will be the first time that the environmental innovation potential of small contractors has been comprehensively examined in the Australian building industry. The closest existing literature is that by Manley (2008) on which the current study builds. This previous work provides an introduction to small firm innovation in the building industry, providing a solid platform for the current study's specific focus on environmental innovation by small contractors, given their strategic importance in addressing climate change.

3. THEORETICAL FRAMEWORK

It is argued here that the best approach to framing the current study of environmental innovation by small contractors is a Synthesised Theory of Service-Dominant Innovation for the building industry, because it captures emerging approaches to value-creation in service industries, at the same time exploring the belief drivers of firm-level capabilities within a given institutional context. A new Synthesised Theory will be developed, drawing in part on existing SDL as developed by Lusch and Vargo (2010). At present SDL is not a developed theory, rather a set of axioms about economic exchanges based on 'intangible resources, co-creation of value and relationships'. The proposed study will advance SDL; developing it into an innovation theory suitable for the built environment. SDL has never before been applied to the building industry. The closest existing literature comprises three studies that apply SDL to similar contexts comprising multiple industries, consulting firms and public transport authorities (Wikstrom et al., 2009, Rahikka et al., 2011, Peters et al., 2012, Hartmann et al., 2014) respectively. None of these studies adopt the strategic focus of the current proposal on environmental innovation by small contractors.

A recent study by Ordanini and Parasuraman (2010) develops an innovation theory based on SDL capabilities and tests it in the hotel industry. This new work is seminal in that it moves away from product-based innovation theories, and service innovation theories derived from them. The research by Ordanini and Parasuraman validated key constructs associated with SDL, which focus on a range of specialised capabilities. A more recent conceptual paper by Lusch and Vargo suggests the value of explicitly incorporating institutions within SDL (2016). Institutions are defined as established practices and are highly context specific. The proposed study will develop new Synthesised Theory that extends the validated capability constructs developed by Ordanini and Parasuraman; updating them to account for the role of beliefs in their formation, the passage of time and different industry contexts. The principal scientific work lies in developing new institutional and belief constructs and measured items. Learnings derived from these two new constructs are critical to the study's development of a high-impact educational campaign.

The proposed study abandons a traditional view of firm performance to embrace a multi-level theory and the deeper insights provided (Lichtenthaler, 2011). Hence, SDL is a firm-level construct, institutions are a system-level construct and beliefs are an individual-level construct. The current paper thus develops the new theory shown in Figure 1.

The model shows that firm-level innovation outcomes are driven by firm capabilities and institutional context, with managers' beliefs being a key influence on firm capabilities. The model is consistent with pervious simple models that realistically, but more crudely show innovation as the result of factors internal and external to the firm (Manley, 2008). It is also consistent with the resource-based view (RBV) of the firm which focuses on capabilities; open innovation literature which focuses on collaborative arrangements with other organisations and knowledge integration; and the democratising innovation literature which focuses on customer orientation.

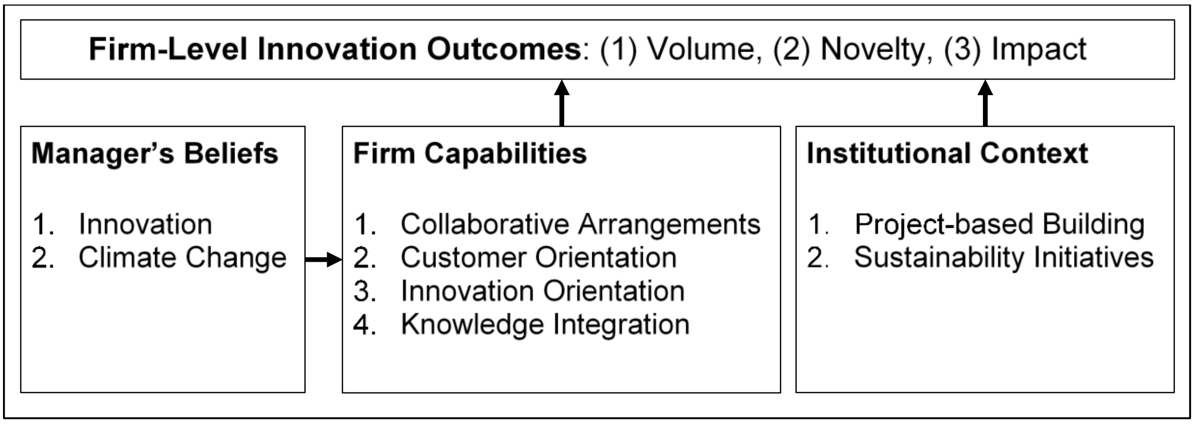

Figure 1: Synthesised Theory of Service-Dominant Innovation
(Based on Ordanini and Parasuraman (2010), Vargo and Lusch (2016) and Lichtenthaler (2011))

6. APPROACH AND METHODOLOGY

The proposed project adopts a rigorous qualitative research design featuring theoretical development, case studies, action research, and Capstone Symposia over a three years program.

Stage 1	Theoretical Development	3 months
Stage 2	Empirical Validation by Case Studies: 1. case study logistics – select and establish contact with 20 firms 2. case study performance – theory-led interviews and firm visits 3. cross case analysis – using directed content analysis 4. theory refinement – reflection on the match between theory and empirics 5. write and publish academic papers in leading journals	13 months 2 months 5 months 2 month 2 month 2 months
Stage 3	Testing Synthesised Theory through Action Research Activity A: Demonstration Booklets 1. assist 10 firms with quantifying innovation benefits 2. write/diffuse booklets based on innovation benefits and theory-led drivers 3. diffuse booklets Activity B: Design Tool Intervention 1. tailor generic Design Tools to make them applicable to context 2. select appropriate tools and adapt to 10 firms 3. implement tool in each firm, document process and assess impact Write and publish academic papers in leading journals	 6 months 2 months 3 months 1 month 8 months PhD student 3 months 5 months 3 months
Stage 4	Knowledge Diffusion within the Building Industry: 1. undertake Capstone Symposia in Sydney, Melbourne and Brisbane 2. write and publish content for industry magazines 3. write advisories for industry associations	3 months

Table 2: Research design and timeline

Stage 1: Theoretical development

Objective: To extend the specification of SDL into a multi-level innovation theory

Methods: Theoretical extension is based on the addition of two new constructs - institutions and beliefs - as drivers of firm-level service innovation, alongside the previously validated construct of capabilities and firm-level innovation outcomes. The extension work accounts for institutions around project-based building and sustainability initiatives. The extension work also accounts for beliefs about innovation and climate change. All of the extension work will be based on the procedure pioneered by Chen and Manley (2014). A well-structured and comprehensive literature search will be undertaken to identify relevant and validated measured items, using directed content analysis, resulting in two parsimonious and comprehensive sets of items.

Outcomes: A Synthesised Theory of Service-Dominant Innovation that advances the frontiers of knowledge in social science and better frames empirical work in similar contexts compared to existing theories.

Stage 2: Empirical validation by case studies

Objective: To advance the knowledge base for innovation in service-dominant contexts

Methods: The theoretical model developed by the project will be empirically tested using a case study approach. The literature indicates the value of qualitative research, suggesting that between 4 and 10 case studies are optimal for theory building and testing (Eisenhardt, 1989). The project will conduct two sub-projects: Sub-project A is 'learning from success' and Sub-project B is 'learning from failure'. Both studies focus on the relationships of small contractors with the rest of the supply chain. 'Success' and 'failure' is determined by whether the innovation met the firm's expectations or not. In each sub-project, 10 case studies will be conducted, falling within the recommended range. The population for both sub-projects will comprise small contractors across Australia, who have been engaged in environmental innovation of any type, comprising product, process, marketing or organisational, at any level of novelty, comprising new to the firm, market or world (OECD, 2005, 47 & 57). The innovation must have taken place in the past three years to aid recall.

The sample will be drawn using databases maintained by industry associations and related building award programs. Early investigation has allowed pre-identification of most of the required cases. The evidence for each case study will be triangulated across: (1) A face-to-face semi-structured interview, framed by the synthesis theory developed by the project, with a senior manager in the firm; (2) Observational data gathered by firm visit/technical tour; (3) Documents provided by the firms. In both sub-projects, learning is facilitated by the synthesis model constructs and underlying measurement items which will provide a subtle, fine-grained and insightful view of innovation drivers. Twenty case studies will be conducted. This high number of cases is required given the acknowledged complexities of project-based production and innovation processes, together with the focus on learning from failure as well as success.

Outcomes: A new and validated theory of firm-level service-dominant innovation that is novel, complete, parsimonious and applicable to the building industry, supported by 20 case studies.

Stage 3: Testing synthesised theory through action research

Objective: To test the value of the new theory in directing efforts to quantify the benefits of environmental innovation by successful small contractors and effectively help unsuccessful small contractors to implement tools to improve their innovation performance.

Methods: The Action Research is organised around two distinct activities. Activity A involves the project team using the newly developed Synthesised Theory to frame further investigation of the 10 successful innovators from Sub-project A, to help them quantify the benefits of their environmental innovations, and then publish their stories. Each story will include appropriate packaging and reporting of the theory-led innovation drivers uncovered in Stage 2. These stories will be published in Demonstration Booklets following the format of the influential Construction Excellence program in the UK (Egan, 1998). One thousand professionally developed and printed copies of the 10 booklets will be produced. The booklets will be vigorously promoted to other small contractors to encourage their innovation efforts. Diffusion of booklets will be by the research team through the Capstone Symposia (Stage 4), by industry associations through seminars, and by small contractors through their networks.

Activity B involves the project team using the newly developed Synthesised Theory to guide development of new Design Tools to be used in further investigation of the 10 unsuccessful innovators in Sub-project B. The project team will help the firms to implement the new Design Tools which aim to create organisational change that improves innovation activity, its environmental impact and the return to the firm. The new tools will be based on recent ideas emerging from Columbia Business School. The study takes these marketing ideas and develops new tools such as journey mapping, 360 empathy, co-creation, ethnographic interviews, storyboarding, concept anchors and elicitation posters (Liedtka et al., 2014), that are applicable to an innovation context in the building industry.

Outcomes: (1) Refinement of the new Synthesised Theory to improve its predictive power (2) Development and validation of new Design Tools to create organisational change (3) 10 easy-to-read and highly publicised Demonstration Booklets quantifying the benefits of environmental innovation by small contractors in the building industry, including theory-led insights about latent innovation drivers; (4) 10 documented firm-level interventions to improve innovation performance, framed by new Design Tools.

Stage 4: Knowledge diffusion within the building industry

Objective: To vigorously promote the firm-level benefits of environmental innovation by small contractors

Methods: Based on 10 Demonstration Booklets and 10 Design Tool interventions, three national Capstone Symposia will encourage environmental innovation. The symposia will be organised with the main industry associations in three states, with whom the research team have good relationships, such as the Housing Industry Association and the Master Builders Association. Presentations from the research team, industry associations and small contractors will be given. Plenty of time will be allowed for discussion with the audience of 100+ small contractors in each state. This discussion will be recorded, transcribed and analysed.

Magazine content and association advisories will also be written and distributed in Stage 4, in part based on the symposia learnings, which will also feed into new research directions. The advisories are particularly important to knowledge diffusion, as is the industry association support of this proposal, where these two factors promise widespread impact. The research team and industry association leaders are passionate about running an intense and wide-reaching educational campaign based on magazine content and association advisories, together with the three national symposia, 10,000 Demonstration Booklets and on-going industry association seminars.

Outcomes: A 25% increase in environmental innovation by Australian small contractors following the educational campaign, which the research team will test on a sample provided by Master Builders Association members in Queensland, with a pre and post survey.

7. CONCLUSIONS

This conceptual paper is based on a desk-top study of secondary sources to justify and design a proposed program of research. The contributions of the paper comprise (1) An assessment of the role of small contractors in environmental innovation, (2) A new theoretical approach to understanding the latent drivers of best practice and (3) A field work-method to understand the beliefs and capabilities that support leading small contractors.

The Synthesised Theory of Service-Dominant Innovation developed here is both useful for the proposed study and has more general applicability as a more nuanced approach to assessing the beliefs and capability of leading firms engaged in constructing a more sustainable built environment.

The current paper makes a theoretical contribution to the understanding of firm performance in an important empirical setting. Future research by the author will involve execution of the proposed study. A limitation of the paper is that the effectiveness of the proposed theory and methods is yet to be tested empirically.

Mongolia's First Cooperative Transformation Attempt on Built Environment through Greening Kindergarten Building

Nergui DORJ[a]

[a] *Mongolia Green Building Council, Mongolia, dnergui@m-icp.com*

ABSTRACT

The Parliament of Mongolia adopted the Green Development Policy in 2014 followed by the adoption of Mongolia's Long-term sustainable development concept (2016-2030) in the beginning of 2016. One of fundamental focus of these policies is an adoption of green building principles into practice in the local context.

Despite several efforts mainly initiated by international agencies and private sector in the past, no cooperative attempts as such have been successfully demonstrated and scaled-up to date.

At the request of the Government of Mongolia (GOM) and with the support of the Global Green Growth Institute (GGGI), Mongolia Green Building Council (MGBC) has carried out a range of policy and technical research and preparatory work to develop the business case and demonstration design for Mongolia's first green public kindergarten.

The main specifics of this project were: (i) close cooperation among different stakeholders, including education users; (ii) preparation of comprehensive package for demonstration and replication of green kindergarten buildings in Mongolia; (iii) use as much as possible locally produced innovative green products and technologies; (iv) undertake cost and benefit analysis of green kindergarten using CAPEX, NPV and other methodologies; (v) preparation of recommendation on potential financing mechanisms to fund the demonstration and replication of green kindergartens; (vi) Preparation of design and technical guidelines for green kindergarten for the Government use.

It was concluded that building a green kindergarten has a positive net social benefits, including greener built environment which can have a greater community impact towards creation of sustainable community through increased energy and heat efficiency, lower CO2 emission, hereby healthier living environment and saving natural resources, even though its initial investment can be higher than that of traditional non-green kindergarten buildings.

1. INTRODUCTION

1.1 Background

Mongolia is a country in North-East Asia with extreme continental climate. Its economy is largely dependent on the mining sector and seasonal agriculture. 40 percent of the total population of Mongolia lives in the capital city - Ulaanbaatar and 67 percent of Mongolia's population is under 35. The demand for pre-school education is higher than its supply and therefore it is considered as one of government policy priorities to build more pre-school facilities to ensure all children have an access to quality pre-school education. In addition, existing pre-school facilities had been built without taking account child health impacts of educational buildings, any environmental sustainability and resource efficiency matters.

Mongolia as one of United Nations member states, committed to green and sustainable development. This commitment has been manifested in numerous policy documents, including "Green Development Policy of Mongolia" and "Long-Term Sustainable Development Concept – 2030" both adopted by the Parliament in 2014 and 2016 respectively. The greening buildings through introduction of green building rating system is one of policy mechanisms to be used for achieving the strategic objective #1 of Mongolia's Green development policy.

1.2 Objective

Against this background, the Ministry of Environment and Tourism (MET) and the Global Green Growth Institute (GGGI) jointly initiated to implement a project on Design and Implementation Planning of Green Kindergarten in Mongolia which could become a model educational facility that are child and environmentally friendly. The team of

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

newly established professional association - Mongolia Green Building Council and the Buildings Technology LLC (BT), the engineering company has been selected to undertake this task of designing first ever in Mongolia green kindergarten building with 125 child capacity in the district where mainly low income families reside.

The main purpose of this paper is to describe the main points and findings of the assessment and design of green kindergarten building through collaborative efforts involving all relevant stakeholders and making a contribution in creation of sustainable built environment in the country.

2 COOPERATION AMONG RELEVANT STAKEHOLDERS

The output of this project is a result of collaborative efforts of MGBC, BT, and Government working group on greening educational facilities, GGGI, representatives of professional associations, building sector and education users. The cooperation among relevant stakeholders began from the very beginning in November 2015 with numerous consultative and capacity building events where the main objective of the project introduced and voices of stakeholders on the need for greening educational facilities and technology options available were heard. In total of such 15 consultative and capacity building events organized by the project team during first 6 months of this project which resulted in final selection of green kindergarten technology options.

3 BUILDING TECHNOLOGY OPTIONS

The following main principles have been used to defining and deciding on green kindergarten building technology solutions:

- Resource efficiency and technology availability locally
- Technology friendliness from both educations users and environment perspectives
- Cost effectiveness
- Overall green building principles, including indoor air quality, comfort ability, use of renewable energy, safety and requirements for outdoor environment
- Encourage local innovation

A comparative analysis has been carried out by a group of architects, construction engineers and other relevant building and infrastructure experts for existing ordinary kindergarten technologies with suggested greener technologies within the framework of final technology design. It shall be noted that the existing building code of Mongolia is used as a benchmark for this analysis.

Based on this analytical work, the design and engineering team prepared the set of building technologies: (1) reinforced concrete frame; (2) floor heating system – TABS; (3) mechanical (AIS-1,2,3 ASS-1-5) and ordinary ventilation system (OSS-1-11); (5) solar system with 32 kW peak capacity; (v) decentralized grey and waste water treatment system; (6) addressable and scalable fire alarm system with monitoring cameras, internal communication, warning and timing system; (7) automated control system with weather station, CO2 sensor and room temperature and humidity sensors.

Regarding architectural planning, below building materials considered most suitable for this kindergarten:

	Building units	Ordinary		Green	
		Materials	Remarks	Materials	Remarks
!	Wall	Light block /360mm/	Brick structure /380mm/ feasible	Euro-block, main block /200mm/	Recyclable and environmentally friendly
2	Insulation	Styrofoam /100mm/	Negative impact on the environment and public health	Mongolia made sheep-wool insulation /100mm/	Has no negative impacts on public health and recyclable
3	External facade	Screen, plaster and paint	Annual maintenance is required, operational cost is high	Air layer /150mm/	Recyclable, long-lasting, annual maintenance is not required, minimal operational cost
4	Window	Ordinary vacuum windows	High level of heat loss	Triple layers of glasses, insulated aluminum frame and low exposure external glass	Minimal heat loss
5	Floor	Ordinary wooden floor covered by carpets	Heat loss from the floor	Heated floor	Comfortable for children and warm from the floor

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

6	Internal wall covering	Oil-based paint	Negative public health impact	1.1 meters tall lower wall cushion and emulsion paint for the upper sections	No negative on children's health, safe and minimal smell
7	Roof	Ordinary metal or black paper		Green roof	Decrease of CO2 emission, energy saving

Table 1: Comparison of building materials for ordinary and green kindergartens
Source: MGBC and BT, 2016 Final design, technology options and financing

The quality of building insulation is most important as Mongolia's weather is extreme continental with -25 to over -40 winter temperature. For this reason, an innovative insulation material shown in two images below produced in Mongolia by Mongolian companies using sheep wool was selected for insulation.

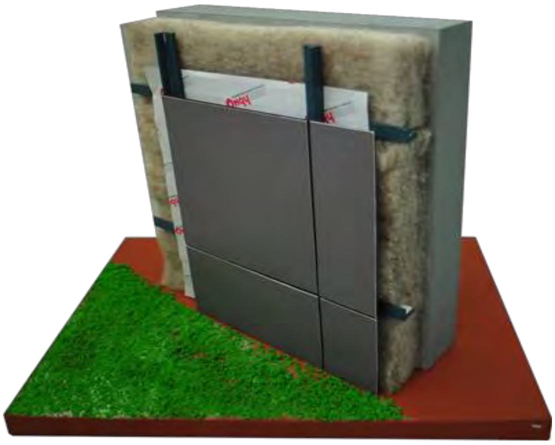

Image 1: Sheep wool insulation for wall

Image 2: Wool insulation for kids convenience
Source: "People in Need", 2014

4. COST-BENEFIT ANALYSIS

After all technologies and building materials selected, the cost-benefit analysis (CBA) for green kindergarten project has been undertaken to find out whether this project is viable and sound investment or not in Mongolia condition from net social benefits perspective. The Capital expenditure (CAPEX) and Net present value (NPV) methods used for the analysis and for doing so the following assumptions have been made:

- The building lifetime is 40 years as instructed by the Ministry of Education, Culture and Science (MECS)
- Social discount rate is 3%
- Inflation rate is 1% annually

The CBA expert-team suggested the below results of their findings:

- Initial investment cost for green kindergarten is 26% higher than the initial investment cost of ordinary kindergarten
- Operational and maintenance costs are expected to be twice lower compared with ordinary kindergarten buildings
- Initial investment payback period is 14 years
- NPV is 1.192 Billion Mongolian tugrugs (MNT) which is equivalent of approximately 596.000USD
- Heating expenses is expected to be 50% lower than that for ordinary kindergarten buildings
- Reduction of electricity costs is 95%
- Water efficiency: 16.6% in drinking water supply; 99.5% cost reduction for waste water treatment
- 91.8-120 tons of CO2 reduction
- Reduction of costs related to child sickness
- Eventual reduction of pressure on public funds
- Positive net social benefits

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

5. POTENTIAL FUNDING MECHANISMS

One of tasks of this project was to carry out an assessment of potential and preferred funding sources for construction of green kindergarten. Based on data available, the following funding mechanisms suggested as potential funding sources:

- State budget
- Local budget
- Grants of international agencies
- Concessional loans from international development banks
- Mixed funding of grants and concessional loans
- Public-private partnerships
- Private sector funding
- Special purpose bond

After potential funding mechanisms identified, an assessment of each funding source was carried out to ensure the government takes it into consideration the most preferred funding courses while making a decision on construction of green kindergarten.

The criteria such as resource availability, expected time to lead to prepare a project and to execute a project, transaction costs and risks have been used for the assessment of funding sources and the result of this assessment suggested that the state budget, concessional loan from international bank and mixed funding of grants and concessional loans from international agencies are likely to be most potential funding mechanisms for construction of green kindergarten.

6. DESIGN SPECIFICS AND PUBLIC PROCUREMENT

This kindergarten building location plan is fully complied with local requirements and standards and is includes space provisions for safety and numerous distance connections to ensure independent movement and activities of kids. Classroom locations were chosen with optimal lighting and ventilation provisions that suit to the local climate conditions. The green house is planned and it will be located in the west side of the facility with 9 to 16 hours of daylight. This will allow children to have an opportunity to get close to the natural environment as Mongolia's long cold winter from Nov-March cannot provide the opportunity for children to play and have any activities outside of the kindergarten facility during this time of the year. Heating and moisture controls of the green house shall be connected to, and monitored by the smart monitoring system /BMS/ of the facility.

As specified in section 2, child and environmentally friendly technologies have been selected for designing this kindergarten. The Figure 1 shows the External lot planning of this kindergarten as an example of design specifics.

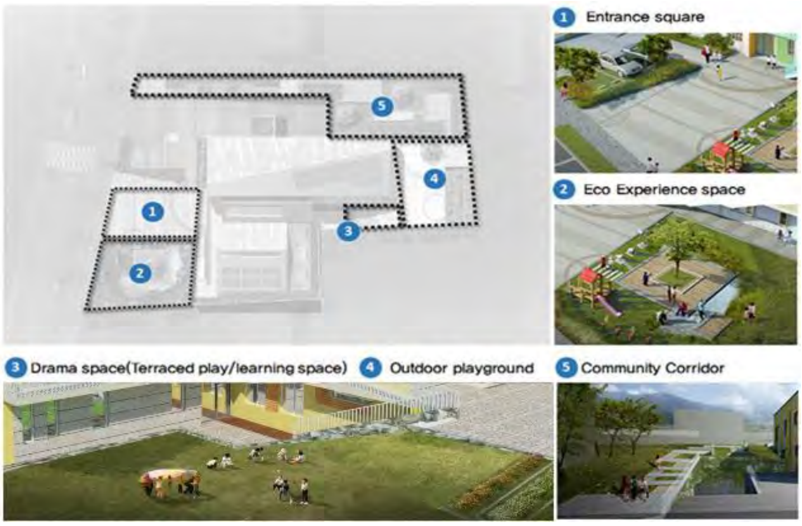

Figure 1: External lot planning
Source: MGBC and BT, 2016 Final design, technology options and financing

The planned kindergarten is going to be a public kindergarten and therefore it was necessary for the project team to looking into public procurement procedures and regulations. The team found out that the greening of kindergarten building is very much in line with public procurement procedures as it can ensure the efficient and accountable use of public funds. The only one issue that was necessary for the project team while implementing this project and the government procuring entity in the future shall be taking into account was the technical specification of the bidding document. The project team after carefully reviewing the model bidding document of the government developed a model technical specification for green kindergarten which reflects all technology and building material options. This model technical specification can be used as it is, otherwise can be slightly modified according to specific local conditions and requirements by government producing entities in the future.

7. CONCLUSION

This assessment identified the importance of closer cooperation of relevant stakeholders to successfully run a project and also smooth start of a green building project combined with national capacity efforts on green building.

The CBA done from net social benefits perspectives suggested that the green kindergarten project is cost effective and has positive net social benefits with twice reduced operational and maintenance costs and is resource and energy efficient.

The state budget, concessional loans and a mixed funding of grants and concessional loans from international agencies are most preferred funding sources for construction of green kindergarten building.

The final design of green kindergarten building meets all required standards and building code of Mongolia and the building is designed to be child and environmentally friendly.

Any public procurement shall be organized in line with public procurement procedures and regulation. The technical specification is an important part of the bidding document of the procurement. Therefore, the project team developed the model technical specification for green kindergarten based on the selected technologies and building materials which can be used as it is or can be slightly modified depending on specific local conditions and requirements.

ABSTRACT

Earth, timber, fibre boards and insulation materials based on wooden and other natural fibres offer a variety of properties, beneficial for eco innovative constructions, that are able to improve the energy and resource efficiency of buildings.

Due to their porosity natural building materials are vapour active and therefore able to buffer moisture. In combination with highly insulated and airtight but vapour permeable building envelopes, modern earth-timber constructions provide stable relative humidity levels indoors and can therefore be naturally ventilated, while achieving highest energy efficiency standards. Experimental evidence suggests that monitored pilot buildings in Berlin do show healthy indoor air humidity levels (around 50%) in wintertime, while mechanically ventilated buildings demonstrate significantly lower values (around 25%), which have to be considered as unhealthy and uncomfortable.

The application of building materials being poor of chemical emissions, particularly volatile organic compounds (VOC) and radon, improves the indoor air quality further, so that intermittent ventilation twice a day will be sufficient to provide healthy indoor air quality, however, the air quality in critical rooms (e.g. small bedrooms), demonstrating a smaller air volume, should be monitored if appropriate ratios of room size to occupancy level cannot be realised.

Through nighttime ventilation in summer, vapour active earth-timber constructions provide evaporative cooling (humidity adsorption at nighttime and desorption during the day). As a result indoor temperatures of earth-timber buildings range around 8 °C below the outside temperature peak, when an appropriate glazing ratio is reflected.

The EU funded research project [H] house is investigating various construction materials regarding water vapour adsorption as well as emission and absorption of harmful substances. Based on this investigation new wall constructions are designed to provide a healthier indoor environment.

Keywords: indoor environmental quality, climate control through natural materials, natural ventilation

1. INTRODUCTION

Occupant's health, wellbeing and also productivity are relying on the indoor environmental quality of our built environment. Renovated and new low energy buildings, developed to be highly airtight, are demonstrating unforeseen shortcomings with regards to increased relative humidity (RH) levels and higher concentration of air pollutants. Reduced air exchange rates increase these problems and are likely to cause damp problems and condensation resulting in mould growth, and, in the worst case, in disorders and outbreak of allergic reactions.

To overcome difficulties with moisture, dwellings nowadays are fitted out with mechanical ventilation systems despite associated constraints such as space requirements, additional costs, system maintenance as well as compromised occupant health, comfort and control. The main criteria for ventilation are as following:

- Control of indoor air humidity;
- Absence of harmful substances;

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Provision of fresh air.

In case of protection against overheating in summer the provision of cooling through heat pumps or other active system is often allowed for, resulting in additional energy demand for the system operation, increased space requirements and an uplift in construction and maintenance cost. It is assumed that through application of appropriate materials, the requirements on all aspects mentioned above can be satisfyingly fulfilled.

The EU funded project [H] house aims to develop eco innovative partition walls providing affordable solutions for a wide-spread application. In this study natural building materials have been compared to conventional materials to identify their potential to improve the indoor environment quality, while limiting the use of technology.

Special emphasis was placed on the improvement of earthen plasters through the addition of aerogels with regards to both, the moisture buffering capacity as well as the adsorption of airborne pollutants. For the moisture adsorption especially velocity and overall moisture uptake were investigated in greater detail.

Comprehensive experiments at material but also at component level have been undertaken to provide a database for the numerical prediction of appropriate material combinations that are able to react to different scenarios, since available surface area, occupation density, air volumes but also the construction of the building envelope might differ significantly between projects.

Accompanying experiments with regards to the emissions of the materials as well as to their adsorption potential of airborne pollutants have been conducted to identify materials that generate the most positive effects on the living environment.

In addition, experimental data coming from the monitoring of a dwelling in Berlin fitted out with earth plasters and wood fibre based partition walls has been evaluated in relation to indoor air temperatures and RH levels.

2. MATERIALS AND TEST METHODS

2.1 Material selection

The material selection was based on an in-depth market analysis focused on natural building materials for internal partition walls, characterised through hygroscopic properties. In addition, natural building materials with no or limited data collection were shortlisted to close a scientific gap. Special emphasis was placed on earth plasters modified with aerogels. In the experimental campaign, the contribution to the water vapour adsorption of one type of aerogel granulate (CMSGI) and two types of aerogel powder (CMSPI and NDPI) was investigated.

For benchmarking purposes, also conventional construction materials have been included. In total approx. 100 materials, grouped into their function of assembly, have been investigated (Table 1).

2.2 Water vapour sorption tests

The voluntary test procedure is determined in DIN 18947 to identify the capacity of earth plasters to adsorb moisture from the air via the specimen's surface within set time intervals. Based on the time in which s specified amount of moisture has been adsorbed, the water vapour sorption class (WS I – WS III) of (only) plasters can be classified. For wall build-ups the 12 hour test procedure was extended to five adsorption and desorption cycles.

2.3 Emission tests

The materials listed in Table 1 were screened for potential emissions prior to the standard tests to estimate the compounds to be expected. Final emission tests ((S)VOCs, radon) for single materials (six types) and 13 combinations of them were carried out in specially designed test chambers over a testing period of 28 days. They were conducted following the requirements of prEN 16516 and evaluated against the German AgBB scheme, in the absence of harmonised evaluation procedures.

Formaldehyde and VOC-analyses were carried out according to ISO 16000-3 and -6 and radon measurements in accordance with a procedure developed by Richter et al.

Function	Material	Thickness [mm]
Finishing materials	Earthen paint, marble powder paint, brush applied earth plaster, dispersion paint	0.5 - 2
Render	Aerogel modified earth plaster, earth plaster	3 – 15
Reinforcement	Flax fibre -, glass fibre – and system compatible reinforcement	0.5
Adhesive	Earth - and system compatible adhesives	2 - 3
Wall lining boards	Earth dry - and cellulose boards, wood fibre -and wood fibre sandwich boards, plywood, gypsum plaster – and - fibre boards, OSSB	12.5 - 31
Insulation	Wood fibre -, flax fibre - and hemp insulation, sheep's wool, straw, recycled clothes, mineral - and glass wool	40 - 80
Load bearing walls	Cross laminated timber	100
Non-load bearing, dry lining and solid walls (boards or blocks)	Dry lining walls based on wall lining boards (as above), earth blocks, wood fibre insulation blocks with cellulose honeycombs core, wood or gypsum fibre sandwich boards with flax core, compressed straw board, AAC	60 - 120

Table 25: Overview of investigated materials.

2.4 Adsorption of airborne pollutants

For adsorption tests according to ISO 16000-24 the chamber supply air was spiked with 1-pentanol, hexanal, butyl acetate, n-decane and α-pinene representing important indoor air contaminants in specified concentrations ranging between 200 and 500 $\mu g/m^3$, being higher than usually measured in indoor air to ensure a distinct determination of the reduction of the test chamber air concentration caused by the material.

The air-purifying performance of the material was determined by monitoring the difference of the inlet and outlet concentration of the test chamber. Tests were carried out for more than nine materials (six single earth plasters with and without aerogel addition, three multi-layer specimens composed of different materials).

2.5 Monitoring of real spaces

Monitoring data has been obtained from three different flats located in Berlin during August 2012 to September 2012 and during November 2012 to January 2013. The flats were either fitted out with natural or conventional building materials. Measurements were carried out with a miniature sensor and data logging system (iButton®) i-buttons, measuring external temperature, indoor air temperature and indoor and outdoor RH.

3. RESULTS

3.1 Water vapour sorption tests

Experimental results shown in Figure 1 and Figure 2 demonstrate that modified and pure earth plasters are characterised through an outstanding water vapour adsorption capacity, which is up to three times higher in comparison to gypsum plasterboards, as evidenced also in [9], [10]. Also earth dry boards, earth cellulose and wood fibre boards demonstrate exceptional moisture buffering potential. Gypsum fibre boards range between earth plasters and gypsum plaster boards.

Additional tests have been performed for other single layered materials, but also at component level (Figure 3.), investigating the potential of entire wall build-ups not only for the immediate moisture uptake but also their potential to provide a comfortable and healthy environment due to seasonal changes. Materials were tested in the most common thickness used for standard partition wall applications and although they differ, a direct comparison of specimens seems useful to identify the most capable materials and their combination. For the first cycle, results

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

are similar to those for wall linings boards, however in the consequent cycles and increase in moisture uptake is noticeable for wall constructed from natural building materials.

3.2 Emission tests

For all tested materials and material combinations low to very low emissions of formaldehyde, VOC and SVOC were determined. Only two of the 19 material combinations did not meet the strict requirements of the AgBB evaluation scheme. The radon exhalation from the earthen materials was low, first of all for earth plasters.

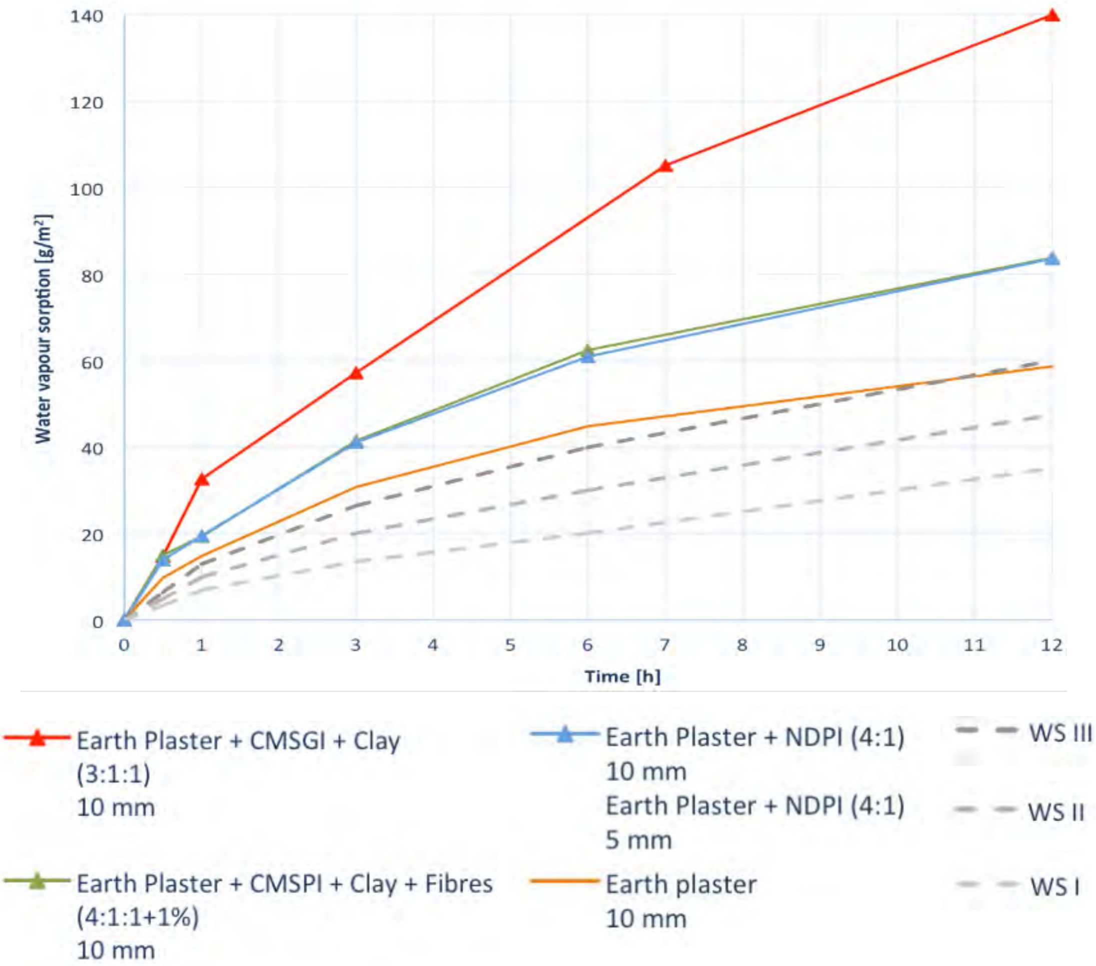

Figure 105: Results of water vapour sorption tests (DIN 18947) of modified and pure earth plasters (mix proportions by weight).

3.3 Adsorption of airborne pollutants

The results from adsorption tests demonstrated significantly different results for pure and modified earthen plasters in comparison to wall lining boards specifically designed for the adsorption of airborne pollutants. It could be shown that the addition of aerogels considerably increased the adsorption of the spiked contaminants. The best performance was observed for ND_{PI} and CMS_{GI} modified plasters similar to the water adsorption behaviour. In general, the polar compounds showed the strongest affinity for all the materials, the non-polar compounds have hardly attached.

3.4 Monitoring of real spaces

Figure 4 shows an extract from the monitoring of the results measured in a South facing living room in a flat fitted out with earth plasters and other natural building materials. RH levels were relatively stable during both periods. Indoor air temperatures were ranging always in comfortable levels, even though outdoor temperatures were above 33 °C. For the other flats, fitted out with conventional building materials relatively low humidity levels indoors during winter and higher indoor air temperatures during summer have been monitored.

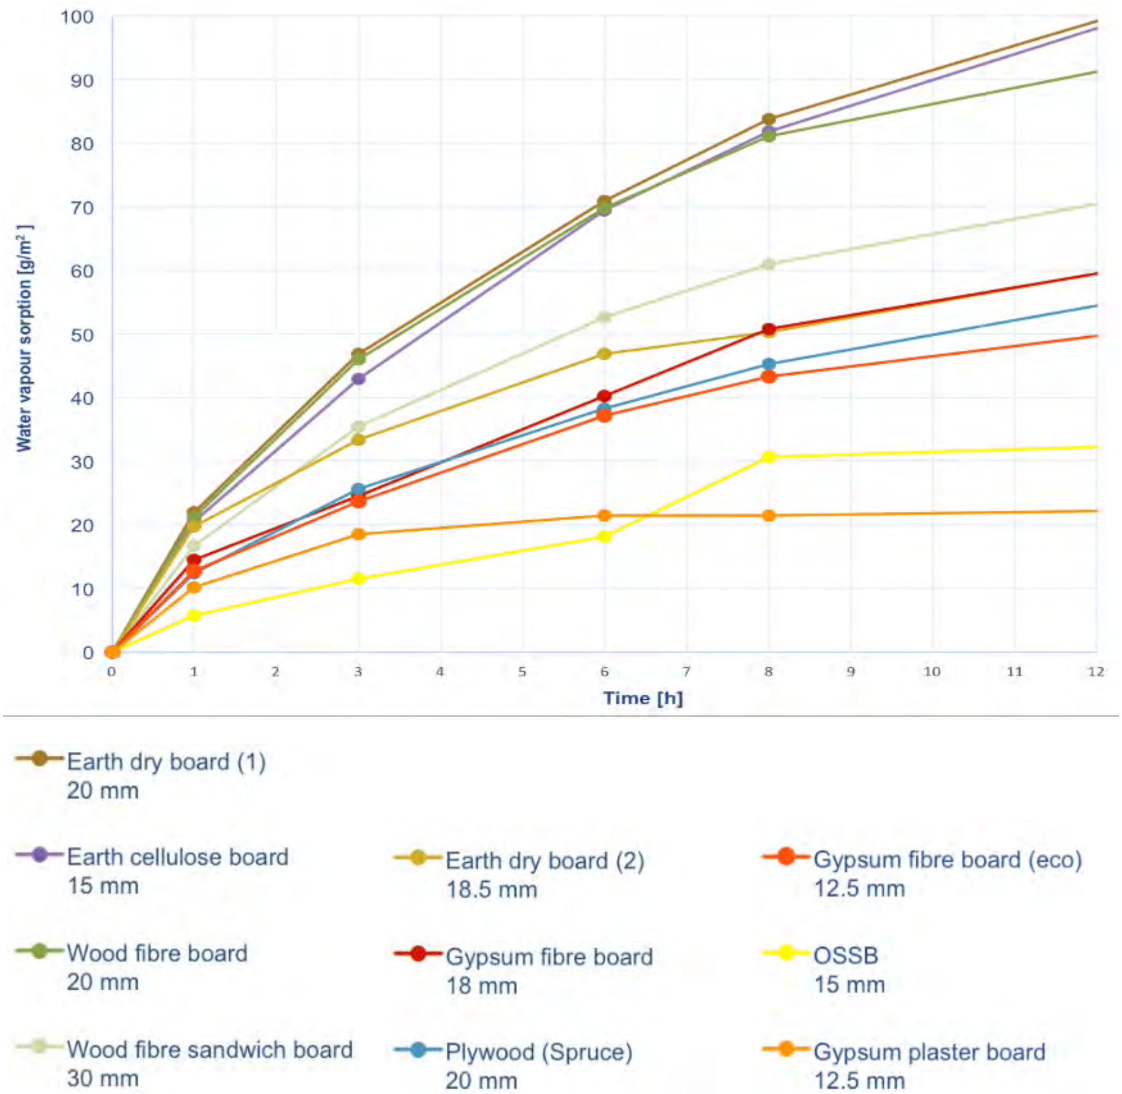

Figure 106: Results of water vapour sorption tests (DIN 18947) of wall lining boards

4. DISCUSSION

4.1 Water vapour sorption tests

Figure 1 shows the potential of aerogels to increase the moisture adsorption of earthen plasters. While the addition of aerogel type ND_{PI} (powder) increased the moisture adsorption only insignificantly, the specimen modified with aerogel type CMS_{GI} (granulate) demonstrated a significant increase of moisture adsorption (> 130%) after 12 hours in comparison to pure earth plasters. In addition the adsorption speed of the pure plaster was increased by approx. 100%. The addition of aerogel type CMS_{PI} (powder) achieved similar results compared to the specimen modified with aerogel type ND_{PI}, although a modified earth base plaster of 5 mm was applied, resulting in a higher plaster thickness in total. The outstanding results of the specimen CMS_{GI} enriched with aerogel granulate are most likely related to the structure of the aerogel itself. However, the amount of aerogel granulate that could be integrated into the mixture while meeting the requirements of DIN 18947 is approx. three to five times higher in comparison to both aerogel powder types, contributing significantly to the increased moisture adsorption.

The comparison of wall lining boards in Figure 106 demonstrates the remarkably high moisture adsorption capacity of earthen dry and cellulose boards as well as wood fibre boards in comparison to standard gypsum plaster and gypsum fibre boards. For the earth based boards the clay minerals are mainly responsible for the outstanding adsorption results, whereas for the wood fibre boards it is their high porosity and respectively high surface area. The adsorption capacity of gypsum fibre boards ranges between earth plasters and gypsum plaster boards, offering robust and good solutions, when budget and construction time becoming key factors.

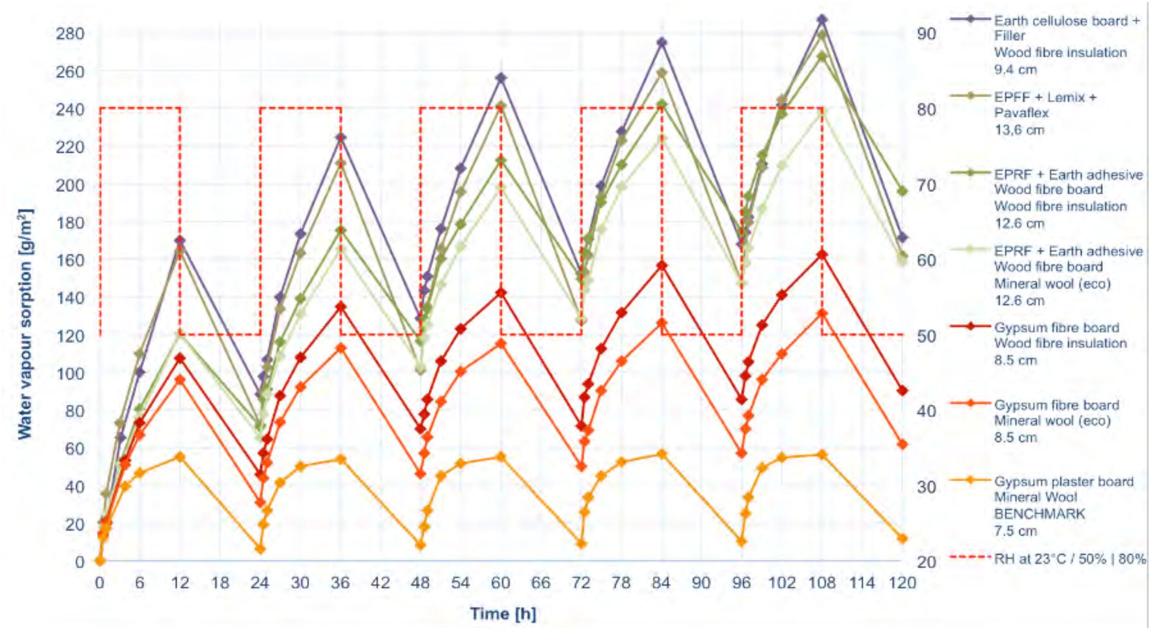

Figure 107: Results water vapour sorption tests (five 12 hour ad- and desorption cycles) of wall build-ups

Although this study is not exhaustive, it was observed that congeneric materials achieved very different results, which becomes obvious comparing the results of specimens earth dry board 1 and 2 (Figure 106). Similar tendencies, but even more distinct were observed for wood fibre and calcium silicate boards.

Material investigations at component level demonstrated the superior performance of natural building materials in comparison to conventional wall build-ups. Figure 107 demonstrates the impact of the earth cellulose board, pure earthen plasters in combination with wood fibre boards and wood fibre insulation or wood fibre flax sandwich boards in comparison to conventional wall build ups with gypsum plaster boards and mineral wool and clearly demonstrate that the insulation layer gets activated in case natural building materials were used, whereas mineral wool does not contribute to the adsorption at all.

The exact benefit on indoor air quality with regards to seasonal changes has to be determined, however it can be assumed that buildings fitted out with such walls, will benefit from evaporative cooling processes during hot summer months.

4.2 Emission tests

It is important to note that the AgBB criteria were developed for individual building materials. For the analysis of wall systems a different set of criteria would be more appropriate. The results can therefore only have an orienting character. Nevertheless it can be established that all other tested natural building materials were uncritical with respect to their emission properties and can be installed in buildings in almost any combination without concern.

4.3 Adsorption of airborne pollutants

The adsorption tests revealed that earth plasters have a good adsorption capacity, which was particularly increased by the addition of aerogel granulate but also by the addition of aerogel powders.

4.4 Monitoring of real spaces

Monitoring data shown in Figure 4 indicate that temperatures in a living area facing South range 6 – 7 °C below outdoor temperatures during hot summer days, which would support the assumption that earth plasters contribute to cooler indoor air temperatures during summer through evaporative cooling.

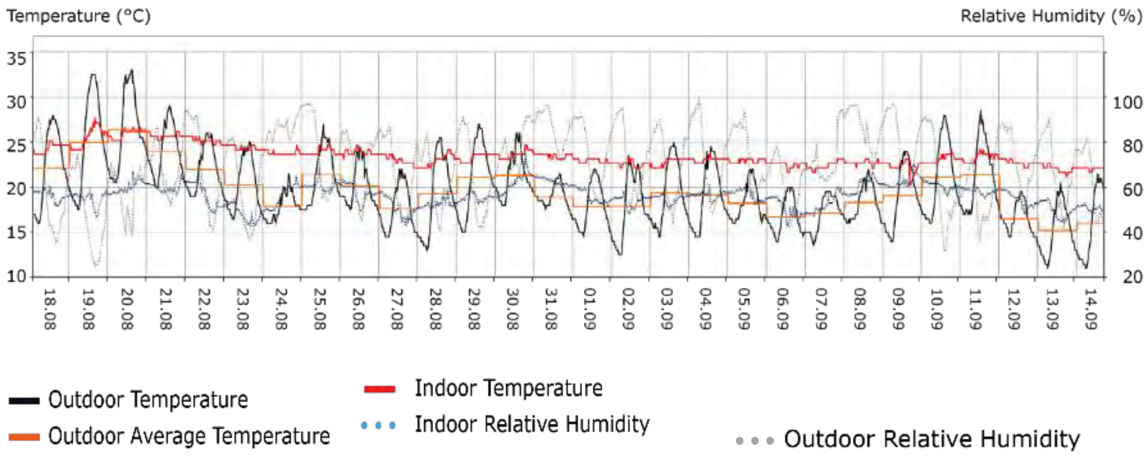

Figure 108: Monitoring results from a living room of a flat fitted out with earth plasters.

5. CONCLUSION AND OUTLOOK

Results presented in this study suggest that low emitting, natural building materials with enhanced hygroscopic properties such as earth plasters modified by addition of aerogels, wood fibre boards, wood fibre flax sandwich boards and strawboards in combination with natural ventilation offer robust alternatives to mechanical ventilation. Through application of materials able to adsorb airborne pollutants, indoor air quality can be enhanced further. Numerical simulations have started to translate current findings into hygrothermal models for the evaluation of indoor environment quality of residential buildings. The impact of air purifying materials has to be investigated further. The models will be used to predict suitability of materials for specific applications and damage-free constructions.

ABSTRACT

Building energy consumption accounts for the proportion of total national energy consumption is quite large, such as the United States accounts for about 40% of total energy consumption, Taiwan for about 30%, and China for 25%. The current strategy to reduce the energy consumption of the building is not only to improve energy efficiency of equipment in buildings (such as the use of high-efficiency air conditioning, lighting, etc.), but also to develop heat insulation materials for building envelopes. This study aims to investigate the relation between optical performance and durability of the heat insulation paint. 23 kinds of heat insulation paint on the market were selected to conduct the natural exposure testing and artificial accelerated aging testing, respectively, and the solar reflectance and emissivity of all samples were measured and compared.

The experimental results indicate that the test samples could produce blue-green algae and dust on the surface due to water vapour in the atmosphere, so the solar reflectance of the samples would have more significant decline. After 2000 hours artificial accelerated aging testing, the emissivity and solar reflectance was reduced by 2% and 10%, respectively.

Keywords: heat-insulation coating, durability, accelerated weathering test, solar reflectance, emissivity

1. INTRODUCTION

All countries in the world are investing a lot of manpower and resources to solve climate change and global warming problems. Energy consumption of building sector accounts for a country's total energy consumption is quite large. For example, building energy consumption accounts for about 40% of the total energy consumption in the United States, Taiwan is about 30%, China about 25%. Therefore, reducing the building energy consumption and urban heat island effect have become one of the most important issues in the world. The current strategy to reduce the energy consumption of the building is not only to improve energy efficiency of equipment in buildings (such as the use of high-efficiency air conditioning, lighting, etc.), but also to develop high performance heat insulation materials for building envelope. It is well known that installation of heat-insulated materials, insulation coatings and energy-saving windows in building envelope has a significant effect on reducing energy consumption. Cool Roof with high thermal insulation performance to reduce the roof temperature, has been proven by the US Environmental Protection Agency. Using cool roof material has been selected as one of the effective strategies to reduce building energy consumption and urban heat island effect.

In the past three decades, many accelerated weathering techniques have been developed and utilized to meet the requirement of rapid development of new cool roof materials. These accelerated test methods attempt to accelerate natural environments with higher stress, e.g. greater intensity of UV radiation and elevated temperature without changing the failure mechanism. With these methods, the performance of cool roof material can be estimated in a short test period. Among those accelerated weathering test methods, a QUV chamber and a xenon arc chamber have been commonly used in industry and academia to test the weathering durability of the coatings. In these two chambers, UVA or filtered xenon-arc radiation and water condensation are provided alternately.

In Taiwan, insulation coatings are cheaper and easier to use than other construction materials. They have been widely used in residential building facades and roofs, industrial manufactory, schools and even farmhouses. However, the claims of thermal insulation properties and durability of the coating are not compulsory requirement, a product-related information between insulation performance and durability of commercially available insulation coating so far is not unified in Taiwan. Therefore, it is necessary to develop the durability testing methods for insulation coating in order to encourage consumers and architects to use more insulation paint. The natural

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

phenomena can cause degradation in polymer systems. The elements of most concern to paints are ultraviolet radiation, moisture, humidity, high temperatures and temperature fluctuations. Thus, it is important for scientists and paint producers to understand durability and expected lifespan of paint products. This study aims to investigate the relation between optical performance and durability of the heat insulation paint.

2. TEST METHOD

The 23 kinds of commercially available paints were collected in this study. The colors of these samples are white, grey, green, blue and red. These paints were coated on the cement brick and steel substrates by using an RDS coating bar (no. 22, coating thickness: 50.29 μm), respectively. The sizes of steel substrate are 10 x 10 x 0.05 and 7 x 14 x 0.05 (length, width, height, cm), and size of cement brick substrate is 10 x 10 x 1 (length, width, height, cm).

Samples were subjected to natural weathering, xenon-arc lamp artificial weathering and UV lamp accelerated natural weathering based on CNS 15200 and CNS 1183, respectively. The testing conditions of these three tests are listed in Table 1. The total duration of the test was 2000 hr. Before and after each 500 hr aging tests, the solar reflectance and emissivity on the coating surfaces of samples were examined. The solar reflectance and emissivity were carried out by means of spectrometer with integrating sphere, allowing characterizing the solar reflectance capability of the samples before and after the accelerated weathering tests. The solar reflectance and emissivity of samples are measured by using UV/VIS/NIR spectrometer and FTIR spectrometer based on ISO 9050 and 10292.

3. RESULTS AND DISCUSSION

Figure 1 to 3 show how the solar reflectance of 20 samples varied with time after 2000 hours weathering testing. All samples show reflectance reductions over time. During the first 500 hours there is a significant variability. The results of natural weathering testing indicated that the data after 500 hours are consistent with optical stability for these samples, with reflectance changes being due to dust accumulation in this study. It is because that Taiwan is located in the subtropical region with high temperature, humidity and high level of invisible pollutants such as dust and toxic aerosols in the air. After 2000 hours of natural weathering exposure the solar reflectance difference changed from 6.22 % to -11.62 % among white color samples, from -2.72 % to -4.20 % among grey color samples, from -0.75 % to -11.92% among green color samples, and from -3.57 % to -11.77 % among blue color samples. On the other hands, the results of two accelerated weathering tests indicated that there is no significant difference on solar reflectance with various colors of coatings.

Figure 3: Solar reflectance versus time for different coating colors by xenon arc exposure test: (a) white-and-grey (b) green-and-blue

Figure 4 to 7 show the comparison between the solar reflectance and emissivity of samples before weathering test and those of after 2000 hours weathering test. The experimental results indicated that the difference between initial solar reflectance of steel plate samples and those after 2000 hours weathering test is in the range of ± 10%. The emissivity deviation of steel plate samples and cement brick is in the range of ± 2 % and ± 5 %, respectively. In the natural weathering test, the maximum and average attenuation rate of solar reflectance is 18.89 % and 8.38 % for steel plate specimens. The maximum and average attenuation rate of the solar reflectance for cement brick specimens is 22.3 % and 5.13 %, respectively. In addition, the specimen subjected to outdoor natural weathering could produce algae on the surface due to moisture in the atmosphere, will lead solar reflectance to be more significant for the decline, but emissivity will not be affected by the dust in the air. It is worth noting in this study that natural weathering test can reflect the effect of actual climate and solar radiation conditions on the thermal insulation properties degradation of coating materials. It usually takes more than 2 years to get the results, not only wasting time, but also the different testing sites will also cause significant differences.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

In the cases of xenon arc exposure and QUV weathering test, the most samples declines in reflectance by only 1.43 % and 3.62 % over the 2000 hours period. The results have been shown in Fig. 5 and Fig. 7 indicated that thermal emissivity declines similar to solar reflectance, but the declines are smaller in magnitude. According to the statistics data of sunshine duration in Taiwan, the area with the largest daily solar energy intensity is Chiayi area, and the UVA energy accounts for 1.23 % of the total solar radiation energy. Thus, 266 hours UV accelerated aging test is approximately equal to 1 year of Taiwan UV radiation exposure. We can deduce that a sample subjected to 2660 hours in xenon test chamber or accelerated weathering QUV tester equals 10 years of outdoor exposure. However, many of the factors, such as temperature, humidity, solar radiation, climate and test material that affect the aging of the paint should be considered. It is theoretically impossible to have a single magic number that you can multiply by weathering tester exposure hours to compute years of outdoor exposure.

4. CONCLUSION

In this study, 23 kinds of heat insulation paint on the market were selected to conduct the natural exposure testing and artificial accelerated aging testing, respectively, and the solar reflectance and emissivity of all samples were measured and compared. The research conclusions are described, as follows:

- The xenon arc exposure and QUV weathering test are suitable for evaluating the durability of paints in Taiwan. A sample subjected to 2660 hours in xenon test chamber or accelerated weathering QUV tester equals 10 years of outdoor exposure.
- In the natural weathering test, the average solar reflectance degradation are 8.38 % and 5.13 % for steel plate specimens and cement brick specimens, respectively. The specimen subjected to outdoor natural weathering could produce algae on the surface due to moisture in the atmosphere, will lead solar reflectance to be more significant for the decline
- In the cases of xenon arc exposure and QUV weathering test, the most samples declines in reflectance by only 1.43 % and 3.62 % over the 2000 hours period. The thermal emissivity declines similar to solar reflectance, but the declines are smaller in magnitude.

ABSTRACT

Date Palm rachis, known as palm leaves, is one of the most abundant pruning wastes that were used traditionally in simple and cheap sheathing in rural areas and Eco-Lodges Egypt and the Middle East. However, due to the natural diversity of Palm Rachis members and the shortage of their mechanical details information, most of the previous palm rachis-based structures failed to cover wide spans while sustaining high flexibility in form and function in the design of multifunctional public halls, as the researches had to depend entirely on onsite decisions due to the absence of the pre-construction structural analysis data. This paper aims to study Palm Rachis as an innovative building material that can be used for constructing eco-friendly and cheap multi-purpose structures that are characterised by form and function flexibility, structural integrity and ease of construction.

This paper suggests using palm rachis to build arched space truss system that is characterized by simplicity in joints, flexibility in form and function and high structural integrity. This aim is served firstly by investigating the previous examples of Palm Rachis structures, then designing an 8m span structural system using Palm Rachis that's structurally analysed using a scaled physical model and digital analysis using SAP2000 in order to address the potentials of the system. This system prove to be structurally safe, flexible, simple and highly qualified for further structural analysis to identify the structural details in depth. This paper is presented to natural building materials researchers, natural builders and activists and Environmental Tourism stakeholders.

Keywords: palm rachis, affordable housing, structural simulation

1. INTRODUCTION

Date Palm residues, shown in Figures 1, are one of the most important agricultural residues that are used traditionally in cheap and rural construction in Egypt (Elmously, 2001). Palm Rachis occupy the largest percentage of the pruning residues quantities of palm trees, with 9.75 ton/ year per palm and 105.3 thousand ton/ year in Egypt which counts for 32% of the total residues (Elmously, 2001). Therefore, Date Palm Rachis became the main renewable resource of natural sheathing materials traditionally in cheap and rural construction in Egypt as shown in Figure 2. In addition, Local contemporary Eco-Lodges utilize Date Palm Rachis, to emphasize the cultural originality of such Environmental Tourism oriented projects. Adrere Amellal, an Eco-Lodge in Siwa Oasis in Egypt, utilized palm rachis in the sheathing of the palm trunk-based roofs as shown in Figure 3 (Alamuddin, 2001). However, the utilization of Date Palm Rachis did not develop as the main structural material of rural construction instead of imported timber in Egypt, due to the natural diversity of Palm Rachis members and the missing mechanical properties of Palm Rachis required for the structural analysis prior to construction.

Figure 109: Date palm main parts (Asdurabali et al., 2015)

Figure 110: Palm trunk and rachis used for traditional roofing In Sinai.(Ibrahim, 2010)

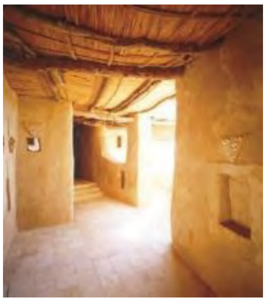

Figure 111: Roofing by palm rachis adrere amellal eco-lodge(Alamuddin, 2001)

Therefore, previous researchers such as (Piesik, 2012) and (Peter Sheehan et al., 2015) had to depend entirely on building physical models in order to design the members structurally according to the onsite structural behaviour of the members. The systems had to depend on strict grids and internal vertical supports according to the onsite behaviour and to ensure safety during the building process. This decreased the structural integrity and flexibility of the form and function of the resulting systems. In addition, unpredictable forces such as wind can be very critical that they can cause the structure to fail later, as they were not taken in consideration.

Thus, the knowledge gap lies within examining the structural safety of date palm rachis-based structural systems in the pre-construction phase without depending on onsite decisions. This paper aims to design palm rachis-based structures that are firm, simple and cost-effective while maintaining the aspects of ease of construction and flexibility in form and function.

This aim is served firstly by investigating the previous examples of Palm Rachis structures, then designing a structural system using Palm Rachis that is structurally analyzed using a scaled physical model and digital analysis using SAP2000 in order to identify the structural potentials and limitations of the system.

2. PREVIOUS EXPERIMENTS OF UTILIZING DATE PALM RACHIS IN CONSTRUCTION

2.1 Arched date palm rachis bundles

(Piesik, 2012) made the first attempt to construct using Arched Palm Rachis Bundles in order to exploit the curved nature of Date Palm Rachis in UAE as shown in Figures 4, 5 and 6. The vault was constructed using arched bundles of Palm Rachis with circular cross section of 20cm diameter to cover a span of 13 m. Every arch was planted 30cm deep in wet soil, and then supported by 4 palm trunks on intervals of 3.25 m approximately and ropes were used to bend the bundles and tie them to the palm trunks. The covering was made using a woven mat over the Rachis purlins that are arranged and tied to the arches. However, it's criticized of using internal trunks every 3.25 m which can interrupt the continuity of the activities inside.

Figure 112: The vault during construction (Piesik,2012)

Figure 5: Internal columns (Piesik, 2012)

Figure 6: Rope based connections.(Piesik,2012)

2.2 Cross arched palm midribs bundles

An improvement from the vault in (Piesik, 2012), (Sheehan et al., 2015) constructed a food shelter in Al-Ain UNESCO world heritage site in UAE using cross arched Palm Rachis Bundles as shown in Figures 7 and 8. Two perpendicular 8x8m grids of arched Palm Rachis bundles were built where the load of each arch is totally distributed on the perpendicular grid of arches (Sheehan et al.,2015). The arches ends are planted 30cm deep in concrete foundation boxes and ropes were used to ensure the stability of the overlaps of the arches. For covering, light tent fabrics were used and fixed to basic nodes to make a tent-like form (Sheehan et al., 2015). However, the future extensions are limited to repeating whole modules, while at the same time. In addition, the tent-like form that was used due to the double curvature in the structure is distant from the majority of the rural context in Egypt.

Figure 7: Cross arched module (Sheehan et al., 2015)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 8: Tent- like covered module(Sheehan et al., 2015)

2.3 Objectives of the suggested system

According to the discussed literature review, the new suggested system in this paper should be characterized of the following:

- Structural integrity: covers the widest span that is capable to host multifunctional halls firmly.
- Form and function flexibility: free of strict grids and internal supports that may interrupt the continuity of the indoor functions.
- Simple yet Durable connections: non-dependent solely on ropes for connections, as ropes will be the weakest points of the system due to their low climatic and structural durability

3. METHODOLOGY

3.1 Mechanical properties measurement

The measurements were taken according to the European Standard EN 408: 2003, which is concerned with the determination of the mechanical properties of Structural timber and glued laminated timber. The 2x2 cm approx. samples were taken from the mid section of the 7 meter-tall Baladi Date Palm Rachis brought from the Nile Valley in Minya Governorate. The measurements took place in the Metalloid Laboratory in Faculty of Engineering, Ain shams University, Egypt.

3.2 Digital structural simulation

Digital simulation is used to identify the structural limitations of the system and to examine multiple spans using SAP2000. SAP2000 is a common structural program in Egypt to analyze simple and complicated structural cases using predefined properties of concrete and steel. Therefore, the required properties are defined manually in the program to calculate axial forces and bending moment on members' sections.

4. DISCUSSION

According to the systems discussed earlier in the literature review, the cross arched bundles interdependence (Sheehan et al., 2015) was the main solution to the need of intermediate columns that were used in the vault (Piesik,2012). This was accomplished by turning the whole structural mesh from a planar 2 dimensional arch into a 3 dimensional structural dome. This solution originally imitates the main concept of Space Trusses.

4.1 Structural development of arched palm rachis bundles

Space truss is used to cover wide spans using interacting light members without disturbing internal supporters (Ambrose and Tripney, 2012). Space trusses originated from plane grid truss that would have high bending moment when used to cover wide spans. This moment is supported by increasing the cross sections of the members or by adding another grid, thus turning into a 3 dimensional truss i.e. space truss (Lan, 2005). However, the design of joints would be critical while using the naturally varied Palm Rachis bundles.

The solution is to depend on friction in order to drive the ends of intermediate bracings into the bundles without any dependence on ropes or metal plates. The arched bundles will have to transform all the bending moment into compression forces while decreasing tension forces as much as possible. Therefore, the arches ought to take the pure compression form i.e. a parabola. The compression forces in the parabolic arch allow using friction connection, as the tension forces resulting from bending that would dismantle the arch range from minimal to none (Ambrose and Tripney, 2012). Therefore, Parabolic Arched Space Truss, shown in Figure 9, is the chosen structure system to design and simulate using Palm Rachis bundles.

4.2 Suggested structural system

The suggested structural system, as shown in details in Figures 10 and 11, was assigned to cover the span of 8m with 6m axis to axis spacing as an initial span that would be modified to understand the limitations of the system according to the simulation results. Additional Structures were added to examine the versatility of the form and function. The cross sections of the arches were assigned to be 20 cm dia., according to the previous works of (Piesik, 2012) and (Sheehan et al., 2015).

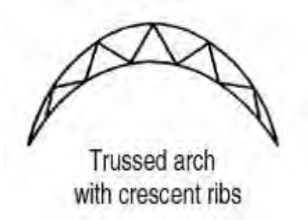

Figure 9: Trussed arch with crescent ribs (Ambrose amd Tripney, 2012)

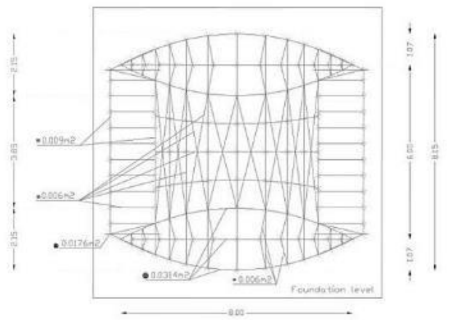

Figure 10: Plan and cross sections of the system (Author)

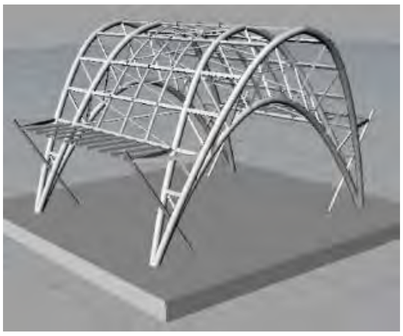

Figure 11: 3D model for the system by rhinoceros 5 (Author)

In addition, a physical model was made by the researchers in order to study the close details of the system, as shown in Figures 12, 13 and 14 The 1:20 scale was chosen due to the available space and manpower limitation. The used material is dried Palm Rachis that were sliced as thin as possible to imitate the true members, as each member on the model imitates 4-6 members in real life.

Figure 12: The main arches of the space truss (Author)

Figure 13: Adding the space truss bracings using friction connections (Author)

Figure 14: The final shape of the physical model (Author)

4.3 Mechanical properties measurements

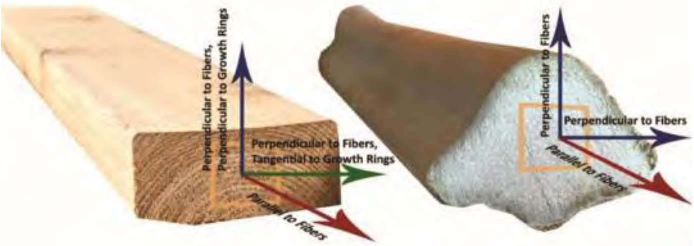

Figure 1113: Comparison of the material axes between timber and palm rachis (Author)

In terms of engineering elastic models, Anisotropic Lignocelluloses structural materials such as wood are usually treated as an orthotropic materials, supposing in the linear orthotropic model that there are 3 perpendicular planes of symmetry in the material, and in the same time the shear behaviour is supposed to be independent of the extensional behaviour and temperature change (Mascia and Lahr, 2006).

The tangential and radial directions in wood are identified according to their intersection with the annual growth rings as shown in Figure 15 (Green et al., 2010). However, due to the lack of growth rings in palm rachis, the mechanical properties which are perpendicular to fibres are similar in both tangential and radial directions.

The perpendicular modulus of Elasticity was measured using compression (EN 408-2003) as shown in Figure 16. The longitudinal modulus of Elasticity was measured using bending (EN 408-2003) as shown in Figure 17. The

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Shear modulus was calculated by the Variable Span Method using flexural test (EN 408-2003) as shown in Figure 18. Due to the limitations of the laboratory, the Poisson Ratios and Stresses were assumed according to the properties of Spruce Wood (Green et al., 2010) that was proven to be close to Date Palm Rachis (Elmously,2001). The mechanical properties are shown in Table 2.

Figure 1114: Compression test perpendicular to fibers (Author)

Figure 1115: Bending test -shear modulus via variable span method (Author)

Figure 1116: Bending test -longitudinal modulus of elasticity (Author)

Property Description	Value
Longitudinal Modulus of Elasticity –E_L	10287.8 MPa
Tangential Modulus of Elasticity-E_T	105.45 MPa
Radial Modulus of Elasticity-E_R	105.45 MPa
Longitudinal-Radial Poisson's Ratio-V_{LR}	0.372
Longitudinal-Tangential Poisson's Ratio-V_{LT}	0.467
Radial-Tangential Poisson's Ratio-V_{RT}	0.435
Longitudinal-Radial Shear Modulus-G_{LR}	109.2 MPa
Longitudinal-Tangential Shear Modulus-G_{LT}	109.2 MPa
Radial-Tangential Shear Modulus-G_{RT}	39.05 MPa
Mass per Unit Volume	0.95 gm/cm^3
Effective Yield Stress	45 MPa
Effective Tensile Stress	54 MPa

Table 26: Mechanical properties of date palm rachis : EN408-2003 (Moisture Content=7%) (Author)

4.4 Digital simulation

The materials properties were defined manually into SAP2000, then the values of Normal Forces and Bending Moments due to Dead Loads and Wind Loads combined were calculated in order to check the safety of the system while covering variable spans as shown in Table 2. The connections were assigned to be firm friction connections and the bundles were assigned to be fully coherent.

The structural check was based on Allowable Stress Design method (ASD), where the actual loads are used in structural calculations, because of the lack of safety codes and adjustments of Palm Rachis as a relatively new structural material. The structural check used the combined stress interaction (CSI) equations, which is used for members such as wall studs and roof truss members that experience bending stress in addition to axial loading in wooden structures (Residential Structural Design Guide, 2000). Combined actual bending and axial compression design is checked

as shown in Eq. 1:

$$\left[\frac{f_a}{F_a}\right]^2 + \left[\frac{f_b}{F_b}\right]^2 \leq 1$$

Equation 1

where f_a is the actual axial load (compression or tension), F_a is the allowable axial load (compression or tension), f_b is the actual bending load and F_b is the allowable bending load.

Clear Covered Span = 8m

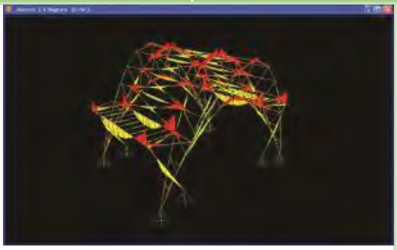

Figure 1117 :Bending moment visualization (red: positive, yellow: negative)

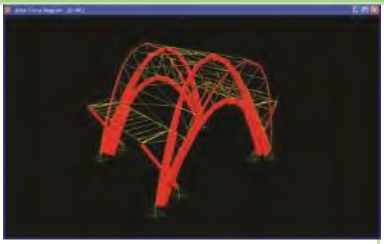

Figure 118: Axial forces visualization (red: compression, yellow:tension)

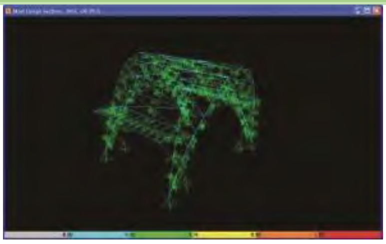

Figure 119: Stresses check on cross sections (green-safe, red-unsafe)

Clear Covered Span= 12m

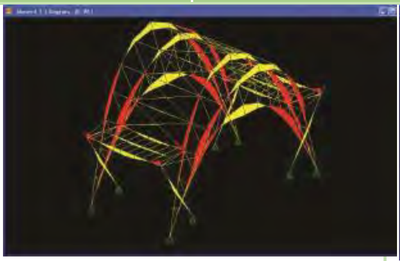

Figure 120: Bending moment visualization (red: positive, yellow: negative)

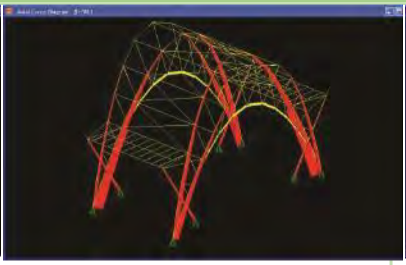

Figure 121:Axial forces visualization (red: compression, yellow: tension)

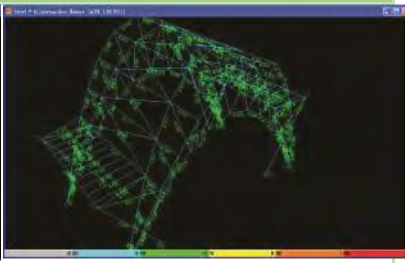

Figure 122: Stresses check on cross sections (green-safe, red-unsafe)

Clear Covered Span= 16m		
		Figure 123: Bending moment visualization (red: positive, yellow: negative)	*Figure 124: Axial forces visualization (red: compression, yellow: tension)*	*Figure 125: Stresses check on cross sections (green-safe, red-unsafe)*

Table 27: Results of structural simulation while covering various spans (Author)

The results as shown in Table 2 from the digital structural simulation showed that the system is safe while covering 8 and 12m. However the system failed at covering 16m due to high buckling at the cross sections of the bracings.

5. CONCLUSION

Date Palm Rachis is a promising material in terms of construction. In this paper, several previous experiments of building using Date Palm Rachis were reviewed. The experiments showed the high potential of the material. However, the systems were not characterised by high flexibility in form and function. Therefore, the parabolic arched space truss structure was designed using Date Palm Rachis to introduce a versatile structure that can be used to cover multifunctional halls and public activities.

The scaled physical model was constructed in order to predict the ease of construction and durability. Then the mechanical properties were measured in order to define the material in SAP2000. The results from the digital simulation showed that the system is highly recommended to cover spans up to 12m. In addition to that, the majority of the normal forces along the members are compression, which means that friction connections are suitable for the structure as long as the used arches are parabolic.

This system can be used for multifunctional public halls such as markets, sport halls and recreational areas. This system provides the necessary flexibility, simplicity of connections and structural integrity, while depending on simple construction utilizing the highly available Date Palm Rachis.

These findings open the door for further structural studies regarding the spacing between the arches, the intensity of the bracings, the coverings and protection against fire and degradation.

Bamboo for the 21st Century

Martin TAM Tin-fong[a]

[a] *Able Mart Limited, Hong Kong SAR, martintftam@gmail.com*

ABSTRACT

Taking forward the COP 20 Resolution (2014 Lima, Peru) to adopt Bamboo as a strategic resource to combat global warming, detailed studies in multiple directions must commence without further hesitation.

Our World have always strived to understood the practical needs of our nations and our regions, and is dedicated to the advancement of society through education and research. The last 15 years have seen a dramatic growth in the variety of commercial bamboo products such as flooring, laminated furniture, building panels, high quality yarn and fabrics, activated carbon and bamboo extracts. Bamboo's appearance, strength and hardness combined with its rapid growth cycle and capacity for sustainable harvesting make it increasingly attractive for advancing socio-enviro-economic growths. The market outlook for bamboo is strong, and international trade runs rampant.

These recent developments have created new opportunities for bamboo markets to be targeted for rural development and poverty reduction. In particular, the emergence of near-source value-addition in modern supply chains increases the sector's potential economic impact on poor rural communities.

This presentation attempts to cover the essential aspects and considerations necessary to support the bamboo revolution/revival from plantation to harvesting, manufacturing to fabrication, marketing to product readiness, in all aspect of human living, from food to travel, from built environment to clothing ......

The search is on ...... , to move human activities along the Bamboo Age ....

1. INTRODUCTION

The effects of global warming are inducted by social changes and environmental oversight (directly or indirectly) by human emissions of greenhouse gases. There is a scientific consensus that climate change attributes human activities as the primary driver. Many impacts of climate change have already been observed, including glacier retreat, changes in the timing of seasonal events (e.g., earlier flowering of plants), and changes in agricultural productivity.

Future effects of climate change will vary depending on climate change policies and social development. The two main policies to address climate change are reducing human greenhouse gas emissions (climate change mitigation) and adapting to the impacts of climate change. Geoengineering is another policy option.

The United Nation's global climate summit 2014 in Lima, Peru, kick-started the tackling of greenhouse gas emissions and 40 countries agreed that Bamboo is a strategic resource against climate change in the Lima, Peru Convention on Climate Change COP20.

In 2015, the Paris Climate Change Agreement signed by 196 countries, for the first time, developing and developed countries have agreed on a common agenda to reduce greenhouse gases, limit temperature rises to two degrees (or 1.5 degrees) of pre-industrial levels, and achieve a zero-carbon future.

1.1 What is bamboo?

Bamboo is one of the fastest growing plants in the world, it grows 1030 mm per day & reaches full height in 4-6 months, and it has unique rhizome-dependent system. The root system can extend up to 100km/ha and live for a hundred years.

There are over 70 categories and 1250 species of bamboo plants worldwide. China is abundant in bamboo species, with over 40 categories and 500 types of bamboo plants, of which the economic bamboo accounts for over 50 categories.

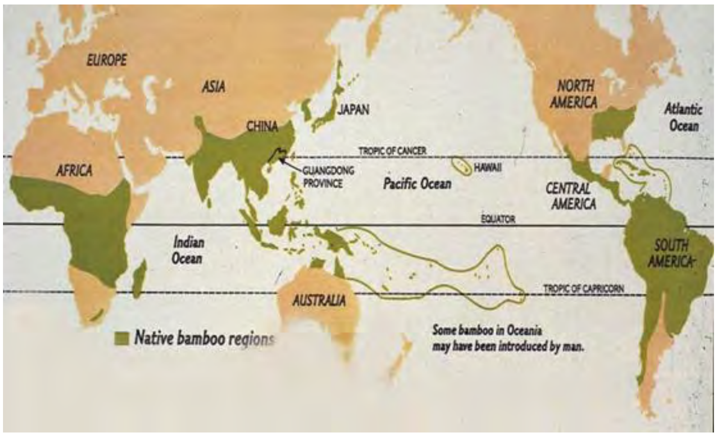

Figure 1: Distribution of bamboo in the world
There are about 70 Genera, 1000 species (not including herbaceous bamboos growing in Latin America)
Source: International Network for Bamboo and Rattan (INBAR)

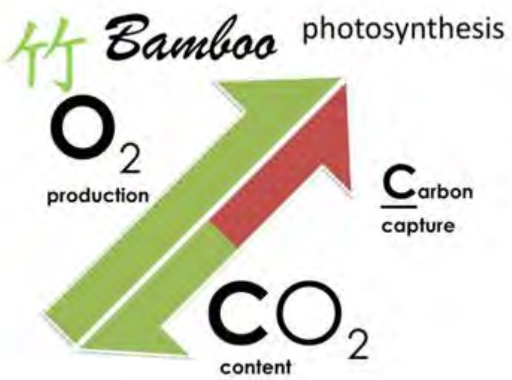
2. WHAT MUST WE DO?

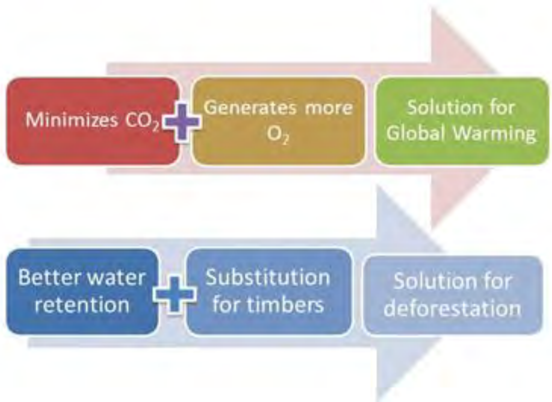
2.1 Fight the climate change

- Bamboo absorbs relatively more CO_2 than trees, thereby releases relatively more O_2 than trees
- Bamboo is a great natural carbon sink - Fast biomass generation and Fast re-growth even after regular harvesting

2.2 Bamboo indirectly reduce greenhouse gas emissions by:

- Producing bamboo products usually requires lower energy than comparable fossil-fuel based products
- Selectively harvested bamboo provides woody biomass
- Transformed into durable products with long life spans increase terrestrial carbon sink





From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.3 Other benefits of bamboo

- Improves the Indoor Air Quality (IAQ) within and around buildings and structures, especially as it relates to the health and comfort of building occupants;
- Positive impacts on natural environment and human health;
- Uses renewable resources more efficiently and wisely;
- Reducing the pace of deforestation, indeed increase forests via bamboo plantations;
- Relieving global warming and natural ecological crisis;
- "Natural Oxygen Bars";
- 2 times negative oxygen ions concentration comparing to evergreen broad-leaved forest (ChaShanZhuHai National Forest Park in Chongqing city);
- Bamboo leaf can capture 4 to 8 g/m of dust;
- Bamboo belt reduce noise (10 to 15 dB by 40m wide belt);
- For climate change mitigation
  - o Rapidly sequesters carbon, avoids fossil fuel use
  - o Offers a highly renewable source of biomass energy – as a substitute for wood fuel and fossil fuels
- For landscape restoration
  - o Rapidly restores degraded lands in the tropics
  - o Thrives on problem soils and steep slopes that are unsuitable for other crops, e.g. HK Tuen Mun highway.
  - o To date, millions of hectares of degraded lands have been restored with bamboo, many millions more can benefit
- For adaptation
  - o Protects communities from natural disasters as a part of sustainable forestry & agro-forestry systems
  - o Rapid growth allows frequent harvesting, helping farmers respond adapt changing weather patterns

Bamboo is the GREEN material to save our planet!

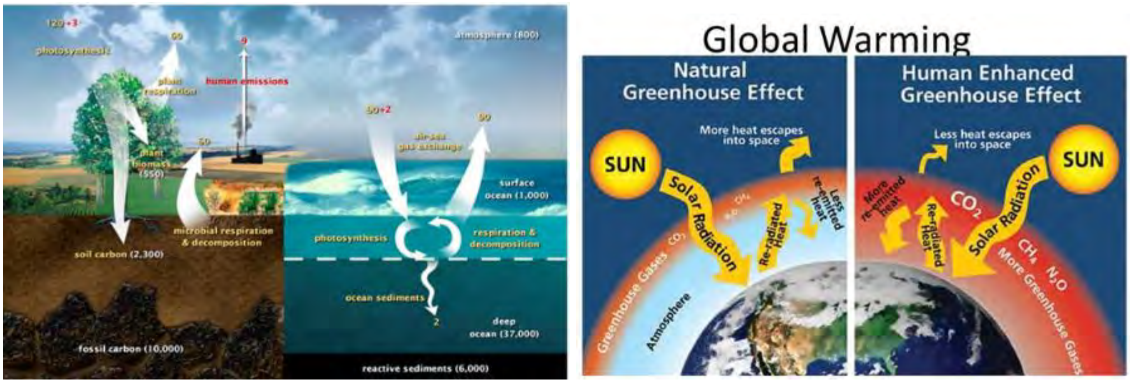


Figure 2: Movement of carbon between land, atmosphere and greenhouse gas effect due to increased CO_2

3. USE AND UTILIZE EXTENSIVELY

3.1 Why use bamboo?

- Bamboo can be harvested within 4 - 6 years
- Extraordinary physical characteristics
- Suitable for all types of structures and constructions
- Light building material for easy transportation & storage

3.2 Facts to be noted

- Are processed and compressed with chemical-based glue
  - o Formaldehyde out-gassing, especially bamboo product made with low quality glue
- Durability
  - o Bamboo flooring last 30 – 50 years (while some solid hardwood last 125 years or longer)

3.3 Economical

Bamboo also widely known as resources that empower the poor. They already play a critical role in supporting poverty alleviation contributing to livelihoods of millions for people worldwide.

3.4 Architecture

3.4.1 As a building material

- Often referred to as the poor man's timber,
- Becoming increasingly popular among Western architects and engineers
- A major building material in many countries, particularly in Asia, Africa and South America
- Well Known for its strong characteristics, light weight and flexible properties
- Can be used for almost all parts of houses, including posts, roofs, walls, floors, beams, and trusses

3.4.2 Mechanical properties

- In general, bamboo is stronger than wood in bending strength, compression strength parallel to grain and is similar in shear strength parallel to grain
- The strength of bamboo in grain direction is extremely high, especially Modulus of Rupture and Modulus of Elasticity. It might be suitable as the raw material for such products as oriented structural boards which bears unidirectional load
- Bamboos have low shear strength parallel to grain. The bamboo veneers can be peeled from straight culms of a thick-walled bamboo species

ZCB – Bamboo Pavilion
By Team from CUHK School of Architecture

The ZCB Bamboo Pavilion is a public event space built for the Construction Industry Council's Zero Carbon Building (ZCB) in the summer of 2015 in Kowloon Bay, Hong Kong. It is a four-storey-high long-span bending-active bamboo gridshell structure with a footprint of approximately 350m² and a seating capacity of 200 people.

It is built from **475 large bamboo poles** that are bent onsite to shape the structure and that are hand-tied together with metal wire using techniques based on Cantonese bamboo scaffolding craftsmanship. The shape is a large diagrid shell structure that is folded down into three hollow columns. These columns rest on three circular concrete footings. A tailor-made white tensile fabric is stretched over the structure and is brightly lit from inside the three legs.

Address: Truong Sa Road, Ngu Hanh Son District, Danang

bamboo restaurant and beach bar to spa resort in Vietnam by Vo Trong Nghia Architects [3]

the beach bar lies adjacent to the infinity pool along the coastal front of the resort complex. visualized as a semi-open space –allowing a constant breeze to flow through– **the structure is composed of bamboo, stone and finished with a thatch roof**. the process in which the robust, natural material was formed was through a method of using fire, soaking and fumigation. approached as a simple, pitched roof structure, the unobtrusive building blends with its tropical setting where the naturally treated bamboo frame reflects the region's characteristics.

Naman Conference Hall in Vietnam by Vo Trong Nghia Architects [4]

The main bearing structure are the **bamboo frames** which overcome a span of 13,5 m in the hall and 4 m in the corridor with the roof height of 9,5m. The arch-like impression is created by the bent bamboo that are part of the main structure. Thanks to the positioning of the glass facade which is stepped backwards into the volume, 3 frames of the arch structure are in the exterior, opening the entrance as the space serves as a foyer to welcome the guests.

3.4.2 Interior design

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4. SUSTAINABLE DEVELOPMENT

Through sustainable management and utilization of bamboo resources, the international community can significantly reduce pressure on fast depleting forest resources conserve biodiversity & fight climate change.

The development of bamboo industry is speeding up, scale and level takes the lead internationally, perfect industrial system has been formed and bamboo industry has become the most competitive industry worldwide. In the east and south of China, bamboo industry has become the strong growth point of economy. The abundant bamboo resources provide not only the basis of the industry but also the extensive development room for the chemical utilization of new bamboo industry.

5. PRODUCT: CLOTHING, FOOD, LIVING, TRANSPORTAND AND LUXURY GOODS

Since the beginning of the century, particularly in recent years, bamboo has entered into multiple-use period, such as bamboo vinegar, leaf, protein of bio and chemical industry, fiber & textile industry, laminated wood, decorative materials manufacturing, distinct ecological tourism of bamboo and commercial & service of bamboo.

5.1 Textiles

- Bamboo fabric is a natural textile made from the pulp of the bamboo grass
- Bamboo fabric has been growing in popularity because it has many unique properties and is more sustainable than most textile fibers
- Bamboo fabric is light and strong, has excellent wicking properties, and is to some extent antibacterial
- Bamboo fiber resembles cotton in its unspun form, a puffball of light, airy fibers
- To make bamboo fiber, bamboo is heavily pulped until it separates into thin component threads of fiber, which can be spun and dyed for weaving into cloth
- Bamboo fabric is very soft and can be worn directly next to the skin
- Many people who experience allergic reactions to other natural fibers, such as wool or hemp, do not complain of this issue with bamboo
- The fiber is naturally smooth and round without chemical treatment, meaning that there are no sharp spurs to irritate the skin

5.2 Bamboo as culinary

- Bamboo is rich in minerals & high in fiber, which can be a great addition to any nutritious, well balanced diet
- Most food center on the bamboo shoots, which are tender and delicious vegetables, used in numerous Asian dishes and broths
- Frequently used for cooking utensils within many cultures, and is used in the manufacture of chopsticks, yakatori sticks etc

6. INTERNATIONAL BAMBOO TRADE

Despite this progress the present lack of uniform international standards for the vast majority of bamboo products has long stood in the way of further rapid growth in international trade. The need and imperative for establishing an international platform to set standards on bamboo is now more pressing than ever.

6.1 Combining state of art knowledge on current research: Industry processes and trade

The newly proposed ISO Technical Committee for Bamboo will provide the bamboo sector with valuable guidance on terminology, methods and stands for major internationally traded products. The technical committee will firstly focus on publishing basic stands, covering terminology and classification criteria of bamboo and their related products.

6.2 Provide scientific and unified approach for evaluating bamboo properties

The committee will establish standards for methods, covering test methods on the physical, mechanical and chemical properties of bamboo.

6.3 Committee to define standards for internationally traded bamboo products

These standards will guide industry globally, with small and medium-sized enterprises in developing nations being among the main beneficiaries. This will lead to improvements in the processing and quality of bamboo products, enhancing their value and competitiveness in the global market.

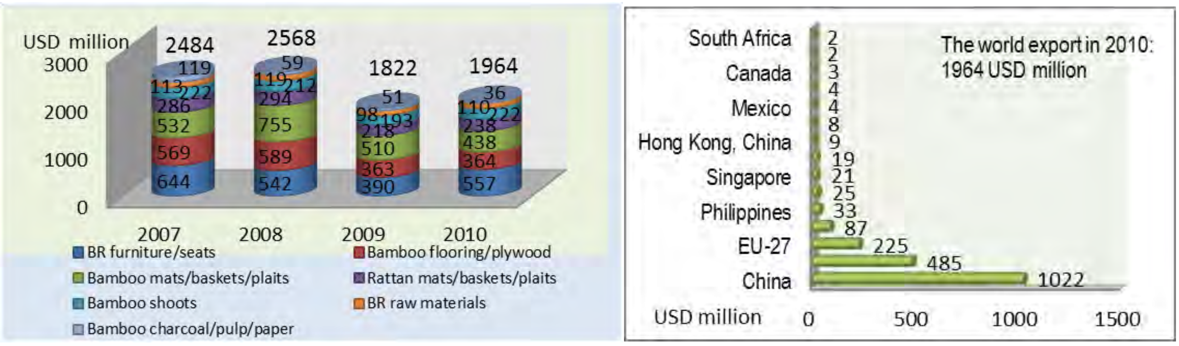

Figure 3: The world export in 2010: USD 1964 million and processing type of bamboo
Source: International Network for Bamboo and Rattan (INBAR)

7. STANDARD SYSTEM OF BAMBOO PRODUCTS IN CHINA

- Standards are applied in bamboo's applications in Furniture, construction, decoration, paper and pulp making, chemicals, textiles, foods, healthcare products, agriculture, electronic and other fields.
- Up to date, China's bamboo related standards include 33 national standards, 70 standards in the forestry sector, 50 industry standards in other sectors and 167 local standards regarding to bamboo and rattan.
- Now there are 19 national standards and 45 standards in the forest sector are under development.

7.1 Policy challenges of developing bamboo industry

- Adjustment of property right of bamboo forest in rural areas: Unreasonable land distribution, forestry right dispute, efficiency and fairness.
- Heavy burden of bamboo farmers: Unreasonable fees charged by local authorities.
- Poor control and management of private bamboo process enterprise: Poor standards and quality control.
- Dilemma of support policies for small-and mid-sized bamboo processing enterprises: Weak R&D abilities and lack of advantage products.
- The sustainable operation system needs improving: The qualification and operation of bamboo forests need improving.
- Bamboo forest insurance: The disaster losses of bamboo forests are not corresponded to the high premium and harsh compensation conditions.
- Early warning of bamboo industry: The market information of the farmers and enterprise are not interrelated, and the information network needs to be improved.

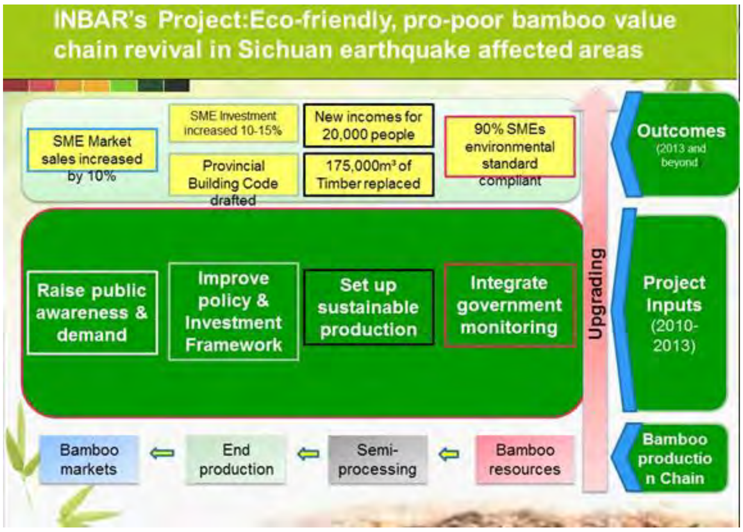
7.2 Policy challenges of developing bamboo industry

- Gradual establishment of GSP system for bamboo industry subsidy policy
- Build up and upgrade bamboo forest insurance mechanism under the financial supports
- Encourage financial organizations to develop financial products adapted to the multiple functions of bamboo industry

7.3 Forestry subsidy policy (Ministry of Finance, State Forestry Administration, 2013)

- Subsidy for forest seedling: 600 yuan/mu for seed orchard and germplasm resource bank, 300 yuan/mu for cutting orchard, and 100 yuan/mu for mother forest and experiment forest;
- Subsidy for afforestation: For artificial afforestation, 200 yuan/mu for arbor forest and woody oil forest, 120 yuan/mu for shrub forest (200 yuan/mu in Inner Mongolia, Ningxia, Gansu, Xingjian, Qinghai, Shanxi and Shanxi), 100 yuan/mu for bamboo forest and other forest including fruit and woody medicine forest; For artificial regeneration and low-efficiency forest improvement, the subsidy standard is 100 yuan/mu. No final cutting is allowed in 10 years for arbor forest established with the subsidy for afforestation from the central finance.
- Subsidy for forest tending: The subsidizing standard for forest tending is averagely 100 yuan/mu, and the subsidy targets young and middle-aged state-owned forest and young and middle-aged ecological forests owned collectively and individually.
- Subsidy for forestry hazard prevention and reduction: Including subsidies for forest fire control, forest disease and pest control, productive hazard relief, and forestry technology extension & demonstration.
- Subsidy for protected areas: Including subsidies for wetland, national forestry natural reserve and closured reserves in sandified area.

Bamboo is a truly unique non-timer forest resource!



8. CONCLUSION

Bamboos' utilization and trade play important roles in many countries, especially in developing countries. Bamboo are commonly called the "poor man's timber", "green gold", and are closely related with people's Livelihood, in some places people say that bamboo are used "from cradle to grave". Bamboos' applications are quite diversified, the bamboo culms can be processed into various products, bamboo shoots can be utilized for food and fodder, the bamboo forests can provide ecological services and develop eco-tourism; besides, bamboo are closely related with civilization in many cultures, they are processed into various art works, and there are different bamboo cultures in many countries in the world. Bamboos are very important for the livelihoods of the people in the producing areas. Now we must use much more bamboo products, especially to improve our built-environment, where these are much scope and room for applications; as demonstrated in the Hang Seng Management College in HK.

ABSTRACT

Empowering war victim community is a challenge where people live in extreme poverty line and left with limited choices to fulfil fundamental needs. While conducting the post war reconstruction programmes lot of international donors were raised hand to support the development of war victim communities, cause Sri Lanka is still a developing country. But, prior to develop the local community there was an urge to understand the local conditions and then sustain their demands. Thus, it was understood using appropriate, sustainable building construction technologies would be a highly viable solution to boost up the process. Within this process Mud-Concrete technology was introduced to build the community centers for identified war victim communities in Batticaloa. Mud-Concrete technology is a novel concept which was developed through utilizing readily available materials and using locally available cost effective resources. This paper explores a conceptual framework, that how an appropriate, sustainable and innovative building technology could serve to empower the war victim communities within their context. Further, it concludes the three stages of research process of introducing the Mud-Concrete technology to local communities and how they bridged together in reaching empowerment within the revitalising programme.

Keywords: community Empowerment, appropriate technology, sustainable building material, Mud-Concrete technology

1. INTRODUCTION

Community empowerment bring up the process of helping communities to growth control over their lives. "Communities" are groups of people that may or may not be spatially connected, nevertheless who share common wellbeing, or identities. ("WHO | Track 1," 2009) These communities could be local, national or international, with specific or broad interests. 'Empowerment' denotes to the process by which people gain control over the factors and decisions that shape their lives. People cannot "be empowered" by others; they can only empower themselves by obtaining more of power's in different forms. (Laverack and Keshavarz Mohammadi, 2011) Empowerment is a powerful approach for solving many community problems. (Kasmel and Andersen, 2011) Within the process of empowering the community, selecting an appropriate technology is an important factor. It should be the ultimate goal of any community development projects.

Appropriate Technology is a concept which represents providing for human needs with the least effect on the Earth's limited resources and it will fill in the gap to make over community development into community empowerment. (Wicklein, 2004) Appropriate technology is based on the idea that advanced technology is often inappropriate for the needs that it is attempting to address within developing countries. The principle behind Appropriate technology curtails the use of non-renewable resources to solve technological problems while encouraging self-confidence. (Wicklein, 2004) According to Robert Wicklein, if technology matters to people, there's a criteria to judge the appropriateness of the technology. (Wicklein, 2004)

DESIGN CRITERIA	DESCRIPTION
Systems-independence	This criteria refers the capability of technological devise to perform the job with minimum supporting facilities
Image of modernity	People must believe the technology should raise their social status as well as meet the basic human needs.
Individual technology vs. Collective technology	Technology must tally with the cultural norms of its community/society. Then that will be the most appropriate technology which will provide the best service to that society.
Cost of Technology	The reduction of costs is an urge, when designing technological devices for developing countries. The cost of the device must be reduced significantly for the people to afford the expense. Thus it could help to meet the basic needs of life.
Risk Factor	The risk to the success of appropriate technology must be considered in detail but not necessarily be totally removed.
Evolutionary Capacity of Technology	Appropriate technology should allow for (i.e., have design characteristics) a continuation of development. This technology should capable to expand and be reconfigured to undertake a higher volume of work or mass production.

Table 1: Design criteria to judge the appropriateness of technology (Wicklein, 2004)

It is clear that rural communities must be transformed to reach empowerment and it will make sure the continuity of sustainable development. In order to get sustainability among rural communities, technology become a booster to reach it. Predominantly, appropriate technology have a strategic position among the transformation process. There were three logical stages have been identified in appropriate technology in community transformation such as development, sustainable development and then empowerment. According to Sianipar et al, frame work of empowerment has been concluded as below. (Sianipar et al., 2013)

	Triple bottom line in sustainable development		Trio perspectives of appropriate technology	Three parties in community empowerment
	Social	People	Social	Community members
	Environment	Planet	Technical	ACADEMIA
	Economic	Profit	Economic	Government
DEVELOPMENT	→	SUSTAINABLE DEVELOPMENT	→	EMPOWERMENT

Table 2: Framework of empowerment (Sianipar et al., 2013)

When considering about sustainable building materials 'Soil' can be considered as a sustainable raw material which has been used extensively for building construction since ancient times, particularly in developing countries. (Al-Ajmi et al., 2016) Soil-based construction has been very popular in ancient times, though it is not so in the present context of the industry. These Earth based techniques are becoming unpopular day by day due to social believes on their strength and durability parameters. Also it is considered that these technologies only employ for poor who runs with low cost budget though these products got eco manufacturing process. Therefore, the attempt is to incorporate the strength and durability parameters of concrete to mud-based constructions and combined the traditional techniques with modern technologies to provide a highly sustainable material for future of construction.

Thus, Mud-Concrete Block (MCB) could be introduced as one of the recent Soil-based product has been developed and patented under Intellectual Property Act No.36 of 2003. (Halwatura, 2016) It discloses the Mud concrete block is a novel product which employs a 'Concrete' made using soil. It is a mixture of soil, cement and water. Mud concrete block comprising, a mixture of fine <10% (≤ sieve size 0.425mm), sand 55 - 60% (sieve size 0.425mm ≤ sand ≤4.25 mm), gravel 30 - 35% (sieve size 4.25mm ≤ gravel≤ 20mm), at least 4% cement and water 18 - 20% from the dry mix. Mixture of Mud-Concrete block could pour into the block moulds without any compaction and then curing to obtain the required strength.

Therefore, it is worth to consider how and why Mud-Concrete technology could use or convert as an appropriate sensitive technology in community empowerment projects in developing countries. Following case study was mainly a beneficiary participant project which conducted in war-victim areas in Batticaloa. Financial assistance was given by foreign donor agencies. General technical advices and the assistance on the new technique as well as the implementation targeting the quality and cost reduction was done by inventors' who were relating to academia. In order to develop the social interaction within immediate community the international donors & Non-Governmental

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

organisation (NGO) were proposed to build a prototype model of community centers in identified areas. The goal of a new community centres set in create a unique place that will unite people in a neighbourhood by providing a setting that will bring the community together, once again. The principle element that these war victim communities lack is a cultural or social bond. By providing a place where members of the community can gather together, celebrate and share their different cultures will ultimately create a new cultural and social bond within the neighbourhood and the greater community. Also by providing a place for everyday activities to take place within the community, rather than remote from its core, will allow for more social interaction.

2. METHODOLOGY

Empowerment as transitional process of a community should be understood completely through scientific thoughts as well as real field problems. (Sianipar et al., 2013) Therefore, three main stages have been identified in the process of empowering the community through a newly introduced building technology.

Stage 01: Research through material innovation - Testing in Laboratory

Stage 02: Identifying the real wants, needs and constraints of the war victim community and adjusting the technology according to the context & people – Taking part discussion of technology, people and interaction

Stage 03: Research through building process - Practice in field

3. DISCUSSION

3.1 Stage 01: Research through material innovation - Testing in Laboratory

The novel concept of Mud-Concrete technology was introduced, in order to develop the strength & durability of soil based construction. Mud-Concrete employs a 'Concrete' made using earth/ soil. Concrete is a composite construction material made out of cement, sand, metal and water. Here, metal (coarse aggregate) governs the strength, cement acts as the binder and sand (fine aggregate) reduces the porosity and water acts as the reactor to cement. In Mud-Concrete, the intended functions of sand and metal of concrete are replaced by fraction of soil. The precise gravel percentage governs the strength of Mud-Concrete. The cement in this concrete is also used as a stabilizer in very low quantities. According to gradual experiment process, the best mix proportions of unique Mud concrete block is achieved through fraction of soils, with minimum cement percentage and optimum water requirement which allows its self-compacting nature. Excess water in the mix will create a porous structure that will later act in cooling the building through convection. This will increase the thermal comfort of the interior than other earth based constructions. Unlike conventional approaches to mud based construction, the MCB as a sensitive technology explained significant innovative ideas which could utilize people ambitions in real world construction.

3.2 Stage 02: Identifying the real wants, needs and constraints of the war victim community and adjusting the technology according to the context & people – Taking part discussion of technology, people and interaction

First of all, several presentations & workshops were conducted to introduce the Mud-Concrete technology to donor and beneficiary communities by inventors. Then selected sites for construction have been visited and soil samples were borrowed for tests. Then the all soil samples borrowed from the proposed sites were analysed at laboratory and introduced possible techniques to bring the soil up to required level. Sample Mud-Concrete block walls were constructed for exhibit to local people and make them familiar with the appearance and the modernity of the block, prior to introduce the technology. Donors and beneficiaries community in the area was identified "Mud Concrete technology" as an appropriate cost effective technology. Therefore, three community centres out of six were decided to construct using Mud-Concrete Blocks.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 1: Borrowed soil samples from each site were tested in laboratory and develop the soil up to required level of construction

3.3 Stage 03: Research through building process - Practice in field

Training programmes and workshops were conducted to introduce the technology to people and maintain a responsive relationship with the local community. Through this programmes skilled and unskilled labour force was identified within the community. Community labour was used to cast the Mud-Concrete blocks at sites. 225mm x 200mm x 150mm size blocks were casted for construction the walls. Cement 1: soil 3: and sand 4 Mortar proportion were used during the masonry construction. Sieving the soil and sand from a mesh size of 6mm is essential in case of removing the coarser particles and to achieve good homogeneity of the mortar in the joints between the blocks. The water content of the mortar is decided by achieving a good workable mix. Once the foundation was done the floor concrete was laid to get a uniform surface to do the block casting. This will make sure a continuous water seal membrane at the foundation level and hence, it will minimize/ totally eliminate water movements due to capillary action as well as can reduce the termite attacks. Further, with this a good workable platform will be created and hence, quality of block production will be endorsed. Project cost also can be reduced by avoiding brick work at the foundation level. Foundation work was kept for 14 days to achieve the strength and until that the labours at the site were used to cast the blocks. 120 blocks were made for a day and the total requirement was 2750 blocks for the whole buildings. As an average amount, 20 days were required to cast the blocks for construct a community building. Hence when the site is ready for waling, the blocks were ready. Several work studies were carried out to find the optimum construction labour/ machinery cost. Several trials were done with 1-3 moulds and found the best as to have 2 laboures at each site while sharing the production cost of 3 moulds among more than 2 sites, to gain the best cost saving for the buildings. With the careful and continuous supervision, the labour cost of a block can be reduced from LKR. 31.20 to LKR.7.15 and this will lead to an extra cost saving of Rs.60, 000.00 by having 3 laboures at the site with 2 moulds and increasing the number of cycle of casting. The calculations are based on reusing of the moulds for at least 10 sites. Further, study was carried out to minimize the Material cost through optimizing added cement from 8% to 4%.

Figure 2: Educating the community people through the building process

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

During the site visits, successful progress was observed towards using MCBs. Then the Form work was developed and introduced most optimum way of casting the blocks with the available resources to maintain easy manufacturing through less involvement of technology. The working community has grasped the essence and the correct technology of casting procedures. By improving the timber mould into steel moulds and having 4" and 6" moulds within the steel frame gives the evidence that the community is satisfied with the MCBs and has optimistic view towards the technology and reflects their attempts of improving the technology more conveniently. According to the project records, the typical prototype modelled community centers constructed through Sand-Crete blocks was cost 2.995 million and Brickwork (rat trap bond) was cost 2.966 million. But the community center constructed through Mud-Concrete block technology was cost only 2.84 million and the technology saved nearly 0.1 million from a building and saved 0.3 million from three projects which constructed at Batticaloa. To control the quality of work, there was a necessity to pre-plan for controllable failures. Therefore, easy handling simple tools were introduced to levelling and aligning the mortar joints and construction of walls. Continuous monitoring and quality controlling measures were provided by inventors/ academia and technical officers during construction and up-to completion of the project.

Figure 3: Easily handled simple tools & techniques were introduced to maintain the quality of construction

4. CONCLUSION

Though there were different walling materials were introduced to build the community centres in identified areas in Batticaloa, Mud-concrete technology was identified as a highly viable solution which could use locally available soil in construction sites. When comparing with the other walling materials MCB took a prime place in load bearing, durability and thermal comfort while maintaining low embodied energy. Further, the Mud-Concrete technology is able to,

- Save cost, quality and time,
- Maintain the flexibility in production, assembly & use,
- Cater the human errors of design, manufacturing and use,
- Flexible enough to adapt for social circumstances,
- Allow to increase the labour productivity and educate the community through the building process.
- Acknowledge all participating groups in the process and transfer of the knowledge across the construction sector.

Thus the research process of Mud-Concrete technology, achieve its appropriateness to the context through stage by stage in empowering the war victim community in Batticaloa.

Figure 4: One of the completed community center building made out of Mud: Concrete Blocks in Batticaloa

DESIGN CRITERIA	DESCRIPTION
Systems-independence	MCB technology is capable enough to standalone, to fulfil the community needs. No need advance techniques or methods. Technology was develop through locally available materials and construction could continue with using simple tools.
Image of modernity	MCB technology is coming with new appearance, textures and colours. Technology is assured with strength & durability aspects. There is a flexibility in finishing work, to achieve different Architectural languages.
Individual technology vs. Collective technology	MCB technology could practice either as an individual technology (ex: construction of individual houses) or as a collective technology (ex: construction of community centers). Technology is flexible enough to adapt according to the context and society.
Cost of Technology	Lot of strategies were used in cost reduction. Starting from raw material (ex: locally available materials) to end product, all the stages in construction were optimised to reduce the cost of block and the construction process. No need advance technologies or advance tools. Technology was flexible enough to make the skilled labour force through the construction process within the community.
Risk Factor	Strength & durability aspects were tested according to the universal standards when developing the technology.
Evolutionary Capacity of Technology	Technology has the capability to expand and be reconfigured to accomplish a higher volume of work and/or more sophisticated production processes. (Udawattha et al., 2016)

ABSTRACT

In the construction sector, cement and concrete are responsible for 8% of total CO_2 emission and this value will increase with respect to the global population growth. Developing a sustainable and green constructive materials for future generation became an urgent need. Without transport needs and with infinite recycling possibilities, earth is one of the building materials with the lowest environmental impact. However, its development is hindered by the time and the manpower required in conventional earthen construction techniques. The purpose of this research is to develop strategy for earth-based material that would be as easy and as cheap to use as current concrete products, then implement it at mortar scale.

To do so, we focused on the modification of earth binder: clay. With the use of sodium hexametaphosphate (NaHMP), we improved the fluidity which allow to cast easily the material; then with addition of magnesium oxide, we enable an internal coagulation during time. Rheological tests show the effect of additives at level clay paste. Furthermore, on the mortar scale, we show that not only NaHMP improve the workability of the clay based concrete but also increases the compressive strength. More, the coagulant also enables the acceleration of formwork removal but also influence the final compressive strength. As main findings, water content, the percentage of dispersant, the ratio coagulant-dispersant are relevant parameters to improve earth based concrete mechanical properties.

Keywords: climate change, innovative process, deflocculation-coagulation

1. INTRODUCTION

Without transport and with infinite recycling possibilities, earth is one of the building materials, with the lowest environmental impact (Anger, 2009; Morel et al., 2007; Shukla et al., 2009), used in most climate and society. Additionally, it provides a very efficient temperature and moisture regulation of indoor living spaces (Parra-Saldivar and Batty, 2006). Nowadays, we can observe a strong development of earth construction due to the current environmental threats. However, it development is limited as the conventional earth construction techniques are time and cost intensive. On the other hand, we have cement and concrete, which are an incredibly easy to use material with a significant environmental impact (Schneider et al., 2011). While science and engineering efforts were invested to improve the understanding and the processing of cement-based concrete, few research and engineering improvements have been brought into earthen material (Ouellet-Plamondon and Habert, 2016).

The objective of this study is therefore to transform earthen architecture by providing a material that is as easy and as cheap to use as current concrete products, thanks to novel technologies borrowed to science and technology of cement and concrete. This technology transfer can be done as cement and clays have a lot of analogies in terms of colloidal interactions and adhesion forces (Pellenq et al., 2008). Though, the cohesion forces between clay particles are much weaker as no chemical reaction occurs in presence of water.

To improve the material fluidity while working at low dosage of water, a careful control of the rheology of clays requires a better understanding of colloidal interactions between particles and knowledge transfer from the fundamental physics of grain and colloidal interactions to the civil engineering. As unique binder in earth, clay, an inorganic negatively charged particle, can have its surface interaction changed with the help of dispersants mainly coming from the ceramic industries. Among common dispersants used, we focus on the use of sodium hexametaphosphate known to guarantee an efficient dispersion of natural clay minerals (Andreola et al., 2006).

On the contrary clay flocculation can be achieved through the introduction of calcium or magnesium ions coming from the dissolution of natural minerals. These ions interact both with the surface of clay particles, the deflocculant and the ions release in solutions (Andreola et al., 2006).

In this paper, we focus on the strategy used to develop a self-compacting clay concrete SCCC at the clay paste scale by modifying the surface charge and the rheological behaviour of earth binder. Then we investigate on the mortar scale the effect of dispersant and coagulant on the final compressive strength. Moreover, we discuss the influence of dispersant on the porosity and the arrangement of clay particles in the mortar.

2. METHODS

2.1 Materials

The studied clay; kaolin FP80 powder is a commercially available clay supplied from Alberto Luisoni AG, Switzerland with a specific density 2.62 and a specific surface area $SSA_{BET} = 9.10\ m^2.g^{-1}$. The mean particle size assessed by Laser Particle Size Analyzer is 8.69µm. The mineralogical phase quantification, the purity of kaolin clay was determined by X-Ray diffraction which reveals that more than 87% of kaolin FP80 is kaolinite clay; specifically a non-swelling clay minerals.

The dispersant investigated in this study is an inorganic deflocculant sodium hexametaphosphate noted here NaHMP sourced from Fischer Chemicals in powder form. Magnesium oxide in a powder form (MgO, 98% purity; Sigma Aldrich) is used as coagulant

2.2 Experimental process:

2.2.1 Rheological measurements

Rheology measurements were carried out on clay pastes in order to study the effect of dispersants on the rheological properties of the suspension such as the yield stress. To compare the results obtained from different measurements, the water to clay ratio (W/C) for clay paste was kept constant. Only the dosage of the dispersant was varied from one sample to another. In this paper, all dosages are expressed as a percentage of the mass of solids in the system and water is deionized. The tested clay pastes were prepared using the following mixing procedure: the dispersant is added to the required amount of mixing water in order to ensure its dissolution before introduction into the solid phase. Water (with or without dispersant) is mixed with clay during 3min at 365rpm with a mechanical stirrer.

The rheology measurements were carried out using a Malvern Kinexus Lab+, a rotational rheometer equipped with vane geometry at room temperature (23 ± 0.1°C). Ten minutes after the first contact of constituents, the cup of the rheometer was filled and covered to limit evaporation, and the sequence was started. The flow curve data acquisition cycle is as followed: an increase ramp from 0.1 to 300 s^{-1} in 300s considered as a pre-shearing to ensure that all samples were in the same reference state of stress then a decrease ramp from 300 to 0.1 s^{-1} in 300 s. The yield stress is obtained at low shear rate during the decreasing ramp using the Bingham model. At this low shear rate, the viscosity effects were negligible.

2.2.2 Mortar sample preparation and testing procedure

To study the mechanical properties and to confirm the adopted SCCC strategy, a model earth mortar is used. The mortar is composed of a binding phase: here kaolinite paste and solid phase: sand (Figure 1).

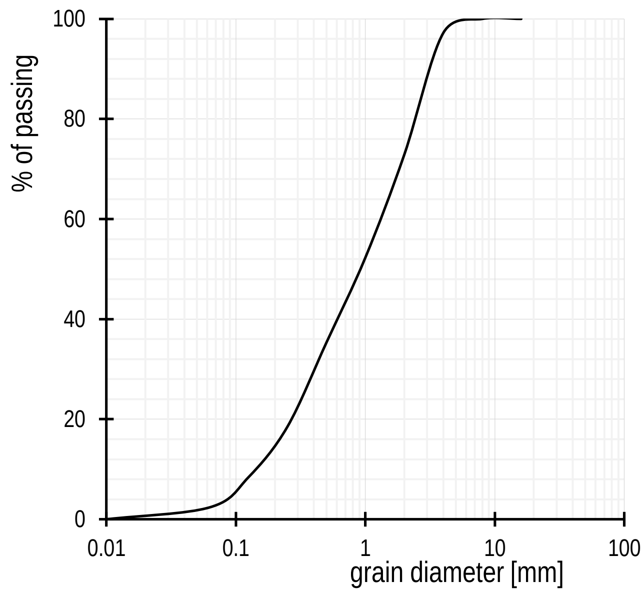

Figure 1: Grain size distribution of sand

The samples were prepared by homogenizing first at dry state sand and clay. Then the liquid phase (water with or without dispersant) is added to the dried grains particles. The samples were mixed then with help of automatic mixer (Laboratory Mortar Mixer, MATEST) for 2 min in order to have a homogeneous consistency. After 2 minutes, the coagulant was added to the mix and homogenize again for 2 minutes. For each samples, 4x4x16 cm mold are filled. The samples are after dried in oven at 105°C to ensure a stability of weight before measurement of compressive strength. The measurements are done using Unitronic 50KN (MATEST) adapted for soil.

3. RESULTS AND DISCUSSIONS

3.1 Strategy for SCCC: Level of clay paste

3.1.1 Defloculation process: Effect of dispersant and stability

The Figure 2 left reports the evolution of yield stress of clay paste as a function of amount of dispersant. It compares the efficiency and the stability range of concentrated clay suspension in presence of NaHMP. The full line represents rheological measurement right after mixing (3min) and the dash line is measurement done after 300 min. To visualize the efficiency of dispersant, the reference paste has a higher yield stress; around 1000Pa; with no workability. The yield stress characterize the force needed to induce flow of suspension. Higher is the value difficult it is to deform the material.

As expected the yield stress decreases with progressive addition of NaHMP. In this regime, the yield stress of the reference paste is significantly reduced and the minimum yield stress is reached at 0.3wt% NaHMP (0.1Pa). At such yield stress, it is observed that the paste is fluid to be cast and does not show any sedimentation with respect to the experiments time. More the dispersants are stable during time as the range of evolution of yield stress are narrow. This results strengthen existing findings highlighted in literatures (Andreola et al., 2006; Landrou et al., 2016). NaHMP is then a robust and efficient deflocculant as the percentage needed to obtain a fluid suspension is low and the yield stress is reduced by factor 1000.

The decrease of yield stress as highlighted in (Landrou et al., 2016) is due to the adsorption of negatively charge phosphate ion in the positive clay rim. This implies an increase of negative surface charge and allow an electrostatic repulsion between clay particles. Indeed it was observed by doing zeta potential measurement that at 0.3wt% NaHMP, the surface charge is above -66 mV. The contact between (-) face / (-) rim is reduced and the formation of weak agglomerate is avoided due to the long range interaction between clay particles after adsorption of phosphate ions.

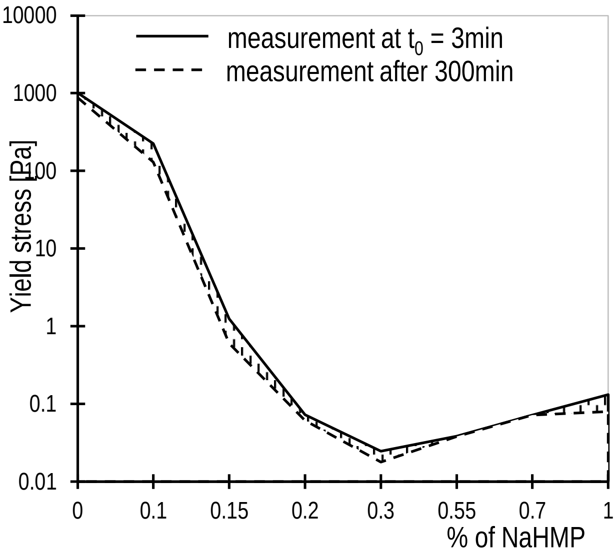

Figure 2: Semi-logarithmic plot: Evolution of yield stress measured for a concentrated clay paste containing different dosage of NaHMP Rheological observation of effect of dispersants and their stability

3.1.2 Coagulation process: Effect of MgO addition

We plot in Figure 3 the yield stress as function of experiment time. The graph represents the rheological behavior of coagulated clay suspensions during time. After addition of MgO to the dispersed paste, it is noted that at t0 that the paste is still fluid and workable to process. However the yield stress increases during time

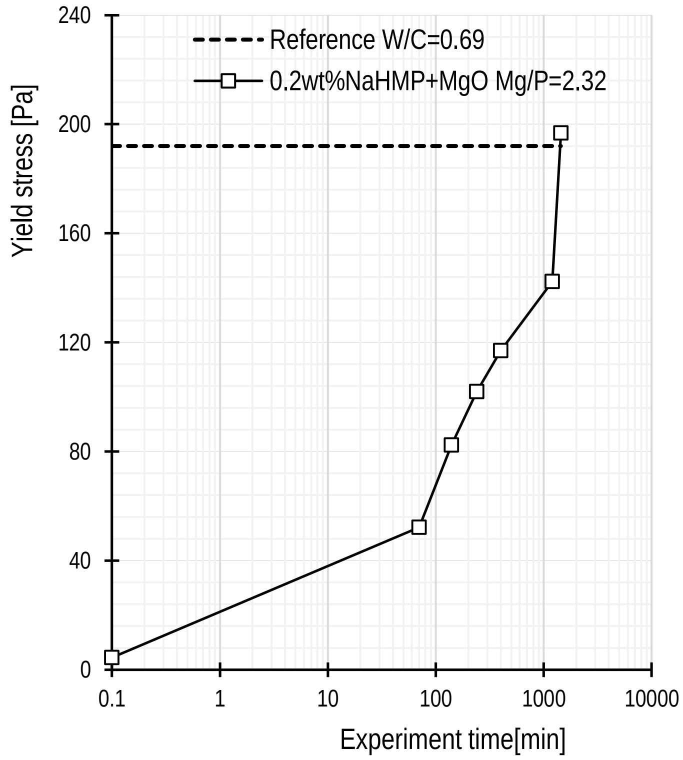

Figure 3: Variation of the yield stress versus experiment time for mixture of kaolinite + 0.2wt%NaHMP + MgO

Contrary to Figure 2 left where the value of yield stress doesn't change during time, the yield stress measured in presence of MgO increases during time which refers to an irreversible rheological behavior. We can suggest a chemical reaction between ions in solution and MgO which allow the hardening during time. MgO action is then highlighted as it delays the coagulation while accelerating the formwork removal. Magnesium oxide acts as anti-plasticizers. Indeed, similar phenomenon is observed in (Landrou et al., 2016) when Ca(OH)2 was used instead

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

of MgO. The authors stress that calcium addition increases the storage modulus during time due to a reaction between calcium and phosphate to form an Apatite based mineral. Furthermore, they reported that the reaction is irreversible and suggest that the delay of hardening can be controlled by the dissolution rate of coagulant.

At this stage, we stress that the deflocculation and coagulation strategy adopted allow the development of SCCC. In fact, using NaHMP allows to fluidify clay based materials at low water while adding magnesium ion allows to coagulate the suspension which harden during time.

3.2 Optimization of mix design: Level of clay mortar

3.2.1 Influence of sand and water content on compressive strength

In the Figure 4, we plot the compressive strength versus the ratio sand/ paste for different mixture. The graph illustrates the influence of water ratio on the compressive strength. As expected, at high water to clay ratio the compressive strength determined is low. More, it was observed sedimentation and bleeding problem at high water content.

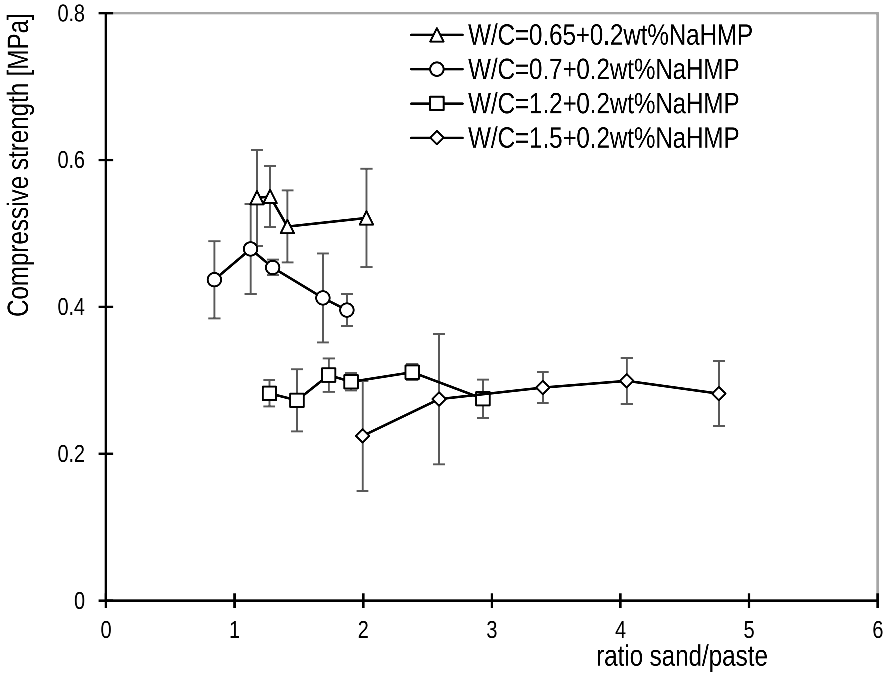

Figure 4: Variation of compressive strength with increase of ratio s/p (sand/ paste) for different mortar mixtures: Change in W/C (water to clay) ratio at constant dosage of dispersant

While the influence of water is anticipated, the influence of sand content or ratio sand/ paste seems to play minor effect on the final mechanical strength even though at low ratio W/C, a maximum can be observed. In fact at high water to clay ratio, the porosity is high and problem such as sedimentation occurs which influence the final strength.

3.2.2 Influence of additives on the mechanical property

In the Figure 5, we illustrate the relationship of NaHMP addition on the compressive strength measured after drying of the sample and stability of the weight. As mentioned in Figure 1, the addition of NaHMP enhance the workability of the clay paste with the reduction of the yield stress. This finding is also highlighted at the mortar level as clay behaviour control the fresh state behaviour of the mortar. However, the graph shows an increase of compressive strength while increasing dispersant amount.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

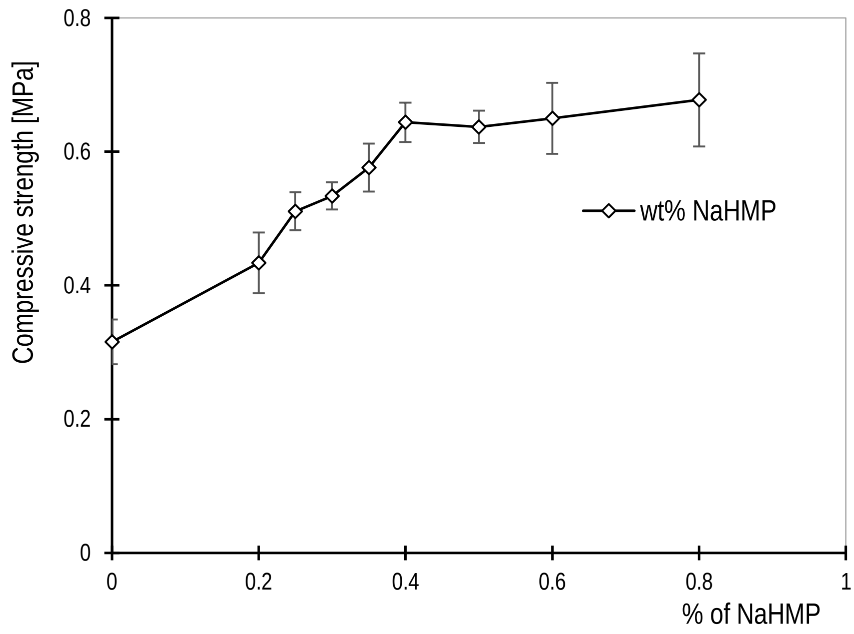

Figure 5: Relationship between the dosage of dispersant and the final strength for a mortar mixture of W/C=0.7 and ratio s/p (sand/paste) = 1.69

The results, even though surprising have been reported recently in (Moevus et al., 2016). It suggests that the compressive strength increase is related to clay re-arrangement at high dosage of dispersant. At low concentration of NaHMP, even though Figure 2 shows a low yield stress, addition measurements as zeta potential measurement reveals not all clay particles are deflocculated while at high dosage the percentage of surface cover by phosphate anions is high. This implies less contact face (-) / (-) edge between clay particles but more a slow contact face (-) / (-) face (Lagaly and Ziesmer, 2003). This re-organization might allow the reduction pore size.

Furthermore, Table 1 reports an increase of compressive strength while increasing the ratio of magnesium to phosphate (Mg/P). Meaning that the deflocculation and coagulation strategy develop to achieve a SCCC improve the final compressive strength of the mixtures.

	Reference	0.8wt% NaHMP	0.8wt%NaHMP+ MgO (Mg/P=1.67)	0.8wt%NaHMP+Mg O (Mg/P=4.85)	0.8wt%NaHMP+ MgO (Mg/P=5.73)
Compressive strength [MPa]	0.31 ±0.03	0.63 ±0.07	0.72 ±0.01	0.82 ±0.06	0.91 ±0.13

Table 1: Evolution of compressive strength for different of mortar samples prepared at water to clay ratio (W/C) of 0.7 and ratio sand to paste (s/p) of 1.69

These findings enable us to determine the key parameters influencing the different steps during the development of a self-compacting clay concrete (SCCC)

4. CONCLUSION

Strategy that has been tested is promising and allow developing a process to cast a clay based concrete as easily as a cement bound concrete. Through a modification of clay properties, adding NaHMP leads to a strong deflocculation of clay particles by creating repulsive forces between particles. The yield stress is reduced and earth material becomes fluid to be poured in the formwork. Then, the addition of magnesium allow to accelerate the hardening process through the dissolution of magnesium and the chemical reaction between magnesium and ions releases in pore solution.

Furthermore, on the mortar scale, we show that not only NaHMP improve the workability of the clay based concrete but also increases the compressive strength. More, the coagulant also enables to accelerate formwork removal but also influence the final compressive strength. As a consequence, water content, the percentage of dispersant, the ratio coagulant-dispersant are relevant parameters to improve earth based concrete mechanical properties, however further works need to be done to identify the effect of bigger aggregates on the compressive strength, but also the morphology of the aggregates and quality of paste on the final strength.

Trend of Dynamic Glass in Green Building

HY CHIU[a]

[a] *Full Treasure, Hong Kong SAR, hychiu@fulltreasure.com*

ABSTRACT

After hundred years (200 to 300 years) when "redox-coloration" chemistry has been discovered; and the research and development on "electrochromism" which has been published for the recent fifty years; and a decade of the emergence of the electrochromic and thermochromic glass in the market, dynamic glass is one of the new trends in the green building development and help earning credit points for green building certification.

Tint of the dynamic glass is adjustable (tintable, darkened from clear) as an automatic sun-shading device when it responses to the environment which is dynamically changing including sunlight, temperature and weather. Chromogenic material is used in the dynamic glass which is darkened at the presence of a physical property (such as heat, ions, UV or gas) and returning to clear when the property disappears.

Electrochromic (EC) and thermochromic (TC) and are two of the major chromogenic technologies found in the market, nowadays, as the dynamic glass in building industry, such that they change color in response to the presence of ions and heat, respectively.

The benefits of dynamic glass in buildings is to reduce the solar heat gain, UV and glare without any shading device(s), either external shading and side fins or internal blinds and curtain, and without reducing the natural daylight performance because it is always see-through, and hence enhancing the comfort level of occupant at any time. The SHGC (solar heat gain coefficient) per each dynamic glass is typically varying from 0.1 to 0.4 with the Tvis (visible light transmission rate) from 6% to 60%, respectively. The reduction of solar heat gain, cooling electricity consumption and peak cooling loading is better than the conventional low-E glazing by 58%, 10% and 22% respectively, and hence the overall energy cost saving is 17% to 30% which makes it the next generation of glazing in buildings.

Keywords: energy saving, high-performance building, dynamic glass

1. INTRODUCTION

Since 1990's, the conscious about environmental protection had led to the "green" considerations in the design and construction of buildings in order to reduce the harms to the earth and optimize the limited resources in the earth. The standards of green building therefore emerged.

The needs of improving quality of life and the awareness of people about their health, well-being, comfort level, happiness and productivity in the built environment lead to the re-thinking about the design of buildings. Besides, the relationship between humans and the nature when they are in the buildings are also addressed. More interaction of the occupants with the nature is enabled for the new design of buildings. People are seeking for balancing to the harmony between humans and nature as it had been practised in the ancient countries. It is an extension of the section of IEQ (indoor environmental quality) in the green building certification standards to more human-oriented consideration about human-nature relationship and again to be standardized as "well building".

Therefore, it is to investigate the re-thinking about interaction and relationship between humans and nature in buildings including: daylighting-to-health, daylighting-to-productivity, natural view-to-human; and how the dynamic glass can help in the aspects. The application includes windows, facades and skylights of buildings.

1.1 Role of window in buildings

Building shall be not only a shelter of humans, but also a comfortable place for them to stay in and minimizing the harm to the earth when either the construction of the building or post-occupancy. Window (and skylight) is one of the major interfaces between humans and nature in buildings.

However, architects are always facing the trade-off between visible light transmission and solar heat gain when designing windows because of the nature of sun light which is a spectrum of ultra-violet (UV), visible light and infra-red (IR) with wavelength of 10 to 400nm, 400 to 700nm and 700nm to 1mm, respectively. When designing window, architects always want the clearest and the largest glass panel the possible to maximize the view and connecting to outdoor for occupants. But it is also the most energy consuming because of the greatest heat transfer through the glass is by radiation (solar heat gain), which is the primary mode of heat flow including conduction and convection; and accounting for over 50 to 93% of heat flow from different directions of buildings.

Therefore, additional design of shading such as external shading, overhang above windows, automatic sun-shading device, internal blinds, shades, curtains; and the orientation of the building facing to the sun over a year are considered to prevent excess energy for HVAC about cooling and heating load in summer and winter, respectively.

However, the blinds or shades remain shut in 59% of area of windows and over 75% of buildings have more than half of their windows are shut by blinds or shades. This includes residential and commercial buildings. This means the function of windows in building is not fully utilized as designed.

As a result, the shade – becomes an unexpected barrier between the occupants and the outdoor view. It may cause decreasing the productivity and health of occupants, gradually, who are not aware.

As part of the evolution of glass over thousand years, dynamic glass can help eliminating the barrier of disconnecting occupants and outdoor view in traditional window and shading system and without compromising the view and solar heat gain.

1.2 Humans in buildings

Productivity of occupants in office will be increased by direct daylighting and/ or natural view available to them, because daylighting enhances positive attitude, improving mood, holding attention, lower absenteeism, fewer errors or defects in products, reduced fatigue, and reduced eyestrain, reducing stress, decreasing anxiety. Proper use of daylighting decreases the occurrence of headaches, SAD (seasonal affective disorder) and eyestrain. People have different response to open view and reflecting on their behavior and activity in building. For example, the garden view enhances the creativity of the occupants.

This can be achieved by having employees closer to windows may have contributed to the productivity increase from 5% to 25%. If it is quantified in hourly salary of employees in the office, the financial benefits is far significant more than that from the energy saving from low-e windows using nowadays. In fact, many countries in Europe require that workers be within 27 feet of a window (Franta and Anstead 1994).

The importance of daylight and large windows in school is also reflected on the finding of 7 to 18% higher scores of students in most daylighting classroom than those in rooms with the least. Their classrooms progress is 20% to 26% and 15 to 23% faster in daylighting and the largest window classrooms, respectively.

Dynamic glass resolves the trade-off between the undesired excess energy from sunlight and the human comfort, that is found in the traditional glass. Therefore, it is a trend that the user-friendly dynamic glass is used in buildings because occupants are beneficial from not only the energy saving by reducing the solar heat gain as low-e glass, but also the reconnecting of human-nature relationship by its capability of self-tinting and sun-shading; and the improvement of their well-being in the buildings.

1.3 Chromogenism in dynamic glass

Chromogenic material is used in the dynamic glass of which the optical property is changed at the presence of a physical property (such as heat, ions, ultra-violet or gas) and returning to clear when the property disappears. It is a reversible process.

Electrochromic (EC) and thermochromic (TC) are two of the major mature chromogenic technologies found in the market, nowadays, as the dynamic glass in building industry. They change the light transmission in response to the presence of ions and certain amount of heat, respectively.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Photochromic material changes the light transmission because of the presence of ultra-violet (UV). It is commonly used in sun glass.

Gasochromic material changes the light transmission because of the presence of particular gas.

SPD (suspended particles device) is controlled by electrical voltage on the liquid-like layer in which numerous microscopic particles are suspended. It changes from clear to dark when voltage is applied and vice versa. In its unpowered state the particles are randomly oriented and partially block sunlight transmission and view.

PDLC (polymer dispered liquid crystal) has been in the market for over 25 years. It is also found in the glass called switchable glass for privacy control as the glass changes from opaque to clear when voltage is applied to the PDLC. In its unpowered stage, the PDLC molecules orient randomly to diffuse light transmission and hence leading to opaque. When voltage is applied the molecules orient in the same direction of light so the light can pass through and hence transparent.

Thermochromism and photochromism are classified as passive control as their self-tinting property; and the electrochromism, gasochromism, SPD and PDLC are classified as active control as color (or tinting level or the degree of darkness) can be manipulated by the user.

2 DYNAMIC GLASS

Over centuries, the studies in the optical effects in electrochromism were developed. For example, the early discovery of Prussian Blue as an excellent dye by Diesbach in 1704, . Berzelius , reported in 1815 about color change in tungsten trioxide with hydrogen. Wöhler, reported in 1824 about color change in tungsten oxide with sodium. Kobosew and Nekrassow, found that the tungsten oxide powders could be colored blue by electrochemical reduction in 1930. Brimm et al , mentioned in 1951 about the reversible color changes. The electrolytic recording paper was proposed by Talmey,], in 1942 for the electrochromic device. A description of electrochromism in W oxide films was made in 1953 by Kraus , . The term “electrochromism” was introduced by Platt , in 1961. S.K. Deb’s publication about electrochromism in W oxide films in 1969, and 1973, are the widely known and cited paper.

The term “smart window” was coined in 1984 by Svensson and C.G. Cranqvist., , . The works and published by Chang (in 1976), Faughnan and Crandall (in 1980), Byker, Harlan J. (in 1994) and C.G. Cranqvist (in 1995) , Monk, Mortimer and Rosseinsky were the important sources of literature in the development. Electrochromic mirror was developed as the rear-view mirrors in automotive market in 1994 to reduce the headlight glare from the vehicles behind. The evolution of chromogenic materials entered into commercialization in the building market since the recent decades.

2.1 Electrochromic – The product

When some of the metal oxides are ionized, it is colored; and it is reversible to colorless when de-ionized. Visible light is retained transmitting through by the electrochromic (EC) glass in the light spectrum during the action, as shown in Figure 1. Tungsten oxide (W oxide) is the most widely studied in electrochromism, while other metal oxides such as nickel oxide, iridium oxide, vanadium oxide, molybdenum oxide and etc. are also the choice. There are five thin layers of the electrochromic device as shown in Figure 2. Sputter deposition is used to coat the thin film layers on the surface of glass substrate in the vacuum chamber. It is coated on the inner surface of IGU (insulated glazing unit) called surface 2 of the outboard lite, as shown in Figure 3.

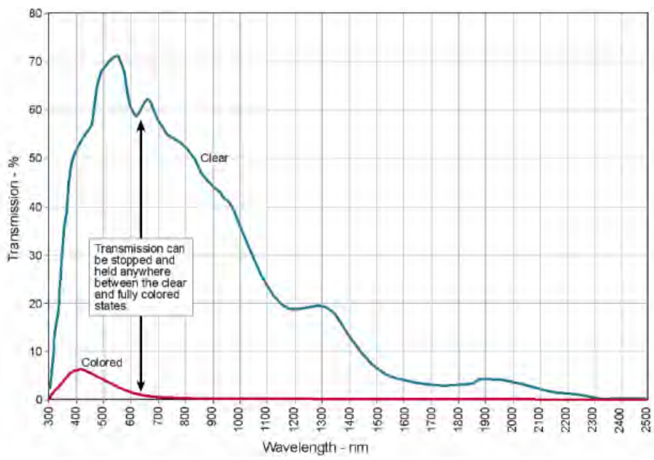

Figure 1: Shading effect of EC glass

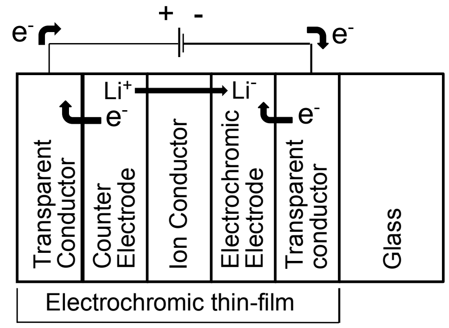

Figure 2: EC thin film

The driving or operating voltage of the EC glass is about 5V DC and the power consumption is about 1 Watt per m^2 when holding the tinted state; and about average on 2.8 Watts per m2 during tinting.

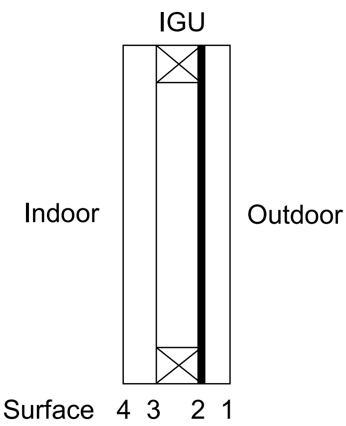

Figure 3: Section view of EC IGU

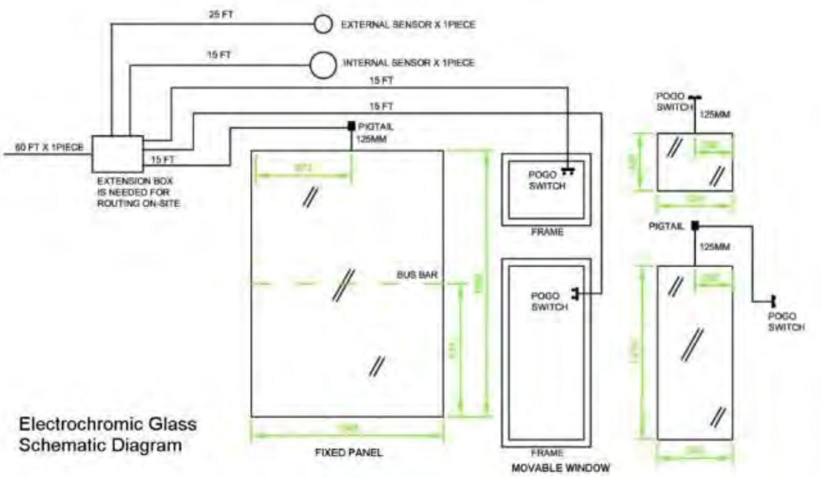

Figure 4: Schematic diagram of EC glass system

Light sensors can be installed in the system as shown in Figure 4 so the light intensity of indoor and outdoor can be compared to control the tint of the glass automatically. Manual mode is enabled when user press on the switch to over-ride the auto mode to select the desired tint at any time.

2.2 Thermochromic – The product

Thermochromic (TC) material changes to colored or more colored when absorbing heat energy, Δ; and returning back (bleaching) to colorless or less colored when the heat energy disappears or less, -Δ. It is a continuous and reversible changing process, see Figure 5. The transition time takes about few minutes to steady stage.

$$TC_{colorless} \underset{-\Delta}{\overset{\Delta}{\rightleftharpoons}} TC_{colored}$$

Equation 1

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

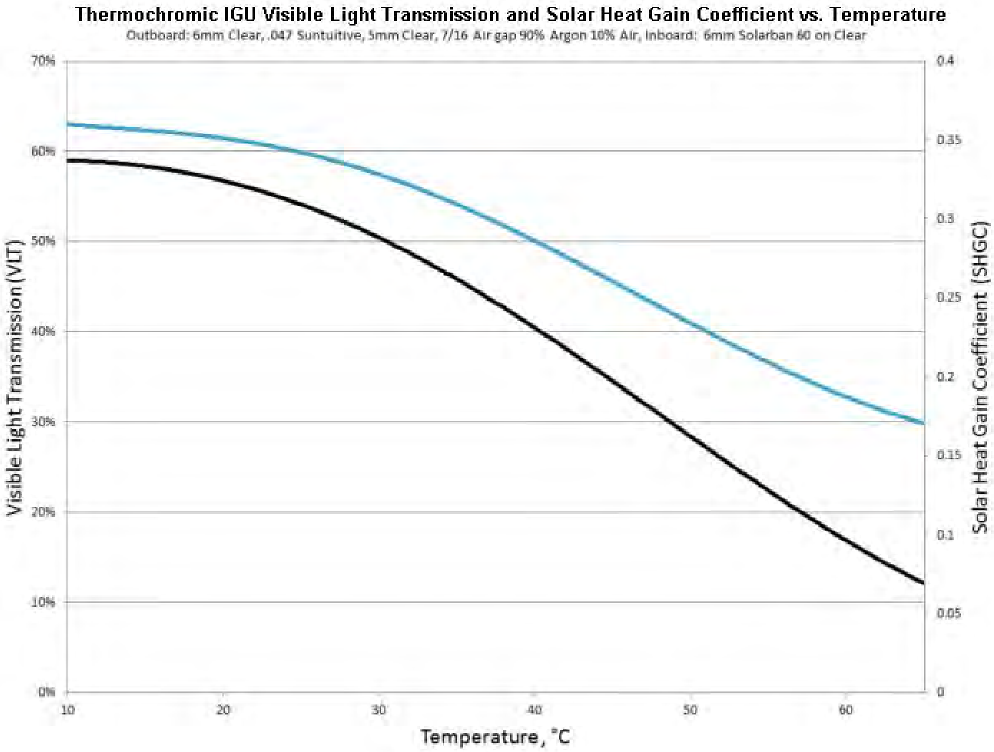

Figure 5: Response of TC glass with temperature

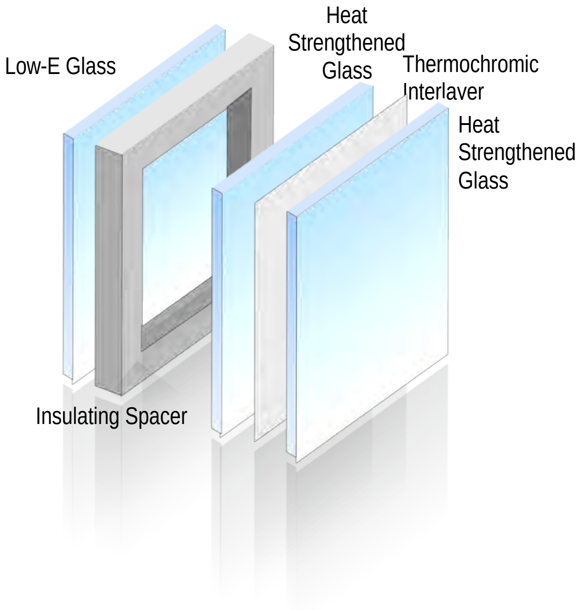

Figure 6: Construction of TC glass

Thermotropic material changes to colored completely when it reaches at a certain temperature; and returns back to colorless when drops below the temperature. It is a two stages changing process.

The TC materials are extruded with PVB (polyvinyl butyral) as a multiple layers which are laminated in between the heat strengthened glass panels, see Figure 6. Furthermore, it is integrating into normal IGU (insulating glazing unit) configuration. All the glass fabrication and lamination process are the typical standard process in the glass industry. From the installation point of view, there is no difference between TC and traditional glass since it does not require any electrical power and wiring as EC glass.

2.3 Quality

As one of the members of glass family, quality standards on dynamic glass are the same in the industry such as ASTM C1046, ASTM C1048, ASTM C1172, BS6206 and etc.

In addition, for the electrochromic glass, ASTM E2141 “Standard Test Method for Accelerated Aging of Electrochromic Devices in Sealed Insulating Glass Units” is commonly referred to describe about the testing and life time of the product.

3. BENEFITS FROM DYNAMIC GLASS

Some of the benefits from dynamic glass are summarised as following. Not only the outperform of the shading of solar heat gain and energy saving over the traditional glass, but also the enhancing human comfort through connecting to the outdoor by the dynamic glass.

Occupant Comfort

- Reduction of heat gain
- Reduction of glare
- Reduction of temperature differential
- Block 99.96% UV and prevent fading of furniture and covers
- Optimal daylighting and view
- Connection to outdoor undistorted view
- Natural lighting
- Increase productivity of occupant

Energy Saving

- Up to 30% energy reduction of buildings
- Reduce heat gain by 58% over low-e glass
- Powered by heat of sun, no electrical power (for thermochromic)
- Low solar heat gain coefficient SHGC (or shading coefficient SC)
- Reduce HVAC and lighting costs
- Downsize heating and cooling system
- A LEED product

Sustainability

- Most energy efficient window system
- Adding values to the buildings
- Adaptive to sunlight changes
- No energy cost (for thermochromic)
- No operation cost (for thermochromic)
- Maintenance-free (for thermochromic)

Design Versatility

- To all types of building, new construction or retrofit (for thermochromic)
- To all possibilities of glass, IGU, curved, shaped, specific thickness
- Window, skylight, façade, vertical or sloped
- Constructed by laminated heat strengthened glass panels (for thermochromic)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.1 Heat gain reduction

Figure 7 shows the reduction of glare and heat from the sunlight. The chart in Figure 8 shows an example of significant reduction in heat gain with over 80% by thermochromic (TC) glass comparing with conventional glass.

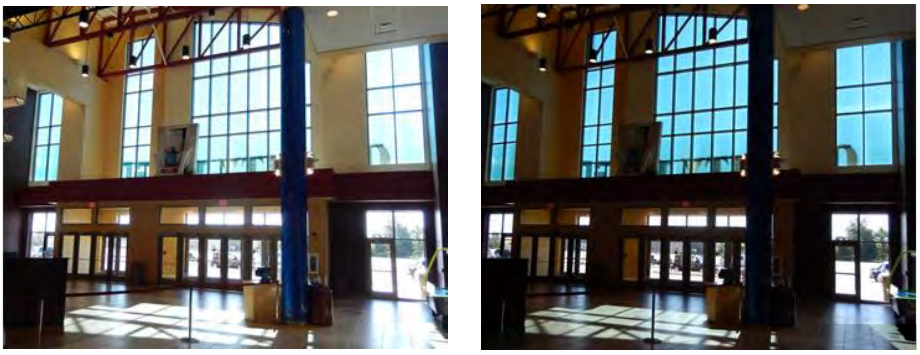

Figure 7: Change of tint of the dynamic glass

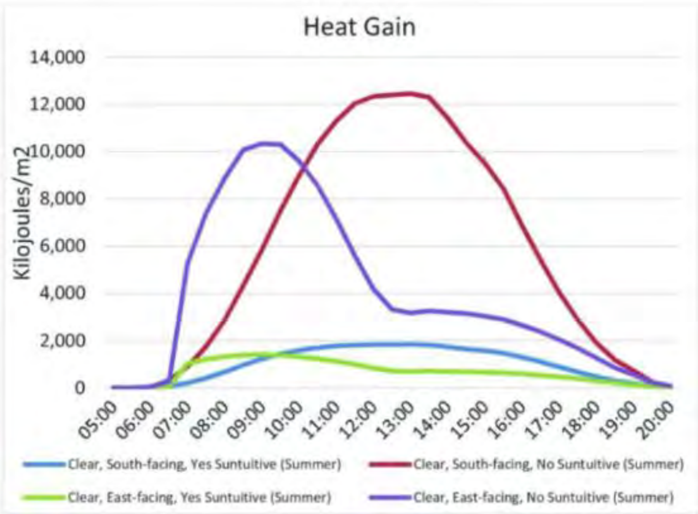

Figure 8: Heat gain reduction of TC glass

3.2 OTTV

Dynamic glass helps drop the OTTV 20 to 70% because of the significant shading capability which is shown in the value of SC, shading coefficient.

Dyn Glass: SC=0.1
IGU (lowE): SC=0.3

heat conduction + heat radiation

$$OTTV_w = \frac{(A_w \times U \times \alpha \times TD_{EQw}) + (Af_w \times SC \times ESM \times SF)}{Ao_w}$$

= Overall thermal transfer value of the external wall, W/m^2

4. CONCLUSIONS

As the next generation of glass, dynamic glass differentiates from “static” (traditional) glass through its adaptive tinting property to the outdoor environment and climate which are changing dynamically. It enhances the interaction between humans and nature and hence improving their well-being and productivity in buildings.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Cost of the dynamic glass is one of the crucial factors of success for massive application in the market. Due to the simplicity of thermochromic (TC) glass in terms of manufacturing, supply-chain model, installation, operation and maintenance, the cost is about one-third to half of that of electrochromic (EC) glass.

The premium cost of dynamic glass over traditional glass is about 30 to 50% more for TC glass and 2 to 2.5 times more for EC glass. It is offset by the outperform of energy saving from less HVAC load and artificial lighting load. The total life-cycle cost (LCC) of the dynamic glass system in long-term is lower than that of traditional glass. The payback period of the dynamic glass is about 3 to 10 years depending on the design and location of the building and electricity cost.

Besides, together with the extended design flexibility of the dynamic glass over the traditional glass and all makes it a new trend in modern buildings.

ABSTRACT

Manual maintenance and repair of cracks in concrete structures are often unsustainable because of associated labor, capital and environmental damage. Introduction of microfibers and superabsorbent polymers is a material solution to restrict crack propagation and enhance self-healing efficiency. Therefore, the study focus on development of a more sustainable cementitous system (cement mortar) comprising of polypropylene(PP) fibers and superabsorbent polymers (SAP) which would facilitate autonomous healing and recover original mechanical and durability properties of mortar.

To investigate crack sealing and recovery in mechanical and durability properties of mortar post healing, specimens were damaged by compressive and flexural loading. Mechanical strength, sorptivity and water penetration of healed mortars were compared to that of undamaged mortar at same age to estimate recovery of original properties while crack sealing was investigated by means of optical microscopy. Experimental results show mortar with combination of PP fibers and SAP showed full recovery of mechanical strength after healing while recovery in durability up to 90% was recorded. Microscopic images show that average crack-sealing ratio of 85% could be achieved under moist condition by combination of SAP and PP fibers while sealing under drier air curing condition is also significantly higher than reference samples with only fibers. Crack width up to 330µm has been found to be completely sealed by carbonate crystals. Furthermore, mortar with SAP and PP fibers retain about 70% of their original 28-day strength after three cycles of loading while reference mortar samples were found to retain only about 40-50% of their original strength.

Effective crack sealing and high recovery of original properties in mortars with SAP and fibers suggest that this material combination would reduce the need for environmentally damaging and expensive repairs during the service life which will be an important step towards achieving economical and environmentally sustainable construction practice.

Keywords: super absorbent polymers, self-healing, green construction technology

1. INTRODUCTION

Cementitous materials are prone to cracking due to action of various loading and environmental factors. Cracks give easy passage to foreign chemicals and moisture into concrete structures which affect its serviceability. Therefore, if micro-cracks can be healed at early stage, it will reduce further propagation and arrest access of contaminants into the structure. Manual repair of cracks is often limited due to accessibility and high cost. Moreover, chemical or cement based repair materials present threats including material incompatibility, health and environmental hazards (De Muynck et al.,2010) which makes their use highly unsustainable. Self-healing in cementitous material is a sustainable solution to maintenance of concrete structures because it reduces the manual repair operations and concomitant environmental hazards. Although cementitous materials including cement mortar possesses autogenous self-healing capability by secondary hydration of calcium silicate hydrate and precipitation of calcium carbonate, the effectiveness of such healing mechanism is only limited to narrow cracks (Edvardsen, 1999; Ter Heide,2005). Yang et al. (2009) observed complete healing of crack width below 50 µm while cracks beyond 150µm were partially healed. It is concluded from the existing studies that the most essential conditions for effective autogenous self-healing in mortar include presence of calcium or carbonate ions, presence of moisture and restriction of crack width typically between 50 – 150 µm (Yang et al., 2009). Therefore, it means that effective healing can be obtained by a dedicated material design which can restrict crack width and source for moisture at the crack site for secondary hydration and precipitation of carbonate to seal cracks.

This study investigates the material design by combination of two different mechanisms on autogenous healing capacity in mortar. The first mechanism is the introduction of polypropylene (PP) fiber to restrict crack widths through bridging action during matrix micro-cracking or macro-cracking. The second mechanism involves the use of superabsorbent polymers (SAP) which can absorb high volume of moisture (up to 500 times of its own weight) and retain in its structure without dissolving. The moisture retained by SAP particles are gradually desorbed and made available for further hydration in the cement matrix. Lee et al. (2010) observed the healing effect of SAP by expansion and blocking of crack opening when moisture ingress through cracks takes place. SAP can also provide internal healing because it absorbs water from surrounding and seal cracks by secondary hydration. Snoeck et al. (2014) reported that combination of PVA fibers and SAP offer effective self-healing even when moisture is not available through secondary hydration and precipitation of calcium carbonate which seal cracks. However, besides sealing of cracks recovery of original properties post-healing is essential for delivering durable and sustainable infrastructure.

The objective of this study is to investigate the ability of combination of SAP and PP fibers to recover mechanical and durability properties of cementitous mortar after healing of damage created by structural loading. In addition, recovery of compressive strength after multiple cycles of loading and sealing of cracks under two different curing conditions is also studied in this article.

2. MATERIALS AND METHODS

The materials used in the study include CEMI 52.5 N Portland cement (500 kg/m^3) which meets ASTM C150 specification, natural sand (1375kg/m^3) with specific gravity of 2.55 and fineness modulus 2.54, polypropylene fibers (manufactured by W.R.Grace Singapore) and potassium based ionic superabsorbent polymers with average particle size ranging between 130-180 µm and water uptake capacity of 56±1g/g of SAP. The average length of polypropylene fibers used in the study is 19 mm with elastic modulus of 3.50 GPa and density 0.91g/cc.

The mix designs of different batches prepared are mentioned in Table 1. Water-cement ratio is maintained at 0.40 for all the mixes. From initial tests on effect of dosage on mortar properties it was confirmed that 0.70% of SAP and 0.60% addition of PP fibers by weight of cement do not affect strength and permeability. Therefore, the combination of PP fibers and SAP comprised of 0.70% SAP and 0.60% PP fiber by cement weight. Two other mixes - with only 0.60% fiber and only 0.70% SAP were studied as reference for comparison of recovery of original concrete properties with those in samples with combination of SAP and PP fibers.

Mix codes	Mix description	Mix ratio (cement:sand:water:SAP:fiber)	Curing condition
Plain mortar	Without SAP and fiber	1:2.75:0.4	27±2 ˚C, RH>95%
Fib0.60_REF1	Mix with 0.60% PP fiber	1:2.75:0.4:0:0.006	
SAP0.70_REF2	Mix with 0.70% SAP	1:2.75:0.4:0.007:0	
M1	Mix with 0.60% PP fiber and 0.70% SAP	1:2.75:0.4:0.70:0.007:006	

Table 1: Mix design and description used in this study

2.1 Methodology to study self-healing

At age of 14 days the samples are subjected to compressive strength test. Strength test has been done to ascertain the compressive strength of the samples from each batch to determine the pre-loading load levels which are 50% and 70% of 14-day strength. After introduction of damage by pre-loading at 14 day, the samples are allowed to cure at 25±2°C and > 95% RH for three weeks for the healing to occur. After three weeks of curing, the samples have been tested for mechanical strength and durability properties to calculate recovery post-healing. At the time

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

pre-loaded samples are tested for recovery of mechanical and durability properties, the samples are 35 day old (14 day of initial curing +21 days of healing period) from the day of casting. Therefore, to estimate the extent of recovery of original properties (if there were no damage), undamaged samples were tested for the same mechanical and durability properties after 35 days of curing. While compressive and flexural strength tests have been conducted to enumerate recovery in strength, sorptivity and depth of water penetration tests are conducted to estimate recovery of durability properties post-healing. Minimum of three samples is tested to attain statistically relevant results. While mechanical strength testing and water penetration was conducted following BS EN standards, sorptivity has been conducted following ASTM C1585.Recovery of mechanical and durability properties upon self-healing is calculated using the following expressions.

$$\text{Recovery in strength}=\frac{\text{Peak strength (MPa) after healing}}{\text{Peak strength (MPa) of undamaged samples at 35 day}}$$

$$\text{Recovery in penetration depth}=\frac{\text{Maximum penetration (mm) in undamaged sample at 35 day}}{\text{Maximum penetration depth (mm) after healing}}$$

$$\text{Recovery in sorptivity}=\frac{\text{Initial sorptivity }\left(\frac{\text{mm}}{\sqrt{\text{s}}}\right)\text{ of undamaged samples at 35 day}}{\text{Initial sorptivity }\left(\frac{\text{mm}}{\sqrt{\text{s}}}\right)\text{ of healed samples}}$$

Recovery of initial sorptivity is considered because initial sorptivity is more sensitive to presence of micro-cracks induced by preloading of the specimens. Secondary sorptivity is contributed mostly by air voids in the specimen and therefore excluded from the calculation of recovery in sorptivity. Recovery greater equal to 1 would mean that the healed samples have completely regained the original concrete properties while a number less than 1 means partial healing of samples in terms of recovery of strength or durability.

2.2 Recovery of compressive strength after multiple loading cycle

Recovery of compressive strength under multiple cycles of loading was studied by subjecting cylinder specimens to three cycles of loading. In each cycle the specimens were loaded to 70% of their ultimate strength and were allowed to cure for 21 days between subsequent cycles of loading. The recovery of compressive strength after three cycles is expressed as percentage of 28-day strength of the mix.

$$\text{R}(\%)=\frac{\text{Compressive strength (MPa)after three cycles of loading}}{\text{28 day compressive strength of the mix}}*100$$

2.3 Measurement of crack sealing

Sealing of cracks was monitored and recorded over a period of three weeks using optical microscope (Olympus SZX10 with Leica illumination system). Prism samples (40x40x160mm) were unloaded at the point of flexural failure and width of the crack formed at failure has been recorded. For controlled creation of crack steel fibers were placed in prism samples targeted for study of crack sealing. Cracked samples were moist cured except M1 which was both moist and air-cured during the healing period. The percentage reduction in crack width is calculated by using the following expression.

$$\text{Percentage reduction in crack width}(\%)=\frac{\text{crack width}_i-\text{crack width}_t}{\text{crack width}_i}\text{x}100$$

crack width_t refers to average crack width recorded at time t (for example, t = 5 when crack width is measured on day 5).

crack width_t refers to average initial crack width recorded just after introduction of cracks.

3. RESULTS AND ANALYSIS

3.1 Recovery of compressive strength

It can be observed from Figure 1 that recovery ratio of strength is considerably higher in M1at 50% and 70% preloading compared to the reference although 35-day compressive strength of M1 is similar to that of pain mortar and SAP0.70_REF2.

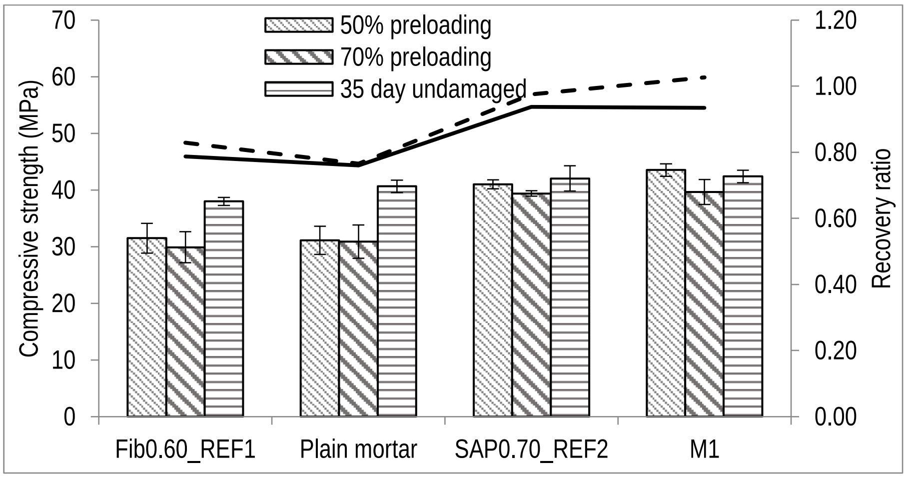

Figure 1: Compressive strength of healed samples, 35day undamaged samples and recovery ratio at 50% and 70% preloading

It can be explained by joint action of fiber and SAP where fibers tend to restrict crack width and SAP particles improve the rate of autogenous healing by supplying moisture to interior of mortar. Generation of hydration products bridge the cracks and impart strength to damaged mortar post healing. Moreover, water desorbed from SAP is rich in calcium ion which reacts with carbon dioxide from surrounding environment resulting in sealing of cracks by precipitation of calcium carbonate at the crack face. Apart from restricting crack width and increasing efficiency of autogenous healing, fibers act as anchors for calcium carbonate crystals. In absence of fibers, the carbonate crystals may not have any anchor to attach to and may be washed away by incoming fluid. SAP0.70_REF2 contained SAP but absence of fibers had little effect on restricting crack propagation which explains its lower compressive strength post-healing.

3.2 Recovery of water penetration

Figure 2 shows samples with SAP and fiber shows higher recovery ratio upon healing. In case of plain mortar and fiber reinforced mortar, healing of microcracks take longer time because of unavailability of moisture in the interior of mortar resulting in partial healing of cracks. Therefore, water under pressure can flow into the concrete without much resistance. In SAP containing samples, healing is more complete because SAP particles can absorb moisture from the moist environment (during curing) and supply for hydration to continue and heal the cracks. Moreover, near the crack faces where there are hydration products calcium carbonate precipitation takes place due to presence of calcium ion (Snoeck and De Belie, 2015).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

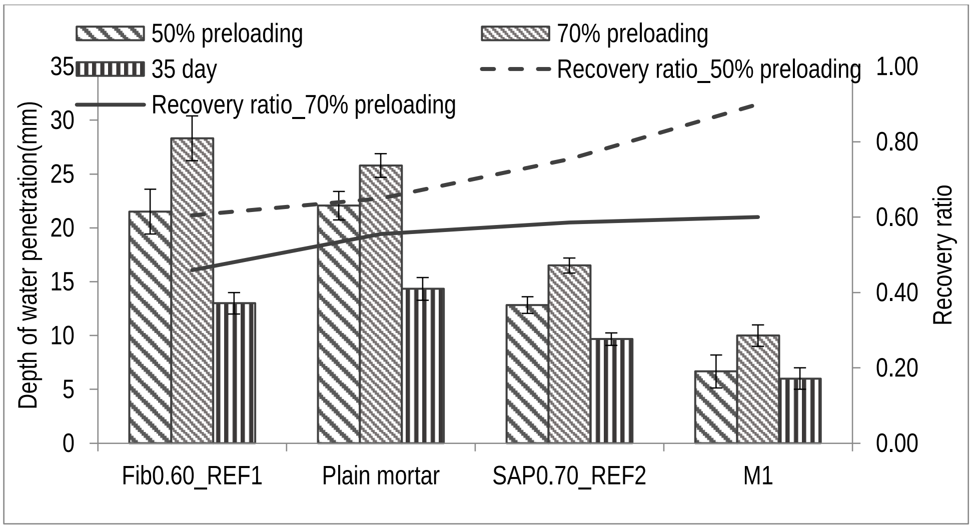

Figure 2: Water penetration depth in healed samples, 35day undamaged samples and recovery ratio at 50% and 70% preloading

Formation of calcium carbonate bridges and seals the cracks. In presence of fibers across microcracks, calcium carbonate can attach to fibers which prevent them from being washed off from the crack face. This explains higher healing ratio in M1 samples. Moreover, voids containing SAP particles create weak planes which make cracks to cross those voids. SAP s along crack faces swell immediately when it comes in contact with water thus blocking further penetration (Snoeck et al., 2014). However, when preloaded to high stress level localized wider cracks are formed which may not be sufficiently bridged by fibers or blocked by swelled SAP particles. It explains similar recovery ratio in M1 and SAP containing reference samples at 70% preloading level.

3.3 Recovery of sorptivity

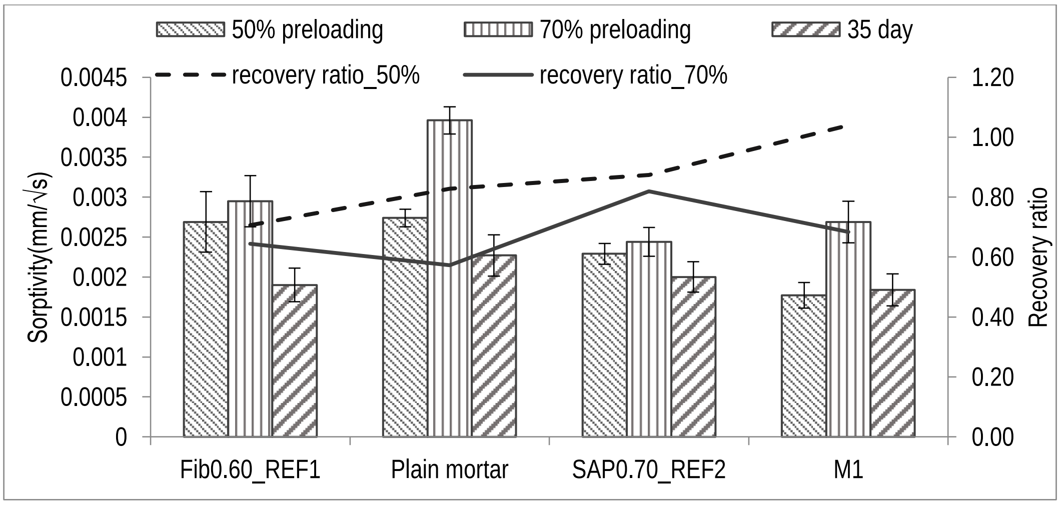

Figure 3: Sorptivity in healed samples, 35day undamaged samples and recovery ratio at 50% and 70% preloading

From Figure 3, one can observe that recovery of sorptivity is highest for M1 samples when subject to 50% preloading although at 70%, the recovery ratio is similar to the reference mortars. This may be attributable to crack profiles created in fiber reinforced mortar under stress. Incorporation of fibers bridge cracks and reduce permeability when the loading is below a certain limit called the threshold level. Above this threshold fibers may cause more localized unrecoverable deformation compared to plain mortar (Hosseini et al., 2009). 70% preloading may have introduced local deformation in the mortar that could not be fully healed or recovered which explains higher sorptivity in M1 samples at 70% preloading.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.4 Recovery of compressive strength under cyclical loading

From Figure 4 one can observe that mix M1 retains highest percentage, about 70% of 28-day compressive strength after being subject to three loading cycles.

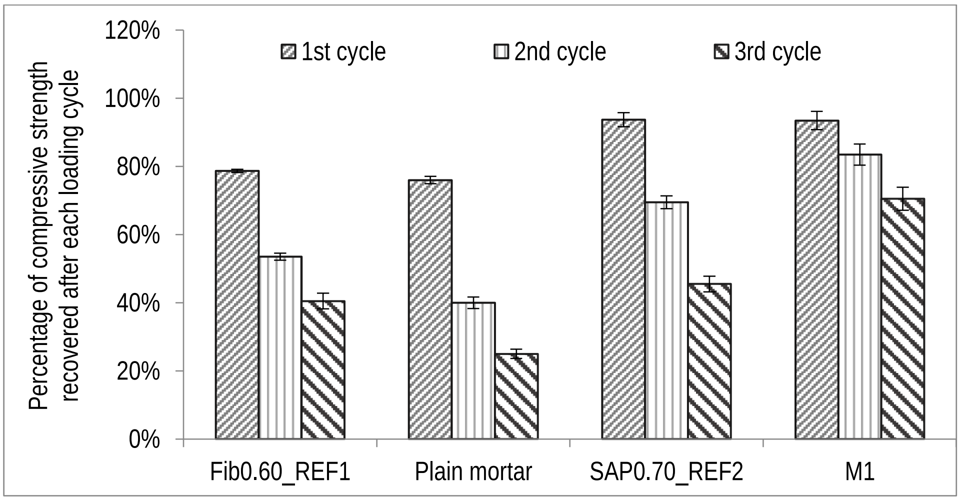

Figure 4: Recovery percentage of compressive strength of mixes subject to three cycles of loading

It may be justified by the role played by PP fibers in mitigating crack propagation which is also observed when Fib0.6_REF 1 and plain mortar are compared. Plain mortar regained only about 25% of its 28-day strength after three loading cycles compared to 40% in case of Fib0.6_REF1. Addition of SAP also plays an important part in accelerating the healing process. With age the microstructure of mortar becomes denser and therefore less external water tends to reach interior of concrete. Therefore, autogenous healing is mitigated due to lower availability of water. Due to their affinity to water, SAP plays an important role by uptaking moisture from the environment and supplying them for faster autogenous healing in damaged mortar. Therefore, controlled crack width due to addition of fibers and autogenous healing by SAP better performance of M1 samples under cyclical loading.

3.5 Sealing of cracks

Figure 5 shows that samples with SAP and fiber showed about 85% crack healing compared to only 30-40% healing in reference samples. Figure 6 (b) and (c) shows only partial healing in plain mortar and Fib0.6_REF1 samples which is attributed to limited availability of moisture at the crack site in absence of SAP particles.

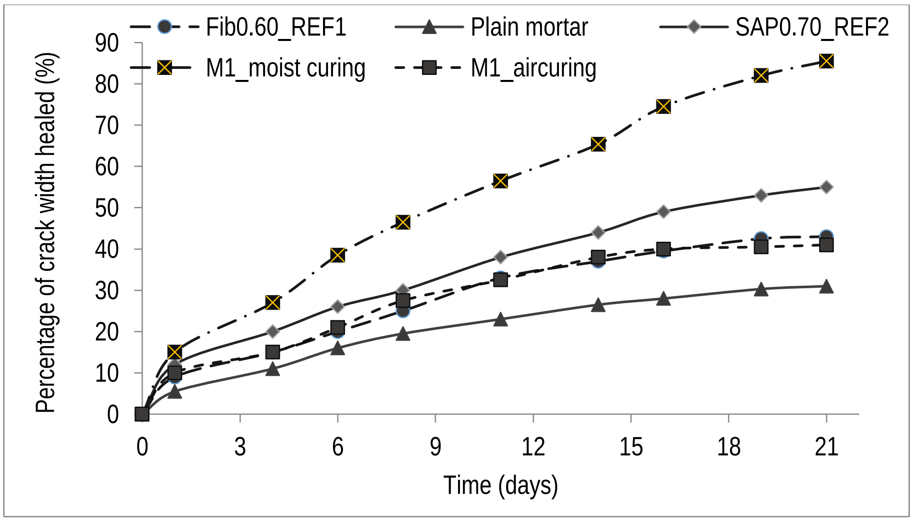

Figure 5: Percentage of crack width healed over the healing period in different mixes under moist curing condition and in M1 under moist curing and air curing condition

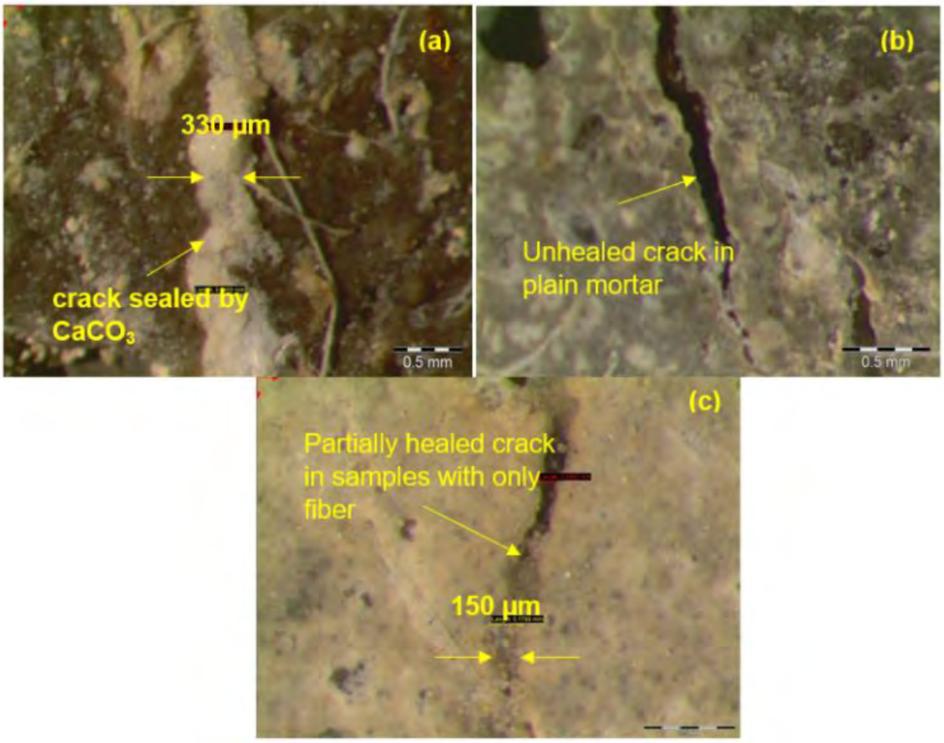

Figure 6: Crack healing in (a)M1 sample (b)Plain mortar samples and (c)Fib0.6_REF1 under moist curing condition

The range of crack width created in M1 samples was 220 – 380 µm at failure while it was in the range of 200 - 300 µm in Fib0.6_REF1. It means that M1 showed slightly higher crack width at failure which may be attributed to weak spots created due to desorption of water from SAP. While complete sealing of cracks up to 330µm was noted in M1 (Figure 6a), cracks beyond 330µm were healed partially.

The unhydrated cement particles near the crack location had ready access to moisture supplied by SAP for further hydration. Moreover, calcium ions at crack face may have reacted with water containing dissolved carbon dioxide or bicarbonate to form calcium carbonate which sealed the cracks. M1samples placed under air curing also shows similar healing ratio as Fib0.60_REF1 which suggests that presence of SAP particles ensure availability of moisture even under dry condition to seal cracks by further hydration or precipitation of calcium carbonate. However, rate of healing under air-curing dropped beyond 12 days because most of the water absorbed by SAP has been desorbed and utilized for hydration.

4. CONCLUSION

The major findings from this study can be summarized as follows:

- Almost complete recovery of mechanical strength has been observed for samples containing SAP and fibers which is considerably higher than samples containing only fibers. It means that durable and strong infrastructure can be delivered by combining reinforcing effect of fibers and healing effect of SAP particles.
- SAP particles play an important role in sealing of crack width. In three weeks, about 85% crack width healing was observed in samples containing SAP and fibers of carbonate and formation of hydration products to seal up the cracks.
- Penetration of moisture is significantly reduced by action of SAP and fibers in healed and undamaged samples which mean that healed structures would be much less prone to damage by ingress of foreign chemicals and would require lower maintenance.

The findings suggest that SAP containing self-healing system would be most suitable in regions with high humidity. The SAP s can draw moisture from the air to facilitate self-healing by further hydration and carbonate precipitation. However, further research is to be conducted to study this system’s effectiveness in dry climate because lack of moisture may slow down or affect the rate of autonomous healing.

Although superabsorbent polymers do not have any health hazard, some precautions may be needed while handling of polypropylene fibers. Fine polypropylene fiber filaments may penetrate in to respiratory system by inhalation that creates respiratory symptoms. Therefore, use of personal protection equipment (PPE), especially face mask and gloves are recommended while handling polypropylene fibers during preparation of concrete mix.

ABSTRACT

Recently, architects have praised expanded metal mesh for its visual penetration and shading performance and thus applied it as an element in the façade design of many buildings. In Taiwan's "Technical Code for the Energy Conservation Design of Buildings", the energy conservation efficiency of a building's perforated metal sheets can be determined using the shading factor Ki, which is related only to perforation rate.

However, some previous studies on perforated metal sheets have suggested that material, color, emissivity, opening shape, and distribution can also influence their energy saving performance. Some studies have even demonstrated that when expanded metal mesh is used for shading purposes, different specific angles of solar radiation can have a significant impact on the energy conservation effect. This phenomenon occurs because the opening form of expanded metal mesh is a type of three-dimensional pattern.

In this study, we built an experimental house with a single room and performed field measurements to investigate the shading performance of expanded metal mesh. We selected three types of expanded metal mesh with different opening forms for comparison and two types of installation angles (upward/downward) to determine the influence of solar angle. The results show that the practical shading factor in downward installation cases is lower than that in the building code, which means that the higher shading performance can be evaluated. When the perforation rates are similar, expanded metal mesh with larger holes have shown better shading performance than that with small openings. However, we found significant reduction in shading performance when the expanded metal mesh was installed upward, which is important for architects in their designs.

Keywords: shading factor, perforation rate, energy saving

1. INTRODUCTION

In recent years, designers have praised expanded metal mesh for its visual penetration and shading performance and have thus frequently applied it as an element of façade design. The difference in the shape of the openings, as well as the distribution of the expanded metal mesh, affect shading performance.

According to Taiwan's "Technical Code for the Energy Conservation Design of Buildings", the energy conservation efficiency of a building's shading device can be determined with the shading factor Ki, which incorporates different directions, depth ratio, and perforation. Considered a perforated shading device, expanded metal mesh's shading factor Ki can be calculated, but only by its vertical projection perforated rate.

However, Blanco et al. (2014) showed that not just perforated rate affects the energy saving performance of perforated metal sheets. Such factors as material, color, emissivity, opening shape, and distribution also influence the surface temperature of perforated metal sheets, thus affecting the indoor thermal comfort. Furthermore, in five different climate zones in Spain, Blanco et al. (2015) discussed the energy saving capacity of different perforation rates, materials, and colors of perforated metal sheets applied in a double-skin system. The results demonstrated that the highest energy efficiency varied, and then the best perforated rates of the perforated metal sheets were proposed for Spain's various climate zones.

Mainini et al. (2013) studied the manner in which the different shapes, materials, and hole distributions of perforated metal sheets and metal mesh grid influenced shading performance. Their results revealed that angle of incidence played an important role and that the three-dimensional pattern of perforated metal sheets achieved different shading performances with specific angles of incidence. Furthermore, Mainini et al. (2015) simulated the energy saving capacity of these two devices applied on different opening ratios of an office building and found that the energy saving can significantly increase only when applied to a curtain wall building. Oowada et al. (2012) studied three different mesh sizes and two installation angles of expanded metal mesh for their shading performance with southern orientation. The results showed that the installation angles achieved different performances.

All of these studies have demonstrated that determining the shading factor Ki of expanded metal mesh by only considering its perforated rate is not enough because many factors may contribute to shading performance. Moreover, relatively few studies have addressed the effect of different mesh sizes of expanded metal mesh on indoor thermal comfort in Taiwan. This study focuses on different mesh sizes of expanded metal mesh and how installation angles may affect not only shading performance but also thermal comfort as a reference for architects.

2. MEASURING SHADING PERFORMANCE

2.1. Field measurement set-up

We built an experimental house, with the measurements of 2 m x 2 m x 2.2 m, to perform field measurements, as shown in Figure 1. The opening was located on the west side, and we installed the expanded metal mesh on half of the opening, as shown in Figure 2. Three pyranometers were set outside and inside the experimental house to compare the opening with the expanded metal mesh against the one without it. The time interval of data collection was one minute, and the experiments were carried out from 9:00 to 18:00 in the summer of 2016.

2.2. Shape and installation method of the expanded metal mesh

The sample size of the expanded metal mesh was 1 m x 1 m, and the material was aluminium, but the mesh sizes of the three samples differed, with Type A being the largest, followed by Type B and then Type C. Details of the samples are shown in Table 1. To understand how sunlight penetrates the expanded mesh grid, two installation methods, downward and upward, were measured, as shown in Figure 3.

3. RESULTS AND DISCUSSION

As shown in Figure 5, solar radiation clearly rose after 12:00 pm due to the direct sun hitting the west-facing opening. Therefore, we only discuss the shading performance of the expanded metal mesh using the data from the afternoon (13:00- 18:00). Shading factor Ki

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

To compare the differences between the shading factor in Taiwan's building code (Technical Code for the Energy Conservation Design of Buildings) and that obtained from our experiments, we defined the practical shading factor Ki', while the shading factor of downward and upward installation are defined as Ki'D and Ki'U, respectively.

The vertical solar radiation measured for the three kinds of expanded metal mesh with the two different installation methods is shown in Figure 6. Figure 6 a-c shows the downward installation, in which a significant reduction of solar radiation can be found in each case, and different fluctuations can be found with each different opening form. However, in the upward installation cases, as shown in Figure 6 d-f, no significant difference was found between whether expanded metal mesh was installed or not. Figure 7 shows the variation of Ki'D and Ki'U of each type of expanded metal mesh, revealing a difference of shading performance between the two installation methods. Figure 7a shows the installed downward situation, in which the Ki'D of Type A has the biggest fluctuation. This may be due to Type A having the largest mesh size. Type B was the most stable. Type C had a smaller fluctuation than Type A, but the average Ki'D, which is shown in Figure 8 is the largest, indicating that the shading performance is the worst of the three samples. This may be due to the mesh size and strand width (W) being the smallest, so this type could not effectively resist the sunlight. In Figure 7b, the Ki'U of all samples installed upward are higher than those installed downward, and the relationships of the samples revealed a similar trend. This is because the sunlight penetrated into the interior much more easily due to the mesh opening direction.

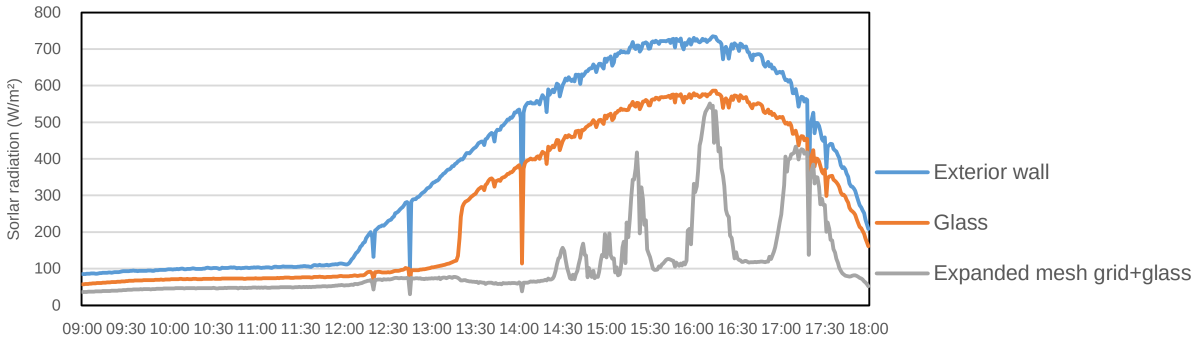

Figure 5: Variation of vertical solar radiation during 9:00-18:00 of type A installed downward

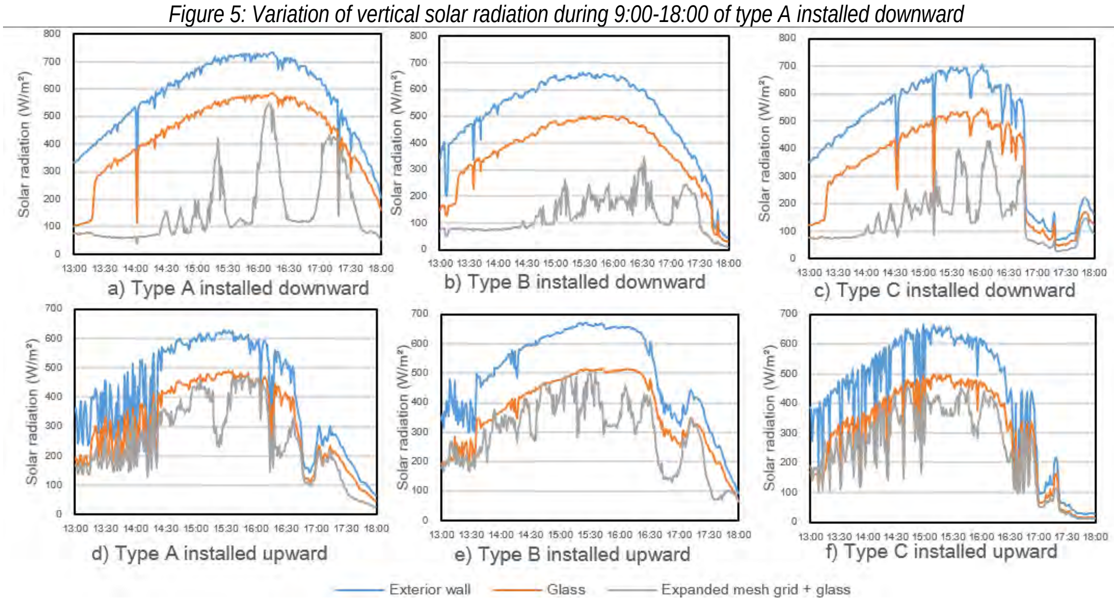

Figure 6: Variation of vertical solar radiation during 13:00-18:00

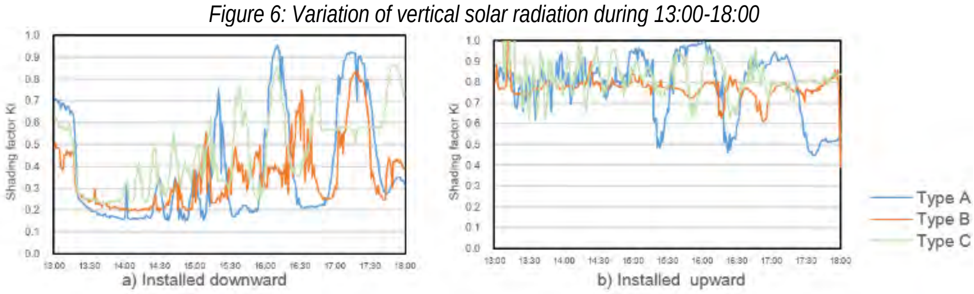

Figure 7: Comparisons of shading factor with difference installation methods

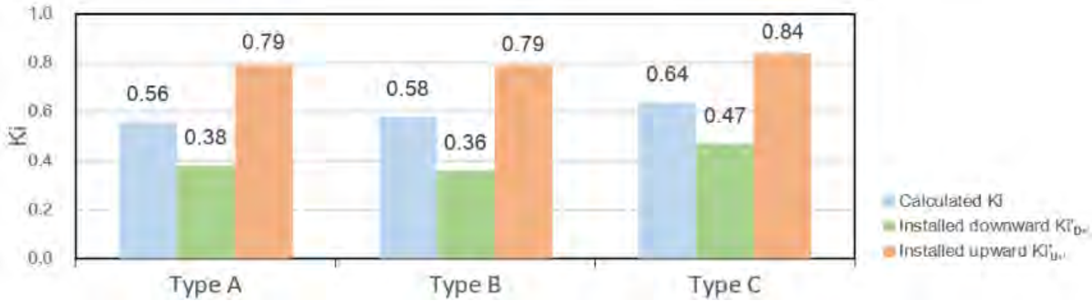

Figure 8: Comparisons of average shading factor Ki

The comparison of calculated Ki (according to the perforated rate) and average practical Ki’ are shown in Figure 8. When we determined the shading performance using only Ki, which was calculated by vertical projection perforated rate alone, the shading performance may be significantly underestimated, and the influence of installation is not considered.

3.2. MRT and OT

Figure 9 shows the variation of MRT of the opening with/without expanded mesh grid. The differences between MRT and OT (operative temperature) when having expanded mesh installed or not are shown in Figure 10. In the installed downward cases, all of the MRT apparently decreased, with Type A showing the best shading performance. This difference may be caused by the shape of the mesh, as well as be related to the solar radiation, which was higher than in other cases, as shown in Figure 6a-c. Therefore, the shading performance was strengthened. In the installed upward cases, the shading effect decreased since the practical Ki'U increased. However, even installed in the "wrong" way, ΔMRTU around 1.42~1.36°C and ΔOTU around 0.75~0.84°C were still found in the measurements. Note that Type C mesh installed upward data is not available due to a technical problem.

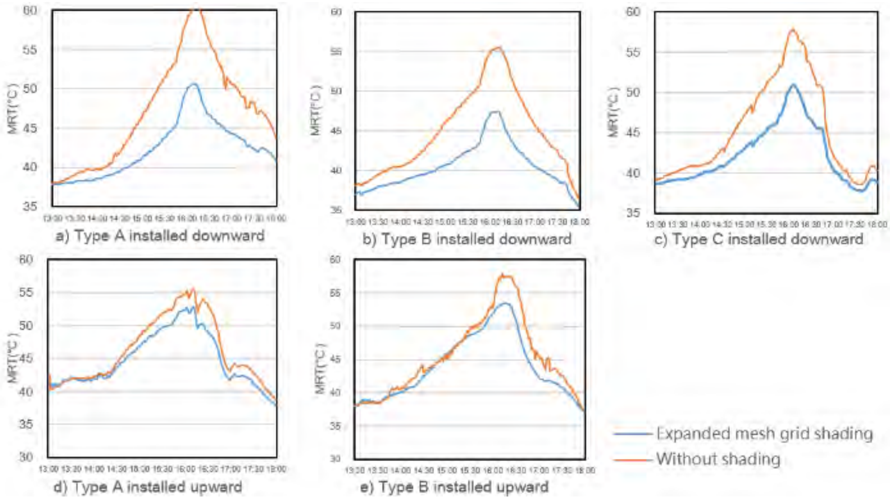

Figure 9: MRT during 13:00-18:00 of the different samples with different installation methods

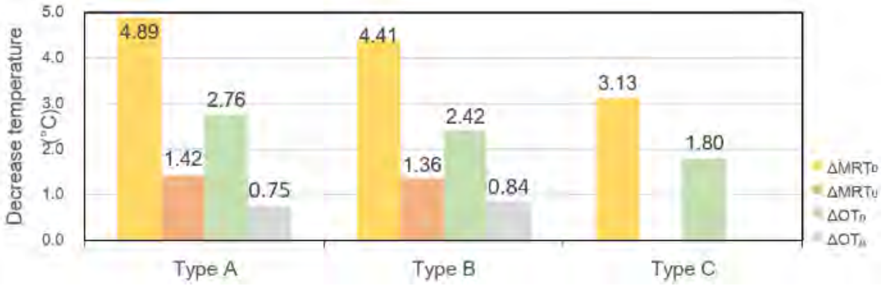

Figure 10: Comparisons of average ΔMRT and ΔOT

4. CONCLUSION

In this study, we carried out field measurements to study the shading performance of expanded metal mesh and found that only considering the perforated rate as shading factor Ki may underestimate shading performance. Furthermore, the installation method of devices plays an important role since expanded metal mesh is a three-dimensional material, and incorrect installation may reduce its effectiveness. Finally, regarding the difference of MRT and OT between the opening with/without expanded metal mesh, the reduction of MRT and can be up to 4.89°C and 2.76°C, respectively, when Type A was installed.

This research mainly focuses on expanded metal mesh installed facing west; however, discussing the influence of other directions, mesh sizes, or perforated rate would be beneficial in future studies.

ABSTRACT

Wooden material is one of the eco-friendly materials with high sustainability. It is on the spotlight recently and getting higher standing in the world, especially countries drew up the regulations of green building and eco building material. But the performance of impact sound insulation of wooden structure floor cannot reach the same level as RC floor. In order to enhance the capability of wooden structure floor, this research set up the wooden structure floor referring by relative regulations, and conformed the performance of Ln,t,w accorded with the regulations, then investigated the effects of impact sound with various covering/surface materials. The result indicates the performance can be raised by putting resilient materials under the covering materials. As for raised wooden floor, the capabilities of impact sound insulation can be improved by inserting the rubber or glass wool under the beams.

Keywords: wooden structure floor, impact sound insulation, resilient material

1. INTRODUCTION

The impact of sound insulation in buildings with light wooden floors is normally much worse than those buildings with heavy floors such as a concrete floor. In Taiwan, most research is focused on improving impact sound insulation of heavy-weight floor such as concrete floors, but little research is about insulation of the other type, light-weight floor. Thus, this study pays attention on the impact sound property of wooden floors which is one of the light-weight floors. The reduction of impact sound by surface material on wooden floors is also taken in account in this study. The experiments of this paper are conducted in the Laboratory of Acoustic Performance in National Pingtung University of Science and Technology(NPUST), and all the experimental procedures are following ISO 140-11(2005) [Acoustics - Measurement of sound insulation in buildings and of building elements - Part 11: Laboratory measurements of the reduction of transmitted impact sound by floor coverings on light-weight reference floors] which includes methods of setting floor, measurement and rating. This research discusses the applicability of wooden floors, and the improvement of light-weight impact sound on diverse surface materials of wooden floors.

2. MEASUREMENT AND EVALUATION METHOD OF IMPACT SOUND INSULATION ON WOODEN-BASED FLOOR BY LIGHT-WEIGHT IMPACT SOUND SOURCE

2.1. Conditions of laboratory and establishment of wooden-based floor

There are two floors in the laboratory, the upper one is as for impact sound source room which the volume is 75.0 m^3; the other one is sound receiving room with volume 115.0 m^3. The area of impact sound testing is 10.5 m^2 (3.5 m * 3.0 m).

2.2. Measurement system and procedure

The thickness of bottom layer plank is 22 mm, and the density is 600 kg/m3. The height and width of truss section under the bottom plank are 120 mm and 180 mm. The length of truss is 3500 mm, and the gaps between trusses is 625 mm. The gaps are stuff with glass wool which the density is 20 kg/m^3. The celling under the floor is made up with plasterboards which the thickness and the density are 13.5 mm and 720 kg/m.

In this experiment, the light-weight source (tapping machine) was placed in the sound source room (the upper room), and microphones were put in the sound receiving room (the lower room). The items of measurement included the reverberation time of sound receiving room, background noise and the sound pressure level of tapping machine. The frequency measured in this research was 1/3 Octave band which range covering 100 to 3150 Hz. Besides, this experiment was conducted with 5 positions of microphones and 6 positions of impact sound source.

2.3. Calculation and evaluation method

- Impact sound pressure level

$$L_i = 10 \log\left(\frac{1}{n}\sum_{j=1}^{n} 10^{L_j/10}\right) \text{ dB}$$

Equation 1

In equation 1, L_j is impact sound pressure level of difference position in a room.

- Normalized impact sound pressure level

$$L_n = L_i + 10 \log A/A_0 \text{ dB}$$

Equation 2

In equation (2), L_i is impact sound pressure level, A is equivalent absorption area, A_0 is reference absorption area.

- Weighted reduction in Impact sound pressure level

$$L_{n,t,0} - L_{n,t} = \Delta L_t$$

Equation 3

$$L_{n,t,r,0} - \Delta L_t = L_{n,t,r}$$

Equation 4

$$\Delta L_{t,w} = L_{n,t,r,0,w} - L_{n,t,r,w} = 72 \text{ dB} - L_{n,t,r,w}$$

Equation 5

In equation (3)~(5), $L_{n,t,r}$ is the calculation normalized impact sound pressure level of wooden based floor with the floor covering, $L_{n,t,r,0}$ is the defined normalized impact sound pressure level of reference floor, ΔL_t is the reduction in impact sound pressure level measured in accordance with ISO 140-11(2005), $L_{n,t,r,w}$ is the calculation weighted normalized impact sound pressure level of the reference floor with the floor covering under test, $L_{n,t,r,0,w}$ is obtained from $L_{n,t,r,0}$ in accordance with Table1.

2.4. Factor types

2.4.1. The difference position and amount of light-weight impact sound source

This study hypothesized the permutations of tapping machine's position may influence the impact sound pressure level of sound receiving room. To argue this point, the experiment conducted with two cases of different amount of positions of tapping machine. In one of the cases, tapping machine was placed at 10 different positions, as Fig.1 shows. Position SL1-1 and SL1-2 were in between joints, SL2-1 and SL2-2 were at the intersection of truss and joint, SL3-1 and SL3-2 were on the joint, SL4-1 and SL4-2 were on the truss, SL5 was at on the intersection of joint and the diagonal of the room, and SL6 was at the central point of truss which was the central point of the specimen as well. There were 6 different positions in the other case: position SL1-1, SL2-2, SL3-2, SL4-2, SL5 and SL6. The single values were calculated by those cases and compared the margin between them.

Frequency (Hz)	$L_{n,t,r,0}$(dB)	Frequency (Hz)	$L_{n,t,r,0}$(dB)
100	78	630	72
125	78	800	69
160	78	1000	66
200	78	1250	63
250	78	1600	60

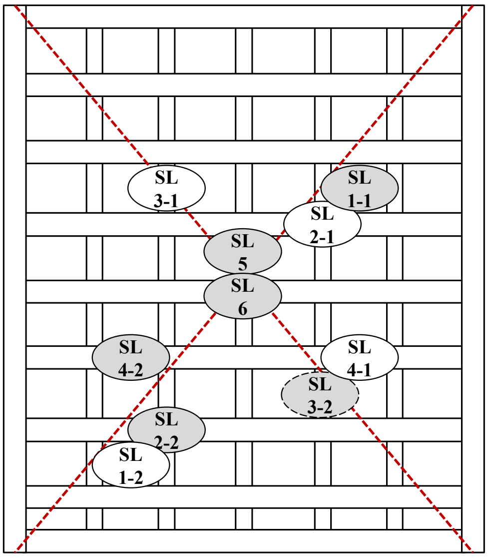

Figure 1: The difference position and amount of light-weight impact sound source on the wooden-based floor.

2.4.2. Factor conditions

To verify the applicability of impact sound experiments and the performance of impact sound insulation, the early stage of this study was focus on installing the wooden floor, discussing the application of measurement and comparison of different parameters of surface materials. The structure of surface materials on wooden floor included surface layer, raised struts, buffer materials and fillers as the Fig.2 shows. The names and sizes of application surface materials showed on table2.

structure	material	specification
surface	composite wooden floor	t = 9 mm ; d= 0.63 g/cm^3
	plywood	t = 15mm ; d = 0.60 g/cm^3
angle	southern pine	3600 mm×38 mm×90 mm ; d = 0.60 g/cm^3
filling material	glass wool	t = 25 mm ; 24K (kg/m^3)
resilience material	glass wool	t = 25 mm ; 80 K (kg/m^3)
t= thickness ; d=density		

Table 2: Application materials in this study.

3. RESULT AND DISCUSSION

number	Surface: composite wooden floor(9 mm) and plywood (15 mm)			condition	result	
	angle	resilience material	filling material	Position amount	$L_{n,t,w}$	ΔL_t
W00a	Wooden-based floor			10	71	-
W00b	Wooden-based floor			6	71	-
W01b	-	-	-	6	63	8
W02a	h= 90 mm；i=450 mm	-	-	10	62	9
W02b	h= 90 mm；i=450 mm	-	-	6	61	10
W03a	h= 90 mm；i=450 mm	-	glass wool t=25 mm	10	60	11
W03b	h= 90 mm；i=450 mm	-	glass wool t=25 mm	6	60	11
WG01	-	glass wool t=25 mm	-	6	60	11
WG02	h= 90 mm；i=450 mm	glass wool t=25 mm	-	6	57	14
WG03	h= 90 mm；i=450 mm	glass wool t=25 mm	glass wool t=25 mm	6	56	15

Note: i=interval；h=high； t= thickness

Table3. The result of impact sound insulation of difference wooden structure floor.

3.1. Comparison of impact sound insulation of wooden-based floor

Table3 shows the results of the impact sound insulation performance of wooden floor. The $L_{n,t,w}$ of light-weight impact sound of the wooden basic floor set up referring ISO in this study is 71 dB. Compared with the standard of type 1 and 2 of light-weight in ISO 140-11, the margin between them is just 1 dB. Fig.3 shows the comparisons of each frequency of them. The T-verification also shows there is no notable discrepancy between them. As the Table4 shows, the wooden floor meets the requirement of specifications.

3.2. Comparison of difference position of light-weight impact sound source

According to ISO 140-11, the tapping machine must be placed in 6 different asymmetric positions, and the minimum of microphones must be 4 at different positions. This study discusses whether the positions of tapping machine influence the impact sound pressure level. In addition, the wooden floor is a heterogeneous material, it may cause the difference of impact sound pressure as well. Compared with single values of 3 different positions, the maximum margin is 3 dB, as Table5 shows.

3.3. Comparison of amount of light-weight impact sound source

The measured results of different amounts of tapping machine shows the difference between single values of light-weight sources is 1 dB in the condition of the raised floor (W02a, W02b). The value of R^2 is 0.9 between the cases of 10 and 6 different positions of tapping machine in three variables of wooden floor, as the Fig.4 shows. Thus, others parameters were conducted with the 6 positions case.

3.4. Improvement of impact sound insulation of wooden-based floor

The result of the experiments shows the $L_{n,t,w}$ of light-weight impact sound of wooden floor with surface material is 63 dB, it is better than the case without surface material which is 71 dB. The case of the raised floor with surface material is 60 dB.

Both of paving surface material on wooden basic floor and the raised floor have effective improvements. The improvement by the raised floor are more significant than the other above the frequency of 250 Hz. Compared with the raised floor with and without fillers in the cavity, the $L_{n,t,w}$ of formal is 60 dB , and the latter is 61 dB. Furthermore, the $L_{n,t,w}$ can be 57 dB if put glass wools under the trusses of the raised floor, as the Fig.5 shows.

object	$L_{n,t,w}$	p-value
W00b	71	0.7

Position 1-1	76	0.7
Position 5(side of the joist)	73	
Position 6(on the joist)	74	
*P<0.05；**P<0.01；***P<0.001		

Table 4: Comparison W00b and light-weight reference floor for the single-number quantities.

4. CONCLUSION

This study set up the basic wooden floor by referring ISO 140-11, confirmed the applicability of the floors, and got the patterns of different impact sound insulations. The $L_{n,t,w}$ of light-weight impact sound of basic wooden floor which built in this study is 71 dB, it tallies with the standard of ISO 140-11. The wooden floor is a heterogeneous material, and it may cause the difference of impact sound pressure as well. To minimize the difference, the positions of tapping machine should take the position of truss of wooden floor into account, and selected 6 asymmetric positions of tapping machine to enhance the accuracy. The light-weight sound insulation of wooden floors can be improved by adding surface materials. The performance can be enhanced by paving buffer materials under the trusses in the condition of the wooden raised floor.

ABSTRACT

The south of Shaanxi province in China is an important conservation area for “the South-to-North Water Diversion Project” and “the Han-to-Weihe River Water Diversion Project” of China. It possesses both unique ecological environments and rich historical and cultural heritages. In order to protect the source of Han River, the local government in this area has implemented a large-scale ecological immigration policy since 2013. At present, it is urgent to construct energy-saving and environmental-friendly rural residences for the immigrants. This paper analyses the characteristics of natural ecosystem, society and culture in Ningqiang Area in the South of Shaanxi Province, discusses the survey results of the traditional residences and the new houses for the immigrants, explores approaches to the design and construction of contemporary green rural residences with regional characteristics and sense of belonging, and makes suggestions for the sustainable development of green rural residences for the ecological immigrants.

Keywords: ecological immigrants, rural residences, green construction technology

1. RESEARCH BACKGROUND AND PURPOSE

The southern part of Shaanxi Province in China is an important protection area for the projects of "South-to-North Water Diversion" and "Han-Wei-Wei" project in China. It is the birthplace of Hanjiang River. It has unique natural ecological environment, rich historical and cultural accumulation. As the southern part of Shaanxi province in 2008 Wenchuan earthquake disaster area, most of the original houses were destroyed, the government launched a "post-disaster reconstruction" construction project. To protect the source of the "South-to-North Water Diversion Project" - the source of the Hanjiang River, the government has implemented large-scale ecological relocation policy since 2013.

The source of Hanjiang River is located in Hanyuan Town, which belongs to Ningqiang County. Therefore, this paper selects Ningqiang County as a case for the study. The purpose is to discuss the ways and methods of constructing green rural houses with regional characteristics and sense of belonging considering based on analysis of both the traditional houses and contemporary houses, and provide useful references for the construction of local re-settlers and relocates based on the problems in existing houses of immigrants.

2. NATURAL ECOLOGY AND SOCIAL CULTURAL CONDITIONS IN NINGQIANG AREA

2.1 Topography: Two mountains clip

Ningqiang is located in Shaanxi, Gansu, Sichuan junction, is a north-south intersection mountain counties. The terrain is varied and has "V" -shaped structure, including different geomorphic types. The highest elevation is 2103.7 meters while the minimum elevation is 520 meters. (Figure 1)

Figure 1: Location of Ningqiang county

2.2 Climate: Humid and rainy

Ningqiang is located in the hot summer and cold winter regions, it has subtropical humid climate, having the annual average temperature of 13°C, extreme minimum temperature of minus 10.3°C, extreme maximum temperature of 36.2°C. The region has high air humidity, intense rainfall and high frequent rainstorms. The overall wind direction in the summer is the southwest wind, in the winter is northeast wind.

2.3 Socio-economy: Full of mobility

Ningqiang is located in the upper reaches of the Han River region, frequent population movements causes the mobility of the social form. The local farming industry are regarded as the main source of income. With the establishment of surface transport, this region, as the transport hub of Sichuan and Shanxi province, enabling tea and other crops to be used as goods to all over the country, plays a significant role in promoting the local economic development.

2.4 Folk culture: Diversified

NingQiang is located in the region surrounded by three Qin, Chu, Shu major cultural circles, the special geographical environment makes it constantly influenced by different cultures and radiation. Coupled with the history of the great migration occurred, the culture showed a diversity of tendencies, along with the characteristics of the North-South cultural transition and the nature of the intersection.

3. TRADITIONAL RESIDENTIAL CONSTRUCTION

3.4. The traditional residential construction mode

3.1.1 Types of residence

It is found that traditional houses in Ningqiang area can be divided into two categories: "one bright and two dark" traditional adobe houses and "courtyard" courtyard houses.

"One bright and two dark" traditional adobe houses

The layout of "one bright and two dark" is the result of natural selection under the restriction of traditional ritual thought and ethics in the background of Chinese agricultural society and regarded as the most basic architectural style inherited from. "One bright and two dark" types of plane layout of NingQiang traditional houses can be divided into two types: the"一" form (Figure 2) and the "L" form (Figure 3,4)， "一" form is the most basic flat form.

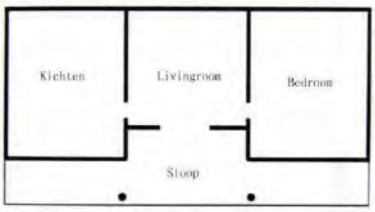

Figure 2: The "一" form plan

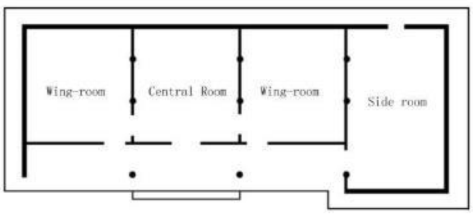

Figure 3: The "L" form plan

Figure 4: The appearance

"Courtyard" type residential courtyard

Ningqiang’s trade exchanges led to the development of local commodity economy, so the local courtyard houses, according to their functions, can be divided into two types: “independent courtyard” and “front shop and back house” residences.

Independent courtyard residential flat form are shown in Figure 5, courtyard-style compound courtyard space uses one courtyard as a structural unit. The form of “Front shop and back house” is similar to the stand-alone patio layout, but it's characterized by the fact that the commercial space and living space is not absolute separated. Connected high-density shops and closed external form of the building make these houses achieve lighting, ventilation and drainage function only by using patio courtyard (Figure 6,7).

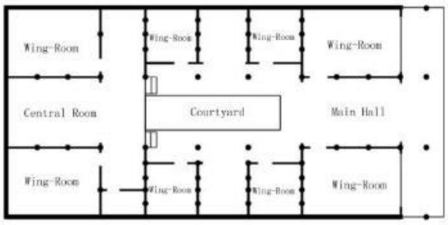

Figure 5: The courtyard house plan

Figure 6: The patio

Figure 7: Overall appearance

3.1.2 Materials technology

The material is made of local building materials suitable for the environment. The structure of residence is both uses the through-jointed frame and the post-lintel frame method. The wall is mainly rammed with 300~500mm thick rammed earth walls and the bamboo-earth walls. Because there are lots of local rainwater, the traditional houses are mostly made of stone blocks, rammed earth, (Angle range is 27°~33°). The triangular space formed in the lower part of the double-slope roof has certain heat insulation and ventilation function. The roof is made of cold-proof tiles and cold- Small green tiles. Eaves have the far-reaching construction and there are cornices under the overhead layer, both having hanging purposes. Most of the windows are open to southern walls, window frames and doors are all made of wood. In addition to building the foundation of the steps, the laying of the streets and courtyards are also covered with quartzite, the foundation part of the building wall is also built with pebbles.

3.5. Low tech ecological wisdom of the traditional residential

3.2.1 Far-reaching eaves and arcades

In order to speed up the discharge of rain, increase the disheartened space and storage space, eaves and arcades have the far-reaching construction. (Figure 8)

3.2.2 Earth and rock segmented retaining structures

Due to the wet and rainy conditions, and the wealth of wood, stone, loess, bamboo and other natural resources, local traditional houses formed with the individual architectural form which is composed by stone masonry, wood structure, and bamboo-earth retaining structure. (Figure 9)

3.2.3 Promote ventilation gable portals

In order to promote the attic space ventilation, people usually set the preformed hole on the gable. And in the winter，people close the hole with wood or bamboo for reduce the loss of warm air. (Figure 10)

a b

Figure 8: Far-reaching eaves and arcades

Figure 9: The gable structure

Figure 10: The hole on the gable

4. THE CONSTRUCTION OF CONTEMPORARY RURAL HOUSE

4.3 The contemporary rural house construction mode

Through the field survey of contemporary self-built houses (Figure 11), it is found that the layout has the following features: compact layout, mostly three-bay and multi-deep layout; brick-concrete structure, the main materials are clay brick and shale Brick; roof can be divided into flat roof or sloping roof, slope roof's form is a combination of traditional residential sloping roof form, the makers add a wooden roof structure above the flat roof; Window area is generally larger than the traditional rural house, mostly using aluminum sliding window and ordinary single-layer glass.

Figure 11: Self-built rural house

a b c

Figure 12: "Beichen" Village

4.4 Problems in the contemporary rural houses

4.2.1 Poor thermal comfort

In a research conducted in the winter, February 2015, researchers personally felt that the thermal comfort of contemporary houses is poor. It could be found from the thermal imaging test data that temperature in the external walls of the house wall was below zero and temperature inside room was the same as the outside temperature or even lower. The villagers set up stoves, coal stoves, charcoal and other heating facilities in the living room to gain more heat. Most villagers living in the "Beichen Village" transform the original open balcony into a closed balcony in order to improve the insulation effect (Figure 12a).

4.2.2 Poor lighting ventilation effect

Due to the restrictions of the relocation of the house base, most of the contemporary rural house use the layout of small width and deep depth, that caused insufficient indoor lighting and poor ventilation problems.

4.2.3 Ignore the drainage design

The design of agricultural houses in the "Beichen Village" resettlement project failed to take full account of the local rainy climatic factors, so the resettlement residents transform the housing in accordance with their own needs. For example, each household installed color plates on the yard and balcony to improve the drainage of the roof (Figure 12b).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4.2.4 Lack of drying storage space

The staircases, each balcony and the yards are filled with debris, agricultural tools and crops needed to dry because of the unique lifestyle of the farmers (Figure 9a), which not only makes the space messy, but also makes it inconvenient to remove the stuff. In order to meet the storage use needs, some farmers will close up overhead space on the first floor next to the door for storage rooms for agricultural tools, timber (Figure 12c).

4.2.5 Lose of regional culture

Ningqiang's contemporary rural houses exist in various forms, different styles, contemporary industrial design and construction of the local houses make the houses lose their unique style features, and also ignores the ancient folk heritage of low-tech construction experiences, the unique characteristics of the houses are gradually losing.

5. GREEN CONSTRUCTION OF ECOLOGICAL MIGRATION IN NINGQIANG AREA

In May 2016, undergraduate students studying in Northwestern Polytechnical University and me attended the "Zhongtian Cup" Fifth China Dream Green Building Creative Design Competition, winning the second prize finally. The content of this contest is the design of the green rural house group in Ningqiang area. "Gathering soil for home" was used as the theme and following green building strategies and methods were applied:

5.5 Low-tech strategy

5.1.1 Ventilation and lighting

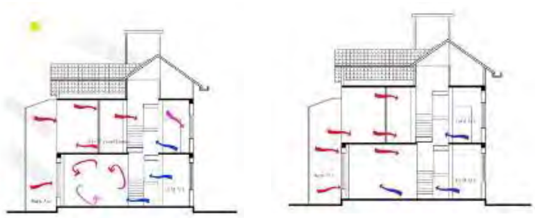
- Natural ventilation: The main room arranged in the windward side of the summer, the auxiliary room arranged in the leeward side, setting the overhead layer (Attic) below the slope roof to strengthen the ventilation,
- Natural lighting: Set up big interval to prevent the houses from blocking the sunlight. Choose a good orientation to guarantee enough sun radiation; Design the size of the window in a rational way so that the room can maximize the acceptance of natural light.

5.1.2 Temperature adjustment

Ningqiang area has the characteristics of hot summer and cold winter. It needs to keep warm in winter and avoid heat in summer.

- Cooling: The sun visor hanging outside that can be controlled can block the solar radiation according to the need, green plant can not only absorb the sun's radiation heat, but also cool down the temperature using leaf' s water transpiration.
- Warm insulation: Ningqiang is located in junction of the cold winter hot summer areas and the cold areas. Compared with the summer heat avoiding, winter insulation is more important. So we choose a right form to reduce the lost of heat, and use the thermal material as the envelope structure to adjust the indoor temperature and humidity.
- Additional sunlight room: Establishment of the sunlight room and the use of the heat generated by solar radiation can be used to regulate the indoor air temperature, to achieve the effect of winter insulation. (Figure 13). During the daytime, solar radiation enters the sunlight room to heat the cold air. Through the air return, the indoor temperature is increased to reduce the heating energy in the winter. In the night, the heat stored in the sunlight room can adjust the indoor temperature to the appropriate state. When it comes to the next day, the sunlight enters into the sunlight room again, and those circles can reduce heating energy consumption.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk



a. daytime b. at night

Figure 13: Work principle of sunlight room

a. daytime b. at night

Figure14: Work principle of ventilation shaft

- Establishment of the ventilation shaft: Setting the ventilation shaft can achieve the summer cooling (Figure 14). During the daytime, the outdoor air is cooled by the down pipe and the surface of the ground. The cold air flows from the bottom to the top through the ventilation shaft. The hot air is taken away by the ventilation shaft and the side window. In the nights, cool air form outside enter into the inside room by windows, taking away the hot air inside the room through the air circulation.

5.1.3 Drain and moisture proof

Due to local rainfall, we use the slope whose value is 35 degrees and the slope should be used in rural houses because it is not only conducive to rapid drainage, but also conducive to people when residents could still have outdoor spaces for conversation or labor. It can also be used to raise the bottom of the foundation. Setting the overhead layer plays the important role of avoiding moisture.

5.1.4 Energy use

- The use of solar energy: Green agricultural houses in Ningqiang area can set up the sunlight room to achieve the passive use of solar energy; the active use of the solar energy is to install solar collectors on the roofs whose slope values are 35 degrees to heat and supply hot water.
- The use of biogas: Replacing the traditional energy with biogas is a good way to solve the problem of energy shortage and achieve the goal of energy saving and environmental protection.
- Collection and re-use of water resources: We design a new system of recycling usage of water, Rain is collected through the eaves, and can be used after the filter for toilet flushing as well as irrigation of plants. Energy utilization cycle diagram is as follows. (Figure 15)

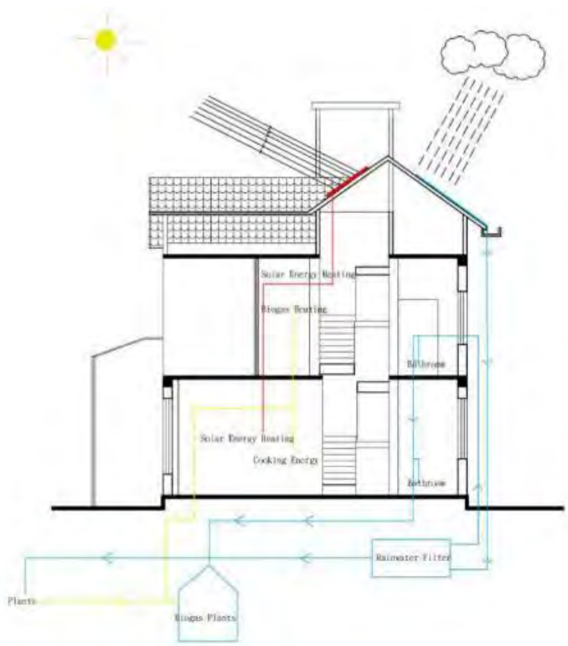


Figure 15: The cycle of energy utilization

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

5.1.5 Material selection

We use materials that are low energy consumption, recyclable, renewable, easily degradable such as grass bricks, straw composite panels, fiber composite panels when we considering the requirement of minimizing the consumption of the architectural materials.

5.6 Integrated construction methods

Compared with the traditional building construction method, the integrated construction method has the advantages of improving the construction quality, reducing the artificial demand and so on. In the construction of green house, the government will train the villagers and teach them how to mix industrial production of the finished product together, so that it could not only save labor costs but also obtain a higher construction accuracy.

5.7 Evoking humanistic care

Due to the earthquake damage, people moved to the resettlement area and the original neighborhood relationship has become fragmented. Considering this particular social phenomenon, it is important to reconstruct the neighborhood network among the villagers. We found that most of the villagers lost their plowing space because of the lack of land after moving. Increase collective farm areas is identified as a great way to not only restore the traditional labor life and achieve the aspirations of the villagers to cultivate, but also enhance neighborhood relations and reconstruct the broken neighborhood relationship through collective labor activity. As shown in Figure 16 is the rural life vision "soil for home".

Figure 16: The rural life vision “Soil for home”

6. CONCLUSION

The South of Shaanxi province in China has a special geographical environment, the construction of contemporary greenhouses is the most suitable way for the development of local houses. We should not only learn from the green experience inherited by the ancients and build new green rural house for residents to adapt to local climate Characteristics and to have comfort, sustainable living space through the low-tech and low-energy strategy, integrated building construction methods and the construction concept that is suitable for local traditional folk and life needs, but also provide reference experience for the construction for immigrants.

ABSTRACT

Particle packing optimization is a process of selecting optimum aggregate proportions that result in minimum voids and maximum density thus requirement of cement and water can be minimized. The concept of particle packing is adopted to determine sustainable concrete mix for interlocking concrete block pavers (ICBP). Typically the aggregates used for the ICBP are 12mm coarse aggregates with manufactured sand and natural sand as fine aggregates. Fresh concrete is poured into the mold and both vibration and compaction is applied to cast the block. The mold is removed soon after the block is cast. Hence a low water cement ratio and high green strength needs to prevent edge falling and cracking of freshly cast ICBP. Present industrial practice seems to be far less economical due to the use of high amount of cement, wastage of aggregates, and high energy consumption of machines due to improper mix proportions. Hence high strength variations within the same batch is visible. Theoretical packing models such as Toufar, De-Larrad, CPM, LPDM, Powers, Shilstone chart were analysed to determine the most suitable packing model. This study proposes improved sustainable mix design using packing density method by optimization of parameters such as water-cement ratio, coarse to fine aggregate ratio, quarry dust to natural sand ratio, cement content and compaction effort. Trial mixes were tested increasing excessive cement content from 20% to 40% in 5% intervals. The water cement ratio of 0.32-0.36 is suitable with 65-70% of fine aggregates. Further, 65-70% of manufactured sand (as a percentage of total fine aggregate) should be used to maintain green strength of the mix. Optimum vibration time should be 5-7 seconds with an optimum compression of 1.7 -2.0 MPa. The study reveals that optimization of mixture design parameters can reduce the cement content by 30% while maintaining the same concrete strength.

Keywords: green construction technology, particle packing optimization, sustainable concrete

1. INTRODUCTION

Heavy usage of cement in modern construction industry has led to numerous environmental problems. The cement industry is one of the main industries which release carbon dioxide, a major greenhouse gas. Raw material extraction to manufacture cement, heavy damage to the limestone deposits on earth when mining are causing major environmental pollution. (Mishra & Siddiqui, 2014) Hence reduction of cement usage in concrete industry is critical for a sustainable future. Particle packing optimization method can be successfully used to reduce the cement content while maintaining the quality of the concrete.

Reducing the cement content of concrete while maintaining the required quality of concrete is challenging. Consider a unit volume of concrete. Aggregate form the skeleton of this unit volume and cement paste will fill the void spaces among aggregates and create a bond between aggregates. If we can reduce the number of void spaces in concrete we can reduce the cement content required for the filing and bonding. Minimizing the voids can be done by selecting aggregates proportion and sizes carefully. Optimization of aggregate is the process of determining the most suitable aggregate particle sizes and distribution to minimize the voids content of an aggregate mix. An optimized aggregate mix will have lesser amount of voids which needs to be filled with cement paste resulting low cement, high quality concrete.

Optimization of aggregates to achieve higher strengths with lower cement content has been studied for various applications over the past decade. Though those studies were successful for more generalized applications, there were limitations when applying the results for specialized applications such as zero slump concrete, pre-cast concrete, roller compacted concrete, self-compacting concrete, high performance concrete etc. The main reason for such limitations in generalized approach is the variation of the required properties of concrete in each application. (I.e. Low water content requirement in zero slump concrete, roller compacted concrete and pre-cast concrete, high water requirements in self-compacting concrete etc.)

Concrete mixes used in ICBP industry seem to be far less economical and highly unsustainable. The manufacturers use high amount of cement to achieve higher strengths. There are high variations in strength within the same batch of blocks. This paper proposes a method to determine concrete mix proportions with the use of particle packing optimization method for ICBP to overcome above mentioned problems.

2. PARTICLE PACKING OPTIMIZATION

Studies on particle packing concepts were started in the 19th century. Earliest studies on particle packing for concrete mixes was presented by R. Feret in 1892 (Goltermann, et al., 1997), (Andersen & Johansen, 1991). Number of literature on particle packing concepts were published in the 1930s describing the optimization of packing followed by Furnas in 1929 and by Westmann and Hugill in 1930 (Goltermann, et al., 1997).

Powers (1968) stated that the voids ratio of a mix of a binary particulate system would be minimum at a particular combination. Voids ratio (U) is defined as the ratio between the volume of voids (E) and the volume of solids (1-E) of a particulate system.

In 1989, Petersen showcased the use of particle packing in relation to the mechanical and the rheological properties. Petersen observed that the model by Aim and Goff predicted the best fit of the theoretical to the experimental packing densities for small particle diameter ratios and that the model by Toufar et al. (Toufar, et al., 1976) produced the best fit for larger diameter ratios. Goltermann et al. (1997) used three models in their tests for the comparison, i.e. the Aim model, the Toufar model and the modified Toufar model. (Andersen & Johansen, 1991; Senthilkumar & Santhanam, 2003) A large variety in particle size and size distribution of natural and crushed aggregates were considered in their research and observed that the Toufar model, and especially the modified Toufar model, agrees very well with the measured packing degrees. The Aim model did not fit the test results and could not be used for the aggregates.

Pedersen & Glavind (1999) stated that when choosing a concrete mix design, it is always necessary to blend the aggregates as densely as possible. Apart from an evident economic benefit, a minimum of binder in concrete results in less shrinkage and creep and a denser and consequently a more robust and strong concrete mix.

The French concrete specialists Sedran and Larrard (De Larrad & Sedran, 2002) have found a method that uses a novel method for concrete mixing. Their software, Bétonlab, is reliable with their mathematical models. In addition to assessing the packing degree by use of the models, the authors presented that models can determine the fresh concrete properties and also the compressive strength.

Kwan & Wong (2008) measured the packing densities of cementitious materials comprising ordinary Portland cement, pulverized fly ash and condensed silica fume. The results for non-blended materials showed that the addition of a superplasticizer would increase the packing densities of ordinary Portland cement and pulverized fly ash, the addition of a polycarboxylate based superplasticizers could reduce the packing density of condensed silica fume.

Wong & Kwan (2014) proposed three tier system design. The mix design would be divided into three stages. At preliminary stage the packing density of the cementitious materials would decide the water demand, and at the second stage the aggregate particles smaller than 1.2mm would decide the paste demand and at third stage the aggregate particles larger than 1.2mm would decide the mortar demand.

From the above studies, it is observed that packing density mix design method can be used to minimize voids to increase particle packing and to reduce the cement content.

3. APPLICABILITY OF EXISTING PACKING MODEL

Several packing models were studied to determine the applicability of existing theoretical packing models for this application. Compressible packing model (CPM), Kwan three parameter model, modified Toufar model were selected for the optimization. The model proposed by Golterman et al., based on the Toufar's model have been validated by comparing around 800 test results from multiple sources. Kwan et al. three parameter model has considered three interaction effects. Loosening effect, wall effect and wedging effect. This is a semi empirical model where he has used experimental data and regression analysis to determine the wall effect, loosening effect and wedging effect parameters. Compressible packing model was developed by de larrad (2002). Out of these three models only compressible packing model addressed the packing process. It uses a compaction index (K) value which suggest a value of 9 for vibration.

To determine the suitability of suggested models, a laboratory experiment was carried out. The results indicated that the predicted packing densities by selected models were not accurate for the given conditions. The selected models could only predict the packing density for pre-defined packing process. Both Toufar model and Kwan 3 parameter model does not consider packing process into the calculation. Compressible packing model considers packing process but K value given for vibration does not satisfy the vibration and compression process applied in the packing process. The observed results were always greater than the results obtained from theoretical models. The figure 1 shows the comparison of selected models with laboratory experiment results.

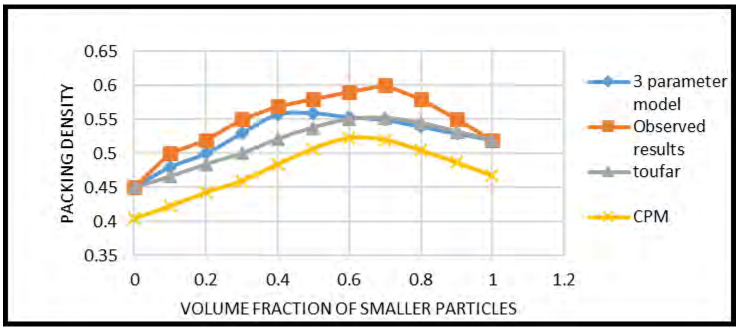

Figure 1: Comparison of packing models

4. EXPERIMENTAL PROGRAM

Considering the concrete mix requirements particle packing optimization found to be the most suitable mix design methodology to follow. 12mm coarse aggregates, quarry dust and natural sand were used as aggregates for the mix. According to Indian Standards (IS15658, 2006) the nominal maximum aggregate size is limited to 12 mm considering the block size. Since the vibration and compaction plays a major role in aggregate packing density, it is essential to select the optimum vibration duration and compression stress. The figure 2 and 3 show the variation of packing density with respect to vibration duration and compression.

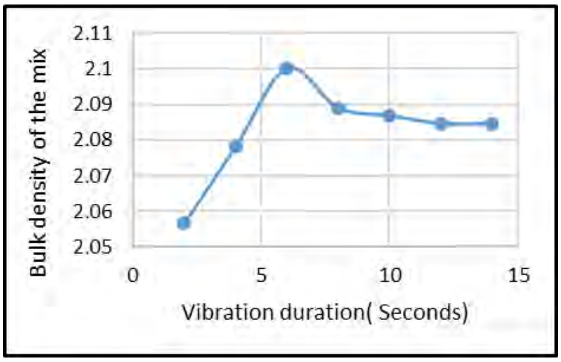

Figure 2: Bulk density Vs. Vibration

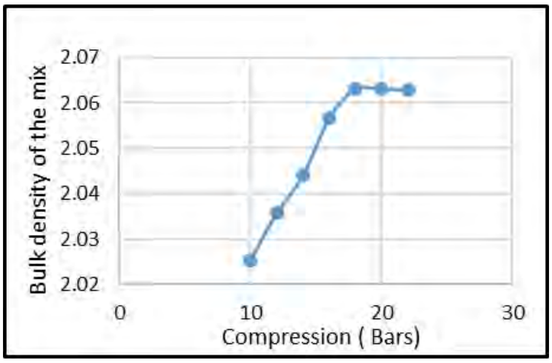

Figure 3: Bulk density Vs. Compression

The optimum vibration period was selected as 6 seconds as shown in figure and the optimum compaction was selected as 18 Bars. The results were used for the selection of aggregate proportions.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4.1 Selection of aggregate proportions

Initially it was planned to optimize the mix using a packing model. But considering the limitations for the applicability of packing model, it was decided to select aggregate proportions using laboratory experiments based on the concept of packing density. Selected vibration and compaction parameters were fixed to determine the aggregate proportions in the laboratory.

4.2 Coarse aggregate to fine aggregate ratio

Aggregates were mixed in proportions and selected vibration (6 seconds) and compression (18 bars) was applied. Then the packing density was determined. The packing density of aggregate mixture is defined as the solid volume in a unit total volume. The aim of obtaining packing density is to combine aggregate particles in order to minimize the porosity, which allows the use of least possible amount of binder. One size fraction of coarse aggregates and Natural sand (river) and quarry dust were selected for the study i.e. 10mm coarse aggregates, 2.36 mm downsize fine aggregate. The values of bulk density of the coarse aggregate were first determined separately. The coarse aggregate and fine aggregate were mixed in different proportions by mass, such as 90:10, 80:20, 70:30 and 60:40 etc., and the bulk density of each mixture is determined. The Figure 4 shows the variation of packing density with respect to aggregate proportions. Addition of fine aggregate increases the bulk density of the mix. However, a stage is reached when the bulk density of aggregate mixture, which instead of increasing, decreases again. Initially when coarse particles are dominant in the mix, voids in between coarse particles are high. Thus, the bulk density is very low. When fine particles are introduced to the mix, it will fill the voids in between coarse particles resulting a high bulk density in the mix. The packing of coarse particles is disturbed and the amount of voids further increase when fine particles dominate the mix. The mix proportion which produces highest bulk density is taken as the optimum mix.

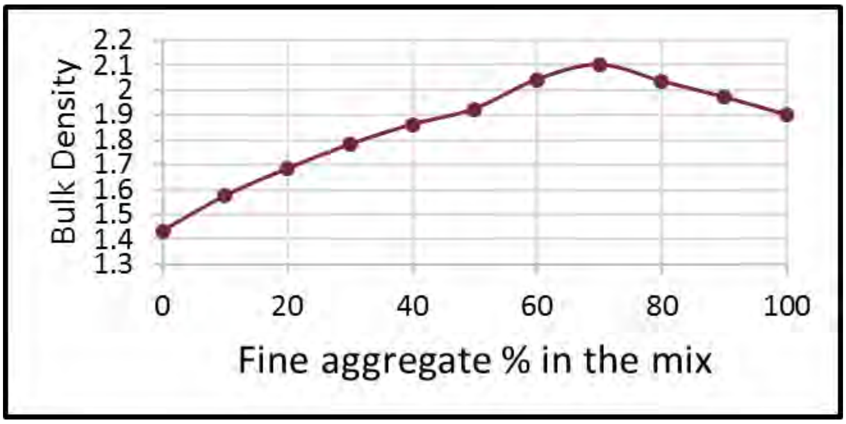

Figure 4: Bulk density vs. fine aggregate % in the mix

4.3 Natural sand to quarry dust proportion

Natural sand to quarry dust proportion in the mix is selected considering the characteristics of ICBP. According to previous studies it was found that adding replacing manufactured sand partially to the mix can significantly increase the strength of the concrete. Plenty of studies have been carried out during past decade and it was found that addition of 50% to 80% quarry dust to the total fine aggregate would increase the strength of the concrete. (Fate, 2014; Uma & Banu, 2015), (Zeghichi, et al., 2012; Priyanka, et al., 2013; Arivalagan, 2013; KrishnaRao, et al., 2013) Quarry dust percentage was selected based on production requirements as well. Since the mold is removed as soon as the block is cast, it is necessary to maintain high green strength in fresh concrete. When the quarry dust percentage is higher, the green strength is high due to the interlocking action in angular quarry dust particles. But on the other hand, high amount of quarry dust will increase the voids in the mix due to the shape factor. Quarry dust may not easily fill the voids in coarse particles. Due to the angular nature of the quarry dust particles, extra effort needs to be applied (Uma and Banu, 2015). But natural sand is round and produces more workable concrete. Hence natural sand can be easily used to fill the voids in coarse aggregates (Fate, 2014). Considering the above limitations in order to maintain high green strength with a workable concrete, 70% quarry dust and 30% natural sand was selected from total fine aggregates.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4.4 Water/ Cement Ratio

Water/cement ratio is critical in ICBP concrete mix. Since a dry concrete mix is used to cast blocks, the water/cement ratio needs to be kept to an optimum level. But too dry mix will break the fresh block after casting as well as the required surface texture cannot be achieved. Too wet concrete mix will slump the block after casting and mold will not be able to remove soon after compaction. Therefore, to select the most suitable water/ cement ratio box test was carried out. Box test revealed that 0.34 - 0.38 W/C ratio provides a better concrete mix which satisfies the required criteria. The figures (5, 6 and 7) shows the surface texture resulted in box test with respect to the W/C ratio.

Figure 5: 0.3 W/C

Figure 6: 0.35 W/C

Figure 7: 0.4 W/C

4.5 Excessive cement paste

Excessive cement paste is the amount of cement paste that will remain after filling all the voids in the aggregate matrix. This cement paste will coat the aggregate and act as a bonding agent for aggregates. Increase of excessive cement paste will increase thickness of the bond between two aggregates thus improving the strength of the bond. Since the aggregate is packed as densely as possible and the water/ cement ratio is kept to an optimum level it is the excessive cement paste that will improve the strength of the concrete. According to Taylor (2012) excessive cement paste can be increased up to 130% to increase the strength of the concrete.

According to table 1 the ACI mix design method uses 588.23 kg/m^3 while the proposed packing density method only uses 369.49 kg/m^3. It is 37.18% saving of cement. The proportions were used to cast paver blocks using industrial machines. Table 2 shows the results obtained from factory trial mixes. Figure 8 shows the final ICBP product.

Excessive paste content %	Quarry kg/m3	SAND kg/m3	Coarse agg. (12mm) kg/m3	CEMENT kg/m3	WATER (After corrected for absorption) kg/m3	7day (N/mm2)	28day (N/mm2)	Grade of concrete

5. CONCLUSION

Optimization of aggregate to minimize the voids in the concrete can be effectively used to reduce the cement content used for ICBP. Even though the reduction of cement content in concrete has been widely studied, the application of such studies is limited. The importance of this study is, it focuses on a specific range of products and apply the particle optimization knowledge to produce high quality more sustainable product. The methodology proposed in this paper can be modified and applied to determine a suitable mix design for any type of concrete product especially in pre-cast industry.

Determination of optimum compaction effort (Both vibration and compression), Determination of optimum aggregate proportion and determination of optimum water/ cement ratio are the three main stages of proposed method. In case if there are more than one coarse aggregates in the mix, the optimum proportion can be determined in several stages. First select the optimum coarse aggregate proportion by mixing coarse aggregates and determining the packing density. Then select the optimum fine aggregate proportion in the same manner. Finally, the selected coarse aggregate mix and fine aggregate mix can be used to find the optimum coarse aggregate to fine aggregate proportions. Optimum water cement ratio can be selected using box test. Water content and the strength has an inversely proportionate relationship. Since the concrete mix is dealing with low water content the strength is not a concern according to the Abrams law (Sear, et al., 1996).

The pilot study shows that the strength of the ICBP can be achieved with a low cement content producing more sustainable ICBP. Industrial survey revealed that the proposed mix uses 37% less amount of cement to achieve the same strength of the ICBP. It can be concluded that the particle optimization method can be used for sustainable concrete applications.

[b] Kogakuin University, Japan, yusuke@cc.kogakuin.ac.jp

ABSTRACT

About 360,000 tons of scallop are unloaded in Japan now, and most of them are concentrated in Hokkaido. The illegal dumping of the scallop shell became the problem, but the recycling rate largely rose by subsidies in late years. However, subsidies are not necessarily continuing permanently.

It was found that scallop shell lime is a natural material with little environmental load and high environmental performance, such as effects of humidity control, absorbing smells and VOC, and preventing mold. In addition, water resistance was confirmed by polished finish, this performance is not appeared in general lime made from limestone.

In this paper, water resistance and environmental performances are compared between scallop shell lime and general lime.

From the result of the examination, it was found that the examination body of the scallop shell lime with polished finish could have both humidity control effect and water resistance performance. From these results, it is anticipated that the scallop shell lime with polished finish is effective as an interior material of the places such as restroom or kitchen.

In addition, in the investigation about the water resistant mechanism, a prediction that expression of water resistance is influenced by the speed of carbonation was provided.

Keywords: indoor environmental quality, scallop shell lime, natural materials

1. INTRODUCTION

Today, about 360,000 tons of scallops are landed throughout Japan, with almost all of that being concentrated in Hokkaido. There was previously a problem with illegal dumping of scallop shells, but in recent years subsidies have been provided, and the recycling rate has increased greatly due to use as soil improvement material, underdrainage channeling material, and in other applications. However, these subsidies will not continue forever. Also, there are substitutes other than shells for applications such as soil improvement material and underdrainage channeling material, and these applications do not make use of the special characteristics of scallop shells.

In previous research, a basic survey was carried out of environmental adjustment type building materials using scallop shell lime, and it was confirmed that this is a building material employing natural materials that has low environmental impact and good performance. It also exhibits water resistance when given a polished finish.

This report examines the use of plastering materials having the added value of environment adjustment function, while comparing between scallop shell lime and regular lime in areas such as differences in water resistance and environmental performance when given a polished finish.

2. OVERVIEW OF REGULAR LIME BASED PLASTERING MATERIALS

In this report, scallop shells ground into powder are called “scallop shell powder,” calcined scallop shell powder is called “scallop shell lime,” slaked scallop shell lime is called “scallop shell paste,” and material such as aggregate mixed with scallop shell paste is called “scallop shell plastering material.” In addition, ordinary finishing is called “mortar finishing,” and further finishing by applying pressure with a trowel is called “polish finishing.”

Quicklimes made by calcining limestone and scallop shell lime have the same ingredient (calcium oxide) aside from impurities such as minute amounts of iron, and scallop shell lime is a material which can substitute for regular lime, as shown by the fact that shell mortar was previously used as a plastering material in Japan.

3. WATER RESISTANCE TEST

3.1 Overview of test

It was thought that perhaps there are differences in the degree that water resistance is exhibited due to factors such as the temperature of the water used when slaking scallop shell lime. Three slaking conditions were established: ordinary temperature (approx. 23ºC), low temperature (approx. 10ºC), and high temperature (approx. 50ºC). Immediately after slaking at ordinary temperature, ice-chilled paste was made by cooling with ice water. A frame was attached to a 20 cm × 20 cm test specimen made using this paste, and 100 cc of water was added. Water was wiped off after 1 minute, and the water absorption rate for 1 minute was found by determining the difference in weight of the test specimen before adding water and after wiping off water.

3.3 Test result

Figure 1 shows the results of water resistance testing. It is evident that shell lime polishing exhibits higher water resistance compared to regular lime polishing. The difference between shell lime polishing 1 and shell lime polishing 2 is likely to be an error arising because the specimen was prepared by hand, rather than an effect due to the different temperatures of water used for slaking.

With regular lime polishing, there are large differences in appearance depending on whether other materials such as cellulose fiber are mixed in, and types with mixed material seem to have a stronger surface luster. However, the results showed it is unlikely that the presence/absence of mixed materials has a major effect on water resistance.

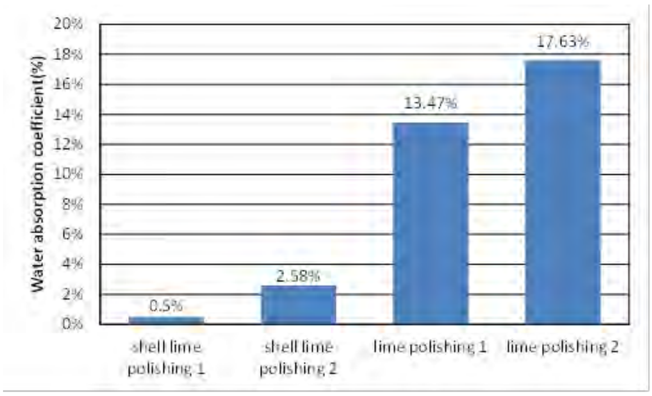

Figure 1: Result of water resistant examination

4 INVESTIGATION OF COMPOSITION VIA XRD ANALYSIS

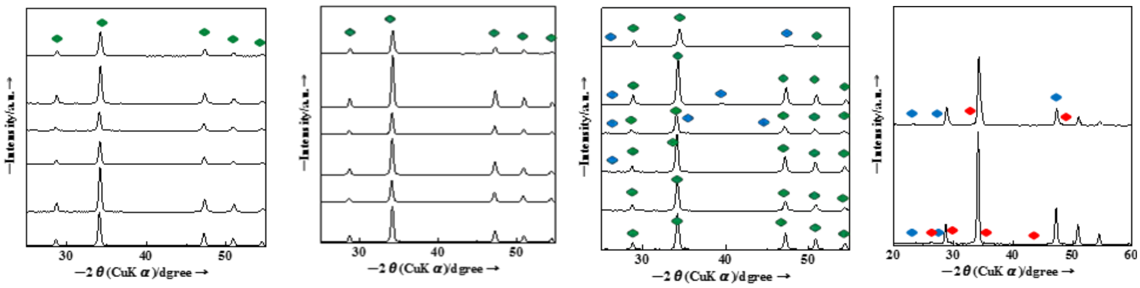
4.1 Overview

Using the paste prepared in section 3, an investigation was carried out to determine whether differences in slaking conditions have an impact on exhibiting water resistance, and whether the method of component growth during the curing stage plays a role in exhibiting water resistance. Also, as shown in Figure 2, it was thought that aragonite, a calcium carbonate component with a horizontal structure allows water to pass through less readily than calcite with its vertical structure, and this may have an effect on manifestation of water resistance. Therefore, the content percentages of aragonite and calcite were investigated through XRD analysis.

Figure 2: Crystal structure of calcite and aragonite

4.2 Test result

Test results are shown in Figure 3. The type slaked at low temperature and the type slaked at high temperature showed no appearance of calcium carbonate, and no difference was evident. The type slaked at ordinary temperature showed appearance of calcium carbonate, primarily of the calcite type. With ice chilling, there was appearance of calcium carbonate of both the argonite and calcite type, and the argonite type calcium carbonate was thought to have an effect on exhibiting water resistance, but as shown by the results of water resistance testing in section 3, there were no differences between the test specimens in terms of water resistance.



Low High Ordinary Ice

Figure 3: Result of XRD analysis

5 INVESTIGATION OF VARIOUS TYPES OF PERFORMANCE USING TEST SPECIMENS

5.1 Overview of test

Table 1 and Figure 4 provide an overview of test specimens. An undercoating and middle coating were applied to a 20 cm × 20 cm plasterboard, and this was given a mortar finish. Then a luster was brought out by applying pressure with a trowel, and the result was taken to be the polished finish.

specimen	under coat	intermediate coat			finish	
	material	material	aggregate	ratio	material	aggregate
shell lime polishing	under coat material	shell lime	shell powder	1:01	shell lime	—
lime polishing		lime	kansui	01:00.5	lime	
shell lime mortar		shell lime	shell powder	1:01	—	—
lime morter		lime	hakuryu	01:00.5	—	—

Table 1: Examination body summary

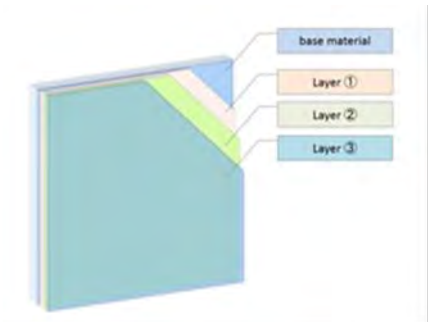


Figure 4: Cross section of the examination body

5.2 Test of moisture adsorption/ desorption performance

In accordance with JIS A 1470-1 "Determination of water vapour adsorption/desorption properties for moisture-regulating building materials — Part 1: Response to humidity variation," the test specimen was left to stand in a constant temperature and humidity bath. The moisture adsorption process was done at 23ºC/ 75% and the moisture desorption process at 23ºC/ 50%, and in each case the process was carried out 12 hours at a time, and changes in test specimen weight were recorded.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 5 shows the results combined with wallpaper data from previous research. The shell lime test specimen has performance almost on a part with regular lime, in terms of both moisture adsorption and moisture desorption rate, and result were obtained with moisture adsorption 2 times or more higher and moisture desorption 3 times or more higher than ordinary wall paper (vinyl cloth). The notable point here is the polished finish, and moisture adsorption/desorption performance on a par with an ordinary mortar finishing was confirmed, regardless of having water resistance.

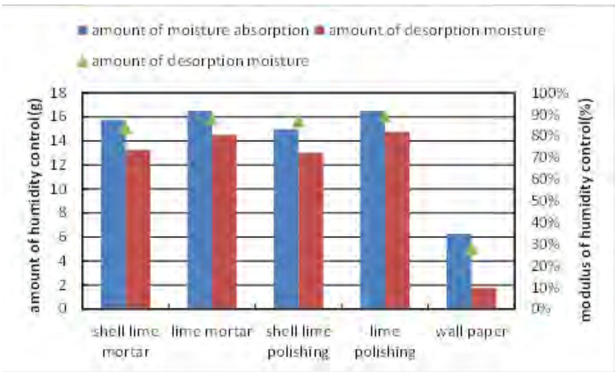

Figure 5: Structure of scallop lime

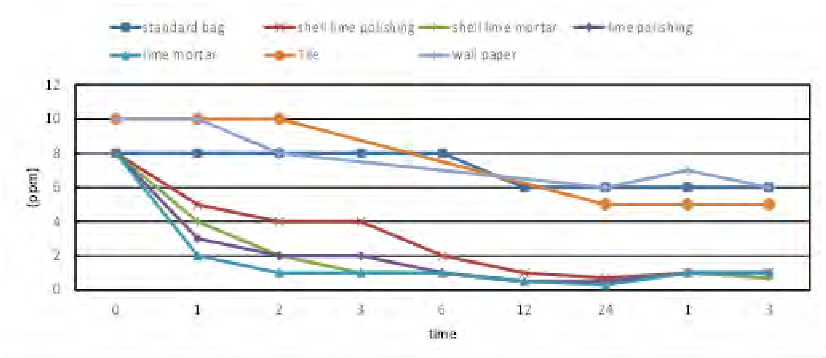
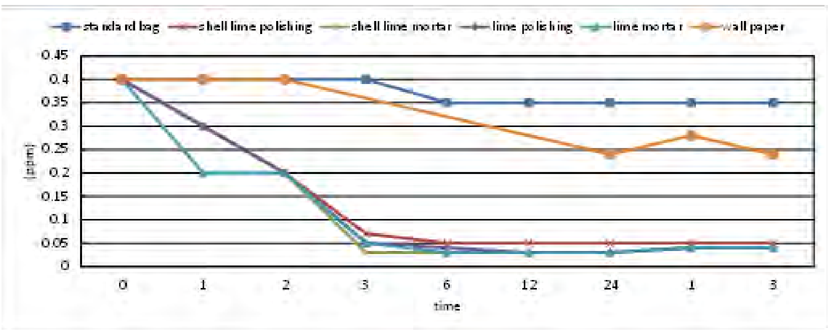
5.3 Adsorption-emission testing for ammonia-formaldehyde

Each of the test specimens in Table 1 was made into a 10 cm × 10 cm size and placed into a bag with capacity of 20 L. Ammonia was set to an initial concentration of 10 ppm and formaldehyde to an initial concentration of 0.4 ppm, and the decline in concentration over time was measured for each test specimen. As shown in Figure 6, the results showed that although there are differences in adsorption speed for both ammonia and formaldehyde, in the end adsorption up to about 1/10 or less was reached after 24 hours for both shell lime polished/mortar and regular lime polished/mortar.



Ammonia



Formaldehyde

Figure 6: Result of ammonia and formaldehyde adsorption examination

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

5.4 Fungus resistance test

Fungus was sprayed onto each type of test specimen: shell lime polished, shell lime mortar, regular lime polished, regular lime mortar, wall paper, plaster board, wood, and earth wall. The inside of the sealed container was set to a humidity of 90% or more, and growth of fungus was observed. The results showed that fungus grew in a condition like white cotton on the plaster board, wood and earth wall, but no growth of fungus was evident on the shell lime and regular lime test specimens.

6 XRD DIFFRACTION IN POLISHED PLASTERING MATERIALS

6.1 Overview of test

Among the items prepared in Table 2, those used as test specimens were: polished finish plastering material made with ice chilled scallop shell paste (shell lime polished), and for comparison polished finish plastering material made from regular lime (regular lime polished).

6.2 Test results

Figure 7 shows the test results. In the shell lime polished specimen, the surface layer is almost entirely calcium carbonate, and in the regular lime polished specimen it is calcium hydroxide. It was confirmed that carbonization progresses more quickly with the shell lime polished specimen. In general, the density of calcium carbonate is 2.7 g/cm^3, and the density of calcium hydroxide is 2.2 g/cm^3. The results suggest the possibility that the difference between these components covering the surface relate to manifestation of water resistance.

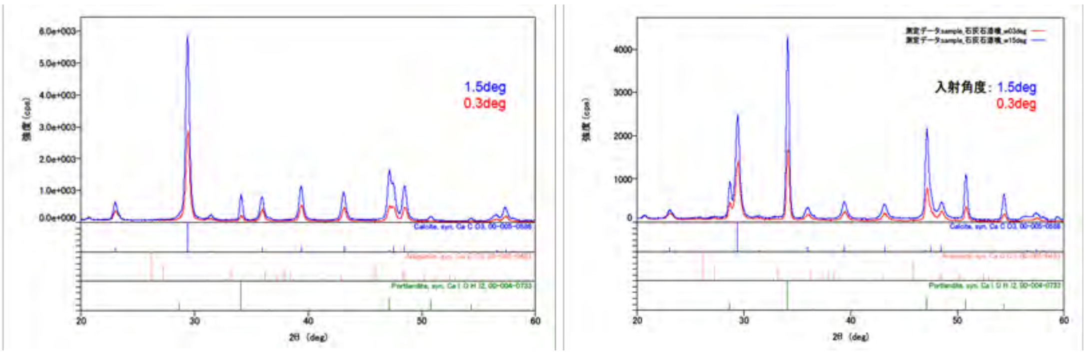


Figure 7: Result of XRD diffraction in polished plastering materials

7 CONCLUSION

In investigating various types of environmental performance using test specimens, it was confirmed that shell lime has moisture-regulating, gas adsorption and anti-fungal performance on a par with regular lime. Also, in water resistance testing, it was confirmed that water resistance typical of scallop polishing is exhibited, and in investigation of the water resistance mechanism, the results indicated that perhaps the high speed of carbonization compared to regular lime has an effect on manifestation of water resistance.

Plastering material using scallop shell lime has outstanding environmental performance, and is an environmentally-friendly building material because it reuses waste. In addition, it exhibits water resistance when given a polished finish, and has potential for use in settings involving plumbing. Even when polished, environmental performance such as adsorption-desorption performance does not degrade, and can be realized together with water resistance performance, and thus there is potential for applications such as wall material in plumbing-related setting such as toilets where odors are a particular worry.

Research on Environmental Safety of Nanomodified Building Materials

Petr ZHUK[a]

[a] *Moscow Architectural Institute (State Academy), Russia, peter_05@bk.ru*

ABSTRACT

The research methodology includes two directions: 1 ecotoxicological; 2 construction materials life cycle analysis. Ecotoxicological researches suggest definition of nanocomponents specifications, tracking of spreading medium, methods for identification of nano-particles in the environment (microscopic, chromatographic, spectroscopic and diffractive). The life cycle analysis was conducted on the base of approaches from risk theory, with the use of graph theory as well, which allowed to consider maximum amount of factors during materials or constructions exploitation under different conditions.

As results of the research, classification of nanomodified construction materials was introduced, risks of cytotoxic components invasion in geosphere components were analyzed, some dependences of nanocomponents toxicity from abiotic factors were studied. Under the method for assessment of environmental safety of nanomodifyied construction materials an approach allowing to consider both positive and negative effect of their utilization at the same time is proposed.

At the stage of designing materials and specific building elements with the use of nanomodifying additions one should foresee both positive and possible negative consequences for the environment. The article proposes ranging environmental risks for certain constructions, materials, nanomodified additions with different areas of use in construction. Approaches to reducing negative impacts on the environment when using certain nanomodifying components are developed.

Keywords: environmental safety, nanomodification, life cycle assessment, ecotoxicological studies

1. INTRODUCTION

The goal of this research was to form a single method for assessment of environmental safety of nanomodified construction materials. Under this assessment it is necessary to consider possible impact on human and the environment during the whole product life cycle. Wide expansion of nanomodification and nanostructurization methods for improving efficiency of different building elements is a reason for developing a single approach to problems of environmental safety on the base of risk theory.

Nowadays the implementation of nanomodified materials in high-performance buildings construction practice tends to grow due to their unique properties. At the first glance, the direct relationship between advanced technologies in nanostructures implementation area and materials which are traditionally used in architecture is rather hard to perceive. At the same time, any materials based on cementing agents (concrete, in particular) are perfect examples of nanostructures, because their durability features are formed as a result of crystallization processes, the scale of which lies exactly in this range. One of the most promising directions is fiber reinforcement of composite materials with carbon fiber and other materials. For instance, advantages of carbon-fiber reinforcing bars are that its durability factors are three times more than of carbon steel, while the density is much lower. Fibers of nanostructured materials can be used both as a complement to reinforcing rods and for fiber reinforcement of polymer materials and materials based on mineral binders. Base directions of nanostructural modification implementation are shown in the Table 1.

Material groups by designation	Nanostructural modification examples	Modification result
Structural materials	Using nanoparticles of silicon dioxide in form of silicic acid synthetic derivatives as an additive to high-strenght concrete.	Increase of imporosity as well as adhesional strength between concrete and steel reinforcement bars or between old and new concrete.
Buildings heat insulation	Electro-chromic, gas-chromic and thermotropic nanocoatings for glass, able to adjust light transmission on their own.	Light transmission of electro-chromic glasses can vary from 80% to 20%.
External finishing materials	Formation of self-cleaning surfaces with photo-catalytic effect due to nanoparticles of titanium dioxide insertion.	Due to the catalytic effect, hydrogen peroxide forms from water under the influence of ultraviolet and destroys organic pollutions which are then washed away by rain.
Internal finishing materials	Implementation of titanium dioxide nanoparticles as additives to coatings.	Protection from bleaching under the influence of natural or artificial light.

Table 1: Directions of construction materials nanostructural modification

Table 1 shows that base materials used in modern construction process, during the making of which nanostructuring technologies are being successfully implemented, are composite materials (in particular, carbon fiber reinforced plastics as well as modified lightweight concretes). In road building nanostructuring is actively used for asphalt concrete modification. Moreover, nanotechnologies are actively used for coating of different materials both for building face and interiors. In addition to those shown in the Table 1, such coatings include anti-graffiti systems, which protect surfaces from painting and corrosion protection systems for metals. One of the first materials referred to as “nano”, named after Richard Buckminster Fuller fullerene was also found useful in architectural and building practices. In particular, it is used as an additive in intumescent (swelling) fire-protective paints. Due to fullerene insertion under the influence of temperature during fire the paint swells and a dense coked cellular layer is formed, which strongly increases heating time to critical thermal point of constructions under protection.

At present there are certain structures built with the use of nanostructured materials. Those are, for instance, bridge across Volga river in Kimry and across Vyatka river, built with the use of nanostructured concrete, as well as bridges near art museum in Sochi and across Mansanares river in Madrid, built with the use of polymeric composite material – carbon fiber. The last structure, built by Acciona company, is 44 meters long and 3.5 meters wide and has an impressive jointless structure without abutments. In the builder company opinion, bridges building is getting easier due to using of carbon fiber reinforcement, and prime cost is lower as well. In particular, the above-mentioned bridge was constructed for two hours and materials include near 12 tons of carbon fiber.

2. EFFECTS ON THE ENVIRONMENT RELATED TO IMPLEMENTATION OF NANOSTRUCTURED MATERIALS

The rise of nanostructured materials implementation for solving architecture and building problems makes experts consider safety of such materials for human and the environment. To get a full picture of materials with nanostructural modification safety we need a method of their environmental assessment. Such assessment must take into account capabilities of nanostructured materials in unburdening the environment. They are related, for example, to ultrafiltration with the help of ferroxane or alumoxane membranes for pollutants discharge, using nanocatalysts for refining processes, lowering waste quantity and production energy consumption as well as getting higher quality materials structure (for instance, glass fiber made from jel or natural disperse formations). Table 2 shows possible positive and negative effects from implementation of nanostructured materials, related to impact on the environment.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Positive effects	Negative effects
Saving in material resources consumption (for instance, reducing of coatings layers thickness due to nanostructuring additives insertion); Reducing of byproducts quantity (through primary reactions with the use of nanocatalysts); Improvement of energy transformation efficiency (by using nanostructured materials); Lowering material costs (for example, by applying small amounts of coatings to surface); Removing burdening materials from the environment (for instance, removing water pollution through nanofilters); Increasing safety (by improving sensor devices while testing materials).	Spreading of nanoparticles in air and water and their diffusion after release from materials; Some of nanostructured materials (for example, with the use of fullerene and nanotubes) do not belong to nature and it is hard for them to embed themselves into ecosystems biogeochemical cycle; Recycling materials with the use of nanotechnologies can be difficult; Cytotoxicity of some nanostructuring components for living cells.

Table 2: Positive and negative effects on the environment related to implementation of nanostructured materials

Taking into account a significant amount of positive and negative dimensions of nanostructured materials implementation there rises a problem of their impartial assessment from the environmental point of view. The assessment system must have complexity and allow comparing materials with the use of nanostructuring additives and without them in case if such materials have the same functional value. For example, comparison of steel and carbon-fiber reinforcement bars. Since the production assessment is going under environment quality control system (ISO standards series 14040-14044), we can use directions already tested on counstruction materials. The main aspects necessary to take into account in full assessment include the following:

- impact on human if ingested;
- environmental impact through all stages of the life-cycle including intrusion into the atmosphere, water, soil, food chains as well as production power consumption;
- positive impact on unburdening the environment through all stages of the life-cycle.

Nanoparticles release from construction materials is possible at any stage of the life-cycle, starting from materials production on out to recycling. Particular attention must be paid to the operational stage. Similar to a range of researches, coatings testing under different effects were performed (attrition, atmospherical effects, hostile environments modeling).

3. RESEARCH ON ENVIRONMENTAL SAFETY OF NANOMODIFIED BUILDING MATERIALS

Under different impacts nanoparticles with size less than 100 nm were released from coatings, but nanocomponents themselves were always bound by the binding matrix. Researches on possible release of TiO_2 nanoparticles from coatings applied to different bases (wood, polymers, ceramics) were conducted under mechanical and atmospheric impacts. At the same time particles with size from 15 to 600 nm diffusion calculation was performed (Hsu and Chein, 2007). Researches confirmed general conclusions that release of free nano-objects from coatings is possible only in case of chemical or thermal destruction of matrix material, but not under mechanical impact. Additional researches are required on processes of possible matrix material containing nanocomponents destruction under environmental impacts. Those processes can lead to release of isolated nanoparticles. For example, such outcome is possible in case of destruction of matrices bearing nanocomponents, made of materials prone to photochemical breakdown. In particular, small amounts of artificial silver particles size from 20 to 300 nm can enter environment from facade paints due to erosion and rain (Kaegi et al., 2010). Nanoparticles are not washed away from dry coatings, but can enter air along with binding during coating surface attrition.

The entrance of nanoparticles in human body is possible through respiration air (via inhalation), with food (via mouth) and through skin. Nanotubes, implemented in many areas, when enter lungs can lead to consequences similar to those from asbestos fibers with the distinction that the latter have larger size (micron range). Nanoparticles can easily pass through cell membranes, which can be used to deliver medicines, but in some cases can lead to negative consequences (Paschen et al., 2003).

For the first time the cytotoxicity of fullerene clusters dissolved in water was discovered on fish brain tissue. The influence on cell membranes is related to presence of free radicals. At the same time fullerene is hydrophobic and poorly soluble in water on its own, but when its concentration reaches around 100 ppm it becomes able to form clusters, which lead to the above-mentioned negative impacts on the environment (Williams, Adams, 2007). When studying nanoparticles toxicity for living cells it is necessary to take into account that this index depends on the following characteristics: mobility, particles size, their chemical constitution, surface charge, shape, structure, etc.

The nanoparticles mobility is regarded as their ability to enter any systems as well as their influence in aerosols and liquid forms. While in medicine such ability of nanoparticles is a unique positive feature, in case of possible environment pollution the appraisal becomes the opposite.

That being said, it is possible to reduce the toxic effect of nanoparticles using functionalisation and derivatisation methods. Functionalisation means joining lesser molecular fragments to surface of, for example, fullerene. This can gradually (approximately two times) reduce toxicity of the same amount of nanoparticles (Williams, Adams, 2007). Fullerene functionalisation reactions include: Diels-Alder reaction (cycloconnection of elements with multiple bond, activated by adjacent electron-withdrawing group), Prato reaction (reaction with attachment of azomethine ylides), Bingel reaction, hydrogenation (during which compounds $C_{60}H_2$ … $C_{60}H_{50}$ are formed). All these reactions are reversible. Derivatisation refers to formation of secondary chemical elements and with its help it is also possible to reduce nanoparticles toxicity in an effective way (Williams, Adams, 2007).

For the full-scale analysis of nanoparticles toxicity at the materials production stage, experts suggest risk theory methods. In particular, the risk is considered as product toxicity by influence duration. For instance, in the Center for the Environmental Implications of NanoTechnology – CEINT of Duke University (North Carolina, USA) researches and comparative analysis of toxicity equivalent of such nanomaterials as fullerene, single-layer nanotubes, alumoxane nanoparticles and titanium dioxide are being conducted under the guidance of professor Mark R. Wiesner (Wiesner et al., 2008). According to experts of the above-mentioned center, the risk in nanomaterials production is equal to such in production of materials traditionally implemented in architectural practices.

Methods for evaluation of risks related to implementation of nanomodified materials have several distinctions. For instance, risk can be calculated as product of toxicity by influence duration (Williams, Adams, 2007), or we can calculate a risk ratio, which refers to a ratio of undesired events amount to current hazard factor scale (full amount of hazardous events) (Godymchuk et al., 2012). In this article, calculations were based on the definition of risk as a product of hazardous situation probability on damage value.

Nanoparticles name	Relative environmental risk index of production, %	Relative environmental risk index of operation, %
Single-layer carbon-fiber nanotubes	20	5
Fullerene	40	10
Alumoxane nanoparticles	35	15
Titanium dioxide nanoparticles	50	20

Table 3: Comparative index of environmental risk at nanomodified materials production and operational stages

Basing on the results of risk calculation, we must note that in general indexes at the operational stage are gradually lower than those at the production stage, which is explained by considerably lower probability of unbound particles entry in the environment. Moreover, there is a correlation between relative risk indexes for different nanoparticle types at both life-cycles stages of the products made with their implementation.

Positive effects may be related to using nanoparticlesas part of construction materials in order to give them fireproof, waterproof, bioresistant features and to secure their longevity. In particular, there are examples of nanostructural components implementation for absorption of possible hazardous components emission through chemisorption. Figure 1 shows the principle of formaldehyde chemisorption frompressed wood boards through implementation of paint base with nanoparticles (Maltsev, 2012).

4. CONCLUSION

At present, a range of fundamental type nanopowders used in building construction is produced on an industrial scale. Those are, in particular, aluminum, silicon and titanium oxides. The fundamental technology of their production is aerosol pyrolysis (Foster, 2006). Several other methods of nanostructuring components production have also been brought to industrial level. Among them is plasma-chemical method, which can provide high efficiency of production and a possibility to lower powder agglomeration. But it is important to characterize not only nanostructuring components production but also materials, in which they are implemented.

Instruments of the graph theory can be proposed as a methodical base for environmental assessment of nanostructured materials, as long as directed graphs and formed matrixes allow considering simultaneously both positive and negative aspects of implementing production in architecture and building. Furthermore, using negative feedback principle, which is widely spread both in environmental studies and in product quality assessment, shows good results. The negative feedback stands for the link which declines the shift from optimum. Risk (toxicity for living cells) parameters and the amount of power lost in nanostructured material production can be used as indicators of assessment system. When using the negative feedback principle it is important to consider noises, which can include accelerated diffusion of nanoparticles in the environment. While in ecology the negative feedback principle is used to define scales of homeostatic plateau, within which the ecosystem preserves self-maintenance and self-regulation abilities, in case of material properties assessment we can simply define the upper limit of its safety at any stage of the life-cycle.
