PUBLISHING DETAILS

This Conference Proceedings for World Sustainable Built Environment Conference 2017 Hong Kong (WSBE17 Hong Kong), which took place in Hong Kong on 5-7 June, 2017.

The Conference was jointly organised by Construction Industry Council (CIC) and the Hong Kong Green Building Council (HKGBC).

The Sustainable Built Environment (SBE) series of conference operates on a three-year cycle and includes five international organisations as co-owners:

- International Council for Research and Innovation in Building and Construction (CIB)
- International Initiative for a Sustainable Built Environment (iiSBE)
- United Nations Environment Programme (UNEP-SBCI, Sustainable Building and Climate Initiative)
- International Federation of Consulting Engineers (IFDIC)
- Global Alliance for Buildings and Construction (Global ABC)

The Conference Proceedings is available at the website of Hong Kong Green Building Council: http://www.hkgbc.org.hk

This proceedings gathers papers presented in the Conference, "WSBE17 Hong Kong – Transforming Our Built Environment through Innovation and Integration: Putting Ideas into Action", presented in Hong Kong. All the papers in this proceedings were double blind peer reviewed by the International Scientific Review Panel of WSBE17 Hong Kong.

The proceedings was prepared from the input files supplied by the authors. The Conference Organisers make no representation, express or implied, with regard to the accuracy of the information contained in this proceedings and cannot accept any legal responsibility of liability for any errors or omission that may be made.

This proceedings is published by the Construction Industry Council and Hong Kong Green Building Council Limited in Hong Kong on May 2017.

WSBE17 Hong Kong:
THE MOST INFLUENTIAL GREEN BUILDING MEGA EVENT

The Construction Industry Council and the Hong Kong Green Building Council jointly welcome you to participate at the World Sustainable Built Environment Conference 2017 Hong Kong (WSBE17 Hong Kong).

Pre-eminent Conference Series

The Sustainable Built Environment (SBE) series began in 2000 and is now the pre-eminent international conference series on sustainable building and construction. The series operates on a three-year cycle with planning in year one, regional conferences in year two and a global conference in year three. Albeit strong competition, Hong Kong won the hosting right of the 2015-2017 cycle global conference, which will conclude the conference cycle by embracing all the top findings from the 20 regional conferences held in 2016.

About WSBE17 Hong Kong

With the theme of **Transforming Our Built Environment through Innovation and Integration: Putting Ideas into Action**, WSBE17 Hong Kong will bring together **1,800** green building advocates, policy-makers, academics, and industry practitioners from over **55 countries**. The three-day event includes conference sessions with top-notch speakers, and around 100 parallel sessions, with an exhibition alongside.

Organisers

Construction Industry Council (CIC)

The Construction Industry Council (CIC) was formed in 2007 under the Construction Industry Council Ordinance (Cap. 587). The CIC consists of a chairman and 24 members representing various sectors of the industry including employers, professionals, academics, contractors, workers, independent persons and Government officials.

The main functions of the CIC are to forge consensus on long-term strategic issues, convey the industry's needs and aspirations to Government, provide training and registration for the construction workforce and serve as a communication channel for Government to solicit advice on all construction-related matters.

CONSTRUCTION INDUSTRY COUNCIL
建造業議會

Hong Kong Green Building Council (HKGBC)

The Hong Kong Green Building Council (HKGBC) is a non-profit, member led organisation established in 2009 with the vision to help save the planet and improve the wellbeing of the people of Hong Kong by transforming the city into a greener built environment. The Founding Members of the HKGBC include the Construction Industry Council (CIC), the Business Environment Council (BEC), the BEAM Society Limited (BSL) and the Professional Green Building Council (PGBC). Its mission is to lead market transformation by advocating green policies to the Government; introducing green building practices to all stakeholders; setting design, construction and management standards for the building profession; and promoting green living to the people of Hong Kong.

Message from Chairman of WSBE17 Hong Kong Organising Committee

Ir Conrad WONG Tin-cheung, BBS, JP

It has been my great honour to work closely with all Organising Committee and Scientific Committee members, and the Conference Secretariat, to bring WSBE17 Hong Kong to life. Since winning the hosting rights in 2014, the Organising Committee has dedicated itself to creating the best world conference ever; one that can inspire in-depth discussions and create a long-lasting impact on the transformation of our built environment, particularly in the interconnected domains of 'Policy & Standards', 'Practice & Business', 'Science & Technology' and 'People & Community'.

The Committee has worked hard for many years to reach this moment. Now, all that remains is for me to wish all delegates an enjoyable, thought-provoking and inspirational time at this important conference.

The planet urgently needs our help. Together, we can create a brighter future for all mankind.

Ir Conrad WONG Tin-cheung, BBS, JP
Chairman
WSBE17 Hong Kong Organising Committee

Honorary Advisors

International Conference President of Past World SB Conferences	Position and Organisation
Mr Felipe PICH–AGUILERA	President, WSB14 Barcelona
Ms Helena SOIMAKALLIO	Chair, Local Organising Committee of WSB11 Helsinki
Prof. Greg FOLIENTE	Co-Chair, WSB08 Melbourne
Prof. Shuzo MURAKAMI	Chair, the National Conference Board WSB05 Tokyo

Mainland China	Position and Organisation
Dr QIU Baoxing	Representative of the Ministry of Housing and Urban-Rural Development & Counsellor of Counsellor's Office of the State Council of PRC
Prof. JIANG Yi	Member, China Academy of Engineering; Director, Building Energy Conservation Research Center (BERC), Tsinghua University

Hong Kong	Position and Organisation
Mr Matthew CHEUNG Kin-chung , GBS, JP	Chief Secretary for Administration, Government of the HKSAR
Mr Eric MA Siu-cheung , JP	Secretary for Development, Government of the HKSAR

Message from Chairman of Construction Industry Council

Sr CHAN Ka-kui, BBS, JP

It is my great pleasure to offer a warm welcome to all delegates coming to Hong Kong for WSBE17 Hong Kong. The Construction Industry Council is proud to be a co-organiser of this important event, which provides a platform that inspires and enables transformation in both the construction industry and the built environment, locally and worldwide.

The Hong Kong construction industry has achieved a great deal in the last decade, from ground-breaking research to innovative new projects. We are delighted to share our experiences with delegates from around the world.

This landmark conference offers valuable insights from the six world renowned keynote speakers, as well as the collected wisdom and experience of the other 400 distinguished speakers. The three-day conference will lead to fruitful discussions and provide a strong foundation for putting ideas into action, which will benefit the long-term sustainability of communities around the world.

Sr CHAN Ka-kui, BBS, JP
Chairman
Construction Industry Council

Message from Chairman of Hong Kong Green Building Council

Sr Bay WONG

The SBE16/17 conference series has, for the first time, expanded its focus from buildings to the overall built environment. It is fitting, therefore, that the series reaches its conclusion in Hong Kong, where our high-rise and high-density built environment poses a number of unique challenges. I believe that our experience in meeting and overcoming these challenges has great value for urban environments around the world.

This high-profile, global conference WSBE17 Hong Kong brings together more than 1,800 of the world's leading green building experts from 55 countries around the planet. I offer my sincere thanks to the Construction Industry Council for its wholehearted support in organising this important event, and to the Government of the HKSAR and the local construction industry for helping us to make this event a success.

On behalf of the HKGBC, I warmly invite you to join hands with us and work together to create a sustainable built environment in communities around the world.

Sr Bay WONG
Chairman
Hong Kong Green Building Council

Message from Chief Executive of the Hong Kong Special Administrative Region

Hon. LEUNG Chun-ying, GBM, GBS, JP

I am very pleased to welcome some 1800 green building professionals from about 50 countries to Hong Kong for the World Sustainable Built Environment Conference (WSBE), 5-7 June. This is the first WSBE Conference to take place in Hong Kong, and it is an honour to host this significant international event as part of our celebrations for the 20th anniversary of the establishment of the Hong Kong Special Administrative Region.

The theme of this year's Conference "Transforming Our Built Environment through Innovation and Integration: putting Ideas into Action", is both timely and apt. I have no doubt that the Conference's innovative ideas and collaborative efforts will help us build a smart and green Hong Kong and, in doing so, contribute to the growing global movement to combat climate change.

I wish you every success at the Conference and a memorable stay in Hong Kong.

Hon. LEUNG Chun-ying, GBM, GBS, JP
Chief Executive
Hong Kong Special Administrative Region

Message from Chief Secretary for Administration, Government of the HKSAR

Mr Matthew CHEUNG Kin-chung, GBS, JP

I offer my warmest congratulations to the Construction Industry Council and the Hong Kong Green Building Council on hosting the World Sustainable Built Environment Conference 2017 in Hong Kong. This year has a special and historic significance as it marks the 20th anniversary of the establishment of the Hong Kong Special Administrative Region. The conference is one of the flagship events celebrating this auspicious occasion.

Against the backdrop of a growing consensus on the need to combat climate change, global citizens nowadays have rising aspirations for an urban built environment which is sustainable, green and smart. As a vibrant, high-density and high-rise international city, Hong Kong is an ideal place for green building advocates, policymakers and academics from all over the world to come together and discuss how to build a sustainable future. Under the theme "Transforming Our Built Environment through Innovation and Integration: Putting Ideas into Action", the Conference provides an invaluable platform for experts to share their expertise, innovative ideas, rich experience and insights on the common vision for sustainability.

The Hong Kong Special Administrative Region Government is committed to turning Hong Kong into a greener metropolis. We have, in collaboration with the industry, spearheaded the development of a sustainable built environment. The wide range of initiatives already put in place include imposing mandatory requirements, providing the private sector with incentives, encouraging government departments to lead by example and driving behavioural change in society. On top of all these, we announced earlier this year Hong Kong's Climate Action Plan 2030+, which not only outlines our longer-term action to combat climate change but also sets out the carbon emission reduction target for 2030. As a member of the global village, Hong Kong needs to respond proactively to this cross-sector, cross-domain subject. With this in mind, we will continue to work closely with various sectors of the community and the general public to make our city more climate-resilient in the long run.

I would like to take this opportunity to extend my deepest gratitude to the hosts, co-owners, organisers, sponsors and participants for making the event possible. I wish the Conference every success and all overseas participants a rewarding and pleasant stay in Hong Kong.

Mr Matthew CHEUNG Kin-chung, GBS, JP
Chief Secretary for Administration
The Government of the Hong Kong Special Administrative Region

Message from Secretary for Development, Government of the HKSAR

Mr Eric MA Siu-cheung, JP

I am delighted to offer my congratulations to the successful organisation of the World Sustainable Built Environment Conference 2017 in Hong Kong which has come to its 7th edition.

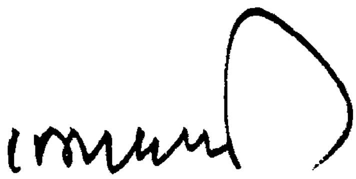
The ascension of the Conference from sustainable building in the 2014 edition held in Barcelona to sustainable built environment in the current edition is a remarkable achievement of the campaign for sustainable development. The move from focusing on the significance of individual sustainable buildings to encompassing the constituent fabrics for the built environment will definitely enhance the performance of the construction industry in combating climate change. I am certain that the local industry and participants coming from all over the world have longed to share together their brilliant ideas and prominent achievements in the global movement. Our joint efforts will be crucial and instrumental in shaping the living environment for our future generations. May I extend my heartfelt gratitude to the Construction Industry Council and the Hong Kong Green Building Council for their great efforts and wish the Conference a resounding success.

Mr Eric MA Siu-cheung, JP
Secretary for Development
The Government of the Hong Kong Special Administrative Region

Message from Secretary for the Environment, Government of the HKSAR

Mr WONG Kam-sing, GBS, JP

Let me extend my best congratulations to the successful organisation of the World Sustainable Built Environment Conference (WSBE) 2017 in Hong Kong. As a densely-populated world city where about 90% of the population lives in high-rise buildings, Hong Kong offers a unique setting for participants from around the world to discuss the challenges and strategies for sustainable built environment. The WSBE signifies the commitment to sustainable buildings which are important in preparing us to be "climate ready". I am sure that participants will benefit from the discussions and exchanges that will help shape a sustainable built environment. My sincere gratitude goes to the Hong Kong Green Building Council and the Construction Industry Council for their outstanding contribution. I wish the WSBE 2017 a great success.

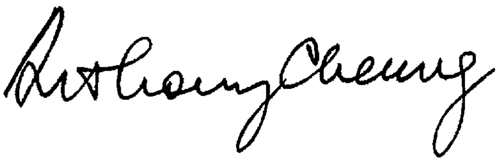


Mr WONG Kam-sing, GBS, JP
Secretary for the Environment
The Government of the Hong Kong Special Administrative Region

Message from Secretary for Transport and Housing, Government of the HKSAR

Prof. Anthony CHEUNG Bing-leung, GBS, JP

I convey my warmest congratulations to the Hong Kong Green Building Council and the Construction Industry Council for the successful organisation of the WSBE17 Hong Kong Conference. Hong Kong is one of the most densely populated cities in the world. Driven by the vision to provide a better living environment for our citizens, the Government has been actively exploring new and innovative means towards green building development without compromising our environment. I sincerely wish all participants from round the globe to join hands in our common mission to "Put Ideas into Action" for a greener Earth with livable and sustainable environment.



Prof. Anthony CHEUNG Bing-leung, GBS, JP
Secretary for Transport and Housing
The Government of the Hong Kong Special Administrative Region

CONFERENCE PROGRAMME

Day 1 • 5 June 2017 (Mon)

08:00 - 09:00	***Registration***
09:00 - 10:00	**Opening Ceremony** **Welcome Remark** **Ir Conrad WONG**, Chairman, WSBE17 Hong Kong Organising Committee **Opening Remark** **Hon. LEUNG Chun-ying**, Chief Executive, Hong Kong Special Administrative Region **Dr QIU Baoxing**, Representative of The Ministry of Housing and Urban-Rural Development & Counsellor of Counsellor's Office of the State Council of the PRC
10:00 - 10:30 *Convention Hall*	**Keynote 1: Mr Matthew CHEUNG Kin-chung**, Chief Secretary for Administration, Government of the HKSAR
10:30 - 11:00 *Convention Hall*	**Keynote 2: Mr SU Yunshan**, Director-General, Department of Science & Technology and Energy Saving on Buildings, Ministry of Housing and Urban-Rural Development, People's Republic of China
11:00 - 11:20	*Coffee Break*
11:20 - 11:50 *Convention Hall*	**Keynote 3: Ms Christiana FIGUERES**, Vice-chair, Global Covenant of Mayors for Climate & Energy
11:50 - 12:00 *Convention Hall*	**Platinum Sponsor's Sharing - Mr Sean CHIAO**, President, Asia Pacific, AECOM
12:00 - 13:30	*Networking Luncheon (Grand Hall, Level 3, Hong Kong Convention and Exhibition Centre)* *For registered guests only*
13:30 - 15:00	**Parallel Session 1**

Session	Venue	Session	Venue
1.1 Mainland China Session - The Comprehensive Scheme on Green Retrofitting and Performance Enhancement of Existing Buildings in China	Level 1 - Convention Hall	1.2 Regional Session - Czech Republic, Italy, Sweden and Switzerland	Level 1 - Theatre 1
1.3 Advanced Building Elements	Level 1 - Theatre 2	1.4 Practices Review of High-Performance Green Buildings	Level 2 - S221
1.5 SBE Assessments - Green Neighbourhoods (1)	Level 4 - S428	1.6 Innovations Driving for Greener Policies and Standards - Microclimate	Level 2 - S223
1.7 Vision-led Sustainable Neighborhoods: Myths and Musts	Level 2 - S224 & 225	1.8 Innovations for Occupant Wellbeing (1)	Level 4 - S426 & 427
1.9 Practices & Methodologies for Green Building Management (1)	Level 2 - S228	1.10 Green Infrastructure in SBE - Hong Kong Cases	Level 4 - S423 & 424
1.11 Processes, Design, Tools and Methodologies in SBE (1)	Level 4 - S421	1.12 Regenerating Urban Space in Neighbourhoods	Level 4 - S425
1.13 Healthy and Sustainable Building for Resilient Future	Level 2 - S226 & 227		

15:00 - 15:20	*Coffee Break*

15:20 - 16:20 *Convention Hall*	**Roundtable 1: Emerging Perspectives for Transforming the Build Environment**
	Session Chair: **Prof. Thomas LÜTZKENDORF**, Director, Centre for Real Estate; Head of Chair, Sustainable Management of Housing and Real Estate, Karlsruhe Institute of Technology
	Speakers: **Ar. TAI Lee-siang**, Chair, WorldGBC **Prof. WANG Youwei**, Chairman, China Green Building Council **Prof. Serge SALAT**, President, Urban Morphology and Complex Systems Institute **Prof. Arno SCHLUETER**, Professor, Architecture and Building Systems ETH Zurich; Principal Investigator, Future Cities Laboratory, Singapore ETH Centre **Ar. Bryant LU**, Vice Chairman, Ronald Lu and Partners

16:30 - 18:00 **Parallel Session 2**

	Venue		Venue
2.1 Mainland China Session - Green Building Design and Technological Challenges of Eco Skyscraper in China	Level 1 - Convention Hall	2.2 Regional Session: Turkey, Greece, Malta and Egypt	Level 1 - Theatre 1
2.3 Advanced Building Systems	Level 1 - Theatre 2	2.4 Policies for High-Performance Green Buildings (1)	Level 2 - S221
2.5 SBE Assessments - Green Neighbourhoods (2)	Level 2 - S222	2.6 Innovations Driving for Greener Policies and Standards - Carbon Assessment	Level 2 - S223
2.7 Deep Energy Saving and Other Innovative Green Measures for Commercial Buildings in Hong Kong, Mainland China and Overseas	Level 2 - S224 & 225	2.8 Innovations for Occupant Wellbeing (2)	Level 4 - S426 & 427
2.9 Practices & Methodologies for Green Building Management (2)	Level 2 - S228	2.10 Transforming SBE Practices - Energy Management (1)	Level 4 - S423 & 424
2.11 Processes, Design, Tools and Methodologies in SBE (2)	Level 4 - S421	2.12 Processes of Urban Regeneration	Level 4 - S425
2.13 Powering Up Smart City	Level 2 - S226 & 227	2.14 Sustainability Assessment of Buildings as Part of Green-Public Procurement Based on the German BNB-System	Level 4 - S428

CONFERENCE PROGRAMME

Day 2 • 6 June 2017 (Tue)

08:00 - 09:00	***Registration***
09:00 - 11:50 *Convention Hall*	**Plenary Session on Climate Change and Sustainable Development**
	Session Chair: **Mr Curt GARRIGAN**, Cities and Buildings Programme Manager, UN Environment – Economy Division

6.3 Smart Initiatives in SBE (2)	Level 1 - Theatre 2	6.4 Deep Renovations - Practices & Performance Review	Level 2 - S221
6.5 SBE Assessments - Design Processes	Level 2 - S222	6.6 Green Construction Materials (1)	Level 2 - S224 & 225
6.7 Innovations Driving for Greener Policies and Standards - Assessment, Analysis and Modelling (2)	Level 2 - S223	6.8 Sustainable Neighbourhoods - Case Study Review (2)	Level 4 - S426 & 427
6.9 Transforming Green Market - Green Economics (2)	Level 2 - S228	6.10 Innovative Practices to Transform SBE (1)	Level 4 - S423 & 424
6.11 Processes, Design, Tools and Methodologies in SBE (4)	Level 4 - S421	6.12 Green Buildings - Occupants' Perspectives	Level 4 - S425
6.13 Place-making - Integrative Design Processes	Level 2 - S226 & 227	6.14 BEAM Plus Neighbourhood: From Theory to Praxis	Level 4 - S428

15:00 - 15:10	*Coffee Break*

15:10 - 16:40	**Parallel Session 7**			
		Venue		Venue
	7.1 Education and Training for Transforming SBE	Level 4 - S428	7.2 SBE Buildings Challenge: Assessment Protocol and Case Studies	Level 1 - Theatre 1
	7.3 Smart Initiatives in SBE (3)	Level 1 - Theatre 2	7.4 Deep Renovations - Processes & Methodologies	Level 2 - S221
	7.5 SBE Assessments - Practices Review	Level 2 - S222	7.6 Green Construction Materials (2)	Level 2 - S224 & 225
	7.7 Innovations Driving for Greener Policies and Standards - Smart Initiatives	Level 2 - S223	7.8 Sustainable Neighbourhoods - Processes and Application	Level 4 - S426 & 427
	7.9 Transforming Green Market - Supply Chain	Level 2 - S228	7.10 Innovative Practices to Transform SBE (2)	Level 4 - S423 & 424
	7.11 Processes, Design, Tools and Methodologies in SBE (5)	Level 4 - S421	7.12 Multi-facet Considerations of Urban Regeneration Policies	Level 4 - S425
	7.13 Place-making - Practices Review	Level 2 - S226 & 227		
16:50 - 17:20 *Convention Hall*	**Keynote 6: Dr Raymond COLE**, Professor, School of Architecture and Landscape Architecture, University of British Columbia			
17:20 - 18:00 *Convention Hall*	**Closing Ceremony** • Speech by **Mr Eric MA**, Secretary for Development, Government of the HKSAR • Presentation of International Youth Competition Awards • Announcement of Host of WSBE2020 by **Mr Nils LARSSON**, Representative of SBE Co-owners • Closing Remark by **Ir Conrad WONG**, Chairman of WSBE17 Hong Kong Organising Committee			

Day 4 & 5 • 8 - 9 June 2017 (Thu-Fri)

Green Building Technical Visits & Eco Tours

Remark: The Organisers reserve the right to update or change the programme content, session and paper allocation as well as venue without prior notice. Speakers and delgates are recommended to check constantly the Conference App to observe the latest programme and venue.

Session 1.1 - Session Organiser: China Academy of Building Research

Mainland China Session - The Comprehensive Scheme on Green Retrofitting and Performance Enhancement of Existing Buildings in China

Level 1 - Convention Hall

Session Chair: YIN Bo
Director, Division of Science and Technology, China Academy of Building Research

The Roadmap on the Development of Comprehensive Scheme on Green Retrofitting and Performance Enhancement of Existing Buildings in China
YIN Bo, Director, Division of Science and Technology, China Academy of Building Research

The Appropriate Technologies and Practical Case Study on Green Retrofitting the Residential Dwellings in the Severe Cold Climatic Zone in China
JIANG Yiqiang, Professor, School of Municipal and Environmental Engineering, Harbin Institute of Technology

The Appropriate Technologies and Case Studies on Green Retrofitting the Healthcare Facilities in China
DI Yanqiang, Head of Division, Division of Construction Technologies, China Building Technique Group Co., Ltd.

The Case Studies and Technology Advancements on Green Retrofitting the Office Buildings in China
ZHAO Li, Deputy Head, Division of Research and Development, China Academy of Building Research

The Study of Energy Efficiency and Retro-Commissioning for Existing Large-scale Public Buildings
ZHU Neng, Professor, School of Environmental Science and Engineering, Tianjin University

Session 1.2

Regional Session - Czech Republic, Italy, Sweden and Switzerland

Level 1 - Theatre 1

Session Chair: François BAILLON
Board member, SBE series; Senior Adviser, FIDIC; Treasurer, Business and Climate Summit Association; Founder, Ideagrama Consultant

SBE16 Prague
Antonin LUPISEK, Head of Department, Architecture and the Environment, Czech Technical University, Czech Republic

SBE16 Torino
Andrea MORO, President, iiSBE Italia, Italy

SBE16 Malmö
Roland ZINKERNAGEL, Lund University, Sweden

SBE16 Zurich
Guillaume HABERT, Professor, ETH Zurich, Switzerland

Session 1.5

SBE Assessments - Green Neighbourhoods (1)

Level 4 - S428

Session Chair: John NG
Chairperson, BEAM Society Ltd.; Honorary Professor, Department of Urban Planning and Design, University of Hong Kong, Hong Kong SAR

LEED Certification and the New Standard of Sustainable Construction in Colombia
Andres PELAEZ, Architect, Universidad Pontificia Bolivariana, Colombia

Comparison Study of China's Eco-City Key Performance Indicator Systems
DENG Wu, Assistant Professor, University of Nottingham Ningbo China, Mainland China

A Human-Oriented Study of The Assessment Method for Sustainable Urban District in China - Comparison of LEED Neighbourhood Development, BREEAM Community, CASBEE-Cities and DGNB Urban Districts
Edison ZHANG Zhidong, GB Tech Consulting Ltd., Hong Kong SAR

Reducing the Impacts of the Built Environment on the Environment through the Integration of Socio-economic Indicators in Certification Standards
Francesco CAPPAI, Civil Engineer, GRIDD-ÉTS École de technologie supérieure, Canada

Development of a Comprehensive City Assessment Tool Applicable to Various Type of Cities Around the World: CASBEE-City (worldwide use version)
Shun KAWAKUBO, Assistant Professor, Hosei University, Japan

Session 1.6

Innovations Driving for Greener Policies and Standards - Microclimate

Level 2 - S223

Session Chair: Otto POON
Chairman, ATAL Engineering Ltd., Hong Kong SAR

The Potential of Applying Local Climate Zone for the Sustainable Planning in Urban Built Environment
CHEN Yu-cheng, Department of Architecture, National Cheng Kung University, Taiwan

Building Envelopes and Their Impact on Our Urban Thermal Environment
MAING Minjung, The University of Hong Kong, Hong Kong SAR

Urban Geometry and Wind Simulation Studies for Comfort in Bangkok Street Canyon
Pattaranan TAKKANON, Professor, Kasetsart University, Thailand

Research of Urban Heat Island (UHI) in Shenzhen Based on Climatic Design and Urban Planning Strategies
YU Wenjuan, Sustainable Design Assistant, Ronald Lu and Partners (Hong Kong) Ltd., Hong Kong SAR

Influence of Moving Vehicles on Pollutant Dispersion in Street Canyon – A Numerical Study
ZHANG Wenjing, Division of Building Science and Technology, City University of Hong Kong, Hong Kong SAR

Session 1.3
Advanced Building Elements
Level 1 - Theatre 2

Session Chair: Jian-lei NIU
Chair Professor of Building Environment and Energy, Associate Head of Department, and Director - Research Centre for Building Environmental Engineering Department of Building Services Engineering, The Hong Kong Polytechnic University; Editor-in-chief, Energy and Buildings Journal, Hong Kong SAR

Filter Facade
Ferdinand OSWALD, Institute of Architecture Technology, Graz University of Technology, Austria

The Impact of Double Skin Façade on the Energy Consumption of Office Buildings Under the Tropical Brazilian Climate
Kenneth IP, Principal Lecturer, University of Brighton, United Kingdom

Climate-Adaptive and Optimized Building Envelope Designs in East Asia
Kevin WAN, Engineer, Arup, Hong Kong SAR

Folded Cardboard Sandwiches for Load-bearing Architectural Components
Stephan SCHÜTZ, Research Assistant, Architect, Bauhaus-Universität Weimar, Germany

Multistorey Frame System for Energy Efficient Buildings
Vlastimil BILEK, ZPSV a.s., Uhersky Ostroh, Czech Republic

Session 1.4
Practices Review of High-Performance Green Buildings
Level 2 - S221

Session Chair: Phil JONES
Chair of Architectural Science, Welsh School of Architecture, Cardiff University, United Kingdom; Visiting Research Professor, Faculty of Architecture, University of Hong Kong, Hong Kong SAR

When will Hong Kong Build its First Passive House? - Concepts and Case Studies around Asia Show Great Possibilities for Energy Savings
Anne JACOBS, Senior Expert, Sustainable Construction, BASF, Hong Kong SAR

Insights into Green Hotels: Case Studies
Duygu ERTEN, Principal, TURKECO Consulting, Turkey

Building Energy Efficiency in Hong Kong: Case Study of a Commercial Building with BEAM Plus Provisional Platinum Rating (Existing Buildings)
POON Ka-man, Business Environment Council Ltd., Hong Kong SAR

An Elemental Approach for Predicting Embodied Carbon of Office Buildings
Srinath PERERA, Professor of Built Environment & Construction Management, Western Sydney University, Australia

Exploring Risks and Rewards Associated with High Performance Manufactured Buildings
Karlson Charles HARGROVES, Senior Research Fellow, Curtin University, Australia

Session 1.7 - Session Organiser: AECOM
Vision-led Sustainable Neighborhoods: Myths and Musts
Level 2 - S224 & 225

Session Chair: WONG Chi-chung
Executive Vice President, Asia; Global Head, Chinese Overseas Investment (COI) Program, AECOM, Hong Kong SAR

Albert KB CHAN, Director of Development Planning & Design, Shui On Land

Belinda YUEN, Professorial Fellow and Research Director, Lee Kuan Yew Centre for Innovative Cities, Singapore University of Technology and Design, Singapore

Claire BONHAM-CARTER, Principal and Director of Sustainable Development, Design and Planning, AECOM, United States of America

Raymond LEE, Director of Planning, Planning Department, Government of the HKSAR

Session 1.8
Innovations for Occupant Wellbeing (1)
Level 4 - S426 & 427

Session Chair: Tony IP
Deputy Director of Sustainable Design, Ronald Lu & Partners, Hong Kong SAR

Research and Development of Noise Mitigation Measures for Public Housing Development in Hong Kong
John HL HO, Chief Civil Engineer, Hong Kong Housing Authority, Government of the HKSAR, Hong Kong SAR

Estimating Typhoon Haiyan's Wind Speeds Using Windicators and Post-Storm Wind Vulnerability Analysis on the Affected Areas
Joshua AGAR, Civil Engineer, University of Philippines Diliman, Philippines

Outdoor Lighting Quality and Glare Rating Evaluation of Night-time Community Parks
KUO Poyen, Associate Professor, Department of Architecture, Chaoyang University of Technology, Taiwan

Better Places for People: Health and Wellbeing Measurement Methods in Workplaces
Maíra DE MACEDO, Architect – Institutional and Governmental Relations Coordinator, Green Building Council Brazil, Brazil

Development of a Home Indoor and Outdoor Environment Visualization System
Yusuke NAKAJIMA, Professor, Kogakuin University, Japan

Session 1.9
Practices & Methodologies for Green Building Management (1)
Level 2 - S228

Session Chair: WONG Wai-kwong
Chief Building Services Engineer/2, Architectural Services Department, Government of the HKSAR, Hong Kong SAR

Incorporating Sustainability Criteria in Commercial Workplace Fit-out Guidelines for a Banking Operation
James WONG Pow-chew, Program Manager, RMIT University, Australia

Adopting Green Building Concepts in Housing Estate Development Projects in Abuja F.C.T., Nigeria: Exploring The Potentialities Of End-Users' Preference
Salisu Gidado DALIBI, Business School of Hohai University Nanjing, Mainland China

Project Management Strategies for Green Business Parks: Critical Success Factors, Barriers and Solutions
SHAN Ming, National University of Singapore, Singapore

Smart, Green + Productive Workplace
Simone SKOPEK, JLL, Canada

Session 1.10
Green Infrastructure in SBE - Hong Kong Cases
Level 4 - S423 & 424

Session Chair: Samuel KWONG
Group Sustainable Development Manager, John Swire & Sons (H.K.) Ltd., Hong Kong SAR

Implementing the Beautification and Sustainable Designs for the Harbour Area Treatment Scheme (HATS) Stage 2A
Andrew LAI, Resident Engineer, Arup, Hong Kong SAR

Building Water Resilience in Sustainable Neighbourhoods: A Progressive Shift in Hong Kong
Edmond WF LIU, Senior Engineer, Water Supplies Department, Government of the HKSAR, Hong Kong SAR

Integrating Water Management Facilities Into The Built Environment - A Smart Green Resilient Approach
Kenneth KWOK, Associate Director, Arup, Hong Kong SAR

Driving Innovations For Green Infrastructure Components
Nicholas AU, Hong Kong Housing Authority, Government of the HKSAR, Hong Kong SAR

Sustainable Engineering Practices in Landslip Prevention and Mitigation Works in Hong Kong
Patrick HO Ho-man, Geotechnical Engineer, Civil Engineering and Development Department, Government of the HKSAR, Hong Kong SAR

Session 1.13 - Session Organiser: Link Asset Management Ltd. / Nan Fung Development Ltd
Healthy and Sustainable Building for Resilient Future
Level 2 - S226 & S227

Session Chair: Chris KWAN
Senior Project Manager, Project & Planning, Link Asset Management Ltd., Hong Kong SAR

Green Buildings - The Foundation for Sustainable Development
Calvin Lee KWAN, General Manager- Sustainability, Link Asset Management Ltd., Hong Kong SAR

Nan Fung's Corporate Initiative for New and Revitalization Development
Samuel WONG, Deputy General Manager, Project Dpt., Nan Fung Development Ltd., Hong Kong SAR

Leading Edge Trend for Resilient Future Building Design
Vincent CHENG, Director of Building Sustainability, Arup, Hong Kong SAR

Exemplar Next Generation Commercial Development - NKIL6512
Bing KWAN, Director, P&T Architects and Engineers Ltd., Hong Kong SAR
Alvin LO, Associate Director of Building Sustainability, Arup, Hong Kong SAR

Session 1.11	Session 1.12
Processes, Design, Tools and Methodologies in SBE (1) Level 4 - S421	**Regenerating Urban Space in Neighbourhoods** Level 4 - S425
Session Chair: Chimay J. ANUMBA Dean & Professor, University of Florida, United States of America	**Session Chair:** Thomas TANG Sek-khuen Managing Director, Kuala Lumpur Centre for Sustainable Innovation, Malaysia
Does the Sequence Matter? - Investigating the Impact of the Order of Design Decisions on the Life Cycle Performance Julia TSCHETWERTAK, Bauhaus-University Weimar, Germany **Rethinking Architectural Passive Cooling Strategies in New Zealand's Non-residential Building Stock** Lesley METIBOGUN, School of Architecture, Victoria University of Wellington, New Zealand **Building in Existing Contexts – Densification** Paul FLOERKE, Associate Professor, Associate Chair, Department of Architectural Science, Ryerson University, Canada **Problems and Prospects of Urban Compaction–A Case of Jaipur City** Sakshi BANSAL, Urban Planner, Malaviya National Institute of Technology Jaipur, India **Where Planning Regulations and Development Practice Collide; the Multi-storey Apartment Building in SubTropical Brisbane Australia** Rosemary Jean KENNEDY, Queensland University of Technology, Australia	**Cultivating a Village Impulse in the Midst of Warsaw, the Jazdów Settlement of Finnish Houses** Dariusz ŚMIECHOWSKI, Senior Lecturer, Academy of Fine Arts in Warsaw, Poland **Productive Transforming of the Urban Traffic Space** HAN Dan, Tianjin University, Mainland China **Nature-based Urban Space Transformation** Kristin BARBEY, Lecturer, Karlsruhe Institute of Technology, Germany **Historic Relationship Between Urban Dwellers and the Tomebamba River** M. Augusta HERMIDA, Professor, Universidad de Cuenca, Ecuador **Transformation from River Channelisation to River Revitalisation** Richard LEUNG Wah-ming, Senior Engineer, Drainage Services Department, Government of the HKSAR, Hong Kong SAR

Session 2.1 - Session Organiser: Shanghai Research Institute of Building Sciences

Mainland China Session - Green Building Design and Technological Challenges of Eco Skyscraper in China

Level 1 - Convention Hall

Session Chair: XU Qiang
Chief Engineer, Shanghai Research Institute of Building Sciences (Group) Co., Ltd.

Evaluation of Green Skyscraper Buildings in China
SONG Ling, Deputy Director, Center for Science and Technology & Industrialization Development, Ministry of Housing and Urban-Rural Development of the P.R. China (MOHURD)

Energy Saving Potential of Air-conditioning System with Low-Grade Energy Bus in Skyscrapers
LI Xianting, Professor, School of Architecture, Tsinghua University

In Pursuit of Excellence: Sustainable High-performance Skyscrapers
ZHANG Bolun, Director, East China Architectural Design and Research Institute

Green Design and Facility Management Systems in Shanghai Tower
YANG Jianrong, Deputy Director, Shanghai Research Institute of Building Sciences (SRIBS)

Session 2.2

Regional Session: Turkey, Greece, Malta and Egypt

Level 1 - Theatre 1

Session Chair: Wim BAKENS
Secretary General, International Council for Research and Innovation in Building and Construction

SBE16 Istanbul
Aygen ERKAL, Secretary General, Türkiye İMSAD- Association of Turkish Construction Material Producers

SBE16 Thessaloniki
Aikaterini TSIKALOUDAKI, Associate Professor, Aristotle University of Thessaloniki

SBE16 Malta
Ruben Paul BORG, University of Malta

SBE16 Cairo
Wafaa NADIM, Architecture Program, German University Cairo, Egypt

Session 2.5

SBE Assessments - Green Neighbourhoods (2)

Level 2 - S222

Session Chair: John NG
Chairperson, BEAM Society Limited; Honorary Professor, Department of Urban Planning and Design, University of Hong Kong, Hong Kong SAR

Value Management as a Tool for Delivering Sustainable Rail Projects
Clinton Ohis AIGBAVBOA, University of Johannesburg, South Africa

Calculation Methodology of GHG Emissions from a Low Carbon Urban Development in an Underdevelopment Country – Case Study from a LEED ND Certified project in São Paulo City/Brazil
Maria Carolina FUJIHARA, Green Building Council Brasil, Brasil; University of São Paulo, Brasil

A Stakeholder-based Assessment Model (SAM) for Resource-efficiency Measures in the Construction Industry
Richard Carl MÜLLER, Karlsruhe Institute of Technology, Germany

Comparative Rich-Picture-Diagram for Assessment of Building Sustainability Label
Sasha Nikolaus CISAR, Chair of Sustainable Construction, ETH Zurich, Switzerland

More Than Green: The DGNB Certification System for Sustainable Buildings and Districts
Thomas AUER, Managing Director & Founder, Transsolar; Profeesor, Building Technology and Climate Responsive Design, Technical University of Munich, Germany

Session 2.6

Innovations Driving for Greener Policies and Standards - Carbon Assessment

Level 2 - S223

Session Chair: Otto POON
Chairman, ATAL Engineering Ltd., Hong Kong SAR

Building Carbon footprint (BCF) Method for Nearly Zero-Energy Building Design Assessment
CHAO Yu-chan, Assistant Professor, Feng Chia University, Taiwan

Integrated Residential Household Energy Consumption and GHG Emissions Modelling at Metropolitan Scale
Raul MARINO, Melbourne School of Design, University of Melbourne, Australia

Building Life Cycle Carbon Emissions: A Review
TENG Yue, The University of Hong Kong, Hong Kong SAR

How Carbon Metric Standard Could Facilitate Innovation for Reduction of GHG Emission from Buildings?
Tomonari YASHIRO, The University of Tokyo, Japan

Climate Action Planning Strategies for Achieving Carbon Neutrality and Net Zero Campus Operation
Vuk VUJOVIC, Director of Sustainability & Energy, Legat Architects, United States of America

Session 2.3
Advanced Building Systems
Level 1 - Theatre 2

Session Chair: Lloyd Martin SCOTT
Dublin Institute of Technology, Ireland

Remarkable Energy Retrofit for Existing Buildings by Advanced Fan Technology: Electronically Commutated Motor Plug Fan
Isaac TSANG Siu-chung, Assistant Building Services Manager, Swire Properties Ltd., Hong Kong SAR

Low Temperature Radiant Cooling Design and Application in Tropical/ Sub-Tropical Countries
Paul CHAN Yim-cheong, Director, Wong & Ouyang (Building Services) Ltd., Hong Kong SAR

Hybrid Air-conditioning System Efficiency for Districts in the Tropics
HSIEH Shanshan, Future Cities Laboratory, Singapore ETH Center, Singapore; Chair of Architecture and Building Systems, ETH Zurich, Switzerland; Industrial Process and Energy Systems Engineering Group, Ecole Polytechnique Federale de Lausanne, Switzerland

Evaluation of Saving Energy with SOFC and Battery Combined System
Takeshi SASE, Cooperative Researcher, Building Research Institute, Japan

Session 2.4
Policies for High-Performance Green Buildings (1)
Level 2 - S221

Session Chair: Richard LORCH
Editor-in-Chief, "Building Research & Information" Journal, United Kingdom

Demystifying and Democratizing The Energy Use Conversation to Support The Net-Zero Challenge
Birgit SIBER, Diamond Schmitt Architects, Canada
Mike WILLIAMS, Rowan Williams Davies & Irwin Inc.

Building Energy Saving Strategy in Hong Kong - "Built-in" + "Plug-in"
CHIU Chun-ting, Electrical and Mechanical Services Department, Government of the HKSAR, Hong Kong SAR

How Sustainable are the Quality Control Procedures for Constructions in Europe?
Frits MEIJER, Senior Researcher, TU Delft / Faculty of Architecture and the Built Environment, The Netherlands

Policy Scenarios of Zero Carbon Building for Hong Kong: To Survive or To Lead?
PAN Mi, The University of Hong Kong, Hong Kong SAR

A Discussion on the Benefits of Environment Performance of the Promotion of Kaohsiung Green Building Specialties Policy
CHAO Chien-chiao, Director General, Bureau of Public Works, Kaohsiung City Government, Taiwan

Session 2.7 - Session Organiser: Swire Properties Ltd.
Deep Energy Saving and Other Innovative Green Measures for Commercial Buildings in Hong Kong, Mainland China and Overseas
Level 2 - S224 & 225

Session Chair: Benny AU
Sustainable Development Manager, Swire Properties Ltd., Hong Kong SAR

Sustainability Strategies on Deep Energy Saving and Energy Management of Property Developer
Raymond YAU, General Manager, Technical Services & Sustainable Development, Swire Properties Ltd.

Overview of Building Energy Efficiency in China and the Upcoming Trend
WEI Qingpeng, Building Energy Research Center, Tsinghua University, Beijing

Cost & Value: Multiple Benefits of Green Commercial Buildings in Western Countries
Phil JONES, Chair Architectural Science, Welsh School of Architecture, Cardiff University, United Kingdom; Visiting Research Professor, Faculty of Architecture, University of Hong Kong, Hong Kong SAR

YKK80 High Efficiency Building - Radiant Control Both Outside and Inside
Kitaro MIZUIDE, General Manager, M&E Design Department of NIKKEN SEKKEI, Japan

Performance Synergy from Integrated Design, Construction and Operation. Case Study on a High Performance Grade A Office - Swire One Taikoo Place
Vincent CHENG, Director of Building Sustainability, Arup, Hong Kong SAR

Session 2.8
Innovations for Occupant Wellbeing (2)
Level 4 - S426 & 427

Session Chair: Srinath PERERA
Professor of Built Built Environment & Construction Management, Western Sydney University, Australia

Outdoor to Indoor Air Quality in Urban Environment
Alexis LAU Kai-hon, Professor, Division of Environment, The Hong Kong University of Science and Technology, Hong Kong SAR

Redesigning Long-Term Senior Care: Design Solutions to Facilitate Different Levels of Care Needs in Senior Housing - Using Hong Kong's Latest Senior Housing as Example
Bryant LU, Vice Chairman, Ronald Lu and Partners (Hong Kong) Ltd., Hong Kong SAR

Occupant-Related Energy Use: A Qatar Office Case Study
Chimay J. ANUMBA, Dean & Professor, University of Florida, United States of America

Purifying City Air in Densely Urban Environment
Jimmy CK TONG, Associate & East Asia Energy Skill Leader, Arup, Hong Kong SAR

A Healthy and Sustainable Living Environment – LOHAS
Josh CHENG, Building Sustainability Consultant, Arup, Taiwan

Session 2.9
Practices & Methodologies for Green Building Management (2)
Level 2 - S228

Session Chair: POON Chi-sun
Chair Professor of Sustainable Construction Materials, Department of Civil and Environmental Engineering, The Hong Kong Polytechnic University, Hong Kong SAR

Green + Smart Buildings
Jiri SKOPEK, Managing Director, JLL, Canada; 2030 Districts

Challenges in Realising Green Building Concepts in Trade and Industry Tower
Joanna WAI, Senior Project Manager, Architectural Services Department, Government of the HKSAR, Hong Kong SAR
Daniel NG, Contract Manager, Guardian Property Management Ltd., Hong Kong SAR

The Perceptible Impacts of Building Envelope on Other Green Building Features: "A Review"
Salisu Gidado DALIBI, Business School of Hohai University Nanjing, Mainland China

Investigating Critical Safety Performance Factors in Green Building Construction Projects: The Case of Singapore
SHAN Ming, National University of Singapore, Singapore

Green Interior Renovation by Architectural Services Department
Vetus LAU, Director, Llewelyn Davies Hong Kong Ltd., Hong Kong SAR

Session 2.10
Transforming SBE Practices - Energy Management (1)
Level 4 - S423 & 424

Session Chair: Tim HILL
Research Director, Eco-business Research, Singapore

Development of an Integrated Energy Simulation Tool for Buildings and MEP Systems, the BEST - A Pilot Study on Simulation of Demand Response with Cogeneration Systems
Ryota KUZUKI, Acting General manager, Energy Strategy Planning Department, Tokyo Gas Co., Ltd., Japan

Driving Ultimate Building Performance through Smart E&M Systems for Sustainable Built Environment
TAI Tak-him, Deputy Director / Trading Services, Electrical and Mechanical Services Department, Government of the HKSAR, Hong Kong SAR

A Case Study to Automate Demand Response on a University Campus
Thomas Mark LAWRENCE, University of Georgia, United States of America

Short-term Load Forecasting Model with Predicted Weather Data
ZHU Guangya, City University of Hong Kong, Hong Kong SAR

Session 2.13 - Session Organiser: CLP Power Hong Kong Ltd.
Powering Up Smart City
Level 2 - S226 & 227

Powering Up for Brighter Tomorrows
Eric CHEUNG, Senior Director - Customer & Business Development, CLP Power (Hong Kong) Ltd., Hong Kong SAR

Big Data Era for Building Management
Amen TONG, General Manager, Technical Services, Airport Authority Hong Kong

Smart Power Control for Peak Load Compensation
Clement WONG, Head of Facility Management Hong Kong Science and Technology Parks Corporation

How Hong Kong to be a Data Centre Hub in Asia in the Next Decade
Charles LEE, Founder and CEO OneAsia Network Limited & Newtech Technology Co Ltd.

Session 2.14 - Session Organiser: Division Sustainable Building, Federal Institute for Research on Building, Urban Affairs and Spatial Development (BBSR), Germany
Sustainability Assessment of Buildings as Part of Green-Public Procurement Based on the German BNB-System
Level 4 - S428

Session Chair: Thomas LÜTZKENDORF
Director, Centre for Real Estate and Head of Chair, Sustainable Management of Housing and Real Estate, Karlsruhe Institute of Technology, Germany

The Assessment System for Sustainable Building BNB by Taking the Example of the Complete Refurbishment BNB Module for Educational Buildings
Julia MÜLLER, Federal Institute for Research on Building, BBSR, Germany

Sustainable Building Assessment System for Research- and Laboratory buildings - Austrian and Swiss Perspective on the BNB Applicability
Alexander PASSER, Assistant Professor, Graz University of Technology, Austria

Natural Resources and Sustainability
Eike ROSWAG-KLINGE, Ziegert Roswag Seiler Architekten

PL·E·N·AR
Planning Aid for Energy Efficient and Sustainable Architecture
Günter LÖHNERT, sol·id·ar planungswerkstatt, Germany

Panel Discussion

Session 2.11 **Processes, Design, Tools and Methodologies in SBE (2)** **Level 4 - S421**	Session 2.12 **Processes of Urban Regeneration** **Level 4 - S425**
Session Chair: Andrea MORO President, iiSBE Italia, Italy	**Session Chair:** Edward NG Professor of Architecture, School of Architecture, The Chinese University of Hong Kong, Hong Kong SAR
Decision Making in the Pre-design Stage of Building Renovation Projects Anne N. NIELSEN, University College of Northern Denmark, Aalborg University, Denmark **A Holistic Thriving Design Approach** Dennis LEE, Managing Director, Architecture: Innovative Limited, Hong Kong SAR **Fostering Sustainable Buildings in Indonesia by Foreign Developer for Resilience** Dennis MUI Heung-fu, (former) Assistant Project Director, Pacific Century Premium Developments Ltd., Hong Kong SAR **Reconsidering the Design of High-rise Mass Housing in Tropical Climates – A Case Study in Malaysia** GAN Hock-beng, G&A Architect, Malaysia FOO Chee-hung, Researcher, Construction Research Institute of Malaysia, Malaysia **Embodied Energy Versus Building Height, The “Premium” of Building Tall** Rolf André BOHNE, The Norwegian University of Science and Technology, Norway	**Energy Benchmarking Tool for Low-Carbon Transformation in Hong Kong: A Scientific Approach and Its Practical Applications** Benny KM CHOW, Director, Hong Kong Green Building Council Ltd., Hong Kong SAR **Sustainability Indicators for the Assessment of the Energy System** Lisa ANDES, Institute of Sustainable Management of Housing and Real Estate (OEW), Karlsruhe Institute of Technology, Germany **Creating Methods, Procedures and Tools for a More Sustainable Neighbourhood Development – Experiences from Germany** Maria BALOUKTSI, Karlsruhe Institute of Technology (KIT), Germany **How Can We Assess the Achievement of the Sustainable Development Goals? – A Review of Indicators and Their Application at the City Level** Roland ZINKERNAGEL, Lund University, Sweden

Session 3.1 - Session Organiser: Shenzhen Green Building Association and Shenzhen Institute of Building Research

Mainland China Session - Turning Green to Gold – Green Practices for Urbanization in China

Level 1 - Convention Hall

Session Chair: YE Qing
Director, The Shenzhen Institute of Building Research Ltd and the President of Shenzhen Green Building Association

QIU Baoxing, Counsellor of Counsellor's Office of the State Council, PRC

TANG Jie, Professor, School of Economics and Management, Harbin Institute of Technology (Shenzhen)

ZHANG Xuefan, Director, Bureau of Housing & Construction of Shenzhen Municipality

WANG Yun, Vice President, China Vanke Co., Ltd.

Kevin MO, Managing Director, Paulson Institute Representative Office

Ying HUA, Associate Professor, Department of Design and Environmental Analysis, The Cornell University

Session 3.2

International Youth Competition (1)

Level 1 - Theatre 1

Session Chair: Edward NG
Chairman, International Youth Competition Sub-committee, WSBE17 Hong Kong Scientific Committee; Professor of Architecture, School of Architecture, The Chinese University of Hong Kong, Hong Kong SAR

Presentation of 8 Shortlisted Teams

Q & A

Final Judging by International Jury Panel

Thomas AUER, Managing Director, Transsolar; Professor, Building Technology and Climate Responsive Design, Technical University of Munich

George BAIRD, Emeritus Professor of Building Science, School of Architecture, Victoria University of Wellington

Greg FOLIENTE, Enterprise Professor, University of Melbourne; Regional Director in Asia-Pacific, iiSBE; Founding Director, nBLue Pty Ltd

Peter GUTHRIE, Professor, Engineering for Sustainable Development, University of Cambridge

Deborah KUH, Head of Greening, Landscape and Tree Management Section, Government of the HKSAR

Christine LOH, Under Secretary for the Environment, Government of the HKSAR

Serge SALAT, President, Urban Morphology & Complex Systems Institute

Arno SCHLUETER, Professor, Architecture and Building Systems ETH Zurich; Principal Investigator, Future Cities Laboratory, Singapore ETH Centre

Session 3.5

Performance Review of Green Buildings (1)

Level 2 - S222

Session Chair: Srinath PERERA
Professor of Built Built Environment & Construction Management, Western Sydney University, Australia

Strategic Study on the Benefit Evaluation of Solar Photovoltaic Promotion Policy in Kaohsiung
CHAO Chien-chiao, Director General, Bureau of Public Works, Kaohsiung City Government, Taiwan

A Baseline Study on Thermal Performance of Prefabricated Modular Buildings in Australia
Sareh NAJI, The University of Melbourne, Australia

Energy Saving Potential of Thermal Broken Aluminum Frames in Hot Climate Areas
Simon WONG, Technoform Bautec Hong Kong Ltd., Hong Kong SAR

Potentials of Energy Efficiency and Generation Strategies for High-rise Office Buildings in Hong Kong
YU Cong, The University of Hong Kong, Hong Kong SAR

Effect of Corridor Design on Energy Consumption for School Buildings in the Cold Climate
ZHANG Anxiao, Tianjin University, Mainland China; Delft University of Technology, The Netherlands

Session 3.6

Innovations Driving for Greener Policies and Standards - Practices Review

Level 2 - S223

Session Chair: Richard LORCH
Editor-in-Chief, "Building Research & Information" Journal, United Kingdom

Leap forward or Snail Speed? Examining Radical Sustainable Innovation
Christian KOCH, Chalmers University of Technology, Sweden

The Progress of Energy Renovations of Housing in The Netherlands
Henk VISSCHER, Professor, Delft University of Technology-Faculty of Architecture and the Built Environment, The Netherlands

Evaluation of Using BEAM-PLUS to Facilitate Waste Reduction in Building Construction
Lara Celine JAILLON, City University of Hong Kong, Hong Kong SAR

Energy, Comfort and Cost Optimization of A Net-Zero Energy Building in Berlin
Olaf BOETTCHER, Federal Institute for Research on Building, Urban Affairs and Spatial Development, Germany

Modeling the Built Environment Element by Element: Uncovering Greenhouse Gas Intensive Policies and Structures with a New Visualization Tool
Verena GÖSWEIN, Instituto Superior Técnico, University of Lisbon, Portugal

Session 3.3
Advanced Building Systems - Energy Generation (1)
Level 1 - Theatre 2

Session Chair: Phil JONES
Chair of Architectural Science, Welsh School of Architecture, Cardiff University, United Kingdom; Visiting Research Professor, Faculty of Architecture, University of Hong Kong, Hong Kong SAR

Analysis of Fourth-Generation District Energy Systems with Renewable Energy Cogeneration by Using Rational Exergy Management Model
Birol KILKIS, Baskent University, Turkey

The Application of Solid Oxide Fuel Cells in Buildings for Electricity, Heating and Cooling Tri-generation Using Natural Gas or Bio-gas from Waste
WANG Qiancheng, Department of Building Real Estate, The Hong Kong Polytechnic University, Hong Kong SAR

Building and Community Energy Retrofit Housing in Wales
LI Xiaojun, Research Associate, Cardiff University, United Kingdom

Geothermal District Heating Investigation of Retired Oil/Gas Wells as Higher-temperature Renewable Heat Sources
GUO Hongshan, Princeton University, United States of America

Session 3.4
Policies for High-Performance Green Buildings (2)
Level 2 - S221

Session Chair: Lloyd Martin SCOTT
Dublin Institute of Technology, Ireland

Baseline and Water Efficiency for Green Building in Taiwan
CHENG Cheng-li, Dean of Design College; President of AIT, National Taiwan University of Science and Technology, Taiwan

A Comparative Study on Economic Policies for Construction and Demolition Waste Minimization
Jack CP CHENG, The Hong Kong University of Science and Technology, Hong Kong SAR

Using Supply Chain Management for Sustainable Public Procurement
Johannes WALL, Graz University of Technology, Austria

Innovative Measures to Protect Residential Developments from Traffic Noise - Hong Kong Experience
LAU Kwok-keung, Principal Environmental Protection Officer, Environmental Protection Department, Government of the HKSAR, Hong Kong SAR

Energy Efficiency for a Sustainable Built Environment in Nigeria
Susanne GEISSLER, SERA energy & resources, Austria

Session 3.7 - Session Organiser: AECOM
High Performance Transportation Hubs: Their Critical Role and Requirements?
Level 2 - S224 & 225

Session Chair: Sylvester Timothy WONG
Vice President, Strategies + Development, Buildings + Places, Asia; Head of Buildings + Places, Philippines & Emerging Markets, AECOM, Philippines

Marc COLELLA, Industry Director, Building Structures Practice Lead, Australia and New Zealand, AECOM, Australia

Kevin POOLE, Executive Director, Third Runway, Airport Authority Hong Kong, Hong Kong SAR

Tony ARMSTRONG, Asia Pacific Representative, International WELL Building Institute

Session 3.8
Innovative Practices for Occupant Wellbeing - Bioclimatic Design
Level 4 - S426 & 427

Session Chair: Clinton ANDREWS
Professor of Urban Planning & Policy Development, Rutgers University, United States of America

Bringing Sustainable Neighbourhood Design into Reality–Case Sharing by Brickell City Centre, Miami
Benny AU, Sustainable Development Manager, Swire Properties Ltd., Hong Kong SAR

On the Study of Thermal Comfort and Temperature Enhancements by Park Features
CK CHAU, The Hong Kong Polytechnic University, Hong Kong SAR

Passive Design Strategies for Building Envelopes in Different Orientations
Elizabeth PARRA, PVG Arquitectos, Colombia

An Integrated Urban Microclimate and Building Energy Model for Early Stage Design
HUANG Jianxiang, The University of Hong Kong, Hong Kong SAR

Re-Thinking Courtyard Housing: Development of Traditional Islamic Courthouses into Zero-Energy Buildings
Osama Mohamed OMAR, Assistant Professor of Architecture, Beirut Arab University, Lebanon

Session 3.9 **Practices & Methodologies for Green Building Management (3)** **Level 2 - S228**	**Session 3.10** **Transforming SBE Practices - Energy Management (2)** **Level 4 - S425**
Session Chair: Thomas LÜTZKENDORF Director, Centre for Real Estate; Head of Chair, Sustainable Management of Housing and Real Estate, Karlsruhe Institute of Technology, Germany	**Session Chair:** Tim HILL Research Director, Eco-business Research, Singapore
Life Story of the Repurposed Shipping Container Alice LF YEUNG, Chief Architect, Architectural Services Department, Government of the HKSAR, Hong Kong SAR **Factors Influencing Human Capability to Practice Sustainability in Facilities Management (FM) – A Review** Fathima Sabrina NAZEER, University of Moratuwa, Sri Lanka **Sustainable Construction: Quality of Life of Construction Workers in Private sector: Case Study of L.P.N. Development Public Co., Ltd.,** Pimchanok SRIRUTTRAKUL, Wisdom Consulting and Solution, Thailand **Mining for Resources: Problem-oriented Building Information Management and Development of Agile Facility Management Methodologies Through Industry-University-Public Collaborations** Yu MORISHITA, Assistant Professor, The University of Tokyo, Japan **Development of MERIT and Normalization Factor for Different Operating Hours for Building Energy Intensity (BEI)** Kevin HOR, Edgenta Energy Services PLC, Malaysia	**Dynamic CO2 and occupancy modelling for predictive control** Alexandros PANTAZARAS, National University of Singapore, Singapore **Retro-commissioning Practice and In-depth Analysis Leading to Efficiency Optimization on HVAC Systems: Case Study on A Retail Mall in China** Jean QIN, Swire Properties Ltd., Hong Kong SAR **Study of Chiller Part Load Values for Hong Kong and Subtropical Climate** LEUNG Wai-ho, Senior Engineer, Arup, Hong Kong SAR **HVAC System Design and Operation Performance of a Low-Carbon High-Rise Tenant Office Building Located in Tokyo** Yuichi TAKEMASA, General Manager, Kajima Technical Research Institute Singapore, Singapore **Optimizing Energy Efficiency for a High Rise Office Tower in Tropics** NG Yong-kong, NYK Engineering and Trading Sdn Bhd, Malaysia
Session 3.13 **Community Empowerment (1)** **Level 2 - S226 & 227**	**Session 3.14 - Session Organiser: Somfy Asia-Pacific Co. Ltd.** **Environmentally Responsive Buildings and Human Interactions** **Level 4 - S428**
Session Chair: Tony IP Deputy Director of Sustainable Design, Ronald Lu & Partners, Hong Kong SAR	**Session Chair:** Anders HALL International Business Development, Somfy International; Chairman, Marketing & Communication, ES-SO (EU Solar Shading Organisation)
The Strategy of Launching Rural Regeneration in Pingtung County Government HUNG Chieh-jen, Pingtung County Government, Taiwan **2030 Districts: Putting Ideas into Action** LI Jiexin, China Lead, 2030 Districts Jiri SKOPEK, Managing Director, JLL, Canada; 2030 Districts **A Critical Discussion on the Role of Architectural Practice in Development of Rural China: for Living Sustainably** LI Ke-han, The Chinese University of Hong Kong, Hong Kong SAR **Retrofit or Behaviour Change? Which Has the Greater Impact on Energy Consumption in Low Income Households?** Melissa JAMES, Senior Experimental Scientist, CSIRO, Australia **Towards a Holistic Methodology: A Practical Approach to Local Energy Planning** Thomas SCHLUCK, Senior Scientist, Hochschule Luzern, Switzerland	**Research and Experiences on Sustainability by ES-SO** Anders HALL, Somfy International; Chairman, Marketing & Communication, ES-SO **The Architect's View on a Design of More Sustainable and High Performing Facades – and It Works!** Mark CURZON, Director of Architecture, Fender Katsalidis Mirams Architects **Case Study - Understanding the key learnings from the use of Automated Solar Shading in Sustainable Buildings** Alistair GRICE, Commercial Specification Manager, Somfy Oceania **Connected Homes: A More Comfortable, Secure and Sustainable Life in the Future** Jean-Pierre DUMAS, Managing Director, iHome Systems **Panel Discussion**

Session 3.11	Session 3.12 - Session Organiser: Allied Environmental Consultants Ltd.
BIM for Sustainability (1) Level 4 - S421	**Emerging Practices in Sustainable Built Environment** Level 4 - S423 & 424
Session Chair: Paul HO Director, Professional Green Building Council, Hong Kong SAR	**Session Chair:** Grace KWOK Managing Director, Allied Environmental Consultants Ltd.
BIM Based Deep Building Renovation Optimization for Sustainability HUANG Lizhen, Associate Professor, Norwegian University of Science and Technology, Norway **Integrating BIM for Sustainable Planning, Design, Construction and Facility Management for Hong Kong's Public Housing Development** Lawrence KW CHUNG, Assistant Director of Housing (Development and Construction), Hong Kong Housing Authority, Government of the HKSAR, Hong Kong SAR **BIM Enabled Life Cycle Environmental Analysis for a Small Scale Zero Energy House** LI Qiyuan, School of Architecture, Tianjin University, Mainland China **The Use of FTA (Fault Tree Analysis) to Evaluate the Contribution of BIM Platform to the Environmental Quality on Rehabilitated Buildings** Monica Santos SALGADO, Federal University of Rio de Janeiro, Brasil **Sustainable Buildings with BIM** Peter KONCZ, Sales Manager, GRAPHISOFT Asia Ltd., Hong Kong SAR	**Acoustics and Lighting Design for Green Building** Henry Chan Chi-kee, Associate Director, Allied Environmental Consultants Ltd. **Showcase of Green Campus Development in Hong Kong – A Case Review of Hang Seng Management College's Master Campus Expansion Plan** Danica CHAN, Environmental Consultant, Allied Environmental Consultants Ltd. **Drive towards Sustainable Development and Management: Case Study on International Commerce Centre** Andy LAI, Senior Consultant, Allied Environmental Consultants Ltd. **Intelligence, Collaboration, Continuity – A Case Study of Improving the Environmental Performance of an Office Building** Lewis LAM, Assistant General Manager (Property Management), Kai Shing Management Services Ltd. **Sustainability Strategies in Towngas Headquarters Building** Nelson LO, Property Management Manager, The Hong Kong and China Gas Company Ltd.

Session 4.1 - Session Organiser: Green Building Research Centre and the Chinese Society for Urban Studies
Mainland China Session - The Development Framework and Professional Best Practices of Healthy Buildings in China

Level 1 - Convention Hall

Session Chair: MENG Chong
Deputy Director, Green Building Research Centre, Chinese Society for Urban Studies, China

Water is the Essence of Healthy Building
ZENG Ji, Deputy Director, Architectural Design Institute, China Academy of Building Research

The Control and Prevention of Indoor PM2.5 against the Health Risks of Occupants
ZHANG Yinping, School of Architecture, Tsinghua University, China

Development of the China Healthy Building Assessment Standards and its Professional Practices
MENG Chong, Deputy Director, Green Building Research Centre, Chinese Society for Urban Studies, China

Technological Innovations and Best Practices of Healthy Buildings
JIA Yan, Founder & CEO, First Human Environmental Technologies (Beijing) Co., Ltd., China

Session 4.2
International Youth Competition (2)

Level 1 - Theatre 1

Session Chair: Edward NG
Chairman, International Youth Competition Sub-committee, WSBE17 Hong Kong Scientific Committee; Professor of Architecture, School of Architecture, The Chinese University of Hong Kong, Hong Kong SAR

Presentation of 8 Shortlisted Teams

Q & A

Final Judging by International Jury Panel

Thomas AUER, Managing Director, Transsolar; Professor, Building Technology and Climate Responsive Design, Technical University of Munich

George BAIRD, Emeritus Professor of Building Science, School of Architecture, Victoria University of Wellington

Greg FOLIENTE, Enterprise Professor, University of Melbourne; Regional Director in Asia-Pacific, iiSBE; Founding Director, nBLue Pty Ltd

Peter GUTHRIE, Professor, Engineering for Sustainable Development, University of Cambridge

Deborah KUH, Head of Greening, Landscape and Tree Management Section, Government of the HKSAR

Christine LOH, Under Secretary for the Environment, Government of the HKSAR

Serge SALAT, President, Urban Morphology & Complex Systems Institute

Arno SCHLUETER, Professor, Architecture and Building Systems ETH Zurich; Principal Investigator, Future Cities Laboratory, Singapore ETH Centre

Session 4.5
Performance Review of Green Buildings (2)

Level 2 - S222

Session Chair: Lan DING
Senior Lecturer, Faculty of Built Environment, University of New South Wales, Australia

The Importance of Understanding The Material Metabolism of The Built Environment
Danielle DENSLEY TINGLEY, Lecturer in Architectural Engineering, The University of Sheffield, United Kingdom

Net Environmental Loads of Mineral Admixtures and Portland Blended Cements
Marcella Ruschi SAADE, University of Campinas, Brazil

Embodied Energy and Global Warming Potential in Construction – Perspectives and Interpretations
Maria BALOUKTSI, Karlsruhe Institute of Technology, Germany

Study of Human Embodied Energy for Masonry Work During Building Construction
Sivakumar PALANIAPPAN, Assistant Professor, Indian Institute of Technology Madras, India

The Life Cycle Cost-Energy Relationship Of Buildings
WANG Jie, The University of Hong Kong, Hong Kong SAR

Session 4.6
Green Construction Technologies (1)

Level 2 - S223

Session Chair: Guillaume HABERT
Professor, ETH Zurich, Switzerland

Watering Type and Water Consuming Assessment of the Green Construction Fence in Taichung City, Taiwan
CHEN Chen-chun, Feng Chia University, Taiwan

Low Carbon Construction Implementation in a Public Housing Development and the Implication to the Life Cycle Decision Making Tool
Felix WONG Yat-hang, Senior Environmental Consultant, AECOM Asia Co. Ltd., Hong Kong SAR

Use of Incineration Bottom Ash for Road Construction in Singapore
Kelvin LEE Yang-pin, Senior Technical Manager, Samwoh Innovation Centre, Singapore

Exploring the Relationships between Construction Phases and Sustainable Construction Principles
Olabode Emmanuel OGUNMAKINDE, University of Newcastle, Australia

Session 4.3
Advanced Building Systems - Energy Generation (2)
Level 1 - Theatre 2

Session Chair: Wafaa NADIM
Associate Professor, The German University in Cairo, Egypt

Exergoeconomic Assessment of a Building Integrated Photovoltaic (BIPV) System: A Case Study of Yasar University, Izmir, Turkey
Arif HEPBASLI, Chairman of Energy Systems Engineering Department, Yasar University, Turkey

Variations of Systematic Solutions for 24-hour Operating Sustainable Small-scale Commercial Buildings
Bumpei MAGORI, Project Lecturer, Institute Industrial Science, the University of Tokyo, Japan

Study on the Potential of Converting Former Military Bunkers into Energy Storage Facilities
Joachim SCHULZE, Research Assistant, Architect M.Sc., Technical University Darmstadt, Germany

An Evaluation of Building Integrated Wind Energy
Mehmet Koray PEKERICLI, METU, Turkey

Session 4.4
Processes of High-Performance Green Buildings
Level 2 - S221

Session Chair: Ron WAKEFIELD
Head of the School of Property, Construction and Project Management (PCPM) and Deputy Pro Vice Chancellor International, RMIT University, Australia

What Are The Most Effective Drivers of Sustainable Development in The Decision Making Process
Hanne Tine Ring HANSEN, Sustainability Engineer, Søren Jensen Consulting Engineers, Denmark

German ÖKOBAUDAT Goes International - An Online Infrastructure for LCA as Basis for International Structures
Tanja BROCKMANN, Head of Division Construction and Environment, BBSR Federal Inst. for Research on Building, Urban Affairs and Spatial Development, Germany

How Actors Can Implement in Practice the General Principles of Sustainability in Their Buildings and Civil Engineering Projects
Thomas LÜTZKENDORF, Director, Centre for Real Estate; Head of Chair, Sustainable Management of Housing and Real Estate, Karlsruhe Institute of Technology, Germany

Driver And Challenges Facing Leadership in Adopting Sustainability in The Built Environment: A Developer's Perspective
ZHANG Xiaoling, Department of Public Policy, City University of Hong Kong, Hong Kong SAR

Analysing the Reference Flows for Energy Efficient Retrofit of Typical Residential Building in Tianjin, China
LIU Lu, School of Architecture, Tianjin University, Mainland China

Session 4.7 - Session Organiser: Swire Properties Ltd.
The Secret Ingredients of Sustainable Real Estate Development
Level 2 - S224 & 225

Session Chair: Ashley HEGLAND
Consultant, Swire Properties Ltd.

Themes/Trends of Sustainable Urban Planning and Sustainable Built Environment
Christopher LAW, Founding Director, Oval Partnership, Hong Kong SAR

Ingredients of Sustainable Real Estate: Criteria, Transparency, Engagement
Ruben LANBROEK, Head of Asia Pacific, GRESB, Singapore

Climate Change and Sustainable Real Estate: The Environmental, Social, and Economic Implications
Liam SALTER, CEO, RESET Carbon

Swire Properties' Approach to Sustainable Real Estate
Raymond YAU, General Manager, Technical Services & Sustainable Development, Swire Properties Ltd.

Session 4.8
Innovative Biophilic Design for Wellbeing
Level 4 - S426 & 427

Session Chair: Alan FOGARTY
Sustainability Partner, Cundall, Hong Kong SAR

System Ecology as a Design Tool for Water Resources and its Environmental Education
DAY Yeong-tyi, Associate Professor, Chung Yuan Christian University, Taiwan

Sustainable Neighbourhood of Shek Wu Hui Sewage Treatment Works
Echo LEONG I-man, Executive Director, AECOM Asia Company Ltd., Hong Kong SAR

Biophilia and Nature-based Features to Support Stress Reduction in Knowledge Workers
Ann CALLAGHAN, Conestoga College, Canada; Algonquin College, Canada

Pioneering "Comprehensive Urban Landscape Technology" (CULT): An Integrated System Model for Urban Sustainability as Community Amenity in a Compact Urban Environment
Thomas CHUNG Wang-leung, The Chinese University of Hong Kong, Hong Kong SAR

Foster a Healthy Community through Active Design & Biophilic Design
WANG Hong, Executive Director, AECOM Asia Company Ltd., Mainland China

Session 4.9 - Session Organiser: Arup
A Collaborative Approach in Delivering Low Carbon Living
Level 2 - S228

Session Chair: Jimmy CK TONG
Associate & East Asia Energy Skill Leader, Arup, Hong Kong SAR

Beyond Energy and Resource Efficiency: Sustainable Building in Digital Transformation
Vincent CHENG, Director of Building Sustainability, Arup, Hong Kong SAR

Investing for Longer-term Development: Financing the New Generation in Sustainability
Carl BERRISFORD, UBS Wealth Management, Head of Sustainable Investing, APAC Chief Investment Office, Hong Kong SAR

Creation of Green Neighbourhood
Edwin CHAN, Project Director, New World Development Company Ltd., Hong Kong SAR

Tall Buildings and Sustainability
Florence CHAN, Director, Kohn Pedersen Fox Associates PC, Hong Kong SAR

Session 4.10
Transforming SBE Practices - Energy Management (3)
Level 4 - S425

Session Chair: Clinton ANDREWS
Professor of Urban Planning & Policy Development, Rutgers University, United States of America

Energy Data Transparency Benefits to Drive Down of Energy Consumption in A Green Hotel
Antonio CM CHAN, REC Engineering Co., Ltd., Hong Kong SAR

ACT-Shop – A Retro-commissioning Scheme for Existing Buildings in Hong Kong
Cary CHAN, Executive Director, Hong Kong Green Building Council Ltd., Hong Kong SAR

Low-Carbon Building Environment Adaptation Countermeasures of Pingtung County
CHEN Ping-hung, Pingtung County Government, Taiwan

Impact of Energy Recovery Ventilation on The Ventilation and CO2 Concentration in One Bedroom Condominium in Thailand
Daranee JAREEMIT, Associate Dean for Academic Affairs, Faculty of Architecture and Planning, Thammasat University, Thailand
Panpisu JULPANWATTANA, Senior Sustainable Designer, Magnolia Quality Development Corporation Ltd., Thailand

Session 4.13
Community Empowerment (2)
Level 2 - S226 & 227

Session Chair: LEUNG Man-kit
Director of Sustainable Design, Ronald Lu & Partners (Hong Kong) Limited, Hong Kong SAR

'Pride the Citizens Action Factor for Resilient Sustainable Cities' Results of the 2016 Questionnaire Research Under Dutch Amsterdam Council Members
Fred SANDERS, Researcher and Lecturer, Delft University of Technology in the Netherlands, The Netherlands

Enhance Public Sustainability Awareness by Feng Shui
Patrick LUI Yin-park, Senior Engineer, Cundall Hong Kong Ltd., Hong Kong SAR

Social Sustainability
Stephen YIM, Chief Architect; Development & Standards, Hong Kong Housing Authority, Government of the HKSAR, Hong Kong SAR

The Application of Social Innovation in Designing an Aged Care Centre in Malaysia
Thomas TANG Sek-khuen, Kuala Lumpur Centre for Sustainable Innovation, Malaysia

Ritualised Place and Community Empower
Wasana DE SILVA, Senior Lecturer, University of Moratuwa, Sri Lanka

Session 4.14 - Session Organiser: The Hong Kong Polytechnic University
PolyU Green Deck : A Catalyst for a Green and Vibrant Community
Level 4 - S428

Session Chair: Alex LUI Chun-wan
Chairman, Green Deck Task Force, The Hong Kong Polytechnic University, Hong Kong SAR

From Grey to Green
Alex LUI Chun-wan, Chairman, Green Deck Task Force, The Hong Kong Polytechnic University, Hong Kong SAR

Improving Neighbourhood Sustainability with Landscaping in the Context of Climate Change: A Case Study of the Proposed Green Deck in Hong Kong
Edwin CHAN, The Hong Kong Polytechnic University, Hong Kong SAR

Noise Mitigation Potential of PolyU Green Deck Proposal
TANG Shiu-keung, The Hong Kong Polytechnic University, Hong Kong SAR

Effect of Green Deck on Local Air Quality
LEE Shun-cheng, The Hong Kong Polytechnic University, Hong Kong SAR

Proposed Green Deck Project: A Framework for Engaging Stakeholders
Esther YUNG Hiu-kwan, The Hong Kong Polytechnic University, Hong Kong SAR

"Smart Green Resilient" Integrative Urban Environment
Wilfred LAU, Director, Arup, Hong Kong SAR

Panel Discussion

Session 4.11	Session 4.12
Session 4.11 **BIM for Sustainability (2)** **Level 4 - S421**	**Session 4.12** **Healthy Building, Human Comfort & Wellbeing** **Level 4 - S423 & 424**
Session Chair: Paul HO Director, Professional Green Building Council, Hong Kong SAR	**Session Chair:** Holger WALLBAUM Full Professor in Sustainable Building, Chalmers University of Technology, Sweden
Assessment of Different Data Collection Methods for the Creation of BIM Models for Existing Buildings Bjoern Arild GODAGER, Assistant Professor, Norwegian University of Science and Technology, Norway **Boost Sustainability Certification by Using BIM** Heinz J. BERNEGGER, Zurich University of Applied Sciences ZHAW, Institute of Facility Management, Switzerland **LCA Integration in BIM Through The Use of Integrated Dynamic Models** Marios TSIKOS, Civil Engineer, Burohappold Engineering, United Kingdom **Visualizing Embodied Impacts Using Building Information Modeling (BIM)** Martin RÖCK, Scientific Assistant, Working Group Sustainability Assessment - Institute of Technology and Testing of Building Materials - Graz University of Technology, Austria **Lifecycle Evaluation of Building Sustainability Using BIM** ZHANG Cheng, Assistant Professor, Xi'an Jiaotong-Liverpool University, Mainland China	**Healthy Buildings & Energy Performance – A Balancing Act** Eriko TAMURA, Assistant Engineer of Building Sustainability, Arup, Hong Kong SAR **Significance of Sky Gardens for Healthy High-rise Living of Urban Children and Old Adults** Tony IP, Deputy Director of Sustainable Design, Ronald Lu & Partners (Hong Kong) Ltd., Hong Kong SAR **Radon Infiltration in Existing Rented Accommodation** Torben Valdbjørn RASMUSSEN, Danish Building Research Institute, Aalborg University, Denmark **A Case Study on Industrial Building IEQ Control and Operation Performance Analysis** WANG Hui, Green Building Engineer, BlueScope Building System (Xi'an) Co., Ltd., Mainland China **Research on the Strategies and Methods in Productive Green Renovation of Existing Urban Communities** DING Xiaoying, Tianjin University, Mainland China

Day 3 • 7 June 2017 (Wed) • Parallel Session 5 • 10:30 - 12:00

Session 5.1	Session 5.2 - Session Organiser: Sweden Green Building Council
Regional Session - Canada, Brazil-Portugal, The Netherlands, Germany and Tallinn-Helsinki Level 1 - Convention Hall	**High Performance Buildings and Sustainable Neighbourhoods in Sweden** Level 1 - Theatre 1
Session Chair: Luis BRAGANÇA University of Minho, Portugal	**Session Chair:** Bengt WÅNGGREN CEO and Founding Chairman, Sweden Green Building Council; Member of the Board, World Green Building Council
SBE16 Toronto Harry Robert BACH, Secretary Treasurer, iiSBE Canada; Director and Treasurer, iiSBE International; Director and Treasurer, Sustainable Buildings Canada **SBE16 Brazil-Portugal** Cristina Engel ALVAREZ, Professor/Coordinator, Laboratório de Planejamento e Projetos, Universidade Federal do Espírito Santo, Brazil **SBE16 Hamburg** Thomas LÜTZKENDORF, Director, Centre for Real Estate; Head of Chair, Sustainable Management of Housing and Real Estate, Karlsruhe Institute of Technology, Germany **SBE16 Tallinn-Helsinki** Pekka HUOVILA, Coordinator, 10YFP Sustainable Buildings and Construction (SBC) Programme **SBE16 Utrecht** Ivo OPSTELTEN, Professor, University of Applied Sciences Utrecht	**Five Cases of Best Practice High-Performance Buildings in Sweden** **LIDL Växjö** Johan AUGUSTSSON, Property Director, LIDL Sweden **Greenhouse Augustenborg** Jenny HOLMQUIST, Environmental Strategist, MKB Fastighet **Solallén** Björn BERGGREN, Senior Consultant/Phd Student, Skanska/Lund University **BRF Viva** Charlotta SZCZEPANOWSKI, Sustainability Director, Riksbyggen Anders JOHANSSON, Project Manager, Riksbyggen. **IKEA Hubhult** Bengt WÅNGGREN, CEO and Founding Chairman, Sweden Green Building Council; Member of the Board, World Green Building Council **Three Projects for Sustainable Neighbourhoods in Sweden** **Citylab** Tomas GUSTAFSSON, Program Director for Citylab Action, Sweden Green Building Council **C/O City** Emilie ZETTERSTRÖM, Communications officer, Sustainability and Innovation, The City of Stockholm **Decode** Åsa NORMAN, Sustainability Consultant, Tyrénd Sarah BRAGÉE, Department Manager of Strategic Analysis, Tyréns
Session 5.5 **SBE Assessments - Green Building Policies** Level 2 - S222	**Session 5.6** **Green Construction Technologies (2)** Level 2 - S224 & 225
Session Chair: Antonin LUPISEK Head of Department, Architecture and the Environment, Czech Technical University, Czech Republic	**Session Chair:** Andrew LEUNG Emeritus Professor, City University of Hong Kong; China Green Building (HK) Council, Hong Kong SAR
From Research to a National Standard: SBTool and Protocollo ITACA Andrea MORO, President, iiSBE Italia R&D, Italy **The Network for Sustainable Federal Building as an Instrument of Quality Assurance in the Implementation of the Assessment System BNB in the Public Sector** Andreas RIETZ, Head of Division Sustainable Building, Federal Institute for Research on Building, Urban Affairs and Spatial Development, Germany **Competing Visions for Building Materials Assessment in US Green Building Certification Programs** Charles Joseph KIBERT, Professor-Centre Director, University of Florida, United States of America **CESBA: Together to a Harmonized Built Environment Assessment** Markus BERCHTOLD-DOMIG, Spatial Planner, Heimaten, Austria **LEED CS in Brazil: Discussing the Validity of the Method for the Improvement of Environmental Quality on Buildings** Monica Santos SALGADO, Professor, Federal University of Rio de Janeiro, Brazil	**Innovative Building Technologies Towards Sustainable Construction – A Comparative LCA and LCC Assessment** Alexander PASSER, Assistant Professor, Graz University of Technology, Austria **A Peer-to-peer Reviewing Framework for Selecting Construction Material Suppliers Using the Integration of Building Information Modelling and Web-Map Service** NGUYEN Thanh-chuong, National Taiwan University, Taiwan **Improving the Sustainable Supply Chain of Housing Industrialization with Transaction Costs Considerations** Queen K QIAN, OTB Research Institute for the Built Environment, Delft University of Technology, The Netherlands **A Research Proposal to Improve the Environmental Performance of the Building Industry, by Increasing the Innovation Activity of Small Contractors** Timothy ROSE, Queensland University of Technology, Australia **Mongolia's First Cooperative Transformation Attempt on Built Environment through Greening Kindergarten Building** Nergui DORJ, Founder and BOD member, Mongolia Green Building Council, Mongolia

Session 5.3
Smart Initiatives in SBE (1)
Level 1 - Theatre 2

Session Chair: Natalie ESSIG
University of Applied Sciences Munich (MUAS), Germany

The New Smart Cities | Cities Built from Scratch and Old Cities Transformed into Smart Cities. Sustainable Growth
Ana Claudia Figueiredo OLIVEIRA, Lisbon Faculty of Architecture, Portugal

Enhanced Engineering Services for Electrical & Mechanical System via Integrated Building Management System, Remote Monitoring Unit, and Geographic Information System
LEE Che-kit, Chief Engineer, Electrical and Mechanical Services Department, Government of the HKSAR, Hong Kong SAR

Decarbonising the City: Micro Energy Grids
Richard WANG, Sustainability Consultant, Arup, Hong Kong SAR

A Multi-disciplinary Approach in Developing Sustainable Built Environment: A Case Study in Hong Kong Kowloon East Development Project (KEDP)
Schuman LAM, The Hong Kong Polytechnic University, Hong Kong SAR

Sy(e)nergies between Mega Event Buildings and the Surrounding Neighbourhoods
Simone MAGDOLEN, Munich University of Applied Sciences, Germany

Session 5.4
Deep Renovations - Policies & Standards
Level 2 - S221

Session Chair: Kenneth CHAN
Director, BEAM Society Limited, Hong Kong SAR

Small, Beautiful, Yet Difficult: Energy Plus Renovation in Small Social Housing Companies
Christian KOCH, Chalmers University of Technology, Sweden

Deep Renovation as Tool for Active Protection of Modern Heritage: The Case of Architecture for The Service Sector
Claudia CALICE, University of Rome, Italy

Future Challenges for Renovation as Experienced by Housing Companies
Liane THUVANDER, Chalmers University of Technology, Sweden

Integration of Sustainability Analyses into Business models for Energy Renovation of Buildings: A Case Study in Norway
Roberta MOSCHETTI, Norwegian University of Science and Technology, Norway

The Development and Practice of Existing Buildings Green Retrofitting in China
WANG Qingqin, China Academy of Building Research, Mainland China

Session 5.7
Innovations Driving for Greener Policies and Standards - Assessment, Analysis and Modelling (1)
Level 2 - S223

Session Chair: Guillaume HABERT
Professor, ETH Zurich, Switzerland

European Horizontal Standardized Methods for the Assessment of the Sustainability Aspects of Construction Works
Ari ILOMAKI, Senior Adviser, Confederation of Finnish Construction Industries, Finland

Life Cycle Energy and GHG Emissions Reductions of Retrofit Options for Existing Dwelling Stock
Greg FOLIENTE, Enterprise Professor, University of Melbourne; Regional Director in Asia-Pacific, iiSBE; Founding Director, nBLue Pty Ltd

Renewable Energy Technologies - Economic Analysis Tool (RET-EAT) for Turkey
Oguz Kursat KABAKCI, Expert on Energy And Natural Resources, Ministry of Energy And Natural Resources, Turkey

Geo-dependent Heat Demand Model of the Swiss Building Stock
Stefan SCHNEIDER, University of Geneva, Switzerland

Quantitative Impact Assessment of SEAP Measures Implementation on Several Districts in the City of Donostia-San Sebastian
Xabat OREGI, Tecnalia Research & Innovation, Spain

Session 5.8
Sustainable Neighbourhoods - Case Study Review (1)
Level 4 - S426 & 427

Session Chair: Ellie TANG
Head of Sustainability, New World Development Company Limited, Hong Kong SAR

Learning from the Lessons of Transit-oriented Development to Improve Urban Planning in China
Frederic Daniel DU VERLE, Urban Planner & Designer, Archimedialab, Germany / Mainland China

A Green Campus Master Plan - The Chinese University of Hong Kong (CUHK)
FUNG Siu-man, Director of Campus Development, The Chinese University of Hong Kong, Hong Kong SAR

Stepping Up to the Water-Energy Nexus Challenges at Tai Po Water Treatment Works
Jeffrey LAI Siu-ming, Engineer, Water Supplies Department, Government of the HKSAR, Hong Kong SAR

Development Strategies for the Green Industry in Pingtung County
KUO Wu-wei, Executive officer, Pingtung County Government, Taiwan

Strategic Planning for Sustainable Neighbourhoods: A Case Study from Palestine
Sameer ABU-EISHEH, Professor of Civil Engineering, An-Najah National University, Palestine

Session 5.9 **Transforming Green Market - Green Economics (1)** **Level 2 - S228**	Session 5.10 **Zero Energy** **Level 4 - S423 & 424**
Session Chair: Tim HILL Research Director, Eco-business Research, Singapore	**Session Chair:** Ron WAKEFIELD Head of the School of Property, Construction and Project Management (PCPM) and Deputy Pro Vice Chancellor International, RMIT University, Australia
Stakeholders View on Commercial Benefits for Energy Neutral Refurbishment of Let Properties Angela GRECO, Delft University of Technology, The Netherlands **How a Changing Socioeconomic Context Affects the Demand for High-performance Buildings** Clinton ANDREWS, Rutgers University, United States of America **Green Lease Insight - Integrated Approach** Andrew NICHOLSON, Executive Managing Director, Head of Asset Services, Asia Pacific, CBRE, RICS, Hong Kong SAR **How Sustainable Planning Increases Real Estate Property Value** Serge SALAT, President, Urban Morphology and Complex Systems Institute, France **Responsible Investing in Green Buildings and Portfolios** Ruben LANGBROEK, Head of Asia Pacific, GRESB, Singapore	**Achieving Net Zero Carbon: A Case Study of Hong Kong's First Zero Carbon Building** Justin LI, Assistant Director - Environmental & Sustainability, Construction Industry Council, Hong Kong SAR **Life Cycle Greenhouse Gas Emissions of Material Use in the Living Laboratory** Marianne Rose KJENDSETH WIIK, SINTEF, Norway **Paradoxical Feasibility of High-rise Zero Carbon Buildings** PAN Wei, Associate Professor, The University of Hong Kong, Hong Kong SAR **Studies of Energy-Efficient Measures and Building Integrated Photovoltaic Toward Net Zero Energy Building** LOU Siwei, City University of Hong Kong, Hong Kong SAR **Net Zero Energy Building Policy: Benchmarking Australian Practices Against Asia Pacific Countries** Usha IYER-RANIGA, Deputy Head International and Co Lead UN 10YFP SBC Programme, RMIT University, Australia
Session 5.13 **Stakeholder Collaboration** **Level 2 - S226 & 227**	Session 5.14 - Session Organiser: Sino Group **Smart and Digital Transformation for Sustainable Living** **Level 4 - S428**
Session Chair: Thomas NG Professor (Construction Engineering and Management), The University of Hong Kong, Hong Kong SAR	**Session Chair:** Jimmy CK TONG Associate & East Asia Energy Skill Leader, Arup, Hong Kong SAR
Green Management by Stakeholder Empowerment - The Hong Kong Housing Authority Experience Ada FUNG, Deputy Director of Housing (Development & Construction), Hong Kong Housing Authority, Government of the HKSAR, Hong Kong SAR **CoLLaboratoire Montreal: Living Experiments for Climate Change Awareness** Carmela CUCUZZELLA, Design and Computation Arts, Concordia University, University Research Chair IDEASBE, L.E.A.P, Canada **Putting Regenerative Development into Action: Understanding the Decision-making Process of a 680 Hectares Regenerative Project** Dominique HES, Director – Thrive Research Hub, The University of Melbourne, Australia **Gamification as A Means to User Involvement in Decision-making Processes for Sustainable Buildings** Hanne Tine Ring HANSEN, Sustainability Engineer, Søren Jensen Consulting Engineers, Denmark **Accelerating HKIA's Carbon Footprint Reduction through Multi-stakeholder Engagement and its Potential for Multi-tenant Facilities** Mike KILBURN, Acting General Manager, Sustainability, Airport Authority Hong Kong, Hong Kong SAR	**Sino's Smart Initiative** Eugene LEUNG, Director, Sino Investment, Hong Kong SAR **Artificial Intelligence in Built Environment** Samson TAI, CTO, IBM Hong Kong, Hong Kong SAR **Smart Eco Home - Project Moses** Andy ANN, CEO, NDN Group, Hong Kong SAR **Policy, Design, and People: Developing a Sustainable East Asia** Vincent CHENG, Director of Building Sustainability, Arup, Hong Kong SAR

Session 5.11	Session 5.12
Processes, Design, Tools and Methodologies in SBE (3) Level 4 - S421	**Occupants' Evaluation of Green Buildings** Level 4 - S425
Session Chair: Kazuo IWAMURA Japan GreenBuild Council, Japan	**Session Chair:** Henk VISSCHER Professor, Delft University of Technology-Faculty of Architectuyre and the Built Environment, Germany
Assessing Sustainable Urban Densification Using Geographic Information Systems M. Augusta HERMIDA, Professor, Universidad de Cuenca, Ecuador **Traffic Quality Index to Intersections Considering Fuel Efficiency** Marta Monteiro da Costa CRUZ, Professor, Federal University of Espírito Santo, Brazil **A Simulation-Based Method to Assess 3D Urban Noise Environment in High-Density Cities** GUO Mengdi, The University of Hong Kong, Hong Kong SAR **Real Coded Quantum-Inspired Evolutionary Algorithm Applied to Sustainable Building** Omar QUISPE POLANCO, Universidad Catolica San Pablo, Arequipa-Peru **Sustainable Neighborhood Regeneration: Holistic Decision Support Methodology Supported by a Software Tool** Paul MITTERMEIER, Munich University of Applied Science, Germany	**Users' Perceptions of Building Performance - An Analysis of the Occupants' Comments** George BAIRD, Emeritus Professor of Building Science, Victoria University of Wellington **Cooperative Research for High Performance Buildings** Herbert Claus LEINDECKER, University of Applied Sciences Upper Austria, Austria **The Role of Perceived Social and Physical Environments on Older Adults´Social Interactions** Piret VEEROJA, University of Melbourne, Australia **Every Breath We Take – Transforming The Health of China's Office Space** WU Xuchao, Associate Director of Energy & Sustainability Services, JLL, Mainland China Louie CHENG, President, PureLiving China, Mainland China **Are Patterns of Use The Key to Resource Efficiency in Office Buildings?** Ken DOOLEY, Granlund Consulting, Finland

Session 6.1	Session 6.2 - Session Organiser: iiSBE
Regional Session - Australia, Mainland China, Singapore, South Korea and Philippines Level 1 - Convention Hall	**SBE Urban Challenge: Assessment Protocol and Case Studies** Level 1 - Theatre 1
Session Chair: Greg FOLIENTE Enterprise Professor, University of Melbourne; Regional Director in Asia-Pacific, iiSBE; Founding Director, nBLue Pty Ltd	**Session Chair:** Andrea MORO President, iiSBE Italia, Italy
SBE Sydney Deo PRASAD, Scientia Professor, CRC for Low Carbon Living **SBE Chongqing** Andrew BALDWIN, Chongqing University **SBE Singapore** Selvam VALLIAPPAN, Senior Manager, Green Building Research, Built Environment Research and Innovation Institute (BERII), Building and Construction Authority, Singapore **SBE Seoul** SHIN Sungwoo, Division of Architecture and Architectural Engineering at Hanyang University ERICA **SBE Manila** Fernando GERMAR, Chairman of Scientific Committee	**A New SBE Challenge Process for a Transnational Generic Framework at Urban Scale** Andrea MORO, President, iiSBE Italia, Italy Nils LARSSON, Executive Director, International Initiative for a Sustainable Built Environment **Case Study - Europe: CESBA MED, CESBA Alps, NewTREND and Felicity Projects** Andrea MORO, President, iiSBE Italia, Italy Stefania UGLOLA, iiSBE Italia R&D, Italy Paul MITTERMEIER, Munich University of Applied Science, Germany Ken DOOLEY, Granlund Consulting, Finland **Case Study - South America: URBENERE Network** Cristina Engel ALVAREZ, Professor/Coordinator, Laboratório de Planejamento e Projetos, Universidade Federal do Espírito Santo, Brazil Luis BRAGANÇA, University of Minho, Portugal **Case Study - Asia: China's KPIs for Sustainable Cities** **Cast Study - North America: DISTRICT 2030** Jiri SKOPEK, Managing Director, JLL, Canada; 2030 Districts

Session 6.5	Session 6.6
SBE Assessments - Design Processes Level 2 - S222	**Green Construction Materials (1)** Level 2 - S224 & 225
Session Chair: Natalie ESSIG University of Applied Sciences Munich (MUAS), Germany	**Session Chair:** Alexander PASSER Assistant Professor, Graz University of Technology, Austria
The Effects of Hong Kong Building Environment Assessment Method (HK-BEAM) Accreditation on Construction and Demolition Waste Minimization CHEN Xi, Department of Real Estate and Construction, The University of Hong Kong, Hong Kong SAR **Contribution of Knowledge in Sustainable Building Design in Emerging Markets– A Case of Vietnam** CHIH Ying-yi, The Australian National University, Australia **Integrated Green Building Assessment Approach for the Next Decade** May SIU, Director, Green Mark Department for New Development, Building and Construction Authority of Singapore, Singapore **Certification of Sustainability–Case Study Analysis of New German Standard** Merten WELSCH, Scientific Associate and Consultant, Federal Institute for Research on Building, Urban Affairs and Spatial Development (BBSR), Germany **Integration of Energy and Material Performance of Buildings: I=E+M** Saskia VAN HULTEN, Senior Consultant, W/E Consultants Sustainable Building, The Netherlands	**Naturally Ventilated Earth Timber Constructions** Andrea KLINGE, Senior Architect, Roswag Architekten, Germany **The Study on Durability Testing of Heat-insulation Coating** CHEN Chien-fu, National Cheng-Kung University, Taiwan **Utilizing Palm Rachis for Eco-Friendly and Flexible Construction in Egypt** Eman Atef DARWISH, Demonstrator, Department of Architecture, Ain Shams University-Cairo, Egypt **Bamboo for The 21st Century** Martin TAM Tin-fong, Founder and CEO, Able Mart Ltd., Hong Kong SAR **"Community Empowerment through Mud-concrete Technology" - Sustainable Building Techniques to Revitalise the War Victim Communities in Batticaloa, Sri Lanka** Rizna AROOZ, Research Assistant, University of Moratuwa, Sri Lanka

Session 6.3
Smart Initiatives in SBE (2)
Level 1 - Theatre 2

Session Chair: Antonio FRATTARI
Full Professor, University of Trento, Italy

Transforming Building Information Modelling to Sustainable Building Asset Management
LEE Che-kit, Chief Engineer, Electrical and Mechanical Services Department, Government of the HKSAR, Hong Kong SAR
CHAN Hor-yin, Senior Engineer, The Electrical and Mechanical Services Department, Government of the HKSAR, Hong Kong SAR

Meter Online - Information Drives Behavioural Change to Save Building Energy
Simon TSUI, CCE Manager - Commercial Accounts, CLP Power Hong Kong Limited, Hong Kong SAR

Energy Efficient Optimal Controls and Smart Energy Management of Buildings and Their Energy Benefits in Real Applications
WANG Shengwei, Chair Professor of Building Services Engineering, The Hong Kong Polytechnic University, Hong Kong SAR

Interactive Building-user Systems for Positive Behavioral Change by Enhancing E-participation of Building Occupants
ZHANG Qianning, Research Scholar, National University of Singapore, Singapore

Review on Demand Control Ventilation
ZHENG Caidan, Faculty of Urban Construction and Environmental Engineering, Chongqing University, Mainland China; National Centre for International Research of Low-carbon and Green Buildings, Ministry of Science & Technology

Session 6.4
Deep Renovations - Practices & Performance Review
Level 2 - S221

Session Chair: Antonin LUPISEK
Head of Department, Architecture and the Environment, Czech Technical University, Czech Republic

The Verification and Implementation of Practical Renovation for net-ZEB Office
Hiroaki TAKAI, Design Department Head Office, Principal Engineer(Environment), Takenaka Corporation, Japan

Humid Wall: Causes and Solutions
Mohamad KHARSEH, Chalmers University of Technology, Sweden

Improving the Market Up-take of Energy Producing Solar Shading: Experiences from Three Cases of Retrofit
Paula FEMENIAS, Chalmers University of Technology, Sweden

Towards a Holistic Approach to Retrofitting: A Critical Review of State-of-the-art Evaluation Methodologies for Architectural Transformation
Stina Rask JENSEN, Aarhus University, Denmark

Renovation Needs and Potential for Improved Energy Performance Depending on Ownership – A Location Based Study of Multi-Family Building Stocks in an Urban Context
Magnus ÖSTERBRING, Chalmers University of Technology, Sweden

Session 6.7
Innovations Driving for Greener Policies and Standards - Assessment, Analysis and Modelling (2)
Level 2 - S223

Session Chair: Holger WALLBAUM
Full Professor in Sustainable Building, Chalmers University of Technology, Sweden

Full Cost Assessment: A Method to Analyse Sustainability of Buildings
Alessandra Akemi YOKOTA, The University of Melbourne, Australia

Integrated System for Energy Optimization and Reduction of Building CO^2 Footprint
Flavio CELIS D'AMICO, University of Alcala, Spain

Environmental Indicators for Monitoring the Swedish Building and Real Estate Management Sector
Kristina EINARSSON, National Board of Housing, Building and Planning, Sweden

Feasibility Study on Implementing Indoor Air Quality (IAQ) Index in Hong Kong
MUI Kwok-wai, The Hong Kong Polytechnic University, Hong Kong SAR

Integrating Capital Cost with Energy Efficiency – Cost@Work
TANG Chee-khoay, CK@Work Sdn Bhd, Malaysia

Session 6.8
Sustainable Neighbourhoods - Case Study Review (2)
Level 4 - S426 & 427

Session Chair: Matthias Georg SULZER
Professor, Swiss Federal Laboratories for Materials Science and Technology, Switzerland; Head Swiss Competence Center for Energy Research – Future Energy Efficient Buildings & Districts, Switzerland

Urban Regeneration Introduced with Resilient City Concept - A Case Study of Pingtung City in Taiwan
CHANG Kuei-feng, Pingtung County Government, Taiwan

The District Cooling System at The Kai Tak Development
LO Siu-kuen, Senior Engineer, Electrical and Mechanical Services Department, Government of the HKSAR, Hong Kong SAR

Study on Business Scheme of a Community-wide Decentralized and Self-reliant Energy Network - Allocation of Co-benefits and Evaluation of Socio-environmental & Economic IRR
Ryota KUZUKI, Acting General Manager, Energy Strategy Planning Department, Tokyo Gas Co., Ltd., Japan

Policy Framework and Instruements for Green Transformation in East Asia
Vincent CHENG, Director of Building Sustainability, Arup, Hong Kong SAR

Session 6.9
Transforming Green Market - Green Economics (2)
Level 2 - S228

Session Chair: Thomas TANG Sek-khuen
Managing Director, Kuala Lumpur Centre for Sustainable Innovation, Malaysia

Economic and Sensitivity Analysis of Net Zero Energy Refurbishment of Terraced Houses
Angela GRECO, Delft University of Technology, The Netherlands

Finding the Value in Deep Energy Retrofits
James Scott BREW, Senior Sustainability Architect, Nikken Sekkei, Japan

Productive Green Roofs
Matthew PRYOR, Associate Professor (Teaching), The University of Hong Kong, Hong Kong SAR

Sustainable Buildings – Impacts on Cash Flow and Business Case Analysis
Thomas LÜTZKENDORF, Director and Head of Chair, Karlsruhe Institute of Technology, Germany

Business for Sustainability: Market Incentives for the Better
Thomas SCHLUCK, Senior Scientist, Hochschule Luzern, Switzerland

Session 6.10
Innovative Practices to Transform SBE (1)
Level 4 - S423 & 424

Comparative Analyses: Urban Quality, Living Standard, Sustainability. Modernist Housing Estates vs 21st Century City
Aleksandar TEPAVCEVIC, University Assistant, Graz University of Technology, Austria

Build Less and Make Cities Smarter by Unleashing Potential of Vacant Spaces
CHAN Lai-kiu, arQstudio Ltd, Hong Kong SAR

Green Transformation of Electrical and Mechanical Services Department Headquarters Building
Dominic LAU Siu-kei, Senior Building Services Engineer, Electrical and Mechanical Services Department, Government of the HKSAR, Hong Kong SAR

Shaping Energetic Neighbourhoods: A Dynamic Approach for a Future Proof Urban Energy Planning
Jürgen KNIES, Jade University of Applied Sciences, Germany

Building Drives for Behaviour Change - Role Model of Sustainability
Tony LAM, Senior Engineer, Arup, Hong Kong SAR

Session 6.13
Place-making - Integrative Design Processes
Level 2 - S226 & 227

Session Chair: Roland ZINKERNAGEL
Lund University, Sweden

Integrated Design Guidance for the Early Process Phase
Günter LÖHNERT, Sol·id·ar Planungswerkstatt, Germany

Responsive Design - The Innovative Approach to Create Sustainable Neighbourhoods and Cities
Mary CHAN, Dennis Lau & Ng Chun Man Architects and Engineers (HK) Ltd., Hong Kong SAR

Conceptualising Sustainable Neighbourhoods Through Collaborative Place-making
Solomon ADEWUMI, University of Dundee, United Kingdom

A Conceptual Model of Integral Sustainable Design Framework
Wilson YIK, Associate (Sustainability), Leigh & Orange Ltd, Hong Kong SAR
Matthew LEE, Assistant Project Designer (Sustainability), Leigh & Orange Ltd, Hong Kong SAR

From Environmental to Social and Cultural Sustainability
Peter YAM, Ronald Lu & Partners (Hong Kong) Ltd., Hong Kong SAR

Session 6.14 - Session Organiser: Hong Kong Green Building Council
BEAM Plus Neighbourhood: From Theory to Praxis
Level 4 - S428

Session Chair: Larry POON
Convener of BEAM Plus Neighbourhood Steering Committee/ Roll-out Taskforce, Hong Kong Green Building Council Ltd., Hong Kong SAR

BEAM Plus Neighbourhood: An Introduction
Larry POON, Convener of BEAM Plus Neighbourhood Steering Committee/ Roll-out Taskforce, Hong Kong Green Building Council Ltd., Hong Kong SAR

Subsidised Sale Flats Development at Fat Tseung Street West
Ada FUNG, Deputy Director of Housing (Development & Construction), Hong Kong Housing Authority, Hong Kong SAR

Transformation of EMSD Headquarters into a Green Building
Antony HO, Arup, Hong Kong SAR

West Kowloon Cultural District
William CHAN, Chief Operating Officer, West Kowloon Cultural District Authority, Hong Kong SAR

Lessons learnt from BEAM Plus Neighbourhood Pilot-testing
Larry POON, Convener of BEAM Plus Neighbourhood Steering Committee/ Roll-out Taskforce, Hong Kong Green Building Council

Session 6.11 **Processes, Design, Tools and Methodologies in SBE (4)** **Level 4 - S421**	Session 6.12 **Green Buildings - Occupants' Perspectives** **Level 4 - S425**
Session Chair: Andrew LEUNG Emeritus Professor, City University of Hong Kong; China Green Building (HK) Council, Hong Kong SAR	**Session Chair:** Kevin EDMUNDS Senior Manager - Sustainable Development, Hong Kong Science & Technology Parks Corporation, Hong Kong SAR
Evidence-Based Approach to Calibration of Whole Building Energy Model Adrian CHONG, Carnegie Mellon University, United States of America; National University of Singapore, Singapore **International LCA Data Network - Demonstration Project for an Open International Online Database Structure** Hildegund FIGL, IBO Austrian Institute for Building and Ecology, Austria **Noise Impact Assessment Study on High-performance of Sound Insolation for Residential Building at Neighboring Taiwan High Speed Rail Station** LIN Wei, Associate Professor, Dep. of Interior Design, Hwa Hsia University of Technology, Taiwan **The Failures of Initial Commissioning, and its Impacts on Overall Building Performance** Madeline Kathleen PARROTT, British Columbia Institute of Technology, Canada **Heating and Cooling Loads of a Poultry Shed in Central Coast, NSW, Australia** ZHOU Yu, The University of Melbourne, Australia	**Sculpting Socially Sustainable Neighbourhoods** Franklin YU, Singular Studio Ltd., Hong Kong SAR **Thermal Comfort Based Occupancy-driven Building Energy Saving Control Strategies** ZHANG Cheng, Assistant Professor, Xi'an Jiaotong-Liverpool University, Mainland China **The Effect of Occupant Behaviour on Real-time Electricity Consumption in Canadian School Spaces** Mohamed H. ISSA, University of Manitoba, Canada **Deep Green Approach to Create Sustainable Built Environments and Neighborhoods - Case Study of Lumpini Place Rama 4 - Ratchada Project** Panita VARA-URAIRAT, Director of Sustainable Development Department, Wisdom Consulting and Solution Co., Ltd., Thailand **M+, Sustainable Design for a Contemporary Art Museum in Hong Kong** Mark RICHARDSON, Senior Engineer of Building Sustainability, Arup, Hong Kong SAR

Session 7.1
Education and Training for Transforming SBE
Level 4 - S428

Session Chair: Samuel KWONG
Group Sustainable Development Manager, John Swire & Sons (H.K.) Ltd., Hong Kong SAR

Private Public Partnership Energy Efficiency Assessment Program at Hong Kong Aircraft Engineering Company, Xiamen Facility, China
Samuel KWONG, Group Sustainable Development Manager, John Swire & Sons (H.K.) Ltd., Hong Kong SAR

Leveraging the Power of Story to Achieve Greater Sustainability
James Scott BREW, Senior Sustainability Architect, Nikken Sekkei, Japan

Embedding Sustainability in Higher Education Course Content: An Industry Perspective
Lloyd Martin SCOTT, Dublin Institute of Technology, Ireland

Importance of Built Heritage for World Sustainable Build Environment
Shahid Ahmad RAJPUT, COMSATS Institute of Information Technology, Pakistan

Developing A Conceptual Framework for Integrating Project Risk Management and Sustainability Objectives
Timothy ROSE, Queensland University of Technology, Australia

Session 7.2 - Session Organiser: iiSBE
SBE Buildings Challenge: Assessment Protocol and Case Studies
Level 1 - Theatre 1

Session Chair: Nils LARSSON
Executive Director, International Initiative for a Sustainable Built Environment

General Intro about the Process and the Idea of Predicted vs. Actual Performance and the CanTeam Protocol
Gordon SHYMKO, President, G.F. Shymko & Associates Inc., Canada

Green and Monitoring in Holiday Inn Express SoHo Hong Kong
Antonio CM CHAN, REC Engineering Co., Ltd., Hong Kong SAR

The 2014 CanTeam Evaluation of 9 Case Studies
Gordon SHYMKO, President, G.F. Shymko & Associates Inc., Canada

Current Proposal for New Canadian Work
Gordon SHYMKO, President, G.F. Shymko & Associates Inc., Canada

UNSW BPE for 50 Dwellings
Lan DING, Senior Lecturer, Faculty of Built Environment, University of New South Wales, Australia

Panel Discussion

Session 7.5
SBE Assessments - Practices Review
Level 2 - S222

Session Chair: Antonin LUPISEK
Head of Department, Architecture and the Environment, Czech Technical University, Czech Republic

Transnational Harmonization of Built Environment Assessment Systems: the CESBA Passport Principle
Andrea MORO, President, iiSBE Italia R&D, Italy

Generating and Providing Embodied Energy and Global Warming Potential Related Information – Recommendations for Construction Product Manufacturers
Angelika HINTERBRANDNER, Graz University of Technology, Austria

Discussing Sustainability in Building Construction: The Potential of SBtool for Brazilian Public Bidding in Fiocruz
Monica Santos SALGADO, Federal University of Rio de Janeiro, Brazil

Assessment Tools for The Sustainability Performance of Building - Development of A Sustainability Assessment Method for Small Residential Buildings in Germany
Natalie ESSIG, University of Applied Sciences Munich, Germany

Session 7.6
Green Construction Materials (2)
Level 2 - S224 & 225

Session Chair: Kevin EDMUNDS
Senior Manager - Sustainable Development, Hong Kong Science & Technology Parks Corporation, Hong Kong SAR

Self-Compacting Clay Concrete: A Sustainable and Innovative Process to Build with Earth
Guillaume HABERT, Professor, ETH Zürich, Switzerland

Trend of Dynamic Glass in Green Building
HY CHIU, Director, Full Treasure, Hong Kong SAR

Upgraded Mineral Sand fraction from MSWI Bottom Ash: An Alternative Solution for the Substitution of Natural Aggregates in Concrete Application
Jacques Rémy MINANE, IMT Lille-Douai, LGCgE-GCE, France

Autonomous Repair in Cementitious Material by Combination of Superabsorbent Polymers and Polypropylene Fibres - A Step towards Sustainable Infrastructure
Souradeep GUPTA, National University of Singapore, Singapore

Session 7.3
Smart Initiatives in SBE (3)
Level 1 - Theatre 2

Session Chair: Vincent CHENG
Director of Building Sustainability, Arup, Hong Kong SAR

Using Advance Thermodynamics and Online Big Data Analytics to Maximize the Chiller Plant Performance
Glen ANDERSON, Vice President, ETC Group, Macau SAR

Transforming Data into Action – Building Energy Management System to Actualize a Sustainable Built Environment
Jovian CHEUNG Man-chit, Electrical & Mechanical Services Department, Government of the HKSAR, Hong Kong SAR

Telecommunications Infrastructure for High Performance Buildings
Philip TAI, Telecommunications Manager, Swire Properties Ltd., Hong Kong SAR

Using Big Data Analytics and Continuous Monitoring to Increase the Return of Investment (ROI) in Projects for Sustainable Building Performance
Rafael NAVARRO, Asia Regional Manager, ETC Group, Macau SAR

Session 7.4
Deep Renovations - Processes & Methodologies
Level 2 - S221

Session Chair: Antonio FRATTARI
Full Professor, University of Trento, Italy

Towards a Holistic Methodology in Sustainable Retrofitting: Theory, Implementation and Applications
Aliakbar KAMARI, Department of Engineering, Aarhus University, Denmark

A Multidimensional Optimisation Approach to Refurbishment Design on a Multi-Building Scale
Claudio NÄEGELI, Chalmers University of Technology, Sweden

Development of Regenerative Design Principles for Building Retrofits
William James CRAFT, University of New South Wales, Australia

Passive Building: Energetic Refurbishment of a Secondary School
Antonio FRATTARI, University of Trento, Italy

Factors Affecting High Performance Building Designs in Nigeria's Built Environment: "The Architects Perception"
Abubakar Yahaya MUHAMMAD, Lecturer, Abubakar Tafawa Balewa University, Nigeria

Session 7.7
Innovations Driving for Greener Policies and Standards - Smart Initiatives
Level 2 - S223

Session Chair: Shengwei WANG
Chair Professor of Building Services Engineering, The Hong Kong Polytechnic University, Hong Kong SAR

Smart Cities: Selection of Indicators for Vitória
Cristina Engel ALVAREZ, Professor/Coordinator, Laboratório de Planejamento e Projetos, Universidade Federal do Espírito Santo, Brazil

Establishing Smart Cities for Sustainability: An Analysis of the Japanese Innovation System and Implications for Asia
Masaru YARIME, Associate Professor, City University of Hong Kong, Hong Kong SAR

PLUSQUA: Potential of Neighbourhoods to Reduce Thermal and Electrical Loads
Matthias SULZER, Professor, Swiss Federal Laboratories for Materials Science and Technology; Head Swiss Competence Center for Energy Research - Future Energy Efficient Buildings & Districts, Switzerland

Adoption of Smart Initiatives in Developing Anderson Road Quarry Site Towards A Sustainable and Green Living Area
Michael LEUNG Chung-lap, Deputy Project Manager (New Territories East) 1, Civil Engineering and Development Department, Government of the HKSAR, Hong Kong SAR

PT Roadmap Towards Operational Energy Neutral Sewage Treatment Works
Valeria ALVARADO, Civil and Environmental Engineering, The Hong Kong Polytechnic University, Hong Kong SAR

Session 7.8
Sustainable Neighbourhoods - Processes and Application
Level 4 - S426 & 427

Session Chair: Phil JONES
Chair of Architectural Science, Welsh School of Architecture, Cardiff University, United Kingdom; Visiting Research Professor, Faculty of Architecture, University of Hong Kong, Hong Kong SAR

Current Challenges of Urban Energy Planning in A Norwegian Municipality
Eirik RESCH, Norwegian University of Science and Technology, Norway

Citylab Action: Guiding Sustainable Urban Development
Jonas LIND, Licentiate Candidate, KTH Royal Institute of Technology, Sweden; Project Coordinator, Sweden Green Building Council, Sweden

The Break-Even Point : Impact of Urban Densities on Value Creation, Infrastructure Costs and Embodied Energy
Serge SALAT, President, Urban Morphology and Complex Systems Institute, France

Barriers and Needs for Energy-efficient Refurbishment at District Level
Tarja HAKKINEN, Senior Principle Scientist, VTT Technical Research Centre of Finland Ltd., Finland

Building Regulations and Urban Policies as Incentives for Application of District Cooling Systems in Singapore
SHI Zhongming, Chair of Architecture and Building Systems, ETH Zurich, Switzerland

Session 7.9
Transforming Green Market - Supply Chain
Level 2 - S228

Session Chair: Amie SHUTTLEWORTH
Global Head of Sustainability Amie Shuttleworth, Cundall, Hong Kong SAR

New Visitors? Small European Companies Entering the Chinese Sustainable Building Market
Christian KOCH, Chalmers University of Technology, Sweden

Sustainable Electrical and Mechanical Services - Vision with Action
CHAN Ming-yee, Senior Engineer / Business Planning, Electrical and Mechanical Services Department, Government of the HKSAR, Hong Kong SAR

Project Manager's Role in Sustainable Building Projects: A Case Study in Canada
Ricardo Ferreira LEOTO, Architect and Sustainable Building Consultant, Faculté de l'Aménagement, Université de Montréal, Canada

A Study on Green Industrial Project Construction Experience
ZHANG Wei, Vice President - Engineering & Innovation, Bulter (Shanghai) Inc., Mainland China

The Economic Cost-benefit Analysis of Green Building Based on the Low-carbon Economic Policy
WAN Shiyu, School of Economics and Management, Beijing Jiaotong University, Mainland China

Session 7.10
Innovative Practices to Transform SBE (2)
Level 4 - S423 & 424

A Revolutionary Study Commons and University Library Extension, The Chinese University of Hong Kong
FUNG Siu-man, Director of Campus Development, The Chinese University of Hong Kong, Hong Kong SAR

Nearly Zero-Energy Care Home Design in Cold Climate in China
HOU Shan-shan, Research Associate, Cardiff University, United Kingdom

Preliminary Study on Natural Ventilation Efficiency in School Stadium by Different Opening Patterns
LI Yenyi, Associate Professor, ShuTe University / TSSBE (iiSBE-Taiwan), Taiwan

Quantifying and Improving Environmental and Human Sustainability in Remote-Region Health Clinics, Australia
Steve BURROUGHS, University of Canberra, Australia

Soaring of Urbanisation - Optimised Approaches through Adaptive and Sustainable Masterplanning
Antony HO, Associate, Arup, Hong Kong SAR

Session 7.13
Place-making - Practices Review
Level 2 - S226 & 227

Session Chair: Wafaa NADIM
Associate Professor, The German University in Cairo, Egypt

From Icon to Community: Repositioning the Image of the Modern Mega-Tower
Bryant LU, Vice Chairman, Ronald Lu and Partners (Hong Kong) Ltd., Hong Kong SAR

Do We Design Our Cities?
Eugenio Maria FONTAN YANES, Director – Architect – BIM Implementation, Enzyme Apd, Hong Kong SAR

Sustainable Residential Building Developments towards Neighbourhood Level – From a Hong Kong Private Developer Perspective
Edward CHAN, Henderson Land Development Co. Ltd., Hong Kong SAR

New Exposition of Sustainability – Linking People, Building and Community
Gary CHEUNG, Consultant of Building Sustainability, Arup, Hong Kong SAR

Sustainable Workplaces in High Density of Urban Areas
Ryusuke KOJIO, Architect, Takenaka Corporation, Japan; General Manager, Design, Takenaka Europe GMBH, Germany

Session 7.11 **Processes, Design, Tools and Methodologies in SBE (5)** **Level 4 - S421**	Session 7.12 **Multi-facet Considerations of Urban Regeneration Policies** **Level 4 - S425**
Session Chair: Kazuo IWAMURA Japan GreenBuild Council, Japan	**Session Chair:** Thomas NG Professor (Construction Engineering and Management), The University of Hong Kong, Hong Kong SAR
Measuring Sustainability in Buildings Using Construction Materials Database Based on Life Cycle Information in Turkey İlker KAHRAMAN, Yaşar University, Turkey **When Digital Fabrication Provides Environmental Benefits: Study of Complex Structures** Isolda AGUSTÍ-JUAN, Scientific Assistant, Chair of Sustainable Construction, ETH Zurich, Switzerland **Sustainable Building Design for Enhancement of Street Ventilation and Air Quality Improvement** Karl AN, The Hong Kong University of Science and Technology; AECOM Environment, Hong Kong SAR **Applicability of Maturity Assessment for Sustainable Construction** Marco SCHERZ, Scientific Assistant, Graz University of Technology - Institute of Technology and Testing of Building Materials - Working Group for Sustainability Assessment, Austria **Development of a Rotatable Outdoor Testbed and the Testing of an Integrated Auto-dimming Lighting and Automated Blind System in the Tropics** WAN Man-pun, Energy Research Institute@NTU (ERI@N) Nanyang Technological University, School of Mechanical & Aerospace Engineering Nanyang Technological University, Singapore	**The Role of Stakeholders in Masterplan Regeneration Decisions** Hannah BAKER, University of Cambridge, United Kingdom **Effect of Residential Tower Geometries on Urban Wind Environment** Ruffina THILAKARATNE, Associate Professor, Chu Hai College of Higher Education, Hong Kong SAR **Health Co-benefits of Low Carbon Policies in the Built Environment: An Australian Investigation into Local Government Co-benefits Policies** Sardar Masud KARIM, The University of New South Wales, Australia **Bai Wan Zhuang, A Beijing Community at The Crossroads - An Analysis About the Sustainable Update of Chinese Old Distinctive Residential Areas** WANG Liang, CAUPD, Mainland China **Methodology for a Sustainable Urban Regeneration: Urban Cell as Dissemination Unit** Miguel AMADO, Instituto Superior Tecnico, Portugal

Poster Sessions

Poster no.:	Paper Title	Venue
1	**Vertical Farm: Integrating Multifunctional Microalgae Cultivation into the Sustainable Built Environment** LEE Tzan-chain, Biodiversity Research Center, Academia Sinica, Taiwan	Level 2
2	**Grid Connected Photovoltaic System Potentials and Performance in 4 University Campuses** Chanikarn YIMPRAYOON, Faculty of Architecture, Kasetsart University, Thailand	Level 2
3	**Building High on Sustainable Use of Water: Hong Kong's Effort** Stephen CATLIN Kit-wai, Water Supplies Department, Government of the HKSAR, Hong Kong SAR KWAN Kai-yin, Water Supplies Department, Government of the HKSAR, Hong Kong SAR	Level 2
4	**Costs and Benefits of Implementing Green Building Policy** FAN Ke, The Hong Kong Polytechnic University, Hong Kong SAR GU Wei, The Hong Kong Polytechnic University, Hong Kong SAR Queena QIAN, Delft University of Technology, The Netherlands Edwin CHAN, The Hong Kong Polytechnic University, Hong Kong SAR	Level 2
5	**A Framework towards Low-carbon Heritage Conservation of Hong Kong: with Analysis of Embodied Carbon** GUO Nan, The Hong Kong Polytechnic University, Hong Kong SAR GU Wei, The Hong Kong Polytechnic University, Hong Kong SAR Edwin CHAN, The Hong Kong Polytechnic University, Hong Kong SAR Esther YUNG, The Hong Kong Polytechnic University, Hong Kong SAR	Level 2
6	**A Discussion on the Benefits of Environment Performance of the Promotion of Kaohsiung Green Building Specialties Policy -the Case Study on Residential Building in Kaohsiung City** KUO Yi-chun, Shu Te University, Taiwan OU Po-cheng, Shu Te University, Taiwan SHIE Chih-chang, Kaohsiung City Government, Taiwan SHIE Yu-chun, Kaohsiung City Government, Taiwan	Level 2
7	**Thermal Behavior of a Low-Cost House Coated With Transparent Infrared Reflective Paint** Ochuko Kelvin OVEREN, Fort Hare Institute of Technology, University of Fort Hare, South Africa	Level 2
8	**Dynamic Solar Shading in Sustainable Buildings** Anders HALL, SOMFY International; European Solar Shading Organization Edson Leroy MEYER, Fort Hare Institute of Technology, University of Fort Hare, South Africa Golden MAKAKA, Physics Department, University of Fort Hare, South Africa	Level 2
9	**The Third Success Factor of Renovations with Energy Ambitions** Anke VAN HAL, Nyenrode Business University, The Netherlands; Delft University of Technology, The Netherlands	Level 2
10	**Thermal Performance as a Parameter of Choice of Materials: Brazilian Antartic Station** Bruna Perovano SIRTULI, Universidade Federal do Espírito Santo, Brazil Filipe Galina COSTALONGA, Universidade Federal do Espírito Santo, Brazil Cristina Engel de ALVAREZ, Universidade Federal do Espírito Santo, Brazil Edna Aparecida NICO-RODRIGES, Universidade +A53Federal do Espírito Santo, Brazil	Level 2
11	**Renovation of Sheung Shui Staff Quarters – Green Building Actions Echoed by the Contractor** LI Siu-lung, Water Supplies Department, Government of the HKSAR, Hong Kong SAR	Level 2

12	**Environmental Impact Assessment of the Central Kowloon Route Project** LAM Man-san, Highways Department, Government of the HKSAR, Hong Kong SAR Franki C K CHIU, Arup, Hong Kong SAR	Level 2
13	**A Comparison on Two Certification Systems: Leadership in Energy & Environmental Design (LEED) and Building Environmental Assessment Method (BEAM) on Green Building In Hong Kong** Ophelia CHU Ka-wai, City University of Hong Kong, Hong Kong SAR Richard CHEUNG Yun-hing, City University of Hong Kong, Hong Kong SAR	Level 2
14	**Research on Emission Evaluation Classification of Healthy Green Building Materials Label in Taiwan** CHEN Cheng-chen, Department of Interior Design, Tung Fang Design Institute, Taiwan LEE Ching-chang, Department of Environmental Occupational Health, National Cheng Kung University, Taiwan CHEN Jui-ling, Architecture and Building Research Institute, Ministry of Interior, Taiwan	Level 2
15	**Sustainability Assessment: An Adaptive Neural Fuzzy Interference System Approach** TAN Yongtao, The Hong Kong Polytechnic University, Hong Kong SAR SHUAI Chenyang, The Hong Kong Polytechnic University, Hong Kong SAR SHUAI Chenyang, Chongqing University, Mainland China JIAO Liudan, Chongqing Jiao Tong University, Mainland China SHEN Liyin, Chongqing University, Mainland China	Level 2
16	**Quantifying Greenhouse Gas Emissions: A Review of Models and Tools at the Precinct Scale** Angela Maria ROJAS-AREVALO, The University of Melbourne, Australia 17Lu AYE, The University of Melbourne, Australia Seona CANDY, The University of Melbourne, Australia	Level 2
17	**Climate Responsiveness and Facade Design of AQUA-Certified School Buildings** Doris C.C.K. KOWALTOWSKI, University of Campinas, UNICAMP, Brazil Leticia de Oliveira NEVES, University of Campinas, UNICAMP, Brazil Vanessa Gomes DA SILVA, University of Campinas, UNICAMP, Brazil Giseli Mary COLLETO, University of Campinas, UNICAMP, Brazil	Level 2
18	**Project Guidelines for Construction of Biodigesters in Poor Communities in Brasil** Lizelda Maria MENDONÇA SOUTO, Polytechnic School of University of Pernambuco, Brazil Sérgio PERES, Polytechnic School of University of Pernambuco, Brazil Emilia KOHLMAN-RABBANI, Polytechnic School of University of Pernambuco, Brazil Viviany NOGUEIRA, Polytechnic School of University of Pernambuco, Brazil Ana Rita DRUMMOND, Polytechnic School of University of Pernambuco, Brazil	Level 2
19	**Development of Solar Photovoltaic Pavement Panels for Application on the Green Deck** MA Tao, Renewable Energy Research Group (RERG), Department of Building Services Engineering, The Hong Kong Polytechnic University, Hong Kong SAR YANG Hongxing, Renewable Energy Research Group (RERG), Department of Building Services Engineering, The Hong Kong Polytechnic University, Hong Kong SAR LU Lin, Renewable Energy Research Group (RERG), Department of Building Services Engineering, The Hong Kong Polytechnic University, Hong Kong SAR	Level 2
20	**Study on the Predictive Model and Adjustment Strategies of Indoor Environment for Susceptible Populations** LU Mei-chen, Department of Architecture, National Cheng Kung University, Taiwan TSAY Yaw-shyan, Department of Architecture, National Cheng Kung University, Taiwan SU Huey-jen, Department of Environmental and Occupational Health, College of Medicine, National Cheng Kung University, Taiwan HSU Nai-yun, Department of Environmental and Occupational Health, College of Medicine, National Cheng Kung University, Taiwan	Level 2
21	**Improvement Strategy of Urban Street Thermal Environment** WANG Wen-an, Tamkang University, Taiwan	Level 2

22	**Study of Climate Adaptive Design of Green Rural Houses in South Shaanxi Province** CAI Wei, Northwestern Polytechnical University, Mainland China HAN Yue, Northwestern Polytechnical University, Mainland China LIU Yi, Northwestern Polytechnical University, Mainland China ZHOU Haoran, Northwestern Polytechnical University, Mainland China WANG Runsheng, Northwestern Polytechnical University, Mainland China	Level 2
23	**Study on Consumers' Willingness to Pay for Products with a Green Building Material Label in Taiwan** TSAY Yaw-shyan, National Cheng-Kung University, Taiwan CHANG Yi-hsuan, National Cheng-Kung University, Taiwan	Level 4
24	**Improving The Relationship Between Eco-Design and Environmental Education – A Case Study of Elementary Schools in Taiwan** HUANG Wei-chih, National Cheng Kung University, Taiwan TSAY Yaw-shyan, National Cheng Kung University, Taiwan HO Shin-jia, Center for General Education, National Taichung University of Science and Technology, Taiwan HO Yen-yi, Department of Interior Design, Shu-Te University, Taiwan	Level 4
25	**Benefits of and Barriers to Green Building Implementation in Hong Kong** HUO Xiaosen, The Hong Kong Polytechnic University, Hong Kong SAR Ann TW YU, The Hong Kong Polytechnic University, Hong Kong SAR	Level 4
26	**Research on Development of a Guide for Environmental Study Classes Using Environment-conscious Technologies of School Facilities** Go MIYAZAKI, Kogakuin University, Japan Yusuke NAKAJIMA, Kogakuin University, Japan	Level 4
27	**Water Use of Thin-Layer Green Roof by Vertical-Flow Constructed Wetlands** PENG Jr-jie, National Taiwan University of Science and Technology, Taiwan CL CHENG, National Taiwan University of Science and Technology, Taiwan	Level 4
28	**"Sponge City", A Mental Experiment with Scientific Solution for "Sustainable Neighborhood"** James XIONG Jian, WSP|PARSONS BRINCERHOFF, Hong Kong SAR Jason YANG, WSP|PARSONS BRINCERHOFF, Hong Kong SAR Yuqi TANG, WSP|PARSONS BRINCERHOFF, Hong Kong SAR Simon TANG, WSP|PARSONS BRINCERHOFF, Hong Kong SAR	Level 4
29	**A BIM Based Integrated BIPV Design System** YOU Qi, China Smart Construction Group, Mainland China OUYANG Antao, China Smart Construction Group, Mainland China BAI Yang, China Smart Construction Group, Mainland China	Level 4
30	**Design Strategies for Sustainability and Integration of Water Treatment Works – Case Study of Sha Tin Water Treatment Works, Hong Kong** Aletta CHIU, Water Supplies Department, Government of the HKSAR, Hong Kong SAR Bevis W L MAK, AECOM Asia Company Ltd., Hong Kong SAR Edward W K LEE, AECOM Asia Company Ltd., Hong Kong SAR	Level 4
31	**Low-Carbon Transport Development Strategy of Coping With Climate Change-the Case of Pingtung County** CHUNG Shih-yen, Pingtung County Government, Taiwan CHANG Kuei-feng, Pingtung County Government, Taiwan CHEN Ming-chang, Pingtung County Government, Taiwan KUO Wu-wei, Pingtung County Government, Taiwan CHEN Yu-jia, Pingtung County Government, Taiwan	Level 4

32	**Potential for Decreasing of Organizational Environmental Impacts: A Case Study of Czech Ministry of Labour and Social Affairs** Antonín LUPÍŠEK, Czech Technical University in Prague, University Centre for Energy Efficient Buildings, Czech Republic Vladimír KOČÍ, University of Chemistry and Technology, Prague, Czech Republic Kateřina SOJKOVÁ, Czech Technical University in Prague, University Centre for Energy Efficient Buildings, Czech Republic Kristina ZAKUCIOVÁ, University of Chemistry and Technology, Prague, Czech Republic Jiří TENCAR, Czech Technical University in Prague, University Centre for Energy Efficient Buildings, Czech Republic Miloš LAIN, Czech Technical University in Prague, University Centre for Energy Efficient Buildings, Czech Republic Miroslav URBAN, Czech Technical University in Prague, University Centre for Energy Efficient Buildings, Czech Republic Jiří CÍGLER, Czech Technical University in Prague, University Centre for Energy Efficient Buildings, Czech Republic Vladimír HORYNA, Czech Technical University in Prague, University Centre for Energy Efficient Buildings, Czech Republic	Level 4
33	**A Preliminary Study on the Performance of Indoor Environment with Green BIM Tools - Taking Light Environment and Thermal Environment as an Example** CHEN Nien-tsu, Department of Interior Design, Tungfang Design Institute, Taiwan CHEN Ying-sheng, Department of Architecture, National Cheng Kung University, Taiwan TSAY Yaw-shyan, Department of Architecture, National Cheng Kung University, Taiwan LIN Chuan-hsuan, Department of Architecture, National Cheng Kung University, Taiwan	Level 4
34	**Study on the Energy Efficiency of the Climatic Based Passive Design by Meinong Tobacco Barns in Kaohsiung** LI Yen-yi, ShuTe University / TSSBE (iiSBE-Taiwan), Taiwan CHUNG Po-ren, Graduate School of Architecture, National ChengKung University, Taiwan LIN Hisn-I, ShuTe University / TSSBE (iiSBE-Taiwan), Taiwan TZENG Ping-chieh, Bureau of Public Works, Koahisung City Government, Taiwan CHEN Chen-Yu, Department of Architecture, ChengKung University, Taiwan	Level 4
35	**Sustainable Midfield Concourse Development at Hong Kong International Airport** Kevin POOLE, Airport Authority Hong Kong, Hong Kong SAR	Level 4
36	**The Use of Recycled Aggregates for Full Depth of Sub-Base in Pavement Construction in Hong Kong** HUI Hok-tung, Highways Department, Government of the HKSAR, Hong Kong SAR	Level 4
37	**Decision Making Process Assisted by Life Cycle Assessment: Greenhouse Gas Emission** Ludimilla de Oliveira ZEULE, Federal University of São Carlos, Brazil Laís David VINHAL, Federal University of São Carlos, Brazil Sheyla Mara Baptista SERRA, Federal University of São Carlos, Brazil Douglas BARRETO, Federal University of São Carlos, Brazil	Level 4
38	**Urban Regeneration Introduced with Resilient City Concept - A Case Study of Pingtung City in Taiwan** CHANG Kuei-feng, Pingtung County Government, Taiwan CHANG Wan-ting, Pingtung County Government, Taiwan LIUNG Hing-heng, Pingtung County Government, Taiwan WONG Wei-jin, Pingtung County Government, Taiwan	Level 4
39	**The Status and Operation Issues Related to Covered Playgrounds of Elementary Schools** HSIEH Hung-ren, National Ilan University, Taiwan LI Ming-da, National Ilan University, Taiwan	Level 4
40	**Study of Public Mood Based on Sentiment Analysis in the City of Bandar Lampung, Indonesia** Munawir, The University of Kitakyushu, Japan; Cokroaminoto Palopo University, Indonesia Fritz Akhmad NUZIR, Bandar Lampung University, Indonesia Bart Julien DEWANCKER, The University of Kitakyushu, Japan	Level 4

41	**Estate Revitalization Scheme Ping Shek Estate: Pilot Project Completed** WONG Man-lung, Hong Kong Housing Department, Government of the HKSAR, Hong Kong SAR LAM Ho-yin, Hong Kong Housing Department, Government of the HKSAR, Hong Kong SAR	Level 4
42	**The Study of Pavement Reconstruction Corresponding to Microclimate Cooling Efficiency in Elementary School Campus** KAO Kuo-sheng, Department of Computer and Communication, SHU-TE University, Taiwan LIN Hung-chun, Grad. School of Architecture and Interior Design, SHU-TE University, Taiwan LI Yen-yi, Grad. School of Architecture and Interior Design, SHU-TE University, Taiwan CHUNG Po-ren, Graduate School of Architecture, National Cheng Kung University, Taiwan LIN Chia-hsiung, Department of Interior Design, SHU-TE University, Taiwan	Level 4
43	**Kai Tak Development - Migrating Towards Vision** YING Fun-fong, Civil Engineering and Development Department, Government of the HKSAR, Hong Kong SAR Sunny LO, Civil Engineering and Development Department, Government of the HKSAR, Hong Kong SAR	Level 4
44	**Sustainable Interior Environments for Historic Buildings: A Case Study of the Presidential Palace of San Anton, Malta** Amber WISMAYER, University of Bath, United Kingdom Carolyn S. HAYLES, INSPIRE @ UWTSD, Mount Pleasant Campus, United Kingdom Nick MCCULLEN, University of Bath, United Kingdom	Level 4
45	**Café des Visions: How to Anticipate and Consolidate Urban Negotiation through Art; a Practice-based Artistic Research** Anna GRABER, Café des Visions, Switzerland	Level 4
46	**The Exploration of Sustainable Neighbourhoods - A Case Study of Shenyang** LI Li-hong, Shenyang Jianzhu University, Mainland China WANG Zhuo, Shenyang Jianzhu University, Mainland China	Level 4
47	**Study on the Shading Performance of Expanded Metal Mesh** LIN Chien-hsun, Department of Architecture,National Cheng Kung University, Taiwan TSAY Yaw-shyan, Department of Architecture,National Cheng Kung University, Taiwan YANG Jhih-hong, Department of Architecture,National Cheng Kung University, Taiwan YANG Yu-fang, Shang Kai Steel Co., Ltd.,Taiwan	Level 4
48	**The Research of Enhancing the Performance of Impact Sound Insulation on Wooden Structure Floor** LIN Fang-ming, National Pingtung University of science and technology, Taiwan FENG Chun-hao, National Cheng Kung University, Taiwan TSAI Yueh-han, National Pingtung University of science and technology, Taiwan	Level 4
49	**Construction of Green Residences for Ecological Immigrants - A Case Study of Ningqiang Area in The South of Shaanxi Province** HE Jiao, Northwestern Polytechnical University, Mainland China LI Jing, Northwestern Polytechnical University, Mainland China LIU Yu, Northwestern Polytechnical University, Mainland China WANG Ding, Shanghai Construction NO.4(Group)Co,Ltd.Architectural Design & Research Institute, Mainland China	Level 4
50	**Optimization of Packing Density Parameters for Reduction of Cement Content in Interlocking Concrete Block Pavers** Chamod Kosala HETTIARACHCHI, University of Moratuwa, Sri Lanka Wasantha Kumara MAMPEARACHCHI, University of Moratuwa, Sri Lanka	Level 4
51	**Development of a Functional Interior Material Using Scallop Shell Lime** Hinako UEHARA, Kogakuin University, Japan Yusuke NAKAJIMA, Kogakuin University, Japan	Level 4
52	**Research on Environmental Safety of Nanomodified Building Materials** Petr ZHUK, Moscow Architectural Institute (State Academy), Russia	Level 4

VII. SBE16 REGIONAL CONFERENCES – TOP & BEST PAPERS

SBE16 DUBAI (17-19 JANUARY 2016)

[Website: http://conference.buid.ac.ae/sbe16/]

1. Certification of Sustainability – Case Study Analysis of New German Standard
   Merten WELSCH[a]
   [a] *Federal Institute for Research on Building, Urban Affairs and Spatial Development (BBSR), Germany, merten.welsch@bbr.bund.de*

   Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 6.5).

2. Thermal Comfort Analysis for the First Passivhaus Project in Qatar
   May KHALFAN[a], Steve SHARPLES[b]
   [a] *University of Liverpool, United Kingdom, m.khalfan@liverpool.ac.uk*
   [b] *University of Liverpool, United Kingdom, steve.sharples@liverpool.ac.uk*

3. Evaluation of Villas Codes in Dubai Green Building Regulation and Specification
   Jaheen NOHA[a], Abu-Hijleh BASSAM[b]
   [a] *Faculty of Engineering and IT, The British University in Dubai, Dubai-UAE, nohamohameed@hotmail.com*
   [b] *Faculty of Engineering and IT, The British University in Dubai, Dubai-UAE, bassam.abuhijleh@buid.ac.ae*

SBE16 TORINO (18-19 FEBRUARY 2016)

[Website: http://sbe16torino.org/]

1. The Break-Even Point : Impact of Urban Densities on Value Creation, Infrastructure Costs and Embodied Energy
   Serge SALAT[a]
   [a] *Urban Morphology and Complex Systems Institute, France· serge.salat@gmail.com*

   Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 7.8).

2. Understanding Variation in Building Energy Analyses: Using Extant Literature to Explain Policy Outcomes
   JC MARTEL[a]
   [a] *University of Kansas, jcmartel@ku.edu*

3. Feasibility Analysis of an Integrated Building Energy System
   Maria BRUCOLI[a], Alessandro GRIECO[b], Michele Antonio TROVATO[c]
   [a] *Arup, London, maria.brucoli@arup.com*
   [b] *Politecnico di Bari Via E. Orabona, 4 70126 Bar, alexgrieco@hotmail.it*
   [c] *Politecnico di Bari Via E. Orabona, 4 70126 Bar, micheleantonio.trovato@ poliba.it*

4. Sustainable Neighborhood Regeneration: Holistic Decision Support Methodology supported by a Software Tool
   Paul MITTERMEIER[a], Natalie EßIG[b], Ahmed KHOJA[c]
   [a] *Munich University of Applied Science, Germany, paul.mittermeier@hm.edu*
   [b] *Munich University of Applied Science, Germany, natalie.essig@hm.edu*
   [c] *Munich University of Applied Science, Germany, khoja@hm.edu*

   Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 5.11).

5. [BIM-GIS Modelling for Sustainable Urban Development]

Sara TORABI MOGHADAM[a], Francesca M. UGLIOTTI[b], Patrizia LOMBARDI[c], Guglielmina MUTANI[d], Anna OSELLO[e]
[a] *Inter University Department of Regional and Urban Studies and Planning, Politecnico di Torino, Italy, sara.torabi@polito.it*
[b] *Department of Structural, Geotechnical and Building Engineering, Politecnico di Torino, Italy, francesca.ugliotti@polito.it*
[c] *Inter University Department of Regional and Urban Studies and Planning, Politecnico di Torino, Italy, patrizia.lombardi@polito.it*
[d] *Department of Energy, Politecnico di Torino, Italy, guglielmina.mutani@polito.it*
[e] *Department of Structural, Geotechnical and Building Engineering, Politecnico di Torino, Italy, anna.osello@polito.it*

6. [Istanbul Metro: A Possible Example of Energy Geostructure]

Luca SOLDO[a], Antonio DEMATTEIS[b], Fabio FURNO[c], Marco BARLA[d]
[a] *Geodata SpA Corso Bolzano 14 Torino (Italy), luca.soldo@geodata.it*
[b] *Geodata SpA Corso Bolzano 14 Torino (Italy), ade@geodata.it*
[c] *Politecnico di Torino, Dipartimento di Ingegneria, Strutturale, Edile e Geotecnica, corso Duca degli Abruzzi 24, Torino (Italy), fabio.furno@studenti.polito.it*
[d] *Politecnico di Torino, Dipartimento di Ingegneria, Strutturale, Edile e Geotecnica, corso Duca degli Abruzzi 24, Torino (Italy), marco.barla@polito.it*

7. [Local Sustainability Profiles – A New Approach to Urban Sustainability Strategies]

Peter ULRICH[a], Edgar GOELL[b]
[a] *ICLEI European Secretariat Leopoldring 3 79098 Freiburg, Germany, peter.ulrich@iclei.org*
[b] *IZT Institute for Futures Studies and Technology Assessment Schopenhauerstr. 26 14129 Berlin, Germany, e.goell@izt.de*

8. [Cultivating a Village Impulse in the Midst of Warsaw, the Jazdów Settlement of Finnish Houses]

Dariusz ŚMIECHOWSKI[a]
[a] *Academy of Fine Arts in Warsaw, Poland, dariusz.smiechowski@gmail.com*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 1.12).

9. [Nature-based Urban Space Transformation]

Kristin BARBEY[a]
[a] *Karlsruhe Institute of Technology, Germany, kristin.barbey@berlin.de*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 1.12).
[Smart and Sustainable Transport through University Campus]

Codrin CUCIUREAN[a], Mihai FLOREA[b], Valerian CROITORESCU[c]
[a] *Scientific Research and Continuous Training Center for Sustainable Automotive Technologies, University Politehnica of Bucharest, Faculty of Transport, Romania, codrib.cuciurean@gmail.com*
[b] *Scientific Research and Continuous Training Center for Sustainable Automotive Technologies, University Politehnica of Bucharest, Faculty of Transport, Romania, mihai_florea@live.com*
[c] *Scientific Research and Continuous Training Center for Sustainable Automotive Technologies, University Politehnica of Bucharest, Faculty of Transport, Romania, valerian.croitorescu@upb.ro*

SBE16 HAMBURG (8-11 MARCH 2016)

[Website: http://www.zebau.de/projekte/sbe16-hamburg]

1. [Innovative Building Technologies Towards Sustainable Construction – A Comparative LCA and LCC Assessment]

Alexander PASSER[a], Gernot FISCHER[b], Richard DEUTSCH[c], Petra SÖLKNER[d], Sebastian SPAUN[e]
[a] *Graz University of Technology, Austria, alexander.passer@tugraz.at*
[b] *Graz University of Technology, Austria, gernot.fischer@tugraz.at*
[c] *Graz University of Technology, Austria, richard.deutsch@tugraz.at*
[d] *Austrian Cooperative Researchm, Austria, petra.soelkner@gmx.at*
[e] *Austrian Cooperative Researchm, Austria, spaun@voezfi.at*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 5.6).

2. Sustainability and Risk
Sarah Ok Kyu STRUNK[a], Christian STOY[b]
[a] *Institute for Construction Economics, University of Stuttgart, Stuttgart, Germany, sarah.strunk@bauoekonomie.uni-stuttgart.de*
[b] *Institute for Construction Economics, University of Stuttgart, Stuttgart, Germany, christian.stoy@bauoekonomie.uni-stuttgart.de*

3. Planning of Ecologically and Economic Optimized District Refurbishments
Rafael HORN[a], Michael JÄGER[b], Roberta GRAF[c]
[a] *Fraunhofer Institute for Building Physics, rafael.horn@ibp.fraunhofer.de*
[b] *Fraunhofer Institute for Building Physics, michael.jaeger@ibp.fraunhofer.de*
[c] *Fraunhofer Institute for Building Physics, roberta.graf @ibp.fraunhofer.de*

4. Life Cycle Approach as a Method for Optimizing Building Services Systems in Extremely Low Energy Buildings
Jens TØNNESEN[a], Torhildur KRISTJANSDOTTIR[b]
[a] *Norwegian University of Science and Technology, Norway, jens.tonnesen@ntnu.no*
[b] *Norwegian University of Science and Technology, Norway, torhildur.kristjansdottir@ntnu.no*

5. Sustainability Profile of Urban Planning in Algiers
Mohamed SRIR[a], Ewa BEREZOWSKA-AZZAG[b]
[a] *EPAU, Algeria, mohamed.srir@gmail.com*
[b] *EPAU, Algeria, ewaazzag@yahoo.fr*

6. Building Life Cycle Assessment: Investigation of Influential Factors in a Helpful Decision Tool
Marie-Lise PANNIER[a], Patrick SCHALBART[b], Bruno PEUPORTIER[c]
[a] *Mines ParisTech PSL Research University, France, marie-lise.pannier@mines-paristech.fr*
[b] *Mines ParisTech PSL Research University, France, patrick.schalbart@mines-paristech.fr*
[c] *Mines ParisTech PSL Research University, France, bruno.peuportier@mines-paristech.fr*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Track 9 - Poster Session).

SBE16 VALLETTA (16-18 MARCH 2016)

[Website: http://www.sbe16malta.org/]

SBE16 UTRECHT (6-8 APRIL 2016)

[Website: https://www.onderzoek.hu.nl/Evenementen/Zero-Transition-SBE16-Conference]

SBE16 ZURICH (13-17 JUNE 2016)

[Website: http://www.sbe16.ethz.ch/]

1. Geo-dependent Heat Demand Model of the Swiss Building Stock
Stefan SCHNEIDER[a], Jad KHOURY[b], Bernard LACHAL[c], Pierre HOLLMULLER[d]
[a] *University of Geneva, Switzerland, stefan.schneider@unige.ch*
[b] *University of Geneva, Switzerland, jad.khoury@unige.ch*
[c] *University of Geneva, Switzerland, bernard.lachal@unige.ch*
[d] *University of Geneva, Switzerland, pierre.hollmuller@unige.ch*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 5.7).

2. Naturally Ventilated Earth Timber Constructions
Andrea KLINGE[a], Eike ROSWAG-KLINGE[b], Christof ZIEGERT[c], Patrick FONTANA[d], Matthias RICHTER[e], Johannes HOPPE[f]
[a] *Roswag Architekten, Germany, klinge@zrs-berlin.de*
[b] *Roswag Architekten, Germany, roswag@zrs-berlin.de*
[c] *Ziegert Seiler Ingenieure, Berlin, Germany, ziegert@zrs-berlin.de*
[d] *Bundesanstalt für Materialforschung und -prüfung (BAM), Berlin, Germany, patrick.fontana@bam.de*
[e] *Bundesanstalt für Materialforschung und -prüfung (BAM), Berlin, Germany, matthias.richter@bam.de*
[f] *Ziegert Seiler Ingenieure, Berlin, Germany, johannes.hoppe@bam.de*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 6.6).

3. The Cost and Environmental Impact Of Service Life Extending Self-Healing Engineered Materials For Sustainable Steel Reinforced Concrete
P. VAN DEN HEEDE[a], B. VAN BELLEGHEM[b], N. DE BELIE[c]

SBE16 PRAGUE (22-24 JUNE 2016)

[Website: http://cesb.cz/]

1. Embodied Energy and Global Warming Potential in Construction – Perspectives and Interpretations
Maria BALOUKTSI[a], Thomas LÜTZKENDORF[b], Seongwon SEO[c], Greg FOLIENTE[d]
[a] *Karlsruhe Institute of Technology, Germany, maria.balouktsi@kit.edu*
[b] *Karlsruhe Institute of Technology, Germany, thomas.luetzkendorf@kit.edu*
[c] *CSIRO Land and Water, Australia, seongwon.seo@csiro.au*
[d] *CSIRO Land and Water, Australia, greg.foliente@csiro.au*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 4.5).

2. Life Cycle Greenhouse Gas Emissions of Material Use In The Living Laboratory
Marianne Rose KJENDSETH WIIK[a], Aoife Anne-Marie HOULIHAN WIBERG[b]
[a] *SINTEF, Norway, marianne.wiik@sintef.no*
[b] *Norwegian University of Science and Technology, Norway, aoife.houlihan.wiberg@ntnu.no*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 5.10).

3. Hygrothermal Behaviour of Wood-based Structures: Full Scale Experiment
Veronika BURESOVA[a], Michal BURES[b]
[a] *CTU in Prague, Faculty of Civil Engineering, Czech republic, veronika.buresova@fsv.cvut.cz*
[b] *CTU in Prague, Faculty of Civil Engineering, Czech republic; University Centre for Energy Efficient Buildings of Technical University in Prague, Czech Republic, michal.bures@fsv.cvut.cz*

4. Global Impulse Sensitivity Analysis for Building Energy Simulation of Residential Quarters
Manuel LINDAUER[a]
[a] *Technical University of Munich, Germany, manuel.lindauer@tum.de*

SBE16 MANILA (13-15 JULY 2016)

[Website: http://sbe16.upd.edu.ph/www.conference.upd.edu.ph/index.php/SBE]

1. Estimating Typhoon Haiyan's Wind Speeds Using Windicators and Post-Storm Wind Vulnerability Analysis on the Affected Areas
Joshua AGAR[a], Jaime Jr. HERNANDEZ[b], William MATA[c]
[a] *University of the Philippines Diliman, Philippines, jcagar@up.edu.ph*
[b] *University of the Philippines Diliman, Philippines, jyhernandez@up.edu.ph*
[c] *University of the Philippines Diliman, Philippines, william.mata@yahoo.com*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 1.8).

SBE16 SINGAPORE (5-6 SEPTEMBER 2016)

[Website: http://www.sbe-series.org/sbe-16/singapore/overview/]

1. Use of Incineration Bottom Ash for Road Construction in Singapore
HO Nyok-yong[a], Kelvin LEE Yang-pin[b], YAP Cheng-chwee[c], TONG Kum-kong[d]
[a] *Samwoh Innovation Centre, Singapore, nyok.yong.ho@samwoh.com.sg*
[b] *Samwoh Innovation Centre, Singapore, kelvin.lee@samwoh.com.sg*
[c] *Land Transport Authority, Singapore, yap_cheng_chwee@lta.gov.sg*
[d] *Land Transport Authority, Singapore, tong_kum_kong@lta.gov.sg*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 4.6).

2. Redefining Indoor Air Quality - Improving the Green Mark Standards based on recent Tropical IAQ Research
Karl WAGNER[a]
[a] *University of Kuala Lumpur, Malaysia*

3. Occupant Behaviour and Direct Rebound Effect in Commercial Building Energy Retrofits
ONG Shu-qing[a]
[a] *Department of Building, National University of Singapore, Singapore*

4. Incorporating Effects of Oblique Waves in the Design of Coastal Protection Structures Under Sea Level Rise
Lydia LIM Sin-hwei[a]
[a] *NUSDeltares Alliance, National University of Singapore, Singapore*

5. The Enclosed Household: Air-conditioning and the Perception of the Household Built Environment
QUEK Ri-an[a]
[a] *Lee Kuan Yew Center for Innovative Cities, Singapore University of Technology and Design, Singapore*

6. Interactive Building-user Systems for Positive Behavioral Change by Enhancing E-participation of Building Occupants
ZHANG Qianning[a], Stephen LAU Siu-yu[b]
[a] *National University of Singapore, Singapore, zqn2814@gmail.com*
[b] *National University of Singapore, Singapore, akilssy@nus.edu.sg*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 6.3).

7. Comparing Microorganisms in Settled Dust from Childcare Centers with Different Ventilation Modes
Caroline CHENARD[a], Stephan SCHUSTER[b], Federico LAURO[c]
[a] *Singapore Centre for Environmental Life Science Engineering, Nanyang Technological University, Singapore*
[b] *Singapore Centre for Environmental Life Science Engineering, Nanyang Technological University, Singapore*
[c] *Singapore Centre for Environmental Life Science Engineering, Nanyang Technological University, Singapore*

8. Use of Sedimentary Rocks for Construction Applications
HO Nyok-yong[a], Kelvin LEE Yang-pin[b], LIM Wee-fong[c], Zhang Weide[d], Cherlyn LEONG Pei-ying[e]
[a] *Samwoh Corporation Pte Ltd, Singapore*
[b] *Samwoh Corporation Pte Ltd, Singapore*
[c] *Samwoh Corporation Pte Ltd, Singapore*
[d] *JTC Corporation, Singapore*
[e] *JTC Corporation, Singapore*

SBE16 BRAZIL & PORTUGAL (7-9 SEPTEMBER 2016)

[Website: http://civil.uminho.pt/sbe16_Brazil_Portugal/]

1. LEED Certification and The New Standard of Sustainable Construction in Colombia
Andrés PELÁEZ[a], Alexander GONZALEZ[b], Laura MARIN[c]
[a] *Universidad Pontificia Bolivariana, Colombia, andres.po.6@hotmail.com*
[b] *Universidad Pontificia Bolivariana, Colombia, alexandergonzalez@upb.edu.co*
[c] *PVG Arquitectos, lauramarin@pvgarquitectos.com*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 1.5).

2. Smart Cities: Selection of Indicators for Vitória
Carolina SIMÕES ROCON[a], Cristina ENGEL DE ALVAREZ[b]
[a] *Laboratório de Planejamento e Projetos, Universidade Federal do Espírito Santo, Brazil, carolinarocon@gmail.com*
[b] *Laboratório de Planejamento e Projetos, Universidade Federal do Espírito Santo, Brazil, engelalvarez@hotmail.com*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 7.7).

3. Historic Relationship Between Urban Dwellers and The Tomebamba River
Pablo OSORIO[a], Mateo NEIRA[b], M. Augusta HERMIDA[c]
[a] *Universidad de Cuenca, Ecuador, pablo.osorio@ucuenca.edu.ec*
[b] *Universidad de Cuenca, Ecuador, mateo0719@gmail.com*
[c] *Universidad de Cuenca, Ecuador, augusta.hermida@ucuenca.edu.ec*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 1.12

4. Traffic Quality Index to Intersections Considering Fuel Efficiency
Fabianne Miranda AGUIAR[a], Marta Monteiro da Costa CRUZ[b], Gregório Coelho de Morais NETO[c], Adelmo Inacio BERTOLDE[d]
[a] *Federal University of Espírito Santo, Brazil, fabianneaguiar@gmail.com*
[b] *Federal University of Espírito Santo, Brazil, marta.cruz@ufes.br*
[c] *Federal University of Espírito Santo, Brazil, gregorioufes@msn.com*
[d] *Federal University of Espírito Santo, Brazil, adelmo.ufes@gmail.com*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 5.11).

5. Comparative Assessment of Selected Sustainability Strategies Applied to Urban Neighbourhoods in Brazil, Germany and Sweden
Karin Regina de Castro MARINS[a]
[a] *University of Sao Paulo, Brazil, karin.marins@usp.br*

6. Passive Design Strategies For Building Envelopes In Different Orientations
Leidy Johana RAMIREZ[a], Elizabeth PARRA[b]
[a] *PVG Arquitectos, Colombia, leidyramirez@pvgarquitectos.com*
[b] *PVG Arquitectos, Colombia, elizabethparra@pvgarquitectos.com*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 3.8).

7. Urban metabolism and food flows: The municipality of Feliz, State of Rio Grande do Sul, Brazil
Eugenia Aumond KUHN[a], Miguel Aloysio SATTLER[b], Lucas Dorneles MAGNUS[c]
[a] *Centro Universitário Ritter dos Reis – UniRitter, Brazil, eugeniaakuhn@gmail.com*
[b] *Universidade Federal do Rio Grande do Sul, Brazil, masattler@gmail.com*
[c] *Universidade Federal do Rio Grande do Sul, Brazil, ldm.oasis@ymail.com*

8. Integrated System for Energy Optimization and Reduction of Building CO² Footprint
Ernesto Enrique ECHEVERRIA VALIENTE[a], Flavio CELIS D'AMICO[b], Fernando DA CASA MARTIN[c], Manuel DE MIGUEL SANCHEZ[d], Patricia DOMINGUEZ GOMEZ[e], Ignacio DELAGADO CONDE[f], Alvaro MOZAS SANTANDER[g], Kevin MORENO GATA[h], Juan Manuel VEGA BALLESTEROS[i], Francisco MARTIN SAN CRISTOBAL[j]
[a] *University of Alcala, Spain, ernesto.echeverria@uah.es*

[b] *University of Alcala, Spain, flavio.celis@uah.es*
[c] *University of Alcala, Spain, fernando.casa@uah.es*
[d] *University of Alcala, Spain, mozasalvaro@gmail.com*
[e] *University of Alcala, Spain, interpatridg@gmail.com*
[f] *University of Alcala, Spain, igdeco@gmail.com*
[g] *University of Alcala, Spain, mozasalvaro@gmail.com*
[h] *University of Alcala, Spain, kevin.morenogata@gmail.com*
[i] *University of Alcala, Spain, juanmanuel.vega@uah.es*
[j] *University of Alcala, Spain, francisco.martin@larentia.es*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 6.7).

9. Assessing Sustainable Urban Densification Using Geographic Information Systems

Natasha CABRERA-JARA[a], Daniel ORELLANA[b], M. Augusta HERMIDA[c]
[a] *Universidad de Cuenca, Ecuador, natashat.cabrera@ucuenca.edu.ec*
[b] *Universidad de Cuenca, Ecuador, daniel.orellana@ucuenca.edu.ec*
[c] *Universidad de Cuenca, Ecuador, augusta.hermida@ucuenca.edu.ec*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 5.11).

10. Project Guidelines for Construction of Biodigesters in Poor Communities in Brasil

Lizelda Maria MENDONÇA SOUTO[a], Sérgio PERES[b], Emilia KOHLMAN-RABBANI[c], Viviany NOGUEIRA[d], Ana Rita DRUMMOND[e]
[a] *Polytechnic School of University of Pernambuco, Brazil, lizambr2004@yahoo.com.br*
[b] *Polytechnic School of University of Pernambuco, Brazil, sergperes@gmail.com*
[c] *Polytechnic School of University of Pernambuco, Brazil, emilia.rabbani@upe.br*
[d] *Polytechnic School of University of Pernambuco, Brazil, vivianynogueira@gmail.com*
[e] *Polytechnic School of University of Pernambuco, Brazil, anaritadrummond@gmail.com*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Track 4 - Poster Session).

11. Decision Making Process Assisted by Life Cycle Assessment: Greenhouse Gas Emission

Ludimilla de Oliveira ZEULE[a], Sheyla Mara Baptista SERRA[b], Laís David VINHAL[c], Douglas BARRETO[d]
[a] *Federal University of São Carlos, Brazil, milla_zeule@hotmail.com*
[b] *Federal University of São Carlos, Brazil, sheylabs@ufscar.br*
[c] *Federal University of São Carlos, Brazil, laiscruzeiro@yahoo.com.br*
[d] *Federal University of São Carlos, Brazil, dbarreto@ufscar.br*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Track 8 - Poster Session).

SBE16 TORONTO (19-20 SEPTMBER 2016)

[Website: www.SBE16Toronto.com]

1. Demystifying and Democratizing the Energy Use Conversation to Support the Net-Zero Challenge

Birgit SIBER[a], Mike WILLIAMS[b]
[a] *Diamond Schmitt Architects, Canada, bsiber@dsai.ca*
[b] *Rowan Williams Davies & Irwin Inc., mike.williams@rwdi.com*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 2.4).

2. Biophilia and Nature-based Features to Support Stress Reduction in Knowledge Workers

Ann CALLAGHAN[a], Shauna MALLORY-HILL[b]
[a] *Conestoga College, Canada; Algonquin College, Canada, ann.callaghan@gmail.com*
[b] *University of Manitoba, Canada, s.mallory-hill@umanitoba.ca*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 4.8).

SBE16 DUBLIN (29-30 SEPTEMBER 2016)

SBE16 HELSINKI AND TALLINN (5-7 OCTOBER 2016)

[Website: http://www.sbe2016.org/]

1. Impact of Urban Density and Building Height on Energy Use in Cities
Eirik RESCH[a], Rolf André BOHNE[b], Trond KVAMSDAL[c], Jardar LOHNE[d]
[a] *Department of Civil and Transport Engineering, Norwegian University of Science and Technology, Norway*
[b] *Department of Civil and Transport Engineering, Norwegian University of Science and Technology, Norway*
[c] *Department of Civil and Transport Engineering, Norwegian University of Science and Technology, Norway*

2. Integration of Energy and Material Performance of Buildings: I=E+M
Erik ALSEMA[a], David ANINK[b], Arjen MEIJER[c], Ad STRAUB[d], Geurt DONZE[e]
[a] *W/E Consultants Sustainable Building, Utrecht, The Netherlands, alsema@w-e.nl*
[b] *W/E Consultants Sustainable Building, Utrecht, The Netherlands, anink@w-e.nl*
[c] *OTB Research Institute, Delft University of Technology¸ Delft, The Netherlands, a.meijer@tudelft.nl*
[d] *OTB Research Institute, Delft University of Technology¸ Delft, The Netherlands, a.straub@tudelft.nl*
[e] *W/E Consultants Sustainable Building, Utrecht, The Netherlands, donze@w-e.nl*

Also presented at World Sustainable Built Environment Conference 2017 Hong Kong (Session 6.5).

3. Energy Savings for a Wood Based Modular Pre-fabricated Façade Refurbishment System Compared to other Measures
Svein Halvor RUUD[a], Leif ÖSTMAN[b], Philip ORÄDD[c]
[a] *SP Technical Research Institute of Sweden, Sweden, svein.ruud@sp.se*
[b] *NOVIA University of Aplied Science, Finland, leif.ostman@novia.fi*
[c] *Umeå University, Sweden, phille_o92@hotmail.com*

4. Geothermal Heat Pump Plant Performance in a Nearly Zero-Energy Building
Jevgeni FADEJEVA[a], Raimo SIMSON[b], Jarek KURNITSKIA[c], Jyrki KESTI[d], Tarmo MONONEN[e], Petteri LAUTSO[f]
[a] *Aalto University, School of Engineering; Tallinn University of Technology*

VIII. SESSION SUMMARY & CONFERENCE PAPAERS

A. Keynote Sessions

KEYNOTE 1

Matthew CHEUNG Kin-chung, GBS, JP, *Chief Secretary for Administration, The Government of the Hong Kong Special Administrative Region*

KEYNOTE 2

SU Yunshan, *Director-General, Department of Science & Technology and Energy Saving on Buildings, Ministry of Housing and Urban-Rural Development, People's Republic of China*

KEYNOTE 3

Topic: The Paris Agreement Meets the Future Where We Need to Be: in Cities That Are Crowded, Clean and Connected, with Buildings That Are Organic, Efficient and Resilient

Christiana FIGUERES, Vice-Chair, Global Covenant of Mayors for Climate & Energy

ABSTRACT

Does the Paris Agreement solve climate change?

No, it seeks to prevent the worst effects of climate change. Insurance industry deems a temperature rise that goes beyond 2 degrees as systemically uninsurable.

Does it include every country and every sector?

It has been adopted by 195 countries and ratified by 110 countries. It constitutes a global business plan for the decarbonization of the economy. That business plan is now being devolved down to the level of countries, states and cities. It includes most sectors of human endeavor but in particular it points toward a transformation of our physical infrastructure (energy, transportation, buildings) and our natural infrastructure (forests and agriculture).

Will it be implemented?

Yes, the advance in clean energy generation technologies and the drop in prices have taken climate change beyond the sphere of politics into the sphere of the market place. The competitiveness of RE is established and will continue to escalate exponentially based on increasing public and private demand. Smart meters and blockchain technology are just two of the many innovations that will escalate RE. In turn the increasing abundance of cheap and clean electricity is catalyzing electric transportation. And electric vehicles may turn out to be one part of the answer on storage. Coal has no future. Oil and gas are quickly losing ground. Benefits of clean technologies are becoming more visible and more valued. Demand for cleaner technologies is on the rise. Decarbonization of the global economy is unstoppable.

What are the implications for the built environment?

Infrastructure is at the center of the climate challenge for three reasons. First because of direct physical impacts due to increasing extreme weather events. Secondly because the interest in and demand for resilient and environmentally responsible urban planning and building is on the rise. Third because of the unprecedented growth in urbanized population over the next two decades.

Those three trends point to a fundamental transformation in the way we plan, build and inhabit our cities. It points to a fundamental transformation in building design, materials, and operational efficiency. The direction is clear: buildings that are organically designed, using materials that obey cradle to cradle or circular principles, and are energy and water efficient. The integration of innovation is giving the best results. Practices such as integrated project delivery and triple bottom line cost benefit analysis are showing the way forward. Finally, the literature shows that this built environment leads to happier and healthier citizens.

KEYNOTE 4

Topic: Infrastructure, Resilience and Sustainability

Peter GUTHRIE, *Professor, Engineering for Sustainable Development, University of Cambridge*

ABSTRACT

The understanding of sustainability has now matured over thirty years since the Brundtland definition came to world attention. Its success in being accepted has also been its shortcoming, in that there is wide diversity in its interpretations applied to different fields.

In the field of civil infrastructure, the emerging concept of resilience is finding more traction with practitioners. Whilst subject to a similar diversity of meanings as sustainability, resilience can be more readily translated into physical interventions to improve performance. Infrastructure can be made more robust, more adaptable, more amendable, to be better prepared for shocks to the system.

Using case studies from a review of infrastructure delivery, past disasters, and current thinking on resilience, this presentation will draw together lessons learned and put forward proposals for action to improve resilience so as to achieve greater sustainability.

KEYNOTE 5

Topic: Environmental Transformation of the Built Environment

Thomas AUER, *Managing Director, Transsolar, Professor, Building Technology and Climate Responsive Design, Technical University of Munich*

ABSTRACT

The European Union's Roadmap for Moving to a Competitive Low Carbon Economy in 2050 ('carbon roadmap') states that in comparison to 1990, CO2 emissions of the building sector should be reduced by 90% by 2050. This will have a significant impact on our environment, and the architecture of buildings and cities will change dramatically. But the requirements for energy efficiency and comfort cannot be fulfilled by technology alone. A balance of passive design strategies and active ones is the key to a well-orchestrated system. This requires a thorough understanding of first principles, where climate-responsive design contributes a piece to this complex puzzle.

The goal is for architecture and climate control strategies to become a synergistic unit, where technology is optimised and/or supplemented where needed. The aim of climate responsive design is to develop buildings that offer maximum comfort while minimizing the use of resources and systems. In this regard, building efficiency and user comfort are closely connected with architecture. Besides, vernacular design principles often illustrate the potential of passive design strategies. We recognise that all aspects of design influence environmental conditions. For a sophisticated climate design it is required that form, material and mechanical systems are synergistic components of a finely-tuned climate control system; and conversely, an environmental control strategy is integral to the architectural concept. A full appreciation of all technical aspects of comfort is essential for advanced climate design, both on a building and an urban scale.

It is necessary to approach design holistically. A holistic approach to design, however, also requires expansion of the focus from individual buildings (at district level) to the overall urban context in order to accomplish the goals defined within the EU carbon roadmap. Mixed-use urban districts provide the potential for energy and water supply strategies in which requirements that vary between different program areas enable synergetic service strategies. In this regard it is essential to deploy climate design in on all scales. Aside from an efficient use of resources, outdoor environmental quality becomes another aspect that is directly linked to urban form, materiality and the design of the public realm.

KEYNOTE 6

Topic: Reframing Environmentalism: Shaping a Positive Future

Raymond COLE, *Professor, School of Architecture and Landscape Architecture, University of British Columbia, Canada*

ABSTRACT

Environmentalism has been variously framed as concern about and action aimed at protecting the environment. Critics argue that its message is alarmist, sets environmental issues apart and contextually disconnected from other pressing societal concerns, and situates responsibility and solutions within the domain of a separate movement and its expertise. The current period of increasing climate and political uncertainty creates a qualitatively different context for environmentalism.

In building design, environmentalism has been exercised through strategies directed at reducing non-renewable resource use and pollutant emissions. What is commonly referred to as “green building” design, for example, has been almost exclusively directed at reducing the degenerative consequences of the built environment on the health and integrity of ecological systems rather than emphasizing positive outcomes. While important and necessary, such a response is increasingly recognized as being an insufficient one.

Rather than reducing destructive impacts, the emerging notion and practice of regenerative approaches views buildings as catalysts for positive change, adding value and enabling the full potential of the social and ecological systems to the unique place they are situated. Regenerative approaches are therefore inherently hopeful and full of promise – a marked contrast to the negative messaging of much of the current environmental discourse. While the technical strategies of green design remain valid, the intention, language and more comprehensive framing of regenerative development offers considerable potential to accelerate the development of a shared vision, shared ownership and shared responsibility. The most significant and necessary shift does not therefore reside solely at the strategic level, but in the mind-set of design teams and clients.

Eventually, perhaps, we will come to view the act of building not as destructive of natural systems and depleting the earth’s resources but as contributing to and supporting the creation of a thriving, resilient and abundant world. To achieve such an ambition, we will need to articulate the vision and associated values necessary to affect and guide positive change and, in particular, how these are communicated to a broader public. Buildings, it would seem, can and should form a critical part of this communication process.

B. Plenary Session on Climate Change and Sustainable Development

Meeting the global challenges related to climate change and resource use requires action at all levels, including national governments, local authorities, private sector and civil society. Globally, the building sector contributes more than one third of the energy consumption, nearly 25% of greenhouse gases emissions and up to 40% of resource consumption. At a time when rapid urbanisation and development in many parts of the world is increasing demand for resources and energy, the building sector plays a critical role in assuring that what is built, now and in the future, meets both the needs of the communities while contributing to address climate change and achieve broader sustainable development objectives.

Led by UN Environment, the Plenary Session on Climate Change and Sustainable Development will take place on 6 June (Day 2 morning) at WSBE17 Hong Kong. Through presentations and interactive panel discussion, influential leaders of several international organisations will discuss:

- Why the building sector is critical to mitigate climate change and achieve sustainable development
- The potential of the building sector to contribute to the less than 2-degree scenario as outlined in the Paris Climate Agreement, as well as to the Sustainable Development Goals (SDGs)
- The pathways and that countries and other stakeholders, including local authorities and the private sector, can adopt to realise climate objectives
- How actions that organisations could take in the building sector contribute to achieving the targets in the SDGs

This session will feature key perspectives, including from Ms Christiana FIGUERES, Vice-Chair, Global Covenant of Mayors for Climate & Energy, and former Executive Secretary of the UN Framework Convention on Climate Change, as well as other organisations representing the public and private sector and the international community. Through presentations and a moderated panel discussion, this session will provide an overview of environmental impact and highlight the potential of the building sector, focusing on solutions and necessary actions to achieve the objectives of the Paris Climate Agreement, and the Sustainable Development Goals.

SESSION CHAIR
Curt GARRIGAN, Cities and Buildings Programme Manager, UN Environment- Economy Division

SPEAKERS

Topic: Hong Kong Government's Initiatives in Combating Climate Change
WONG Kam-sing, GBS, JP, Secretary for the Environment, The Government of the Hong Kong Special Administrative Region

Topic: The Paris Agreement Is a Blueprint for a Comprehensive Economic and Technological Transformation in the Way We Live, Move and Work, and Buildings are at the Nexus of This Revolution
Christiana FIGUERES, Vice-Chair, Global Covenant of Mayors for Climate & Energy

ABSTRACT

The Paris Agreement is not merely an environmental treaty. It is a blueprint for a comprehensive economic and technological transformation in the way we live, move and work. None of these are independent of each other, but rather they all mutually reinforce each other.

There are three main building blocks of the new urban paradigm: energy, transportation and the built environment. Energy is being rapidly decarbonized thanks to the dramatic drop in costs of renewables over the past 8-10 years and the incipient storage technology. Transportation is going shared, driverless and electric. Buildings are at the nexus of the energy and transportation revolutions. Buildings need to keep pace with those revolutions in order to benefit from them, and to provide an integrated living experience of high quality to dwellers.

C. Roundtable Sessions

The Roundtable Sessions at WSBE17 Hong Kong echo with the conference theme "Transforming Our Built Environment through Innovation and Integration: Putting Ideas into Action". Roundtable 1 emphasises "Ideas" on emerging trends and forward-looking principles to transform the build environment. Roundtable 2 focuses "Actions" and practice-focused viewpoints on leading the changes to drive the sustainable built environment.

ROUNDTABLE 1

Topic: Emerging Perspectives for Transforming the Build Environment

The construction and real estate sector faces multiple challenges that the solutions today may not be optimal for the future. The knowledge of emerging trends is thus indispensable for the development of innovative and integrative solutions to transform the built environment.

A group of international industry experts and representatives from various stakeholder groups will gather to stimulate a vibrant dialogue to discuss how the emerging perspectives relate to the topics of high-performance building, deep building renovation, sustainable neighbourhood and community empowerment.

SESSION CHAIR

Thomas LÜTZKENDORF, Director, Centre for Real Estate and Head of Chair, Sustainable Management of Housing and Real Estate, Karlsruhe Institute of Technology (KIT), Germany

SPEAKERS

Topic: Winning the Battle against Climate Change

TAI Lee-siang, Chair, WorldGBC

ABSTRACT

WorldGBC represents a body of diverse building industry players seeking to overturn the threat posed by Climate Change. This presentation provides an outline of the main strategies and thrusts of the relatively young global organization. In addition, Lee Siang will share from his experiences, both as an architect and urban planner, the holistic principles to unlock the potential of traditional wisdom and ground up efforts to achieve total sustainability. In particular, he will focus the discussion on strategies in cities – the highly urbanized future of mankind.

Topic: An Emerging Trend of Green Building Development in China

WANG Youwei, Chairman, China Green Building Council

Topic: How to Create High Real Estate Value with Sustainable Urban Planning

Serge SALAT, President, Urban Morphology & Complex Systems Institute

Topic: Towards Buildings as Active Agents in Low Carbon Cities

Arno SCHLUETER, Professor, Architecture and Building Systems ETH Zurich; Principal Investigator, Future Cities Laboratory, Singapore ETH Centre

ABSTRACT

Towards Buildings as Active Agents in Low Carbon Cities

For future-proof cities, buildings need to evolve from passive consumers to active agents in the urban fabric, balancing and trading energy, resources and fostering comfort, indoors and outdoors. This poses challenges on many ends which needs to be overcome to transition towards a more sustainable building stock. We can call them the Three Grand Challenges:

Dealing with complexity

Future efficient buildings employ sophisticated building systems to ensure efficient operation, energy generation and occupant comfort. These systems span across different domains, over the entire building lifecycle. Increased complexity not only means a higher risk of false installation, malfunction and improper operation, it also means different skillsets of people that design, plan build and operate buildings. The challenge therefore is: how do we address the increasing complexity in our designs, our processes and adapt the skillsets of people involved in the building process?

Human-in-the-loop

With all technology, we sometimes forget that buildings are actually made for humans. Energy efficiency is therefore nothing without maintaining or even improving occupant comfort and human well-being. Whereas we understand well the building and systems physics, the occupants, their stochastic behavior and differencing preferences remain as a challenge. How can be design, build and operate environments that that respond, adapt and thus learn from the humans it is inhabited by? Furthermore, as buildings are artefacts with very long lifecycles, how do we design buildings and buildings systems that are flexible, expandable and fit for change?

New Models

Knowledge without realistic chance of implementation has not impact. We are beyond just technological solutions. The solutions we develop must take into account the specificities of the built environment such as the large scale, long lifecycles and risk aversion. This requires an understanding of its fundamental economic mechanisms in order to leverage and eventually change them. The grand challenge is to make efficient systems economically viable. This calls for new business models that leverage cross-benefits, that leverage the lifecycle, that control and mitigate risk in order to create economic incentives for implementing new approaches on a large scale.

Topic: Disruptive Innovations Transforming Sustainable Built Environment

Bryant LU, Vice Chairman, Ronald Lu and Partners

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

ROUNDTABLE 2

Topic: Leadership Driving for the Sustainable Built Environment

This Roundtable focuses on the importance of leadership in driving change. Expert panelists will discuss the use of data to showcase outcomes and results in order to demonstrate environmental, financial and other benefits, as well as using decision-making tools to clarify and help leaders make sense of different types of challenges. The case of Singapore and Hong Kong will be raised on how government leaders approached developing policies for sustainable buildings and environment, and a specific corporate leader will share experience on how decisions have been made and what will continue to drive change.

SESSION CHAIR

Christine LOH, Under Secretary for the Environment, The Government of the Hong Kong Special Administrative Region

SPEAKERS

Topic: Why we should be Assessing Building Performance from the Point of View of the Users and How It Can Be Done
George BAIRD, Emeritus Professor, Building Science, School of Architecture, Victoria University of Wellington

Douglas WOO, Chairman & Managing Director, Wheelock and Company Ltd.

Topic: Innovative and transformative leadership in the built environment – The Cynefin decision-making framework and the search for tipping points
Greg FOLIENTE, Enterprise Professor, University of Melbourne; Regional Director in Asia-Pacific, iiSBE; Founding Director, nBLue Pty Ltd

Topic: Singapore's drive towards a Sustainable Tropical City
TAN Tian-chong, Deputy Managing Director, Built Environment Research and Innovation Institute, Building and Construction Authority

ABSTRACT

Singapore has been striving towards achieving a sustainable built environment for more than a decade. A number of initiatives were shaped and successfully implemented under the Singapore's Green Building Masterplans, covering a wide range of policies, programmes and measures. Driven by government leadership through BCA, we have greened (certified through BCA Green Mark standards) over 30% of buildings in Singapore and are on track to achieve our goal of greening at least 80% of our building stock by 2030.

Moving forward, an aspirational goal is set for Positive Energy Low-rise, Zero Energy Medium-rise and Super Low Energy High-rise (PE-ZE-SLE) Buildings in the Tropical Urban City. The government, industry, and academia are jointly developing a technology roadmap to guide the implementation and further spur innovation in green buildings.

Topic: Building Inclusive and Sustainable Communities through Transit Integration
Lincoln LEONG, Chief Executive Officer, MTR Corporation

ABSTRACT

Hong Kong's experience in building sustainable and inclusive communities through transit integration may have relevance to cities around the world that are facing challenges arising from urbanisation. It is an example of how `value capture' principles can be adopted in an urban environment to help cities meet their development needs for housing and transportation in ways that are user-friendly, and also financially and environmentally sustainable.

In Hong Kong, the MTR Corporation's railway services form the backbone of the local public transport system, carrying around 5.6 million passenger journeys every weekday with a world-class on-time performance of 99.9%.

Residential and commercial properties have been developed above or adjacent to railway stations and depots to create communities that are fully integrated with the railway network, and also offer a range of facilities and services to meet the diverse needs of individuals of all ages.

In this way, Hong Kong has evolved an integrated rail and community development model that is financially and environmentally sustainable for the long term. Through integrated station development, railway patronage is stimulated, profits from property sales can be used to finance new railway projects, and fares can thus to kept at reasonable levels without the need for government subsidies.

The model follows a transit-oriented development approach centred around a high-quality low-carbon railway service, which connects to bus, minibus, tram and taxi services. Building residential and commercial properties above railway stations optimises the use of scarce and valuable land in an urban environment. Seamless transport connections provide maximum convenience for people living and working above the stations, while unnecessary road traffic is also reduced.

To promote sustainable building design, construction, operations and maintenance, new residential property developments are required to achieve Hong Kong BEAM Plus Gold certification as a minimum.

D. Parallel Sessions

i. Mainland China Sessions

(1) The Comprehensive Scheme on Green Retrofitting and Performance Enhancement of Existing Buildings in China
Session Organiser: China Academy of Building Research

SESSION OUTLINE

From 1995 to 2005, China's building stock nearly tripled, and it is expected to nearly triple again by 2030. This forum will investigate the goverence of existing buildings in China from the policy perspective, the technology for improving energy effiency of buildings, and the standards for green retrofitting.

Strategies have been develop to response to different climatic conditions, building types and users. It will lead to different technical approaches and considerations on the green retrofitting policy and performance enhancement of buildings. Case studies will be used to illustrate the implementation process.

The forum has invited five experts to share their professional insights and academic research with us, including the retrofit of green roofs, retro-commissioning, and retrofits of existing commercial buildings, building performance enhancement of existing residential dwellings and the experience on sustainable building operational and management.

SESSION CHAIR

YIN Bo, Director, Division of Science and Technology, China Academy of Building Research (CABR)

SPEAKERS AND PRESENTATION TOPICS

1. The Roadmap on the Development of Comprehensive Scheme on Green Retrofitting and Performance Enhancement of Existing Buildings in China
YIN Bo, Director, Division of Science and Technology, China Academy of Building Research (CABR)

2. The Appropriate Technologies and Practical Case Study on Green Retrofitting the Residential Dwellings in the Severe Cold Climatic Zone in China
JIANG Yiqiang, Professor, School of Municipal and Environmental Engineering, Harbin Institute of Technology (HIT)

3. The Appropriate Technologies and Case Studies on Green Retrofitting the Healthcare Facilities in China
DI Yanqiang, Head of Division, Division of Construction Technologies, China Building Technique Group Co., Ltd. (CBTGC)

4. The Case Studies and Technology Advancements on Green Retrofitting the Office Buildings in China
ZHAO Li, Deputy Head, Division of Research and Development, China Academy of Building Research (CABR)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

(2) Green Building Design and Technological Challenges of Eco Skyscraper in China
Session Organiser: Shanghai Research Institute of Building Sciences

SESSION OUTLINE

According to the global tall building database of the CTBUH, around half of the Top 10 completed skyscrapers in the world are located in China, including Shanghai Tower (Shanghai, 632m), Ping An Finance Center (Shenzhen, 599m), and Guangzhou CTF Finance Centre (Guangzhou, 530m), etc. The design, construction, and management of super skyscraper bring a unique challenge to the green building development. The session will start with the discussion on the development of evaluation standard for the green skyscraper buildings in China and extend to the energy-saving strategies focusing on the low-grade energy bus in the HVAC system. Performance enhancement of the green skyscraper buildings is one of the key focus areas. Finally, the session will present a business case study on the green design features and facility management of the tallest building in China – Shanghai Tower.

SESSION CHAIR

IXU Qiang, Chief Engineer, Shanghai Research Institute of Building Sciences (Group) Co., Ltd.

SPEAKERS AND PRESENTATION TOPICS

1. Evaluation of Green Skyscraper Buildings in China
   SONG Ling, Deputy Director, Center for Science and Technology & Industrialization Development, Ministry of Housing and Urban-Rural Development of the P.R. China (MOHURD)

2. Energy Saving Potential of Air-conditioning System with Low-Grade Energy Bus in Skyscrapers
   LI Xianting, Professor, School of Architecture, Tsinghua University

3. In Pursuit of Excellence: Sustainable High-performance Skyscrapers
   ZHANG Bolun, Director, East China Architectural Design and Research Institute

4. Green Design and Facility Management Systems in Shanghai Tower
   YANG Jianrong, Deputy Director, Shanghai Research Institute of Building Sciences (SRIBS)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

(3) Turning Green to Gold – Green Practices for Urbanisation in China Session Organiser: Shenzhen Green Building Association and Shenzhen Institute of Building Research

SESSION OUTLINE

Shenzhen is a winner of C40 Cities Annual Awards for Best Finance & Economic Development Project of 2016. The city has a population of 15 million and an annual GDP growth rate of 10%. Shenzhen is one of the most inspiring and innovative cities tackling climate change. The session will present the action plan/program, implementation strategy and the challenges of Shenzhen to tackle the climate change. For the governance of climate change, it involves policy on setting up targets, monitoring and restricting the carbon emission and energy use, and the implementation of legal system. Market driver is one of the approaches to lead the green city transformation. A business case study on green building development in city transformation will be presented from a leading property developer in China. To conclude, the session will discuss the potential to increase credit rating of green bond to drive the sustainable development in China.

SESSION CHAIR

YE Qing, Director, The Shenzhen Institute of Building Research Ltd and the President of Shenzhen Green Building Association

SPEAKERS AND PRESENTATION TOPICS

1. QIU Baoxing
   Counsellor of Counsellor's Office of the State Council, PRC

2. The Action and Challenges of Climate Change Governance in Shenzhen
   TANG Jie, Professor, School of Economics and Management, Harbin Institute of Technology (Shenzhen)

3. Low-Carbon Development in Shenzhen – Policy and Implementation,
   ZHANG Xuefan, Director, Bureau of Housing & Construction of Shenzhen Municipality

4. A Business Case of Vanke in Green City Transformation,
   WANG Yun, Vice President, China Vanke Co., Ltd.

5. Increasing Credit Rating of Green Bond to Drive the Green Building Development in China
   Kevin MO, Managing Director, Paulson Institute Representative Office

6. Ying HUA
   Associate Professor, Department of Design and Environmental Analysis, The Cornell University

(4) The Development Framework and Professional Best Practices of Healthy Buildings in China
Session Organiser: Green Building Research Centre and the Chinese Society for Urban Studies

SESSION OUTLINE

With the joint efforts of China Academy of Building Research, the Chinese Society for Urban Studies and the China Architecture Design & Research Group, China has developed its "Assessment Standard for Healthy Building" (T/ASC 02-2016), and published in the first quarter of 2017. The session will cover a wide range of topics, including the development of the China Assessment Standard for Healthy Building, the best professional practices and its applications, the control and prevention of the exposure of indoor air pollutants PM2.5 against the health risks of occupants, the technological innovations and business case studies on how to monitor, manage and control the indoor air quality for the occupants in dwellings.

SESSION CHAIR

MENG Chong, Deputy Director, Green Building Research Center, Chinese Society for Urban Studies

SPEAKERS AND PRESENTATION TOPICS

1. Water is the Essence of Healthy Building
   ZENG Ji, Deputy Director, Architectural Design Institute, China Academy of Building Research

2. The Control and Prevention of Indoor PM2.5 against the Health Risks of Occupants
   ZHANG Yinping, School of Architecture, Tsinghua University, China

3. Development of the China Healthy Building Assessment Standards and its Professional Practices
   MENG Chong, Deputy Director, Green Building Research Center, Chinese Society for Urban Studies, China

4. Technological Innovations and Best Practices of Healthy Buildings
   JIA Yan, Founder & CEO, First Human Environmental Technologies (Beijing) Co., Ltd., China

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

ii. Regional Sessions

There are four Regional Sessions discussing the intensity and importance of the specific issues in relation to sustainability in the 20 countries which held the SBE Regional Conferences in 2016. Common challenges and differences will be identified, and the significance of current conditions, initiatives and trends will be explored.

The sessions are presented by the 20 Regional Conference Organisers and chaired by SBE16 Conference Series Co-owners.

Session 1.2

CZECH REPUBLIC, ITALY, SWEDEN AND SWITZERLAND

SESSION CHAIR
François BAILLON, Board member, SBE series; Senior Adviser, FIDIC; Treasurer, Business and Climate Summit Association; Founder, Ideagrama Consultant

1. SBE16 Prague
   Antonin LUPISEK, Czech Technical University in Prague, University Centre for Energy Efficient Buildings, Czech Republic

2. SBE16 Torino
   Andrea MORO, President, iiSBE Italia, Italy

3. SBE16 Malmö
   Roland ZINKERNAGEL, Lund University, Sweden

4. SBE16 Zurich
   Guillaume HABERT, Professor, ETH Zurich, Switzerland

Session 2.2

TURKEY, GREECE, MALTA AND EGYPT

SESSION CHAIR
Wim BAKENS, Secretary General, International Council for Research and Innovation in Building and Construction

1. SBE16 Istanbul
   Aygen ERKAL, Secretary General, Türkiye İMSAD- Association of Turkish Construction Material Producers

2. SBE16 Thessaloniki
   Aikaterini TSIKALOUDAKI, Associate Professor, Aristotle University of Thessaloniki

3. SBE16 Malta
   Ruben Paul BORG, University of Malta

4. SBE16 Cairo
   Wafaa NADIM, Architecture Program, German University Cairo, Egypt

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Session 5.1

CANADA, BRAZIL-PORTUGAL, THE NETHERLANDS, GERMANY AND TALLINN-HELSINKI

SESSION CHAIR
Luis BRAGANÇA, University of Minho, Portugal

1. SBE16 Toronto
   Harry Robert BACH, Secretary Treasurer, iiSBE Canada; Director and Treasurer, iiSBE International; Director and Treasurer, Sustainable Buildings Canada

2. SBE16 Brazil-Portugal
   Cristina Engel ALVAREZ, Professor/Coordinator, Laboratório de Planejamento e Projetos, Universidade Federal do Espírito Santo, Brazil

3. SBE16 Hamburg
   Thomas LÜTZKENDORF, Director, Centre for Real Estate; Head of Chair, Sustainable Management of Housing and Real Estate, Karlsruhe Institute of Technology, Germany

4. SBE16 Tallinn-Helsinki
   Pekka HUOVILA, Coordinator, 10YFP Sustainable Buildings and Construction (SBC) Programme

5. SBE16 Utrecht
   Ivo OPSTELTEN, Professor, University of Applied Sciences Utrecht

Session 6.1

AUSTRALIA, MAINLAND CHINA, SINGAPORE, SOUTH KOREA AND PHILIPPINES

SESSION CHAIR
Prof. Greg FOLIENTE, Enterprise Professor, University of Melbourne; Regional Director in Asia-Pacific, iiSBE; Founding Director, nBLue Pty Ltd

1. SBE16 Sydney
   Deo PRASAD, Scientia Professor, CRC for Low Carbon Living

2. SBE16 Chongqing
   Andrew BALDWIN, Chongqing University

3. SBE16 Singapore
   Selvam VALLIAPPAN, Senior Manager, Green Building Research, Built Environment Research and Innovation Institute (BERII), Building and Construction Authority, Singapore

4. SBE16 Seoul
   SHIN Sungwoo, Division of Architecture and Architectural Engineering, Hanyang University ERICA

5. SBE16 Manila
   Fernando GERMAR, Chairman of Scientific Committee, SBE16 Manila

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

iii. SBE Challenge
Session Organiser: iiSBE

SBE Urban Challenge: Assessment Protocol and Case Studies

SESSION OUTLINE

The performance assessment of small urban areas is complex, since it raises questions of scale (how large is a small urban area?), suitable key performance indicators, appropriate reference performance benchmarks (similar areas or historical values or...?).

Research and professional teams from several countries will present, analyse and discuss their own approaches to small-area urban performance assessment in the session, supported by case studies where possible.

The sessions will compare the various methods and tools that have been used to describe and assess key performance aspects of small urban areas (e.g. neighborhoods or urban districts). This is an area of research that is under active development in a number of countries around the world and the session should therefore be of environmental and social impact.

SESSION CHAIR
Andrea MORO, President, iiSBE Italia, Italy

SPEAKERS AND PRESENTATION TOPICS

1. A New SBE Challenge Process for a Transnational Generic Framework at Urban Scale
   Andrea MORO, President, iiSBE Italia, Italy
   Nils LARSSON, Executive Director, International Initiative for a Sustainable Built Environment

2. Case Study - Europe: CESBA MED, CESBA Alps, NewTREND and Felicity Projects
   Andrea MORO, President, iiSBE Italia, Italy
   Stefania UGLOLA, iiSBE Italia R&D, Italy
   Paul MITTERMEIER, Munich University of Applied Science, Germany
   Ken DOOLEY, Granlund Consulting, Finland

3. Case Study - South America: URBENERE Network
   Cristina Engel ALVAREZ, Professor/Coordinator, Laboratório de Planejamento e Projetos, Universidade Federal do Espírito Santo, Brazil
   Luis BRAGANÇA, University of Minho, Portugal

4. Case Study - Asia: China's KPIs for Sustainable Cities

5. Case Study - North America: DISTRICT 2030
   Jiri SKOPEK, Managing Director, JLL, Canada; 2030 Districts

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

SBE Buildings Challenge: Assessment Protocol and Case Studies

SESSION OUTLINE

Building Performance Evaluation compares performance in key aspects (e.g. energy, emissions, water, IEQ, cost) that was predicted at the design stage through simulations and other predictive methods and tools, with the actual performance as assessed during the operation of the building, after at least two years of operation.

Research and professional teams from several countries will present, analyse and discuss their own approaches to BPE in the session, supported by case studies where possible.

Such building performance evaluations are extremely useful to all major actors in the industry who want to have a better understanding of the gap in performance between design and operations.

The Canadian iiSBE team has previously undertaken this type of building performance evaluation, and presented the results of the evaluation of nine Canadian case studies at the 2014 WSB Conference in Barcelona. The results were of considerable interest and utility to the Canadian industry, and we anticipate that many other research-oriented teams may find their results to be of equal value in their own regions.

SESSION CHAIR

Nils LARSSON, Executive Director, International Initiative for a Sustainable Built Environment

SPEAKERS AND PRESENTATION TOPICS

1. General Intro about the Process and the Idea of Predicted vs. Actual Performance and the CanTeam Protocol
   Gordon SHYMKO, President, G.F. Shymko & Associates Inc., Canada

2. Green and Monitoring in Holiday Inn Express SoHo Hong Kong
   Antonio CM CHAN, REC Engineering Co., Ltd., Hong Kong SAR

3. The 2014 CanTeam Evaluation of 9 Case Studies
   Gordon SHYMKO, President, G.F. Shymko & Associates Inc., Canada

4. Current Proposal for New Canadian Work
   Gordon SHYMKO, President, G.F. Shymko & Associates Inc., Canada

5. UNSW BPE for 50 Dwellings
   Lan DING, Senior Lecturer, Faculty of Built Environment, University of New South Wales, Australia

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

iv. BEAM Plus Neighbourhood: From Theory to Praxis

Session Organiser: Hong Kong Green Building Council Limited

Session 6.14

SESSION OUTLINE

At the Habitat III Cities Conference in Quito, Ecuador, in late 2016, the New Urban Agenda was adopted by the Untied Nations to set a new global standard for sustainable urban development by taking into the account of the Paris Agreement on Climate Change. The Agenda also put emphasis on the role of cities in social inclusion, economic prosperity and environmentally responsive and resilient urban systems through improved urban planning and design, collaboration and effective use of resources, promoting quality public spaces, supporting green initiatives and infrastructural provisions etc. This echoes the need for a concerted approach to tackling multiple challenges in city and urban development.

Neighbourhood, as a basic “city block”, can play a critical role in sustainable urban development. The compact and dense urban morphology in Hong Kong also implies that the notion of neighbourhood can vary in different degrees in both its scale and typology. With this in mind, BEAM Plus Neighbourhood, the first rating tool in Hong Kong to assess urban sustainability at a neighbourhood or community scale, was developed to assist the development industry in integrating a broader framework of sustainability indicators at the inception or masterplanning stage of a development project before it proceeds to the implementation phase. It aims to fill the current gap in the BEAM Plus Suite of building-level tools: New Buildings, Existing Buildings and Interiors.

The Neighbourhood tool places emphasis on the design and provisions for space between buildings, and embraces socio-economic as well as ecological aspects of a development. Assesssment by the tool is divided into seven performance aspects: Community, Site, Materials and Waste, Energy, Water, Outdoor Environmental Quality, as well as Innovations and Additions. By adopting a more holistic approach to the assessment such as the foregoing, it is hoped that BEAM Plus Neighbourhood would play a key role in creating more liveable and healthier environment in Hong Kong.

To ensure greater relevance, user-friendliness and smooth operation of the tool, HKGBC engaged three life projects to undergo semi-internal pilot-testing conducted berween 2015 to 2016 prior to recalibrating the launch version of the tool. The three projects are: the Subsidized Sale Flats Development at Fat Tseung Street West of Hong Kong Housing Authority (HKHA), the Transformation of EMSD Headquarters into a Green Building and the West Kowloon Cultural District of West Kowloon Cultural District Authority (WKCDA).

In this session, the notion of BEAM Plus Neighbourhood, its relevance to the Hong Kong context and what the tool measures will be summarised, followed by a sharing of the experience in the tool application by the three pilot-testing project users, and finally, a discussion of the lessons learnt throughout the pilot-testing process.

SESSION CHAIR

Lary POON, Convener of BEAM Plus Neighbourhood Steering Committee/ Roll-out Taskforce, Hong Kong Green Building Council (HKGBC)

SPEAKERS AND PRESENTATION TOPICS

1. BEAM Plus Neighbourhood: An Introduction
   Larry POON, Convener of BEAM Plus Neighbourhood Steering Committee/ Roll-out Taskforce, Hong Kong Green Building Council (HKGBC)

2. Subsidized Sale Flats Development at Fat Tseung Street West
   Ada FUNG, Deputy Director of Housing (Development & Construction), Hong Kong Housing Authority, Government of the HKSAR, Hong Kong SAR

3. Transformation of EMSD Headquarters into a Green Building
   Antony HO, Associate, Arup, Hong Kong SAR

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4. West Kowloon Cultural District
   William CHAN, Chief Operating Officer, West Kowloon Cultural District Authority, Hong Kong SAR

5. BEAM Plus Neighbourhood: Lessons Learned from Pilot-Testing
   Larry POON

Subsidised Sale Flats Development at Fat Tseung Street West

Ada FUNG[a]

[a] *Hong Kong Housing Authority, Government of the HKSAR, Hong Kong SAR, ada.fung@housingauthority.gov.hk*

ABSTRACT

The Hong Kong Housing Authority (HKHA) adopts a people-centred approach to provide quality homes for people in need. When designing new public housing developments, HKHA is committed to build for the future by taking into account quality, comfort, sustainability, as well as neighbourhood friendliness.

The introduction of BEAM Plus Neighbourhood (ND) provides a valuable reference for HKHA to enhance the design of public housing in a wider community scale, as demonstrated by its pilot project of the Subsidised Sale Flats Development at Fat Tseung Street West (FTSW).

The FTSW Development comprises a 41-storey domestic block providing 811 flats, estate management facilities, a semi-basement car park and associated external works. The planning and design of the FTSW Development aims to create a sustainable, cost effective and healthy living environment while taking into account the integration with the surroundings, optimization of environmental qualities and enhancement of greening opportunities.

To build for the community effectively, it is vital to engage the stakeholders with inclusiveness, transparency and creativity. We have conducted rounds of community engagement workshops and district council consultations during the early planning and design stages of FTSW. Feedback received was thoroughly considered and has been reflected in the revised master planning of the project, in which the original two single aspect domestic blocks were transformed to one site specific block with specially designed flats to combat surrounding fixed plant noise constraints. This not only allows wind permeability and open view for the neighbourhood, but also enables deferred closing of the existing Fat Tseung Street West Playground for construction at a later stage, so that the disruption to public services could be minimized.

The site abuts public road and streets on three sides while the vehicular access is segregated from the pedestrian route. Residents can access the development conveniently with the covered walkway system and enjoy vehicle-free pedestrian environment. Given the advantages of its siting, the FTSW Development was designed in conjunction with HKHA's adjacent comprehensive development at the North West Kowloon Reclamation Site 6 from which it is provided with convenient access to public open spaces, sports centre and public library, welfare facilities, retail facilities and transportation hubs including a public transport interchange and the adjacent Nam Cheong MTR Station. The covered pedestrian network serves the community at both the pedestrian and podium levels promoting a vibrant neighbourhood. Commuters can also easily access to the adjoining public housing development at Lin Cheung Road and the waterfront by a long span footbridge over the West Kowloon Highway.

To facilitate the enjoyment of outdoor amenity spaces, we connect different portions of external areas by barrier free access and covered walkways. Moreover, technical studies have been conducted not only to ensure desirable outdoor environment in terms of air quality, noise, natural lighting, thermal comfort etc., but also to seek opportunities to improve the micro-climate environment of the neighbourhood, such as the introduction of a three-storey void at the main entrance to maintain good wind environment and visual permeability.

In line with the commitment of HKHA, the FTSW Development has also attained Gold rating in the provisional assessment under the BEAM Plus New Building scheme. Uses of materials, energy and water etc. have all been optimized in the design and construction stages to reduce the carbon footprint and future energy consumption of the development.

The FTSW Development is scheduled to complete in 2020 and will form part of the vibrant community together with other new public housing developments in Cheung Sha Wan district. With the accomplishment and recognition of this pilot project in the BEAM Plus ND assessment, HKHA shall continue to build for the community with holistic considerations of urban sustainability and neighbourhood friendliness, and enhance the planning and design of public housing developments with reference to the guidelines and good practices promulgated in BEAM Plus ND.
Keywords: BEAM Plus neighbourhood, build for community, neighbourhood friendliness

Transformation of EMSD Headquarters into a Green Building

Ernest HY YEUNG[a], Raymond KF LEUNG[b], Antony WT HO[c], Vicky CY NG[d]

[a] *Electrical and Mechanical Services Department, Hong Kong*
[b] *Electrical and Mechanical Services Department, Hong Kong*
[c] Ove Arup & Partners Hong Kong Ltd, Hong Kong
[d] *Ove Arup & Partners Hong Kong Ltd, Hong Kong*

ABSTRACT

The Electrical and Mechanical Services Department Headquarters (EMSD HQs) was nominated by the Hong Kong Green Building Council (HKGBC) to participate a pilot-scheme of the BEAM Plus Neighbourhood rating tool (BEAM Plus ND) which will be officially launched in December 2016.

The EMSD Headquarters is located in 3 Kai Shing Street, Kowloon Bay, Kowloon, Hong Kong with a project site area of about 28,160 m2 with a Piazza of 2,417 m2. It has been being put into operation since 2005, was formerly the cargo terminal building occupied by Hong Kong Cargo terminals Limited (HACTL). It is an eight-storey building comprising workshops, car parks, and office space with a gross floor area (GFA) of about 74,414 m2.

In 2005, EMSD exhibited successfully an excellent showcase of sustainable development, by converting the former air cargo terminal into their current Headquarters (HQs). EMSD HQs is one of the Green Check Points of Kowloon East to promoting low carbon buildings and providing diversified environmental friendly information to the public. In 2015, EMSD decided to further enhance the sustainable performance of EMSD HQs to maximize the benefits to neighbourhood community. Transformation works will be carried out for the EMSD HQs to further improve the building and the site, and to enhance the environmental performance and sustainability of the development in the connection to the neighbourhood and the society.

As part of the Transformation, the modification of the Piazza will provide a green and sustainable area for public use. Thermal comfort and Urban Heat Island studies were conducted to optimize the design of the Piazza. The proposed soft landscaping area in Piazza will provide a quality leisure and recreational open space. It will allow various activities, such as outdoor exhibition and gathering venue, for public enjoyment. As discovered from the flood risk assessment, the surface runoff from the existing public open space plaza would be decreased by around 14% under 50-year rainfall event due to an increase in permeable area resulting from the proposed development after the Transformation.

The Revamp of the Education Path redesigned both interior and outdoor area of the EMSD HQs, aiming to raise the public awareness of the sustainability initiatives. It will be operated to showcase and promote sustainable lifestyle by mean of education and community collaboration for the visitors and the occupants of the EMSD HQs.

To cut the energy consumption of individual HVAC system, the project site will be connected to the Kai Tak District Cooling System (KT-DCS). It is anticipated to be completed by June 2017. KT-DCS will provide a maximum allowable cooling capacity of 6,600kW to the project site. It covers the cooling demand of 5,000kW by centralized air-conditioning system in the project site, which is over 95% of the site annual cooling energy.

West Kowloon Cultural District

William CHAN[a]

[a] *West Kowloon Cultural District Authority, Hong Kong SAR, william.chan@wkcda.hk*

ABSTRACT

Stretching across 40 hectares of reclaimed land, the West Kowloon Cultural District (WKCD) provides world-class arts and cultural facilities for gestating both international and local arts and cultural developments. To coherent with its Sustainable Master Planning Framework, the West Kowloon Cultural District Authority (WKCDA) was engaged by the Hong Kong Green Building Council (HKGBC) to be one of the Pilot Projects for the new BEAM Plus Neighbourhood certification.

With the broader framework of urban sustainability governed by the BEAM Plus Neighbourhood, WKCD demonstrated a commitment on implementing urban sustainability with top-down strategy from master planning level to building level. 3 stages of public engagement exercises were carried out from 2009 to 2011 for collating stakeholders and public concerns. With this placemaking landmark, the socio-economic study confirmed the positive impact on social cohesion to adjacent communities. There is a waterfront promenade along the seaside providing wonderful Harbour view, and part of the site area is public accessible open and greenery area, especially the Park at the west of the WKCD. These greenery areas help to reduce the urban heat island effect by maximizing intra-urban heat island index. Covered linking bridges and subways are planned to provide convenient walkable paths for enhancing the accessibility of both the district and adjacent developments. To provide better outdoor air quality, the local transportation network is planned to be connected with outside roadway network at basement level, so that the pollutant source from vehicles can be separated from the ground floor where people access at most of the time for different kinds of activities. Also, the first smart bike rental system in Hong Kong has been introduced in the district to promote health and sustainable life style as well as reducing the carbon emissions from vehicle.

With a well district planning, infrastructural style utilities are planned. Majority of the cooling load of the non-domestic developments are supported by an energy efficient district cooling system. In addition, to minimize the influence of daylight access of neighbouring sensitive buildings due to WKCD development, vertical daylight factor on the facades of adjacent sensitive buildings are examined. High visual quality of public accessible open space is also recognized. Through this third party benchmarking tool, WKCD was granted the Platinum rating in December 2016.

With this achievement, it forms a role model of Green and Sustainable Master Planning for developments with compact cities characteristic.

BEAM Plus Neighbourhood: Lessons Learned from Pilot-Testing

Larry POON[a]

[a] *Hong Kong Green Building Council, Hong Kong, larrycfpoon@wongtung.com*

ABSTRACT

As the global trend moves from building sustainability to urban sustainability, BEAM Plus Neighbourhood (ND) is the first BEAM Plus rating tool to place emphasis on the public realm and socio-economic elements. In so doing, it demands a more holistic approach to assess a project's performance.

With the objective to set the appropriate benchmark and embrace a wider range of project types, BEAM Plus ND embarked the first ever pilot-testing amongst the BEAM Plus suite of tools prior to its launch. Three real projects of different scale and use were selected, namely, the Subsidized Sale Flats Development at Fat Tseung Street West of Hong Kong Housing Authority (HKHA), the Transformation of EMSD Headquarters into a Green Building and the West Kowloon Cultural District (WKCD) of West Kowloon Cultural District Authority. The pilot-testing was instrumental to the further refinement of the tool. The lessons learned came in three ways:

- Refining scoring structure to ensure more balanced distribution of credits in different performance aspects;
- Modifying credit requirements to ensure realistic expectations and benchmarking criteria and
- Exploring new methodology to improve the relevance and practicality of the assessment.

Overall speaking, the pilot-testing of BEAM Plus ND confirms the flexibility of the tool in its application to different typologies in Hong Kong. While BEAM Plus ND is primarily intended for use in new development, the EMSD HQ project demonstrates the tool's versatility for adaptation to existing neighbourhood.

The project at Fat Tseung Street West comprises a single multi-storey tower which represents a typical residential development in Hong Kong. Despite the site constraints, it demonstrates that by thoughtful site planning and design it can be a good neighbour itself, creating a more cohesive environment with likeable amenities for enjoyment by the local community. At WKCD project - the largest cultural district in Hong Kong – much thought and effort has been invested in the public realm. It is also a prime example where citizens' view takes centre stage and the stakeholders' interests are empowered.

v. Sponsored Sessions

(1) Vision-led Sustainable Neighborhoods: Myths and Musts
Session Organiser: AECOM

Session 1.7

SESSION OUTLINE

Why is it time to reboot established approaches to neighborhood planning? When is a vision not a vision? And what are the myths and musts for achieving vision-led planning?

Fact
Asia is one of the world's fastest urbanizing regions, providing significant opportunities and challenges for those shaping new developments or regenerating and re-integrating older ones. It has the ability to tip the scale for the rest of the world through its successes and failures. However, societal needs and environmental challenges in cities are growing in complexity.

Worldwide, there is reducing availability of green-field versus brown-field land. And decades of galloping urbanization now raise the challenges of preserving the natural resources, heritage and public realms that distinguish and nurture the city, and that connect citizens with the city and with each other. Future climate change particularly for coastal cities and those in flood plains also makes the challenges even more complex.

The factors driving designs of future new towns are considerably evolved from those that shaped the "older" new towns – such as Shatin, Hong Kong's first new town development forty years ago. Also, Hong Kong, Macau, Guangzhou and Shenzhen are now not only cities, they are part of arguably the world's largest metropolis – the Pearl River Delta. How can we achieve sustainable neighborhoods in the face of urbanization on such a scale? Beyond meeting the basic necessity of housing, what role should the built environment play – in resilience and sustainability - in the future? How can the built environment take on a more adaptive and citizen-friendly form for neighborhood communities to flourish?

Make up your own mind
What are the myths and musts of achieving sustainable neighborhoods? This AECOM-moderated session will engage panelists and audience participants in an exchange of experiences and innovative ideas to better anticipate and address the future design and delivery of sustainable neighborhoods that achieve jointly positive economic, environmental and social impact.

(2) Transportation Hubs: Their Critical Role and Requirements? Session Organiser: AECOM

Session 3.7

SESSION OUTLINE

Beyond dispute, the continuous expansion of transportation infrastructure to connect more of the global population to more of the world has been achieved up to now at a heavy cost to the environment.

This AECOM-moderated session will engage panelists and the audience in an exchange of experiences and ideas on how to continue providing transportation facilities that enrich people's experiences of the world and enhance the future economic competitiveness of their cities and countries, with the least possible environmental degradation.

This session provides a practical discussion on the challenges of integrating these large scale additions to the built environment successfully. It features the WSBE17 host city of Hong Kong as one of its case studies. Hong Kong is a microcosm of so many of the world's most pressing, transportation-related environmental challenges and, at the same time, also at the forefront of piloting and practicing many of the world's leading ideas for solutions. As the city moves forward with its strategies to update its role in the Pearl River Delta – and as Asia's world city - we look at the globally pioneering approaches being implemented for the signature land, sea and air infrastructure to help its continuous evolution as a Smart City. How do high performance transportation hubs translate into high performance as a Smart City, and as a sustainable city?

(3) Deep Energy Saving and Other Innovative Green Measures for Commercial Buildings in Hong Kong, Mainland China and Overseas Session Organiser: Swire Properties Ltd.

Session 2.7

SESSION OUTLINE

Electricity use in building remains the largest source of local carbon emission in Hong Kong, accounting up to 63% of the total emission. Enhancing energy efficiency in our new and existing building stocks becomes crucial to our commitment in meeting Hong Kong's carbon target and also fulfilling both Hong Kong's Climate Action Plan 2030+ and Energy Saving Plan 2015-2025+.

With Gross Floor Area of 27.2 million square feet, Swire Properties recognize the potential significant contribution it can make to our climate. It starts its energy saving journey as early as 2001 with firm determination, clear vision, professional knowledge, researches and use of design tools. It strives to achieve the committed targets at the outset through concerted efforts of the whole team at both design and operational stages.

In this parallel session, we deep dive into our long-term energy saving strategy and practice, ranging from high-level management system to day-to-day data analysis over building services systems in Hong Kong and mainland China. Our ten-year collaboration with Tsinghau University contributes to various successful energy efficient case study. The knowledge accumulated also join together with advanced technology and best practices brought up by top-tier consultancy firm to implement in our new building. These are also demonstrated by another case study in Japan. Going beyond energy efficiency, the total package of 'multiple benefits' derived from green sustainable building will also be discussed.

ABSTRACT

This paper presents the sustainability strategies on energy management implemented by a property developer, which achieved deep and continuous improvement in the period from 2001 to 2015. It aimed for reducing electricity consumption across their portfolios in Hong Kong over the years, and strategically established a comprehensive energy database for monitoring and analysing the energy data. This "Knowledge-based energy management" involved the collecting, analysis of operating data and turning them into information for determining strategies to enhance the operation efficiencies of their plant and equipment. It also involved the carrying out of practical researches through both in-house efforts and collaboration with universities and equipment manufacturers.

With a sufficient understanding of energy use and building performance, ambitious energy targets were set. Energy management opportunities (EMOs) were then identified and implemented systematically. This amounted to a 16% reduction in electricity energy consumption despite a 16% increase in gross floor area from 2001 to 2015. Three key issues will be discussed in this paper including database establishment, energy improvement practices and energy efficiency research. It is concluded that the "Knowledge-based energy management" strategy has potential to be success industry-wide.

Keywords: sustainability strategies, knowledge-based energy management, energy saving

1. INTRODUCTION

Hong Kong is one of the high density financial and commercial cities in the world. As much of our activities take place indoors, buildings consume substantial amount of energy. In 2013, over 92% of electricity generation was consumed by these buildings and around 66% of it was contributed by commercial sector (Hong Kong Energy End-use Data 2015). To cope with the energy saving plan of HKSAR (i.e. reduce energy intensity by 40% by 2025 using 2005 as the base) (Energy Saving Plan, 2015) and implement low-carbon living and working style, contribution from the commercial sector is important.

Nowadays, commercial buildings are always better managed. The control of major building services installations like, heating and ventilation air-conditioning (HVAC) system, electrical distribution system, lighting system, lift and escalator system are normally integrated into the building management system (BMS) to facilitate daily operation. Developers are more willing to invest as it can increase their rental income and reputation. Nevertheless, operators of the building tend to focus in routine operation and prevention of equipment breakdown instead of operation efficiencies. They are conservative and prefer replacing inefficient building services installation until the end of their equipment life. This case study investigated a developer in Hong Kong, who works in another way and their energy saving journey showcased the success of transforming routine operation into a Knowledge-based management and strategy.

2. CASE STUDY

2.1 Background of the case

This case study is a developer established in 1970s in Hong Kong. It owns and manages office, retail, hotel and residential properties, with a focus on mixed use developments in prime, accessible locations across Hong Kong, Mainland China and the United States. Up to 2015, they have investment properties (office, retail and hotel) of over 2.72 million square meters (Annual Report, 2015).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Since 2001, this developer have worked to reduce electricity use, by monitoring and analysing data collected and stored in a comprehensive energy database, setting energy efficiency targets and developing strategies and actions to meet these targets. Up to 2015, over 37 million kWh energy consumption was reduced despite there was increase in portfolios size. In percentage, this amounted to a 16% reduction in electricity energy consumption despite a 16% increase in gross floor area from 2001 to 2015. By implementing knowledge-based energy management and continuously evaluating their operation, they set an ambitious target for 2020 of reducing annual energy consumption by 64 million kWh electricity (26%) compared with 2008 baseline (Annual Report, 2015).

What makes their operation efficiencies and energy management different is that they act on information and researches; collaborate with academia to sustain their initiatives; actively influence their stakeholders and make their energy performance transparent through the yearly sustainable development (SD) reporting and carbon disclosure project.

Their energy improvement journey can be described in 3 stages:

- Establishment of database and using extensive operating data to monitor building performance from early 2000's
- Develop Knowledge-based energy management system, reduction plan and influencing others from 2006
- Carry out practical researches, collaborate with universities and put newly discovered measures into practice from 2010

2.2 Methodologies

2.2.1 From dataset to knowledge-based

It has been long in the building industry that building operation data collected with the BMS are not fully utilized. Indeed, these data are extremely useful in analysing the building performance, especially in energy management and evaluate system efficiencies.

The reasons they are not used are that most of them are raw data, lack of housekeeping or even not properly logged. And it is extremely difficult to analyse such "big data" without technical expertise and systematic management. To begin with, this developer started to build up a high level energy database from 2001. By means of simple utility bills and analysis tools, the energy data, in correlation with other parameters such as occupancy level and outdoor temperature, are transformed into valuable information. It is extremely useful as it can give the management a full picture of how the energy is utilized throughout the years (Figure 1).

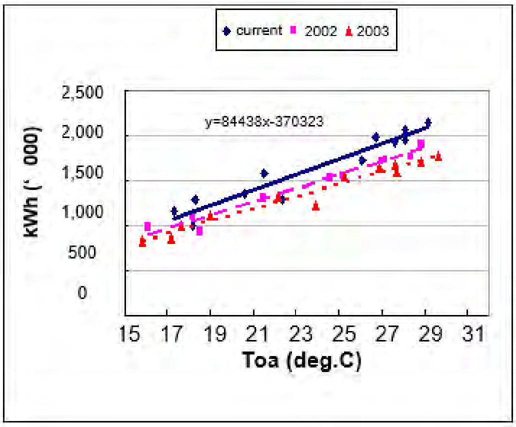

Figure 1: Energy database with correlation with outdoor air temperatures (TOA)

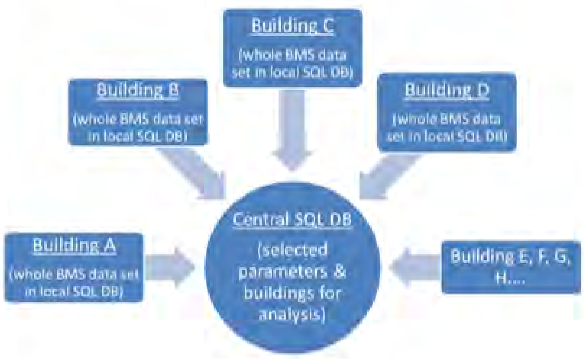

Figure 2: Strategy in logging BMS data in SQL DB

Besides energy data, BMS hourly operating data like, supply and return temperatures, flow rates, damper and valve positions can also provide a lot of information in the characteristics, performances and efficiencies of different building services installation. However, the data amount and network requirement can be enormous that BMS network may not able to cater. In 2005, the developer started to collaborate with BMS vendors in establishing hardware and software strategies and investigating the technology breakthrough in building individual BMS logging database. Instead of tradition csv, text or excel files, they explored a way to use Structured Query Language (SQL) database (DB) that is optimized for large data storage and prompt data retrieval. Individual and central databases

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

were built to mitigate the network loading and prioritize frequent analysing data. Figure 2 is a diagram showing the strategy on how to manage the large amount of monitoring data from individual buildings.

With the aid of energy and BMS databases above, energy consumption and system performance are easily keep tracked and analysed. Management would be easy to establish energy baseline and improvement plan for upcoming years. Measurement and verification methods can also be developed for verifying the success of initiatives by means of the data.

2.2.2 From knowledge to internal and external energy strategy

Establish targets and strategies internally

By reviewing the extensive operating data in a systematic way, raw data are transformed into information and knowledge. Improvement opportunities could be identified through the regular equipment performance monitoring. For instance, the chiller control optimization was identified based on the analyses of chilled water / condenser side water supply and return temperatures and electricity power consumption; VAV system static pressure reset was reviewed based on the statistic of VAV boxes damper position. A series of methodology for practical use of operating data was thus developed such as, energy performance analysis in chiller performance and chilled water system (Yu and Chan, 2012), feasibility study in conversion of cooling tower, VSD chillers, duct static pressure reset (Zhang et al., 2015), automatic tube cleaning system and chilled water differential pressure reset (Xuefeng et al., 2015). Those operating information not only give simple performance evaluation, but also facilitate management decision on operation optimization as well as replacement investment. Figure 3 showed a chiller performance analysis using year round operating data and design figures from the manufacturer, to justify whether the chiller should be replaced.

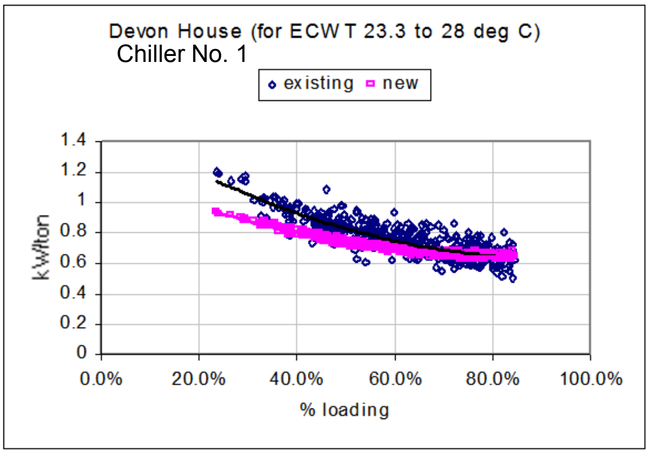

Figure 3: Strategy in logging BMS data in SQL DB

Instead of relying advices from energy consultant or equipment manufacturer, self-studies with actual site operating data provide more objective findings. Figure 4 is a road map showing the energy analysis they have been carried out in past years. Sometimes, it can speed up energy saving opportunities and bring out new initiatives as data are readily on hand for in-depth analysis. More importantly, the effectiveness of energy saving opportunities and new initiatives can be closely monitored. Detailed measurement and verification (M&V) can be done to verify the saving and summarize the pros and cons of different measures for future implementation.

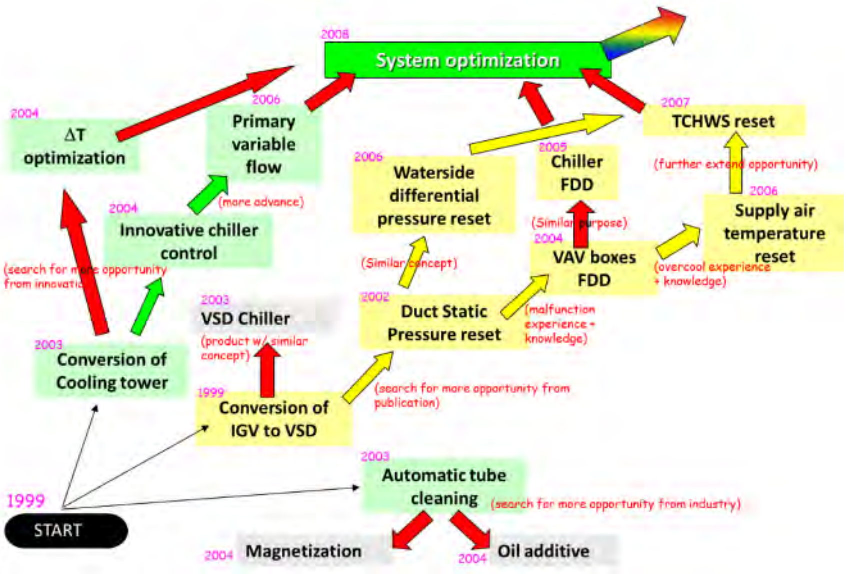

Figure 4: Road map of energy analysis in past years

Readiness of data also helps in other ways, e.g. meeting local energy codes, acquiring international recognition (e.g. BEC2012, ISO 50001), professional awards and developing reduction plan. Long before the implementation of mandatory energy audit initiated by Hong Kong government in 2012, the developer was able to carry out similar audits from 2010 and establish an ambitious energy plan, i.e. target for 64 million kWh electricity saving a year (26%) by 2020 for Hong Kong portfolio with 2008 as the baseline.

Benchmarking with others globally

In addition to internal target, it is also good to a company to step up to the industry globally. In 2006, the developer spearheaded a 'Best-in-class' exercise to benchmark and share best practices with peer companies in the USA, Australia, the UK, Singapore and Hong Kong. The objectives were to understand the practices adopted by industry leaders and ways to enhance each participant's performance through sharing of knowledge. The developer did not only manage their own consumptions but more importantly influenced others and facilitated other owners to reduce carbon emission.

Influencing stakeholder and the society

Success of sustainability is building on the cooperation with all stakeholders. Instead of own long-term energy reduction target, initiatives should also extend to stakeholders by various programs like tenant engagement.

Electricity consumption of tenants accounts for over 40% of the total consumption of a typical office building in Hong Kong (Annual Report, 2015). Management companies, indeed, can play an active role to encourage energy saving in the tenant side.

In this case, free energy audit was provided to the tenant. They started to carry out free energy audits for its office tenants and explore improvement opportunities in their premises. According to the information collected, about 44% of their office areas had been audited and the tenants' power intensity has been reduced by 35% from 2009 to 2015 (Figure 5).

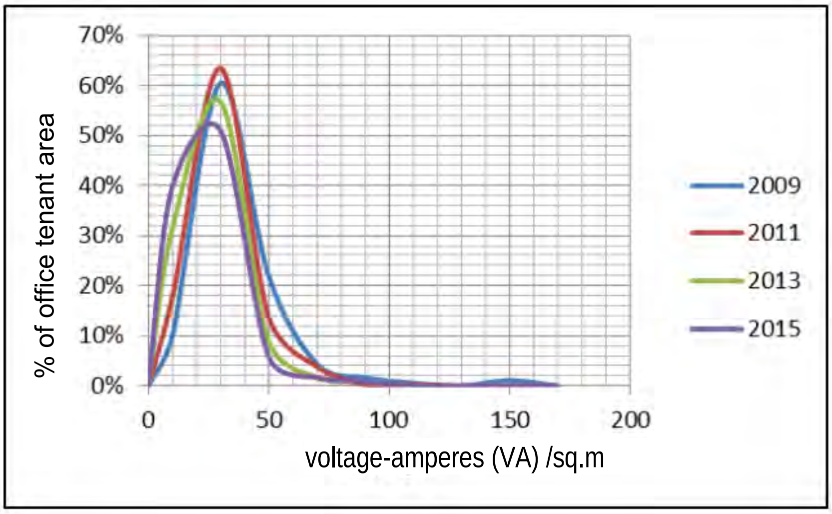

Figure 5: Reduction on tenant's power intensity from 2009 to 2015

Furthermore, increasing energy conservation awareness among own staff and tenants through targeted campaign can help decrease the cooling demand in office and retail portfolios, and thus further reducing the total building energy consumption. For example, the developer implements "Green Pledge" with tenants to apply a series of green initiatives that help improve the environmental performance of their office premises, encourages the tenants in shopping malls to join the Green Shop Alliance that join forces to promote green shopping practices by putting forward the green initiatives.

2.2.3 From experience to action research and new initiatives

Technology comes in steps. In the past, energy reduction can be easily achieved by chiller and LED replacement. However, it is making difficult in further saving if there is no major breakthrough in technology advancement. Though developers can make a different step, they can partner with universities as they have valuable experience and operating data to share. In this case, the developer demonstrated a good movement as they have established a joint research centre with an international grade national university, Tsinghua University, to carry out researches on optimization of plant efficiencies of existing buildings. Operating buildings can be used as living laboratories for testing pilot initiatives in energy efficiency improvement and to put newly discovered measures into practice.

Academia can involve at various phases of development to help optimize energy efficiency through the life cycle of buildings also, e.g. integrated design at planning and testing and commissioning stages and monitoring based commissioning in operating stages. This kind of collaboration can result in substantial energy savings, and also help influence and share new knowledge with colleagues, partners, industry peers and researchers about new building technologies and management processes.

Moreover, we can partner with equipment vendor. Synergy can be found when building owner, suppliers and academia are pull together. With the technical support from equipment manufacturer, operating experience from building owner and in-depth analysis from universities, new energy initiative and control algorithm can be discovered and refined. For instance, the developer developed a fault detection and diagnosis (FDD) program of VAV terminals with Hunan University and Honeywell Limited and won the ASHRAE Technology Award in 2013.

3. DISCUSSION

In previous sections, we have identified different aspects in forming a sustainable energy strategy. That included the development of database and knowledge, establishment of internal and external strategies and partnering with equipment vendors and academia.

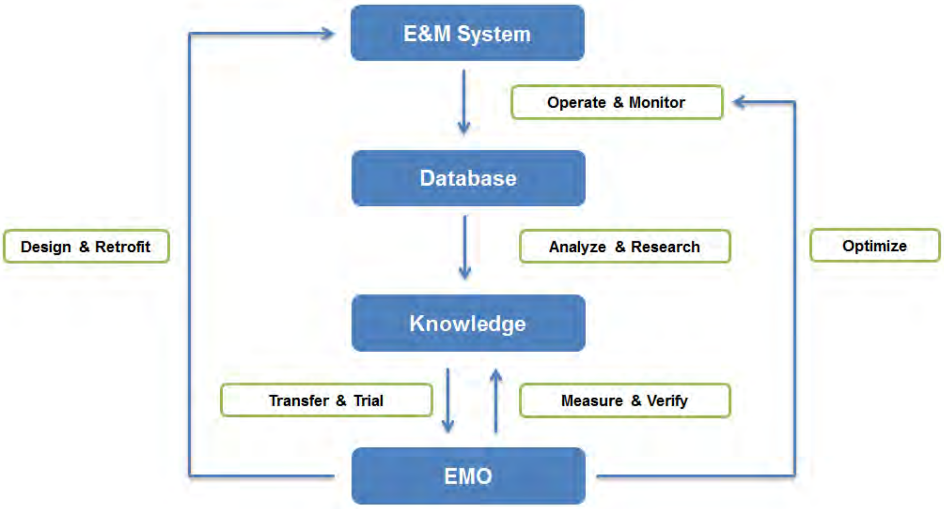

Figure 6: Process of knowledge-based management

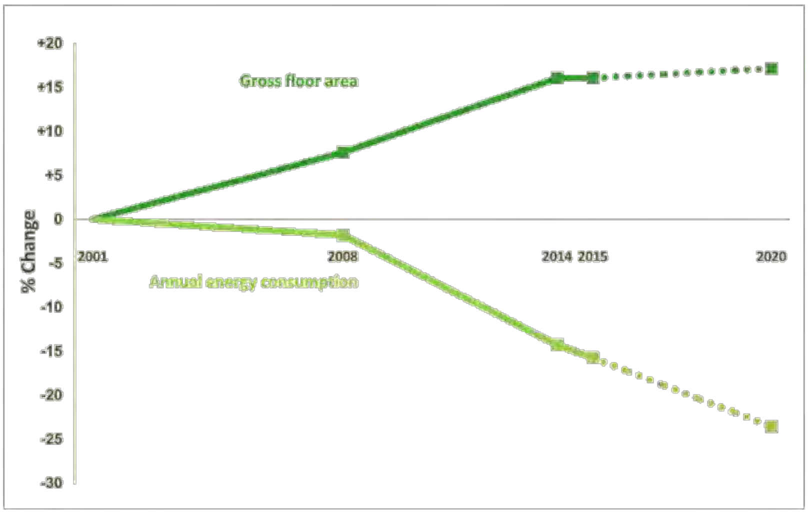

Figure 7: Energy saving trend and projection of the developer from 2001 to 2020

The main concept of this idea is Knowledge-based management (Figure 6). First of all, build a database integrating the data collected from different electrical and mechanical (E&M) system. With simple data mining tools, data can be clustered into information and knowledge with a series of analysis and researches by professionals, engineers and operators. Individual initiative and strategy can then be set, including short term EMOs and long term reduction strategies. The implementation can be supported by manufacturer and academia as they have expertise in product design and installation. Performance is closely monitored by means of sensors afterwards and allowed benchmarking with others. Experiences and knowledge are accumulated throughout the processes. Figure 7 summarized the developer's energy reduction trend despite the increase of gross floor area from 2001 to 2015.

Difficulties in setting up the database and energy management system

Data from BMS and energy meters can be enormous. For instance, a 70-storey high grade A office buildings with VAV system and having area around 2,000 sq.m per floor, can have more than 40,000 BMS points and more than 100 energy meters installed in total. If data are logged in every 5-minute, there will be over 11 million data set per day. Data mining process can be exhaustive if they are not properly managed and analysed. At the same time, buildings that were built over 15 years ago may not have the capability to log such a large amount of data in terms of hardware and software provision. Moreover, owners may not invest in such infrastructure as there is no direct payback from them.

Nevertheless, prioritizing the BMS points to be logged and selecting the right logging interval may solve the problems. For instance, less frequent energy data is more critical than routine hourly operation data as energy data can provide clues in major energy use installation. Instead, operating data can be logged at designated interval and specific periods (e.g. a few weeks in summer and winter times) to mitigate the loading on the hardware and software infrastructure.

4. CONCLUSION

Apart from traditional operation and maintenance practices and preventative maintenance, Knowledge-based management could be another way in enhancing energy efficiency and forming energy management strategy. With the establishment of energy and operating databases, analysis could be carried out effectively. The operation data would be turned into valuable knowledge, and strategies and initiatives are then established which eventually enhance the building performance. Moreover, synergy and innovation could also be stimulated.

In conclusion, Knowledge-based management in sustainability strategies is viable and would be a new way out in energy management.

ACKNOWLEDGEMENTS

The case study presented in this paper was supported by Swire Properties Limited.

ABSTRACT

The paper presents fruitful results from ten-year collaborative research and practice carried out by Tsinghua University – Swire Properties Joint Research Centre on energy efficiency in HVAC systems in large-scaled commercial buildings. Substantial savings were obtained through retro-commissioning on HVAC systems with the assistance of control performance modelling during the building operation. The optimization was achieved not only by conventional system re-balancing/fine-tuning, but also through innovative technologies like data-driven modelling of chillers. Hand-in-hand joint efforts of the academia and the industry consolidated practical guidelines of testing and commissioning (T&C), and a series of case studies for building energy efficiency.

The knowledge accumulated from the existing building study was also transferred to the new building design and construction processes to improve the whole life-cycle building sustainability. T&C was stressed during the whole process from the design stage of T&C provision, the construction stage of T&C specifications to the operation stage of performance tests. This paper shares the experiences of the building energy consumption target setting and control during the whole process of design, construction and operation, through the joint efforts of a private sector and a university.

Keywords: HVAC system, innovative technology, energy saving, existing building, new building

1. INTRODUCTION

The buildings sector consumes about one-third of world energy and associates with almost one-third of global carbon dioxide (CO2) emissions. Energy efficiency in buildings was well recognized as an important approach to alleviate global warming and to achieve a sustainable future. However, a recent-published IEA report shows that building energy use has risen nearly 20% since 2000 although significant efforts on policy was adopted in recent years to improve building energy efficiency. Thus, the multiple-discipline joint-efforts may offer an alternative solution to industry and government on this crucial topic.

The collaboration of a private sector and the academia on building energy efficiency has been continued for ten years taking the real operating buildings as the living laboratories. The relationship started as the pilot study in 2007 and further developed to Tsinghua University – Swire Properties Joint Research Center for Building Energy Efficiency and Sustainability in 2011.

As the pioneer and leader in green building design and management with a long history on continuous improvement, the private sector is committed to incorporate environmental sustainability principles and practices throughout the business operations with long term goals and action plans.

The joint efforts not only fulfilled significant energy saving in the operating portfolio, but also demonstrated the increasing commitment on the real estate sustainable development and the influence to the industry by participated in the international research projects, i.e. IEA Annex 53, IEA Annex 66, and the US-China Clean Energy Research Center.

The field of this collaboration focuses on energy efficiency and sustainable built environment in commercial buildings, especially on Heating, Ventilation, and Air-Conditioning (HVAC) systems which dominate energy use in buildings. In this paper, the ten-year research and practice collaboration journey of the private sector and the

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

academia is presented. The innovative technologies developed from the real applications as well as deployed into the reality are introduced.

2. FROM OPERATIONAL DATA TO EVALUATION METRICS

The collaborative works initiated from HVAC system and Indoor Environment Quality (IEQ) data gathering for saving potential analysis. The metrics to evaluate system performance, which were standardized and applicable for all HVAC systems, had been developed based on the collected data.

2.1 Operational data gathering and analysis in existing buildings

The operation of condensing water pumps and cooling towers not only affects electricity consumption in condensing side, but also influences energy performance of chillers. A case study below demonstrates the performance evaluation methodology.

Based on the annual hourly records of chiller saturated condensing temperature (SCT), chiller condensing water leaving temperature (CDWLT) and entering temperature (CDWET), and the outdoor wet bulb temperature (WBT), the performance of condensing side can be evaluated by three temperature differentials (dT) as shown in Figure 1a to 1c.

The first considered temperature difference, dT1, refers the differential between SCT and CDWLT which reflects heat transfer performance of the condenser. For common fresh water cooled chillers, dT1 should be maintained lower than 2K, otherwise the condensers should be cleaned for higher chiller efficiency, as shown in Figure 1a.

The second consideration, dT2, refers the differential between CDWLT and CDWET which is usually designed to around 5K. If the actual dT2 is obvious higher or lower than 5K, problems may be hidden in the operation of condensing pumps. Figure 1b shows annual hourly measured dT2 in the case. If dT2 during the year are significant higher than 5K, the insufficient condensing water flow rate could be identified, which deteriorated the performance of the efficiency.

The last considered, dT3, refers the differential between CDWRT and WBT which reflects the heat and mass transfer performance of cooling towers. In this case all-year round measured dT3 are shown in Figure 1c. It is obviously that dT3 in off-peak season are much larger than that in peak summer time. Based on the measured data analysis, a cooling tower operation scheme was suggested to achieve a smaller dT3 in the off-peak season, which resulted in higher chiller efficiency.

2.2 Metrics to evaluation system energy performance

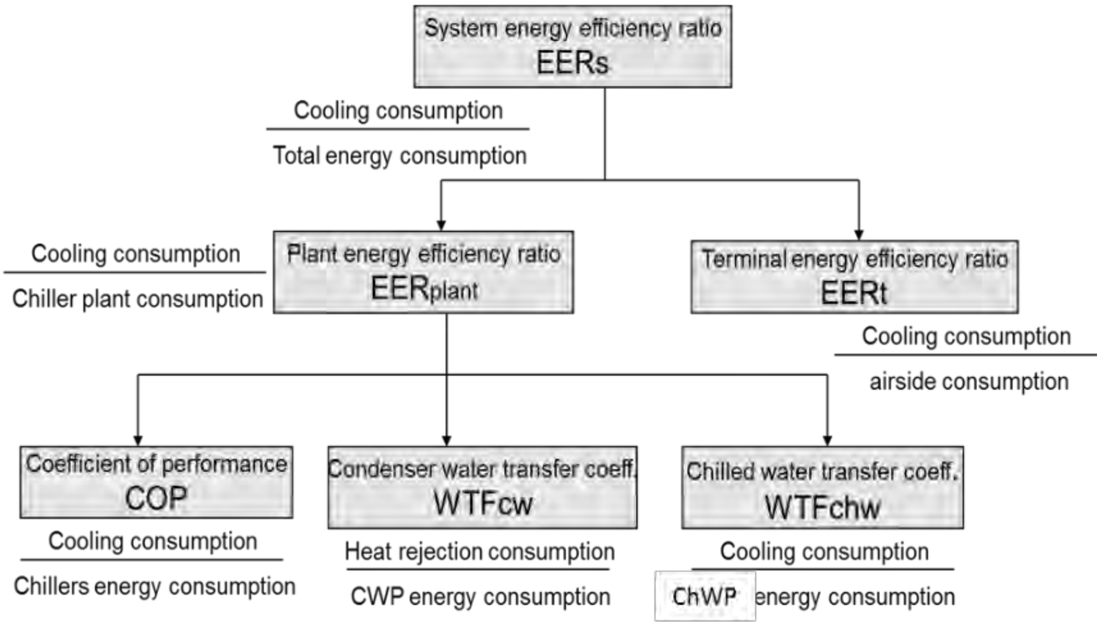

Figure 2: Key Performance Index (KPI) of HVAC system to evaluate energy performance of major systems / equipment based on measured operational data

The case studies of the existing buildings drew the conclusion that it is necessary to develop a systematic way to dig out energy saving potentials for built environment maintenance based on measured data. A standardized Key Performance Index (KPI) system was developed as the efficiencies of major systems / equipment in HVAC systems which can also be proposed for benchmarking, for target setting and control, as shown in Figure 2. Those metrics of efficiency can be compared with other similar systems on the apple-to-apple basis.

As shown in Figure 3, operational performance of 56 chiller plants were evaluated by the metrics and huge saving potentials in systems were figured out by the benchmarking.

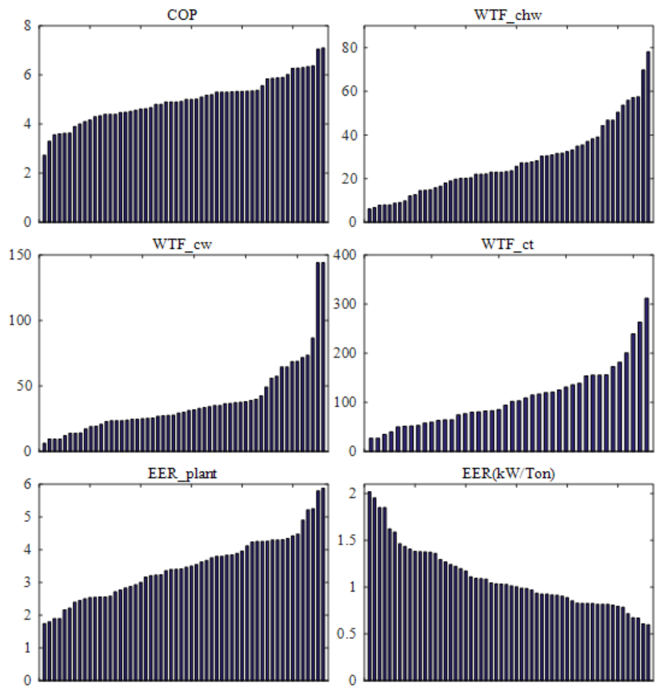

Figure 3: Benchmarking of 56 chiller plants through developed metrics on energy efficiency

3. FROM OPERATIONAL OBSERVATIONS TO MODELING AND ALGORITHM

The data-based evaluation on system performance disclosed significant saving potential on the operating systems in buildings. New methodology/technologies were also developed from the above exercises using the real buildings as the living laboratories for testing pilot initiatives on energy efficiency analysis and improvement. Fundamental studies were carried out including modelling and simulation and fine-tuned during the application of the algorithm for control to realize actual energy savings and efficiency improvement.

3.1 Concise graphic - Analytic method for chilled water system characteristics analysis

The phenomenon of "large flow – small ΔT" is always found in variable flow chilled water systems. A concise graphic-analytic method is introduced for the analysis on the overall performance characteristics of a group of cooling coils and identifying the probable problems.

The method uses the ideal curve of the relative cooling load vs. the relative flow rate as the baseline for the analysis. The cooling load imbalance and the hydraulic imbalance are analysed for their impacts on "large flow – small ΔT" phenomenon, which presents "collapse" in the performance curve.

Cooling load imbalance analysis

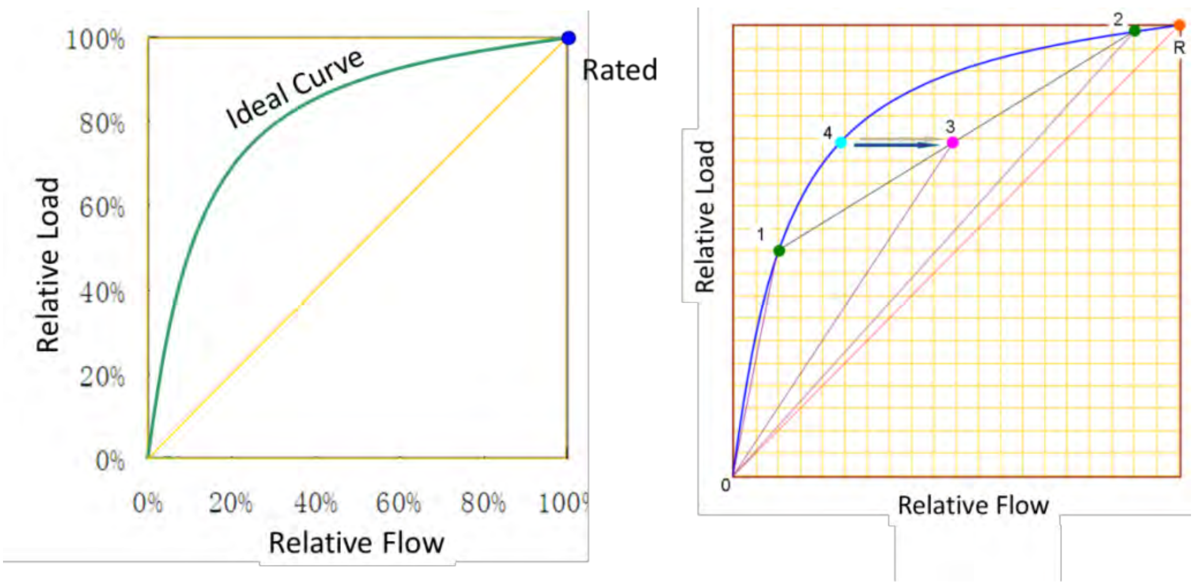

Figure 4: Cooling load imbalance analysis

If the two identical coils are working under different loads as "Point 1" and "Point 2" in Figure 4, the overall system operating condition is "Point 3", which deviates from the ideal curve.

Hydraulic Imbalance Analysis

For the two identical coils, the control valve of one coil is faulty and fully open while the relevant air-side system is switched off. The other coil is under normal operation with the operating curve of "061R". The overall system characteristic would be "543" (Figure 5a). If the malfunctioning valve is partially open, the system curve would be "5'4'3'".

If the two identical coils are in operation, one is under normal control, the control valve of the other coil is faulty and fully open. The overall operating curve would be shifted to "53R" (Figure 5b).

Figure 5: Hydraulic imbalance analysis

3.2 Data-driven modelling of chiller

Chillers are the most energy consuming equipment in HVAC system. As the development of chiller technology, the rated efficiency of large scale centrifugal chillers or screw chillers is high. However, the chiller operating conditions always deviated from the rated point and lead to significant energy waste. Thus, it is important to continuously monitor the chiller operating points and make necessary optimization or retrofitting to improve the operating efficiency.

The chiller efficiency can be represented by the thermodynamic perfection of the cycle, which is defined in Equation 1. It illustrates deviation of operational COP, as defined in Equation 2, to the best condition which follows the reversed Carnot cycle as shown in Equation 3. The modeling is a typical data-driven type since all the parameters of the model can be measured directly from real operating system.

$$\gamma = COP / ICOP$$

Equation 1

$$COP = q / W$$

Equation 2

$$ICOP = T_{ev} / (T_{co} - T_{ev})$$

Equation 3

In above equations, is the thermodynamic perfectness, COP is the coefficient of performance, ICOP is the COP in the reversed Carnot cycle, q is the cooling energy produced (kW), W is compressor power (kW) and T is temperature in Kelvin. Subscripts ev and co represent evaporating and condensing respectively.

For constant speed chillers, the main influencing factors to the thermodynamic perfection are compressing pressure differential between evaporation and condensation, as well as the refrigerant mass flow rate. The former one can be represented by the differential between saturated evaporating temperature and saturated condensing temperature, expressed as dTev,co. The latter one can be approximately substituted by partial load ratio (PLR), which is the ratio of actual cooling output to rated cooling capacity.

The hourly operating data of chillers are shown in Figure 6. It was found that the running points of the chillers were far from the rated point, shown as the star in the Figure. It can be seen that the chiller thermodynamic perfection is quite low during most operation conditions. New chillers with relative smaller compression ratio were selected to replace the existing ones to make actual operation points closer to the rated point. Millions of kWh electricity savings were accomplished from this proper chiller replacement since the modeling and measured data played the important roles in this case.

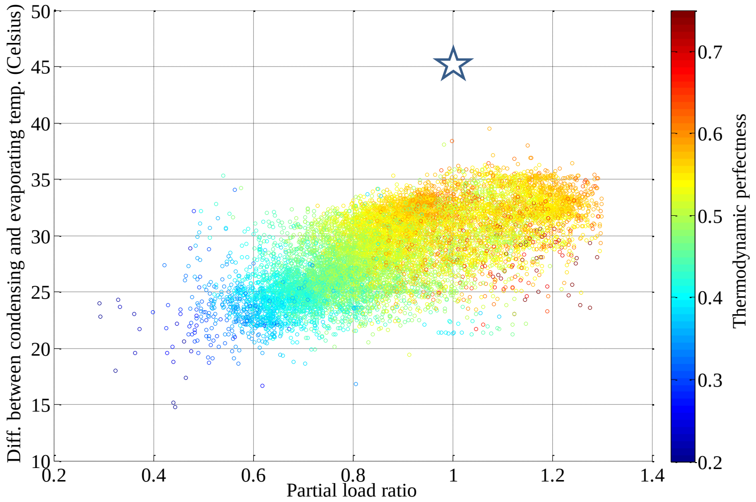

Figure 6: Chiller thermodynamic perfectness map with hourly measured data during a year

4. FROM OPERATIONAL EXPERIENCES TO DESIGN CRITERIA

Integrated Design Approach (IDA) is a concept where consideration of environmental performance of the development is placed at the start of a project and the objectives are to be met by the concerted effort of the development team. The knowledge accumulated from the existing building study was also transferred to the new building design and construction processes to improve the whole life-cycle building sustainability.

4.1 Solving oversizing capacity problems

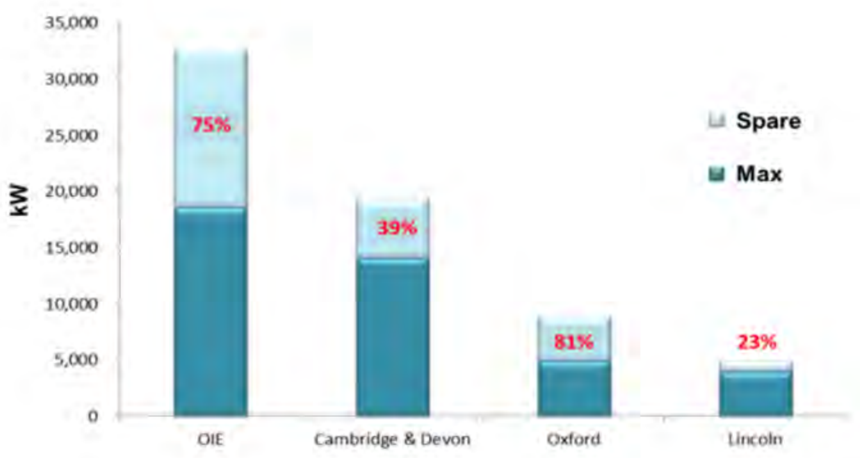

Figure 7: Oversized chiller plants

Oversizing of plant and equipment is a very common issue within the building industry. The result indicated the amount of oversizing ranges from 23% to 81% after a survey on several commercial buildings (Figure 7). The problem of oversizing increases the capital cost and sacrifices the system energy performance.

Variable speed drives can’t solve the problem of oversizing. Although the variable speed drives can maintain a reasonably high efficiency during some part load conditions, the control range would be narrowed and the equipment would run at low efficiency if the loading is too low and has exceeded the turn down ratio limit.

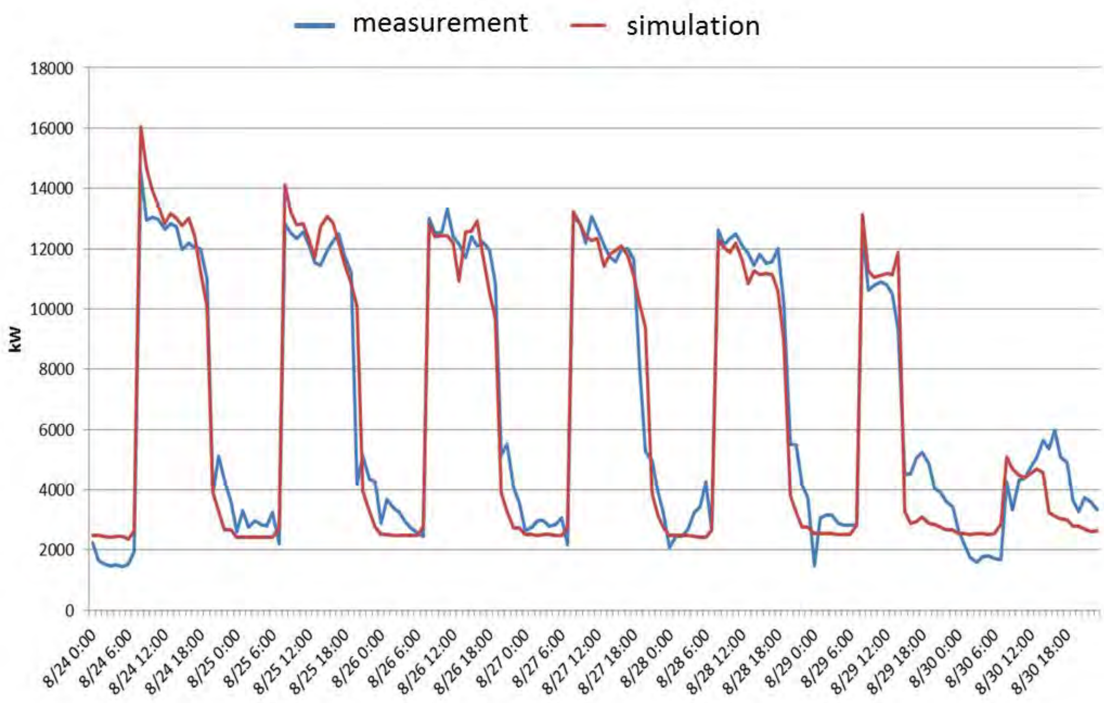

Figure 8: Calibrated simulation

Oversizing starts from load calculations which are done by computer simulation. The design input parameters are usually based on handbooks and local code of practices, which usually differ from the real situation. With the reference to the data collected as the input parameters, the simulation exercise showed that the estimated cooling load is much closer to the real demand (Figure 8). The database of the existing buildings would play the more active role for new building design. Further research works should be carried out on how to choose more realistic design parameters based on the operating data.

4.2 Detailed design for T&C and operation

In system design and equipment selection, part load efficiency should be addressed as the most important issue. The equipment should have the capacity to cater for a wide range of loading while maintaining the high efficiency. This can be achieved through the use of multiple units with different capacities and selecting of equipment with the right operating range and part load characteristics.

System efficiency should also be evaluated together with the current operating practices taking into account the control robustness. Too complicated control logics depending on multiple sensors would not be a good solution as multiple soft sensor errors are always difficult to be identified. To evaluate the system performance, sufficient provision of sensors/gauges/testing points is recommended. The guidelines of sensors/gauges/testing points provision need to be worked out with the detailed specifications.

Testing and commissioning (T&C) is the critical procedure to put the designed system to the real operation. Performance tests of major systems/equipment are standardized by the joint-efforts. The performance tests methodology and the relevant standard forms are developed for chillers, pumps, cooling towers, air handling units, primary air units, water balance, air balance, VAV systems and water-side system resistance analysis.

4.3 Publications and workshops

The Joint Research Center published a book entitled <The Analysis on Common Disputed Technical Topics for Building Energy Efficiency> (Figure 9) in August 2015. This co-publication, which is available in selected bookstores in Mainland China, presents six technical cases and explains the related concepts of integrated design and whole-process management, a system that enables commercial developers on energy efficiency throughout the building development process.

The six technical cases were summarized by the two parties together with their own opinions/methodology developed from accumulated practical experiences as well as the in-depth research works. In each case, the common misunderstanding areas were pointed out and clarified with detailed analysis.

Figure 9: Publications

The plant study case was also cited as a showcase in <2014 Annual Report on The Development of Building Energy Efficiency in China> (Figure 9), and it was the second time since 2010 (Figure 9) the joint-effort of energy performance and best practices adopted was recognised.

In past years, workshops sharing experiences from the Joint Research Center were hold every year in Beijing and/or Hong Kong. The research and practice collaboration pushed the boundaries of building energy research to the application and developed new benchmarks in building energy efficiency and sustainability. The platform also helps sharing with the industry peers and researchers about new building technologies and management processes related to achieving greater energy efficiency.

5. FURTHER COLLABORATION AND CHALLENGES

In the future phase of this collaboration project, one of the focuses is to build an Energy Management System (EMS) for the company's commercial buildings across Hong Kong and Mainland China. The EMS will allow real-time remote monitoring of the buildings' electricity consumption data. Both parties are expected to work hand-in-hand to optimize the structure of EMS and to investigate potential energy saving opportunities through the on-line system by built-in expert rules.

EMS had been developed by some developers with different features based on their particular needs. However, the data quality and data utilization are still facing big challenges.

The information management functions of BMS are also planned to be used for monitoring-based commissioning. The accumulated knowledge would be incorporated to develop the online fault detection and diagnosis (FDD) strategies as the existing BMS may not suit our demand. The joint-efforts are necessary to put this forward successfully.

ACKNOWLEDGMENTS

Cost & Value: Multiple Benefits of Green Commercial Buildings in Western Countries

Phil JONES[a]

[a] *Welsh School of Architecture, Cardiff University, United Kingdom; Faculty of Architecture, University of Hong Kong, Hong Kong SAR, jonesp@cardiff.ac.uk*

ABSTRACT

This chapter reviews the cost of green buildings, together with their quantifiable and qualitative added value. It reviews energy costs in relation to other benefits of green building design and retrofit, at building, community and national scales. Where data is available it presents cost benefits and also discusses benefits of a more qualitative nature.

Keywords: green buildings, energy, cost and value

1. INTRODUCTION

It is widely accepted that a green and more sustainable building will provide added value to its owners and occupiers, justifying any cost increase incurred in its design and construction. However, it has been difficult to attach an actual financial value to the benefits of green buildings, to assess whether they are more attractive to tenants and occupiers, and, the extent to which they attract a financial premium in terms of any increased rental and sales value. Generally, the main recognized quantifiable return on an investment in green design has been the energy savings, and even this is often uncertain in relation to the finished building, and how its users operate it. However, there is the potential for multiple benefits arising from green buildings, in addition to the actual energy savings. The IEA report, ‘Spreading the net: the multiple benefits of energy efficiency improvements’, published in 2012 (Ryan and Campbell, 2012), recognizes the wider benefits of ‘clean energy’ projects, which in addition to being of direct benefit to the individual or organization implementing the project, also has benefits for both national and global economies. However, such ‘non-market’ and socio-economic benefits are often difficult to quantify. Projects are often assessed by energy professionals, with little experience of how energy efficiency might impact on other non-energy sectors. The report also recognized the “rebound effect”, by which non-energy sector benefits may result in the predicted energy savings being less than expected. A report by the US IEA, ‘Assessing the Multiple Benefits of Clean Energy’ (Environmental Protection Agency, 2011) identified environmental and health benefits, and a broad range of economic benefits, as well as reducing stress on the energy system.

Green buildings using clean energy systems can also enjoy the wider economic and environmental benefits. Although currently not well understood, the potential added value of the total package of benefits can be considerable, and much greater than just the energy savings alone, though there also may be rebound effects as introduced above for clean energy systems in general. For example, a rebound effect through the take up of affordable warmth in houses that are designed or retrofitted to be more efficient to heat, which is a positive benefit.

On a life cycle cost basis, even allowing for any rebound effects, the energy savings alone should typically exceed any additional design and construction cost premiums, within a reasonable payback period. There may be increased costs associated with green buildings, especially retrofitting existing buildings to a greener standard. However, by adopting an integrative holistic design approach, these additional costs can be reduced, to an affordable level, and potentially to a level comparable with standard building costs for new build, and within acceptable budgets for retrofit. In addition to energy savings, operations and maintenance costs have the potential to be reduced, for example, through the use of less complex environmental systems for heating, cooling and ventilation.

Energy costs are generally small in comparison to overall business operating costs, which are usually dominated by staff costs. For commercial buildings, green design can lead to a better quality indoor environment, which can improve worker productivity, and occupant health and well-being. This can result in improved productivity ‘bottom line’ benefits for businesses. However, in spite of these potential benefits, the improved indoor environmental quality associated with green buildings has not generally been a priority in building design and construction.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Buildings that are not designed with sustainability credentials may in future be considered high risk, which might affect their rental income and future asset value, in turn affecting their return on investment. So, buildings with better sustainability credentials could enjoy increased marketability, and their asset value should increase over time. They should be able to more easily attract tenants and to command higher rents and resale prices, and as a result offer a greater overall yield on investment.

Future trends in building regulations to reduce carbon dioxide emissions have also become a concern to building owners, as regulations place greater emphasis on the existing building stock. Changing tenant requirements and investor risk screening may also affect the value of buildings that do not have green credentials. The indication is that in markets where green is becoming more main-stream, there are emerging 'brown discounts', where buildings that are not green, may rent or sell for less. There is therefore an increasing interest in retrofitting existing buildings. Therefore developing retrofit solutions for different building types, and new investment models to address financing retrofits, are crucial to maintaining a building's future asset value.

In summary, green and more sustainable buildings need not necessarily incur significant additional design and construction costs. Their impact scales up to national and global levels, for example, energy cost savings at building scale will result in reduced carbon dioxide emissions at a global scale. The benefits are both quantitative and qualitative, and in future, developers who do not provide green buildings, will potentially incur an investment risk, and reduced marketability. However, these factors and benefits, although having been identified over the last decade or more, have yet to make a marked penetration into the building construction and operation industry. When assessing the benefits of a green building, the main analysis is still generally based on cost of energy saving measures versus cost of energy savings.

This paper reviews the above cost and value benefits associated with green building design. It is based on a review of some of the emerging findings from research and practice, with the main focus on office buildings and housing. It contributes to the activities of the EU COST T1104 Action, Smart Energy Regions, which is exploring a regional approach to implementing low carbon policy into practice in the built environment.

2. COST AND VALUE

The additional cost of a green building relates to how much money is spent on the building compared to a non-green building. If a 'bolt-on' approach is used, the costs are easily identified in relation to the additional 'bolt-on' items of construction or equipment. Such a 'bolt-on' approach tends to incur relatively higher additional costs compared to a holistic and more integrative design approach, where costs may be reduced. Where a more holistic approach is used, it can be difficult to assess costs precisely, as the additional 'green' technologies used in the building may be offset by reducing costs in other areas. For example, the increased cost of a high performance façade may be offset by reduced costs for heating and cooling equipment. Also, a green feature may also be simultaneously used as a more traditional building element, for example, when a Photo Voltaic (PV) panel over a window can 'double up' as a shading device.

The value of a green building can be related to the overall return on the investment, which may be in quantitative terms, for example, energy saved, or, of a more qualitative nature, such as, improved quality of life, although such qualitative improvements can also result in cost benefits. Assessing payback on investment using a single cost parameter, such as the cost associated with energy savings, does not recognize the total value of a green building in use. Added value aspects might include multiple benefits, such as, for a commercial building: more satisfied occupants; longer tenancies and higher lease rates, reduced absenteeism and an overall higher asset value; future proofed and reduced risk of obsolescence; less need for refurbishment in the future; higher demand from institutional investors and satisfying corporate social responsibilities; and, lower operating and maintenance costs.

There is a growing body of evidence, which identifies increased costs and added value benefits for office buildings. It has been shown that, in general, the costs associated with green offices are often exaggerated, and their added value underplayed. The World Green Building Council's report in 2013 (World Green Building Council, 2013), based on a variety of building types in United States, United Kingdom, Australia, Singapore and Israel, summarised a range of benefits from adopting a green building approach, and stated that, whereas the increased design and construction costs associated with a new green building are perceived to be as high as 29%, the actual cost increases found in practice are less than 12.5%, and sometimes equal to, or even slightly less than, the costs of a standard building. Some ten years earlier Kats, et. al. published a report (Kats G, Leon A, & Adam B, 2003)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

indicating that the additional costs of a green building were on average (from a sample of 33 buildings) around 2% and this could be repaid ten-fold over a twenty year lifetime through lower energy, water and waste costs, lower environmental and emissions costs, lower operations and maintenance costs, and savings from increased health and productivity. They reported increased productivity and health contributing 70% of the benefits, reduced operations and maintenance 16%, and energy savings 11%.

The increased costs for a green building may therefore often be over-estimated, whilst the additional value-added benefits are not always appreciated, and are generally underestimated, or not considered at all. Johnson Controls (Johnson Controls, 2012) reported a range of value-added benefits that green buildings exhibit, including: increased resale value (2-17%); increased rental rates (5.8-35%); higher occupancy rates (0.9-18%); lower operating expenses (30%); higher net operating income (5.9%); lower capitalization rates (50-55 basis points); and, productivity gains (4.8%).

A study by Davis Langden (Davis Langdon, 2007) has also identified benefits for green building owners including: potential higher occupancy rates; higher future capital value; reduced risk of obsolescence; less need for refurbishment in the future; ability to command higher lease rates; higher demand from institutional investors; lower operating costs; mandatory for government tenants; lower tenant turnover; and, less cost to maintain and operate.

Further studies by RICS (RICS, 2005) identified green building benefits to: be quicker to secure tenants; command higher rents or prices; enjoy lower tenant turn over; cost less to operate and maintain; attract grants, subsidies and other inducements to do with environmental stewardship, increase energy efficiency and lessen greenhouse gas emissions; improve business productivity for occupants, affecting churn, renewals, inducements and fitting out costs; and, benefit occupants to an extent that may even exceed the underlying asset's value.

In 2010 Eichholtz et al (Eichholtz P, Kok N, & Quigley JM, 2010) reported a study of some 10,000 buildings indicating that there was an effective rental premium of around 7%, and selling premium of 16% for green office buildings in the US. Pivo and Fisher (Pivo G and Fisher JD, 2009) found that green buildings had up to 5.9% and 13.5% higher market values, driven by 9.8% lower utility bills, 4.8% higher rents, and 0.9% higher occupancy rates. A study by McGraw-Hill (MacGraw Hill 2013) looked into the payback period for green investments and operating costs. It was found that over a one-year and a five-year period, new green buildings were expected to reduce operating costs by 8% and 15% respectively, and by 9% and 13% for retrofits. The payback times were expected to be eight years for new green buildings and seven years for green retrofits. Building values were expected to increase by 7% and 5%, and asset values by 5% and 4%, for new build and retrofit respectively.

A recent study (Nils Kok and Avis Devine, 2015) showed that improved property performance is strongly correlated to green building certification. The research analysed ten years of financial performance data across a 58 million square feet office portfolio in the USA and Canada, indicating: net effective rents on 3.7 % higher in LEED certified properties, and 9.5% higher with ENERGY STAR certification in the U.S. compared to similar non-certified buildings, and 18.7% higher in Canadian buildings having both LEED and BOMA BEST certification; tenant renewal rates were 5.6% higher in Canadian buildings with BOMA BEST Level 3 certification than in buildings with no BOMA BEST certification; tenant satisfaction scores were 7% higher in Canadian buildings with BOMA BEST level 3 and 4 certification than in non-certified buildings; energy consumption per square foot was 14% lower in U.S. LEED certified properties than in buildings without certification.

However, although there are positive signs that green buildings attract higher value in the US, a study by RICS on London offices was not so positive (Chegut, P, Eichholtz, and N Kok, 2012.), and failed to identify improvements of significance.

The energy savings for new build may be related to three levels (table 1). The first is the level of energy reductions (also relating to carbon dioxide emission reductions) in relation to typical improvements in Building Regulations. In the UK typically there would be 25% carbon dioxide reductions between subsequent upgrades of building regulations, which may be every 4 to 5 years. These are considered relatively easy to achieve in an incremental way. The next level might relate to the best level of energy reductions associated with building environmental assessment methods, such as LEED and BREEAM, which are typically 40 to 50%. Finally savings relating to a PassiveHaus level of performance would be of the order of 75%, the remaining 25% potentially provided by renewables, creating a carbon neutral building. Actual energy use will vary with building type and location, but ballpark average levels (UK) might be 200kWh/m2 per year for housing, and 360kWh/m2 per year for offices, with average energy costs of £12/m2 per year and £25/m2 per year respectively.

Level	% savings	Description
1	25	Building regulation improvements
2	40-50	High LEED BREEAM
3	75	PassiveHaus

Table 1: Levels of energy savings

Retrofiting existing offices can yield similar benefits as new build. A US study (Pacific Northwest National Laboratory, 2011) has identified three levels of approach to office retrofit: (i) commissioning, which can typically achieve up to 25% energy savings. An example from a US study of commissioning projects found that office buildings typically realised 22% energy savings through 'existing building commissioning, with an average simple payback period of 1.1 years (Evan Mills, 2009); (ii) standard retrofit, which can typically produce 25-45% savings with payback period of less than 4 years. Such retrofits generally adopt a cost-effective low risk approach, typically using a package of component-level replacements of existing equipment; (iii) Deep retrofits, which are based on an integrated whole-building approach to energy savings projects. Savings of 45% and higher, with a typical payback period of up to 3 years, are achievable when upgrades to the building envelope are combined with retrofits of lighting and mechanical systems. In order to achieve a good performance for a building in use, it is essential to provide a high level of commissioning, and operations and maintenance. The report identified a range of benefits from improved operations and maintenance, including: energy savings; reduced comfort complaints; equipment that operates adequately until the end of its planned useful life, or beyond; improved indoor environmental quality; safe working conditions for building operating staff. It identified energy costs typically constituting 30% of overall operating costs, leading to a substantially increased net operating income and asset value.

The above discussion has focussed on a green approach to commercial buildings, covering both new build and retrofit. For housing, the increased costs associated with new build together with value added benefits, cover a similar range as for offices. However, whereas a component approach to retrofit can be affordable, though perhaps limited in benefits, 'deep' retrofits are generally currently considered high cost, and difficult to finance. In the UK, homes account for more than 28% of total UK energy use, with related carbon emissions (based on 2009 Figures). In the UK, the rate of new build for housing in a year is around 120,000, of a total housing stock of around 27 million, which is a renewal rate of around 0.5% per year. It is expected that 80% of existing dwellings will still be in use in 2050, so housing retrofit is a major area for saving energy and reducing carbon dioxide emissions. A large demonstration programme of housing retrofit was carried out in the UK between 2010 and 2012. Reported results from this programme (M Baeli, 2013) indicated that energy saving measures from deep retrofit schemes could produce on average around 63% energy reduction with most cases in the range 50% to 85%, and for an average cost of around £77,000, from a range of about £45,000 to £118,000. In addition, for most cases between £42,000 to £100,000 was spent on non-energy saving improvements. Clearly these costs are high in relation to potential payback. However, there are indications that costs can be reduced, and if combined with value-added benefits, can sometimes make deep retrofits financially acceptable. This will be discussed later, with to recent case studies.

3. ENVIRONMENTAL ASSESSMENT METHODS

Green' labels are often used to assess the green credentials of a building. A range of Environmental Assessment Methods are now available to apply to buildings in order to assess their performance during design. They include BREEAM (UK) and LEED (US), and they address a range of design aspects, such as indoor environment, material use, location, etc, as well as energy performance. There have been studies to assess the cost of achieving a high assessment rating and the return on the investment. The cost increase associated with majority of certified green buildings typically ranges from <0% to 4%. Higher levels of certification (such as BREEAM Very Good and LEED Silver/Gold) have been shown to have a cost increase in the range from 0% to 10%. Highest levels, such as BREEAM Excellent and LEED Platinum have increased costs of around 2% to 12.5%.

A review of ENERGY STAR and LEED projects (J Jackson, 2009) has identified rent and occupancy premiums that not only pay for the additional green development costs, but also provide an attractive internal rate of return (IRR) on green investments, for an incremental cost of between 1 and 5%.

David Langdon (Davis Langdon, 2007) has indicated from their research in Australia that the initial impact on construction costs (compared to non-Green projects) is likely to be in the order of 3 – 5% for a 5 Star solution, with a further 5% plus for a 6 Star non-iconic design solutions.

A review of recent studies has found that office buildings with green certifications command between around 2 to 27% higher rents than otherwise comparable buildings (Appraisal Institute and the Institute for Market Transformation, 2013). There are also significantly higher occupancy rates for buildings with green and efficient certifications.

However, the cost of an environmental assessment can be considerable. For some companies, the value is in having the certificate, and not always in the improved performance, so there are sometimes pressures to deliver a high assessment rating level for minimum investment.

4. ORGANISATION COSTS

Green building costs, and in particular related to energy performance, should be looked at in the context of the total organisation costs of a building, especially for commercial and public buildings. Studies have estimated that building construction costs and energy savings are a relative small proportion of total organisation costs. For commercial buildings, staff costs make up the bulk of operational expenses, with over 85% of total workplace costs spent on salaries and benefits, compared to less than 10% on rent, and less than 1% on energy (World Green Building Council, 2013).

Operational costs can greatly exceed design and construction costs over a buildings lifetime. Examples of two whole life-costing studies for offices have been described by Evans (Evans, R, Haryott, R, Haste, N and Jones, A, 1998) and Hughs (Hughes, WP and Ancell, D and Gruneberg, S and Hirst, L, 2004). Evans quotes a ratio of 1:5:200, for design/construction costs to operating costs to business costs, respectively. Hughes, however, questions the validity of this ratio, and suggests a ratio of 1:0.4:12, as being more realistic for commercial buildings. However, this still indicates that business costs, a large proportion of which will be staff salaries, outweigh design, construction and operating costs, which include energy costs (typically 30% of operational costs). Design costs can also be included in this ratio, simplistically as 10% of construction costs. Other studies have suggested that an initial 2% upfront investment for a green building will generate a return ten times higher than the initial investment over the life cycle of the building (Kats G, Leon A, & Adam B, 2003). They report that salary costs (USA) of around $65,000 are roughly ten times higher than operations and maintenance costs, which include energy and rent, energy being only 1% of overall costs.

The above analysis implies that the largest return on investment should arise when green buildings also improve business productivity.

5. PRODUCTIVITY, HEALTH AND QUALITY OF LIFE

The previous section has argued that the benefits of increased productivity for a green building outweigh any energy savings, and by itself justifies increased design and construction costs. So life-cycle assessments based on energy savings alone, only provide a relatively small part of the potential overall value benefits to an organization. David Langdon reported that the Building Commission of Victoria indicated that optimal levels of indoor environmental quality would increase Australian workforces' productivity by as much as 30% (Davis Langdon, 2007).

Therefore a major aim of green building design is to achieve good standards of indoor environment, which can in turn improve worker productivity, and occupant health and well-being. In commercial buildings, sick building syndrome (SBS) has often been associated with spaces that have poor indoor environments, usually associated with air-conditioned offices. As long ago as 1984, the World Health Organization (WHO, 1984) reported that 30% of buildings globally may have indoor environments that contribute to SBS. More recently, Heerwagen (2010) (J. Heerwagen, 2010) reported that up to 20% of workers might be affected. Reducing SBS symptoms can potentially reduce absenteeism, as well as increasing productivity, and creating a more favourable working environment, which in turn can reduce staff churn.

As already discussed, an estimated average increase in productivity for a green building with a good environment is 4.8% (Johnson Controls, 2012), with increases up to 30% suggested in some reports (Davis Langdon 2007). If the cost of an office worker is estimated at around £30,000 per year (UK), a 4.8% improvement in productivity would therefore be equivalent to a value of around £150/m2 of office floorspace per year (roughly assuming 1 person per 10m2). If the average sick leave is about 7.0 days per year, using the same estimated staff costs, and assuming 220 working days per year, the average cost of absenteeism is estimated at around £100/m2 per year. A 10% reduction in absenteeism would benefit the business by around £10/m2 per year. These estimated potential cost benefits totalling some £160/m2 are relatively large compared to typical energy cost savings of typically around £3 (to a maximum £30)/m2 a year.

Loftness et al, (Loftness V, Hartkopf V, Gurtekin B, Hansen, D, Hitchcock R, 2003) presented results from eight case studies linking individual temperature control to productivity gains of up to a 3%; fifteen studies linking improved ventilation with up to 11% gains in productivity; twelve studies linking improved lighting design with up to a 23% gains in productivity; and, thirteen studies linking the access to the natural environment through daylight and operable windows to individual productivity gains of up to an 18%. Lucuik et al, (Lucuik M, Trusty W, Larsson N, and Charette R, 2005) cited 35% less absenteeism in spaces with higher office ventilation rates.

Fisk (W.J. Fisk, 2000) has identified for the USA, potential annual savings through productivity gains are $10 to $30 billion from reduced Sick Building Syndrome symptoms and $20 to $60 billion from direct improvements in worker performance that are unrelated to health.

However, although the benefits of a good environment on staff moral and productivity seem obvious, improved indoor environmental quality has not generally been a priority in building design and construction.

6. FUTURE PROOFING

Both businesses and householders are becoming increasingly concerned of the future energy performance of their property. Energy costs, though often considered relatively small for the majority of businesses and households, are rising significantly. Also, security of energy supply may become an issue in future. Energy related building regulations are expanding to consider existing as well as new build. The value of a building in future may therefore be affected by its energy performance, carbon dioxide emissions, and its indoor environmental quality. These may affect the rental income, resale value, and the future overall value of real estate assets, in turn affecting their return on investment.

There may also be affects of extreme weather events and changes in weather patterns that might affect future insurance costs, in relation to a building's resilience. As building buyers, tenants and investors, begin to understand these risks, non-green buildings may become obsolescent. Green buildings may be considered a lower risk, which could result in a higher yield on investment. Interest rates on building related loans may be less for green buildings, reflecting their reduced risk. A green building, whether new or retrofit, can therefore future-proof against these potential cost liabilities.

A positive stance towards environmental issues may in future impact on supply chain acceptance. A company's 'green' real estate can demonstrate a visible signal of the adoption of an environmental policy. It may even contribute to a firm's success in attracting and retaining high-quality employees.

7. CORPORATE RESPONSIBILITY

Carroll's pyramid of Corporate Social Responsibility (Carroll, AB, 1991) for a business includes ethical and philanthropic responsibilities, alongside economic and legal responsibilities. The economic and legal responsibilities relate mainly to its shareholders, owners, and employees. The ethical and philanthropic level responsibilities relate mainly to public interest, which includes the environment.

Green buildings can form a major part of a company's Corporate Social Responsibility Strategy. They have many tangible benefits to a company, as discussed in previous sections, together with the less tangible benefits that can contribute to a favorable corporate reputation. A company therefore may be inclined to choose a green building in comparison to a standard building, to enhance its environmental credentials. A green building can therefore meet both social responsibilities whilst achieving cost savings and other 'quality of life' and economic benefits.

8. MARKETABILITY

There are many reports that relate to the added value of green buildings. Generally they support the argument that buildings with better sustainability credentials enjoy increased marketability. Green buildings are able to more easily attract tenants and to command higher rents and prices. In markets where green has become more main-stream, there are indications of emerging 'brown discounts', where buildings that are not green may rent or sell for less.

The World Green Building Council's report (World Green Building Council, 2013) focusing on commercial buildings, explained that green buildings have a higher asset value, as evidenced by higher sale prices, with higher rental/lease rates, lower operating expenses, higher occupancy rates and lower yields (leading to a higher transaction price). They can be quicker to secure tenants, command higher prices enjoy lower tenant turnover, cost less to operate.

However, as discussed above, there are some barriers relating to understanding the benefits of green buildings, including, the assumption that it costs more to build green, the fact that green strategies are not widely understood, construction companies lack experience, there is a lack of awareness of the market, a shortage of engineers with experience of operating green building systems, a lack of incentives for owner-investors as opposed to owner-occupants. There is also a perceived lack of evidence between lower energy costs for building occupiers, and the benefit to the landlord. Leases do not generally take account of green issues. However green leases can provide benefits to both tenants and landlords (Langley, Hopkinson, Stevenson, 2008). The tenant will benefit from reduced energy bills and improved indoor environments, whilst the landlord can benefit from longer lease periods, a more stable tenant base, and a higher asset value on their estate.

9. FUEL POVERTY AND HEALTH

The 'rebound' effect introduced above (Ryan and Campbell, 2012) may occur when energy savings are not fully realised due to other benefits. One such benefit is affordable warmth in fuel poor housing. Fuel poverty is defined as when a household pays more than10% of its annual income on energy, and extreme fuel poverty is when they pay more than 20% of annual income on energy. In some countries this is becoming of epidemic proportions. For example, up to 25% of UK households, and up to 33% in Wales, live in fuel poverty (Association for the Conservation of Energy, 2014).

Fuel poverty will often result in households not being able to achieve sufficient warmth. Substandard housing is already estimated to cost the UK National Health Service £2.5 billion a year (National Housing Federation / ECOTEC, 2010). When energy saving measures are applied in fuel poor communities, often a large proportion of the benefit will be 'taken back' in improved comfort. This take-back, or rebound effect, has been estimated to be up to 50% of the expected energy saving measures (Lomas, 2010).

Referring to the above, some 25% of the UK's 26.4 million housing may experience fuel poverty, which generally contributes to substandard environments, and or the need to improve energy efficiency. This would equate to around 6 million dwellings. Based roughly on the above £2.5 billion health impact from substandard housing, the potential health impact cost per dwelling would equate to an average of £400 per substandard dwelling per year. If say a retrofit dwelling has a health benefit lifetime of twenty years, this equates to a saving of £8,000 per retrofit, by the health industry. So, from this simplistic analysis, reducing fuel poverty can potentially save the health industry considerable amounts of money.

10. COMMUNITY BENEFITS

The above discussion has focussed on the building scale benefits from green buildings, in terms of reduced energy costs, improved well-being and productivity, and increased building asset value. There are also potential benefits to the community in which the building is located. Green housing can increase wealth through reduced operating costs. Green commercial buildings can improve the quality of the built environment, attracting higher value businesses, and creating higher value jobs. There are also jobs associated with green industries, which are often appropriate to the mix of available skills within the local community. For example, the construction sector could create 400,000 new jobs from making buildings more energy efficient to meet the requirements of the Energy Efficiency Directive (European Commission, 2014).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

It is difficult to quantify the cost benefit of a green building to the community, but it could be of a level equivalent to the benefit to the building operator, as benefits of increased productivity, asset value may all be reflected in downstream community economic and quality of life benefits, and the increased value feeds through to the community, through higher wages, green jobs, and less pollution.

11. ENVIRONMENTAL DAMAGE

Burning fossil fuel contributes to considerable environmental damage at a global and national level, which results in huge cost penalties. The DARA group have reported (DARA 2012) that climate change is already contributing to the deaths of nearly 400,000 people a year and costing the world more than $1.2 trillion a year, with developing countries bearing the brunt, through deaths from malnutrition, poverty and their associated diseases. Air pollution caused by the use of fossil fuels is also separately contributing to the deaths of at least 4.5m people a year. By 2030, it is estimated that the cost of climate change and air pollution combined will rise to 3.2% of global GDP, with the world's least developed countries forecast to bear the greater cost, of up to 11% of their GDP.

The Stern Review (Stern N, 2006) estimated that the overall costs and risks of climate change will be equivalent to losing at least 5% of global GDP each year and the estimates of damage could rise to 20% of GDP or more. In contrast, it suggests that the costs of reducing greenhouse gas emissions to avoid the worst impacts of climate change can be limited to around 1% of global GDP each year.

The most environmentally damaging business sectors are oil and gas producers, followed by industrial metals and mining. These together accounted for almost a trillion dollars' worth of environmental harm in 2008 (PRI, 2010). In 2003, research results on socio-environmental damages due to electricity production and transport (European Communities, 2003) showed that, if the external cost of producing electricity from coal were to be factored into electricity bills, 2-7 eurocents per kWh would have to be added to the then current price of electricity in the majority of EU Member States.

The European Environment Agency reported that air pollution in Europe cost more than 100 billion euros in 2009 alone due to health and environmental damage (European Environment Agency, 2011). Emissions from power plants in Europe made up the largest share of the environmental damage costs, at £56.8bn-£96.4bn. The construction and operation of the built environment is closely linked to these industries. If we assume 40% of electricity is used in buildings the environmental damage equates to around £120 per household per year across Europe. That includes damage associated with global warming, acid rain, resource depletion, habitat destruction by fuel extraction, environmental damage from processing and transportation, and photochemical smog.

Future increases in environmental damage and resource depletion, could potentially lead to governments to apply a "polluter pays" principle. This in turn will affect the built environment, with reduced asset values for non-green buildings, higher insurance premiums on companies, carbon taxes, and the costs associated with retrofits that could be the subject of future changing building regulations.

12. CASE STUDIES

Many of the studies discussed above have been associated with large-scale surveys. However, there are an increasing number of green building projects, both new build and retrofit that are yielding invaluable information on green building design and the resulting benefits. The following case studies, carried out by the author, are used to further evidence some of the above discussion points.

Office design (Figure 1): A green approach to modern office design should adopt an integrative systems approach, to maximise performance, reduce costs and improve reliability. The EMPA zero energy office in Zurich is a good example of this approach, using a combination of ‘smart’ façade design, thermal mass cooling and renewable energy supply (Jones P J and Kopitsis K 2005). It uses a central atrium for night cooling in summer, using a ‘’passive’ approach by exposing the concrete ceiling to absorb daily heat gains from the space. At night the building is naturally ventilated through the atrium, cooling the building down. This is combined with a ground ventilation cooling system, which operates during the daytime, typically cooling outside air by up to 8oC for delivery to the occupied space. The building is highly insulated and does not need a conventional heating or cooling system. The increased cost of the façade is offset by the reduced costs of the environmental systems, so the total costs are comparable to a standard office building. The mechanical ventilation ground cooling system that operates during

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

the day, provides enough fresh air for occupants, and not the larger quantities that would be associated with more traditional air-conditioning systems. Therefore, fan power and space for ducts and systems are reduced. The EMPA building uses passive thermal mass ceiling cooling. This, to some extent, decouples the cooling from the ventilation system. Whereas a standard air cooling (heating) system would be based on the ventilation being provided by the heating and cooling system. This holistic approach to design leads to multiple cost and value attributes, including: lower fan power; less space for plant; less space for air distribution; greater use of space for occupants; good thermal comfort; better air quality; more stable easier to control conditions; good use of daylight. Such an integrative systems approach to new commercial buildings can therefore provide an overall more sustainable design solution at affordable costs.

Figure 1: EMPA zero energy office

Energy positive house (Figure 2): An energy positive house (Welsh School of Architecture, SOLCER Project) has been designed within an affordable budget, equivalent to the standard costs of good quality one-off social housing. It incorporates near PassiveHaus standards, PV and solar thermal renewable energy systems, and has thermal and electrical storage, within the cost budget. The design adopted a systems approach integrating reduced energy demand, renewable energy supply and energy storage. It has electricity grid back-up, for periods when the energy storage system is not sufficient. Its energy positive design means that it can export more energy to the grid than it imports from the grid.

Figure 2: Zero carbon house (SOLCER project)

Individual house retrofits (Figure 3): The SOLCER Project has also carryed out retrofits of existing social housing. The first one completed in September 2014 (Figure 3a) used a whole house 'deep' retrofit systems approach including, solar PV (the whole of the south facing roof is replaced with a PV roof system), MVHR, external wall insulation, battery storage, and increased airtightness. The total package of measures cost around £27,000, with an estimated carbon dioxide emission reduction of 70%. An additional £25,000 was spent by the housing association to bring the house up to current standards. This compares with a previous case study (Figure 3b) for a similar size end-terrace house, which cost around £54,000 to achieve 80% carbon dioxide emission reductions with an additional £70,000 spent on non-energy saving improvements. This previous case study was one of the TSB cases discussed above (M Baeli, 2013), and generally adopted a less integrative more 'bolt-on' approach.

Figure 3a *Figure 3b*

Figure 3: Examples of social housing retrofit. Figure 3a shows a recent retrofit where the whole south facing roof has been replaced by a PV panel. Figure 3b shows a 'bolt on' approach to PV.

For the SOLCER house, prior to retrofit, the house was unoccupied, thus losing the housing association around £450/month in basic rent. Post retrofit, a tenant was easily found, and the house rented at an increased rate of around £540/month (plus 20%), therefore achieving considerable multiple cost benefits for the housing association. There are currently around 20,000 such empty houses in Wales, in many cases where this approach could be implemented, bringing current unoccupied housing back into the market place, so they become an asset rather than a liability to their owners. Bringing empty houses into use also benefits the community and reduces the need for new build.

Large-scale retrofit

Housing retrofit programmes are often carried out on large samples (Jones PJ, et al, 2013). An example is that of the whole housing stock in the Neath Port Talbot local authority in Wales. This targeted lower cost 'elemental' energy saving measures, rather than the deep whole house approach discussed above. It was carried out between 2004 to 2007, and some 49,831 households were assessed, and 28,799 energy efficiency measures carried out to 18,832 properties. Around 28,799 tonnes of carbon dioxide emissions were saved. The project took advantage to provide multiple benefits in addition to energy savings, including: improved comfort; creating 54 new jobs, 127 workers receiving training; 2,305 households removed from fuel poverty; a total £10.3 million invested in the Borough. This project demonstrates the added value that can be applied to large-scale retrofit projects.

The earlier single house and the large-scale retrofit projects have illustrated the range of cost versus energy savings and carbon dioxide emission reductions in relation to shallow elemental measures and deep whole house measures (Figure 4). The recent single house retrofit (Figure 3a) illustrates the speed at which costs are being reduced through a more systems based approach. Both scales illustrate the range of value added benefits in addition to energy savings.

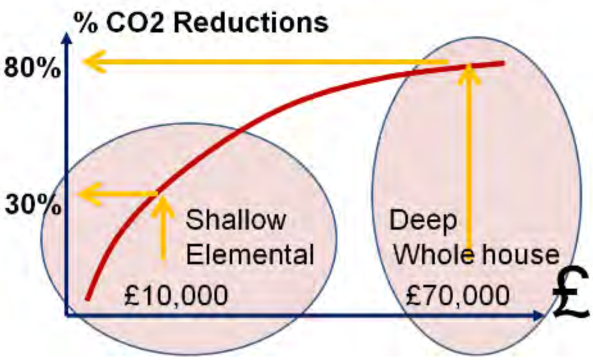

Figure 4: Range of retrofit costs versus carbon dioxide emission reductions (Jones PJ, et al, 2013)

These above case studies indicate that, for new build, it is now possible to achieve near zero carbon performance at an affordable cost. The cost of deep retrofits for housing is also being reduced significantly. Both of these developments have involved a systems approach, carefully selecting the most appropriate combination of reduced energy demand, renewable energy supply and energy storage, to meet the requirements of the specific buildings in question.

13. THE VALUE OF GREEN BUILDINGS

The above sections have introduced a number of issues associated with cost and value of green buildings. Some of the areas covered have associated the estimated costs of the value added aspects of green buildings. In some sections, an estimation has been provided, based on rough values from the literature, with some 'back of envelope' estimates. The intention has been to provide an initial estimation for an overall cost and value estimate. In the estimations, neither increased energy costs nor interest rates have been considered, so they should be considered 'ball park' Figures.

In the past, a cost analysis has mainly related increased cost of a green building against the reduced operating costs, which have been mainly energy savings. What the above discussion has identified is a range of added value factors, some of which are potentially considerably higher than the potential energy savings. It has also identified a scale of value added which benefits not just the building owner, but also considers benefits at community and national (and global) levels. At the national/global level, benefits include, reduced environmental damage (eg. from climate change and air pollution), reduced national health costs (eg. arising from affordable warmth and improved well-being), and security of energy supply and reduced energy imports. At a community level, there is the potential for green jobs, a better quality built environment, and higher value local economic activities. At a building level, which is where the majority of this discussion has been based, the benefits are associated with energy savings, increased value of the building, future proofing, and improved health, well-being and productivity. Table 2 summarises these three areas of green building multiple benefits.

National / Global	Community	Building
• Carbon emissions reduction. • Reduced use of resources. • Security of energy supply. • Improved public health and well-being, and reduced health related costs. • Reduced environmental damage.	• Jobs. • Skills and training. • Local economy. • Less pollution.	• Increased resale value. • Increased rental rates. • Higher occupancy rates. • Lower operating expenses. • Higher net operating income. • Lower capitalization rates. • Increased energy efficiency and lessening greenhouse gas emissions. • Reduced risk of obsolescence. • Less need for refurbishment in the future. • Lower tenant turnover affecting renewals, inducements and fitting out costs amongst others. • Quicker to secure tenants. • Better indoor environment: health, well-being and productivity gains. • Attract grants, subsidies and other inducements to do with environmental stewardship. • Higher demand from institutional investors mandatory for government tenants. • Contribute to company CSR policy.

Table 2: Summary of potential green building cost and value benefits

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Office buildings have the potential for considerable added value, in relation to the increased asset value of the building, productivity gains, as well as energy savings, which are relatively small compared to the total benefits. The above discussion has identified a range of sources of information in this area. These have been interpreted into an overall cost value performance. Figure 5 indicates the range of cost benefits for a new 'green' office taken from the above review. Retrofit offices will have a similar range of benefits, although not to the extent of new offices.

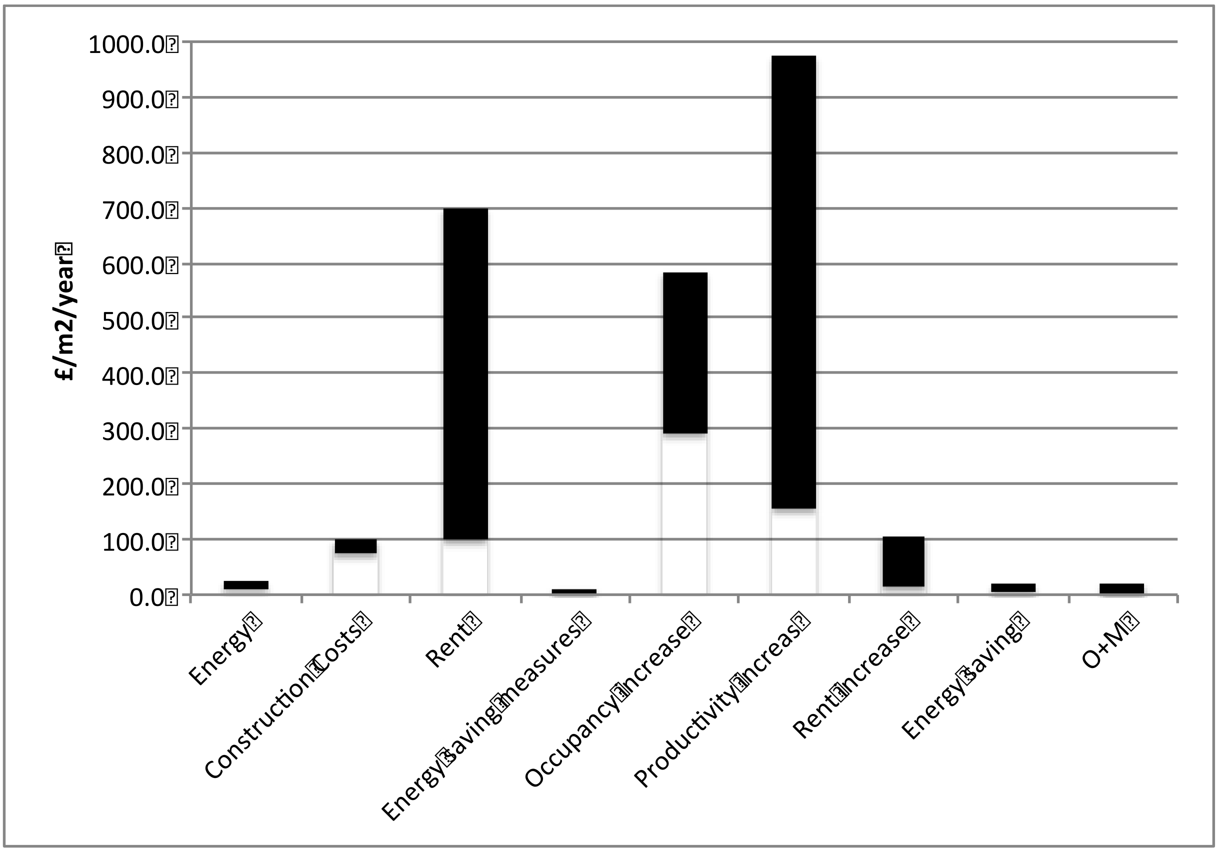

Figure 5: Potential cost savings for a 'green' office

New houses designed to green standards will also incur a range of benefits. The national/global, and to some extent the community benefits, will be as for offices. The building benefits include energy savings, increased value of the building, future proofing, affordable warmth, and improved health and well-being. The range of cost b benefits are summarised in Figure 6.

For new build offices and housing, the increased costs associated with low to zero energy performance are being driven down by new technologies, integrated into the building design through a systems approach. This was demonstrated in the case studies presented above. The cost of retrofit is also being significantly reduced, through the lowering of costs for renewables, improved understanding of the process, and, as for new build, a more systems based approach. This was also demonstrated in the above case studies, for deep housing retrofits. The above discussion has also indicated that retrofit of office costs are highly beneficial with relatively short payback times, in just terms of energy savings.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

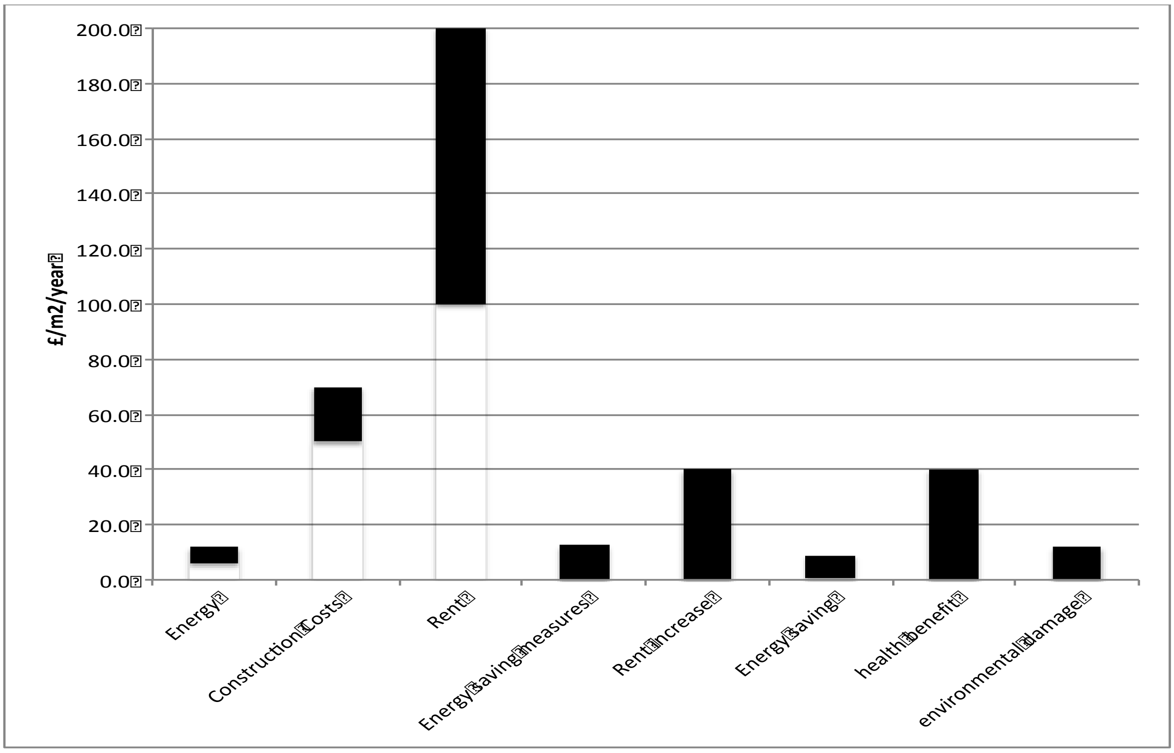

Figure 6: Cost and value benefits for a new 'green' house

14. CONCLUSIONS

This chapter has highlighted the multiple benefits from green building design, in addition to the usual focus on energy savings. There are of course significant energy savings and carbon dioxide emission reductions to be achieved for both new build and retrofit. However, it is the additional 'value added' multiple benefits that are becoming increasingly attractive, and to some extent they are zero or low cost, as the energy savings alone justify the initial green design costs. In summary, green buildings do not necessarily incur significant additional initial cost. For new build, and retrofit, costs are being reduced. The benefits are multiple and both quantitative and qualitative, and are realised at a building, community and national / global scale. Energy savings alone can potentially exceed any design and construction cost premiums, within an acceptable payback period The total benefits can far outweigh any additional cost outlay. Developers who do not provide green buildings incur investment risk, and reduce marketability. Non-green buildings may now be considered short term, and can potentially spiral down the economy. Green buildings can provide better places to live and work, a higher value asset, and generally spiral up the economy at building, community and national levels, and promote tangible benefits to people.

Addressing the low carbon agenda at a building development level may be termed 'bottom-up', compared to say 'top-down' approaches, such as large-scale renewables, carbon trading, smart meters, and green-deals. A bottom-up approach, which is based within an overall systems approach, can be termed 'smart-up', with reference to the added value of a green building as it impacts at higher levels of community and national/global scale, providing the potential for cost and other benefits at these higher levels. It also localises the low carbon agenda, as it promotes economic activity at a regional scale, with potential social benefits, through jobs, local investment and ownership. Top-down approaches may also be termed 'smart' but they are often associated with high risks, and any added benefits are generally more 'big industry' commercial and national based. Smart-up has the potential to reduce the pressure on top down scenario's, making them easier to implement, as demand is reduced, being displaced by building based distributed generation. These factors all contribute to the overall value-added outcomes.

YKK80 High Efficiency Building - Radiant Control both Outside and Inside

Kitaro MIZUIDE[a]

[a] *M&E Design Department of NIKKEN SEKKEI, Japan*

1. INTRODUCTION

Located in the metropolitan city of Tokyo, Japan, the new YKK headquarters building is named "YKK 80" because it was completed in 2015, which marked the 80th year since the company was founded. Tragically, in March 2011, just one month after design began, the Great East Japan Earthquake and disaster occurred. Japan rapidly shut down all of its nuclear power plants (nearly 30% of Japan's total energy supply) and reassessed their energy supply and demand as well as their seismic vulnerability. This allowed the owner and design team to reassess the energy, comfort, sustainability, and seismic design requirements for this project—ultimately leading to much more innovative, integrated, comfortable, healthy, and aseismic design solution.

The project site is a 5-minute walk from Akihabara station, and the longer axis of the site is 70 meters (230 feet) in length, faces westward, and overlooks a metropolitan expressway. These constraints immediately established several energy, daylight, noise and view design challenges for the hot and humid summer climate of Tokyo.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2. ENERGY EFFICIENCY

Using a passive first approach, an exterior “sudare screen”, or Japanese traditional blind, was used over the entire west facing façade to block and filter direct solar gain while maintaining daylight and views. This sudare screen is positioned 1.5 meters (~5 ft.) in front of the glazed façade utilizing the cantilevered floor structure as overhangs. The screen is made of "Y" shaped aluminium bars making a delicate filtering of light. Clear double glazing with automatically controlled bottom-up or “climbing” blinds also provides solar shading while still allowing exterior views. The sudare screen also helps filter outdoor noise, creates a safe service space for maintenance of exterior installed mechanical systems, and even provides lightning protection—ultimately providing 6 functions for a single cost (shading, reflecting daylight, noise filter, deck enclosure, maintaining views, and lightning protection)

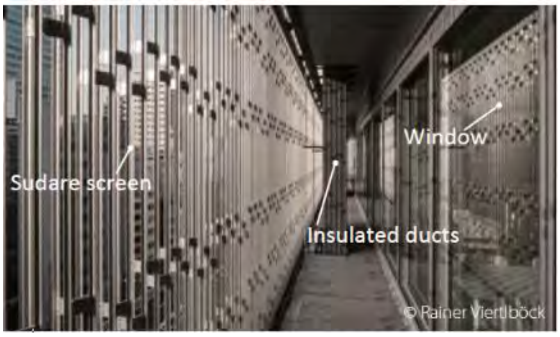

Photo 1: Sudare screen/ maintenance deck

Figure 1: Details of sudare screen/ perimeter image

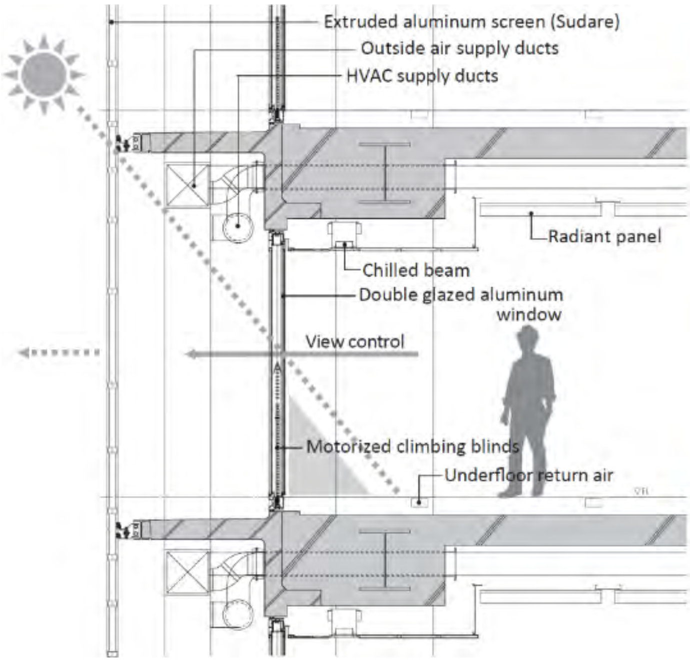

Figure 2: Multi-functional facade system

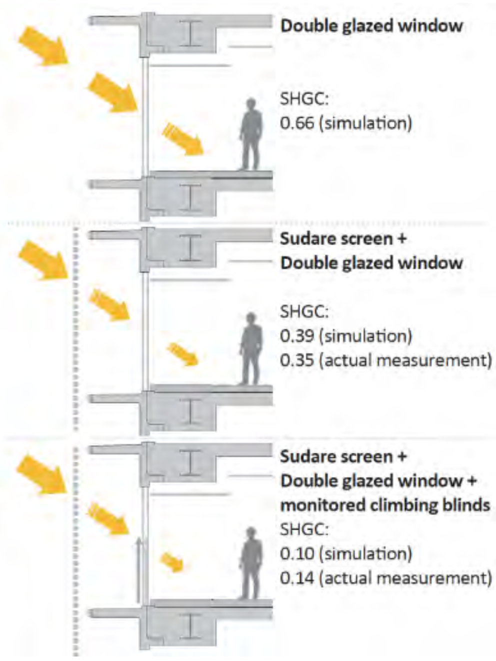

Figure 3: SHGC diagram

Daylighting is maximized by controlling the light coming through the windows with automatic solar adjustment of the angle of the blind slats every 10 minutes. Through post-occupancy evaluation, which was completed in February 2016, more than 80% of the occupants were satisfied with the indoor lighting conditions noting that it was "bright enough" and "not too bright" (no presence of glare). Ceiling integrated LED lighting and controls for dimming or turning off lighting in vacant areas using daylight and motion sensors, extends the value of the energy saving façade design to the indoor environment.

With direct solar heat gains mitigated and daylight and lighting optimized, a properly sized, high-efficiency HVAC system could be designed. A custom, radiant ceiling panel cooling/heating system was designed to facilitate integration of hot/cold water piping with lighting and low-velocity (slight) air flow. This slight air-flow concept came from the memory of experiencing a natural breeze under the shade of a tree. Small fans, functioning as diffusers, provide the slight air flow behind the inclined radiant panels and allow greater variation in temperature set points.

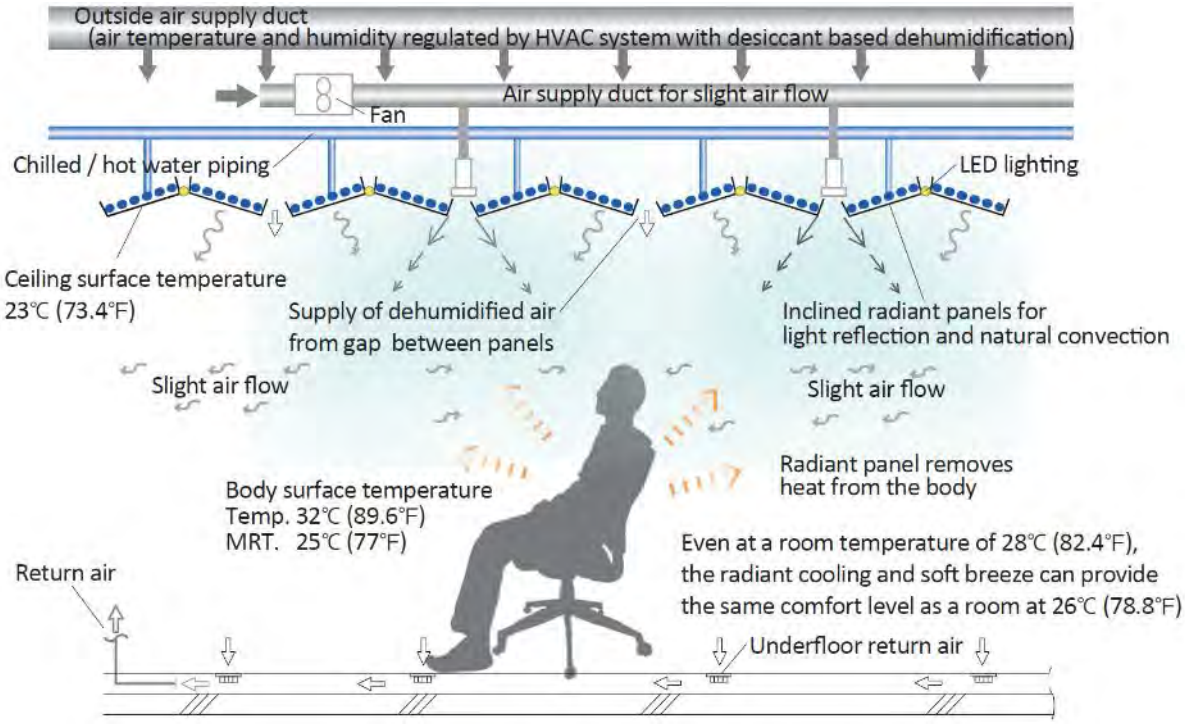

Figure 4: Conceptual drawing of HVAC system

Figure 5 shows the quantity of energy consumption for control of the sensible heat load on the vertical axis and the difference between outside temperatures and an average of all room air temperatures on the horizontal axis. This proved that if room temperature is increased by 1K (kelvin) in cooling mode, energy savings is 8.6MJ/h (source energy 23.3MJ/h). Similarly, lowering the room temperature by 1K while in heating mode, saves 12.0MJ/h (source energy 32.4MJ/h). The chilled water temperature is relatively high which contributes to the high performance operation of the chillers.

Thermal loads in the interior zone, where the temperature does not significantly change, are met by the radiant ceiling panel system. However, the variable thermal load near the exterior windows is met using an Active Chilled Beam. Together, this zoned approach provides for a very efficient distribution of both energy and comfort.

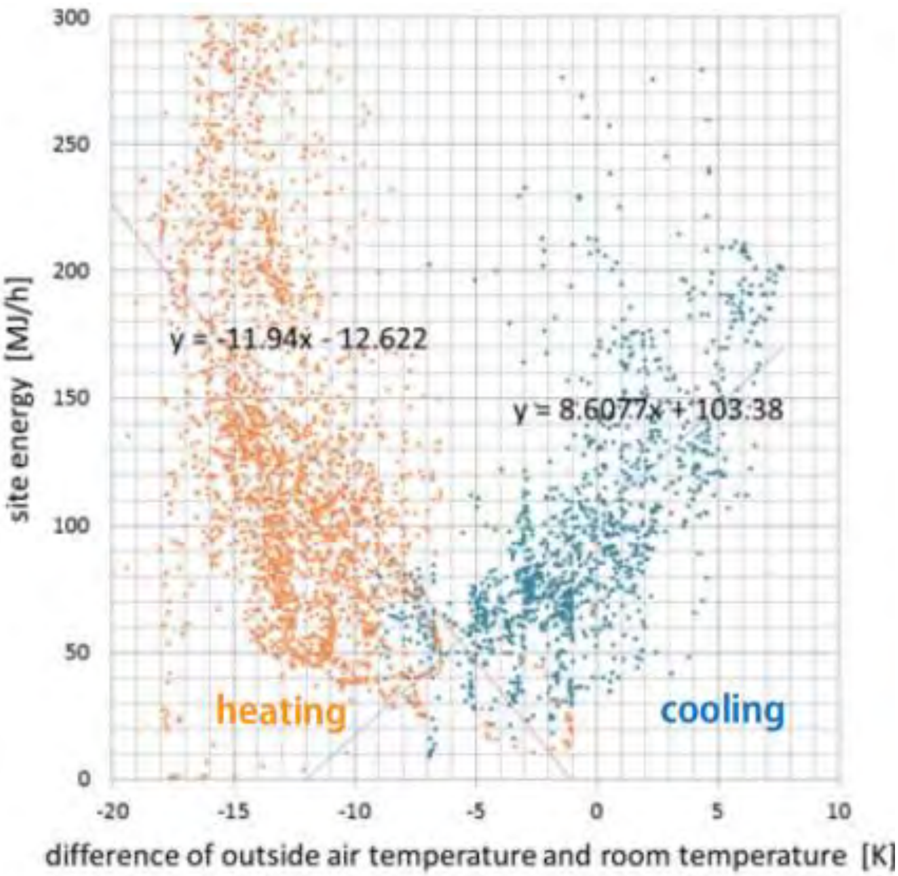

Figure 5: Energy savings from YKK actual temperature set point mitigation

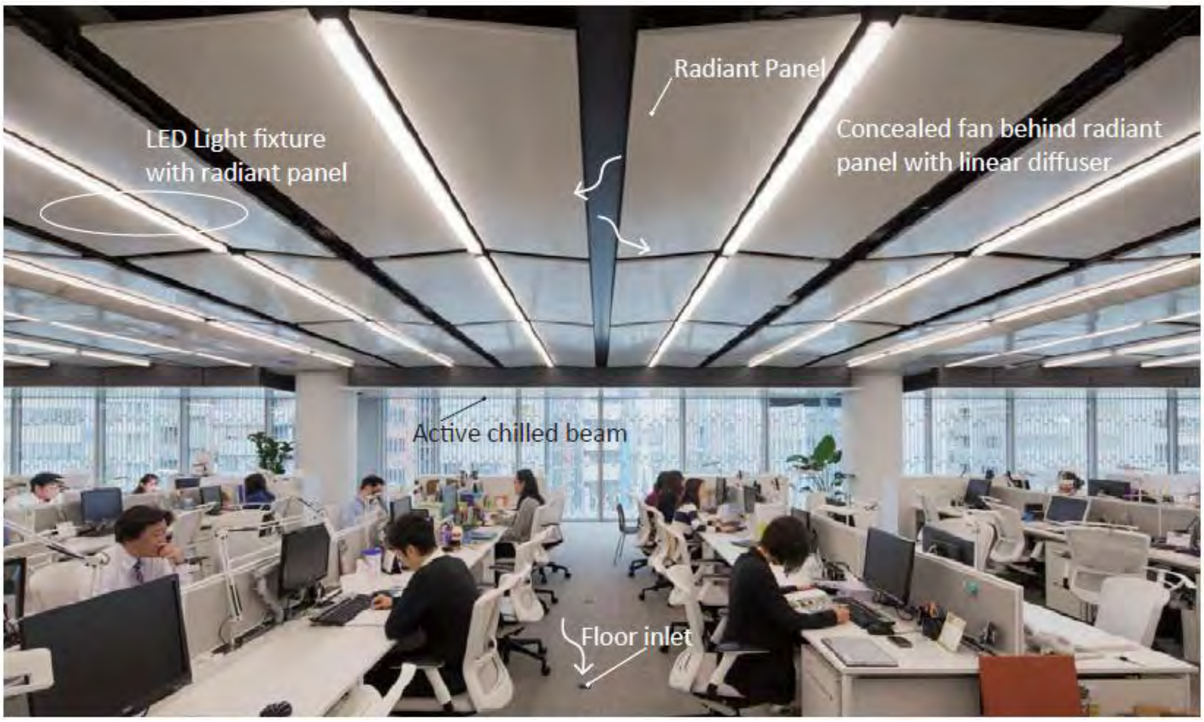

Photo 2: Interior image

Other energy reduction strategies include active plug-load management and geo-exchange. Each desk is equipped with an electric outlet or receptacle which is capable of showing electricity consumption for that desk. It is also equipped with a sensor which detects an occupant's presence and the power is automatically turned off when nobody is present.

Earth-to-air energy exchange occurs using a trench in the seismic isolation layer to preheat or precool outdoor air through an underground tunnel. In addition, well water for direct thermal exchange is used as an untapped natural resource in the lower level air handlers.

The final energy results are shown in both Table 1 and Figure 6. These results, when modeled using Energy Plus against an ASHRAE 90.1 baseline, demonstrate a 27.5% savings (site energy) and, when comparing actual results to the baseline, they indicate a 32.5% savings (site energy) and indicate a 53 % (source energy) savings compared to an average Tokyo regional office building.

	Site	Source
ASHRAE Baseline	153.65 kWh/m^2-yr (48.71 kBtu/ft^2-yr)	1,371 MJ/m^2-yr (120.74 kBtu/ft^2-yr)
Proposed (modeled)	111.40 kWh/m^2-yr (35.31 kBtu/ft^2-yr)	1,034 MJ/m^2-yr (91.06 kBtu/ ft^2-yr)
Actual	103.69 kWh/m^2-yr (32.87 kBtu/ft^2-yr)	932 MJ/m^2-yr (82.08 kBtu/ft^2-yr)

Table 1: Annual energy performance summary

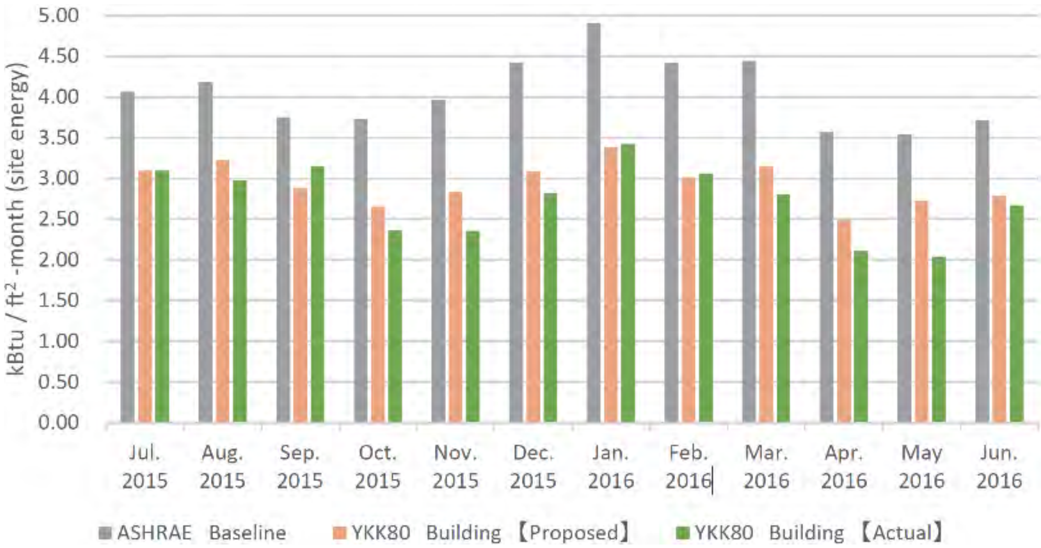

Figure 6: One year monthly operating data of building energy performance

3. INDOOR AIR QUALITY AND THERMAL COMFORT

Excellent indoor air quality is maintained throughout the year by utilizing air handling units with desiccant-based dehumidification, a Dedicated Outdoor Air System (DOAS) and proper control of the quantity of outdoor air based on CO_2 concentration. The minimum quantity of outside air, which is taken through the air handlers, is supplied to the space above the radiant ceiling panels. This air is continuously returned at the floor level and is then returned to the rooftop air handlers. Figure 7 shows indoor CO_2 concentration data on the vertical axis, which was measured by floor and time of day when the air handlers were in operation, and the average temperatures of each season (summer, shoulder seasons, and winter) on the horizontal axis. CO_2 concentration has been maintained around

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

707 ppm throughout the year, indicating very good air quality. Additionally, MERV 13 filtration of supply air was used to control respirable particulate matter, pollen and dust.

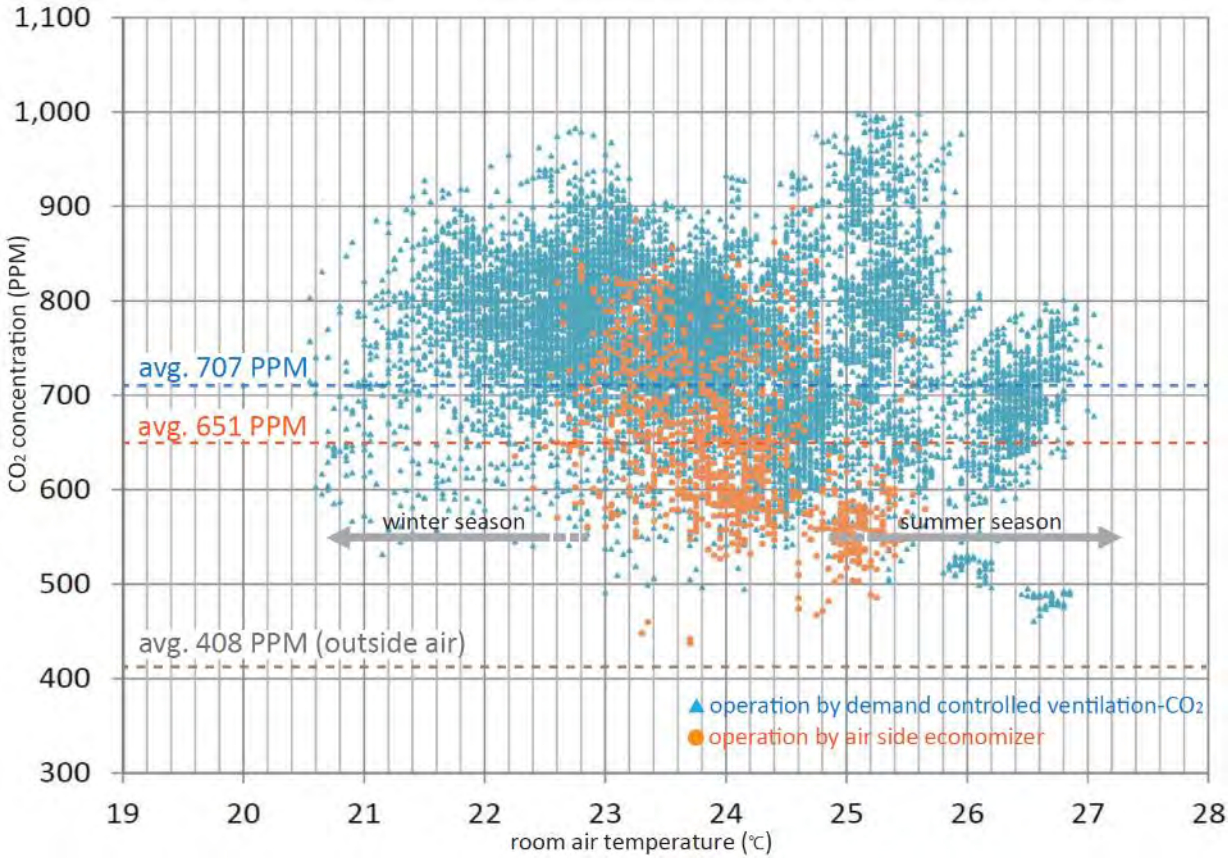

Figure 7: Relationship of CO_2 concentration and room temperature

Using a detailed 3-dimensional Building Information Model (BIM) and Computational Fluid Dynamics (CFD) comfort verification of the radiant cooling assisted by the slight air flow system was confirmed during the design phase. Additionally, experiments were conducted with subjects in a mock-up research laboratory to verify comfort in areas using the slight air flow (Figures 8, 9). Figure 10 shows the relationship between the room temperature, Predicted Mean Vote (PMV=0), Mean Radiant Temperature (MRT), and air speed-- referencing Thermal Comfort from the 2013 ASHRAE Fundamentals Handbook. It was determined that when the average radiant temperature is lower than the air temperature of the room, the room temperature could be increased by around 2ºC--from 26ºC to 28ºC (78.8ºF to 82.4 ºF)--keeping the PMV the same if the air is supplied with a slight air flow of 0.2 or 0.3m/s (0.66 or 0.98 ft/s) with a MRT of 25ºC (77 ºF). The mock-up research and lab experiment, with over 150 participants, confirmed comfort in over 75% of the participants using higher temperature set points with a slight air flow--demonstrating compliance with ASHRAE Standard 55-2010 (Figure 11).

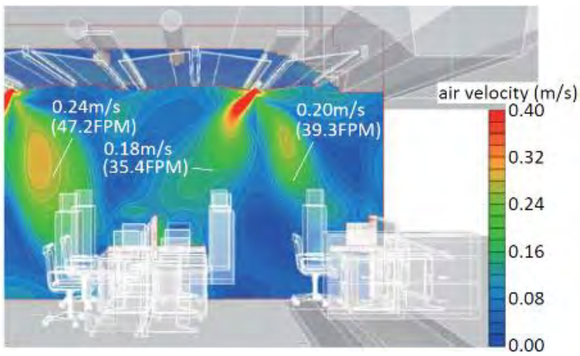

Figure 9: CFD coupled with BIM (air velocity)

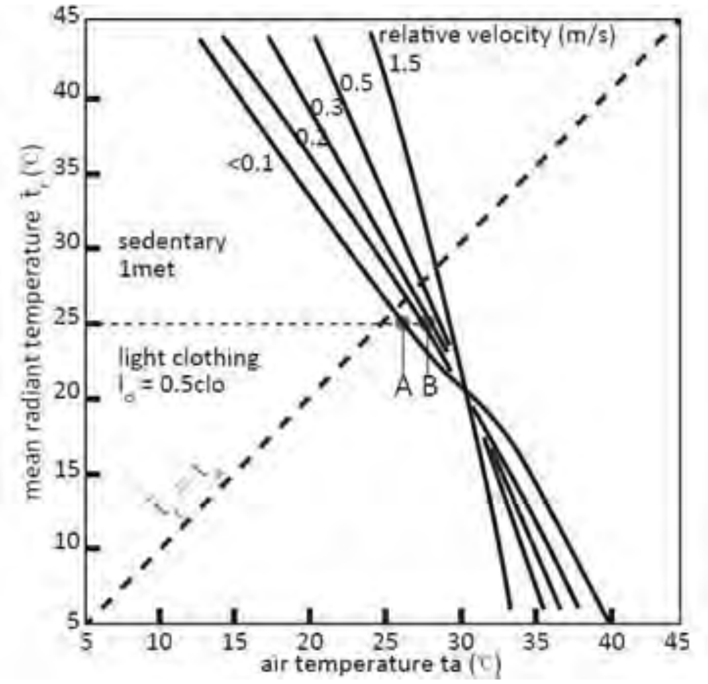

Figure 10: Air temperature and MRT necessary for comfort (PMV=0) of sedentary persons in summer clothing at 50% RH

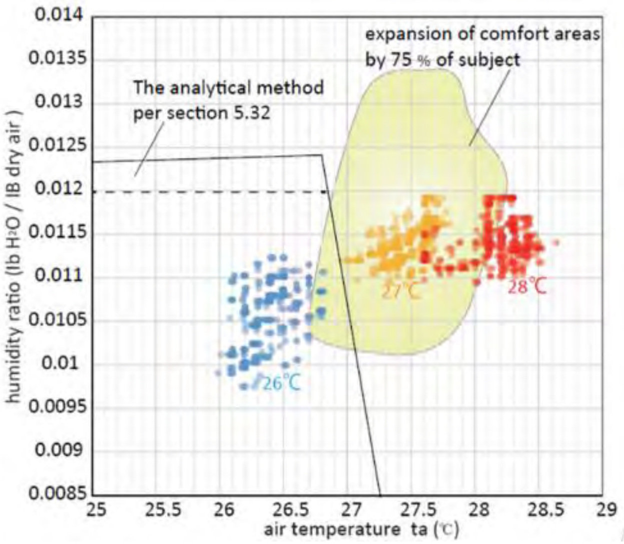

Figure 11: Expansion of comfort zone

4. INNOVATION

The real innovation of the YKK80 building was in meeting the challenges brought forth by the 3/11 disaster and the entire owner, design and construction teams commitment to utilize an integrated design process in response to that. The key innovations include: the multi-functional façade design, the “under-the-tree” breeze radiant cooling system, the design, mock-up and lab comfort verification process, and the enhanced commissioning and ongoing measurement and verification. Today, YKK80 is one of the lowest energy consuming offices in Japan with verified occupant comfort (Figure 12). Beyond energy savings and comfort, YKK invites visitors on regular facility tours and utilizes graphic-based data from their Building Energy Management System (BEMS) to communicate the value of energy and water reduction strategies. Another innovation feature is a state-of-the-art, real-time earthquake detection system designed to provide immediate response and safety information for occupants. The entire building rests on seismic isolation pads.

5. OPERATION AND MAINTENANCE

Two years of performance verification was included in each team members contract and uses sophisticated BEMS data to support operation and maintenance. The entire team (owner, designer, contractor, manufacturers, and operators) will participate in this ongoing performance verification until two years after occupancy. Detailed real time monitoring of energy and environmental systems (cooling/heating, plumbing systems, water use, electricity, and lighting) is provided by the Building Automation System (BAS). This information is reported monthly at a commissioning meeting and contributes to ongoing energy-savings and improved occupant comfort. Figure 6 on page 5 shows one year of actual monthly operating data as compared to the ASHRAE baseline and energy simulation.

6. COST EFFECTIVENESS

YKK80 utilized an integrated design process to optimize the whole building as a system and to utilize single elements, such as the sudare screen or the sloped radiant ceiling panels, for multiple functions. Still, the initial investment was greater than a conventional similar office building. The increase in the initial (2013) investment was JPY720 million (~$7.2 million USD) or JPY34,418/m^2 (~$32 USD/$ft^2$). The present day utility cost savings are JPY66 million (~$630,000 USD) per year, or JPY 3,155/m^2 ($2.8/$ft^2$), which is 52% less than a similar sized Tokyo office building. Using a simple payback analysis, this will require just under 11 years to pay back the additional investment—assuming utility costs do not increase. It should be noted that even with a modest productivity gain of 5% (much higher increases have been documented in other green office buildings) this 11 year payback period would be less than 2 years.

7. ENVIRONMENT IMPACT

The actual reduction in CO_2 emissions is 22.6kg-CO_2/m^2 (4.64 lbs/ft^2) or 32% below the baseline (CO_2 emission factor in Tokyo, Japan, Electricity: 0.496kg-CO_2/kWh ; Natural Gas: 2.23kg-CO_2/kWh ; Tap Water: 3.129kg-CO_2/m^3).This building also incorporated high-efficiency water-saving equipment (water closets: 3.8L (1 gallon US) water per flush, faucets with 14 second shut-off timer), and currently consumes 65% less tap water than that of an ordinary office building in Japan. In addition, 100% of the non-tap water necessary for a bio-film process is provided using treated wastewater and reclaimed rain water.

8. SOCIAL ENGAGEMENT/ CONCLUSION

YKK understands the importance of being a good corporate citizen and integrating themselves with the local community. Examples of their community engagement include: utilizing outdoor plants (with signage) on their site that have been present in their neighbourhood since the Edo period; promoting farm-to-table food utilizing their rooftop garden; and offering local handicraft manufacturer's opportunities to hold workshops and exhibition events using the area around the building entrance. YKK staff also participate in the local traditional festival and allow their lobby to be used for displaying the "Mikoshi" or sacred portable shrine.

Based on the latest data from Tokyo Metropolitan Government, YKK80 energy performance is in the top 1% of the 465 buildings sampled.

Focusing on the initial project goals of energy-savings, comfort, health, seismic safety and cost-effectiveness in the life cycle design, the YKK80 building has clearly met, and even exceeded these goals—providing a new benchmark for green office buildings in Japan.

ABSTRACT

Taikoo Place Phase 2A Tower (TKP2A) is Swire Properties Ltd new and prestigious office development project. It is redeveloping Somerset House in Taikoo Place on Quarry Bay, Hong Kong with a target occupation date in 2018. The key objective of TKP2A is to develop a best in class, green and sustainable building from demolition, design, construction to operation. This will be a leader of high performance sustainable buildings in Hong Kong.

TKP2A embraces modern integrated design. This positions sustainability at the key elements of design and brings the design team together from the earliest project stage to jointly develop solutions. This fosters innovation and the application of new technologies and processes.

With the desire for TKP2A, to push low carbon construction significantly beyond what had already been achieved across current Swire's Building properties it was essential to approach design from a non-conventional starting point. From this early vision a design team was formed, with green and sustainability as the core values at the heart forming a design platform and integrating the multidisciplinary design team together with various departments from Swire Properties. At this early stage, project goals were set and every member of team was empowered to develop towards these goals through design charettes and regular workshops. This ensured that future challenges were identified early and mitigated, enabling a new level of low carbon construction to be attained.

This integrated design process and key elements of design are discussed in this paper.

Keywords: integrated design, sustainable construction, high performance

1. INTRODUCTION

Taikoo Place Phase 2A Tower (TKP2A) is Swire Properties Ltd new and prestigious office development project. It is redeveloping Somerset House in Taikoo Place on Quarry Bay, Hong Kong with a target occupation date in 2018.

The key objective of TKP2A is to develop a best in class, green and sustainable building from demolition, design, construction to operation. This will be a leader of high performance sustainable buildings in Hong Kong.

TKP2A embraces modern integrated design. This positions sustainability at the heart of design and brings the design team together from the earliest project stage to jointly develop solutions. This fosters innovation and the application of new technologies and processes.

With the desire for TKP2A, to push low carbon construction significantly beyond what had already been achieved across Swire's Building Stock it was essential to approach design from a non-conventional starting point. From this early vision a design team was formed, with Arup's Building Sustainability group at the heart providing design platforms and integrating the multidisciplinary design team. At this early stage, project goals were set and every member of team was empowered to develop towards these goals through design charettes and regular workshops. This ensured that future challenges were identified early and mitigated, enabling a new level of low carbon construction to be attained.

This integrated design process and key elements of design are summarised in this paper.

Figure 1: Rendering of TKP2A

2. INTEGRATED APPROACH TO HIGH PERFORMANCE BUILDING

Sustainability in the context of today's building market has taken on a holistic nature where many different initiatives are required to interact to enhance and sustain the triple bottom line: environmental, social and economic drivers.

The design of the building must embed systems, technologies and interfaces that enable operators and occupants to achieve the highest sustainable performance throughout the buildings life.

Excellent cross-team coordination and integration work is crucial for the project to achieve real performance enhancements. Starting from the early design stage, the TKP2A project team together with Swire Properties building operational team and Swire Properties sustainability team had a deep involvement in the TKP2A design. This wealth of building operation experience was essential in developing design driver. As such, TKP2A was designed by occupant and operational needs. The measured energy performance data of several buildings in Taikoo Place was given to the design team for them to identify a genuine energy performance benchmark. The design team could then test the performance of various green strategies against this benchmark.

A number of charrettes occurred across the project team, design team and operational teams at early stage. These included facade, sustainability, mechanical and electrical systems, demolition, green construction etc. The charrette acted as a communication platform to highlight the requirements of performance quantification, operational and maintenance activity, design constraints etc. It was a key and successful tool in project delivery.

3. SUSTAINABLE DEMOLITION

To first task was the demolition of Somerset House. As such a sustainable waste management plan was developed. Sustainable demolition aims to minimise the use of resources, i.e minimising waste sent to landfill.

Through in depth discussions with the structural engineer an understanding of the safe execution of demolition processes, waste handling procedures and waste sorting methods were developed. Then a sustainable waste management strategy was proposed which outlined demolition waste and material treatment. Three hierarchal principles were followed:

Waste avoidance

Reuse of materials is the most effective way to minimise waste generation, Swire Properties collaborated with local charities to donate fixtures and fitting for onward distribution to the needy. This extends the fittings service life and

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

avoids waste by reuse of good quality of interior fittings such as furniture, carpet, electrical appliances and equipment. A number of local charities or institutes are in operation e.g. Crossroad, Industrial Relation Institute etc. There are also some waste recycling programs organized by local government e.g. Computer Recycling Programme by the Environment Protection Department which will collect donated computers and electrical appliances for onward distribution.

Waste recovery

After all reusable materials are taken out, the materials are then processed for recycling. The main source of waste is the permanent structure of Somerset House accounting for over 86% of waste by weight of the whole project, over 70,000 tonnes. There are several waste concrete recyclers in Hong Kong. Over 75% of the broken concrete (normally smaller than 400mm in size), plus other inert C&D waste including rocks, boulders, rubble and bricks were distributed to local recyclers for recycling. These inert wastes go through a series of crushing and screening processes to become recycled aggregates of different grades. Recycled aggregates serve a wide range of applications including road sub-bases, filter layers, ingredients in concrete and the filling of bridge columns. The broken concrete will also mix with the recycled glass sand and titanium dioxide to form eco-paving blocks which will be re-utilised in hard landscaping.

Another major source of waste is the reinforcing steel bars in concrete structures and aluminium scraps from window frames. Processes for metal recycling are common and these materials were easy to recycle.

The overall performance of demolition waste recycling for TKP2A is over 75% by accounting for waste not taken to the local public fill. Approximately 35,300tons of embodied carbon was be saved by the reduction of virgin materials.

Figure 2: Recycling of waste metal in TKP2A project during demolition

4. LOW CARBON CONSTRUCTION

Swire Properties take a great effort on the sustainable development industry. With closely collaboration with Swire's Technical Services and Sustainability Department (TSSD), the embodied carbon for material selection and carbon emission during construction has been evaluated and managed properly.

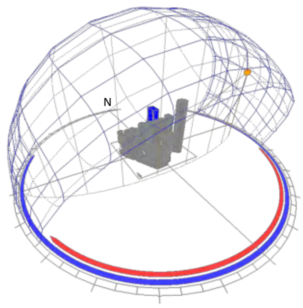
The embodied carbon of building materials can be taken as the total carbon emissions released over its life cycle. This includes the process of extraction, manufacturing and transportation. Several low carbon construction strategies have been considered during the initial design stage in order to avoid large wastages of materials in TKP2A tower.

4.1 Utilization of low carbon material

Use of high recycled content materials which are regionally sourced can significantly reduce the emissions of embodied carbon from transportation and raw material extraction and manufacturing. Strategies to reduce of all these factors were considered.

Concrete mixed fly ash – TKP2A uses fly ash to replace cementious material in concrete, as cement has a very high embodied carbon content to add significant benefit.

Reinforcement steel is a major material in high rise buildings. It is common to adopt around 10% to 20% recycled metal into the steel.



Use of regionally manufactured and sourced materials within the project can effectively reduce transportation carbon emissions. According to the international green building certification system – LEED Core and Shell, a regional material is defined as material which is extracted and manufactured locally within 800km of the site. The overall target of recycled content of materials and regional manufactured material is 20%.

4.2 Higher flexibility for interior layout design

With the collaboration with architectural and structural design team, a range of initiatives are adopted in the design in order to avoid excessive material consumption and wastage due to frequent changes of tenant layout.

Knock-out panels were designed into the floor slabs. These reduce the additional renovation works for the installation of internal escalators or staircases by future tenants. Integration with the structural engineer is required in order to locate this movable panel into the building structure.

Application of digitally addressable wireless control systems for lighting. This allows for the easy adoption of various zoning and lighting control strategies based on tenant's needs by programming and eliminating any additional wiring works for future tenant rezoning. Installation of additional energy saving controls e.g. occupancy sensor, daylight harvesting is relatively simple when using wireless control systems.

5. IN USE ENERGY CONSUMPTION & CARBON EMISSIONS

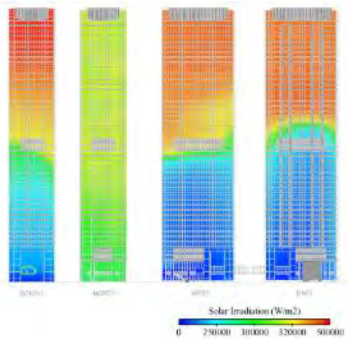
TKP2A has been designed to minimise operational carbon emissions. This requires a number of integrated initiatives across the energy design hierarchy. Through the design platforms, design charettes and integrating the multidisciplinary design team at this early stage, the building operational consideration and the characteristic of energy consumption for existing buildings nearby the project site has been referred and a more suitable design approach that fit the needs for TKP2A has been identified. This design hierarchy ensures that building loads are minimised with passive design before they are served with highly efficient active services and finally grid supplied electricity is replaced with renewable energy.

5.1 Passive design

Passive energy design is reduction of building loads with the use of architectural features. The excellent thermal properties (solar controlled glazing and opaque insulation) of the building envelope effectively insulates the building from Hong Kong's hot climate.

The external shading devices which were designed in response to TKP2A's solar environment, help to further block the unwanted solar heat gain throughout the year. The overall OTTV of proposed model is around 19W/sq.m. in the office tower as compared to the statutory maximum OTTV requirement for offices of 24W/sq.m.

At the same time as blocking solar heat gain the glazing also allows the whole office tower to experience daylight. Artificial lighting is automatically dimmed when daylight is present. This reduces artificial lighting energy consumption.



From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 3: Sun path analysis and solar heat gain study from building envelope

5.2 Active design

TKP2A includes a range of energy saving systems which enable the building to substantially reduce energy consumption beyond local and international code. With collaboration with architectural team, building services design consultant and Swire TSSD and Taikoo Place Management Office (TPMO), a selection of the key systems are noted here.

High Performance Chiller and Plant Optimization. Cutting edge, high performance centrifugal variable speed chillers and optimised chiller sequencing will deliver cooling effectively for the buildings life. Starting from the review of chiller plant operational data from existing buildings, together with the consideration of condenser water temperature and building loads, chillers dynamically adjust and operate at the optimum efficiency in order to obtain an optimization control and operation. This strategy obtained around 5% of total building energy consumption.

100% Free Cooling and Air Economisers. The side core design in TKP2A enables floor by floor fresh air intakes. This in turn increases the potential fresh air intake volume allowing 100% free cooling with an air economising. This cooled air system enables a chiller bypass when the outdoor conditions are cooler.

Demand Control Ventilation. Carbon dioxide (CO2) levels are a good measure for the fresh air requirements as people breathe out CO2 and require more fresh air. CO2 monitoring systems in the office area of TKP2A detect the occupancy levels so that the amount of fresh air can be adjusted in accordance with the demand. A similar system in the car parks detects carbon monoxide. These detectors are installed in basement car parks to monitor the pollutant concentration levels and modulate fresh air delivery based on traffic conditions.

Energy recovery

When stale and cold air is exhausted from buildings it contains useful energy, heat recovery collects this useful energy for use in the building. The high efficiency heat wheel has been designed to recover energy from office and toilet exhausts.

High efficient lighting

Lighting energy is a major consumer of energy in office buildings. The lighting design has, optimised lighting lux levels, high energy efficient light tubes and high reflective luminaires as well as an effective lighting grid arrangement. These measures reduce lighting power levels by almost 40% compared to local code levels.

Efficient air movement

Moving air around buildings with fans consumes significantly quantities of energy. High efficiency fans with brushless direct drive motors (EC plug fan) are a new technology which reduce fan energy consumption by almost 20%.

The overall building energy saving for the proposed TKP2A is about 33% as compared to the HK Building Energy Code Version 2012 as baseline. The annual building energy cost saving is about 28% as compared to the ASHRAE Standard 90.1 (2004) baseline setting.

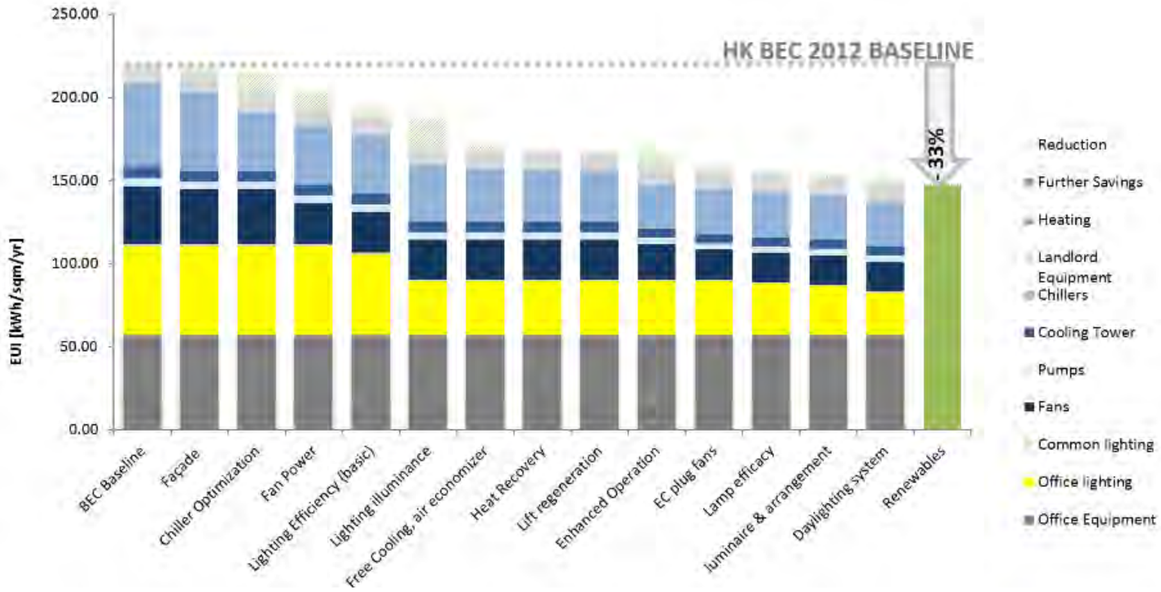


Figure 4: Annual energy reduction of TKP2A from HK BEC 2012 baseline

5.3 Waste to renewable energy

After application of passive strategy and active system, large portion of building energy has been reduced. On-site renewable energy generation is one of the strategy to further reduce the residual energy of the building. For a high-rise high energy intensity building with limited building footprint and usable roof area, TKP2A pushed the boundaries and worked with the government to introduce waste cooking oil power generation. A commercial building first in Hong Kong.

In Hong Kong, an estimation of 20,000 tons used cooking oil and 175,000 tons of grease trap waste each year are generated from eateries and food businesses which is typically disposed of at landfill. Hong Kong's landfill sites are going to be exhausted by 2020. The Environmental Bureau has set a target of a 40% reduction in food waste to landfill by 2022. To help achieve this, food waste can be used for bio-diesel production. Biodiesel is normally made from feedstock such as used cooking oil, grease or disposed animal fats.

The 200 kW (electricity) bio-diesel generator proposed for TKP2A consumes 540L a day approximatly of B100 grade bio-diesel made of 100% food waste. Eventually around 135,000L of waste cooking oil will be reused annually. Provided the waste oil production from F&B tenants and hotels in Swire's protfoilos approximates 20,400L annually, all the used cooking oil could be utilized by the power generation plant. 15% oil demand of generator is fulfilled and there is sufficient capacity to take up more waste cooking oil from other from eateries and food businesses. As such TKP2A bio-diesel generator completes the cycle of waste-to-energy for the community.

The generator provides electricity for the building and the waste heat from the generators is used to generate cooling. This energy cascade maximises the usable energy from the system. In energy terms, over 400 MWhrs of renewable energy is generated. It is equal to 278 tons of CO_2 emission being off-set by 1400 trees. It provides over 2% of the total building electricity consumption.

5.4 Wind performance and outdoor comfort at open space

The new development will contain a range of public spaces, streetscape amenities and a new elevated walkway corridor naming Taikoo Plaza and Taikoo Gardens that will enhance the setting and context of a distinctive and emerging area of Hong Kong. The concept for this landscape proposal is a contemporary reinterpretation of the landscape that surrounds the city of Hong Kong with its particular geological nature and cultural refinement through craftsmanship using noble materials.

Figure 8: Masterplan of Taikoo Place

Vegetation

Provide highly vegetated areas and dense planting to reduce urban heat island effect and improve the micro-climate within the scheme. Address the green ratio requirements. It also minimizes the impact on urban heat island effect. Compared to the existing development having 3 buildings, the current building plan with massive public space and greenery obtain around 2ºC reduction at local area.

Sustainability

Provide an enhanced environment to the neighbourhood where sustainable techniques can be included to mitigate energy use, water consumption, air pollution and bring a potential layer of biodiversity into the site especially within the core landscape areas. Provide an enhanced environment to the neighbourhood where sustainable landscaping techniques can be included to reduce energy use and water consumption and mitigate air pollution as well as urban heat island effect.

Social connectivity

Create an inclusive landscape and open space framework that encourages outdoor activities, promenading and passive recreational activities, where residents, workers and visitors can have an enjoyable and calm experience relaxing, meeting and mingling in an outstanding urban landscape.

6. FURTHER SUSTAINABILITY

Other than the material use reduction and operational carbon emission reduction, the project team also considered other sustainable design elements which further enhanced the building performance and thus beneficial to the building occupants.

6.1 Performance verification of design elements

Project team put an effort on the performance verification and design review on the system and key design elements by modelling and simulation. For example, a computational fluid dynamic (CFD) model has been applied to verify the air distribution effectiveness of AC system. The solar irradiation with 3D rendering tool has also been applied to verify the performance of PV system and analyses the reflective glare impact to surrounding buildings. It built up a sophisticated quality control measures for TKP2A and a new practice to future projects.

6.2 Enhancement to future tenants and building operators

With an integrated collaboration among the architect and MEP engineers during design stage, additional centralized exhaust systems were designed into the central core. These are available for future tenants to connect their individual exhaust ducts to for air exchange during fit-out periods. This minimizes the spreading of odours and cross contamination between tenants. Further collaboration with operational and maintenance team would help to understand further the needs and criteria from the building users. Earlier involvement with O&M team would also help enhancing a more user-oriented design to this project.

7. CONCLUSION

The demolition, construction and ongoing maintenance of buildings consumes significant quantities of resources. This is particularly prevalent in the higher end property market which demands the best of current provisions. As such TKP2A followed a focused approach to sustainability where by all possible efforts were made to reduce resource consumption. As was noted in this paper, this process was driven by Arup's Building Sustainability team, and involved the integration of all members of the design team, project team and operation teams from the early stage to realize the vision of Swire Properties.

(4) The Secret Ingredients of Sustainable Real Estate Development Session Organiser: Swire Properties Ltd.

Session 4.7

SESSION OUTLINE

What constitutes a sustainable built environment? And how do the myriad of stakeholders involved contribute and collaborate to this objective?

Beyond high performance buildings, engagement and collaboration with building users, the community, and other parties are essential to making and keeping sustainable places. This session will establish a platform with experts from a range of disciplines to discuss:

- The environmental, social, and economic factors that make up a sustainable built environment
- The role of impact measurement and data transparency in supporting sustainable real estate development
- The complexities of managing climate change in real estate

With the aim of bringing a broader view to the management requirements for a sustainable built environment, this session aims to the support the conference theme of “Putting Ideas into Action”.

SESSION CHAIR

Ashley HEGLAND, Consultant, Swire Properties Ltd.

SPEAKERS AND PRESENTATION TOPICS

1. Themes/Trends of Sustainable Urban Planning and Sustainable Built Environment
   Christopher LAW, Founing Director, Oval Partnership, Hong Kong SAR

(5) Emerging Practices in Sustainable Built Environment
Session Organiser: Allied Environmental Consultants Ltd.

Session 3.12

SESSION OUTLINE

Themed "Emerging Practices in Sustainable Built Environment", this 90-minute Parallel Session (hereinafter the "Session") will focus on how sustainability best practices can be applied to local buildings with the aid of case studies.

In general, a typical building has a "lifespan" of over 50 years. It is without doubt that operation and maintenance phase plays an important role in the environmental performance of a building throughout its life cycle. One of the common lessons learned from the case studies is the importance of a "body check-up" for buildings through conducting regular audits to collect data, which provide the basis for identifying areas of improvement and enhancing environmental performance. A few case studies also demonstrate another way of improving environmental performance through collecting feedback from stakeholders such as staff members. These role models serve as good examples of stakeholder engagement when it comes to enhancing sustainability of buildings.

The Session will first begin with individual presentations, followed by a question-and-answer session, where speakers and audience will exchange insights on the topics presented.

SESSION CHAIR

ABSTRACT

As one of the world's most competitive cities, Hong Kong has a growing shortage of undergraduate places. This increase in demand for tertiary education drives vigorous campus development and expansion.

Being one of the self-financed higher education institutions in Hong Kong, Hang Seng Management College ("HSMC") has undergone a strategic campus expansion plan with the commitment towards sustainable growth and development while maintaining the quality of built environment and optimising usage of existing and new facilities to meet needs and expectations of students. This paper presents how HSMC tallies campus development projects toward their sustainability goals through (1) green campus design in master planning; (2) on-going building operation and maintenance; and (3) stakeholders' engagement. Buildings under the campus development project have garnered the final platinum and provisional platinum rating respectively under the BEAM Plus for New Buildings, which is a Hong Kong's green building assessment scheme. The successful story of HSMC campus development shall serve as a model for future school or campus development of similar scale in Hong Kong and on an international stage.

Keywords: sustainability, sustainable campus, green building design, maintenance and operation, stakeholder engagement, green education, community outreach, holistic approach

1. INTRODUCTION

Hang Seng Management College (hereinafter "the College") is a non-profit-making private university-level institution aims to be a leading private university pursuing excellence in teaching, learning and research in Hong Kong. Established in 2010, it was restructured from the former Hang Seng School of Commerce. College facilities and services has been highlighted as one of the strategic focus areas in the College Strategic Plan 2013 – 2018 – Road map to University and Beyond. Key strategies include affording a modern and stimulating campus environment to facilitate and support teaching and learning activities by expanding the original campus.

Sustainable campus concept was integrated in its Master Campus Expansion Plan and the newly developed premises were awarded the highest Platinum Rating under the BEAM Plus for New Buildings which is a comprehensive environmental assessment scheme for buildings in Hong Kong. The Master Campus Expansion Plan has demonstrated the College's commitment to support local sustainability development as well as its leadership role in teaching environmentally social behaviour and its status as a world-class institution.

1.1 Project overview

The Master Campus Expansion Plan aims at expanding the physical facilities of the College from the original Hang Seng School of Commerce campus and buildings located in Sha Tin. In the Master Campus Expansion Plan, four new buildings were developed under Phase I and Phase II. They were the S H Ho Academic Building (Block A), the Sports and Amenities Centre (Block B) and the Lee Quo Wei Academic Building (Block D) and which comprise a total GFA of about 34,000 m^2 as well as the HSMC Jockey Club Residential Colleges (Site F) comprising three resident blocks housing 1,200 students.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 1: 3D rendering of the campus of Hang Seng Management College

1.2 Sustainable campus approaches

Hang Seng Management College endeavours to maintain a sustainable growth in campus development. As a campus for 21st Century, the College recognises a greater social awareness and demand in the industry and community. Thereby, the College adopted sustainable campus approach which can demonstrate the mission of an educational institution to communicate a sustainable future to young generations.

The campus is not only conceived as a physical space for activities but also a learning campus where students can participate and understand sustainable issues through daily use of the buildings. During the design and construction stages, the concept of sustainable campus was realised by embracing a variety of green design features and the new buildings were awarded Final Platinum (Block A, Block B, Block D) and Provision Platinum (Site F) under the BEAM Plus for New Buildings.

Beyond the design and construction stages of the buildings, sustainable considerations are also integrated into on-going building operation and maintenance with a series of stakeholder engagement programme in maintaining a sustainable campus. The College is a showcase of a holistic development of a sustainable campus in terms of the following approaches:

- Green campus design
- On-going building operation and maintenance
- Stakeholder engagement and community outreach

2. GREEN CAMPUS DESIGN

The development of a sustainable campus started with the conceptual stage of the expansion project. The College adopted a variety of green designs and features in the development of sustainable campus.

2.1 Site planning and design issues

The College took a proactive approach to integrate green elements into site design in order to minimise the adverse impact of the campus expansion to the locality and to enhance the site and its surrounding neighbourhood. The site design fulfilled 100% of all relevant sub-items in the Urban Design Guidelines in Hong Kong Planning Standard and Guidelines. Particularly, a stepped height design approach was adopted for the entire site to optimise the building massing which reserved a visual corridor viewing the ridgeline of Tate's Cairn and allowed a visual connection existing greenery slope from different angles away from the site.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

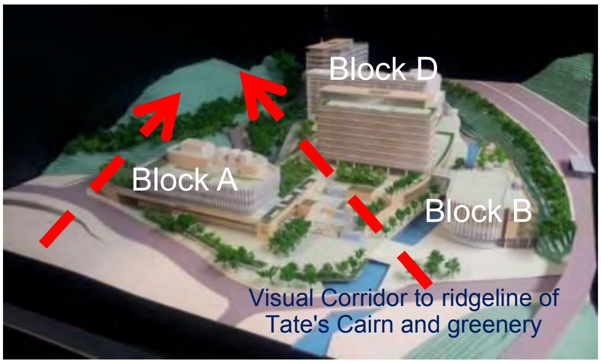

Figure 2: Illustration of stepped height design approach

Within the site, extensive greenery was given more than the statutory requirement for the improvement of the site ecological value while its social value was not overlooked. More than 30% of soft landscape was well blended with different recreation provisions each as lawn, farm, shade for seating facilities, and plaza to provide pleasant environment for students socialisation. Bamboo which is fast-growing, highly adaptable and good at CO_2 absorption was selected as the major species to further maximise the environmental benefits.

Figure 3: Bamboo planting in campus

The design of the site is to realise students' socialisation and personal growth which cannot be distinguished in modern education. With the Open Campus Policy, the greenery, open space, outdoor sitting areas and bicycle racks were provided to encourage site usage by locals and public so as to enhance the liveability of the surrounding areas for the seek of a sustainable neighbourhood.

2.2 Life cycle perspectives in building materials

A careful selection and design in building materials and assembly from cradle-to-grave can greatly improve the building sustainability. Loose fit design was adopted to give flexibility of the multipurpose space to cope with activity changes over time. Modular glass wall partitions inside library are fully demountable, reusable and recyclable, and the partitions are kept away from the false ceiling to avoid disruption due to physical changes in the future. Standardised ceiling panels, doors and classroom furniture was adopted to enable different arrangement with minimum extra components.

Having a tremendously faster growth rate than trees, bamboo is a one of the solutions to preserve trees. The College applied Bamboo extensively in interior fitting-out works and classroom furniture such as bamboo chairs, working tables and shelves. The selection of rapidly renewable products greatly reduced the carbon footprint of a building.

Figure 3: A collection of bamboo furniture

2.3 High performance cooling design and energy efficient system

Given the high proportion of total campus energy consumption in air conditioning system, the College looked for various efficient designs and modern technologies to enhance the energy efficiency and reduce the energy use. The cluster of newly developed buildings enables the condition for developing a Central Chiller Plant System. With the advantage of economy of scale, the Central Chiller Plant which consists of two 950 TR Chillers and two 250TR Chillers can sufficiently provide the cooling for the whole campus. This arrangement reduces the overall cooling capacity with less diversity factor compared with a de-centralised chiller plant for each building, thus, energy consumption can be reduced with the same cooling demand.

To infuse innovative ideas into the detailed design, chilled ceiling system were installed in the Lee Quo Wei Academic Building. This system could significantly reduce annual energy consumption cost of MVAC by 20% in the first year operation. The system also has an active control of fresh air supply with no return air which prevent the cross infection and the spread of disease with sufficient supply of fresh air. The design demonstrates how an efficient system reduces energy consumption without the compromises of services quality. To further reduce the carbon footprint of the site in combating climate change, renewable energy such as PV panels were installed on the roof floor of each buildings residential blocks in the College which could offset 4.3% energy use in common area.

Figure 4: On-site overview of chilled ceiling air conditioning system

2.4 Rainwater and grey water recycling

Utilisation and conservation of water resources is a crucial part of green building design. Simply the application of water saving faucets as well as water closet and urinal devices, the College can achieve an annual fresh water saving by more than 25% and an annual sewage discharge reduction by more than 35% respectively.

Furthermore, rainwater harvesting system was installed to better utilise water resources. The system which consists of pneumatic pump sets and filtration system distributes the treated rainwater to the water tanks for cleansing, irrigation and AC condenser water make-up installations. It is estimated that reclaimed water recycled from rainwater is 2,250 m^3/year. With the provision of residence for the students, there is a great amount of domestic wastewater where grey water recycling was regarded as a possible measure in utilising water resources. Grey Water Recycling Treatment Plant was installed in residence blocks which employs a compact biological process and submerged aerated filter. Annual grey water recycled from showers and basin is estimated to be 2,700 m^3/year.

2.5 Pleasant indoor environment

Considered that the exposure to daylight can improve heath and studying performance, the building design optimised the site topography, layouts in interior spatial design and fenestration design so as to maximise the access of daylight. To prevent glare effect on the building users at the Sports and Amenities Centre, additional shading device system was installed. It also avoids direct view from the outside to protect privacy of the building users.

Indoor air quality is another critical factors for the health and comfort of the building users. Low-emitting paint and sealant were selected for interior fitting out works. Measurements on parameters of both outdoor and indoor pollution sources were also conducted before occupancy according to the benchmark of IAQ Certification Scheme of Hong Kong Environmental Protection Department. The measurement results demonstrated a satisfactory indoor air quality and the Excellent Class of IAQ Objectives were achieved.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Allowing an undisturbed teaching and living environment for teachers and students, acoustic windows were installed in the residential blocks to mitigate the traffic noise induced from Tate's Cairn Highway; environmental-friendly bamboo acoustic wall panels were installed in the lecture hall to suit the associated reverberation time for speech clarity; partition with excellent sound insulation and absorption performance were also adopted.

3. ON-GOING BUILDING OPERATION AND MAINTENANCE

On-going building operation and maintenance is an unneglectable part to retain the sustainable campus after occupancy. As a benchmarking, the College is targeted to go through the BEAM Plus for Existing Buildings with the support of the Consultant Team. Several aspects are highlighted to demonstrate the upcoming plan towards a sustainable campus.

3.1. Building management system

In order to better manage the building operation performance, the College installed building management system (BMS) in support of the management of lighting system and MVAC system in particular. This system provides instant data of the operational energy use allocation and demand pattern as well as easy diagnosis of system failure for maintenance. Operation data such as pressure, temperature, flow rate, on/off status for monitoring operation and function are recorded by the system. This enables management to review the overall energy policies and targets in the campus operation based on real life data and analysis.

3.2. Monitoring and audit

It is essential to have continuous monitoring on the environmental performance in order to demonstrate the commitment of a sustainable campus development. Auditing tools such as energy audit, carbon audit and waste audit which comprises a process of inspection, survey and analysis of the energy and resources consumption flow as well as the waste generation streams can help assess the building performance and identify opportunities for improvement. With the assistance of Consultant Team, the auditing systems will enable a continuous improvement in sustainable performance.

3.3. Waste management system

While extensive waste management practice was implemented during the construction period of the College, waste management strategies and categories during the building operation will be greatly altered. As the College is providing resident places for students, food waste is one of the strategic focus on waste reduction. Food waste recycling scheme has been initiated for waste reduction in the College canteen. The food waste will be delivered to a composter for processing. The treated food waste will then be used as the organic fertilisers and applied on the organic farm on the roof top of the Sports and Amenities Centre. The food waste recycling scheme not only serves as a solution in reducing food waste generation, it can also arouse the 3R concepts of reduce, reuse and recycle within the campus.

Figure 5: Organic farm on the rooftop

4. STAKEHOLDER ENGAGEMENT AND COMMUNITY OUTREACH

Human culture and knowledge are always an indispensable part in driven a sustainable future. Engaging stakeholders in the process of sustainable campus development enables direct feedback of users' satisfaction on building performance and increases the buy in of sustainable initiatives. As an educational institution, the College also intends to advocate sustainable campus development through green education and community outreach programme.

4.1 Sustainability and feedback loops

To strive for a long term sustainable development of the campus, a Working Group on Energy Conservation and Sustainability was formed in 2015 to identify and facilitate implementation of practical measures on energy conservation and sustainability by engaging staff and students. It comprises staff members from the Campus Development and Management Office, Information Technology Services Centre, Student Affairs Office, Vice-President (Organisational Development)'s Office and student representatives who are all major stakeholders of the campus. The Working Group is responsible for conducting regular review of the energy consumption level and measures on sustainability, and identifying practical College-wide initiatives and communication channels to staff, students and the wider community relating to energy conservation and sustainability with the mission to raise awareness of sustainability.

Feedback loop was also established by conducting user survey with staff members and students on the building performance including health, safety and environmental comfort, temperature, noise, light, air quality, ventilation and relative humidity. Consequently, the air conditioning settings were fine-tuned and the operation hour of each building system was revised according to the survey results. The feedback loop provided input for the management to review maintenance policy and energy efficiency policy and highlight the problems that should be duly addressed and solved.

4.2 Green education and outreach programme

As an educational institution, the College does not see the design and management of physical structures as the only opportunity in contributing sustainability. Green education can influence young generations and the community in creating a sustainability culture. A series of green campus events for staff and students have been held in since the year of 2015, including Greening Workshop, Organic Planting Day, Visits on Organic Farm. Three Green campus tours were also organised within the campus in 2016 using the BEAM Plus awarding building blocks as a demonstration on sustainable campus development.

To communicate its sustainable mission to the wider community, the College has been organising various education events. For instant, "HSMC Symposium on Sustainability and Bamboo" was held in collaboration with UNESCO-APEID in Jul 2015. The College presented the campus itself as a showcase of sustainable campus especially on the use of bamboo in replacing wood consumption. Around 300 participants including students from universities and secondary schools, professional bodies' members, the public, HSMC Board and Council members, and staff members joined the events. The event enabled an outreach of a boarder community in enhancing the awareness of sustainability of the students and exchanging experiences with professionals from the broader field of sustainability.

Figure 6: Scenes at the symposium and green campus tours

5. CONCLUSION

As Hang Seng Management College is developing into one of the leading tertiary educational institutions in Hong Kong, it endeavours to maintain a sustainable growth in campus development. The Master Campus Expansion Plan has realised the ideas by embracing a variety of green design features and successfully benchmarked its performance by getting the highest Platinum Rating under the BEAM Plus for New Buildings. Considering the entire building life, the integration of green designs in the new buildings development is regarded as the very first step in the journey of a sustainable campus. After occupancy, the College is preparing to push forward the sustainable system and practice in on-going building operation and maintenance. To further benchmark and improve the sustainable performance, the College is targeted go through the BEAM Plus for Existing Buildings.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

As an educational institution, people and community is the core value in campus development. Stakeholders engagement in the management and evaluation of buildings performance and the advocacy of sustainable campus through education and community outreach programme process have been regarded as a crucial part in realising a sustainable campus. With such, the College is a showcase of a holistic development of a sustainable campus for future school or campus development of similar scale in Hong Kong and on an international stage.

ABSTRACT

Hong Kong is one of the most densely-populated, highly commercial, and fast-paced societies in the world. The topic of green construction and sustainable buildings has been a common theme in the industry for quite some time. Popular green building accreditation schemes such as BEAM Plus, LEED, or China GBL are the most often attain green building certification system in Hong Kong; the certification systems act as a driver to ensure healthier, more efficient and environmentally sustainable working and living environment. However, as the life cycle of a typical building in Hong Kong is to be maintained more than 50 years, the operation and maintenance of the building very often plays a more substantial role in maintaining a continuity of the environmentally sustainable life cycle of the building.

This paper presents a case study for the International Commerce Centre (ICC), ICC is the tallest building in Hong Kong, one of the forerunner in terms of environmentally sustainable building; during the design and construction phases of ICC (2003 to 2010), the project has acquired BEAM 4/04 certification, the management office of ICC and some of the tenant offices have acquired LEED Commercial Interiors. In the operational stage, ICC has been operate the building in an environmentally sustainable manner and is current targeting to acquire BEAM Plus Existing Building certification.

This study aims to identify the importance of early planning, integrated design, building management policies, operation and maintenance, and continual monitoring and improvement on the building systems in attributing to a sustainably built and operated building in Hong Kong.

Keywords: sustainable, green body check, high-performance building, education and training, energy saving, green rating tool, green building management

1. INTRODUCTION

Hong Kong is one of the most densely-populated, highly commercial, and fast-paced societies in the world. The topic of green construction and sustainable buildings has been a common theme in the industry for quite some time. Popular green building accreditation schemes such as BEAM Plus, LEED, or China GBL are the most often attain green building certification system in Hong Kong; the certification systems act as a driver to ensure healthier, more efficient and environmentally sustainable working and living environment. However, as the life cycle of a typical building in Hong Kong is to be maintained more than 50 years, the operation and maintenance of the building very often plays a more substantial role in maintaining a continuity of the environmentally sustainable life cycle of the building.

This paper presents a case study for the International Commerce Centre (ICC), ICC is the tallest building in Hong Kong with 118 storeys and Gross Floor Area of 273,000m^2, one of the forerunner in terms of environmentally sustainable building; during the design and construction phases of ICC, the project has acquired BEAM 4/04 certification, the management office of ICC and some of the tenant offices have acquired LEED Commercial Interiors. In the operational stage, the property management team has been operating the building in an environmentally sustainable manner.

1.1 Sustainability of ICC

ICC was originally designed with 3 buildings blocks, the three building block are then reduced to one building block to open up the outdoor plaza and landscape area, to improve microclimate around buildings. Below are other sustainable measures ICC has adopted, both in its design and operation.

1.2 Air

Fresh air intake of ICC is located on top of podium, away from outdoor pollutant sources. Fresh air is pre-treated by the Variable air volume primary air handling units. The amount of supplied pre-treated air can be varied and controlled by CO2 sensors. The designed ventilation in tenant spaces supports the well-being and comfort of occupants.

ICC provides regular maintenance of filters on air side system. Titanium dioxide (TiO_2) are provided in areas where pollutants are likely to be arise, such as toilet, lift. Frequent general cleaning is provided in occupied areas to maintain the proper indoor air quality.

Green fit-out guideline is issued to provide guidance to tenant's fitting-out contractor to adopt environmental friendly materials and equipment for fitting out works and comply with the requirements on green working manner.

ICC has obtained Excellent Class in HKSAR IAQ Certification Scheme and IAQwi$e. The HKSAR IAQ Certification Scheme is a voluntary scheme for offices and public places, to improve the indoor air quality (IAQ) and promote public awareness of the importance of IAQ. The IAQwi$e Certificate is to encourage and recognise participants achieving IAQ standards beyond the HKSAR IAQ Certification Scheme requirements. To achieve Excellent Class in IAQwi$e, participants are required to obtain Excellent Class in HKSAR IAQ Certification Scheme, and demonstrate achievement(s) in education or promotion of IAQ awareness amongst stakeholders or general public. Both of the certificates are valid for 12 months, ICC renews the HKSAR IAQ and IAQwi$e certificate annually, to show continual improvement in ICC's IAQ.

1.3 Noise

ICC is situated next to the Western Harbour Crossing, West Kowloon Highway and above MTR Kowloon station. To provide a good acoustic environment of ICC, enhanced acoustic insulation, like Integrated Glazing Unit System is provided to minimise the intruding noise from nearby traffic and fixed plant noise.

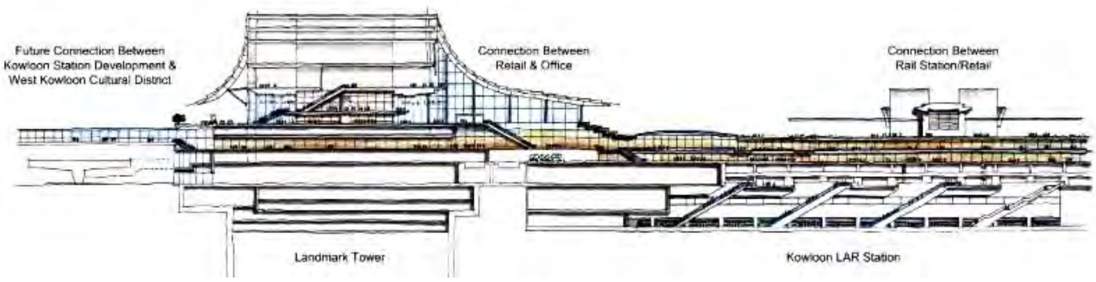

Figure 2: Section of ICC podium

Noise and vibration control measures are also adopted in building services equipment in ICC. All mechanical equipment are installed with vibration treatments to mitigate noise and vibration transmission.

1.4 Energy

During the design stage, daylight analysis was conducted to optimise the daylight assess and the use of artificial lighting. Low-e glass was chosen for the curtain wall system together with a depth restriction design on office room to maximize effective daylight access. Daylight access is also enhanced by the "dragon-tail" atrium located on the north side of the tower, beneath a roof formed by the shingled scales of the façade. The "dragon tail" atrium is shown in Figure 2 above.

Figure 3: Curtain wall system of ICC

Comprehensive metering infrastructure were incorporated during design of ICC, Power management system connected with various E&M systems and equipment were installed to monitor energy use and power quality. This system enables the estate management to audit the energy performance, setup the benchmark, setup the energy goals and targets, and establish the policy and action plan.

Chiller plant control system optimizer is adopted in chiller plant control system which optimises sequencing control of chillers and cooling tower to meet the cooling load with the most energy efficient manner.

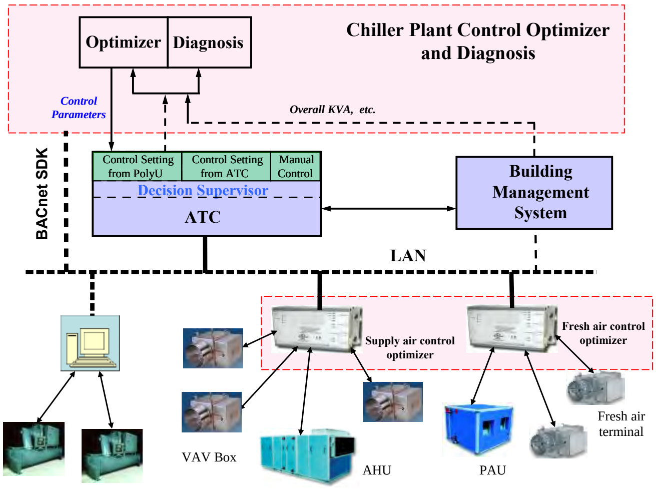

Figure 4: Chiller plant control system optimizer

ICC has undergone an energy optimization study to develop energy efficient control strategies, which mainly involve optimal chiller sequencing control, cooling tower sequencing control, optimal water pressure differential set-point control, AHU supply air static pressure rest control and DCV-based fresh air control, optimal chilled/cooling water temperature set-point reset strategy etc.

Double deck lift with destination control system is provided in ICC to maximise the efficiency. This system shortens the waiting time in lift lobbies and riding time in lift cars, provide optimised elevating service for passengers. Power is also regenerated from the lifts during braking and connected to the supply network, thus to reduce energy consumption. It helps boosting up the handling capacity by 15%.

ICC adopts energy saving management activities including turn off the escalators during non-peak hours, suspend half of the passenger lifts during non-peak hours at various zones, switch off the normal lighting at common area during non-office hour for various zones and shorten the running hours for air handling units at Sky Lobby. These activities save 142,143 kWh in total annually.

ICC is one of the first buildings to obtain ISO 50001 Energy Management standard, ICC's ISO 50001 was granted in 2011. ICC also obtained Excellent Class in the Energywi$e Certificate annually starting from year 2011. Energywi$e is to encourages participants to adopt energy reduction measures covering the key energy consuming facility. To achieve Excellent Class in Energywi$e, participants are required to fulfil 50% and 9 or more additional pre-set energy saving targets.

Moreover, there is a provision of energy audit service to ICC tenants upon request. Energy consumption analysis with energy management opportunity will be offered to the tenants.

1.5 Sustainable material use

To reduce construction waste and carbon footprint of the construction materials of ICC, the life cycle approach during the construction was adopted by using environmental friendly materials, such as high portion of PFA (35%) in concrete, structural steel with postconsumer recycled content, steel couplers, non-ozone depleting materials, certified wood and recyclable materials.

Figure 5: Environmental friendly materials

1.6 Water

During the operation, ICC adopts various measures to recycle the water waste as far as practicable. Bleed-off water from cooling tower plant is recycled for flushing water use to reduce consumption of flushing water. Condensate water from AC system is collected and recycled for cooling tower use. Native and drought-tolerant plant species are selected to reduce irrigation water use.

1.7 Waste

ICC provides the waste compactor and food waste decomposer in the refuse room to reduce the carbon emission of transport of waste and to reduce food waste.

Figure 6: Waste compactor and food waste decomposer

ICC has obtained the Excellent class of the Wastewi$e Label annually starting from October 2011. Wastewi$e is to encourage Hong Kong organisations in adopting measures to reduce the amount of waste generated within their establishments or generated through the services and products they provide and recognise the waste reduction efforts of those companies. A series of management strategies are adopted to reduce waste. Waste management programme and glass bottle recycle scheme in ICC increases the recycling rate of paper, aluminium cans, plastics and glass. Green housekeeping reduces the wastage of materials by updating the checklist of stock, and 'First-In-First-Out' principle to avoid materials expired before consumption.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 7: Green housekeeping and glass bottle recycling scheme

1.8 Green Body Check

On top of all the works being carried out, ICC did not ceased to improve continuously. In order to further quantify and qualify the sustainable built environment in ICC, a "Green Body Check" in 2016 based on Hong Kong Building Environment Assessment Method (BEAM) Plus Existing Building(EB) Version 2.0 Comprehensive Scheme, is proposed to be conducted in the building thoroughly. The following areas are focused in terms of BEAM Plus (EB):

Management

Objectives, policies and procedures were reviewed to ensure a sustainable operation manner. It included management on green procurement, ISO 140001 & 50001, proper operation and maintenance, indoor air quality and pest control, etc.

Site aspect

The site location was reviewed regarding the adequacy of local amenities and public transport provisions, reduction of travel needs and reliance on private vehicles. Also, to minimise any potential negative impacts on the neighbours, noise and light pollution controls were reviewed and seen if necessary actions shall be taken. Another features related to the reduction of heat island effect and amenities features for O&M and building users, were also reviewed.

Material use

Proper material purchase and disposal could reduce environmental pollutions via manufacturing and disposal process. The review included material purchasing plan, avoidance the use of ozone depleting substance, waste and food waste management, recycling facilities and establishment of waste reduction target and etc.

Energy use

The energy consumption by the building services system were assessed by comparing with the benchmarks derived from audits of similar building type. It included energy management, and analysis, regular commissioning, comparison of benchmark and future improvement and etc.

Water use

The quality and quantity of the water use were assessed through management and audit. It included water conservation plan, provision of water efficiency devices, water quality survey, reuse of process water, regular plumbing and drainage inspection, water metering and audit and provision of twin tank system for fresh and flushing water and etc.

Indoor environmental quality

The indoor environment qualities were checked which might impact on the human health and comfort, as well as improvement of quality and functionality. It included ventilation, thermal comfort, hygiene, indoor air quality, control of environmental tobacco smoking, room acoustic and background noise and etc.

Innovation

Innovative ideas and designs were discussed and determine the feasibility of new innovations in order to achieve more ambitious targets and exemplary performances.

2. FINDINGS AND RECOMMENDATIONS

Using BEAM Plus for Existing Building as a tool, a range of workshops with the building management team were conducted as "Green Body Check". Operation and management best practices previous developed and implemented have been appreciated by the certification tool. Moreover, some improvement opportunities or value-adding actions were identified for considerations by the team.

2.1 Management plan and action

Occasionally, management practices were implemented but the formulation of procedures or plans were not developed and often the intended goals or targets cannot be executed effectively. From the result of "Green Body Check" carried out, green purchasing plan and water conservation plan were not developed and are thereon produced by the team and implemented thereafter.

Procurement of equipment and goods are carried out by the procurement department where environmental friendly products are always considered. However, the range of equipment and goods under governing or the environment attributes of products are not clearly identified. After the implementation of the green purchasing plan, the team can set the specify goals and targets for the procurement of the governing products, but also setting guidelines/ requirement on the environment attributes of the products.

Water Conversation is one of the major targets of ICC, water saving opportunities were previously investigated such as reducing the water usage of cooling system. However short term and long term water saving targets, the method of monitoring water consumption and regular water audits were not scheduled. With the addition of water conservation plan in place, the team can regularly monitor the water consumptions, conduct water audit and implement the water conservation plan regularly to reduce the water use in an orderly manner.

2.2 System audit

"If you don't measure, you cannot improve". In order to clearly set out the goals and target for different environmental performance of building, a range of audits shall be conducted regularly to benchmark the environmental performance of the building. The frequencies of each audit shall be set in corresponding plans and procedures for the management team to follow.

Energy and water audit shall be carried out yearly to determine the energy and water usage of the building systems, to continuously benchmark ICC's performance in respect to Hong Kong and/or International green building standards.

Indoor air quality monitoring shall be carried out regularly to determine the air quality of the internal occupying spaces of the building.

Comfort surveys with regards to thermal, acoustical and possible nuisance caused by odour or vibration shall be regularly carried out to investigate if any problems where raised.

2.3 Management opportunity

Based on the findings on regular audits and feedbacks from stakeholders, management opportunities can be explored in greater details, and continuous benchmarking can give the management directions and focal points for improvement strategies Thus, it is most importantly to allocate resources and manpower efficiently and strategically.

3. CONCLUSION

International Commerce Centre not only is the tallest building in Hong Kong, it is also one of the best managed buildings in Hong Kong. The facilitate management team of ICC well understands the fact that a sustainable management is as important as the sustainable design of the building where the building is anticipate to operate more than 50 years and perhaps more.

However, even when the facilitate team is operating the building in an effective and sustainable manner, regularly checking and continuous benchmarking the buildings performance against recognized green building schemes or other equivalent tools would drives the team further in achieving more ambitious goals and create continuity in their operation.

ABSTRACT

Commercial Buildings Consume A Large Portion of The Total Energy Consumption In Hong Kong And Energy Use Is A Major Element Contributing to The Emission of Carbon And Global Warming. Facilities Managers Have To Be Conscious of Their Roles in Shaping the Use of Energy of Buildings. Through Employing Available Technologies, Collaborating With Stakeholders From Within The Building and The Community As Well As Continuing Sustainable Facilities Management Practices, It Is Possible To Improve The Environmental Performance Of Commercial Buildings. The Tallest Commercial Building In Hong Kong Would Be Used As A Case Study To Illustrate How This Model Could Be Applied And The Results That Have Been Achieved That Could Derive A Win-Win For Businesses And The Society.

Keywords: high-performance building, corporate social responsibility, energy

1. INTRODUCTION

1.1 Our present environmental challenges

From construction to demolition, stocks of buildings in the built environment are the major consumer of energy. Over 68% of the greenhouse gas that leads to global warming is attributed to the burning of fossil fuels to produce energy. According to the Electrical and Mechanical Services Department (EMSD) in Hong Kong (HK), among all facilities in commercial buildings, air conditioning system consumes most of the energy (26%). Other mechanical systems such as lifts and escalators are also at the top of the chart. This pattern of energy consumption among HK's buildings is no different from other metropolitan cities worldwide, thus making this issue of global significance.

Apart from energy, waste management is another important issue In HK. Based on 2013's data from the Environmental Protection Department, 63% of the municipal solid waste went to landfills with 37% waste could be recycled. The existing 3 landfill sites in HK are about to saturate with one as early as 2017. With little alternatives to handle municipal solid waste, there is an urgent need in HK for all to act immediately to support the waste reduction movement.

Unlike new buildings that could take advantage of the latest energy efficient technology and waste separation facilities during the design stage, the performance of the existing building stocks would have to resort to other ways to improve their environmental performance. With proactive management strategy, diligent and practical work approach, it is feasible to achieve energy and waste reduction in existing buildings. This does not give rise to instant upgrading of facilities and render the existing facilities immediately useless.

1.2 Important role of property and facility management professionals

Property and facility managers (PFM) who run buildings, have an active role to play. PFM take care of all aspects of the building during the building's life cycle. With efficient building operation and good maintenance of facilities, owners and occupants are benefited while environmental impacts of buildings could be minimized.

PFM not only take care of the basic functions such as security, cleaning and maintenance of building facilities but they also take care of occupants' needs, the building's community and the society at large. It is often assumed that the building management staff would operate the building according to the design of the architect and building consultants. Very often, there is a mismatch between the design intent and the actual operation of the building. In a less than optimal operation setting such as the number of occupants fall short of expectation, the building facilities may not be fully utilized and wastage could occur. Besides, since buildings consume a large amount of energy and produce a significant amount of waste, PFM have the responsibility to evaluate the operational needs and adjust the use of resources to drive for optimality.

2. A THREE-SPHERE FRAMEWORK FOR BUILDING OPERATION

In order to improve the environmental performance of buildings, thus minimizing the environmental impacts of buildings to the society, we propose PFM to implement a three-sphere framework in their operation incorporating elements in the form of intelligence, collaboration and continuity. This framework can be applied and adapted to all types of buildings.

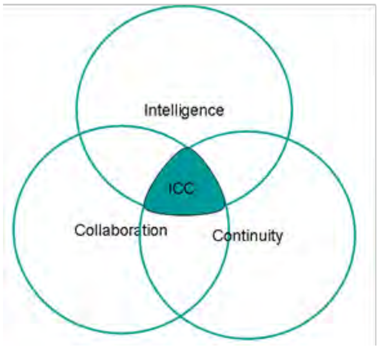

Figure 1: Intelligence, collaboration and continuity framework

2.1 Intelligence - Integration of people, place, process and technology

The task of the PFM is to integrate people, work process, place, and technology. It is only when these four elements are considered will the building achieves its optimal operational efficiency. There are a few layers of intelligence. First of all, there is people's intelligence. Intelligent people are those who possess sufficient know-how, make informed choices by studying the operating data of buildings and make decision based on balancing interests of stakeholders and the environment. Well planned on-going trainings and exercises will ensure the members of the PFM possess the necessary skill sets to operate the building efficiently.

The second layer of intelligence relates to process intelligence that could lead to improvement. PFM must also make use of various different processes that help to track the building performance effectively. One of which is to follow a process in designing, undertaking, tracking and improving the building operations by applying the plan-do-check-act quality management process. The application of ISO 14001 Environmental Management System to the building management would enable a systematic process keeping track of the data with measurable metrics to evaluate the effectiveness of different improvement programs.

The third layer of Intelligence refers to the use of intelligent building facilities that has provided PFM with performance tracking and feedback mechanisms. The intelligent systems help to collect data and make them appear in a meaningful data format for the ease of analysis. The use of Building Management System (BMS) is one of the ways in which multiple facilities can be controlled and monitor. It also helps to ease operators dealing with repetitive tasks resulting in productivity improvement.

2.2 Collaboration - Vitalizing the trade experts and recognising the contributions from stakeholders from within and outside the building environment

Collaboration refers to the process in which people work together with the same goal to achieve in their mind. There are altogether three-tier of collaborations.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

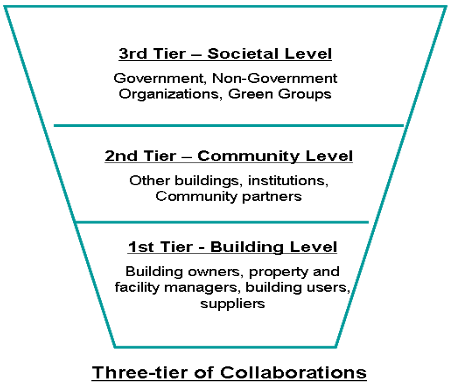

Figure 2: Three-tier of collaborations

In the primary tier, collaboration is done within the building. This tier of collaboration involves building owners, PFM, suppliers and building users. These four entities work together in order that a common goal such as minimizing the environmental impacts in the course of the building operation could be achieved. The building owner acts as the driver for the goal of minimization of environmental impacts while PFM execute the process by working together with suppliers and building users.

The secondary tier covers the local community. This level of collaboration will start to work outside the building and with people who have the stakes in the community, thus benefiting the environment through sharing of good practices.

The tertiary tier covers the societal level collaboration. The Government and organizations operating on a territorial-wide platform from time to time put forward schemes and programmes of raising the awareness of citizens about environmental protection. PFM's participation in the new programmes could lead to building management tasks being conducted in a more environmentally friendly manner.

2.3 Continuity - Working towards a common goal of reducing environmental impacts

While it is good by setting up a common goal and starting to work with stakeholders from within and outside the building environment, those benefits could only have lasted if the good cause is applied continuously and in a consistent and sustainable manner. The application of the life cycle testing and commissioning method in the building operation is one of the ways to sustain good building operational practices. Building owners and PFM should take a long term view by first conducting a short to medium term resource allocation plan to support building operation. With this plan, building users can also obtain a clear picture of how the building is going to be operated consistently and prepare themselves to adapt to the building practices that will be good for the environment.

3. CASE STUDY

We shall make use of a commercial building as a case study which has applied this 3-sphere framework in its operation.

3.1 History and background

The commercial building is situated in the West Kowloon and is classified as a super-tall building. The building is built on top of mass transit rail station. It is a composite building with over 80% of floor area used as office premises serving over ten of thousands of people forming a new neighbourhood in the district. The building is equipped with mega scale chilled water plants, cooling towers and close to 100 lifts and a large number of escalators. With the large building scale and the associated population, the consumption of energy and the waste production are expected to be significant. With minimizing the environmental impacts of this building in mind, these two items must be controlled and monitored.

3.2 Design and environmentally friendly construction

The building is designed based on the HK green building standard, the Hong Kong Building Environmental Assessment Method (BEAM) under version 4/04 new building category and achieving a high rating at that time. From both the cost and the environmental protection point of view, the tenants are encouraged to adopt green interior fit-out standards such as BEAM Plus Interior and LEED (Leadership in Energy and Environmental Design) for Interior Design and Construction and work together with the building owners, the architect and the PFM to achieve the standard.

3.3 Putting framework into practice

The company that operates the building has clear goals and visions that have put environmental protection in their top agenda of businesses. In line with the company's vision and mission, the building's PFM has instituted the cultural of 'greenkeeping is a habit' into its operation.

3.4 Intelligence - Smart people operate intelligent system

The building is operated by a team of building management professionals in the scale of about 200. The building management team has qualified professionals who are affiliated to various different professional institutions and the key members of staff have achieved green building professional accreditations. Their know-how can enable them to identify the environmental issues associated with their daily tasks and devise suitable ways to resolve those issues.

In order to effectively identify and conduct appropriate measures to minimize the environmental impacts from the building operation, the building management team has instituted different process intelligence into its operation based on the requirements of BEAM Plus (Existing Building), ISO 50001 Energy Management System, ISO 22301 Societal-security Business Continuity Management System and OHSAS Occupational Health and Safety Management System. The use of quality management cycle is the cornerstone of their operation.

BMS is used to facilitate the operation, control and monitoring of building services. BMS engineers are stationed in a central control centre to ensure all parts of building system is under good condition and any abnormality will be observed at an early stage to eliminate possible interruption to the systems and minimize unnecessary disturbance to building users. Power Monitoring System (PMS) is added as an additional module to analyze data to capture the peak and off-peak as well as seasonal variations. Optimization of energy usage is done by gathering and analyzing various different sets of data followed by adjusting the system's operational parameters.

Energy saving opportunities are sought by optimizing air conditioning system operating parameters together with professionals in the field and continuously explore cutting edge practices with scholars from universities. For instance, robust chiller sequencing control and optimal control of cooling tower using hybrid quick search method are some of the examples that no additional hardware is required to be added. Energy audit is carried out yearly by independent and qualified energy assessor to help the team identifying further areas for improving the energy performance.

3.5 Management by walking around (MBWA)

Additional process like MBWA is instituted in the team's operation. MBWA requires the management and supervisory staff members of the building conducting regular inspection covering all areas as a housekeeping good practice. This corresponds to the first level of energy management opportunity conceptualized by BEEO (EMO I). Through MBWA, some of lamps were taken out and the lumens of some of the lamps were dimmed. Some facilities were turned off for several more hours daily for energy saving. Some corridors were cordoned off and occupants were re-directed to use other passageways to minimize the use of energy during non-peak hours.

3.6 Integrated waste management

An integrated waste management plan has been adopted. The building management team has worked together with the tenants to educate the occupants on waste reduction and recovery of waste for reuse and recycling purpose. A central waste recycling facility is made ready for tenants to handle recyclables. A total of 26 types of recyclables are collected from tenants. The collected recyclables will be distributed to responsible and reputable

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

non-Government organizations for handling. Food waste from tenants, hotels and restaurants are collected with onsite decomposer to further reduce the waste load. The composite decomposed from food waste is mainly used by gardeners to work on the building's landscape features with the rest taken to other organic farms in the New Territories.

3.7 Collaboration - Promotion and education

Tenants are invited to give out their ideas and suggestions on green practices through regular meetings with building management staff. Bi-monthly news flash is provided to occupants about the latest green practices of the building management, helping the management to raise occupants' awareness of maintaining a low carbon office environment. Various kinds of campaigns are launched to raise awareness of occupants on green management. These include "Celsius 26" campaign. This campaign encourages occupants to set a higher temperature inside their premises with the indoor temperature of all common areas set to 26 Degree Celsius. For waste management campaign, the 'Say No to Disposable Utensils' campaign encourages more occupants to bring their own utensils to work place and reduce the disposal of plastic. The indoor air quality is maintained at a high level based on the local and international standard.

In addition, as a way to demonstrate their commitment towards reducing the environmental impacts of building operation, the building management has agreed with tenants to setup and make available a comprehensive environmental management plan on dealing with environmental issues and on reducing environmental impacts to the community and society. Tenants are consulted to establish waste separation facilities inside their premises for the ease of sorting and sifting waste.

On the community level, the building management has delivered presentations in various seminars and share energy management and green initiatives with different participants including business leaders, stakeholders and students. Through these sharings, best practices can be exchanged with participants and existing building performance can be reviewed and reflected upon based on insufficiency. Professionals, local and overseas property management companies, education institution have visited to the building.

On a societal level, the building has participated in different kinds of schemes and programmes which aim to promote environmental protection awareness among citizens in the society. The building has joined all the programmes put forward by the Hong Kong Awards for Environmental Excellence (HKAEE). This includes the HKAEE's sectoral award under the property management sector, the continuous participation of the waste reduction programme, indoor air quality maintenance programme, energy reduction program and carbon reduction programme. The building management has participated in these programmes for more than 5 years consecutively. The building management of the building has raised its standard by joining the low carbon-office operation programme (LOOP) initiated by the Hong Kong World Wild Fund for the past 5 years. The participation of these programmes requires support from tenants, occupants and staff in order that measureable carbon reduction could be tracked and monitored.

3.8 Continuity

The building owners and building management has committed to a long term view of environmental protection and minimizing the environmental impacts of the building to community and society. The essence of corporate social responsibility, the triple bottom line and the 'use less, waste less' culture are instituted in the team during the operation and maintenance. For instance, materials and supplies are selected that can last for 5-10 years and reduce the need for short term replacement. It also continuously maintains the established processes and best practices such as the adoption of the latest green building standard, demonstrating their competence and commitment to independent auditors of ISO 9001 Quality Management Standard, ISO 14001 Environmental Management System, ISO 50001 Energy Management System, ISO 22301 Societal security - Business continuity management systems and OHSAS 18001 Occupational Health and Safety Management Standard. In addition, continuously participating in schemes and programmes put forward by the Government and other green groups is a way to support the Government's initiatives on energy saving and waste reduction.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.9 Result

In terms of energy consumption, Figure 1 shows the total energy consumption of the building in the past 5 years. Following the above-mentioned framework with careful execution of good building management practices, the total energy consumption of the building has dropped with over 10 million kWh of energy was conserved. There is also a continuous decreasing trend throughout the 5 years. Besides, the building's Energy Utilization Index (EUI), a measure of energy consumption in buildings, has also reduced from 153kWh/m²/annum to 136 kWh/m²/annum up to 2016, see Figure 2. The carbon emission has also followed by a decreasing trend, see Figure 3.

In view of waste recycling, successful waste recycling begins with waste separation in which the participation rate of waste separation recycle programme increased from 60% in 2010 to 90% in 2016. The recyclables collected increased from 96,000kg in 2013 to 120, 000kg in 2016 with 25% increment, see Figure 4.

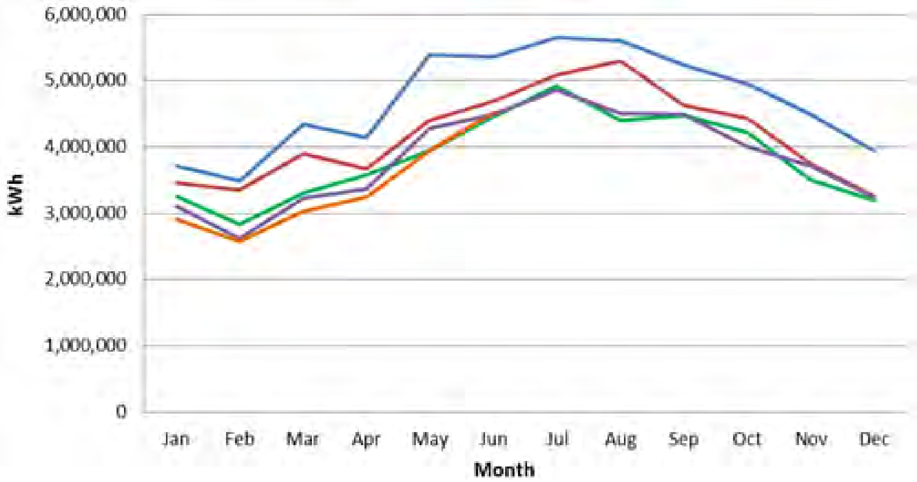

Figure 1: Annual energy consumption from 2012 to 2016

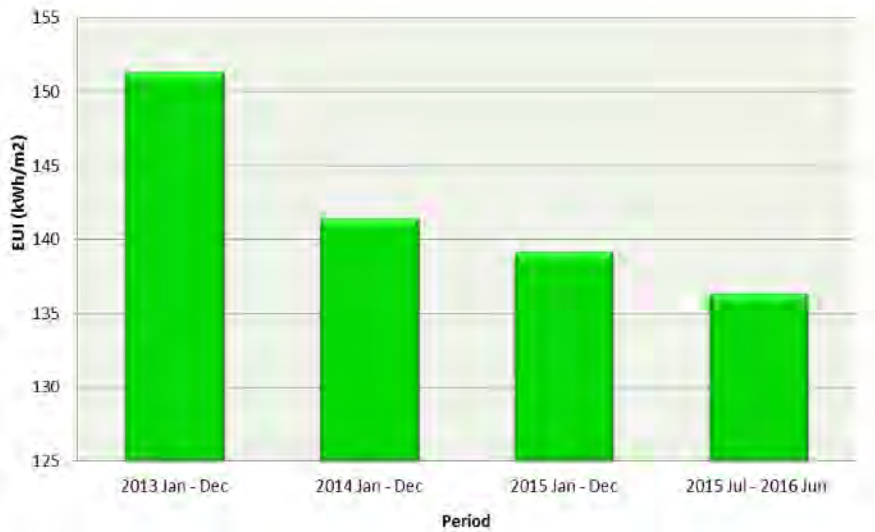

Figure 2: Trend of energy utilization index (EUI)

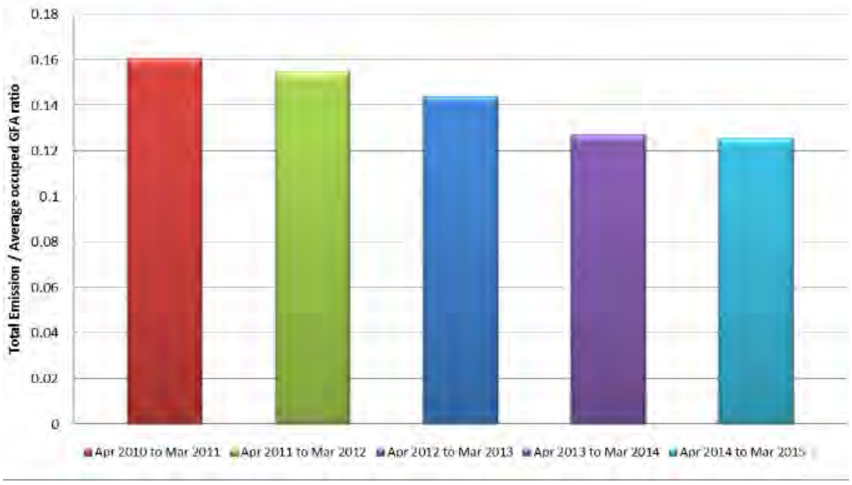

Figure 3: Trend of carbon reduction

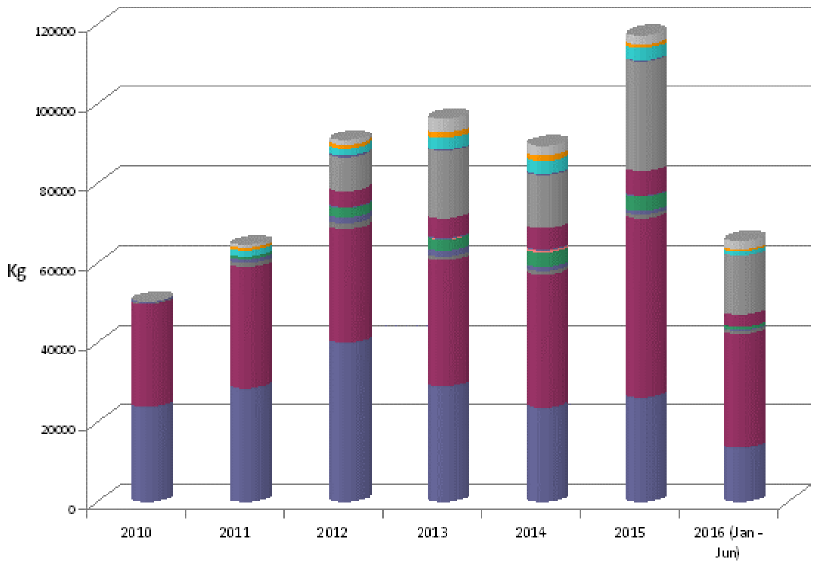

Figure 4: Annual recycle quantity from 2012 to 2016

4. CONCLUSION AND SUMMARY

The resources being used to construct and operate a commercial building will bring environmental impacts to the society. The existing building stocks account for the most of the building stocks in HK and there is a need to keep track of the environmental performance of existing building stocks. A 3-sphere framework incorporates intelligence, collaboration and continuity is proposed that could be applied to the operation of existing commercial buildings. The framework essentially integrates the people, process, place and technology working from the building level towards the societal level. The framework requires a long term commitment of building owners and building management to maintain but the benefits to the environment could be significant. This framework has been applied to a commercial building and good results have been achieved in terms of minimizing the energy usage and waste production. This framework can be applied to other buildings and further developed to derive a universal model of building operational practices for the good of the environment.

(6) A Collaborative Approach in Delivering Low Carbon Living
Session Organiser: Arup

Session 4.9

SESSION OUTLINE

To make a sustainable environment into reality, many parties are needed. To start, we need investors that have a vision to provide the resource to kick start a project. Next, we need to have developers to put together a team to plan and execute projects that focus on sustainable development. During the design of the projects, architects and consultants need to work closely with all the relevant parties to bring the vision into the physical world. In this session, UBS have been working with investors that are keen to creating sustainable projects. We also have New World Development Company Limited to share about the projects that realized in the recent years. KPF is a well-known architect firm that delivers many sustainable buildings around the world. Lastly, we also have Arup as a total engineering consultant to share a holistic approach to integrate multi- disciplinary professionals in realizing many green and sustainable projects.

After the individual presentations, the panel will provide their views in how working together is the key success of creating the new sustainable world for our future.

SESSION CHAIR

Jimmy CK TONG, Associate & East Asia Energy Skill Leader, Arup, Hong Kong SAR

SPEAKERS AND PRESENTATION TOPICS

1. Beyond Energy and Resource Efficiency: Sustainable Building in Digital Transformation
   Vincent CHENG, Director of Building Sustainability, Arup, Hong Kong SAR

2. Investing for Longer-term Development: Financing the New Generation in Sustainability
   Carl BERRISFORD, UBS Wealth Management, Head of Sustainable Investing, APAC Chief Investment Office, Hong Kong SAR

3. Creation of Green Neighbourhood
   Edwin CHAN, Project Director, New World Development Company Ltd., Hong Kong SAR

4. Tall Buildings and Sustainability
   Florence CHAN, Director, Kohn Pedersen Fox Associates PC, Hong Kong SAR

(7) Powering Up Smart City
Session Organiser: CLP Power Hong Kong Ltd.

Session 2.13

SESSION OUTLINE

CLP's session will include building management of Hong Kong Airport, world-class Data Centre, smart power control from Science Park and CLP's energy management services. Our moderator will introduce the speaker background and do a shorten wrap up after each topics.

Presentation Rundown:

Powering Up for Brighter Tomorrows *by CLP*

- In this digital era, CLP has been proactive in innovating smart energy solutions to meet and exceed the expectations of our business and residential customers, and striding towards a smarter city.

Big Data Era for Building Management *by Airport Authority Hong Kong*

- Pilot trial of utilizing big data to enhance building management at North Satellite Concourse is completed in Feb 2017. The cloud-based software uses powerful analytics and performance monitoring dashboards to promote proactive operations, such as predictive maintenance and energy saving opportunities identification.

Smart Power Control for Peak Load Compensation *by Hong Kong Science and Technology Parks Corporation*

- Power supply at peak load is always inefficient and expensive. Capacity of electrical installation needs to cater for the peak load. Hence there is much benefit in reducing the peak load – reduce the use of less efficient generator, defer the transmission and distribution system upgrading, reduce the electricity tariff and finally, the reduction of CO2 emission. This presentation shows the experience in using a smart power control for peak load compensation in one of the buildings in Hong Kong Science Park

How Hong Kong to be a Data Centre Hub in Asia in the Next Decade *by Hong Kong Data Centre Association*

- Role of data centres in smart city development and how Hong Kong to be developed as a data centre hub in Asia in the next decade, especially when facing stiff competition from other Asian countries such as Singapore, Taiwan and Japan.

SPEAKERS AND PRESENTATION TOPICS

1. Powering Up for Brighter Tomorrows
   Eric CHEUNG, Senior Director – Customer & Business Development, CLP Power (Hong Kong) Ltd., Hong Kong SAR

2. Big Data Era for Building Management
   Amen TONG, General Manager, Technical Services, Airport Authority Hong Kong

3. Smart Power Control for Peak Load Compensation
   Clement WONG, Head of Facility Management Hong Kong Science and Technology Parks Corporation

4. How Hong Kong to be a Data Centre Hub in Asia in the Next Decade
   Charles LEE, Founder and CEO OneAsia Network Limited & Newtech Technology Co Ltd

(8) Healthy and Sustainable Building for Resilient Future Session Organiser: Link Asset Management Ltd. / Nan Fung Development Ltd.

Session 1.13

SESSION OUTLINE

The new commercial development at 77 Hoi Bun Road, Hong Kong, is a fine business case for developers in building Green Buildings, which has been a global trend in the last decades.

Climatic challenges, energy performance, efficient use of resources, users' health and wellness, ease of maintenance and safe operations of the building systems, site impacts and amenities as well as neighbourhood engagement have all been carefully considered by the multi-disciplinary team with an aim to achieve new benchmark for Grade-A office buildings.

Nan Fung Development Ltd. and Link REIT both have strong commitments to the environment, and sustainable development is central to their business philosophies:

- Nan Fung will share the developer's perspective on how their vision is being realised through sustainable new and revitalization developments.
- Link will share about the green building projects and corporate initiatives they have implemented in recent years.
- Arup will share the leading trends in resilient future building designs.
- P&T Architects and Arup will share on the holistic design approach in realizing the exemplary next generation commercial building.

Speakers will hold a panel sharing session on how an integrated design approach is the key to future sustainable and healthy development.

SESSION CHAIR

Chris KWAN, Senior Project Manager, Project & Planning, Link Asset Management Ltd., Hong Kong SAR

SPEAKERS AND PRESENTATION TOPICS

1. Green Buildings - The Foundation for Sustainable Development
   Calvin Lee KWAN, General Manager- Sustainability, Link Asset Management Ltd., Hong Kong SAR

2. Nan Fung's Corporate Initiative for New and Revitalization Development

(9) Sustainability Assessment of Buildings as Part of Green-Public Procurement Based on the German BNB-System Session Organiser: Division Sustainable Building, Federal Institute for Research on Building, Urban Affairs and Spatial Development (BBSR), Germany

Session 2.14

SESSION OUTLINE

In Germany, adherence to the principles of sustainable development is an essential aspect of procurement by the public authorities. This applies both to the planning and construction of new buildings (high performance buildings) as well as to modernization projects (deep building renovation). The Federal Ministry for the Environment, Nature Conservation, Building and Nuclear Safety (BMUB) formulated with the Guideline for Sustainable Building essential requirements for Federal Buildings. The Assessment System for Sustainable Building (BNB) provides a tool which supports planning and evaluation and is used in public procurement. It is freely accessible on the internet. The BNB simultaneously and equally addresses the classic three dimensions of sustainability and the technical implementation and the planning process as cross-sectional qualities. Both LCA and LCC are used.

In the workshop, the BNB will be presented using the example of the modernization of school buildings and the planning of research and laboratory buildings. Practical examples from Germany and Austria will be explained. In other lectures, possibilities for the increased use of renewable raw materials as well as tools for the support of integrated design are discussed.

The workshop is aimed at representatives of the public sector as well as developers and users of planning and assessment tools. In the moderated discussion, the public authorities deal with certification systems as well as the importance of integrated design for sustainable construction.

SESSION CHAIR

Thomas LÜTZKENDORF, Director, Centre for Real Estate; Head of Chair, Sustainable Management of Housing and Real Estate, Karlsruhe Institute of Technology, Germany

SPEAKERS AND PRESENTATION TOPICS

1. Sustainability Assessment of Buildings as Part of Green Public Procurement – An Introduction

Sustainability Assessment of Buildings as Part of Green Public Procurement – An Introduction

Thomas LÜTZKENDORF[a], Andreas RIETZ[b]

[a] *Karlsruhe Institute of Technology, Centre for Real Estate, Karlsruhe, Germany, thomas.luetzkendorf@kit.edu*
[b] *Federal Institute for Research on Building, Urban Affairs and Spatial Development, Berlin, Germany, andreas.rietz@bbr.bund.de*

ABSTRACT

The special session organized by the Federal Ministry for the Environment, Nature Conservation, Building and Nuclear Safety (BMUB) will present and discuss the principles and tools for green or sustainable public procurement. On the basis of examples and experiences from Germany, transferable recommendations for action are to be developed.

Sustainable procurement is a key component in public administrations. With the introduction of the Guideline for Sustainable Building, the Federal Government has enforced an important component of its sustainability strategy in the public sector. In the first step, the Federal Building Authorities are obliged by edict to evaluate their buildings, using the Assessment System for Sustainable Buildings (BNB). BNB has become the most important tool to implement high quality standards. The actual task is, to establish good conditions for a broad implementation of the BNB into the daily work of the public sector in total. The BNB provides a practical tool for holistic sustainability assessment for federal buildings. It is specially adapted to the procedures and needs of the public sector and can therefore be used to support sustainable procurement. In addition to the federal government, this can also be applied by federal states and municipalities and other public builders / clients. Further information is available on the "Sustainable Building Information Portal", see www.nachhaltigesbauen.de.

In the workshop the German Assessment System BNB will be explained and discussed on the basis of two examples: the assessment of the refurbishment of educational buildings and the planning of new research and laboratory buildings including a sustainability assessment. Additional examples from Germany, Austria and Switzerland are presented. In other papers, the possibilities of using renewable energy to operate buildings, as well as the application of principles of integral design, are discussed. It is planned to discuss with the participants the application possibilities of sustainability assessment systems for public procurement.

Keywords: policy and regulation, sustainability assessment tool, public sector, procurement

1. INTRODUCTION

The public sector has a special role and responsibility in the implementation of the principles of sustainable development. In particular, it fulfils tasks aiming at enabling the targeted control of social development. Besides safeguarding public interests, the objectives pursued include the conservation of natural resources and the protection of the environment and health. The public sector has a wide range of policy instruments to support the achievement of these objectives, including public procurement.

The public sector, considering its comparatively high share of investments, has a significant market power. The states or public authorities, in their role as a consumer, can stimulate the market towards environment-friendly and socially acceptable goods and services and promote the development and proliferation of environmentally and socially compatible innovations. Therefore, they can and should act as a role model in the field of the implementation of sustainable development principles.

Public authorities recognised at an early stage the importance of integrating environmental and social standards into the procurement processes, as well as the tendering and contracting procedures. There are various initiatives, guidelines and examples at both the international and European. A gradual transition from green public procurement (GPP) to sustainable public procurement (SPP) is also evident [EC, 2016b].

The GPP and SPP principles can also be applied to the procurement of buildings or the tendering and contracting of design and construction services. A prerequisite is the definition of clear goals for the performance of buildings. In addition to the specification of the technical and functional requirements, EN 15643-1 [CEN, 2010] recommends setting goals for the environmental, social and economic performance of buildings. In order to take into account the objectives of sustainable development in the design, construction and use of buildings, guidelines, databases and tools, as well as sustainability assessment systems, have been developed in Germany to support the public sector bodies. These can also be applicable to all types of clients and developers.

2. PUBLIC PROCUREMENT FOR CONSTRUCTION WORKS IN GERMANY

In Germany, adherence to the principles of sustainable development is an essential aspect of public procurement. This applies both to the design and construction of new buildings (high performance buildings) as well as to refurbishment projects (deep building renovation). This is linked to a long tradition which goes back to the nineties. Although the procurement activities were initially focused on the aspects of the environmental friendliness of buildings and issues related to the selection of construction products, already since then, the situation has started changing. The attention has consistently started been directed towards the implementation of sustainable development principles in the design, construction and operation of buildings and construction works. To promote activation and provide support, the round table "Sustainable Building" was established by the Building Ministry, where both industry and science are represented.

The Federal Ministry for the Environment, Nature Conservation, Building and Nuclear Safety (BMUB) formulated with the Guideline for Sustainable Building essential requirements for federal buildings. This provides an important basis for the sustainable procurement of buildings. Additionally, it forms the basis for a set of databases and tools required for sustainability assessment. All these have been produced with public funds and are freely available – see www.nachhaltigesbauen.de.

The Assessment System for Sustainable Building (BNB) provides a tool which supports the design and assessment of sustainable buildings and is used in public procurement. The BNB addresses the three dimensions of sustainability simultaneously and equally. In addition to sustainability requirements, also requirements for the technical and functional performance of the building, as well as requirements for the quality of the design, construction and management processes, are formulated within this system. The assessment is based on a predominantly quantitative approach including the use of both life cycle assessment (LCA) and life cycle costing (LCC).

For the application of BNB various work aids and data sources are available. Among others, the provision of basic data for the calculation of Life Cycle Analysis (LCA) and Life Cycle Cost (LCC) is necessary. This data is stored in freely available databases. Additionally, calculation and documentation tools are available for simplifying the application of BNB, while preventing multiple entries. Guidelines and system-specific brochures provide basics principles for calculation and assessment and up-to-date information – see http://www.nachhaltigesbauen.de/sustainable-building-english-speaking-information/publications.html. For the early design stages and design competitions, special tools are available. The BNB system comprises various types of buildings (e.g. office buildings, educational buildings, laboratory buildings, etc.) as well as defined building-related tasks (e.g. design of new buildings, optimisation of the operation of existing buildings, refurbishment projects). It can be transferred to other building and use types.

3. PRACTICAL EXPERIENCES

The sustainability aspects must be integrated throughout the entire design and procurement process. This begins with a uniform sustainability understanding, the basic decision about the start of design and construction work and the formulation of goals already in the task definition (client's brief). It is possible to take into consideration sustainability aspects already in the early design stages and in the assessment of competition entries.

Sustainability assessment systems can initially be used as a checklist of sustainability criteria. It is a way to ensure that all relevant topics and requirements (including the ones related to sustainability) are taken into account in the design of buildings. Sustainability assessment systems are therefore evolving into tools ensuring the consideration of the "overall performance" of buildings.

Individual requirements and standards for the relevant characteristics of the building are indicated through the provision of benchmarks and quality levels as design and decision-making tools.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

It has been proved to be of fundamental importance to ensure the consideration of sustainability aspects in terms of its "breadth". This means to ensure a complete treatment of all aspects - from aspects related to the technical and functional quality to aspects related to the environmental, economic and social performance of buildings. Additionally, information about the quality of the site has to be provided. This is not be assessed, but only treated as additional information. However, the quality of the design and execution processes is also assessed.

In Germany, the compliance with sustainability requirements must be demonstrated not only as a whole (presented as a percentage of compliance with all the requirements), but also in its subparts, and therefore, the compliance with the requirements of every single "pillar". In the early design stages, it has proven useful to define individual indicators.

One way of further developing and refining the sustainability assessment systems and the qualification of the employees is the exchange of experience. In Germany, the Network for Sustainable Federal Building was set up for this purpose.

4. CONCLUSION

The development and application of sustainability assessment systems assist in the integration of sustainability aspects into public procurement. Developing special system variants for the public sector has the advantage that the special requirements and objectives of these institutions can be addressed. In Germany, for the remaining real estate market, the sustainability assessment system DGNB (German Sustainable Building Council) is available. It was developed and introduced in parallel with the BNB system.

It is recommended not only to use a sustainability assessment system during the design process, but also in view of obtaining a certificate or label showing the level of overall performance that has been achieved. Experience in Germany has shown the advantages of defining objectives and targets for all partial requirements. This facilitates the design process.

Besides having data and tools available, it is also important to maintain and expand the competence of the public sector in the field of design, construction and operation of buildings. In Germany, a special training program has been set up and established for the further education of public employees on the topic of sustainable construction. Through this program, they become more receptive to their responsibility as customers in the area of sustainable construction and are better prepared to integrate the relevant sub-themes into the task definition, tendering and awarding of public contracts. Additionally, they are better equipped to ensure the quality of the design and execution.

It is also important to consider sustainability aspects in the use/ operation of buildings. This is closely linked to sustainability reporting on the public building stock.

The Assessment System for Sustainable Building BNB by Taking the Example of the Complete Refurbishment BNB Module for Educational Buildings

Julia MÜLLER[a]

[a] *Federal Institute for Research on Building, Urban Affairs and Spatial Development (BBSR), Germany, julia.mueller@bbr.bund.de*

ABSTRACT

Sustainable building is a key issue for the public procurement in Germany since the mid-1990s. The Federal Ministry for the Environment, Nature Conservation, Building and Nuclear Safety (BMUB) formulated essential and mandatory requirements for the Federal Buildings, which are regularly further developed with the Guideline for Sustainable Building and the Assessment System for Sustainable Building BNB. Besides sustainable new buildings the sustainable development of existing buildings needs to be considered equally. Around two thirds of the building stock were erected before the first Ordinance on Heat Conservation in 1977 and most of them have not yet undergone complete energy efficiency improvement. Furthermore, existing buildings represent a high ecological value. Extending the period of use of existing buildings is one way to save resources and protect the environment. Currently especially the refurbishment of educational buildings becomes an important construction field. Therefore, also an assessment system for refurbished educational buildings is necessary. Within the framework of a research project, the BNB was adapted for existing educational buildings. Basis are the BNB-modules “New Construction” and “Complete Refurbishment” for office buildings. To meet the special requirements of these buildings some assessment criteria had to be substantively revised.

Keywords: policy and regulation, sustainability assessment, existing buildings

1. SUSTAINABLE PLANNING, CONSTRUCTION, USE AND OPERATION OF BUILDINGS

The starting point for developing principles and assessment criteria for sustainable building is the overarching concept of a policy of sustainable and future-enabled development, which is based on the three dimensions of sustainability ecology, economy and socio-culture. This concept simultaneously addresses ecological, economic and socio-cultural requirements as equally important aspects. In the national approach the technical quality is included as a cross-sectional quality because the technical properties of a building have a strong impact on sustainability quality. The same applies to the process-related aspects of planning. While the quality of the planning process already strongly influences the other sustainability qualities in the early planning phase, it also determines the degree to which the planned quality is actually implemented during execution. In addition, qualities regarding the location profile are also examined because a building and its location always interact with each other.

As a tool for the sustainability assessment of buildings the Federal Building Ministry published the Guideline for Sustainable Building for the first time in 2001. This Guideline explains the generally valid principles and methods for sustainable planning, construction, use and operation and can be used as a tool for taking aspects of sustainability throughout the entire life cycle of buildings. Since it was updated in 2013, the Guideline now covers not only new buildings, but also refurbishment and building conversion projects. While the Guideline for Sustainable Building provides an explanatory framework document for implementing and operationalising sustainable planning, building, utilisation and operation, the Assessment System for Sustainable Building (Bewertungssystem Nachhaltiges Bauen: BNB) delivers verification methodology to be applied. For all federal buildings, the silver standard of the BNB is the minimum standard that must be adhered to. The gold standard should be the target for selected buildings. First model projects by the federal government have shown that the highest sustainability requirements of the gold standard are economically feasible while providing a high level of user comfort.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2. ASSESSMENT SYSTEM SUSTAINABLE BUILDING (BNB)

The Assessment System transposes the requirements set forth in the Guideline into a structure of evaluation criteria and assessment benchmarks. The aim here is to describe and assess the sustainability quality in its entire complexity. The system takes a comprehensive view of the entire life cycle of buildings, giving equal consideration to ecological, economic and socio-cultural qualities as well as technical and process qualities. The BNB is also a quality management system for planning, building, using and operating buildings. It can be used by owners and planners as a checklist, a decision-making and planning tool as well as a basis for discussion and agreement.

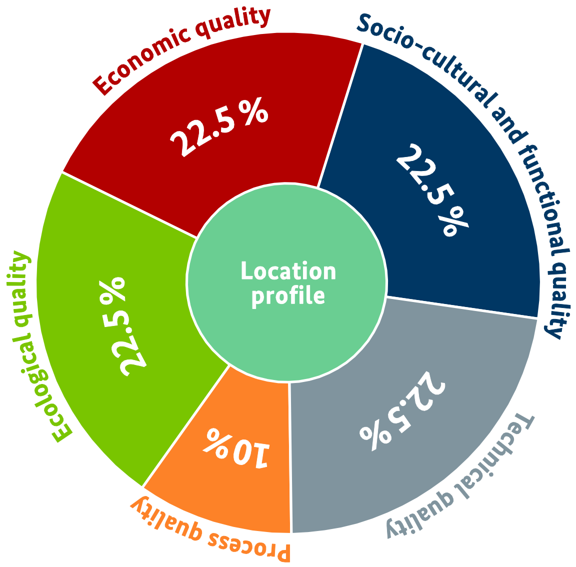

Figure 8: Weighting of the main criteria groups (BBSR)

Sustainability assessment according to the BNB

The Assessment System BNB is structured on the levels of the main criteria groups which are derived from the five sustainability qualities and the location profile, and the individual criteria. Assessing with the BNB the quality of each main criteria group is quantitatively mapped on the basis of the individual criteria. The assess-ment is carried out for each individual criterion by assigning an assessment score according to defined rules and assessment standards. The individual results are compiled within the respective main criteria group while the individual criteria are weighted with a fixed factor of relevance 1 to 3 depending on their relevance for the protection goals. The degree of fulfilment within the main criteria group is calculated using the ratio between the maximum possible score and the score actually achieved. The results of the main criteria groups are calculated with a defined weighting factor to identify the total degree of fulfilment. The quality standard reached - gold, silver or bronze - depends on the degree of fulfilment. The conformity test, a binding examination of the result documents, ensures the quality assurance within the scope of certification.

System variants

For selected types of buildings and uses the BNB system provides specific system variants so that the particular requirements can be systematically taken into consideration in the sustainability assessment. Basically, the dimensions, principles and qualities of sustainable building equally apply to all types of buildings. Nevertheless, different types of buildings have many type-specific characteristics. This may make necessary different priorities, other individual aspects or a different weighting factor in the sustainability assessment. The system variants are:

- Office and administration buildings
- Educational buildings
- Laboratory buildings
- Inter-company vocational training facilities
- Outdoor facilities

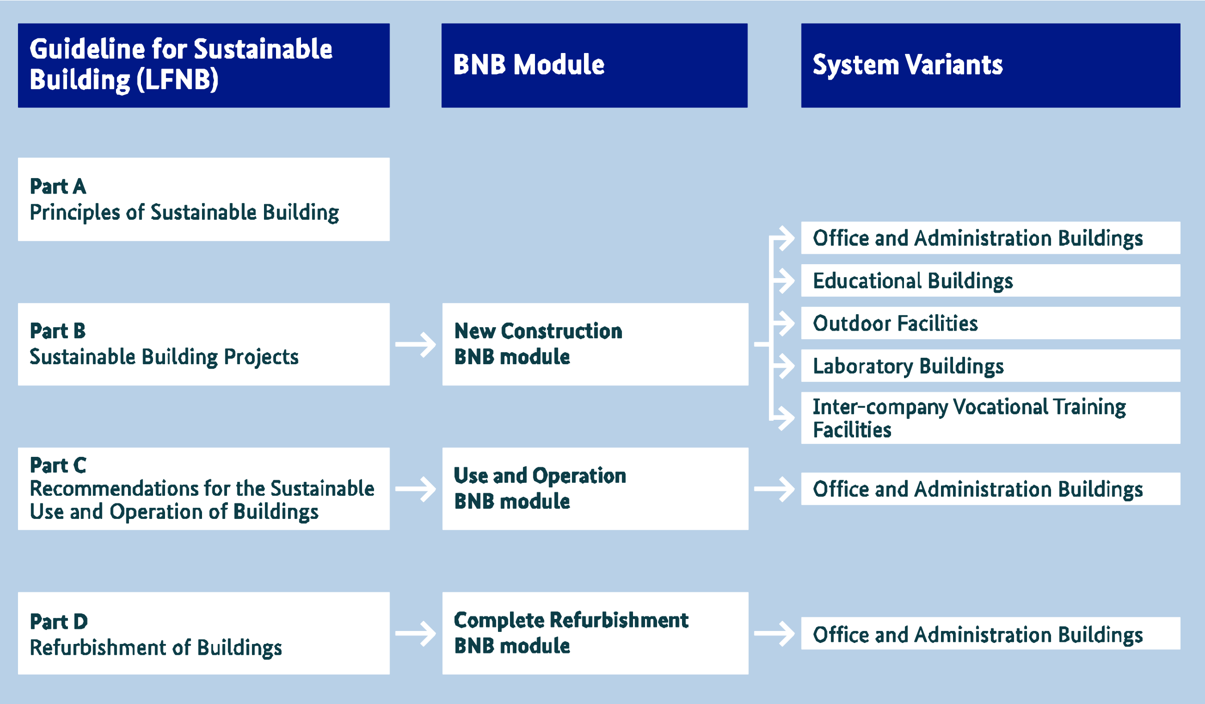

Figure 2: The BNB and its modules and system variants (BBSR)

If it is not possible to clearly assign a building to one system variant due to its location, type of building or use or scope of the project, analogous application of the BNB is generally possible. In this case, the general conditions for the respective country, climate zone or building type must be identified. The aim is to consider the protection goals of sustainability in the project as broad as possible.

Modular layout

A building as well as its use and operation processes can undergo multiple sustainability assessments during the life cycle of the building. For this purpose the BNB has a modular structure with following three modules:

- New construction module
- Use and operation module
- Complete refurbishment module

The BNB modules reflect the cases planning and erecting new buildings, using and operating buildings, as well as planning and performing refurbishment and conversion projects.

Principles of sustainable refurbishment

The principles of sustainable development must be implemented for existing buildings in much the same way as in the case of new buildings. When it comes to qualifying and converting existing buildings, the same ecological, economic and socio-cultural aspects must be equally taken into account. However, the special requirements of the existing building must be considered without generating excessive costs in relation to the benefits. The Complete Refurbishment BNB module is made up of unchanged criteria for new buildings, modified criteria for new buildings as well as specific criteria for existing buildings. The set of criteria reflects the special features of refurbishment projects. The only structural difference exists in the two additional criteria “Stock-Taking” (5.1.6) and “Demolition Planning” (5.1.7), as part of the process quality.

Focus of examination is the entire building and not individual structural intervention measures alone. This means that the building which results from refurbishment or conversion will be considered. Accordingly, the products and building parts already installed into and remaining in the existing building are considered in conjunction with the selected assessment criteria and calculations. The scope of application of the Complete Refurbishment BNB module depends on the complexity of refurbishment, which is a function of the scope of the measure, its depth of

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

intervention in the building and the type of measure. A distinction is made between “complete refurbishment” and “partial refurbishment”. Complete refurbishment is characterised as follows:

- Scope of the measure: complete refurbishment means construction work on an independent, existing structure in its entirety.
- Depth of intervention in the building: the purpose of complete refurbishment is to provide an existing building in its entirety with characteristics and features that correspond largely to those of a new building. Existing buildings are largely stripped down to the structurally relevant elements of the building.
- Type of measure: complete refurbishment encompasses comprehensive work on existing buildings and generally several types of measures. It is characterised by interaction between repair work, refurbishment work, conversion work and interior work.

All building measures of existing buildings that do not go along with this definition are so called partial refurbishments. One of the main differences is that partial refurbishment projects mostly lead to an analogous application of the Complete Refurbishment BNB module since the individual aspects cannot be fully assessed. For partial refurbishment measures the determination of the total degree of fulfilment with the Complete Refurbishment BNB-module usually means an unreasonable level of effort and is hence dispensable. Furthermore, a quantitative assessment of partial refurbishment measures using benchmarks is generally impossible for certain criteria because a general benchmark cannot be developed in view of the wide range of different construction measures. However, the individual measures performed within a partial refurbishment project must be in line with the requirements of sustainable building. A binding target agreement table must be formulated without determining the total degree of fulfilment nor any partial degrees of fulfilment.

3. SUSTAINABLE REFURBISHMENT OF EDUCATIONAL BUILDINGS

Currently around 70% of the educational construction projects are refurbishment projects. Therefore, besides the BNB assessment system for refurbished office buildings, which was introduced 2013, also the assessment of refurbished educational buildings will become an important field for the federal government, the federal states and the municipalities in Germany.

Education and educational facilities are an important part of our society. Educational buildings are part of the public life and can act as a link between different social groups with different cultural and social backgrounds. At the same time, educational buildings must adapt continuously to changes in society. The concept for educational buildings must hence offer sufficient flexibility because of the different functional requirements with a view to room types and functions, use times and the different users.

Within the framework of a research project, the BNB criteria were adapted for existing educational buildings. Basis were the BNB-modules “New construction” and “Complete refurbishment” for office buildings. Besides the criteria of these two BNB-modules who were adopted as they stand, some criteria had to be substantively revised to meet the special requirements of refurbished educational buildings.

Education specific aspects

The sustainability assessment for educational buildings pays particular attention to user needs. The aim is to enable the highest possible degree of user satisfaction in the building, flexible, diverse and synergistic use of rooms and areas, spatial qualities inside and outside and, through public accessibility, to have the building anchored and accepted in the neighbourhood. Especially with the criteria profiles 3.1.5 “Visual Comfort”, 3.1.7 “Outdoor Use Qualities”, 3.1.9 “Indoor Space Quality”, 3.2.1 “Barrier-free Building”, 3.2.4 “Accessibility” and 4.1.3” Cleaning and Maintenance-friendliness” (vandalism prevention), these aspects are brought more into focus. Outdoor areas of educational buildings are regarded as an integral part of the building structure because they should not be separated from the teaching function. For educational buildings the barrier-free accessibility has to be realised for the entire building so that all rooms are reachable and usable. Being able to obtain space, high-quality materials and equipment boosts identification with and appreciation of the building and also helps to prevent vandalism and preserve long-term value.

In order to take the enormous diversity of building types into account, there are also some criteria as 2.1.1 “Building-related Lifecycle Costs” or 6.1.4 “Traffic Connections”, which define differentiated requirements for different use types as schools and universities.

The Educational Buildings system variant does not foresee any quantitative assessment of space efficiency - this is the only structural difference - because the circulation areas are used as recreational areas and increasingly for informal learning so that their dimensions are usually more generous.

Refurbishment specific aspects

Besides the specific educational demands there are also specific requirements concerning existing buildings which the BNB module variant for refurbished educational buildings is taking into account in particular with the criteria of the Life cycle analysis (1.1.1-1.1.5, 1.2.1), the 2.1.1 “Building-related Lifecycle Costs” and 2.2.2 “Adaptability”.

Assessing complete refurbishment measures, the eco-balance assessment is influenced in a positive way when the construction is saved. The assessment standard is considering the fact, that an existing building generally won´t reach the energy efficiency of a new building. The old building substance, which remains in the building, is only recognized in the “end of life” life cycle phase.

Measures with buildings worth listing must be performed in a manner that complies with the needs of such buildings and thus constitute an important aspect of sustainable construction. This must also be considered in sustainability assessments. So for listed buildings the opportunities to improve the energy efficiency is even more limited. Therefore, these buildings can get additional points in the cases of a low thermal transmittance coefficient of the opaque outer walls or a high ceiling height. Moreover, within the assessment of the 2.1.1 “Building-related Lifecycle Costs” of listed buildings, special conditions can be claimed by deducting the project-specific costs of the costs of manufacture. Also the adaptability of listed buildings is limited and therefore the criterion offers special rules for some indicaors, if fulfilling was not possible - or only with a disproportionate effort - because of conditions of preservation.

4. INSTRUMENTS OF SUSTAINABLE BUILDING

All criteria profiles of the Educational Buildings system variant of the BNB system – as well as all other system variants – and more detailed information can be downloaded from the Sustainable Building Information Portal www.bnb-nachhaltigesbauen.de as a general platform.

Furthermore, various fundamentals, information and tools are available for the integrated design, planning and assessment of sustainability aspects in the construction sector. In addition, application tools are available to make it easier to calculate, record and comprehensively document sustainability aspects. The most important are:

- eBNB (Internet-based assessment and documentation tool)
- Data and databases such as ÖKOBAUDAT (www.oekobaudat.de) or WECOBIS (www.wecobis.de)
- eLCA (eco-balance instrument)
- Brochures on different system variants
- System for sustainability requirements in design competitions (SNAP)
- Procurement tools (sustainability compass)

The BMUB's Sustainable Building Information Portal www.nachhaltigesbauen.de provides general information and basics on sustainable building and all necessary guides and tools, construction material and building databases along with information about research projects and events.

5. FUTURE-PROOF PLANNING OF EDUCATIONAL BUILDINGS

Well planned educational buildings support the teaching process and promote the sense for building culture. Being defining components in the neighbourhoods and spaces for learning and living for a variety of people, school- and university buildings have a high social relevance. Therefore, especially for educational buildings, a high quality is very important. A holistic planning process is basis for reaching this high standard. To minimise the impact on the global and the local environment, the energy consumption and the life cycle costs while meeting all user requirements, more than a highly insulated building envelope and optimised MEP-systems are required especially for existing buildings. Because of the interactions of the different relevant topics sustainable building is a complex task. In order to find the best strategies and solutions all stakeholders need to work together. The Assessment System for Sustainable Building for refurbished educational buildings is providing a holistic criteria catalogue.

Sustainable Building Assessment System for Research- and Laboratory buildings - Austrian and Swiss Perspective on the BNB Applicability

Alexander PASSER[a]

[a] *Graz University of Technology, Austria, alexander.passer@tugraz.at*

ABSTRACT

Green Public Procurement (GPP) calls for the use of the public authorities purchasing power to foster environmentally friendly goods and services. As the building sector is a top priority in terms of maximizing energy efficiency, accounting for up to 40% of global and European energy consumption, the goal of the International Energy Agency (IEA) is to achieve an 80% reduction in global emissions by 2050.

Within the paper the applicability of GPP for the buildings' design process is elaborated. The different stages in the procurement process for buildings are explained and the interdependencies of the complex process of design and construction of buildings and related sustainability performance are discussed.

On the base of two international case studies, the applicability of building sustainability assessment methods is briefly discussed. These methods ensure a holistic life cycle perspective within all phases of design and construction, which can easily be implemented in the procurement process. However only with the commitment from the purchaser as well as from involved design team the implementation of sustainable building projects is possible.

Keywords: green public procurement, sustainability assessment, sustainable design process, BNB

1. PUBLIC PROCUREMENT AND BUILDINGS

How can the COP 21 agreement against climate change be linked to public procurement?

Well, it has been proven that public authorities are one of the major purchasers of goods and services around the world. Green Public Procurement (GPP) calls for the use of the public authorities purchasing power to foster environmentally friendly goods, services and, in this case, construction works, to make an important contribution towards more sustainable consumption and production. Although GPP is only a voluntary instrument, the vision is to change the market forces due to a different demand-driven innovation policy - „Market Pull“.

In Europe, public authorities spend more than 16% of EU's GDP – nearly 1.8 Trillion Euros – on buying goods such as office equipment and building components, and purchase services such as buildings maintenance and transport services. In that sense, it is obvious that GPP has a key role in the efforts to implement Sustainable Development Goals (SDGs) and become a more resource-efficient, circular economy. The European Commission and a number of European countries have developed guidance documents and recommendations, in the form of national GPP criteria. For the applicability in the procurement process, GPP requires the inclusion of clear and verifiable criteria for products and services i.e. the inclusion of e.g. environmental ones. In the Austrian case, based on the new EC public procurement, repealing Directive EC and national regulations, new legally approved criteria were developed. They include the level of innovation, risk mitigation (both technically and economically) and new positive incentives (synergy effects, additional benefits, etc.).

Within all industry sectors, the building sector is a top priority in terms of maximizing energy efficiency because the most cost-effective energy savings can be found in the residential and commercial buildings. Due to the fact that the building sector accounts for up to 40% of global and European energy consumption, the goal of the International Energy Agency (IEA) is to achieve an 80% reduction in global emissions by 2050. In Europe, the EU Parliament approved a recasting of the Energy Performance of Buildings Directive in 2010 that requires member states to propose measures to increase the number of nearly zero-energy buildings and to encourage best practices for cost-effective transformations of existing buildings into nearly zero-energy buildings (Passer et al. 2016).

Evidence gathered from office buildings across Europe indicates that the most significant contributors to operational environmental impacts are due to lighting, heating, cooling and ventilation services. In Europe their relative importance primarily varies according to the thermal performance of the building and its climatic location respectively. (EUROPEAN COMMISSION 2016)

Second most significant environmental impacts are related to the production of construction products. These - so called embodied impacts - arise in the life cycle of construction products due to their material extraction, processing and transportation, production, installation into the building or construction works, maintenance and end of life. In this respect, the recycling and re-use of construction materials and products, as well as whole building elements, can contribute to reducing environmental impacts and development of a circular economy. (EUROPEAN COMMISSION 2016)

For the overall life cycle sustainability performance, the buildings service life plays a major role, which can be influenced by other than technical factors too. For example, the building's technical and functional performance as a healthy and attractive working environment can contribute to a longer service life-span and minimise the need for renovations or the building´s demolition. Evidence shows that in a healthy building with good indoor air quality and good socio-functional performance, e.g. as daylight comfort, the workforce is more productive and less illness-related absences occur. (EUROPEAN COMMISSION 2016)

In Europe an overall – holistic consensus has been reached (CEN 2012) that the buildings' performance assessment shall only be done on the buildings level, including all dimensions of sustainability, namely the environmental, the economic, the socio-cultural as well as the technical and the functional performance of a building, pictured in Figure 1.

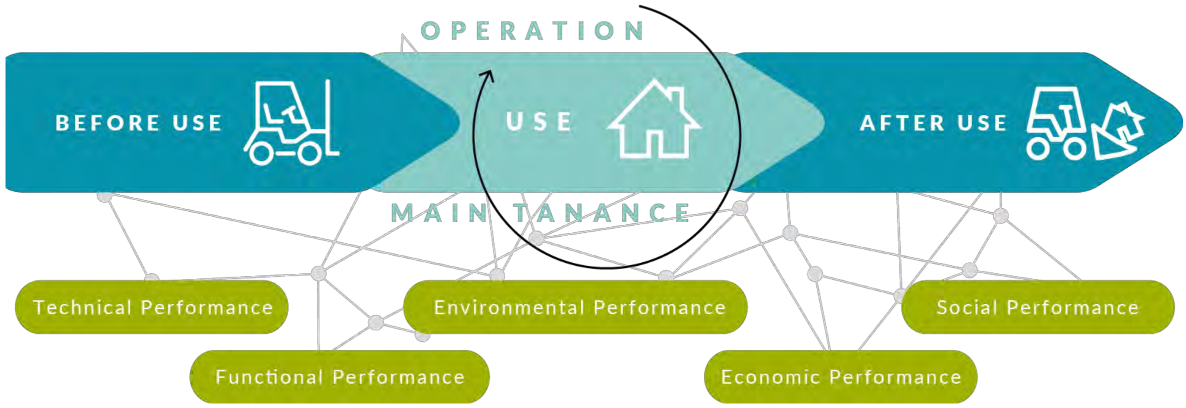

Figure 1: Life cycle of buildings (AGNHB TU Graz)

In the past years a various number of building certification systems like LEED, BREEAM, HQE, DGNB, BNB, SGNI, ÖGNI and TQB were placed on the market to promote green and sustainable buildings. Recently, an increasing demand for such labels has been noticeable. In these building certification schemes aspects of sustainability (economic, social and environmental as well as functional and technical) are considered very differently. However, as all these building certification schemes are based on assemment criteria, they are applicable for GPP and related activities for public authorities. As the German Assessment System for Sustainable Building (Bewertungssystem Nachhaltiges Bauen: BNB) was developed by the German Federal Building Ministry to be used for public buildings, its applicability from an Austrian and Swiss perspective will be assessed on the case of the Sustainable Building Assessment System for Research- and Laboratory buildings.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2. APPLICABILITY IN THE DESIGN PROCESS

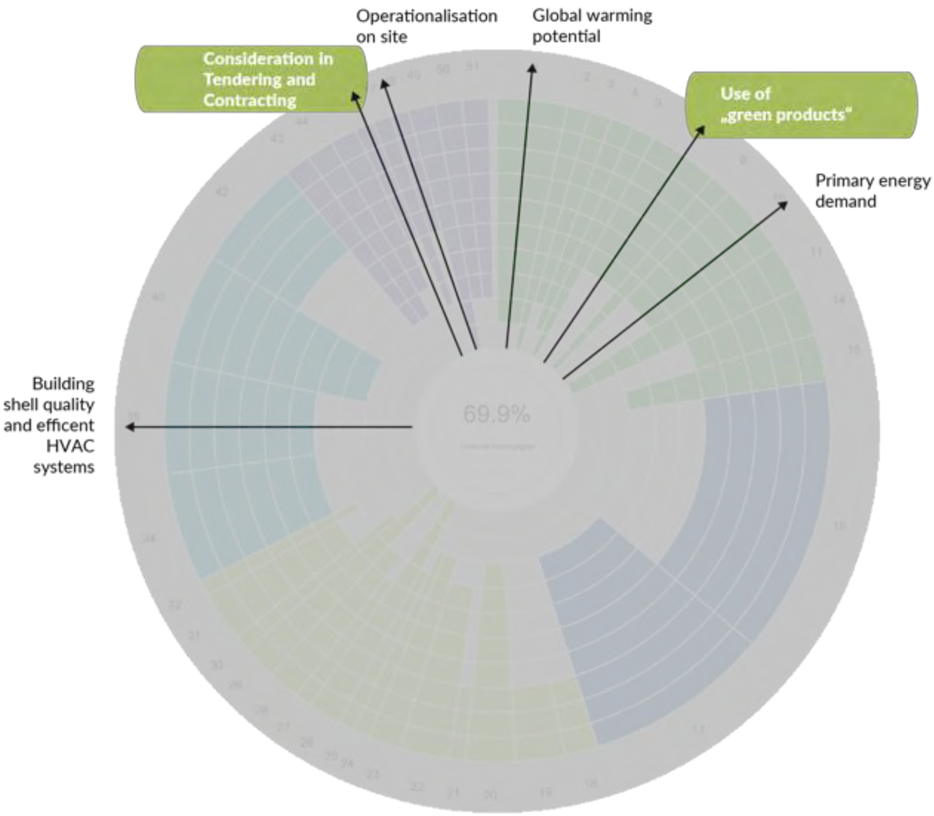

Figure 2: Consequences of GPP for the design and tendering process (AGNHB TU Graz)

Designing and procuring buildings with higher sustainability performance while reducing environmental impacts is a complex process. Figure 2 illustrates the different goals that need to be integrated in the design and procurement process, based on the aimed fulfilment level of different assessment criteria as well as according to the different life cycle phases.

As the implementation level of the goals into the procurement process can have a significant influence on the outcome, the distinct sequence of procurement activities with related contracts are of high relevance. This is because each type of contract brings with it distinct interactions between the procurer, the building design team, the contractors and the future occupants as well as facilities managers. Moreover, they each have advantages and disadvantages in seeking to procure a building with an improved sustainability performance.

According to the EC GPP process (EUROPEAN COMMISSION 2016), depending on the procurement route adopted, some of these contracts may be awarded to the same contractor but in most cases, they are let separately. Some contracts may be integrated in a design and build (DB) or a design, build and operate (DBO) arrangement, with the detailed design process, the main construction contract, the installation or provision of energy services and even facilities management all potentially co-ordinated by one contractor. It is therefore important to identify the main points in the sequence of procurement activities where GPP criteria should be integrated. To this end, these criteria are arranged to reflect the most common procurement activities and are accompanied by a guidance document, which provides general advice on how and when GPP criteria can be integrated into this process. It also suggests, based on experience from projects across the EU, how the procurement sequence could be managed in order to achieve the best results, issues to consider at key stages along the process and specific types of expertise that may help to obtain better outcomes.

Sustainability criteria in the buildings life cycle

Within the different life cycle stages different sustainability assessment criteria need to be defined and checked for a building project. Figure 3 illustrates the possibilities of the definition of project target goals and the related building sustainability certification process. In most building certification schemes the project goals are assessed at the beginning with the pre-certification process of the buildings design and are awarded with a final certificate after its completion ensuring that all goals and requirements are fulfilled.

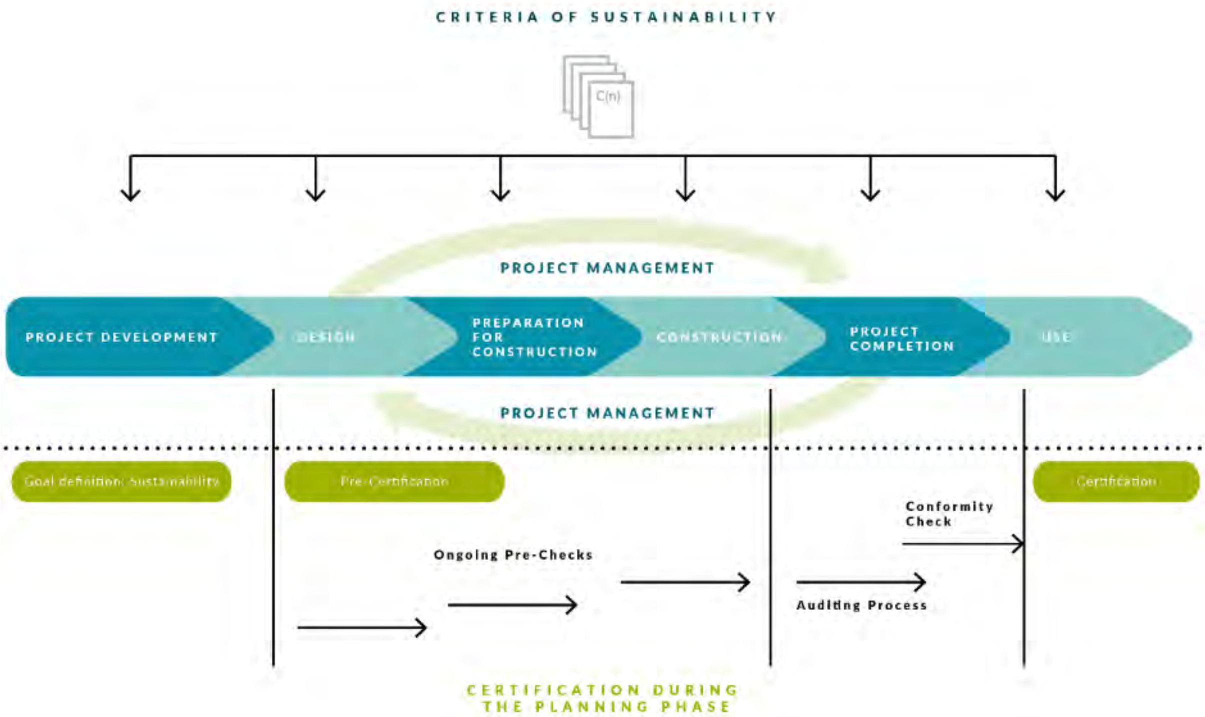

Figure 3: Sustainability criteria in the buildings life cycle (AGNHB TU Graz)

The complex process of design and construction of buildings and related sustainability performance is often checked by the use of a professional sustainability expert (e.g. Auditor, Accredited professional (AP), etc.). This expert checks the fulfillment of the goals defined from the GPP and then communicates with the design team as well with the procurer. Figure 4 illustrates the design process and the parallel process of sustainability performance integration.

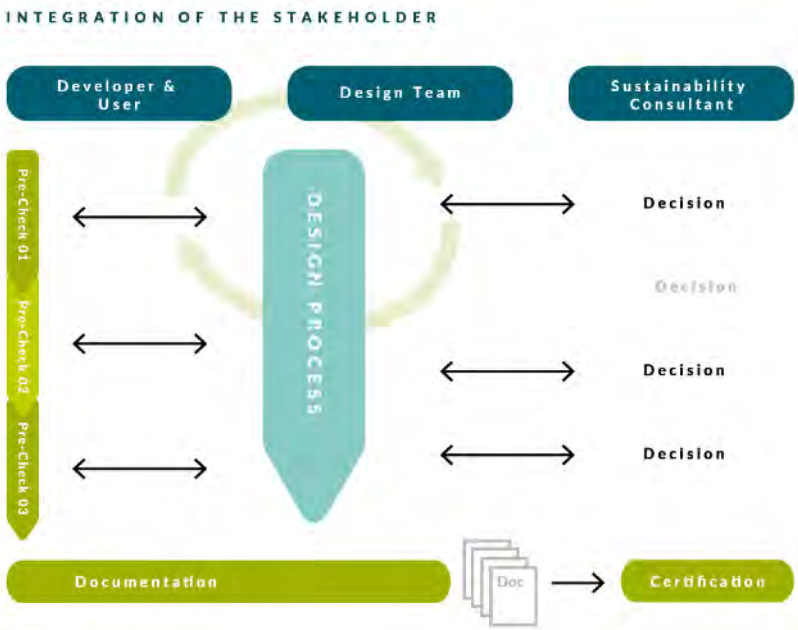

Figure 4: Integration of the stakeholder (AGNHB TU Graz)

3. OUTLOOK - SUSTAINABILITY ASSESSMENT OF BUILDINGS AS PART OF GREEN PUBLIC PROCUREMENT

In a joint activity in the years 2011-2013 BNB, DGNB and ÖGNI developed an assessment method for laboratory buildings based on the BNB assessment method. For the case of two ongoing projects, the applicability and national adaptability of the BNB sustainable building assessment methods in Austria and Switzerland is explained.

MED CAMPUS Graz (Austria)

The building complex as a modern university building, research and teaching facilities centers will have space for around 1700 employees and 4300 students and 68.000m2 gross floor area.

From the project's inception, its development was aligned towards a sustainable and healthy campus in the broadest sense, and this has resulted in a GPP process by the inclusion of sustainability performance targets already in the public competition requirements. Before the process inception a target catalogue on the basis of the ÖGNI assessment criteria was developed, which is the Austrian adaptation of the BNB/DGNB method. In an interdisciplinary, iterative design process, the buildings performance was constantly optimized and checked from a sustainability perspective, which led to a precertification at the end of the buildings design. The achievable goals formed the basis for the requirements and the tender specification respectively. For the construction phase, regular updates of the precertification were used as a monitoring tool. For the final certification, on-site measures were performed to finally evaluate the building's real life performance.

GLC ETH Zürich (Switzerland)

As a second case study, the GLC project from ETH Zurich, demonstrates the integration on GPP processes in Switzerland. Due to the general sustainability requirements of ETHZ all building projects must reach a high fulfillment degree (>65%) of the SGNI assessment scheme, which is the Swiss adaptation of the BNB/DGNB method.

All projects from the architectural competition were assessed with the focus of the criteria that can be assessed in early design stages. In the following, a coordinated initial assessment between ETH and awarded design team has taken place, which then acts as an objective agreement with specific planning requirements to be included in the contracts. The next step was the commissioning of the design team. With the preliminary project, the assessment procedures were established, and ETH is only controlling the target agreement. The precertification was conducted with the preliminary project, where ETH provided the auditor function. The design team and their sustainability experts provided the project details for the assessment. After the building completion, the GPP process ends with the final certification and hand over to the users.

OUTLOOK GREEN PUBLIC PROCUREMENT

Due to the reached common understanding for the importance and urgency of sustainability targets to be implemented in the construction sector, green public procurement could foster the efforts of public authorities towards environmentally, economically and socio-culturally high (better) performing built environment. GPP can have many direct and indirect environmental and economic life cycle benefits. Apart from the immediate environmental gains, e.g. through the purchase of a more sustainable product, it can be a crucial market driver to foster a critical mass of sustainable products.

The use of building sustainability assessment systems, such as the BNB method, ensures a holistic life cycle perspective within all phases of design and construction towards diminishing long term implications. The variety of the developed methods and tools allows the procurers to make transparent, scientifically based decisions. However, all tools, data and methods need to be publically available in advance in order to avoid any discrimination.

Findings from both case studies show that that only with the commitment from the purchaser as well as from involved design team the implementation of sustainable building projects are possible.

However more research on the systemic interdependencies of design decisions and related multi criteria decision making process remains an open task. In order to facilitate the applicability in the design process, it is also necessary to simplify and automate the assessment methods and align it with conventional steps in planning and procurement processes, i.e. through the implementation in Building Information Modeling (BIM).

The awareness of the achieved (higher) sustainability performance and related efforts is an ongoing learning process on its own that has just begun.

ACKNOWLEDGMENTS

The Author would like to thank Andreas Rietz (BBSR) and Thomas Lützkendorf (KIT) for the possibility to contribute to the BMUB workshop on Sustainability assessment of buildings as part of green public procurement based on the German BNB-System. The case studies described in this paper were carried out in the project MED CAMPUS Graz by Medical University of Graz and Bundesimmobiliengesellschaft m.b.H. with the general planer Riegler - Riewe Architects ZT GmbH (architects, commissioned by BIG) and Team TU Graz. The second case study was provided by Christian Stoy (PBK AG) as consultant and Daniel Nötzli (ETH Zürich) for the building project (GLC). We would like to thank all for their support and their inputs.

Natural Resources and Sustainability

Eike ROSWAG-KLINGE[a]

[a] *Ziegert Roswag Seiler Architekten, roswag@zrs-berlin.de*

ABSTRACT

Modern construction worldwide is based on fossil resources like steel, concrete, oil and gas. In Germany the building sector consumes approx. 50% of all fossil resources used to build, maintain and operate the build environment.

Natural resources like earth and wood offer an enormous potential to reduce building services, enable low-tech buildings and to decrease the carbon footprint of the construction industry.

A new movement towards earth, wood and other natural building materials is evolving globally. In Germany a number of research projects in this field are developing inventive solutions for construction, resulting into the development of standards and a number of innovative pilot projects. Along with Austria and Switzerland, Germany plays a leading role with regard to a new natural build environment.

Keywords: earth, wood and timber, low-tech, lifecycle, natural build environment

1. INTRODUCTION

Around half of the world population lives in buildings erected out of earth as earth is one of the oldest building materials of the human kind. Those constructions are most often simple, non-durable huts being located in developing countries, however, the material is also used in applications such as historic buildings around the world, whereof a number are listed as UNESCO World Heritage. Since the 1980s eco movement, earthen architecture is developing further in various countries. In Germany, the earthen construction association 'Dachverband Lehm' established in collaboration with a network of ambitious manufacturers an in-depth technical knowledge for earthen building materials. Recent DIN standards ensure nowadays a very high product quality and enable a wider application.

Timber but also the fast growing grass bamboo, have induced in forested areas a similar tradition as a building material. Especially for timber construction, several pilot projects with innovative, material optimised solutions have recently been erected in Europe, not only exceeding the limit for high-rise buildings but also offering cost and time efficient solutions through prefabrication.

2. LOW-TECH BUILDING SYSTEM OUT OF EARTH AND WOOD

When it comes to the internal environment, natural building materials are characterised through an outstanding humidity buffer capacity, adsorbing around three times more moisture from the air in comparison to conventional materials (e.g. gypsum plaster boards). Applied to the interior, they lead to relative stable and healthy humidity levels indoors ranging between 40% and 60%. In addition, natural building materials are not only low emitting but are able to adsorb harmful substances such as VOC's from the air. Through these specific material properties they contribute to an improved indoor environmental quality as established in H-House, a European Research Project. In combination with vapour permeable envelope construction, earth and timber materials allow modern energy efficient and highly airtight buildings to be naturally ventilated. Fitted out with energy efficient building technology and renewable energy resources these building could be build as low energy and as well as plus energy buildings.

ZRS, a Berlin based architectural and engineering practice, has successfully built and monitored a number of residential buildings in and around Berlin, following this low-tech approach. In collaboration with Prof. Hausladen the idea of vapour active, energy efficient, natural construction has been adapted to a multi storey production building for Flexim GmbH in Berlin Marzahn which is currently under construction.

Building regulation rarely assess the ecological footprint of construction. Trough the use of renewable resources in combination with a low-tech approach the impact on the build environment can significantly be reduced.

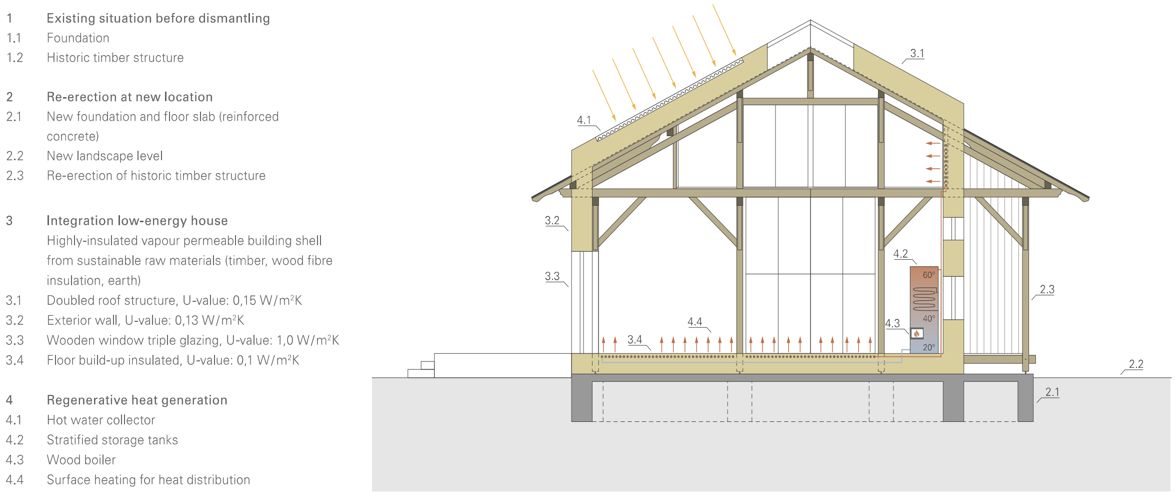

Figure 1: Natural low-tech building system, the peat barn in Schechen, Bavaria, © ZRS-Berlin.de.

3. CIRCULAR CONSTRUCTION WITH EARTH AND TIMBER

Using reversible joints and constructions earth, timber and other natural materials can be reused endless while transforming buildings over centuries. This has been a common strategy until the end of the 19th century, before the consumption-oriented period started, where fossil resources were depleted.

A historic peat barn in Schechen, Bavaria has been relocated and transformed three times since its initial construction in the year 1810. In 2006 it was dismantled in Kolbermoor 15 km away from its current location. The integration of a new workshop and two flats was done in timber, earth and natural fibres as a reversible construction, following the historic model, without compromising energy efficiency and airtightness.

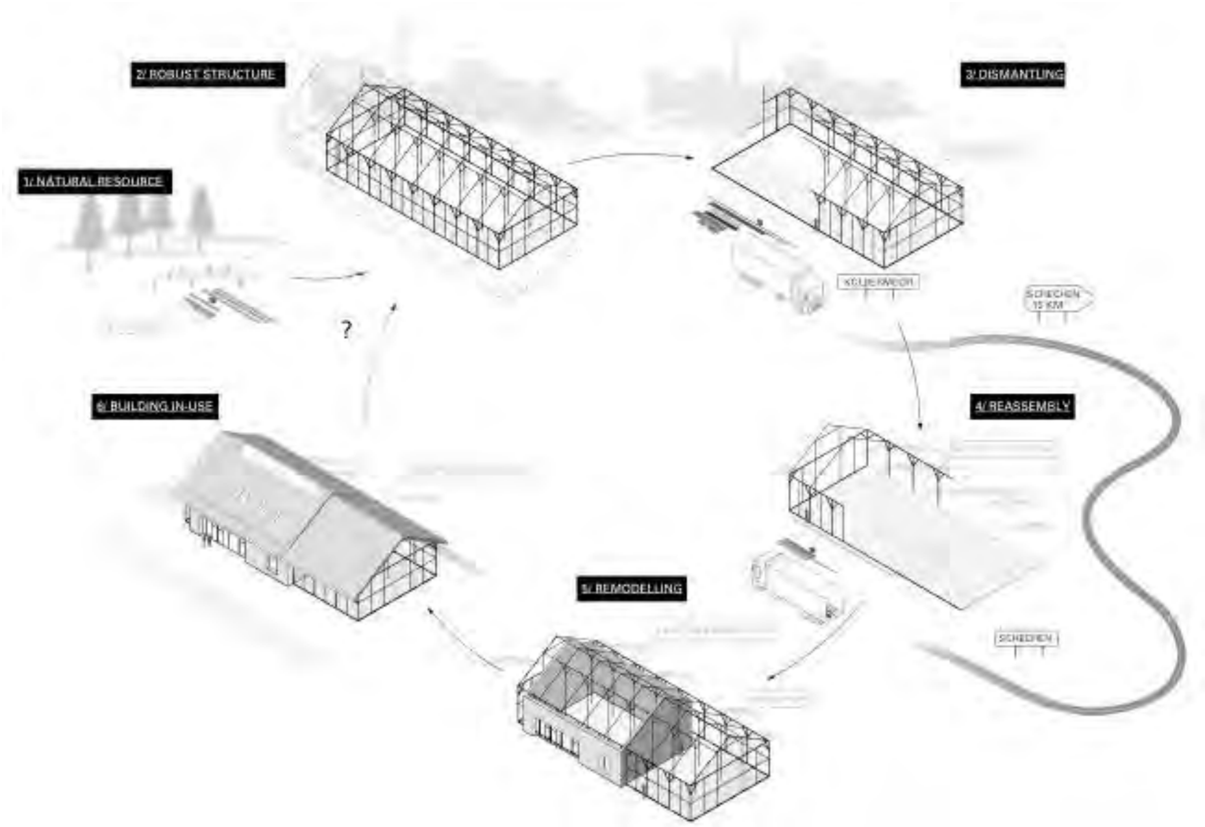

Figure 2: Life cycles of the peat barn in Schechen, Bavaria © ZRS-Berlin.de.

4. FUTURE VISION – DIE NACHWACHSENDE STADT (THE NATURAL REGROWING CITY)

The Berlin based network "Die Nachwachsende Stadt" (NWS) (the natural regrowing city) is researching, designing and building resource positive projects inside the existing urban fabric. The design focuses on social aspects like participation and well being of the inhabitants, general environmental and resource aspects. The NWS is a mixed used city with short distances between working and living spaces.

Projects realised by the network like the Artis carpenter workshop showcases how a clean industry can be integrated into an inner city context. The trade building protects the adjacent residential scheme against noise emitters (noisy street and concert hall) and delivers heating energy to its neighbours. A NWS vision is a mixed-use project at Gotenstraße in Berlin-Schöneberg combining housing with a founding centre for new Berliners with a refugee background. The building is designed as a seven-storey timber structure with visual surfaces as a low-tech low energy building.

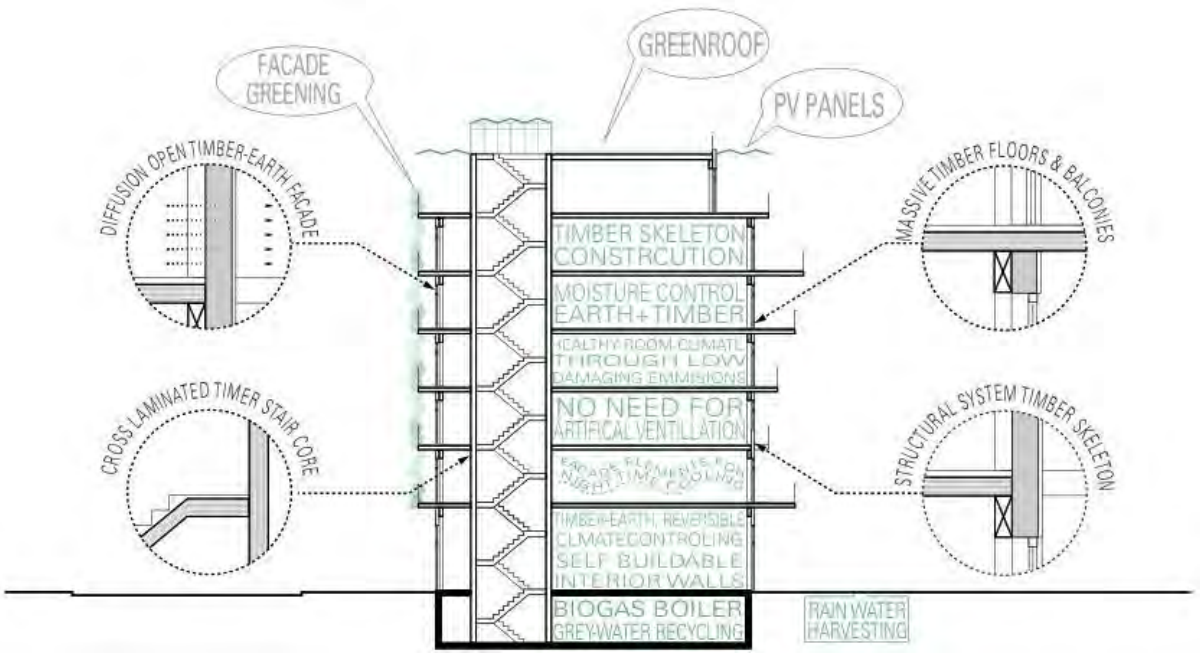

Figure 3: NWS incubator Gotenstraße, Berlin, © ZRS-Berlin.de

5. CONCLUSION AND OUTLOOK

Traditional, natural building methods offer globally an enormous potential to be transformed into a resource positive architecture of the post fossil society. Research and pilot projects as well as an open-minded society are needed to start the transformation process. If high-tech-oriented countries like Germany start to use their engineering potential for a global low-tech idea a dialogue between different cultures is possible and can be the driving force of the urgently required change.

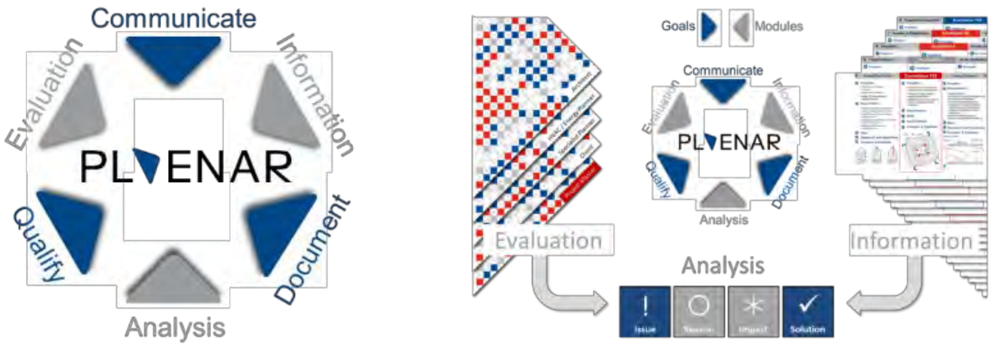
PL·E·N·AR Planning Aid for Energy Efficient and Sustainable Architecture

Günter LÖHNERT[a]

[a] *sol·id·ar planungswerkstatt, Germany, loehnert@solidar-pw.de*

ABSTRACT

PLENAR is a design guide for structuring of basic principles of building design for the preparation and implementation of an integrated design process. Without this process ambitious projects won´t succeed. Main focus is the support of a common, interdisciplinary understanding of planning philosophy regarding energy efficiency and sustainability, among all partners involved in a building project.



PLENAR consists of three main goals which include

1. Communication among actors involved by well-structured discussion formats
2. Qualification of participants and project goals by interdisciplinary approaches
3. Documentation of results in suitable formats for decision making and QA

Facilitating these goals PLENAR provides correlating application modules including

4. Evaluation: Using a given matrix, interrelations of relevant criteria can be evaluated individually by actors, the next step is to compare and assess the results.
5. Information: A database provides generic information on criteria and their correlations with a focus on energy efficiency and sustainability.
6. Analysis: The individual assessments of the relevant correlations made by the participants are discussed to derive the main goals for the individual project.

The presentation will inform planners, interested customers, and companies about the current state of development to promote the progress towards a professional web-based application which would support assessment systems in particular.

Keywords: integrated design process, sustainable building, energy efficiency, design guidance

1. BACKGROUND – OBJECTIVE - POTENTIALS

The complexity of design processes increases continually. The potential of influence on energy performance, comfort and cost efficiency, as the most essential characteristics of sustainable building design, lies in early design stages. Hence, already in state of demand planning certain conditions have to be settled to define a requirement profile with an entire space allocation plan and holistic project goals.

Therefore, it is necessary that a common understanding of planning philosophy regarding energy efficient and sustainable building is set from the very beginning among all project partners. The early and constructive examination of the most important criteria and their correlations as well as their impact on sustainability quickly leads to this common planning understanding and guarantees a higher quality of the entire planning process. PLENAR can be used and adapted by all design teams for their individual project.

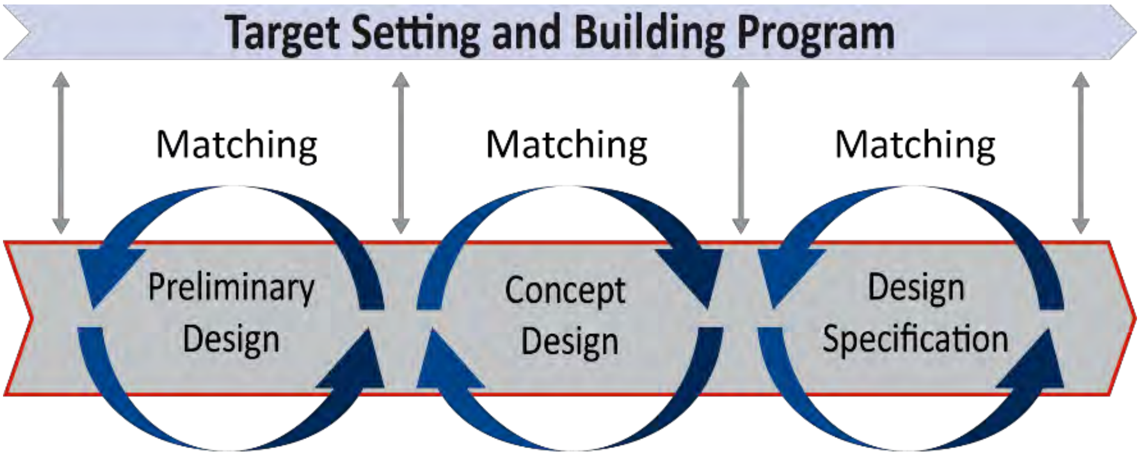


Figure 9: Optimization by iteration loops during an integrated design process

The planning aid PLENAR enables in a short period of time

- An improvement of transdisciplinary understanding on energy and sustainability-oriented relations for all project partners: client, architect, professional planners, user, facility manager and others
- The development of an individual project master as a baseline for the specific project requirement profile and the structuring of the projects integrated design process by selecting and adapting the type and number of relevant criteria
- The development of a project roadmap for the further approaches in the integral design process with concepts to iterations in individual planning stages to optimize the entire planning and implementation process
- The documentation of results as a requirement profile for target agreements and performance specifications as a to-do-list for planners
- The documentation for the building certification as a verification and optimisation for planning objectives when applying assessment systems

2. APPROACH

The design guidance is based on extensive experience of comprehensive project support focussing integrated building design, energy efficiency and sustainability. All correlations (Figure 10) are assessed individually concerning their degree of influence on energy efficiency and sustainability by each actor.

Example: Correlation no. 21 represents the relation between building mass distribution (criteria no. 2) und flexibility (criteria no. 6). The assessment of the actors is determined and compared to a reference (master). Significant deviations to this master, but also among actors, allow a structured discussion. By this way misunderstanding among participants and information gaps can thereby be eliminated. Moreover, the actors will get insight to their role during an integrated design process.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

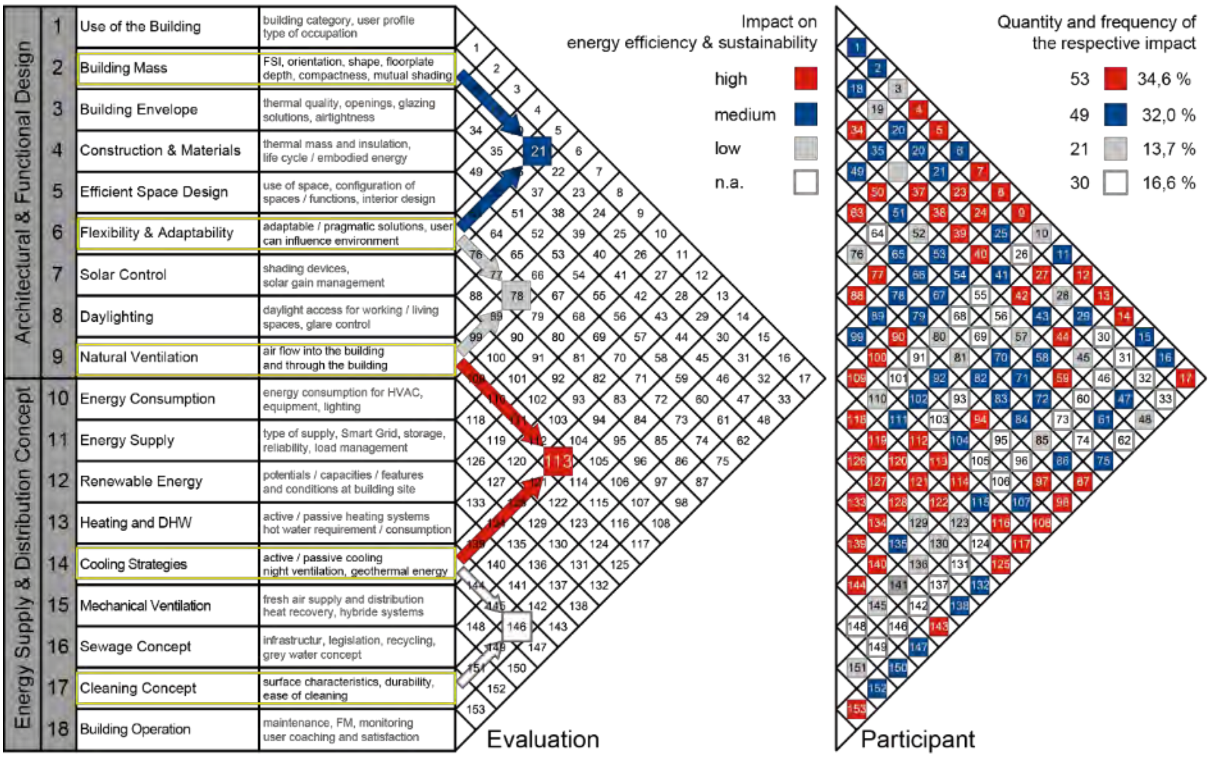

Figure 10: The correlation matrix for an individual application for planning actors

All planning participants, such as architects, energy planners, client and other experts evaluate 153 correlations resulting from 18 criteria, e.g. for office buildings, according to their individual assessment and experience. If possible, all correlations are to be assessed completely with regard to their impact on energy efficiency and sustainability and to be determined in the matrix according to the evaluation level (high, moderate, low or not applicable).

Hence, in the early planning stage each member of the interdisciplinary team has to deal with the same questions. This means, all project participants gain an extensive insight into the planning complexity and, above all, beyond the boundaries of their own planning discipline.

2.1 Evaluation of the individual knowledge

The results are analysed on the basis of the assessments made by the actors, i.e. they will be compared among each another and mirrored to a (master-) reference matrix provided by the design guidance PLENAR. This process gives an overview of the individual knowledge of all actors involved (Figure 11).

With a professional supported and moderated discussion, the different perspectives of the actors can be brought to a common level. Thus, individual expertise is exchanged and expanded for each participant. In the first iteration of the discussion process only the assessments with substantial deviations (deviation of 3 levels) are considered. In a second loop the deviations of level 2 can be discussed on demand as well.

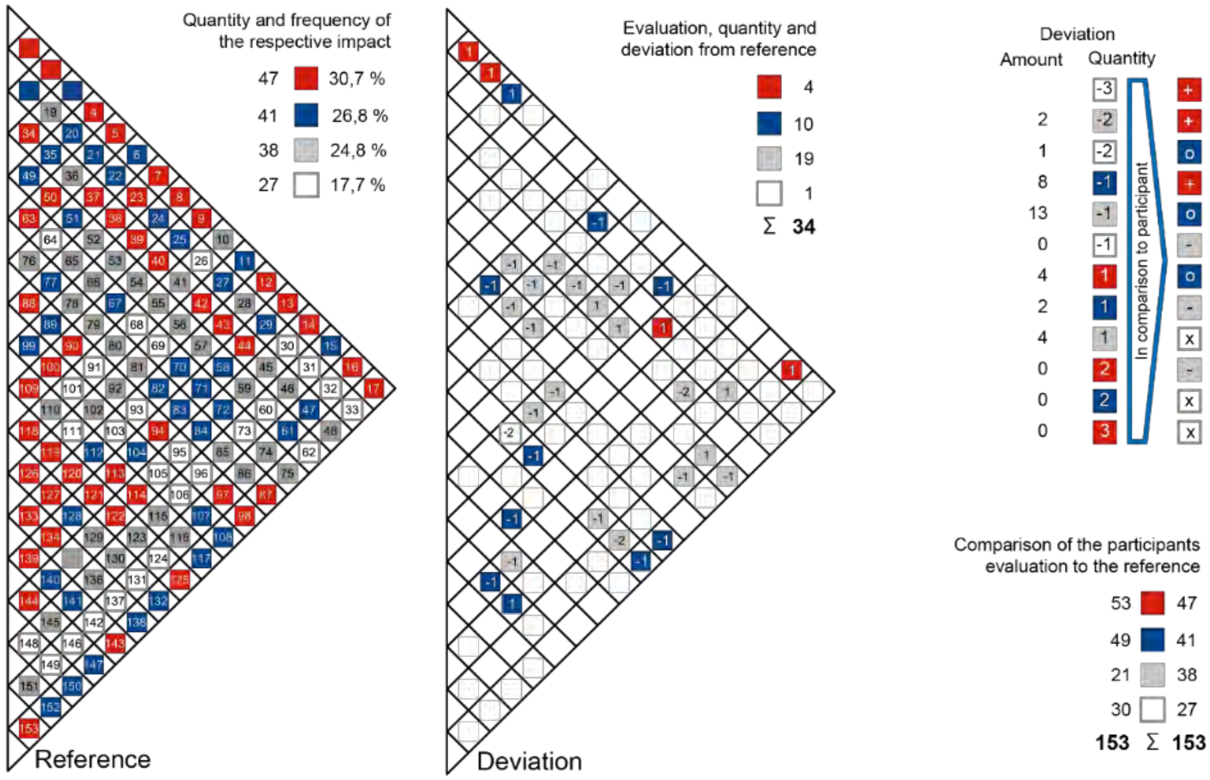

Figure 11: The individual correlation matrix is compared to a reference matrix (master) and evaluated

PLENAR is applicable on different levels. Information level 1 (Figure 12) gives a rough description of the related criterion and its specification and a recommendation for the planning to its user. This level is the basis for evaluating the correlations of individual assessments regarding their respective relevance and the degree of their influence on energy efficiency and sustainability.

Information level 2 describes a variety of information about the potentials of the respective criteria, requirements, risks, standards and guidelines, concepts and examples, such as generally formulated sheets for the requirement and performance specifications (Figure 13). In a discussion, this additional information provides well-founded information to qualify and simplify the planning process.

2.2 Information about the correlations (Level 1)

The database provides supportive generic information for the interdisciplinary discussion of the actor's assessments. This is done for all 18 criteria. If the correlation between two criteria has a high impact on energy efficiency and sustainability (e.g. correlation 113 marked in red), corresponding relevant information is provided as well (Figure 12).

This information can also be adapted and documented according to the respective project specific requirements of the construction project. In this way you fulfil the prerequisites for compiling a performance specification sheet for further planning steps.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

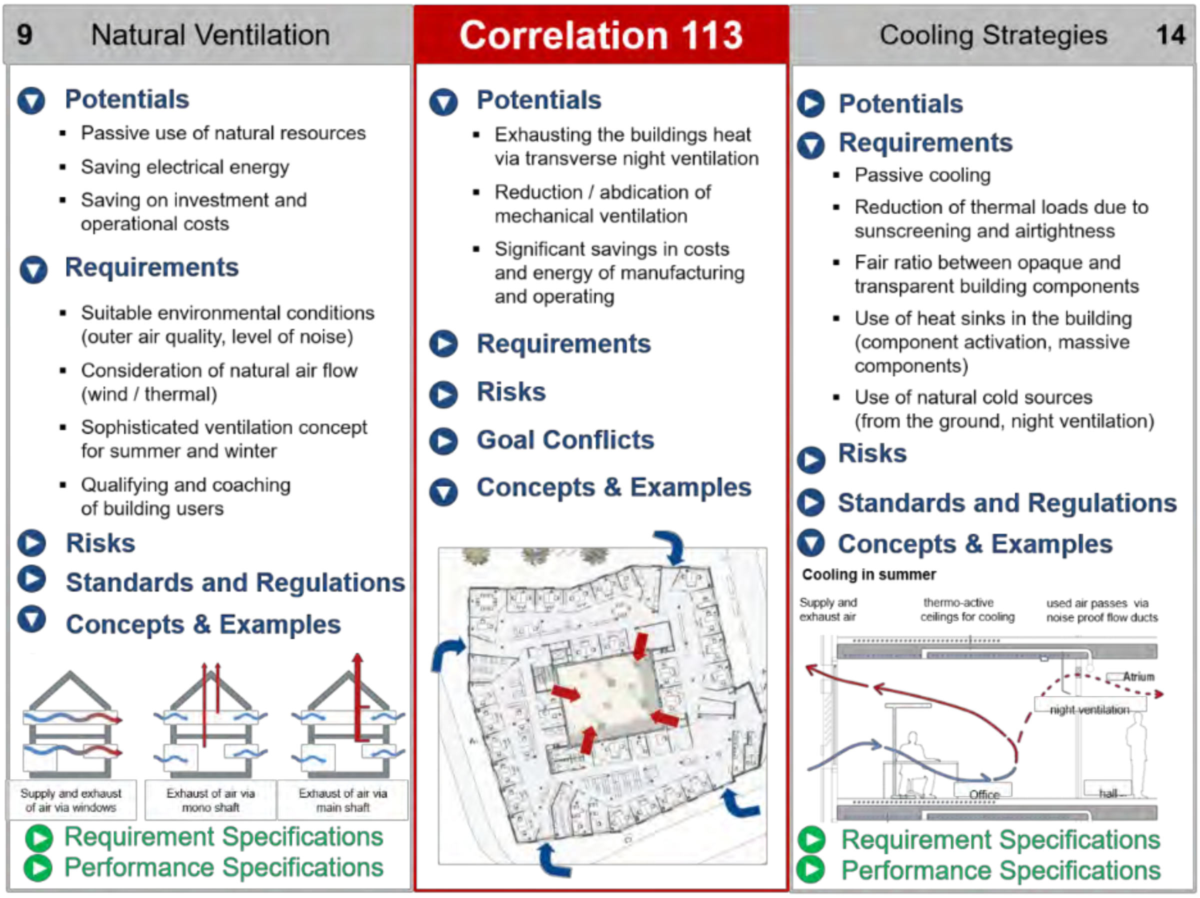

Figure 12: Correlation example 113: Natural ventilation versus cooling strategy

Information: As a communication basis a database provides information on all criteria provided and relevant correlations of high, moderate and low impact. In the discussion different levels of knowledge of the individual actors are balanced and the database is expanded continuously by the feedback of each project implementation. This is true for all building type applications.

Communicate contents and attitudes. Deviations of assessments will be analysed and interpreted in comparison to the chosen reference (generic master, individual project matrix, individual actor's assessment). Important deviations are preferably discussed in a kick-off workshop.

2.3 Profile of requirements and implementation concept (Level 2)

For sustainable design, the requirements profile must be defined with clear project targets and subsequently a complete building program, which is then to be transferred into a performance specification sheet and implementation concept. The starting point and guideline are the confirmed project targets resulting from and addressed in the sustainable building certification system.

The example in Figure 13 shows requirements for a qualified ventilation concept: air quality, user acceptance, low energy demand, low operating costs and noise distribution. The performance specification sheet instructs the relevant measures to be implemented.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 13: Requirement specs define requests - performance specs determine related steps for a successful realisation

Qualification: The professional exchange for the assessment of correlations and the relevance for the certain project qualify both the actors and the entire planning process. As a target agreement, elaborated content and results are documented in a requirement specification and in the performance specification sheet based on it.

Document the integrated design process. With the help of PLENAR, all results of the assessment, the discussion and the specification of the connections for the optimisation of energy efficiency and sustainability can be structured and documented bindingly, for all subsequent planning steps.

2.4 Analysis of effective conclusions

The respective interrelation of tasks, targets, issues and target conflicts, requirements and desires as well as their backgrounds and effects can be analyzed in a subsequent context analysis (Figure 14) in order to develop solutions. In further planning progress, design related specifications are defined and updated or re-defined especially for the current project. As a directive for the objective implementation they are then documented in a comprehensive performance specification manual serving as an instruction book as well.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

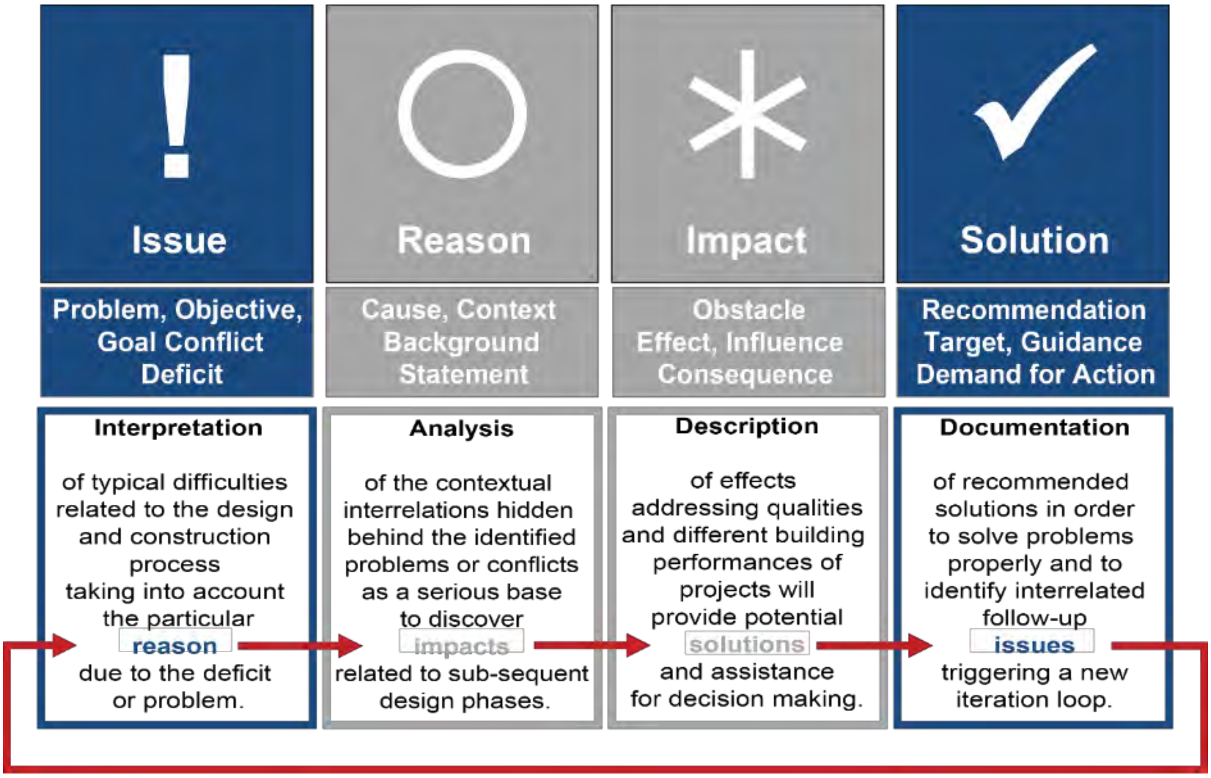

Figure 14: The context analysis is a method for the holistic analysis of correlations in the context of tasks and solutions of all kinds, in order to create a solid basis for the decision-making process.

By using the method of context analysis, tasks, issues, goal conflicts and deficits or problems can be identified in a dialogue with all planning actors. Their backgrounds should be described as well as the respective effects, for example on comfort or operating costs, can be identified systematically. Only this kind of view on the entire context will give the opportunity to deal with questions in a comprehensive way.

For example, solution approaches of the context analysis will also be developed resulting from contradictions and problems with review of the requirement and performance specification sheets or with deviating in goal statements during design progress.

Thereby this method is an important instrument for the elaboration of decision papers and also, based on comprehensive consideration, an element for the integrated planning and implementation process.

3. FUTURE PROSPECTS

In order to provide the tool for planning teams in all kinds of projects, it is to be developed as a web-based application. For individual adaption. As a result, it gives an important contribution to the improvement of the interdisciplinary planning and building culture towards integrated design, energy efficiency and sustainability. In addition to the use of PLENAR as design guidance in building projects, it is also suitable for (interdisciplinary) teaching at universities as well as for further education and training through the academies of architects and engineers chambers.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

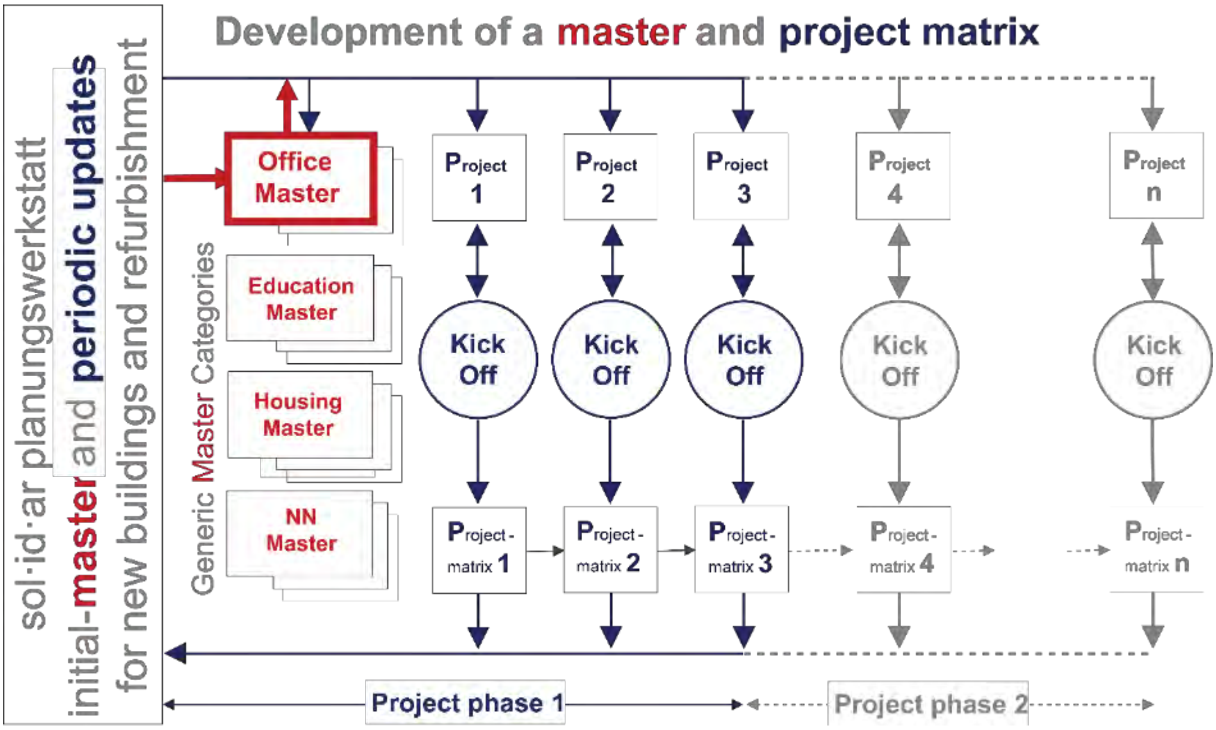

Figure 15: Development of master and project matrix: By applying PLENAR in different projects with different building categories, different masters for different building uses will be created

Moreover, it is also reasonable to use the tool to educate sustainability coordinators and auditors of sustainable building certification systems such as DGNB and BNB in Germany, LEED, BREEAM, etc.

The development for professional applications will provide so-called masters for building categories like office building, housing, education buildings, etc. for both new buildings and refurbishment (Figure 7). Thus, PLENAR qualifies itself frequently by the implementation into design processes and feedback from application practice.

(10) Smart and Digital Transformation for Sustainable Living
Session Organiser: Sino Group

Session 5.14

SESSION OUTLINE

Smart and digital transformation is now and not in the future. With the process of making our world smarter in every aspect of our lives, data from Internet of Things (IoT) and artificial intelligence (AI) for process are the essential enabler. As one of the leading developers, Sino Group has a good number of initiatives in transforming their building portfolio into a better environment for better experience. These initiatives includes providing healthy and sustainable living space in shopping malls, offices, and residential buildings, enhancing user experience through smarter application of technology and apps. Exemplary of implementing technology, Project Moses is making eco homes a reality and connecting with the community through AI and IoT. Specifically in the built environment, AI can help in finding the energy use pattern and allow smart control to match the supply and demand of our resources within our buildings. Lastly, beyond using the technologies, the top-down and bottom-up approaches in making our building development more sustainable for our future generations will be covered.

After the individual presentations, the panel will share their views on how to bring the smart and digital transformation into reality so that we can enjoy a sustainable world for ourselves and our children.

SESSION CHAIR

ABSTRACT

Urbanization in East Asia is growing at an unprecedented rate. Growing Asian cities sustainably will shape the world's path to environmental sustainability and benefit future generations. Apart from the challenges of adopting technologies suited to local climate conditions, the energy needs of high-rise buildings differ from that of low-rise buildings, thus requiring different solutions.

As part of the solution to combat climate extremes, sustainable development of the built environment requires concerted efforts from all stakeholders, including people from the public and private sectors, professionals, and citizens in general. This is not a simple task, as building sustainability is a multi-faceted problem. Collaboration and strong leadership from both public and private sectors to initiate the green movement at all levels are needed. It will require continuous support and actions from government officials to develop the right policies, professionals to innovate in their design practices, and citizens and users to adopt behavioural and lifestyle changes. Specifically:

1. On policy – set priorities for sustainable development policies, set the roadmap and the action plan for long-term strategies, and make institutional arrangements to implement the policies and strategies;

2. On design – redefine building industry practices, especially the standardization of new design strategies for green transformation;

3. On people – change the mindset of people and encourage behavioural change toward more sustainable lifestyles, both at work and at home.

This paper summarizes the above framework and presents specific projects that illustrate its effectiveness. In particular, a case study of green policy development is discussed to show how a top-down approach can drive sustainable development. In addition, a bottom-up approach is illustrated by a building project that demonstrates how buildings can achieve sustainability at an individual level. Finally, a case of fostering low-carbon living through sustainable community-making is presented as an example of behavioural transformation.

Keywords: policy and regulation, smart building, community empowerment

1. ON CONTEXTS OF SUSTAINABILITY IN ASIA

While climate change and decarbonization have been an urgent focus for the world today and many strategies and collaboration opportunities have been proposed in different parts of the world, annual carbon-tracking statistics suggest that we are still on the "business-as-usual" path. In particular, unprecedented urbanization in Asian countries and its potential contribution to carbon emissions will become a serious global challenge ahead that we must better understand and manage.

Ever since C40, a leadership group representing 40 major cities around the world, was founded in 2005, it has demonstrated that cities have the power necessary to mitigate climate change, and the mayors of C40 cities have already been using their power to take action to reduce greenhouse gas emissions. Beyond strategies taken at state and city levels, actions can also been further elaborated at the building and individual levels. The possible solutions for this complex climate change problem have to be rolled out in a holistic way, i.e. from various groups including policy decision makers, industry practitioners, and the public.

2. ON POLICY

Policy issues related to sustainable development are complex and multi-faceted. An effective regulatory system is required to control and incentivize behaviours of various stakeholders by distributing rights and responsibilities for sustainable development in a fair way. In Asia, many policy initiatives are happening in China, Japan, South Korea,

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

and Singapore, most of which are formed under a policy framework with policy priorities clearly identified, possible policy instruments evaluated, and the actions of different institutions and departments coordinated.

Setting policy priorities is very important in driving policy development. As different cities have different unique situations due to geographical, political, and economic contexts, and also citizen preferences, effective policies can only be formed through taking into account and balancing all these factors to find the priorities that are workable. In terms of policy instruments, some examples are regulations, code and standards, tariff and taxes, demonstration projects and public sector procurement, guideline and information provision, as well as education and training. In addition, given the multi-disciplinary nature of sustainable development, different institutions and departments are often involved. Therefore, coordination and clarification of responsibilities is needed to realize the targeted impact from the proposed policies.

In addition to a top-down approach, where policies are driven downstream, feedback aiming to revise or improve the original policy is also important. This can take the form of a bottom-up approach, where industry practitioners can provide valuable feedback to inform policy formation. Both top-down and bottom-up approaches are essential in terms of incorporating building sustainability methodologies into project execution.

Example - HKGBC HK3030 and HKSAR energy saving plan in Hong Kong

In order to adapt to climate change and the increasing local demand for electricity, Hong Kong has established a greenhouse gas (GHG) reduction target of 50% by 2020 and has been exploring options to achieve the objective. In the public consultation paper published by the HKSAR government in 2010, the main method outlined is to target the supply side of energy, which consists of diversifying the energy mix. However, it is also important to consider the demand side of energy. Buildings in Hong Kong consume over 90% of total electricity, and account for over 60% of total GHG emissions. As a result, the Hong Kong Green Building Council (HKGBC) has proposed a 30% reduction of electricity used in buildings by 2030 compared to the 2005 level (HK3030 Campaign). This is considered to be an aggressive yet achievable target given the government’s support and available technology that can be utilized. This goal will propel Hong Kong towards a more sustainable future.

Based on the technologies used in a number of award-winning green building projects, Hong Kong should be able to achieve higher energy efficiency in buildings by over 50% compared to the 2005 level. Given the increasing building stock and higher energy consumption per capita, the HK3030 Campaign should be able to reduce 58% of electricity consumption when compared to the Business-As-Usual (BAU) consumption.

The HK3030 campaign is proposed to complement the Energy Saving Plan, which was proposed in 2015. The Energy Saving Plan aims to reduce energy intensity by 40% by 2025 through economic, regulatory, educational, and social means. This includes enhancing green performance of government buildings by requiring at least BEAM Plus Gold, reducing electricity use by 50% by 2020, and then further evaluating reduction goals for 2020-2025. On the regulatory side, the Energy Saving Plan outlines methods such as tightening energy related standards and requirements under the energy efficiency ordinances, especially those pertaining to buildings. Additionally, the government hopes to promote energy efficiency efforts by encouraging public educational programs and community campaigns. This will hopefully encourage wider adoption of green building concepts by the private sector as well.

3. ON DESIGN

The successful realization of sustainable neighbourhoods and buildings relies on the adoption of integrated solutions during design, construction, and operation by all practitioners. The multi-disciplinary nature of the building industry requires strong collaboration among parties to gather input from various disciplines to realize the design, e.g. structure, building physics, façade, as well as mechanical, electrical and public health (MEP) and other specialist consultants.

For the structural aspect, the design should provide integrity for the building for a long lifespan and resilience to possible local natural disasters. In order to incorporate different areas of concerns, wind, fire and seismic risks should be considered where appropriate. Furthermore, sustainable material that will provide equivalent strength should be considered and Life Cycle Analysis (LCA) would be a helpful evaluation tool. Building physics brings a fundamental understanding for improving the design of building fabrics and surrounding spaces, and to achieving buildings that will respond well to the climatic conditions of their chosen site, function efficiently, are pleasant to occupy and hence, economical to run. The building envelope or façade is another key element for sustainable building. A high-performance, low-energy façade greatly impacts the other systems in the building. MEP systems in buildings safeguard the basic requirements on health and safety and provides the most efficient ways to achieve those requirements. Beyond the building itself, the district energy system, renewable energy and micro grid are also popular sustainable elements to incorporate.

Example - Parkview Green in Beijing

Parkview Green is a building structure that includes offices, retail space, and a hotel. It is enclosed by a glass and ETFE plastic glazed envelope that creates a uniform and easily controlled microclimate environment. The air buffer zones created by this envelope improves the insulation of the building from Beijing's drastic seasonal changes in temperature – in the winter, the buffer zone enhances thermal insulation, and in the summer, the buffer zones facilitate output of hot-air and induces cold air from the lower entrances of the building.

Figure 1: Parkview Green in Beijing, China

Eco-shelter - Parkview Green features a total of four towers, which includes premium-graded offices, a six- star hotel, four floors of retail space—all inside a micro-climate enclosure. The main difficulty in constructing Parkview Green with its current characteristics was to find durable and light glass-like materials to line sloping roofs. At the end, ETFE (Ethy Ltetra Fluoro Ethlyene) was selected because of its weight, high-corrosion resistance, and resilience towards a large range of temperatures. The material was used in conjunction with the "through-air" principle, which naturally ventilated the building through automatic panels in the façade that open and close accordingly. Air ducts were then laid three meters underground, which took air in from the street level to maintain the soil temperature at 15-17 degrees Celsius year round.

Green accomplishments –The technologies used in this project has allowed us to reduce energy use by 50% when compared to similar buildings. As a certified Platinum LEED (Leadership in Energy and Environmental Design) building, it is one of the world's most sustainable architectural developments that protect its visitors from outdoor air pollution and sandstorms, which are both major threats in Beijing.

Anti-quake designs – Each part of the building was fitted such that each contact point and adjoining section provides flexibility in sideway movements, which absorbs seismic shocks in the case of an earthquake. This includes the 235 meter cable suspended footbridge, the longest in Asia, which is integrated into two buildings on opposite ends of the bridge. The integration into the buildings help absorb seismic shock and increases the resilience of the bridge against an earthquake.

Fire protection – While it is energy efficient, the building and its enclosed nature brought some fire safety concerns. As a result, a "melting system" was implemented to the ETFE top, where it melts in the case of a fire to maximize natural ventilation. There is also a special safety area and path for people and fire trucks to enter and leave the complex safely and efficiently.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Green pyramid – Parkview Green is a pioneering project for sustainable buildings with its façade, sustainable design, and resilient facilities. This will provide occupants and visitors a comfortable and safe experience.

4. ON PEOPLE

As urbanization speeds up in all the major Asian cities, taller buildings are built, and the living space per person is becoming more and more compact. A major challenge is how to maintain a liveable but compact built environment with many vertical cityscapes. The creation of quality living spaces becomes imperative to attract people to live in the city.

Designing buildings for urban residents affects neighbourhood development as well, due to factors such as people movement from outdoor to indoor spaces, wind environment or availability, daylight accessibility, and the urban heat island and street canyon effect. In order to build a sustainable community, responsiveness to people's living environment is very important and it can be achieved through evaluating the micro-climate in the area of development. A micro-climate study covers wind and natural ventilation availability, sun shading and solar heat gain, daylight accessibility and glare, thermal comfort and odour and pollutant dispersion. Beyond the design phase, post-occupancy evaluation and energy audits are essential to provide feedback in order to further improve people's living environment.

Space should be designed not only for current use, but also for positive behaviour change that leads to a sustainable future. Occupant behaviour greatly impacts energy use through lighting and ventilation, and also through the choice of ecologically-friendly products. One example of using technology to facilitate behaviour change is through smart metering. Lastly, many demonstrations for Lifestyles of Health and Sustainability (LOHAS) living are available, and sample eco-home exhibitions are used for educational purposes.

Example - Huilanwan Sunrise Village in Taiwan

The vision of this project is to provide a space for life to unfold — where residents are united as a community through exchanging ideas, sharing beliefs, and committed to a community created on the basis of a healthy and sustainable lifestyle (LOHAS).

Figure 2: Huilanwan Sunrise Village in Taiwan

Health – Huilanwan Sunrise Village hopes to encourage a healthy lifestyle by integrating concepts of urban farming and allowing residents to plant and harvest their own food. Additionally, local restaurants provide healthy food options and all nutritional information on food is displayed on either the packaging or the menu. The village also has fitness amenities such as a gymnasium, swimming pool, and indoor jogging path.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Wellness – Wellness does not only pertain to physical health, but to mental health as well. Huilanwan Sunrise Village encourages activities that will enhance both physical and mental health through establishing groups such as the sailing or flying club. The activities are designed to encourage integration with nature and social interaction between residents. The pedestrian path that spans between and around buildings is also designed for pedestrians to maximize their exposure to nature and to other people.

Sustainability – Computer simulations have allowed developers to maximize daylight and natural ventilation through building design, orientation, and landscape, and to enable all visitors to enjoy the advantages of sustainable design. Green roofs are installed to reduce the urban heat island effect and decrease solar radiation influence on higher floors in buildings, and enhanced natural ventilation is used to improve energy efficiency with regards to electricity used for indoor ventilation. In the summer, buildings are cooled through maximized wind flow and surrounding water features. On the other hand, outdoor spaces are able to retain more heat in the winter through protection from surrounding buildings. Other strategies used to enhance the sustainability of the project include solar PV, rainwater recycling, BMS, energy efficient lighting, and A/C. Together, these measures are expected to conserve 58,000 kWh of energy, 60,000 tonnes of water, and reduce CO2 emissions by 30,000 tonnes annually when compared to the building of similar scale in Taiwan.

5. CONCLUSION

In the past century, the world has experienced the fastest urban development ever in the history of mankind. In order to reverse the huge negative impact of development, a paradigm shift is necessary. Green transformation in the building industry is required. This comes not only from the top-down policy approach, through building practitioners' actions, but also through market forces from bottom-up as well as occupants' responses. Environmental sustainability has huge economic potential, especially in Asia where cities are growing, but different markets have their unique opportunities and challenges. It is therefore important to understand the key drivers and barriers for each market. In general, the building market can be categorized into new buildings and existing buildings, each of which has its own characteristics. The new building sector has fewer constraints, whereas the existing building sector faces more limitations in terms of sustainable improvement. To retrieve or re-energize the aged building assets and reduce the operating costs, building-specific survival strategies must be developed. Effective sustainable development can be achieved through combining different approaches.

Session Organiser: Somfy Asia-Pacific Co. Limited

Session 3.14

SESSION OUTLINE

Smart and digital transformation is now and not in the future. With the process of making our world smarter in every aspect of our lives, data from Internet of Things (IoT) and artificial intelligence (AI) for process are the essential enabler. As one of the leading developers, Sino Group has a good number of initiatives in transforming their building portfolio into a better environment for better experience. These initiatives includes providing healthy and sustainable living space in shopping malls, offices, and residential buildings, enhancing user experience through smarter application of technology and apps. Exemplary of implementing technology, Project Moses is making eco homes a reality and connecting with the community through AI and IoT. Specifically in the built environment, AI can help in finding the energy use pattern and allow smart control to match the supply and demand of our resources within our buildings. Lastly, beyond using the technologies, the top-down and bottom-up approaches in making our building development more sustainable for our future generations will be covered.

After the individual presentations, the panel will share their views on how to bring the smart and digital transformation into reality so that we can enjoy a sustainable world for ourselves and our children.

SESSION CHAIR

(12) High Performance Buildings and Sustainable Neighbourhoods in Sweden
Session Organiser: Sweden Green Building Council

SESSION OUTLINE

The Swedish construction sector's extensive activities in the environmental sphere are of international interest. Sweden is also famous for their pursuit of sustainable development in the field of urban building and planning. In this session, five cases of best practice high-performance buildings and three projects for sustainable neighbourhoods in Sweden are presented.

SESSION CHAIR

Bengt WÅNGGREN, CEO and Founding Chairman, Sweden Green Building Council; Member of the Board, World Green Building Council

SPEAKERS AND PRESENTATION TOPICS

Five Cases of Best Practice High-Performance Buildings in Sweden

1. LIDL Växjö

(13) PolyU Green Deck: A Catalyst for a Green and Vibrant Community Session Organiser: The Hong Kong Polytechnic University

SESSION OUTLINE

Located at Hung Hom since 1957, The Hong Kong Polytechnic University (PolyU) has been witnessing the changes and development in this area over the past 60 years. The far from satisfactory urban planning model, rapid growth in population and economic activities in nearby districts have brought along many teething problems: heavy traffic, air and noise pollution, poor connectivity, lack of open space and many others. Not only the 30,000+ staff and students of PolyU suffer, the physical and mental well-being of nearby communities and the daily commuters have also been adversely affected. PolyU, a university which cherishes a sustainable future, is committed to finding an innovative solution to revitalize the districts.

With "To learn and to apply for the benefit of mankind" as its motto, PolyU is committed to blazing new trails and bringing positive changes to society. In order to solve the problems faced by Hung Hom old district and to revitalize the nearby districts, PolyU initiated the Green Deck idea in 2012 and engaged a consultant in mid of 2013 to conduct a feasibility study. With the encouraging findings, the University has embarked on extensive community engagement exercise and a wide variety of related research.

Over 100 PolyU academics have been involved in a number of related practical research in the past few years and the research findings has confirmed that the Green Deck is an obvious choice for a sustainable future.

Chairman of Green Deck Task Force and PolyU research teams will share their findings and insights with conference participants on this social innovative project.

1. INTRODUCTION

In 1948 at the time when Sir Patrick Abercrombie prepared the Preliminary Planning Report of Hong Kong, Hung Hom was already a small residential neighborhood of medium density (200-1200 persons per acre) along the eastern shore of Kowloon Peninsula north of Tsim Sha Tsui. Large areas of reclamation were proposed in the harbor along the east coast of Kowloon Peninsula to be used for residential development in the south and industrial development in the north. Over the next half century, these reclamations were realized step by step, and finally becoming the present East Tsim Sha Tsui, Hung Hom and Whampoa. The Abercrombie's plan was prepared to guide city development in the next 50 years. At that time, the total population in Hong Kong was estimated to be about 1.5 million; and this plan had proposed an increase of 0.5 million to make a total of 2 million. One very interesting feature in this report was about the proposal of a cross-harbor tunnel from the center of Hong Kong Island to the tip of Kowloon Peninsula. This concept was also realized in 1972 by the completion of the Hong Kong-Hung Hom Cross Harbor Tunnel, linking Hung Hom on the Kowloon side to Wanchai on the side of Hong Kong Island. In 1974, two years after its completion, the tunnel's average daily traffic volume had reached almost 40,000 vehicles.

Looking back from today, the Hong Kong population projected in Abercrombie's plan was under by a long way. The 2001 Hong Kong Census has identified a total population of 6,708,389, 3.5 times higher than the projection. Hong Kong has transformed from a medium size city into a high density Metropolis. Today, Whampoa is largely residential, much of Hung Hom, a high density mixed development neighborhood and East Tsim Sha Tsui, a major urban commercial center. To support urban growth of the city, Hung Hom not only accommodates more people, it has provided homes for three major urban facilities, viz. the Hong Kong Polytechnic University (PolyU), the Hung Hom MTR Station and the Kowloon entrance to the Hung Hom Cross Harbor Tunnel. These facilities co-existing in a high density environment would create many opportunities if treated appropriately, or if not, many problems. Unfortunately today, the Hung Hom neighborhood around PolyU is facing many deeply rooted problems of enormous proportions resulting from 50 years rapid urban development with little consideration on contextual implications, such as heavy traffic, polluted air, lack of amenities, broken down connectivity and depressed neighborhoods. Aiming to turn this negative situation around to become a sustainable and vibrant area, a Green Deck is proposed to be constructed over the cross-harbor tunnel toll plaza so as to achieve the following objectives:

- To improve district air quality and community health
- To extend community connectivity and access to the harbor
- To enhance local amenities and environmental quality
- To revitalize depressed urban centers and upgrade local economy

2. AIR QUALITY AND COMMUNITY HEALTH

With about 120,000 vehicles passing through the Hung Hom Cross Harbor Tunnel Toll Plaza daily, the tunnel design capacity of 78,000 vehicles per day has long been exceeded. The air quality in and around the toll plaza has remained to be extremely poor during most parts of the day due to constant traffic congestions in the toll plaza and vehicles slowly converging and moving into the tunnel tubes. A roadside monitoring station 400m away from the Cross Harbor Tunnel entrance facing PolyU has found nitrogen dioxide (NO_2) and particulate matters (PM) concentrations exceeding the standards of the Hong Kong Air Quality Objectives. This study also cites much higher potential cancer risk for the bus waiting crowds due to long bus queues with running engines. The current environment is a street cannon situation, with unfavorable wind and pollutant dispersions, thus people on the street are exposed to relatively high road-side pollutant concentrations.

It is anticipated that incorporating the proposed Green Deck with air treatment facilities, all pollutants will have a significant decrease. The improvement of PM and carcinogenic compound in the area would be from 30% to 60% and the Hong Kong Air Quality Objectives can be met. Consequently, the cancer risk of different target groups has 30% to 70% reduction. After Green Deck being built, the overall cancer risk would be decreased over 50%. Furthermore, the proposed bus waiting lounges in the Green Deck would further protect passengers from exposure to polluted air. Other studies have also supported that a clean and green environment can lower the risk of chronic illness including cardiovascular and respiratory diseases, obesity, depression and anxiety. In the long term, healthcare expenditure can be reduced as people may visit clinics and hospitals less often and length of stay in hospitals can also be shortened. A green environment with nicely built walking and bicycle paths, does not only enhance the connection of different areas, but also facilitate people to walk and exercise regularly.

In Hong Kong's sub-tropical climate, the summer is long, wet and hot, reaching above 30 degrees Celsius quite easily during the day. The existing toll plaza will then become an enormous heat island causing agonizing discomfort to large crowds of people who pass through this area and adds to the cooling loads of buildings in the vicinity. The Green Deck would introduce urban greening to improve the environmental quality within urban areas by mitigating urban heat island (UHI) effect and improve thermal comfort by moderating micro-climatic conditions and providing shading. It can bring other benefits including the ability to attenuate noise levels, improve air quality, reduce urban storm water runoff and enhance stress recovery.

3. DISTRICT CONNECTIVITY THROUGH PEDESTRIAN / VEHICULAR SEPARATION

Since the Hung Hom MTR Station and the Hung Hom Cross Harbor Tunnel are located in close proximity, the volumes of vehicular, rail and pedestrian traffic in this area are all very heavy. Nearby neighborhoods are split up by roads, trunk roads, toll plaza and railroads into isolated islands leaving almost no rooms for pedestrians. Street environment has also deteriorated and become confusing to pedestrians. District connectivity amongst neighboring communities in Hung Hom, Homantin, King's Park and East Tsim Sha Tsui is almost broken down. There are two old pedestrian footbridges spanning across the toll plaza linking MTR Station to PolyU, which connect to outside areas, and they are heavily utilized especially during morning and evening peaks. A recent study has found the congestion on the northern footbridge is particularly alarming. During morning peaks, congestion restricts on pedestrian flow (Level of Service, 'LOS' D) and thus becomes undesirable. Evening peak conditions are even worse since pedestrians had to follow a high density crowd while moving slowly on the bridge ('LOS' E). Steep stairs are provided on the footbridges for passengers to transfer from bus to train, and vice versa. In a highly congested condition with large crowds moving through, these stairs could give rise to accidents especially for accident prone children and elderlies.

Upon completion of the proposed Green Deck, which includes a green park on the upper deck and a pedestrian concourse in the intermediate level, pedestrian circulation would be elevated above vehicular and rail traffic, thus it would greatly improve the current situation. The upper deck and the intermediate level of the proposed Green Deck would have significant effect in diverting pedestrians. Simulated pedestrian flows show that during both morning and evening peaks, the corresponding service standard would improve significantly ('LOS' B).

The physical environment for pedestrian circulation would also improve considerably since the upper and intermediate levels of the proposed Green Deck would provide multiple points of pedestrian entry for multi-directional connections among the surrounding neighborhoods. The intermediate level would be all weather protected and with accesses to many social facilities which may be located on this level. As such, the proposed Green Deck would provide area wide connectivity to the Hung Hom, Homantin, King's Park, East Tsim Sha Tsui communities, the MTR station and the Hung Hom/East Tsim Sha Tsui harbor front.

4. ENHANCING LOCAL AMENITIES AND SATISFYING SOCIAL NEEDS

As most large scale social projects, the Green Deck would have many stakeholders. Due to the high concentration of activities and movements, other than people who live, work and study locally, large crowds of people move through this area every day by using the MTR station, bus stops, and also passing through streets, walkways, and footbridges. For the tens of thousands of these people, there is a lack of public amenities to serve them. For example, very limited urban space is devoted to serve the pedestrians. There is not even a district wide pedestrian signage system. Within 1 km of the proposed Green Deck site, there is no public information center, no sizeable parks, no significant community facilities or libraries. Long queues of bus passengers stand in lines under small canopies in the open engulfed in polluted air waiting for their buses every day.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

A recent study has found that a significant proportion of residents were dissatisfied with the neighborhoods' air quality (29.6%), noise level (25.9%), and greenery (22.1%). Furthermore, the top three of areas which needed to be "greener" were Cross-Harbor Tunnel Toll Plaza (49.2%), MTR Hung Hom Station and Hong Kong Coliseum (44.5%), and Whampoa & Hung Hom (43.8%). Most people indicated that forest and botanical gardens (49.8%), tame grassland (38.5%) and sports and recreation facilities (38.5%) were the most needed in the neighborhoods.

The Green Deck would provide a landscaped park of about 43,000 m^2, which would consist of pleasant footpaths and a variety of outdoor and semi-outdoor venues for passive and active recreation, with a number of indoor facilities for sports and cultural activities all for public use. The intermediate level would further make available about 30,000 m^2 indoor space for bus waiting lounges and a variety of community facilities for different uses such as meeting, exhibition or retail.

Another study commends the 3-layer concept of the Green Deck: an upper level as an open green park; a middle level for circulation, meeting/exhibition, retail and mechanical functions, and a lower zone for the existing Cross Harbor Tunnel Toll Plaza. Thus, the Green Deck will in effect be a layering of three different programs with different purposes and functions to satisfy various social needs among different user groups such as locals, commuters, tourists, business people, students and the driving community.

The same study also identifies vital connections, which would be re-established by the Green Deck among various currently fragmented urban fabrics in this area and further extended out to neighboring communities as foot paths and bicycle tracks in a pleasant park like and other attractive settings, thus enticing the adoption of a walking and cycling habit by the local communities.

5. REVITALIZING DEPRESSED URBAN CENTERS AND UPGRADING LOCAL ECONOMY

A feasibility study was commissioned by PolyU in 2014, and the cost of construction of the proposed Green Deck was estimated at $5 billion at 2014 price level. Despite the high cost, the overall direct and indirect benefits are long term and substantial.

It is argued that the Green Deck would revitalize a depressed urban center covering parts of Hung Hom, East Tsim Sha Tsui, and Homantin, which are currently disconnected, underutilized and stagnant for many years, affecting the lives of hundreds of thousands people. Numerous studies, local and overseas, have found desirable view and environment would lead to higher values in properties. In this light, the proposed Green Deck would have a catalyst effect on neighborhood improvements, upgrading both the physical conditions of the neighborhood and the values of thousands of properties in the vicinity. Government revenues would also be increased due to higher rates to be charged on these properties and future land sales.

The Hung Hom MTR Station deck and East Tsim Sha Tsui are currently underutilized prime urban sites with efficient infrastructural access and adjacent to the proposed Green Deck, thus positioned to potential substantial gains. In a conference at PolyU in December 2015, the Hong Kong Tourism Board proposed to develop a new conference center on the Hung Hom MTR Station deck, taking advantage of the location and the hotel, retail, entertainment facilities in East Tsim Sha Tsui, to support the constrained convention tourism due to a lack of suitable urban venues.

Tourism is one of the four pillar industries for Hong Kong employing nearly 80,000 people. However lately, tourism development is losing steam due to a lack of new attractions. The proposed Green Deck would be a unique attraction in its own right, and it would bring about an agglomeration effect to a cluster of other nearby attractions such as the clock tower, the Avenue of Stars, Tsim Sha Tsui promenade, the Science Museum and the History Museum.

The tangible and intangible benefits brought about by the Green Deck are widely spread and difficult to be accurately valuated. A recent study identifies that urban green infrastructures are underrated. Since environmental and social goods are usually not traded in the market. By only evaluating the economic benefits, the total benefits of the investment would be underestimated as the non-marketed goods are neglected. Thus, from the social point of view, the proposed Green Deck could be beneficial to the public.

6. CONCLUSION

Through public consultation in the past few years, the proposed Green Deck has been receiving overwhelming supports from the society. Due to the high initial construction cost, what it would need is a strong political will and a vigorous government leadership for its implementation.

ABSTRACT

Climate change harms environmental, social and economic sustainability at the community level. Building green open spaces proves to be a useful measure to cool their surrounding areas. This paper aims to preliminarily build a model to help decision-makers strategically use landscapes to mitigate warming climate. In this article, the cooling capacity of green open spaces was identified and evaluated. Then the thermal benefits were identified and defined. Afterwards from the operationalised definitions, formulas were developed to quantify the benefits. Lastly, a case study of a proposed green platform called Green Deck was conducted to show how the model works. The results show a significant capability of landscaping works to enhance sustainability through combating climate change at the neighbourhood level. A strategic thinking path for government is also raised to improve the decision-making of landscape works.

Keywords: landscaping, climate change, cost-benefit analysis

1. INTRODUCTION

Climate change and urban heat islands (UHIs) are the major causes of warming climate in Hong Kong. At the neighbourhood level, heat stress caused by warming microclimate is supposed to impact on both human health condition and human behaviour performance. Thus, cooling the microclimate is one of the main objectives to improve the community livability and sustainability. As a form of landscape, green urban parks are effective to mitigate the warming temperature by cooling its surrounding areas, which are called 'park cool islands' (PCIs). Based on PCI theories, this paper aims to preliminarily build a model to help decision-makers strategically use landscapes to mitigate warming climate. Firstly, using literature review, equations about PCIs' thermal benefits to their neighbourhood areas were formed. Then, the calculated benefits were used in benefit analysis, a partial use of the cost-benefit analysis, to develop a mathematic model to evaluate their monetary values. Afterwards, a case study of a planned overhead platform called 'Green Deck' was conducted with the model. Lastly, the results of the case study were discussed, and some policy and research recommendations were given.

2. PREDICTION OF PARK COOL ISLAND

A PCI is the neighbourhood area of a green park which has a lower temperature than other parts of the city. In this research, a PCI is described by two dimensions, its size and the magnitude of the decrease in temperature.

At the decision-making stage, the size of a PCI can only be estimated by the size of the park. Although some studies using remote sensing and other measure technologies have revealed that the scope of a PCI is not linearly related to the size of the park. Jauregui's conclusion that the cooling effect of a park can reach one-park width beyond its boundary has often been cited and validated and is also used in this research.

The magnitude of the decrease in temperature differs with different geographic contexts. The maximum intensity of a PCI in Hong Kong has been calculated as approximately 1.4℃. Thus, the average park cool island intensity was assumed as 0.7℃, which was rounded off as 1℃ in this research. As the intensity inside a park is stronger than it outside the park, 1.5℃ is used, as a rounded-off value of 1.4℃.

3. BENEFIT ANALYSIS AND CASE STUDY

3.1 Method basis: Cost-benefit analysis (CBA)

Cost-benefit analysis (CBA) is a widely used policy decision-making tool. Using CBA in an environmental project can ensure the goal of ecologically sustainable development. Thus, in this research CBA can well reveal whether a green open space can improve its neighbourhood sustainability.

CBA has the capability to evaluate the monetary values of the well-beings that are not traded on the market. This capability relies on two methodology paths, contingent valuation and revealed preference. In this research, the revealed preference method, in which data mainly derive from the official databases and professional works, was used.

The steps of CBA were given by Hanley & Spash. Although only the benefit analysis was used in this research. These essential steps were still obeyed.

3.2 Identify the benefits

In the first step, the benefits of this research should be defined. The benefits were defined as the benefits brought by the PCI of a park.

Secondly, based on the literature review, four kinds of such benefits were identified. They are health benefits, saved energy consumption, increased productivity and increased recreational activities.

The warming weather causes various diseases. Consequently, more morbidities and mortalities would emerge. Besides impacts on human health, the increasing temperature also causes changes in human behaviour. Building users will use more energy to keep the indoor environment thermally comfortable. In the workplaces, a higher temperature may cause lower productivities. The hot weather also prevents people from going outside for recreational purposes. The baseline temperature of the influences on productivity and park use are both 25°C.The change patterns of the four benefits are summarised in Table 1.

Item	Change Pattern	
Morbidity	4.5% with 1°C change	
Mortality	(Rate) 6.86 with 1°C change	
Electricity Consumption	Residential	20.2% with 2°C change pre year
	Commercial	6.1% with 2°C change per year
Gas Consumption	Residential	4.8% with 2°C change (Positive) per year
Productivity	4% with 2°C change	
Recreational Activity	$y=-3.6393x+141.89$ y = number of park users x = change of temperature	

Table 1: Change pattern of each item adaptable to Hong Kong

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Based on Lin's equation, the increased recreational rates due to the thermal effect of a park under each certain temperature were calculated and shown in Table 2.

Daily Mean Temperature	Increased Recreational Activity Rate	Annual Number of Days
27°C	12.5%	30.3
28°C	13.7%	32.8
29°C	15.0%	37.9
30°C	16.7%	30.6
31°C	18.8%	3.8
32°C	21.5%	0.2

Table 2: Increased recreational rates due to the thermal effect of a park

3.3 Model development

Then the economic impact of each of these benefits was modelled by benefit analysis. The equations are shown in Table 3.

<table>
<tr><th colspan="2">Benefit</th><th>Economic Impacts</th><th>Formulas</th><th>Factors in the Formula</th></tr>
<tr><td rowspan="3">Health Benefit</td><td rowspan="2">Reduced Morbidity</td><td>Hospital Admission Fees</td><td rowspan="2">BMB=NRMB×(HF+RAD)</td><td rowspan="2">NRMB=reduced number of morbidity; HF=average hospitalisation fee; RAD=cost of a restricted active day</td></tr>
<tr><td>Restricted Active Days</td></tr>
<tr><td>Reduced Mortality</td><td>Loss of Statistical Value of Life</td><td>BMT=NRMT×SVL</td><td>NRMT=reduced number of mortality; SVL=statistical value of each life</td></tr>
<tr><td colspan="2">Saved Energy Consumption</td><td>Saved energy fees</td><td>BEC=∑(REC×UPE)</td><td>REC=reduced energy consumption of each kind of building; UPE=unit price of energy of each kind of building</td></tr>

3.4 Case study resulting

The last step of CBA was conducted using a case study. An overhead platform called the Green Deck was chosen. The key neighbourhood information of this research, summarised in Table 4, were acquired from the databases of JLL, WCWP, Esri, Census and Statistics Department, and Campus Development Office of The Hong Kong Polytechnic University.

<table>
<tr><td>The Green Deck</td><td colspan="2">The Park Cool Island</td><td colspan="2">Area of Frequent Park Users</td></tr>
<tr><td></td><td colspan="2"></td><td colspan="2"></td></tr>
<tr><td>Area of the Green Deck</td><td>43,000m^2</td><td colspan="2">Area of PCI</td><td>426,568m^2</td></tr>
<tr><td>Population in PCI</td><td>8,122</td><td colspan="2">Employees in Poor Air-Conditioned Environment</td><td>532</td></tr>
<tr><td>Total Gross Floor Area of Commercial Buildings</td><td>507,156m^2</td><td colspan="2">Average Daily Park User</td><td>9,250</td></tr>
</table>

Table 4: Basic information of the green deck and its neighbourhood area

The bus drivers, logistics workers and construction field workers were assumed to work in a poorly air-conditioned environment.

The study about park using pattern in Hong Kong shows that 59% frequent users prefer to using parks within 15-minute walk. Thus, a circle area with 800 metres' radius and centred at the centre of the Green Deck was used to present where the predicted frequent users of the Green Deck may be located. The attractiveness from other nearby parks and using frequency of the frequent users are also accounted in estimating the average daily park user number.

Some other key data for the research were also found from the academic works and official sources. These figures and their reference sources are listed in Table 5.

Name of Figure	Figure
Median Monthly Wage	HK$177,600
Hospital Admission Fee	HK$1,110
GDP per Capita	HK$311,359.8
Energy Consumption of Commercial Buildings	135.48kWh/m^2/yr
Energy Fee for Commercial Buildings	HK$1.2/kWh
Annual Number of Days under 25°C above	186
Discounted Rate	4%
Recreational Value of Green Parks	HK$13.2

Table 5: Other key figures for the research

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The results of the benefit analysis are summarised in Table 6.

Benefit	Stakeholder	Annual Benefit in Current Value	Benefit of Present Value over 50 Years
Reduced Morbidity	Neigbhourhood Population/ Government/ Business Sector	HK$5,899	HK$126,509
Reduced Mortality	Neighbourhood Population	HK$175,990,430	HK$3,780,658,908
Saved Energy Consumption	Building Users	HK$2,555,993	HK$54,908,318
Increased Productivity	Business Sector	HK$1,688,121	HK$36,264,530
Increased Recreational Activities	Neighbourhood Population	HK$2,279,445	HK$48,967,458

Table 6: Results of benefit analysis

4. DISCUSSIONS

The model developed above can be used as a tool to help governments from a financial perspective to predict that how much a landscape project enhances the three pillars of sustainability at the community level in facing climate change. The results could be further used for strategic policy decision-making by answering three questions. Firstly, whether landscapes are needed to combat climate change? Secondly, where is the most efficient location? Thirdly, how to adjust the social policies to maximum the green landscapes' thermal benefit?

The most direct information that the thermal benefits shows is that they can enhance all the three pillars of sustainability. The neighbourhood environment can be reflected by health benefit. The environmental sustainability is also benefited from the reduced energy consumption. For economic sustainability, the industrial's performance can be improved by the fewer workers' sick absences, the less energy consumption and the higher productivity. For social sustainability, the poverty can be reduced by the less morbidity and mortality and the less energy consumption fee. It will also increase the social integration at the community level by increasing recreational activities. Thus, based on the local government sustainable development strategies and the monetary value given by the model, the government can judge whether to use green open spaces to mitigate the climate change. As some of the benefits can enhance two or three kinds of sustainability, the relationship between each kind of sustainability and each benefit will be the direction for further research.

It is shown that land use is the main factor that can influence the result from the model. The land use in this paper mainly contains three sorts, residential area, commercial area and industrial area. According to this research, residential areas enjoy the most kinds of thermal benefits, including health benefits, saved energy consumption, and increased recreational activities. Thus, residential areas may be the priority to use green landscapes to combat climate change. While, commercial areas, which are assumed to mainly accommodate workers in the well air-conditioned building, enjoy fewer kinds of benefits. These benefits are health benefits and saved energy consumption. Thus, commercial areas may be medium favouring this mitigation effort. The industrial areas, which are assumed to provide poorly air-conditioned workplaces to workers, enjoy only one kind of benefit, which is increased productivity. Thus, this kind of place may be the least suitable place to use green landscape to mitigate climate change. However, it requires more case studies and sensitive analysis to judge whether this order is correct and reasonable in the future studies.

In this study, we also found some other factors related local public policy and policy performance might have a determinant impact on the value of the thermal benefits. Thus, in the operation stage of the landscapes, some public policies can be adjusted to help the landscapes bring larger benefits. For instance, the power rate can be regionally increased to encourage a lower dependence on air conditioners. Another example is the gross floor area and land utilisation policies can be modified to make the most use of the thermal benefits.

An additional discussion is about the Green Deck. Such kind of overhead landscape is an innovative measure to make the urban areas greener and resilient to the warming climate. It broadens the vertical greenery practices. It also breaks the size limitation of the green roofs. And from this research, it is shown that the Green Deck can bring considerable monetary value. In the future, the comparison between the Green Deck and the conventional practices are expected to be studied.

5. CONCLUSIONS

In this paper, a model was built to help decision-makers strategically use landscapes to mitigate warming climate. The cooling effect of green landscapes can bring four kinds of benefits to their surrounding communities, including health benefit, saved energy consumption, increasing productivity and increased recreational activities. These benefits were modelled into four equations to measure the monetary value of each benefit. With the result from this model, governments can deal with warming climate by making decisions about whether to use green landscapes, where is the best location, and how to adjust related policies to make the best use of such kind of thermal effect. However, before really forming a practical decision-making tool, further some research is still required.

Noise Mitigation Potential of PolyU Green Deck Proposal

TANG Shiu-keung[a]

[a] *The Hong Kong Polytechnic University, Hong Kong SAR, shiu-keung.tang@polyu.edu.hk*

ABSTRACT

The Green Deck project is a proposal of PolyU. In this project, a big deck with greenery on its top and some special functional floors underneath is proposed to cover the current Cross Harbour Tunnel toll area. It has many benefits and the noise reduction at locations far from the deck is one of them. However, the noise underneath the Green Deck in the current toll area and the bus terminal area will be increased by the reverberation due to the deck. Also, since the toll areas and the bus terminal area cannot be concealed, strong sound radiations from the openings are expected. This will seriously increase the noise levels at nearby areas, especially the entrance and the podium of PolyU. It is proposed to use micro-perforated sound absorbers as louvres together with strong sound absorptive ceiling to mitigate the strong sound levels underneath the deck. The micro-perforated louvres will be installed along the boundaries of the Green Deck facing PolyU. It can be made transparent so as to allow for sufficient daylight penetration. A numerical ray-tracing study is carried out to investigate how far the noise mitigation proposal can help reducing the noise levels under the deck. Results show that the Green Deck with the above noise mitigation measure can lower down the noise levels at PolyU and the nearby establishments by 3 to 20 dBA. The noise level underneath the deck will remain high, but it can be kept at a level which is comparable to the current situation without the deck.

Keywords: adaptable design, sound insulation, noise control

1. INTRODUCTION

Recently, there is a proposal on the building up a Green Deck which will cover the toll area of the Cross Harbour Tunnel. The proposed deck is large and is expected to be able to foster strong connectivity between various areas surrounding the toll area. The current conceptual design of the Green Deck is shown in Figure 1.

In principle, the deck will cover the traffic within the toll area of the Cross Harbour Tunnel and will provide some acoustical protection to the surrounding building if one sticks to the principle of noise reduction due to obstruction of the direct-line-of-sight. However, this deck tends to tunnel the sound sources, resulting in the accumulation of acoustical energy under the deck. This energy will then radiate out of this semi-enclosed under-deck cavity at the openings. These openings then act as large horns which radiate sound powerfully into the surroundings. Such radiation can be so powerful to result in significant rise in noise levels at locations even several kilometres away. It appears that some openings are directed towards PolyU and/or near to PolyU, the MTR station and the buildings flanking Hong Chong Road (and even Austin Road). Such accumulation of sound energy also results in very high noise level under the deck. This will affect all the vehicle drivers in this area.

Figure 1: Conceptual design of the green deck

The major objectives of this study are to estimate the effect of the Green Deck as it is currently proposed and to explore appropriate noise mitigation measure. Since the design of the deck is not in its final stage, the mitigation measure proposed later in this report is indicative and can be used as a reference for the final design.

2. NUMERICAL SIMULATIONS OF GREEN DECK'S EFFECTS ON NOISE

The site in concern is too big so that the finite-element or boundary-element methods are not applicable because of computer resources constraint. The ray tracing method is commonly used in this circumstance.

2.1 The ray-tracing modelling

In this study, numerical modelling using ray tracing algorithm implemented in ODEON v.8 is carried out for the octave bands from 125Hz to 4kHz (Traffic noise frequency range). The ray-tracing technique is originally used in optics. In acoustics computation, the sound energy radiated out from a source is assumed to be carried by rays which move in a straight line until they hit a reflecting surface. The energy of a ray will be reduced according to the sound absorption properties of the surface it hits. Each ray has an initial energy which is the total sound energy emitted by the source divided by the number of rays used for computation. ODEON is a piece of software which combines the ray-tracing algorithm with image source methods for more reliable results and faster calculation (hybrid model). In ODEON v.8, the reflection based scattering method and the oblique Lambert are adopted for better handling of scattering.

Figures 2a and 2b show the computational models in the ODEON for the cases without and with the Green Deck respectively. The numbered blue dots represent the check points where noise levels are calculated.

2.2 Change of noise levels due to the green deck

In order to make the noise reduction relevant to traffic noise, the normalized traffic noise spectrum in EN1793-3 is adopted to produce a single A-weighting rating. This is a common method to study the performance of frequency-sensitive noise attenuating devices. Table 3 illustrates the rise in noise levels after the installation of the Green Deck. Negative figures devote noise reduction.

Check Point	Location	Noise Level Increase (dB)

Table 3: Rise in noise levels after installation of green deck
**Weighted by normalized traffic noise spectrum*

The highlighted check points in Table 3 are within PolyU. One can observe that there is a considerable level of noise level increase at locations on PolyU podium facing the proposed Green Deck. Overall, the presence of the Green Deck, as it currently designed, will increase the noise levels on PolyU podium by ~ 5dBA on average, which agrees with the conclusion of the empirical approach in Section 2. At location at PolyU entrance landing connecting to the footbridge (Check point #22), the noise level will increase by 8 dBA. Under the Deck, the noise level increase can be above 12 dBA. The corridor connecting PolyU and the HungHom MTR station needs careful design to shield off noise.

3. NOISE MITIGATION MEASURE PROPOSAL

To reduce the noise levels, it is proposed to add louvres and sound absorption to the Green Deck and surroundings. Louvres with 50% opening are proposed to be installed along Hong Chong Road. Conventional porous sound absorbers, like fibreglass, are not so suitable to be used in this region because of the high large particulate concentration. Micro-perforated panel absorbers are proposed as they can be cleaned if necessary and are transparent. Sound absorbers are added to the bottom of the deck and on the external wall of Hung Hom Station facing Hong Chong Road. Footbridges linking Hung Hom Station, the cavity under the Deck and PolyU are proposed to be fully enclosed so as to further reduce the noise intruding into PolyU podium level.

In the Odeon model, louvres are added along the edge of the Green Deck along Hong Chong Road from Cheong Wan Road to the deck's ending near Core Q (Figure 3). The louvers drop from the bottom of the deck to 9.8 m level. Figure 4 shows the schematics of the proposed noise mitigation measure. The MPAs are located on the inner side of the louvers along the deck. Table 4 shows the absorption coefficients of the metal louvres and MPA with 50mm air spacing adopted in the simulation.

In addition, 2-inch thick fibreglass panels are proposed to be installed as the sound absorbers under the proposed Green Deck and on Hung Hom Station external wall next to the cavity under the Green Deck. Sound absorption material that have the equivalent absorption coefficients, can be used in construction. Further, the footbridges linking PolyU, the cavity under the Green Deck and the Hung Hom station are enclosed by rigid walls in the simulation model.

Surface	Material	Sound Absorption Coefficient					
		125Hz	250Hz	500Hz	1kHz	2kHz	4kHz
Roads, outdoors	Rough concrete	0.02	0.03	0.03	0.03	0.04	0.07
Windows, Curtain wall	Glass, large panes of heavy plate glass	0.18	0.06	0.04	0.03	0.02	0.02
External wall, PolyU tiles	Marble or glazed tiles	0.01	0.01	0.01	0.01	0.02	0.02
Buildings façade	smooth painted concrete	0.01	0.01	0.02	0.02	0.02	0.05
Poly podium ceiling	smooth concrete painted or glazed	0.01	0.01	0.02	0.02	0.02	0.02
Micro-perforated panel absorbers (MPA)	Micro-perforated member mounted with 50mm air gap with attaching surface	0.00	0.05	0.15	0.50	0.60	0.40
Fibreglass, 2-inches thick	2 inches thick 48kg/m^2 fibreglass blanket without backing	0.17	0.86	1.00	1.00	1.00	0.98

Table 4: Sound absorption coefficients of material surfaces in the simulation

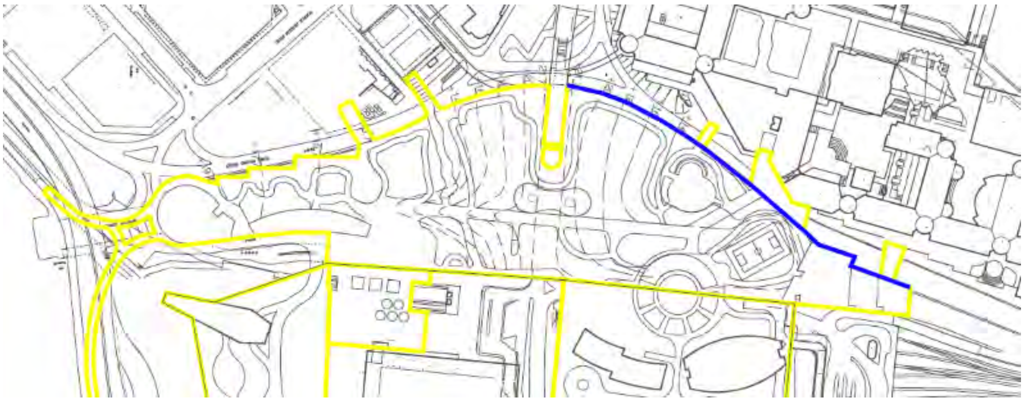

Figure 3: Mark-up plan of green deck and vicinity

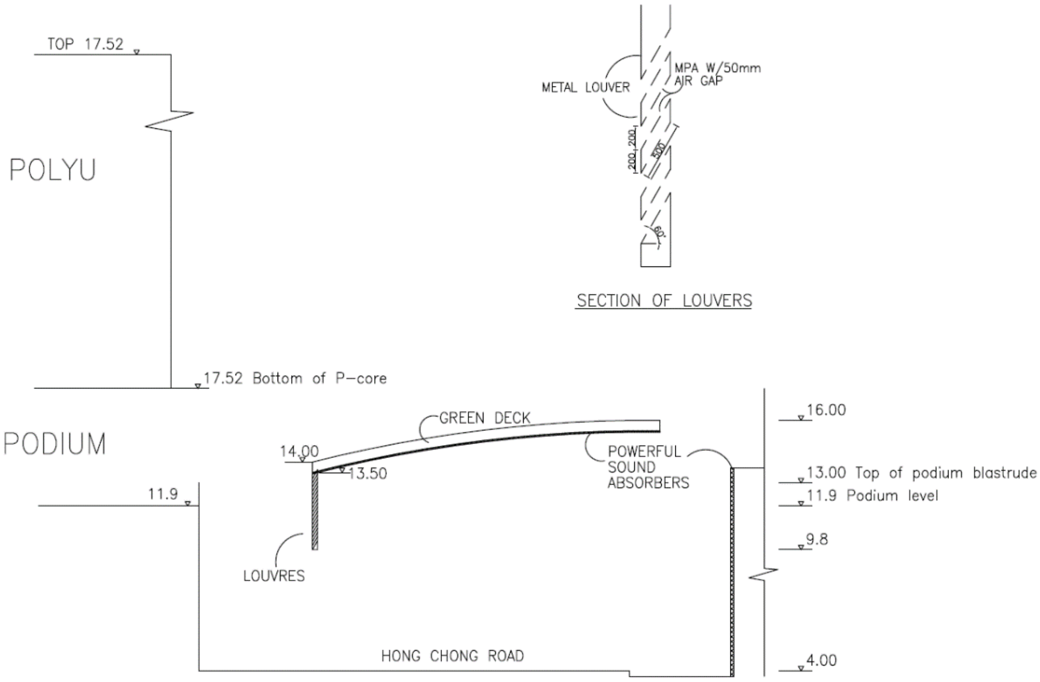

Figure 4: Schematics of the proposed noise mitigation measure

More checkpoints are added in order to understand the noise levels at higher levels of the PolyU façades and the areas near to the Hunghom MTR station and the Hong Kong Coliseum. Figure 5 illustrates all the checkpoints adopted.

With the proposed mitigation measure, the noise levels at checkpoints in PolyU are at least not worse than those the 'no deck' condition. The sound absorbers under the deck are reducing the sound energy from under the deck, resulting in a slight decrease in the noise level to all check points under the deck. At higher height, the noise reduction can be as high as 16 dBA. The noise reductions at the checkpoints nearby the Hunghom MTR station and the Hong Kong Coliseum range from 3 to 20 dBA (Figure 6).

The footbridges between Hung Hom Station Exit A and PolyU are now enclosed and thus isolated from the cavity under the Green Deck, resulting in a very impressive reduction of noise levels at those checkpoints.

4. CONCLUSIONS

Noise levels at various locations on PolyU podium and entrance facing the Cross Harbour Tunnel toll gate areas are simulated using a ray-tracing algorithm. The present simulation results confirm the potential of high noise levels on PolyU podium facing the proposed Green Deck. The noise level at PolyU entrance will increase by 8 dBA, while some locations along the PQ, CD and DE cores will receive a noise level ~ 5 to 6 dBA above the present Figures. The noise levels underneath the deck will also be very high. A 12 dBA increase in the noise level is obtained under the deck.

It is proposed to use louvres together with micro-perforated sound absorbers and powerful sound absorbers as the noise mitigation measure. The lourves and the sound absorbers are proposed to be lined along the Green Deck's near edge (along Hong Chong Road) while the other sound absorbers are proposed to be lined beneath the deck and on the wall of Hung Hom Station (along Hong Chong Road). The noise level at PolyU entrance, which will be the worst location affected by the Green Deck in term of noise, is estimated to be ~5.4dBA higher than the current condition in the absence of the noise mitigation. However, with the proposed noise mitigation measures, the Green Deck would be able to reduce the current traffic noise level at PolyU by ~3dBA on average, while the noise levels

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

under the Deck remain nearly unchanged. The noise reductions at locations nearby the Hunghom MTR station and the Hong Kong Coliseum are found to be within 3 to 20 dBA.

ABSTRACT

During one month sampling in the Hong Kong Polytechnic University roadside monitoring station, we found that roadside air pollution is very serious which chronically affect human health; especially the people have long-term activities along the roadside. Many students and staffs of the Hong Kong Polytechnic University have to be exposed the roadside pollution because they need to walk through a crowded pedestrian bridge. The results show the gaseous pollutant, hourly average nitrogen dioxide (NO2) concentration have ~10% of the total period of sampling time (1133 hours) exceed the proposed new local standard (200 µg/m3). From the particulate matters (PM), HK AQO proposed 100 and 75 µg/m3 as PM10 and PM2.5 24-hr average standard and seldom days have been reported exceed the local standard. But the Hong Kong roadside PM10 and PM2.5 average concentration level is ~50% to 68% higher than WHO AQG (50 and 25µg/m3).

In order to evaluate the effect of green deck on local air quality, the comparison test has been conducted in roadside and PQ podium during the morning and evening peak hours. All pollutants have significantly decreased. PM10 concentration has reduced around 48% and 38% in PQ podium than the value measured in roadside monitoring station in morning and evening peak hour. The OVOCs species, i.e. formaldehyde and acetaldehyde, are ~11-17% and ~27-29% reduced. Total VOCs concentration is reduced ~30% in PQ podium. The concentration of BTEX has ~30% to 60% reduction.

The risk assessment was conducted to evaluate the chronic health impact for HK PolyU staff. Formaldehyde exposure via inhalation is 1.34E-06, which was higher than acceptable criteria 1.00E-06. The other carcinogenic pollutants, i.e. acetaldehyde and benzene, exposure level were within the acceptable level.

Keywords: air pollution, risk assessment, carcinogenic compounds

1. INTRODUCTION

Air pollution at roadside is very serious in Hong Kong. Many studies have demonstrated that vehicular emission is one of the major sources of air pollutants, such as fine particulate matters (PM2.5), Volatile Organic Compounds (VOCs), Oxygenated Volatile Organic Compounds (OVOCs) and Nitrogen Oxidize (NOx). The high pollutant levels at roadside draw much public attention. Recently, The International Agency for Research on Cancer, (IARC) has defined PM2.5 as a carcinogenic pollutant, as PM2.5 contains many kinds of chemical species cause severe impact to human health. In addition, the many carbonyls pollutants are also seriously effect on human health, since it contains many carcinogenic chemicals. The heavy traffic flow in Hung Hum Cross harbor tunnel contributes large amount of pollutants and affect the people nearby. During the morning and afternoon peak hours, many PolyU students, staffs and passengers have to take much longer time to walk through the congested footbridge and hence prolong the exposure time to air pollutants. Green deck project is proposed by PolyU to build a green deck to decrease the human exposure to the air pollutants from traffic as well as to alleviate air pollution at roadside by using new material with NOx removal ability for building green deck. Understanding on the chemical speciation and levels of pollutants are very important for the Green deck project. From previous study, we found that the annual roadside PM2.5 value is around 19% higher than the proposed Hong Kong PM2.5 standard and ~75% higher than the National Ambient Air Quality Standards (NAAQS) PM2.5 standard. In this study, a monitoring program will be conducted to investigate the concentrations and chemical speciation of different pollutants (VOCs, NOx, PM and carbonyls) near the cross harbour tunnel.

2. METHODOLOGY

2.1 Site description

Roadside monitoring station

The roadside monitoring station has established by the Hong Kong Polytechnic University (HKPU) and the site is between P core and Q core ground. It is located in a street canyon in a residential and commercial area, facing Hong Chong road, leading to the busiest cross-harbour tunnel in Hong Kong. The station is about 400 m away from the tunnel entrance. Besides restaurant/household cooking, industrial or other anthropogenic sources were not found in the vicinity (photo 2.1.1). This monitoring station was used to simulate non-green deck situation.

Podium monitoring station

The site is located in HKPU campus (P core and Q core podium). Photo 2.2.1 shows the location of PQ podium monitoring site. It is a temporary site we choosing for effect of green deck on air quality estimation. The green deck will be built in the same floor of PQ podium and facing the Hong Chong road. The PQ podium is a better place for air quality effect for roadside monitoring station and green deck. The location was selected to simulate green deck scenario.

Photo 1: The roadside monitoring station

Photo 2: The podium monitoring station

2.2 Instrument description

Particulate matters and gases

The real-time PM10, and PM2.5 monitoring data were collected by KIMOT with one hour per data. CO, NOx, NO2 data was collected by TSI and Thermo gas analyzer with 1 min per data.

2.3 Carcinogenic compounds analysis

Volatile organic compounds (VOCs)

Andersen Instruments Inc. Series 97-300, Ambient Volatile Organic Canister Sampler (AVOCS) will be used to collected whole air samples into pre-cleaned and pre-evacuated 2-liter SUMMA stainless steel canisters at uniform flow-rates. Sampling and analysis of the samples, e.g. GC-MSD/FID/ECD analysis, was conducted in accordance with the USEPA Method TO-14 (USEPA, 1997) with slight modifications.

Oxygenated volatile organic compounds (OVOCs)

OVOCs in air will be collected by drawing air through a cartridge impregnated with acidified 2,4-dinitrophenylhydrazine (Waters Sep-Pak DNPH-silica), which was very reactive toward carbonyls. Ozone scrubber was connected before DNPH-silica cartridge in order to prevent the interference of ozone. The sampled cartridges were plugged at both ends and placed inside of glass screw-capped vials. They were further placed into a tin can for protection during shipment and storage. The exposed cartridges were stored inside a refrigerator and returned to the Air laboratory in a cooler chilled with blue ice. The cartridges were then analyzed by extraction and HPLC according to the U.S. EPA TO-11A method. Analysis was done by the laboratory of The Hong Kong University of Science and Technology.

2.4 Risk assessment

The risk assessment was conducted for the HKPU students, staffs and the people waiting for the buses by followed equation:

Risk=CDI×PF, where CDI is Chronic Daily Intake, which is calculated via intake rate, exposure time, and human weight. PF is potency factor which could be investigated from US Environmental Protection Agency (EPA) standard.

If the value larger than 1×10-6, means people surrounded suffer the health risk.

3. RESULTS AND DISCUSSION

3.1 Effect of green deck on local air quality

Particulate matters

Figure 1 shows the comparison of PM10 concentrations at non-green deck situation and green deck situation during morning peak hours. The PM10 concentrations with green deck ranged from 40.0 to 102.8 μg/m3 with the mean value of 57.7 μg/m3, while the mean concentration of PM10 was 29.9 μg/m3 with non-green deck. It was found that there was a significant decline of PM10 concentrations with green deck situation compared to the values with non-green deck. The mean reduction rate of PM10 concentrations with green deck situation was around 48.2% during morning peak hours. The comparison of PM10 concentrations during evening peak hours gives the similar result (Figure 2). The mean concentration of PM10 was 70.5 μg/m3, which was ~38.3% lower than that with non-green deck situation during evening peak hours.

Carcinogenic compounds

The Volatile Organic Compounds (VOCs) and Oxygenated Volatile Organic Compounds (OVOCs) were measured. From definition of different countries, e.g. U.S., Canada, European Union, Volatile Organic Compounds (VOCs) are organic chemicals, which have low boiling point, and high vapor pressure, which evaporates from natural sources and anthropogenic sources, e.g. painting and coating. VOCs including many different species, Oxygenated Volatile Organic Compounds (OVOCs) are the product of VOCs via photochemical reaction. The chemical characteristics of some VOCs and OVOCs are dangerous to human health and have cancer risk, which was called by carcinogenic pollutants, e.g. benzene, formaldehyde, acetaldehyde. Formaldehyde is the one of the important carcinogenic pollutants defined by the U.S. Environmental Protection Agency (EPA), the guideline of many U.S. states for ambient formaldehyde concentration should be lower than 3-30 μg/m3 (U.S.EPA), based on the acute or chronic exposure. U.S. Occupational Safety & Health Administration (OSHA) have defined that chronic formaldehyde intake rate should be lower than 0.2 mg/kg/day, the HKPU roadside level have almost reached this health guideline (US EPA).

Table 1 shows the concentrations of main carcinogenic compounds measured with non-green deck and green deck situation during morning and evening peak hours. It can be seen in Table 1 that the benzene, formaldehyde and acetaldehyde concentrations with green deck situation were 0.97, 7.57 and 3.18 μg/m3, respectively, which were much lower than that with non-green deck situation where the values were1.45, 9.10 and 4.48 μg/m3 during morning peak hours. As shown in Figure 3.3 and Figure 3.4, the concentrations of carcinogenic compounds determined were decreased with green deck situation in both morning and evening peak hours. The reduction rates of concentrations for benzene, formaldehyde, and acetaldehyde were 33%, 16.8%, and 29.0% during morning peak hours and 33%, 11.0% and 27% during evening peak hours.

Acetaldehyde	4.48	3.18	29%	3.85	2.82	27%

Table 1: Comparison of concentrations of carcinogenic compounds at roadside station and podium monitoring station during morning and evening peak hours (µg/m3)

3.2 Cancer risk calculation of carcinogenic compounds in green deck and non-green deck

From the toxicological point of view, benzene exhibits cancer risk and can cause aplastic anemia and polycythemia. According to the U.S. EPA's weight-of-evidence classification system for carcinogenicity, benzene, formaldehyde and acetaldehyde is designated as human carcinogen (Group A) with sufficient evidence of carcinogenicity in humans.

The following generic equation is used to calculate the chronic daily intake (CDI):

$$CDI = \frac{\text{Concentration (mg/m}^3\text{)} \times \text{Intake rate (m}^3\text{/day)} \times \text{Exposure (days/life)}}{\text{Body weight (kg)} \times 70\text{(yr/life)} \times 365\text{(day/yr)}}$$

where the average body weight and the intake rate for adults are 70 kg and 20 m3/day as the US EPA recommends. The exposure duration is (0.5 hr/day×260day/yr×40yr/life)/(24hr/day)=216.7days/life for bus-waiting people and HKPU staff; (0.5 hr/day×260day/yr×4 yr/life)/(24hr/day)=21.7days/life for HKPU students.

According to U.S. EPA Integrated Risk Information System (IRIS), the CPF for formaldehyde, acetaldehyde and benzene is 0.0455, 0.0077 and 0.0273 (mg/kg/day)−1, respectively.

Based on the above equations, the cancer risk for HKPU students and bust-waiting people, HKPU staff in non-green deck and green deck scenario was estimated and listed in Table 2 and Table 3. Regarding the health's risk assessment, bus-waiting people and the HKPU staff has much higher cancer risk than HKPU students, because of long exposure time. For the cancer risk of bus-waiting people and HKPU staff in Table 3 the findings revealed that the cancer risk of formaldehyde exposures via inhalation was higher than acceptable criteria of 1.00E-06. The cancer risks of benzene and acetaldehyde were within an acceptable level. It is indicated that cancer risk from formaldehyde was larger than the cancer risk from benzene and acetaldehyde. But the cancer risk in green deck and non-green deck scenario for bus-waiting people and HKPU staff is higher than U.S. EPA acceptable level. But the cancer risk with green deck situation has 30% to 70% reduction.

HKPU Students			
	Non-green deck	Green deck	Reduction
Benzene	1.96E-08	7.33E-09	-62.60%
Formaldehyde	1.34E-07	9.01E-08	-32.76%
Acetaldehyde	8.9E-09	5.93E-09	-33.37%
Cancer Risk	1.63E-07	1.03E-07	-36.39%

Table 2: Cancer risk for HKPU students

Bus-waiting people and HKPU staff			
	Non-green deck	Green deck	Reduction
Benzene	1.96E-07	7.33E-08	-62.60%
Formaldehyde	1.34E-06	9.01E-07	-32.76%
Acetaldehyde	8.90E-08	5.93E-08	-33.37%
Cancer Risk	1.63E-06	1.03E-06	-36.39%

Table 3: Cancer risk for bus-waiting people and HKPU staff

4. CONCLUSION

In order to evaluate the effect of green deck on local air quality, the comparison monitoring has been conducted in roadside and podium during the morning and evening peak hours to simulate the non-green deck and green deck scenarios. All pollutants have significantly decreased. PM10 concentration has reduced around 48% and 38% in green deck situation than the value measured with non-green deck situation in morning and evening peak hour. The carcinogenic compounds, which including benzene, formaldehyde and acetaldehyde, have 10% to 60% improvement with green deck situation. Based on the estimation, the improvement of particulate matters and carcinogenic compounds is over 30% to 60%.

The cancer risk calculation was conducted to evaluate the chronic health impact for buses-waiting people, HKPU staff and HKPU student. The results shows that bus-waiting people and the HKPU staff has much higher cancer risk than HKPU students, because of long exposure time. The cancer risks of benzene and acetaldehyde were within an acceptable level, except for formaldehyde. It is indicated that cancer risk from formaldehyde was larger than the cancer risk from benzene and acetaldehyde in the Hong Kong roadside. In addition, cancer risk of bus-waiting people and HKPU staff is higher than U.S. EPA acceptable level with two scenarios (green deck and non-green deck scenarios). But the cancer risk with green deck situation has 30% to 70% reduction. After green deck being built, the cancer risk will be decrease over 50%.

ABSTRACT

Identifying the key actors/ stakeholders and their real interests is vital in the decision making of urban development projects. Taking stock of stakeholders' influence in urban development projects' decision making, a Stakeholder Engagement Framework was developed for the planning of the Green Deck project in Hong Kong where no client brief has been prepared for this public project; and was only carried through research consultancy initiatives. The aim of this research study is to involve the public right at the planning stage through engagement exercises. The paper also highlights the Stakeholder Analysis Matrix which helped in identifying the level of importance and influential power of each stakeholder so as to empower their full capacity through appropriate engagement exercises. This study sums up the role and involvement of key stakeholders as well as, community consultation as a potent tool in the decision making and strategy formulation of urban development projects.

Keywords: stakeholder engagement, green deck project, Hong Kong

1. INTRODUCTION

The successful implementation of any sustainable design project can only be achieved through a cooperative effort from government, business sectors and public sectors, so that the key sustainable design criteria from the stakeholders are incorporated into the design process as early as possible. Transparency, legitimacy, commitment, communication and meaningful involvement are the key principles of public engagement that lead to better and more legitimate decisions (Tabbush & Ambrose-Oji, 2011; Kelly et al., 2004 in Cascettaa and Pagliaraa, 2013; Yang, 2014).

Yang (2014) purports that the growing number of researches conducting stakeholder analysis in urban planning clearly shows that stakeholders have an influence in urban development projects' decision making. Lawson and Kearns (2010) suggests that identifying the real interests of stakeholders, as well as merely identifying the key participants (Jones, 2003) is vital in the decision making of urban development projects. Therefore, stakeholder engagement is considered a viable planning decision making process for the proposed Green Deck project in Hong Kong where no client brief has been prepared for this public project; and was only carried through research consultancy initiatives.

The aim of the research study is to develop a framework for stakeholder engagement for the proposed Green Deck Project with the following objectives:

- To identify and prioritize the stakeholders to determine their level of importance and influential power regarding the project;
- To ascertain the community activities that would facilitate and encourage public engagement for the Green Deck project;
- To develop a framework for public engagement mechanisms with involvement of the different stakeholders in the early stage of a project

2. THEORETICAL FRAMEWORK OF STAKEHOLDER ENGAGEMENT

2.1 Public engagement in planning

Public participation or engagement can be defined as 'a process by which people, especially disadvantaged people, can exercise influence over policy formulation, design alternatives, investment choices, management, and monitoring of development interventions in the communities' (The World Bank, 1992: p. 2). As indicated in Table 1, Arnstein (1969) defines public participation as "the redistribution of power that enables the have-not citizens… to be deliberately included in the future" (Arnstein, 1969: p. 216). If policy-makers and planners seek public

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

participation, it is necessary, indeed axiomatic, that there would be distribution of power (Arnstein 1969). According to this view, unless citizens have a genuine opportunity to affect outcomes, participation is mainly regarded as ‘therapy’ and ‘manipulation’ of participants (Arnstein 1969).

<table>
<tr><td>Citizen Control</td><td rowspan="2">These two highest levels allow the have-nots to have major decision-making or full managerial power.</td><td rowspan="3">Degree of Citizen Power</td></tr>
<tr><td>Delegated Power</td></tr>
<tr><td>Partnership</td><td>Allows the have-nots to negotiate and engage in trade-offs with traditional power holders.</td></tr>
<tr><td>Placation</td><td>Ground rules allow the have-nots to advise, but retain for the powerholders the continued right to decide.</td><td rowspan="3">Degree of Tokenism</td></tr>
<tr><td>Consultation</td><td rowspan="2">Allow the have-nots to hear and to have a voice. However, “they lack the power to insure that their views will be heeded by the powerful”.</td></tr>
<tr><td>Informing</td></tr>
<tr><td>Therapy</td><td>Real objective is not to enable people to participate in planning or conducting programmes, but to enable powerholders to “educate” and “cure” the participants.</td><td>Non-participation</td></tr>
</table>

Table 1: A ladder of citizen participation (Arnstein, 1969, 217-224)

Rio Earth Summit Agenda 21 makes it clear that participation of the community is essential for urban development to be environmentally, economically and socially sustainable (United Nations, 1992). This is supported by Tabbush & Ambrose-Oji (2011) suggesting that public engagement brings forth better decision making as it take into account the local communities and other stakeholders’ knowledge and opinions. In fact they further state that decisions are more legitimate when it involves the concerned public.

2.2 Issues in public engagement

The success of public participation depends on the power to influence decision-making (Abbott, 1996; Arnstein, 1969, 1975). In addition, a wide range of stakeholders has emerged in recent years. Different interests, aims, and goals often arise. Conflicts also arise between and among stakeholder groups, about who knows best regarding what criteria and principles should be followed (Cotter, Boyd &Gardiner, 2001; Fowler, 1981). This largely creates the challenge in deriving consensus among the different stakeholders. Moreover, culture adds an extra dimension to the complexity of public participation in which the role of culture in establishing the identity of people and the success of urban landscapes (Zukin, 2000; Hayden 1995). Furthermore, Yung & Chan (2011) identifies the following issues in public participation related to the planning and conservation in Hong Kong. It includes different preferences between the general public and the government, inadequate knowledge for the public to evaluate planning and conservation projects, conflicts of interest from the different stakeholders, lack of effective mechanisms and supportive government framework, power disparity and propaganda and mobilization of interest groups.

2.3 Study area

The Cross Harbour Tunnel in Hong Kong is one of the most congested tunnel plaza in the world where it is used by about 120,000 vehicles per day, has adversely affects the air quality of the district. With this scenario, the Hong Kong Polytechnic University has come up with an idea to tackle this long standing problem – a green deck over cross harbor tunnel plaza. The Green Deck Project is proposed over the existing Toll Plaza and the Tunnel Portal of Hung Hom Cross Harbour Tunnel. This project will encompass the construction of a deck which stretches from the northern tip of the Hong Kong Polytechnic University (PolyU) campus to the Tsim Sha Tsui East Harbour Front. The deck will also intend to connect the podium of the PolyU campus with that of the MTR Hung Hom Station and the Coliseum. The project is envisioned to reinforce the urban renewal and be a major environmental improvement to the existing location. The Green Deck Project will provide a sustainable and green environment in the neighborhood precinct which is a scarcity for Hong Kong.

3. METHODOLOGY

3.1 On-street community survey

Aside from literature review, an on-street community survey was conducted among local pedestrians, PolyU students and staffs as well as the local residents and passers-by within the vicinity of the study area. The purpose of this stage is to identify the stakeholders involved in the public engagement process based on their level of importance, influence and determining their needs and concerns. The community survey questionnaire was developed as a tool in determining the sentiments of the identified key stakeholders who will be the users of the Green Deck Project. The survey questionnaire provides a brief background of the proposed project and has 9 questions, however, only the results of questions 7 and 8 are discussed in this paper since both are relevant in the development of the Stakeholder Engagement Framework. Question 7 pertains to the public/ stakeholders' suggested public engagement activities while Question 8 refers to the stakeholder identification and prioritization as what the public/ stakeholders perceived.

The on-street community survey was undertaken with the help of student helpers in three districts in Hong Kong which are directly involved in the project due to its proximity; namely Hung Hom, East Tsim ShaTsui and Ho Man Tin. Each district has a survey station/corner manned by a team of three to four student helpers. A table and a roll-up banner showing the concept plan, photos and brief information about the Green Deck project was displayed along each survey station/corner. A laminated photo of the existing site, the proposed site development plan of the Green Deck project are supplementary information attached to the questionnaires.

3.2 Stakeholder analysis

A stakeholder analysis was conducted based on the community survey results. The stakeholder analysis is a process and an approach that aids the decision making and the strategy formulation of urban development projects (Jones, 2003; Lawson and Kearns, 2010; Yang, 2014). It is a tool used in identifying and prioritizing key actors/ stakeholders for involvement (Gupta, 1995; Jepsen and Eskerod, 2008; World Health Organization, 2015) for the successful implementation of a the project. In the stakeholder analysis process, the stakeholder identification refers to the list of stakeholders and identifying their interests regarding the urban development project; while stakeholder prioritization signifies the analysis of stakeholders' level of importance and influence on the urban development project.

4. RESULTS AND DISCUSSIONS

4.1 Personal characteristics of the key stakeholder respondents

The personal characteristics of the key stakeholder respondents in each district are presented in Table 2 & 3. Out of the 590 on-street community surveys conducted, 63.56% of the respondents are the users of the proposed project and 95.59% respondents who are local residents.

Characteristics	East Tsim Sha Tsui District	Hung Hom District	Ho Man Tin District	Total (3 Districts)
Total No. of Respondents	241 (40.85%)	180 (30.51%)	169 (28.64%)	590 (100%)

Table 2: Total number of respondents in the three district

Gender: • Male • Female	281 (47.63%) 307 (52.03%)	Sector: • Government • Community, NGO • Developer • Dev. & Const. Experts • Business • End Users (PolyU Staff and Students)	12 (2.03%) 19 (3.22%) 10 (1.69%) 4 (0.68%) 36 (6.10%) 508(86.10%)
Age: • 18 & below • 19-45 • 46-64 • 65 above	72 (12.20%) 370 (62.71%) 121 (20.51%) 27 (4.58%)	Status • Residents • Tourists	564 (95.59%) 11 (1.86%)

Education: • Primary • Secondary • Tertiary	23 (3.90%) 191 (32.37%) 373 (63.22%)	No. of Visits in the proposed area: • Very rarely • 2-3 days a week • Everyday	221 (37.46%) 142 (24.07%) 208 (35.25%)

Table 3: Personal characteristics of the three districts

4.2 Stakeholder analysis matrix

A stakeholder matrix (Tabbush & Ambrose-Oji, 2011) which indicates the level of importance and influence on the decision-making process will guide the formulation of the public engagement framework. This matrix was used throughout the study to help prioritize the stakeholders based on their importance and influence as well as in determining the different engagement actions applicable to each prioritized stakeholders. As indicated in Figure 1, a public engagement action that will consistently satisfy the stakeholders classified under the 'high importance but low influence' axis can be developed while another public engagement action the will engage closely and actively the stakeholders distinguished under the 'high importance and high influence' axis. In addition, a public engagement action that will provide continuous information to stakeholders under the 'low importance but high influence' axis while another public engagement activity that may monitor the stakeholders under the 'low importance and low influence' axis.

A. HIGH IMPORTANCE. LOW INFLUENCE **KEEP SATISFIED**	B. HIGH IMPORTANCE. HIGH INFLUENCE **ENGAGE CLOSELY AND INFLUENCE ACTIVELY**
C. LOW IMPORTANCE. LOW INFLUENCE **MONITOR with MINIMUM EFFORT**	D. LOW IMPORTANCE. HIGH INFLUENCE **KEEP INFORMED**

Figure 1: Stakeholder matrix (Tabbush & Ambrose-Oji, 2011)

4.3 Identification of stakeholders

Stakeholders in urban development are individuals or organisations who can affect or be affected by the achievement of a project. Analysing stakeholders is an indispensable process for urban development. Although various methods have been used in theory and practice for stakeholder analysis, the main aims are to identify stakeholders and their interests, prioritise these stakeholders, and subsequently, make appropriate decisions. The identified list of stakeholders are:

- Government Sector- the different departments such as the Planning Department, Building Department, Transport Department, Lands Department and Environmental Protection Department, etc.
- Community- the NGOs (e.g. Friends of the Earth, Designing Hong Kong, etc.), district councillors, and other concern groups (religious, and social groups, conservationists, etc.).
- Development and construction experts- the Architects, Planners, Contractors, Developers and other allied professionals.
- Developers
- The End Users –the PolyU staff and students, TST and East TST passersby, commuters, residents, visitors, workers, etc.
- Business Sector- the retails and restaurants owners and tenants, financial groups, etc.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4.4 Prioritization of stakeholders

Based on the community survey's stakeholder analysis matrix as shown in Figure 2, the government sector is still considered by the respondents as the sector with the 'highest importance and highest influence'. The development and construction experts as well as the developers came next as the second and third sectors which also have 'high importance and high influence'. These two sectors have moved its level from the 'low importance but high influence' in the previous survey to the 'high importance and high influence' matrix grid. Another sector which retained its 'high importance yet low influence' status is the end users.

Noteworthy also is the community sector which was identified as the sector with 'low importance but high influence' from the previous survey, has gone up to the 'high importance and low influence' level together with the end users. Lastly, the sector which was considered with 'low importance and low influence' in the previous survey are now identified by the key stakeholders as a sector with 'high importance but low influence' and joined the ranks of the end users and community sectors. With these results, appropriate public engagement strategies can be provided to the sectors under the two levels such as the 'high importance but low influence' (i.e. the User and Community, and Business sectors) and the 'high importance and high influence' levels.

The sectors with 'high importance and high influence' must be engaged closely and actively in the planning and implementation of the proposed project. While the User and Community, and Business sectors with 'high importance yet low influence' must not only be kept satisfied in terms of providing public engagement activities regarding the proposed project, but should also be capitalized through public participation to increase their influence to move the project forward.

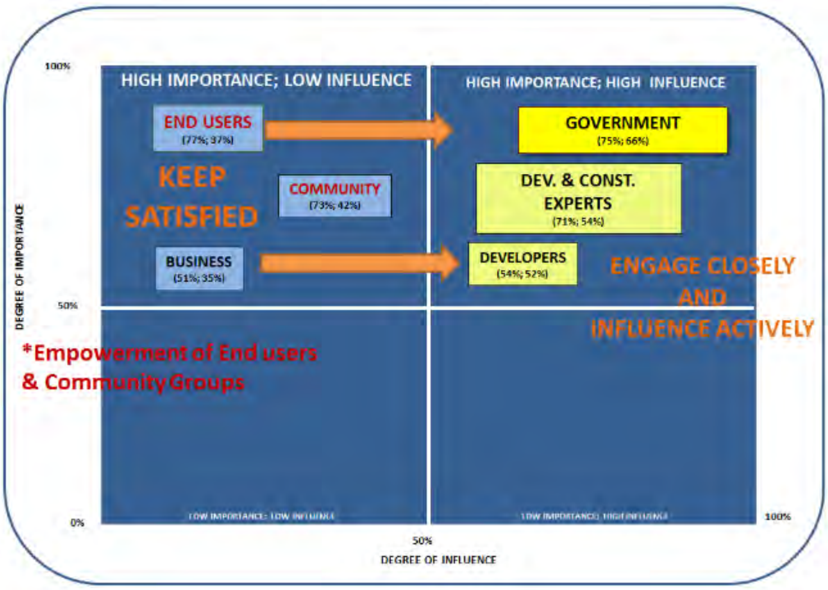

Figure 2: Stakeholder matrix analysis

4.5 Suggested community and experts participation activities

As shown in Figure 5, all sectors and stakeholders have identified unanimously the public engagement activities which are grouped in A, B, C and D. Group A is intended to inform and notify the stakeholders about information regarding the project. In Group B, the stakeholders are encouraged to attend the activities relating to the project. While with Groups C and D, they are more active consultation and involvement opportunity for the stakeholders. While the public engagement activities that are grouped in B and C were agreed by the six sectors except for the Developers & Construction Experts which they didn't have a say on these activities. The public engagement activities were grouped according to the level of engagement from passive to active engagements. Nevertheless, all these public engagement activities are the top five public engagement activities identified by the sectors to be important to consider for the implementation of the Green Deck project.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

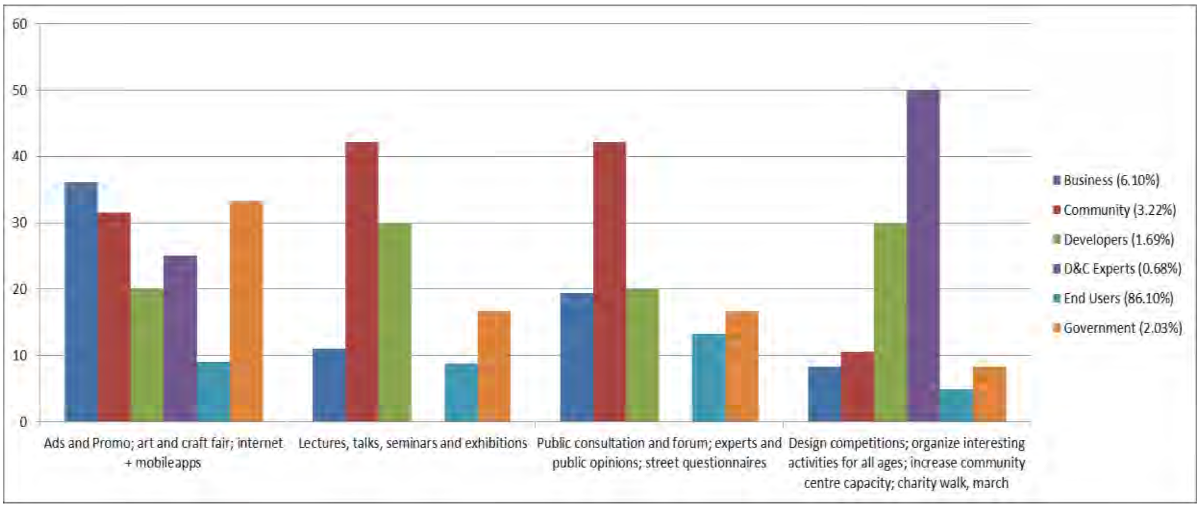

Figure 3: Top five suggested community and experts participation activities

5. CONCLUSION

This paper presented the need for stakeholder engagement, highlights the stakeholder analysis and the various strategies for engaging stakeholders as specified in the stakeholder Engagement Framework. This research implicates the development of a framework that engaged stakeholders of the proposed Green Deck project which can be applied to strengthen and promote the ties of key stakeholders for the betterment of the project. The relevance of stakeholder engagement in the urban development process has a major influence on the project outcome in terms of plans, ideas and future directions. This study also sums up the role and involvement of key stakeholders as well as, community consultation as a potent tool in the decision making and strategy formulation of urban development projects. Furthermore, the study also raises the importance of empowerment of end users and community groups. Further research is needed to identify the ways to empower certain stakeholder groups. Lastly, the principles of transparency, legitimacy, commitment, honesty, communication, meaningful involvement and respect in all interactions can be applied for the successful implementation of urban development projects that are basically rooted from the people, for the people and by the people.

"Smart Green Resilient" Integrative Urban Environment

Wilfred LAU[a]

[a] *Arup, Hong Kong SAR,*

ABSTRACT

A high density city like Hong Kong relies on a complex web of systems and services to sustain and thrive. Whilst the proposed Green Deck is an exemplar of integrating infrastructure system with a pleasant urban environment, yet contemporary systems thinking is bereft of a converging mechanism to deal with land use, urban design, mobility and infrastructure in a holistic manner. SGR (Smart Green Resilient) offers one such approach, providing the necessary direction to synchronize multiple urban development aims into a wide-ranging yet integrated objective to meet the challenges of the "new normal". This talk will discuss integrative urban environment to illustrate the innovative Smart Green Resilient philosophy which was developed from extensive participation in East Asia's urbanization, serving as a conceptual framework to future proofing our city.

vi. Paper Sessions

Track 1: Smart Initiatives & Advanced Building Systems

Session 1.3 Advanced Building Elements

Filter Façade

Ferdinand OSWALD[a]

[a] *Institute of Architecture Technology, Graz University of Technology, Austria, ferdinand.oswald@at.tugraz.at*

ABSTRACT

The Filter Facade has the goal of reducing air conditioner split units usage in buildings by increase the comfort of interiors of residential high rises in subtropical climate regions with natural ventilation. It describes how to Optimize Building Renovation of Residential High Rise in Subtropical Region by modifying existing building structure to optimize natural ventilation.

Keywords: optimized building renovation of residential high rise in subtropical region

1. INTRODUCTION

Over recent decades, residents living in modern residential buildings in tropical metropolises are increasingly using split-system air conditioners. The use and energy consumption of such systems in those regions are enormous, and especially the latter is a serious disadvantage in operating air conditioning systems. It is assumed that the additional energy consumption of seven-million metropolis Hong Kong alone will rise to 6.8 GWh per annum due to the use of ventilation systems. The South Eastern Chinese coastal region with its 150 million inhabitants requires an energy quantity of 145 GWh per year to cool their apartments with air conditioners. At the same time, these split-system air conditioners continue to heat up the urban environment with their warm exhaust air, discharging 40% of required cooling energy in the form of heat into the ambient air, thus also exacerbating negative effects of the urban heat island. According to statistical calculations, the worldwide urban population will almost double by 2050, increasing from 3.5 billion to 6.3 billion. Subsequently, energy required for cooling will almost double by 2050 as well. Given that the urban population cannot do without air conditioning, this forecasted growth is bound to pose a huge challenge to energy production and the carbon footprint. For future conurbations in sub-tropical regions, therefore, it will be of crucial importance to seek specific solutions for problems such as overburdened energy grids and local climate change. Reducing the use of split-system air conditioners is an urgent issue. It seems possible to increase comfort and reduce mechanical ventilation at the same time with the help of specifically natural ventilation systems for residential housing in tropical regions. Results from specific research projects and scientific measurement furthermore produced evidence that specific natural cross ventilation can optimize human behaviour for periods of up to 85 % of the year (e.g. Hong Kong) see Figure 1

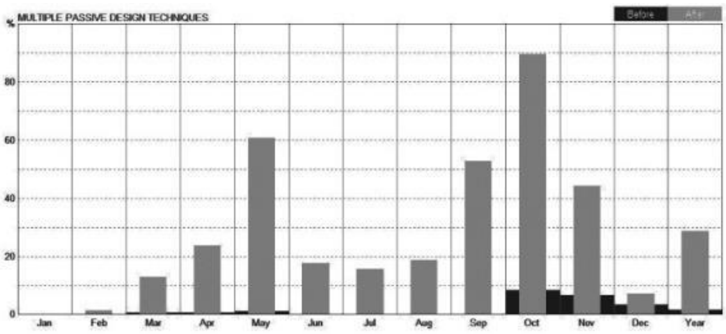

Figure 1: Percentage of comfort throughout the year and per month achieved through natural ventilation in Hong Kong, data from psychrometric chart

2. OPTIMIZED MODIFYING OF EXISTING HIGH RISERS

The floor plans of most residential high rises in tropical and sub-tropical regions do not allow for cross ventilation. This problem is demonstrated for the example of the Tung Lam residential high rise of the frequently used HARMONY type in Figure 2. Ventilation of the flats is possible through façade openings only but even the wind catchers (vertically disposed wind swords with an angle of 45° to the front end wall) do not work as expected. Cross ventilation across the corridors is impossible with this type of building, since walls of the flats confine the corridors on both sides. This results in blocking of the air flow at the access corridor.

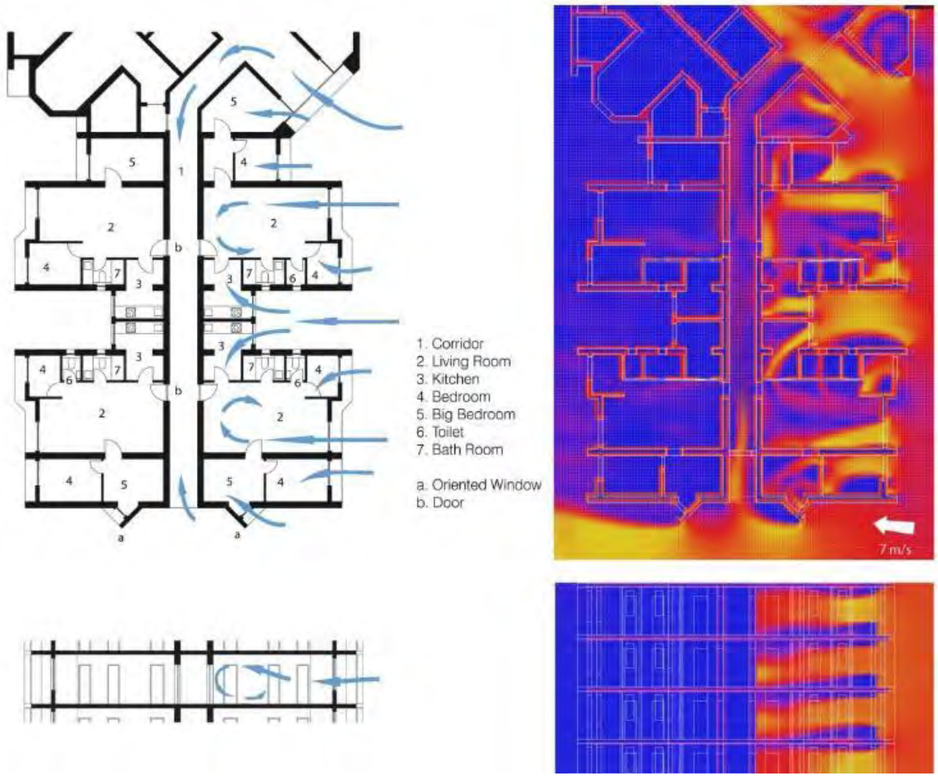

Figure 2: Study of the air flow with the floor plan section of the HARMONY type Tung Lam residential high rise in Hong Kong. Sketch of the air flow and Computational flow simulation with colour coding of speeds: low – medium – high velocities in blue – red – yellow. Simulation software VASARI.
Left: floor plan, top: vertical cross section

2.1 Modification

In a first step it was concluded that openings from the flats towards the access corridor will be a remedy. Possible openings can be the entry doors of the units but also additional skylight windows near the roof of the flats, favourably with adjustable cross section. Such configurations have proven to be effective in other buildings (e.g. Urban Tulou). Furthermore, the ineffective wind catchers were replaced by conventional bay windows with openable side wings. The most important measure was a change of the floor plan by an additional channel across the access corridor between the living units. For this purpose, the adjacent rooms in each unit must be slightly downsized. These modifications will allow cross ventilation from the façade openings to the windward units, and via the access corridor towards the leeward flats. All modifications are illustrated in the following Figure 3.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

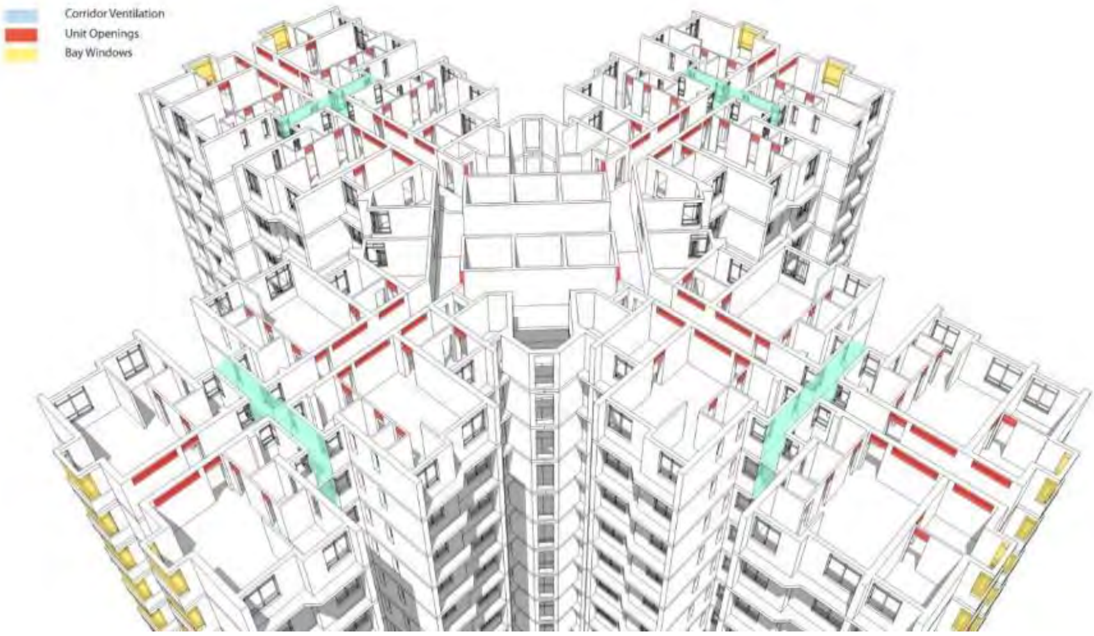

Figure 3: Modified Building: Study of the modified building structure of the HARMONY type Tung Lam residential high rise in Hong Kong,

However, with this configuration the addressed problem will appear: air from the windward apartments enters the corridor and then, instead of leaving through the openings of corridors, penetrates the apartments opposing the corridor (Figure 4). This would transfer potential contaminants from the windward apartments to the leeward apartments.

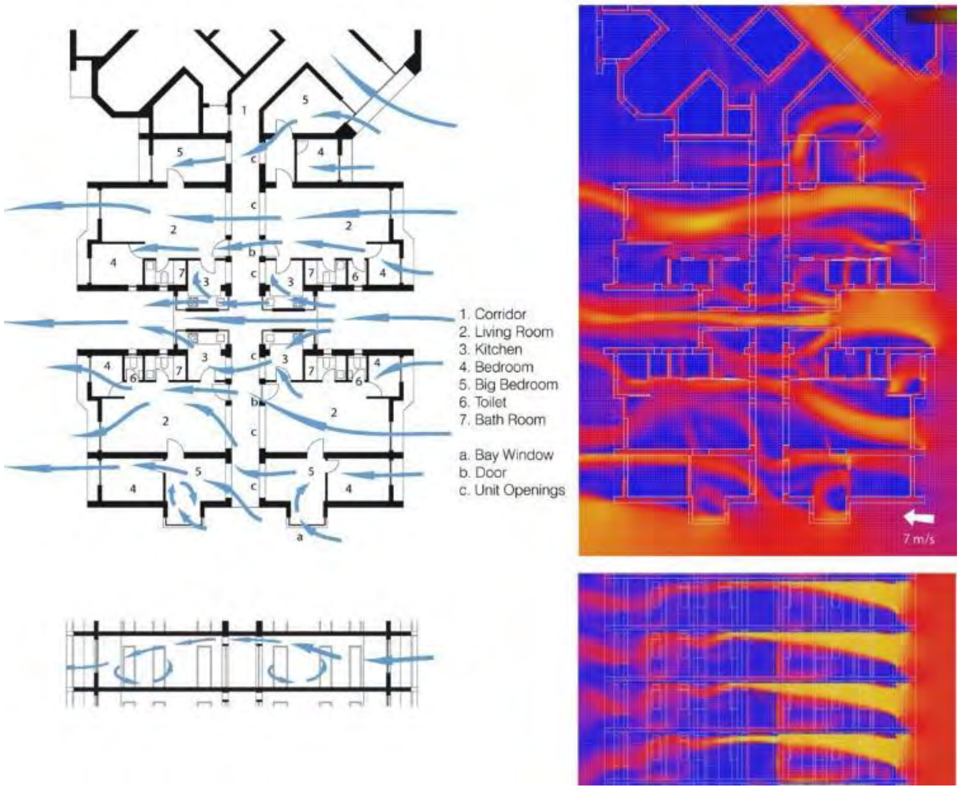

Figure 4: Modified Building: Study of the air flow with the floor plan section of the HARMONY type Tung Lam residential high rise. Left: lines of the air flow in the floor plan. Right: Computational simulation of the air flow with colour coding of wind speeds: low – medium – high velocities in blue – red – yellow. Simulation software VASARI.

In order to counteract this unpleasant behaviour the following concept optimization was developed.

2.2 Concept optimization

The openings of the windward apartments to the corridor are closed while the openings of the opposing apartments remain open. As can be seen in Figure 5, the simulation indicates that the flow field is strongly affected by this relatively simple modification. The ventilation of the windward apartments is ensured by inflow through the windward façade and suction from rooms adjacent to the additional “channel” between the apartments. Corner ventilation via the bay window with openable lateral wings supports the ventilation of the windward front-end unit.

The altered flow conditions provide enough airflow towards the corridor. Therefore, the leeward apartments are well ventilated by inflow through the corridor openings while the outflow is forced through the side windows adjacent to the “channel”.

This concept will be evaluated with CFD and wind tunnel experiments in a proposed research project “Optimized Natural Ventilation”. VASARI was used to show up the conceptual idea of the proposed study. This tool or its follow-up product may be used for the following project in a preliminary manner to get a first impression.

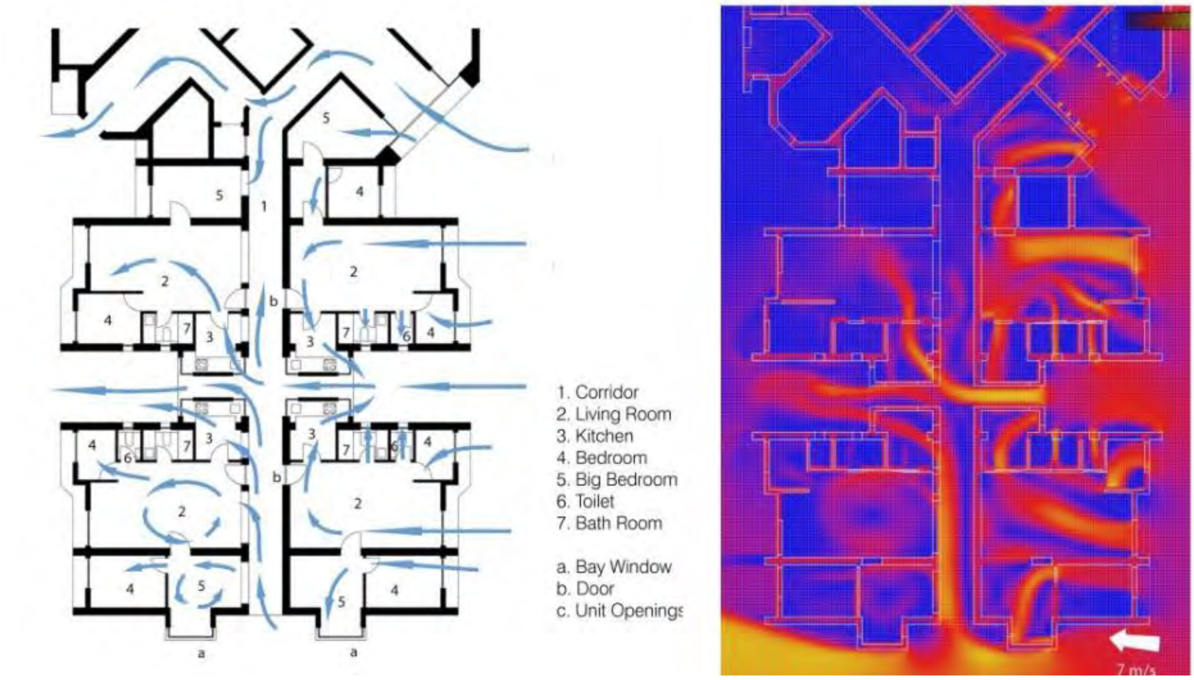

Figure 5: Optimized Modified Building: Study of the air flow with the floor plan of the HARMONY type Tung Lam residential high rise. Left: lines of the air flow in the floor plan. Right: Computational simulation of the air flow with colour coding of wind speeds: low – medium – high velocities in blue – red – yellow. Simulation software VASARI.

3. PROJECT OPTIMIZED NATURAL VENTIALTION

The aims of the research project “Optimized Natural Ventilation” are to promote conceptual and methodological principles in developing architectural concepts to guarantee increased comfort by means of natural ventilation in residential buildings, not just in tropical and sub-tropical regions. The project will deliver underlying basic information enabling the development of specific openings for large cities. In addition, criteria accounting for problems such as air pollution and noise load will also be fulfilled. The project aims to identify optimum airflow dynamics and the highest possible air change rate (ACH) with account for urban environment, floor plan and façade of a residential building. Concepts will be assessed and results compared with wind tunnel experiments and computational fluid dynamics, thus establishing the best combinatorial models. The hypothesis is that there exist optimized conditions for natural ventilation for residential rooms accounting for the urban building arrangement, floor plan configuration and façade openings.

Hong Kong is regarded as a vanguard of innovative implementations in residential housing throughout continental China, providing widespread basic knowledge and innovative developments to other Chinese metropolises. The derived results will be applied on-site on a 1:1 scale mock-up in realistic conditions, as well as tested and compared to the elaborated basics by measurements. Implementation will be realised in the course of cooperation`s between European and Asian institutions.

A further step will be to apply the results from this project to future research activities. A strategy for commercial exploitation of the project results will be an cooperation with OEMs of window and filter systems. Those companies have the aim and possibilities to develop and certify the opening systems for the markets in Asia and Europe.

ABSTRACT

Double skin façade (DSF) is an attractive architectural element in modern office buildings that, while giving a transparent appearance to buildings, can potentially be able to moderate the indoor thermal conditions and reduce energy demands. Developments in warmer climate countries such as Brazil are beginning to consider the application of DSF technology as a solution to improve thermal and energy performance in their buildings. Building upon the experience of a comprehensive research programme on the study of the thermal performance of office buildings with DSF, from which key design parameters affecting the thermal behaviour of DSF have been identified and evaluated, this study aims to examine the impact on energy consumptions. Using an office building model with an optimised DSF, this study assesses the energy consumptions when the building is fully air conditioned or operated under a mixed mode ventilation strategy. Models with similar characteristics but with single skin façade are also studied for comparison. Computational models developed for this study are evaluated using the dynamic simulation program IESVE which integrates building fabric thermal behaviour and environmental systems operating under the climatic conditions of the Brazilian city Rio de Janeiro. The results indicate that natural ventilation can provide the necessary thermal comfort in over 34% of the year in the building model with DSF under mixed mode ventilation strategy, that can potentially reduce 21% of annual cooling energy when compared to the fully air conditioned model. However, energy savings due to the addition of DSF alone are relatively small - 15% in full air conditioned model and 6% in mixed mode ventilation model. The benefit to thermal energy consumption is therefore marginal. However, comprehensive whole life evaluation is needed to provide a holistic assessment when other beneficial contributors, such as lighting, smart glazing and integrated PV are taken into consideration.

Keywords: double skin façade, tropical climate, building energy simulation

15. INTODUCTION

Increasing environmental awareness and the need to reduce the energy consumption have encouraged researchers to focus on more efficient building envelopes. In this context, there is a growing interest in double skin facade (DSF) as a potential passive system to reduce energy consumption with the attraction of its modern transparent envelope. Although benefits such as 'energy consumption reduction', 'increased ventilation and thermal comfort', and 'visual and aesthetic quality enhancement' are reported in the literature, there is still little knowledge and experience available about the DSF's operation, especially during hot seasons and under hot climates (Ghaffarianhoseini et al., 2016). Moreover, majority of the existing studies have focused on the DSF cavity as an 'isolated' structure, which is often treated as a local feature without taking into account its thermal interaction with the user space (Barbosa and Ip, 2014).

DSF consists of an additional external skin, usually made of glass, applied external to the conventional building façade so forming an air cavity between the two layers. Although DSF was developed as an effective enhancement to traditional façades for colder climates, its application has been reported as a potential technology for reducing cooling loads in hot climates such as in China (Zhang et al., 2010), Spain (Torres et al., 2007), Singapore (Chou et al., 2009), United Arab Emirates (Radhi et al., 2013) and Malaysia (Rahmani et al., 2012). Overcoming climatic variations has instigated recent investigations of additional features such as sun protection devices, modification of façade geometry, adaptive ventilation schemes and integration of photovoltaic systems (Agathokleous and Kalogirou, 2016).

Previous comprehensive research on the thermal performance of office buildings with DSF for tropical climate conditions (Barbosa and Ip, 2014; Barbosa et al., 2015a; b, Barbosa and Ip, 2016) has investigated the influences of architectural configurations and climatic conditions on the thermal performance of buildings with DSF and predicted the annual thermal acceptance levels of optimized naturally ventilated models with DSF under Brazilian climate conditions. Building upon these outcomes, this paper extends the study to incorporating mechanical ventilation. Using a building model under the climate of Rio de Janeiro, this study investigates the impact to the energy consumptions of using full air conditioning or mixed mode ventilation when applied to the cases with or without DSF.

1.1 DSF operation and energy consumption

The DSF can be considered as a type of thermal chimney that can promote natural ventilation in the building due to solar induced thermal buoyancy and pressure variations that resulted from the effects of wind around the building. The stack effect that occurs within the DSF is driven by the temperature difference between the warmer cavity air and the outside cooler air (Gratia and De Herde, 2007a; Kim and Sohn, 2009). The difference in temperatures is not only related to the model configurations - such as glazing type and area, presence of shading devices within the cavity and its materials - but also significantly to the level of solar radiation incident on the outer layer of the DSF.

Another important parameter that contributes to the resulting air movement within a naturally ventilated building is the wind effect. When wind approaches a building, it creates a distribution of static pressures on its exterior surface, the magnitude of which depends on the wind direction, wind speed, air density and surrounding obstructions (ASHRAE, 2009).

In naturally ventilated buildings with DSF, fresh cooler outdoor air is normally drawn through openings from the opposite façade, which passes through the user space before being extracted into the DSF cavity. In air conditioned buildings, the windows are sealed. Use of DSF can reduce the cooling load by reducing the direct solar gain and buoyancy driven air movement in the cavity continuously removes the heat trapped within it (Chan et al., 2009).

Different architectural configurations have been tested to determine the reductions in energy demands of buildings with DSF, such as cavity depth (Rahmani et al., 2012), application of different materials properties on the façade layers (Chan et al. 2009, Mingotti et al., 2013), position and angle of shading devices (Gratia and De Herde, 2007b) and opening size (Chou et al., 2009). Recent review of studies on the performance of DSFs, mainly based on temperate climates, has concluded that the technology can potentially reduce the air conditioning consumption up to 50% when compared to conventional facades, as such DSF has been recognised potentially as an effective option for reducing the energy use in buildings (Sanchez et al, 2016).

2. METHODOLOGY

1.1 Models description

In this study, an optimized DSF base case model has been developed based on the outcomes of previous research on the performance of the DSF under tropical climate conditions. Its consists of an 11 storey open plan office building with dimensions of 12m x 16m and 3.5m floor-to-floor height. A fixed clear glass vertical DSF cavity was applied to the north face forming an air cavity of 1m.

The model considered the design parameters that maximize the annual acceptable comfort levels in the occupied space (Barbosa et al., 2015a) such as closure of the cavity bottom and its extension 3.5m above the roof of the building to avoid poor ventilation on the top floors. North windows, placed at the top of the walls, were sized to achieve similar flow rates across all floors levels. South windows, positioned at the bottom of the walls, were fully open. A concrete shading device was positioned within the cavity and a white masonry wall was used on the inner layer of the DSF. The longest sides, facing north/ south orientations, were modelled with horizontal windows sized to achieve balanced flow rates across all floors and air buoyancy force is enhanced by concrete shading device within the cavity. The model also considered the influence of the surrounding environmental conditions on the thermal performance of the DSF of a naturally ventilated building such as orientation and predominant wind (Barbosa et al., 2015b). Building upon the base case model, four case study models have been established, which consider the use of full air conditioning or mixed mode ventilation with single skin façade (SSF) or DSF, as illustrated in Figure 1.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

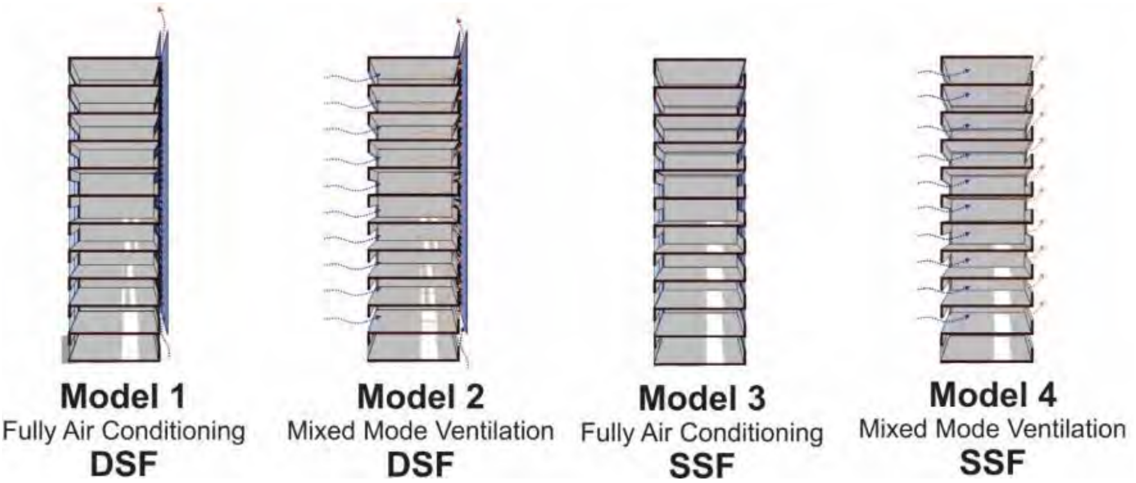

Figure 1: Section of models used on the simulations

For the models 1 and 2 with DSF, a clear single glazing outer layer was applied to the north face forming an air cavity of 100 cm extending 3.5 m above the roof. The cases with SSF were modelled with an external concrete shading device. Table 1 shows the building model fabric material properties and the description of internal heat gains applied during the office hours for the whole year. Full internal gains were applied from 8 a.m. to 12 a.m. and from 1 p.m. to 5 p.m. and half capacity was considered for one hour during the lunch time, before and after working hours.

Building envelope	U value
Roof	0.18 W/ m²K
Ground floor	0.28 W/ m²K
Opaque part of façade (Thickness = 0.27m)	0.61 W/ m²K
Window (12mm clear single glass)	3.9 W/ m²K
Double skin	
Clear single glass (shading factor = 0.87)	5.04 W/ m²K
Shading device (Absorptance = 0.14)	
Use of the building	Total gain
Internal heat gains (People + Equipment + Lighting)	36.9 W/ m²

Table 1: Building model fabric materials characterisation and description of internal heat gains

Inter-program comparison technique was used in this study as a viable means to validate the physical phenomena involved in the dynamic thermal behaviour of the DSF. Simulation models with similar geometry and fabric materials as well as internal heat gains and external boundary conditions, within the range of the operating parameters, were created and applied to another proprietary industry accepted CFD software Flovent (Mentor, 2014). Results of a series of 'snapshot' steady state quantitative outcomes and airflow profiles across the floors of the base case model were generated and compared to those obtained from the IESVE software, which showed close agreements. In the absence of a fully validated dynamic CFD simulation tool for a whole building, these consistent quasi-dynamic results were deemed to provide adequate evidence of confidence for the purpose of this preliminary study.

1.2 Modelling process and simulation analysis

The building's dynamic behaviour in conjunction with the prescribed ventilation strategies were simulated using the integrated simulation software IESVE (2016). The tropical climate of Rio de Janeiro city (latitude 22.9° S, longitude 43° W) was selected for this study. The climate diagnosis through the psychometric analysis (Schuch and Ono, 2010) indicated that the city was uncomfortable for 64% of the year, mainly due to the occurrence of high temperatures and relative humidity with annual averages of 27°C and 80%, respectively. In terms of wind speed, the city experiences lower than 4m/ s for 81% of the year.

Both DSF and SSF have been considered to highlight the benefits and constraints of the application of the second facade layer on the building. Fan coil air conditioning system has been implemented during the working hours. When air conditioning is used, the windows are fully closed and no natural ventilation is allowed. Mixed mode ventilation with operation strategy based on comfort criteria has also been studied.

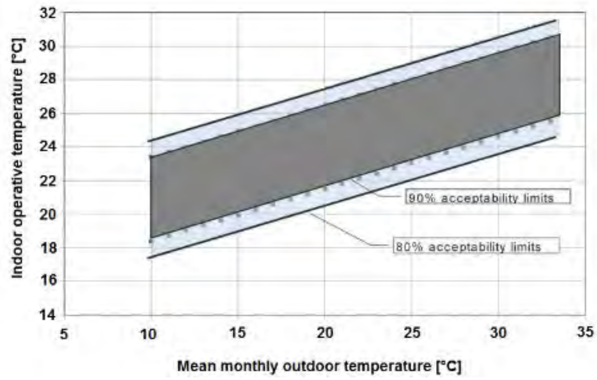

Figure 2: Acceptable operative temperature ranges for naturally ventilated spaces from ASHRAE 55 (2013)

The graph of thermal acceptability in Figure 2 (ASHRAE 55 2013) shows the concept of the adaptive approach in which there are variations in acceptable indoor comfortable (operative) temperatures under different mean outdoor temperatures and acceptable limits. Thus, people in warm climate zones tend to tolerate higher indoor temperatures than people living in cold climate zones. Considering the range of outdoor temperatures in Rio de Janeiro, 27°C was defined as the maximum temperature allowed within the offices during the working hours.

For the mixed model ventilation cases, the windows were set to open when the room temperature is lower than 27°C and the outside air temperature is at least 2°C below the room air temperature.

The results are used to evaluate the impact of the application of the second layer on the building facade on the cooling energy demand. Moreover, it compares the energy consumption of a full air conditioning model with mixed mode ventilation option.

3. RESULTS

Figure 3 shows the sum of the cooling plant sensible loads for all rooms in the building over the months of the year during the working hours of cases 1 (fully air conditioning model with DSF) and 2 (mixed mode ventilation model with DSF), respectively. For the building with DSF, the mixed mode case consumes 21% less energy than the fully air conditioned case. This difference is up to 49% during the winter months, which indicates the potential of natural ventilation in meeting the thermal comfort.

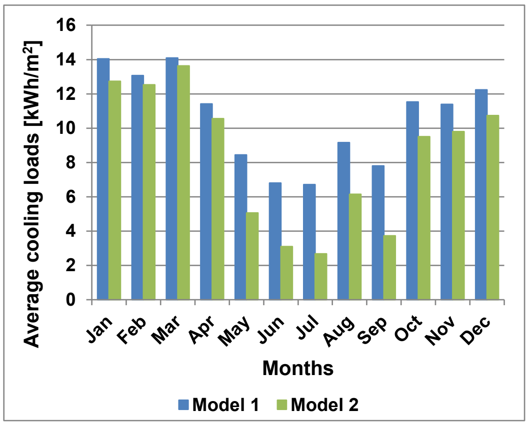

Figure 3 – Comparison of cooling loads of DSF models 1 (fully air conditioned) and 2 (mixed mode ventilation)

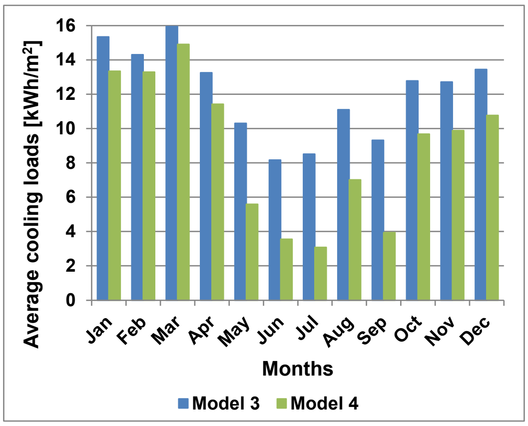

Figure 4 – Comparison of cooling loads of SSF models 3 (fully air conditioning) and 4 (mixed mode ventilation)

Comparing the cooling loads of cases without the double skins, the results show that the mixed mode case consumes 27% less energy than the fully air conditioned case, as shown in Figure 4. The results illustrate that thermal acceptance can be achieved for significant part of the year without requirements of air conditioning under

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

this climate condition. Such strategy gains energy and environmental benefits, resulting in improved indoor air quality, reduction in operational costs and higher occupant satisfaction.

For the models with full air conditioning, the case with DSF consumes 15% less energy than the case with SSF. This can be explained by the reduced solar gains as the double skin provides an additional filtration to solar heat gains. The moderation of temperature difference between the cavity and the room can also contribute to the lower energy consumption. For mixed mode ventilation models that allow natural ventilation, the results showed that the energy consumption for the building with DSF is on average only 6% lower than the SSF case. The building thermal performance is therefore not substantially enhanced with the application of the second skin, which can be partly due the overheating promoted by the DSF, especially during the hot days. Furthermore, the radiation emitted by the heated shading device can increase the heat gains into the building especially when windows are open.

Air conditioning is not required in about 34% of the working hours in a building with DSF adopting mixed mode ventilation. However, it increases to 41% in the model with SSF (Figure 5). Although the DSF works as a thermal chimney promoting air movement under low wind speeds, the solution was unable to significantly improve the building's thermal performance. Therefore, if the building thermal performance only is considered, the conventional less costly and simpler single skin façade (SSF) is more appropriate to be implemented in this tropical climate.

4. CONCLUSION

This study examines the energy consumption of a building with or without an optimized DSF under tropical climate. The models are tested under fully air conditioned and mixed mode ventilation strategies. The results indicate that for the building with DSF, indoor comfort conditions can be met by using naturally ventilation in nearly 34% of the time in the year. Conceptually there is potential energy saving opportunity which should be considered before committing to full air conditioning. Energy savings of 21% can be achieved in mixed mode ventilation systems when compared to fully air conditioning buildings with DSF. However, when considering models with and without DSF, the energy savings are small – 15% in fully air conditioned model and 6% in mixed mode ventilation model. Prior to adopting DSF, simpler and less costly options such as shading devices, strategic openings and fabric materials should therefore be considered.

Within the constraint of necessary assumptions, simplifications and limitations of simulation tools currently available, results of this research have demonstrated that thermal acceptability in a naturally ventilated building with DSFs under Brazilian climates is similar to its single skin counterpart; the benefits of the thermal performance alone can therefore not sufficiently justify such an expensive design feature. However, application of DSF is still at its infancy and, with the advances in technologies, its full potentials are yet to be explored. With the likely increasing use of glazed façades in office buildings in Brazil, there is a clear necessity to develop guidelines and performance data related to DSF and to develop detailed methodology for its evaluation. Comprehensive whole life evaluation is recommended to provide a holistic assessment when other beneficial contributors such as lighting, smart glazing and integrated PV are taken into consideration.

ABSTRACT

Large scale, multi-use commercial developments are trending in major cities development in East Asia. With more mega scale buildings constructed, the impact on energy consumption and carbon emissions would be great. Climate-adaptive designs and optimized building energy strategies would be imperative to enhance the building adaptability to the local climates and improve the overall building energy efficiency. Next generation of the energy interactive building design provided a platform to address complicated combination and optimize different building design parameters on the impact towards the building energy consumptions.

Optimized envelope design strategies could be an effective approach to shelter building to its own climates and create pleasant indoor environment. Interactive and parametric optimization at early stage design will allow for the identification of design parameters in which the design team can take into consideration. A generic commercial office building is identified and in two locations with distinct climate zones in East Asia are chosen. With the energy interactive optimization, a clear combination of design parameters can be identified. An annual thermal load decrease of 8.2% and 6.5% as compared to the ASHRAE 90.1-2007 envelope baseline for Hong Kong and Seoul respectively.

Keywords: adaptable design, climate responsive architecture, facade optimization, building energy use

1. INTRODUCTION

The scientific work by the Inter-governmental Panel on Climate Change (IPCC) have raised public concerns about energy use and revealed the impact towards the environment (Solomon et al., 2007). It is generally acknowledged that the drivers of climate change were due mainly to the anthropogenic activities in raising the greenhouse gas concentration in the atmosphere. High-rise office building development is one of the fastest growing areas in the building sector especially in major cities in East Asia (Jiang, 2005). On a per unit floor area basis, energy use in large office building development with full air-conditioning can be 70-300 kWh/m^2, 10-20 times that in residential buildings (Jiang, 2006). With more tall buildings constructed (with 20 stories or more), the impact on energy consumption and carbon emissions are expected to growth (2% increase of carbon dioxide annually between 1971 and 2004) (UNEP, 2007).

Energy efficiency and sustainability issues are important considerations during the architectural design, and at all stages of the evaluation procedures. Two important issues that building architects and engineers need to identify is climatic responsive design and identifying the most effective strategy that the building should adopt to ensure true energy savings (Wan et al., 2012). The new generation of high-performance envelopes has transformed the way in which architects approach building design with a shift in emphasis from built form to performance and from structure to envelope. In the realm of high-performance buildings, the envelope has become the primary site of innovative research and development (Velikov and Thun, 2013). Climate responsive design and energy interactive design approaches are believed to be key to drive for the next generation smart building envelope designs.

2. NEXT LEVELS OF SUSTAINABLE BUILDING ENVELOPE DESIGNS

Buildings, energy and the environment are key issues faced by building professions worldwide, and energy is a key element in the overall efforts to achieve sustainable development (Jiang 2005 & 2006). Sustainable building designs provide a good solution to enhance the overall building energy performance. Overall thermal transfer value (OTTV) has been used as a conventional indictor to evaluate the building envelope performance particularly in subtropical climates due to its effectiveness in the consideration of the three major envelope heat gain components: (i) conduction through opaque walls, (ii) conduction through window glass and (iii) solar radiation through window glass (Hui, 1997). Previous sustainable building design experiences focuses on optimizing each design parameter individually, where the sensitivity of each design parameter is generally known. However, the dynamic interaction of all the different design parameter is less studied, providing an opportunity for improvement in the design process through the simultaneous optimization of different parameters.

2.1 Conventional sustainable building designs

The aforesaid design approach provides a useful guideline for the architect or designer to have an idea about the impact of key design parameters to the thermal performance of the building facade. Through considering the thermodynamics and the energy flux between the external built environment and the internal loads, a basic understanding of the thermal behaviour of the building envelope is established, but the overall building energy usage cannot be fully establish. Accounting for the interactions between the multiple design parameters, simultaneously optimizing multiple envelope design parameters and establishing the energy building consumption at the zone level would be extremely useful and desired the building design process.

2.2 Energy interactive building designs

Architectural design would have close interaction with the indoor climate and the environment (Givoni, 1998). Defining the values of the input parameters is often a difficult task and there is no one way solution to address all design concerns (Lam et al., 2008). Maximizing the window opening would enhance the daylight penetration but imposing the solar heat gain and increase the building cooling load. Balancing the window-to-wall ratio and the darkness of the glazing as well as optimizing the length of the extended building shading are complicated and every combination would have different implication towards the building energy consumptions. Along with the blooming of computation power, interactive building design approach is realized via the integrative and open-source platform (Figure 1). EnergyPlus have been chosen as the energy simulation software and there are a few compatible optimization solvers for EnergyPlus including Grasshopper's Galapagos, OpenStudio, GenOpt, and JEPlus. Grasshopper's Galapagos was chosen for its simplicity and user friendliness. The parametric optimization tool is integrated with the five components as below:

- Rhinoceros
- Plugin: Grasshoper
- Plugin: Honeybee and EnergyPlus
- Optimization solver component: Galapagos

A 3D building geometry is developed on the platform of the parametric optimization tool and the key building envelope design parameters are defined, such as the window U-value, solar heat gain coefficient (SHGC), wall U-value, window-to-wall ratio (WWR), and shading depth. A building description file for Energyplus (.idf file) including the building envelope and system details would be generated. Building energy simulations will be carried out and the zone cooling energy and heating energy use based on a combination of the design parameters would be visualized on the 3D model in parallel. The parametric optimization could also analyse the interaction between parameters by the genetic algorithm and optimize the best combination of the parameter values towards the zone energy consumption. The methodology would be further discussed in the next section.

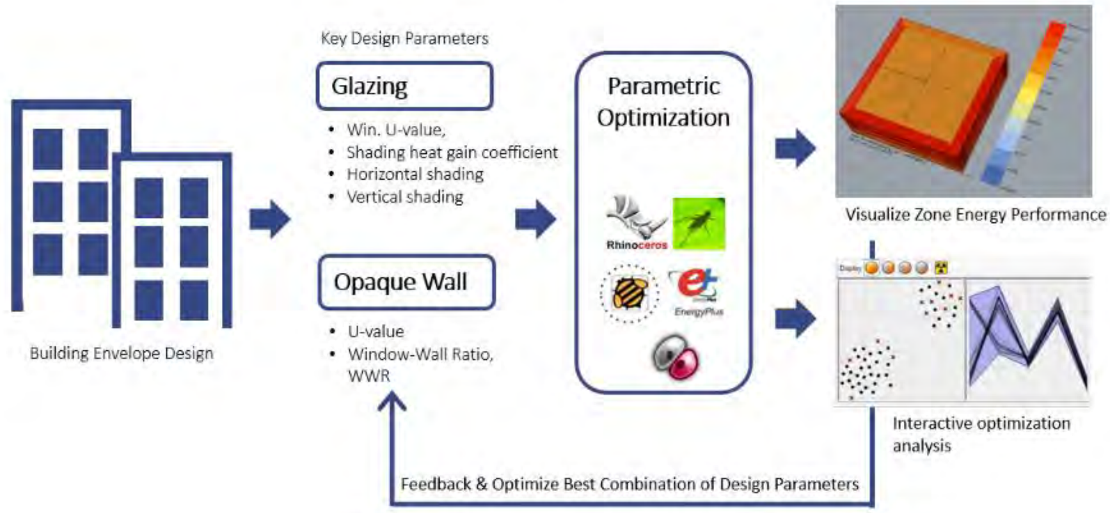

Figure 1: Energy interactive design approach

3. METHODOLOGY

Simulated Annealing (SA) was chosen as the optimization solver for this study, where it follows one solution candidate's iterative jumps across the solution space to approximate for the global optimum point (Kirkaptrick et al., 1983). Each iterative jump and its legitimacy are affected by the temperature of the system, where the candidate should converge towards the global optimum. The design approach focuses on the building envelope parameters, which are mentioned in Section 2.2. These parameters are limited to a certain range, reflecting actual building designs. A step function is also introduced to reduce the number of cases and allowing the solver to refine its search.

A generic office building was developed to serve as a baseline reference for comparative energy studies. The a base case is a 35x35m, 20 stories building with perimeter zone of 4m depth, an interior zone of 6m depth, and an internal core area of 15x15m. The interior zone and perimeter zone are set as open office area and the interior core, for simplicity, is set as corridor area. The bottom and uppermost floor are simulated for their thermal load, with an adiabatic block in between. The building's annual thermal load is calculated by multiplying the bottom floor's thermal load by 19, to reflect the floors replaced by adiabatic block. A range is set for each design parameters for envelope through experience of a typical office building, with a step introduced to reduce the number of possible iterations while maintaining a fine enough resolution to observe differences (Table 1). The indoor loads and ventilation requirements references ASHRAE 90.1-2007 and ASHRAE 62.1-2007 (Table 2) (White et al., 2007; Stanke et al., 2007). The equipment load uses 20W/m^2 (EMSD, 2007) a typical load density as found in office buildings.

Key Design Parameters for Envelope	Range	Step
Window-to-Wall Ratio	0.3 – 0.8	0.05
Window SHGC	0.2 – 0.9	0.05
Window U-Value (W/m^2·K)	1.5 – 6.0	0.5
Wall U-Value ((W/m^2·K)	0.4 – 2.0	0.2
Horizontal Shade Depth (m)	0 – 1.0	0.25
Vertical Shade Depth (m)	0 – 1.0	0.25

Table 1: Key design parameters for building envelope

Design Parameters	Open Office	Corridor
Lighting Power Density (W/m^2)	12	5
Equipment Power Density (W/m^2)	20	0
Occupancy Density (prs/m^2)	0.05	0
People Outdoor Air Rate (L/s·person)	2.5	0.3
Area Outdoor Air Rate (L/s·m^2)	0	0.3

	Hong Kong	Seoul
ASHRAE Climate Zone	2 – hot climate	4 – mixed climate
Cooling Set-Point	23°C	26°C
Heating Set-Point	22°C	20°C

Table 3: Climate zone and set-points

In this study, two major financial cities within Asia with two distinct climate zones are chosen, them being Hong Kong and Seoul. The cooling and heating set-points of the buildings are based on the local energy codes (EMSD, 2012; MOLIT, 2015). Hong Kong is located in ASHRAE climate zone 2, with a hot climate, where cooling is dominant. Seoul is located in ASHRAE climate zone 4, with a mixed features of hot summer and cold winter, where heating is slightly dominant.

The air conditioning system is defined as an Ideal Air Load system, thus it is possible to simulate the annual cooling energy load and annual heating energy load. The optimization study aims to reduce the total annual thermal load, which would thus reduce the energy consumption of the HVAC system, normally found to be over 40% of the total building energy consumption.

4. BASELINE CASE

A baseline case is developed for each of the city, where the indoor set-point and internal load are set as described in Section 3. The baseline building envelope are developed based on ASHRAE 90.1-2007 (White et al., 2007) and summarized in Table 4. Table 5 shows the simulated annual cooling and heating load of the building located in the two studied cities.

Design Parameters	Hong Kong	Seoul
Window-to-Wall Ratio	0.4	0.4
Window SHGC	0.25	0.4
Window U-Value ($W/m^2 \cdot K$)	3.97	2.84
Wall U-Value (($W/m^2 \cdot K$)	0.70	0.37
Horizontal Shade Depth (m)	-	-
Vertical Shade Depth (m)	-	-

Table 4: Baseline envelope configuration

Building Energy Component	Thermal Energy Use	
	Hong Kong	Seoul
Annual Cooling Load (kWh)	7,633,743	552,250
Annual Heating Load (kWh)	608,866	5,504,085
Annual Thermal Load (kWh)	8,242,609	6,056,335
Thermal Load (kWh/m^2)	336.4	247.2

Table 5: Summary of the thermal load for the simulated baseline

5. OPTIMIZATION RESULTS

The optimization solver will generate large amounts of cases as it searches for the optimal solution. The results are plotted on a multi-dimensional graph (Figure 2), where the first three axis depicts the simulation output, them being the annual thermal load (total), annual cooling load (cooling), and annual heating load (heating). The six remaining axis depicts the building envelope parameters. Each line shown on the plot depicts one design scenario, where the intersection of each axis describing the results (first three axis) or the input parameters (remaining seven axis). The colour scheme of the plot follows that of the annual thermal load, with blue being lower value and red being higher value.

5.1 Building envelope optimization for Hong Kong

Hong Kong's thermal load is dominated by cooling load. It is also well known that the external solar radiation is a dominating factor in heat gain through building facade. This echoes to the local OTTV calculation where the shading coefficient have a heavier weighting factor than wall U-value. From the results plot, a lower annual thermal load is achieved when the following factors are met:

- Minimize envelope U-value to minimize heat transfer from outdoor to indoor in hot summer months
- Lower window SHGC to reduce solar heat gain
- Reduce WWR to reduce solar heat gain through window.
- Window's U-value is also higher than that of the wall, thus reducing WWR will also reduce heat transfer
- Maximize shading depth to reduce solar heat gain through window

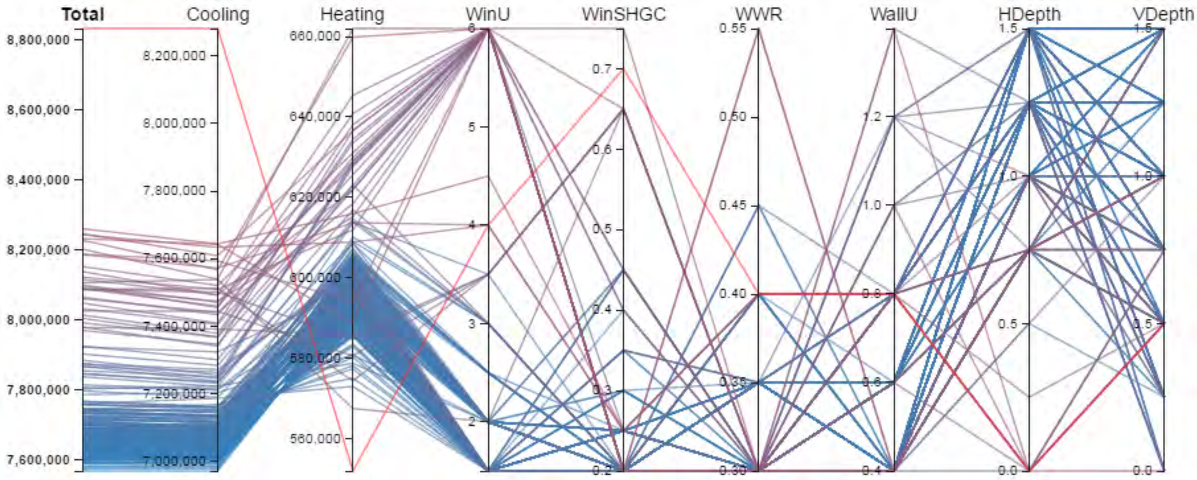

Figure 2: Optimization results – Hong Kong

The optimal case was found to have the below configuration, which resulted in thermal loads as shown in Table 6. Noting that the HVAC system takes up approximately 40% of the annual energy consumption of the building, an 8.2% decrease in annual thermal load will approximately lead to a 3% decrease in annual total energy consumption. Other than finding the optimal case, the solver also populated the solution space with numerous different cases. This allows for the consideration of different envelope designs which may yield similar reduction in annual thermal load.

Figure 3 shows the top 10% results of the optimization run, where the annual thermal load decrease from the baseline case ranges from 7.7% to 8.2%. An observation from the above plot is that the solver prefers a longer horizontal shading depth over a longer vertical shading depth. This can be explained by Hong Kong's high solar angle over the year, thus a longer horizontal shading depth would block out more solar radiation.

Design Parameters (Hong Kong)	Design Values
Window-to-Wall Ratio	0.3
Window SHGC	0.2
Window U-Value (W/m^2·K)	1.5
Wall U-Value (W/m^2·K)	0.4
Horizontal Shade Depth (m)	1.5
Vertical Shade Depth (m)	1.5

Table 6: Optimal envelope configuration of Hong Kong

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Building Energy Component	Thermal Energy Use	% Difference
Annual Cooling Load (kWh)	6,972,526	-8.7%
Annual Heating Load (kWh)	594,896	-2.3%
Annual Thermal Load (kWh)	7,567,422	-8.2%
Thermal Load per Area (kWh/m^2)	308.9	

Table 7: Optimized case energy simulation results of Hong Kong

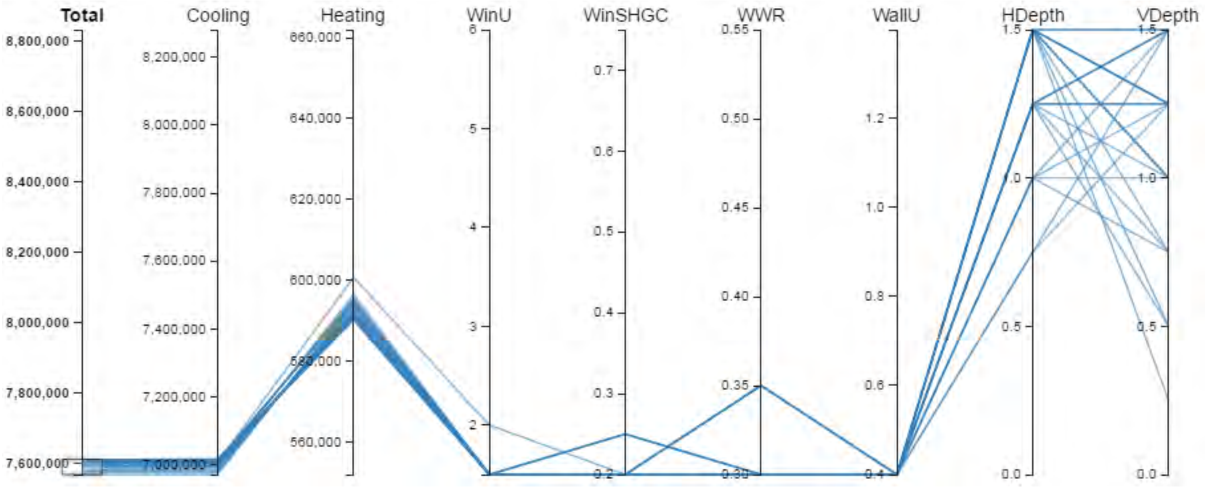

Figure 3: Optimization results – Hong Kong (Top 10% Results)

5.2 Building envelope optimization for Seoul

In Korea, the annual thermal load is dominated by the heating load. An optimal building design is required to balance the building cooling and heating load in different seasons. From the results plot (Figure 4), a lower annual thermal load is achieved when the following factors are met:

- Minimize envelope U-value to reduce heat loss during winter
- High SHGC to allow for higher solar heat gain during winter, even though there will be an increase of cooling load during summer
- Minimize shading to maximize solar heat gain during winter
- A balanced WWR to minimize heat transfer through the window but also to allow for incoming solar radiation

The optimal case was found to have the configuration as shown in Table 8 and the thermal loads results as shown in Table 9.

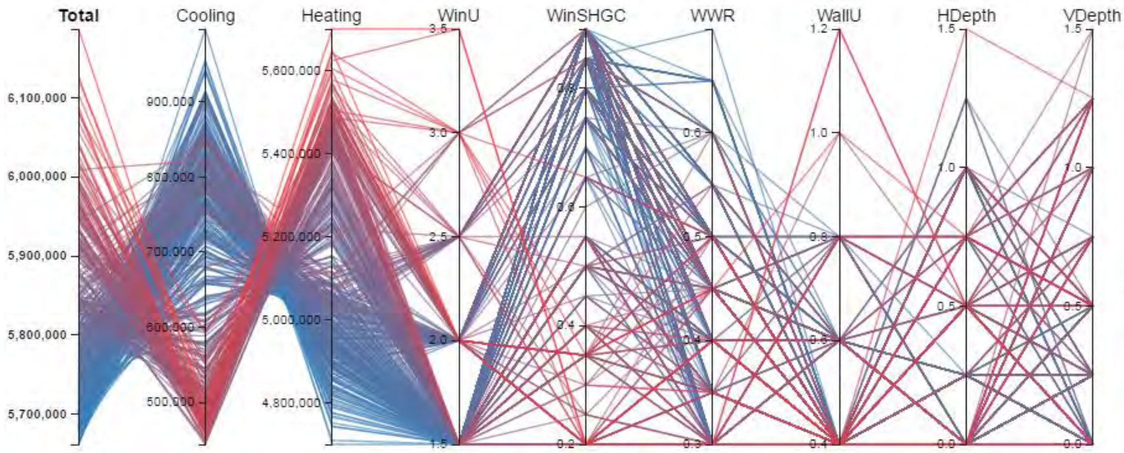

Figure 4: Optimization results – Seoul

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Design Parameters (Seoul)	Design Values
Window-to-Wall Ratio	0.45
Window SHGC	0.9
Window U-Value (W/m²·K)	1.5
Wall U-Value (W/m²·K)	0.4
Horizontal Shade Depth (m)	0
Vertical Shade Depth (m)	0.45

Table 8: Optimal envelope configuration of Seoul

Building Energy Component	Thermal Energy Use	% Difference
Annual Cooling Load (kWh)	865,187	56.7%
Annual Heating Load (kWh)	4,796,533	-12.9%
Annual Thermal Load (kWh)	5,661,720	-6.5%
Thermal Load per Area (kWh/m²)	231.1	

Table 9: Optimized case energy simulation results of Seoul

The optimal case would greatly increase the annual cooling load. As the study case only reports the thermal load, special care should be taken when choosing for the optimal case, where energy cost saving should also be taken into account.

Observing the top 10% results, where the annual thermal load decrease ranges from 6.0% to 6.5%, the factors leading to a lower annual thermal load can be clearly showcased. It is also observed that there are leeway in the selection of window SHGC and of shading depth. There are also no strict restriction in choosing a WWR. The plot also shows that the cooling load can be significantly decreased while maintaining a high overall decrease of annual thermal load. By lowering the WWR and slightly increasing the shading depth, the cooling load can be decreased while not significantly compromising the heating load nor annual thermal load.

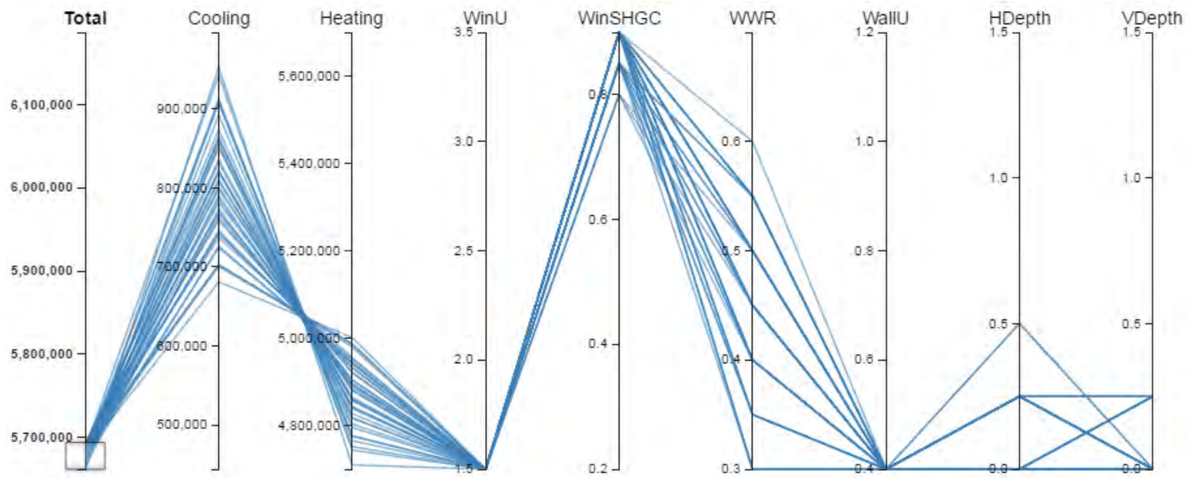

Figure 5: Optimization results – Top 10% results – Hong Kong

6. CONCLUSION

Interactive and parametric optimization at early stage design will allow for the identification of design parameters in which the design team can take into consideration. With the initial settings in the above two cases, clear design parameters can be found after utilizing the optimization solver within Grasshopper. The optimal case found by the solver returned results with annual thermal load decrease of 8.2% and 6.5% as compared to the ASHRAE 90.1-2007 envelope baseline for Hong Kong and Seoul respectively.

Over 200 cases were generated by the solver during each run, giving the design team numerous design iterations where similar savings may also be achieved. The optimization parameters are not limited to those in the above study. Internal load, other envelope properties, nearby surrounding building shading effects, and HVAC settings can all be simultaneously studied. As each parameter will dynamically affect each other and the overall thermal load, by utilizing the increasing computational power available, numerous optimized design options can be

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

generated for better designs. It is believed that energy interactive design approaches would be the driver for future sustainable and climate responsive designs.

Folded Cardboard Sandwiches for Load-bearing Architectural Components

Stephan SCHÜTZ[a]

[a] *Bauhaus-Universität Weimar, Germany, stephan.schuetz@uni-weimar.de*

ABSTRACT

The high resource demand of the building sector clearly indicates the need to search for alternative, renewable and energy-efficient materials. This work presents paper-laminated sandwich elements with a core of corrugated paperboard that can serve as architectural components with a load-bearing capacity after a linear folding process. Conventional methods either use paper tubes or glued layers of honeycomb panels. In contrast, the folded components are extremely lightweight, provide the material strength exactly where it is statically required and offer many possibilities for design variants. After removing stripes of the paper lamination, the sandwich can be folded in a linear way at this position. Without the resistance of the missing paper, the sandwich core can be easily compressed. The final angle of the folding correlates with the width of the removed paper stripe. As such, this angle can be described by a simple geometric equation. The geometrical basis for the production of folded sandwich elements was established and many profile types were generated such as triangular, square or rectangular shapes. The method allows the easy planning and fast production of components that can be used in the construction sector. A triangle profile was used to create a load-bearing frame as supporting structure for an experimental building. This first permanent building completely made of corrugated cardboard was evaluated in a two-year test to confirm the efficiency of the developed components. In addition to the frame shown in this paper, large-scale sandwich elements with a core of folded components can be used to fabricate lightweight ceilings and large-scale sandwich components. The method enables the efficient production of linearly folded cardboard elements which can replace normal wooden components like beams, pillars or frames and bring a fully recycled material in the context of architectural construction.

Keywords: adaptable design, green construction technology, folded components, corrugated cardboard sandwich, architecture, construction

1. INTRODUCTION

Future-proof architectural constructions must possess many characteristics. They should be constructed solid and durable as well as inexpensive and sustainable, while the quantity of used material and production energy has to be as low as possible. Components made of corrugated cardboard can make an important contribution in this context because of many ecological advantages like low embodied energy, excellent recycling rate and residue-free production process. However, they are currently rarely used in the architectural field. Only in some cases they are used as core material in walls or as thermal insulation panels.

As corrugated cardboard materials are rarely used in the construction sector, only a small selection of literature and projects can be found. Lu et al., Nordstrand and Abbès et al. provide an approach to the issue of stability of corrugated sandwich panels. The strength values of the presented material (compressive strength, tensile strength, bending) as well as the use of folded components are discussed in detail by Schütz. Tian and Lu, Ayan and Pohl explore the structural and architectural use of corrugated cardboard. Eekhout et al. present basic approaches and implemented architectural projects. Basic knowledge on folded paper objects are presented by Jackson and Zeier. Miura and Sakamaki analyse folding in a deeper way and folded lightweight structures are presented by Hilmar.

In this paper, five hypotheses are postulated. First, an exact zone of folding is definable by removing a strip-like part of the inner face material (e.g. with a CNC controlled milling machine). Second, the width of this zone relates to the resultant angle of the folded component and this relation can be described with a simple equation. Third, the profiles are solely producible by longitudinal folding. Fourth, the paper removal on both sandwich surfaces allows more sophisticated profiles with convolutions in two directions and leads to a huge amount of design varieties. Fifth, the production of folded multipart elements with load-bearing capacity is possible.

2. MATERIAL

The core of the sandwich plate consists of corrugated and flat paper layers that are glued with Sodium silicate (CAS 1344–09–8) to form a block. The sinusoidal corrugated layer has a wave separation of 8 to 9,5mm and a wave height of 4 to 5,3mm (coarse wave A). The core consists of 100% recycled paper with a weight of 110g/m^2. This paper has a thickness of 140 to 159µm and the weight of a block is 65kg/m^3 with a tolerance of 15%. The block is cut into flat panels of 5 to 100mm thickness. The surfaces of the panels are covered with so-called kraft paper by using PVA-glue. This paper consists of about 30% recycled material, has a weight of 280g/m^2 and a paper thickness of 348µm. The maximum size of the sandwich panels is 3130 x 1260mm. The here presented methods and results refer to sandwich panels with a material thickness of 30mm and linear folds.

Figure 1: Corrugated cardboard sandwich (left) and core material (right)

3. METHODS

The folding of a flat element generates a zero line that divides the material into an inner zone of compression and an outer zone of elongation. In a homogeneous material like a metal sheet, the zero line runs through the geometric centre. This can be seen in the left section of Figure 2.

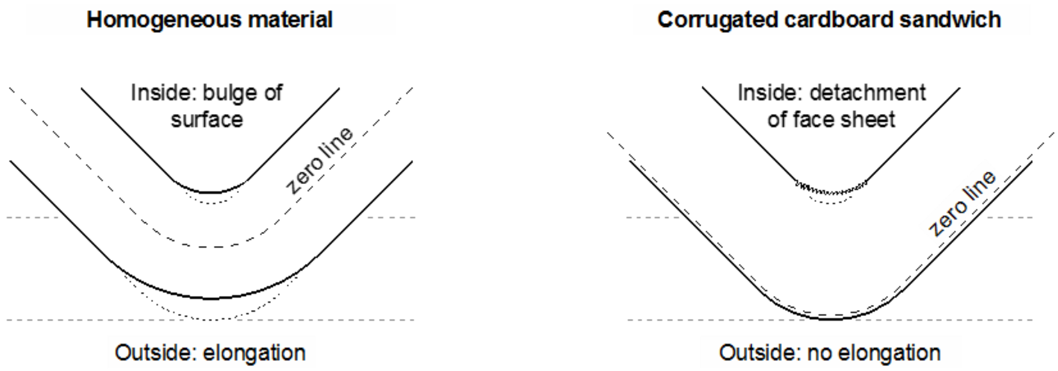

Figure 2: Folding of homogeneous material (left) and corrugated cardboard sandwich (right)

Corrugated cardboard sandwiches are inhomogeneous, therefore the structure of core and cover material should be considered separately. The surface paper has a high tensile strength and flexibility due to bending. The core is very pressure-resistant under vertical load but it is very sensitive to lateral compression. This feature turns out to be a great advantage in this case. The zero line migrates close to the outer surface paper and just a zone of compression remains at the inside. This can be seen in the right section of Figure 2. The resultant curve describes a circular arc segment, which results in a unique aesthetic appearance. During the folding process, the inner surface is compressed in such a way that it separates itself from the core structure. To avoid this detachment a stripe-like part of the inner surface paper is removed. Then, the folding process runs effortless and the longitudinal edges of the remaining papers touch each other. This indicates the end of the folding process. Figure 3 shows the section through a corrugated cardboard plate before and after the folding process. It clarifies the relation between starting angle α_1 and resultant angle α_2.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

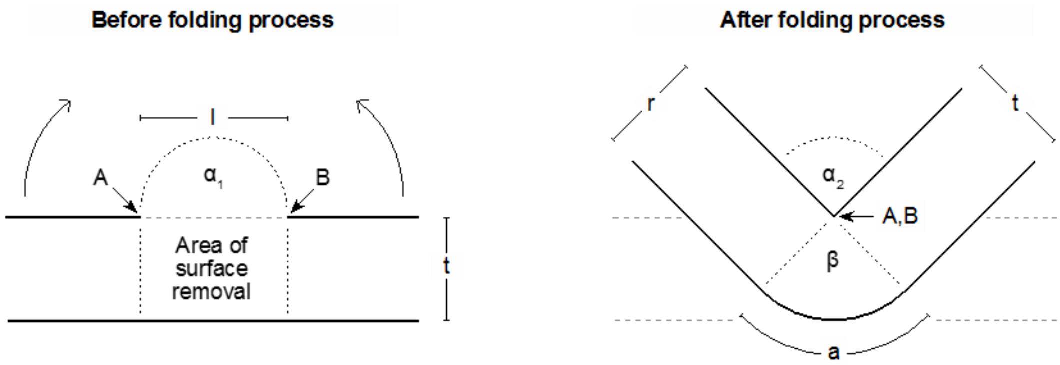

Figure 3: Unfolded corrugated cardboard sandwich (left) and folded element (right)

This folding process can be described geometrically by an equation. Their derivation is as follows. The material thickness t corresponds to the radius r.. The width l of the removed paper defines the distance $\overline{AB}$ between the longitudinal edges of the remaining surface paper. The folding process to the resultant angle α_2 creates the internal angle β. The arc length a corresponds to l as well as A and B are congruent. If a final angle α_2 is given, the strip-like paper removal can be calculated by using the formula of the circular arc:

$$a = \pi \cdot r \cdot \frac{\beta}{180°}$$

Equation 1

Since r is known by the given material thickness t, the angle β remains as the only unknown parameter. Because a is equal l, the final formula reads as follows:

$$l = \pi \cdot r \cdot \frac{(180° - \alpha_2)}{180°}$$

Equation 2

The equation shows, that the width of the paper removal is inversely proportional to the resulting angle. More material must be removed to obtain a smaller angle. The geometric coherences relate only to the inner angle and the arc length. That is why the equation can be used for any material thickness.

4. RESULTS

A load-bearing architectural component like a beam or a pillar is producible by multiple folding of a formerly flat plate into a profile. The following example of a pillar is based on an equilateral triangle and shows the application of the presented formula. Figure 4 shows the folding process schematically.

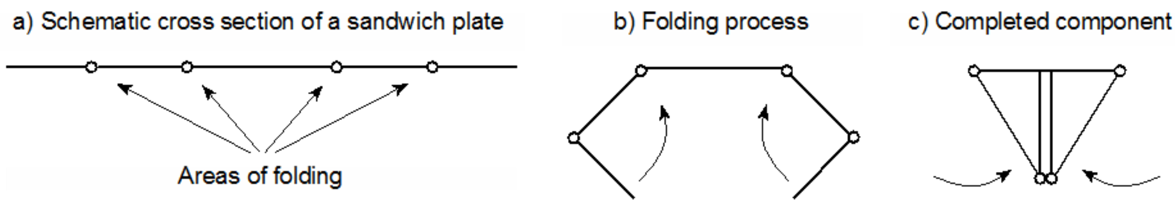

Figure 4: Folding process of a triangular pillar

The profile is made of a honeycomb plate with a thickness of t = 30mm. The dimensions are w = 308mm and h = 223mm. One half of this symmetric profile is considered for identification of the areas of paper removal. This is shown in Figure 5.

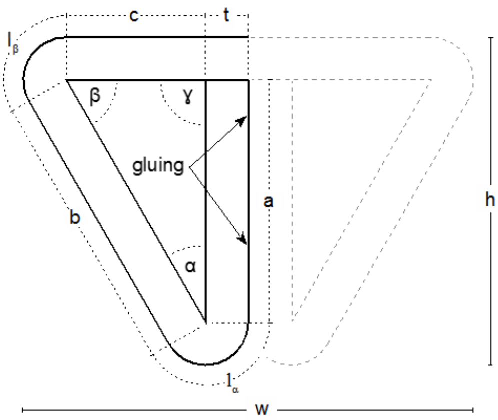

Figure 5: Half section of the described pillar with single segments

The half of the profile is a right triangle with the opposite side a, the hypotenuse b and the adjacent side c. These lengths are calculated by using the angle laws and the given dimensions for w (width) and h (height) as well as t (material thickness) of the desired profile. The two surfaces that touch each other after folding are glued with standard PVA glue. The total developed view of the component is composed of a sequence of lengths whose sum must to be doubled. The two important areas of paper removal are l_α and l_β. Both can be calculated with Equation 2. The total length of the developed view l_{total} is calculated with the following equation:

$$l_{total} = 2 \cdot (t + c + l_\beta + b + l_\alpha + a)$$

Equation 3

With the method presented here a variety of different types of profiles can be produced. Figure 6 shows the horizontal section through a selection of pillar-profiles based on basic geometrical shapes. In principle, hollow profiles (see Figure 6a, 6b, 6c) and double material profiles (see Figure 6d, 6e, 6f) can be distinguished.

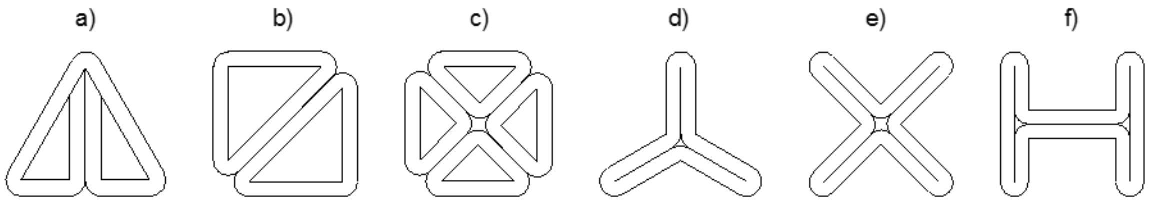

Figure 6: Hollow profiles (a, b, c) and double material profiles (d, e, f)

The profiles shown above can be used as role models for ceiling structures. Figure 7 shows the vertical section through two individual beams (see Figure 7a, 7b) as well as a ribbed slab (see Figure 7c). This is enabled by continuous folding and gluing of the substructure. The extension to a large-size ceiling sandwich is possible by gluing of an additional plate on the bottom side (see Figure 7d).

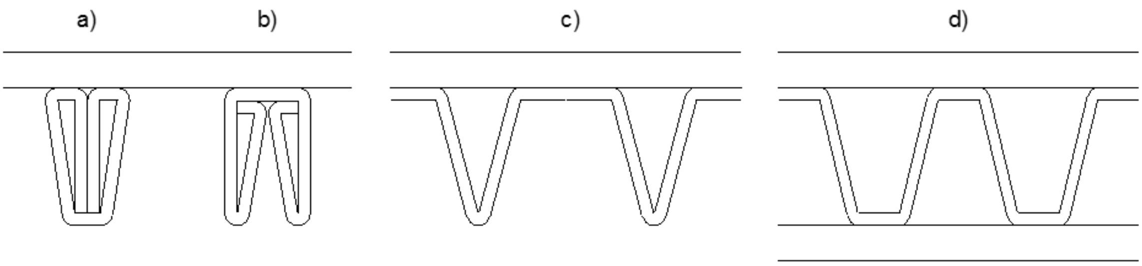

Figure 7: Single horizontal beams (a, b), a ribbed slab (c) and a sandwich ceiling (d)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The profile shown in Figure 5 is the starting point of a framework that serves as load-bearing structure of an experimental building, which is entirely made of corrugated cardboard panels. The building is called "Open Source: Cardboard" and combines the advantages of folded elements for construction and flat sandwich panels for thermal insulation. With a length of 5.05m, a width of 3.36m and a height of 3.58m, the permanent pavilion offers space for at least six student workplaces. Figure 8 shows the views and the interior.

Figure 8: South facade (left), north facade (centre) and interior (right)

5. DISCUSSION

The results confirm the hypotheses made above and show the simple planning and production of load-bearing folded corrugated cardboard elements. The profiles possess aesthetic curves in the area of folding and thus a continuous surface. Thereby, open cut edges are avoided what facilitates stability and uniform appearance. The production is simple with a standard two-axe milling machine.

Now, a hitherto rarely considered material can be used in in the construction sector. It has a great potential to replace normal wooden beams and pillars as well as ceilings. A beam with a length of 300cm and a height of 22cm carries a load of 400 kg with only little deformation. Beside the here presented profiles, other hybrid components can be created by the addition of thin wooden plates. This opens up an entirely new field of research.

The method provides an enormous variety of profile variants whose shape not only depends on static aspects but also on aesthetic design specifications. The way of calculation and the principle of production are comprehensible and the used material is cheap. Even complicated folds are feasible and allow the production of multi-folded supporting elements. Two ways of production can be distinguished. First, the simpler so-called wrapped profile with material removal on just one side and second, the zigzag profile with processing on both surfaces. The profiles are adaptable to almost any every construction principle with elongated load transfer and also slab-like elements are producible. As seen in Figure 8, the successful application of folded cardboard sandwiches as load-bearing elements was proven in a two-year evaluation between July 2014 and July 2016.

Despite all the advantages, some problems should not go unmentioned. Not all types of sandwich board can be folded in the manner described herein. The core material must be compressible in direction of the folding force effect. The surface material should be elastic enough to bear the bending due to folding without breaking. Future research should explore other materials that provide similar material properties like corrugated cardboard panels. The maximum dimensions of the described sandwich panels are the reason for limitations in the length and profile size of the folded parts. Additions by overlapping are possible but that increases the production costs. The double material profiles as well as the ribbed slab and the sandwich ceiling require a paper removal on both surfaces. This should not pose a big problem with using modern CNC machines, however, it also increases the production costs. Finally, also the basic properties of the paper material should be considered. Its sensitivity against water or fire remains even though the facing material is resistant against such influences. This still causes problems in building approval of such components.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

6. CONCLUSION AND OUTLOOK

I reported the efficient design and production of load-bearing components that are made of folded corrugated cardboard panels. A simple design strategy allows the easy planning and the fast production. An evolutionary step could be the production without milling. In this case the core material of the sandwich is covered partly in the production process. An advanced research field could be the prefabrication of large-scale walls and ceilings for architectural projects. Here, the folded sandwich components can serve as core material as well as stiffening components. Hybrid constructions with wooden parts are also conceivable in this context. All in all, the method enhances the capability of corrugated cardboard sandwiches and offers a new way of construction to the architectural sector.

ABSTRACT

A combination of concrete and timber elements can lead to advantageous structural and environmental solutions. Especially in the case of multi-storey buildings concrete floor structures could significantly improve acoustic and fire safety building performance and at the same time they can ensure horizontally rigid floor structures from the perspective of spatial rigidity. Subtle HPC precast frame thus represents effective alternative to timber-based framework by providing possibility to build higher buildings, while allowing the other structures to be based on wood. Technical parameters of HPC structural frame and environmental qualities connected with the higher use of renewable materials can result in construction of multi-storey energy efficient buildings.

Results of long-term research project and development of a new optimized precast construction system based on high performance concrete is presented. The system is particularly aimed for building construction in passive or zero-energy standard. High performance concrete used for the superstructure enables lowering of concrete consumption up to 50 - 70%. Developed structural concepts have been proved by theoretical and experimental results. The paper presents in more detail a construction of the experimental RC frame and a LCA study of developed subtle HPC frame, which is compared with standard solution.

Keywords: high performance concrete, precast frame, wooden envelope

1. INTRODUCTION

Nowadays, there is an increasing tendency to build multistory wooden based buildings usually from CLT (cross laminated timber) panels or using timber frames. However, there are limitations in a space rigidity of multistory timber structures, in acoustic performance of timber floor structures and in a fire safety. The combination of light concrete frame with concrete floor structure and wooden based other parts of structure (envelope, partitions, roof structure) could solve some of these problems. Significant advantages of subtle elements are material and energy savings during production, transport, manipulation and construction on building site. Accumulative properties of RC structures can contribute to thermal stability of buildings indoor environment. This will mainly help buildings that need cooling in summer. On the other hand, concrete frame provides stronger load bearing structure in comparison to timber structure. In the same time such composite structures will be more resilient and better prepared for extreme situations in a changing environment.

Figure 1 presents a concept of concrete subtle frame for construction of houses in passive energy standard. The concept is based on a combination of subtle load bearing HPC frame with building envelope and other parts like partitions, roof structure etc. mainly from wood or other biobased materials.

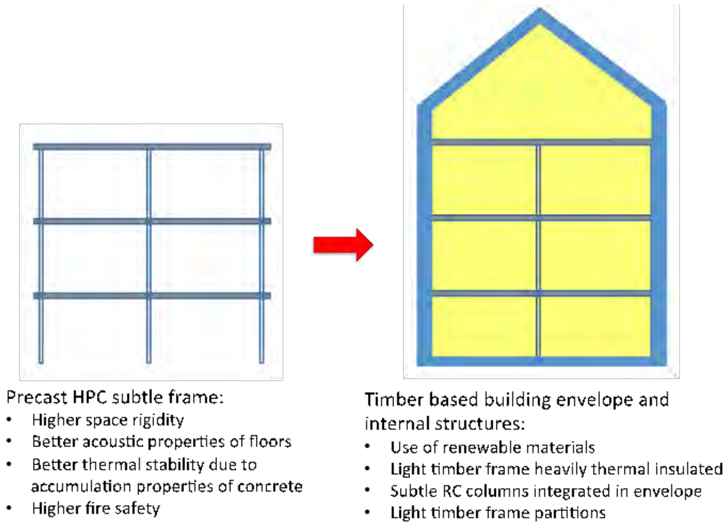

Figure 1: Concept of structural system for multi-storey energy efficient buildings from precast HPC frame and timber based other structural parts

Developed structural frame from high performance concrete (HPC) is aimed for 2 to 6-storey residential and civil buildings (health and social care, education, temporary housing, administration). The combination of timber and concrete can enhance utilization of renewable structural materials also for construction of larger buildings. Concrete floor structures offer advantages in comparison with whole timber structures in the field of acoustics, fire safety, accumulation of thermal energy and spatial rigidity.

2. CONCEPT OF EXPERIMENTAL OSEEB RC FRAME

Experimental structure has been built within the third year of the research project TA03010501: "Optimized subtle frame for energy effective buildings" (OSEEB). The aim of the project was to develop a universal and variable load bearing structure for energy efficient buildings that meets the criteria of sustainable development. The concept of load bearing structure is based on a subtle HPC precast system. The principal aim was to minimize the amount of used material by lightening of the structure using shape optimization of structural elements from high performance concrete. Because of lower self weight of the lighter structure a load on footing bottom, demand on transport and consequent environmental impacts are decreased. Ground plan of the experimental load bearing frame is apparent from Figure 2.

Structural details of the OSEEB system are designed to minimize thermal bridges and to enable maximal variability of ground plan, structural height and full height etc.

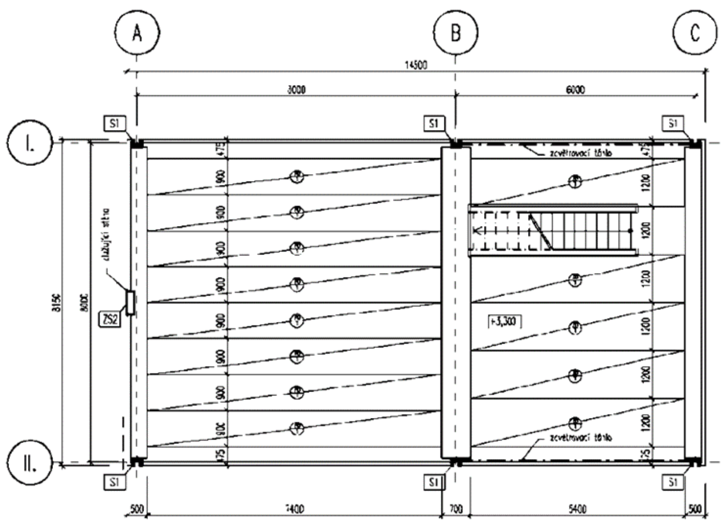

Figure 2: Ground plan of the experimental OSEEB frame

Implementation of experimental frame should show technological consequences and will enable testing of individual structural components on real structure. Structural elements are slab girders and floor panels, subtle multi storey columns, and foundations structural elements – precast pocket footings (alternatively from recycled concrete) and foundation sills. Development of the structural components was accomplished within previous years of the research project. Optimization process resulted in final shapes of cross sections, methods of lightening of structural elements and their mutual connection systems. Experimental structure will be also used for monitoring of structural performance under the long term load.

2.1 Description of experimental OSEEB frame structure

Precast experimental OSEEB frame is designed as two storeys, basementless structure with ground plans dimensions of 8.15 x 14.5m with pitched roof from timber beams. Maximal height of the ridge is 9.3m above the terrain level, the structural height of the 1st floor is 3.8m, the structural height of the 2nd floor is 2.9m and the height of the attic is 2.9m.

Load bearing structure has two bays with axial columns distance of 8 x 8m and 8 x 6m. Main vertical load bearing elements are two storeys C shaped columns from high performance fibre concrete with cross section of 180 x 250mm; main horizontal load bearing elements are prestressed slab girders with notches for embedding of floor panels. Girders and floor panels have equal height of 300 mm in order to create flat soffit and free plan in larger spanned floor structures. Floor panels are lightened by lightening elements from secondary raw materials (recycled material Stered), alternatively from light weight building materials (liapor concrete). Floor panels are from HPC with standard reinforcement or prestressed. For larger spans there is the option of cross fastening of floor slab by post tensioning method. Cables for post tensioning are anchored into side girders. HPC columns are designed from concrete class FC70/85, steel B500B, alternatively B550B, girders, bracings and floor panels from concrete class minimally FC60/75 reinforced by tensioned cables Y1860S7 with diameter of 15.7mm and reinforcement B500B. Columns are embedded into footings from recycled concrete with dimensions of 1.8 x 1.8m and 2.0 x 2.0m and height of 1.05m. Girders are connected to columns by Peikko corbels, longitudinal side beams (bracings) are mounted on girders notch and connected by shear spikes in order to ensure horizontal rigidity of individual components connections.

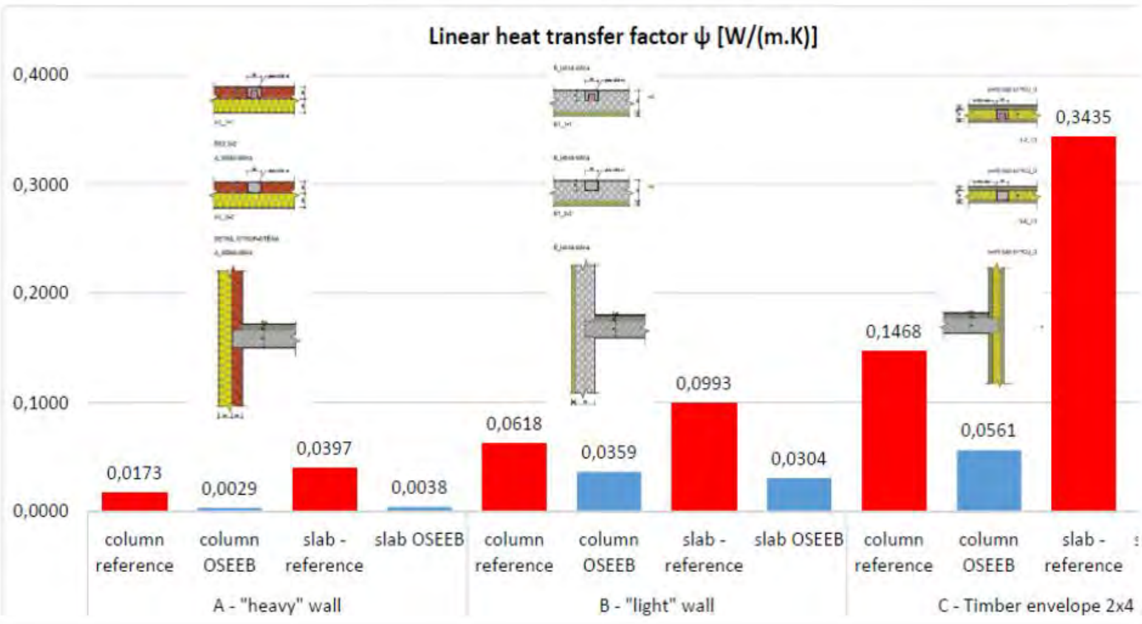

Figure 3: Comparison of linear heat transfer factor ψ for assessed variants of building envelope

2.2 Energy optimization of buildings using OSEEB

The aim of building energy optimization of OSEEB was to eliminate risks of thermal bridges, to minimize heat transfer of main structural parts placed in the building envelope and structural solution enabling continuous layer for air tight and water vapour barrier. Following structural details have been optimized: (i) Columns in the building envelope, (ii) Horizontal beams and slab, (iii) Column footing. Three material variants of building envelope as ceramic blocs with ETICS, foamed concrete with ETICS and timber building envelope based on 2 x 4 system have been taken into account. All variants were designed for the same thermal performance of U = 0.15 W/m^{2}K meeting requirements for low energy and passive buildings in the Czech conditions.

Linear heat transfer factor ψ [W/m.K] was determined according to Czech standards for selected structural variants and compared to common design and size of columns (300 x 300mm) and beams (250 x 700mm). Minimal columns cross-sections and flat horizontal beams of the same height as the slab enable integration into building envelope and minimizing of thermal bridges. Inner side of the column in the part designed as “C” profile is filled with thermal insulation, which again helps to reduce thermal bridges. The results of optimization and comparison to common solution are shown in Figure 3. Significant reduction of thermal bridges is obvious.

3. CONSTRUCTION OF EXPERIMENTAL OSEEB FRAME

Experimental structure OSEEB – Optimized subtle frame for energy effective buildings – was built in UCEEB (University Centre for Energy Efficient Building, CTU in Prague) in Bustehrad area. Precast structural elements of OSEEB frame were produced in company ŽPSV at the end of the year 2015. The company AZS 98 provided precast pocket footings and foundation sills from recycled concrete and company Peikko delivered connecting corbels. The erection of frame started after land remediation by placing the precast pocket footings in February 2016 (Figure 2), installation of above-ground parts of the structure took place during March and April 2016, see Figure 4 to 9. Firstly, subtle two-storey columns were assembled followed by stiffening wall and foundation sills (Figure 5). Subsequently, flat girders and longitudinal stiffeners were fitted to columns by Peikko´s corbels (Figure 6). After temporary securing of girders against torsion, the floor panels were installed - prestressed elements per module 8m and non-prestressed panels per module 6m. (Figure 8).

Figure 4: Precast pocket footing

Figure 5: Assembling of subtle columns, stiffening wall and foundation sills

Figure 8: Structure of experimental frame with unfinished ceiling above 2nd floor

Figure 9: Finished load bearing structure of experimental OSEEB frame

Peripheral girders at ceiling levels provide rigidity of the frame in longitudinal and transverse direction. Girders are connected to columns by Peikko corbels and by shear spikes in order to ensure force transmission in the plane of the ceiling from all load combinations. After assembling of floor structures, the shear spikes and joints between panels and girders were sealed by concrete grout SikaGrout. Experimental OSEEB frame structure was finished in April 2016 (Figure 9). In the first stage, the both floor structures were implemented as laterally non-prestressed, followed by a first static load test. After performing load test, the floor structure of the span 8 x 8m above 2nd floor was additionally prestressed and static load test was repeated.

4. LIFE CYCLE ASSESSEMENT OF SUBTLE FRAME

A set of environmental information data on concrete components and related processes has been collected and determined within the research performed at the Faculty of Civil Engineering, Department of Building Structures of the Czech Technical University in Prague. These data are based on regionally available materials and are based on source data provided by companies producing and/or selling their products mainly on the Czech market. The data have been stored and organized in CONCRETE LCA$^{\text{Tool 3.0 CZ}}$.

A simple two-storey experimental building with a ground plan of 8.15 x 14.5m was chosen for life cycle analysis (LCA) study covering environmental assessment and comparison of two selected concrete frame structure alternatives (Figure 2 and 9). The house is designed with a very universal layout enabling design of many feasible structural and material alternatives.

4.1. Description of concrete frame structures alternatives

The complex (LCA) was performed for two various RC frame structures that were designed for afore mentioned building. This analysis focuses primarily on load-bearing structures and does not cover building envelope, partitions and surface finishes. The analysis covers transport of the raw material to the prefa plant, concrete production, transport of prefabricated elements to the building site, demolition and deposition of the concrete at the end of the structures lifespan. The RC frame structure's alternatives are as follows:

- V1 reference precast RC frame structure from concrete C30/37 and C40/50 with columns dimensions of 400 x 400mm, girders 550 x 650mm, stiffeners 190 x 600 mm and hollow core prestressed panels with thickness of 265 mm.
- V2 subtle HPC frame structure from concrete HPC70/85 with subtle columns as shown in Figure 6, girders dimensions of 500 x 300mm, 700 x 300mm, stiffeners 470 x 300mm and floor structure panels as described in chapter 2.1. HPC for floor panels and columns is reinforced by dispersed steel fibers (1% vol.).

4.2. Inventory of input data and LCA results

In the following analysis the expected life span of frame structures was considered for all alternatives equally 100 years. Construction life phase covers: amount of used concrete (precast elements), amount of individual components needed for concrete production, amount of the reinforcement divided according to a type of reinforcement and related transport to construction site. End of life phase calculates with the amount of waste from demolition, amount of demountable components that can be reused and related transport.

Aggregated impact data for specific life cycle phases construction are presented for primary raw materials consumption and primary energy consumption in Figure 10. It is evident that environmental impacts in the construction phase are significantly higher in comparison with end of life phase. In Figure 10 shows the influence of individual components such as cement, aggregate, water, admixtures etc. on primary energy consumption. It is apparent that main environmental impact is due to cement and steel reinforcement. Transport, construction process, aggregates and admixtures cause minor effect.

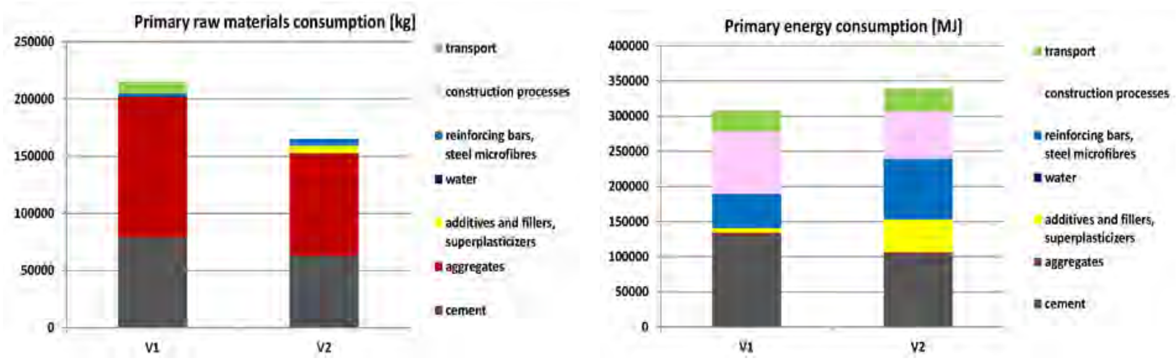

Figure 10: Aggregated data - Primary raw materials and primary energy consumption

Figure 11 presents the final comparison of assessed alternatives. 100% is represented by V1 (precast RC frame structure from C30/37 and C40/50). The environmental values of both variants of frame are comparable in primary energy consumption and emissions criteria. In total 20% of raw material consumption and 11% water consumption can be saved by utilizing V2 alternative, structure as optimized subtle HPC frame.

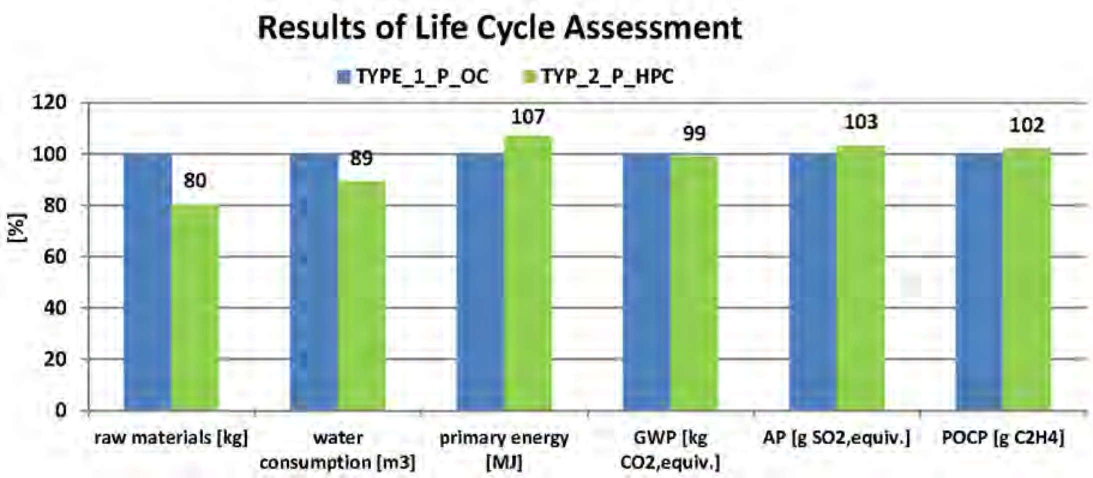

Figure 11: Aggregated data of assessed variants frame (GWP – Global warming potential, AP – Acidification potential, POCP – Photochemical ozone creation potential)

5. CONCLUSION

Two alternatives of RC frame structures have been analysed and compared. The results of analysis proved expectation that subtle HPC frame structure is the environmental friendly alternative from two assessed alternatives. The results show that the high quality of mechanical and environmental performance of new silicate composites creates the potential for wider application of High Performance Concrete in building construction in the future. The further advantage of subtle HPC frame can appear in areas with regulated size of built-up area (e.g. in dense inhabited town areas). With higher demands on thermal insulation parameters of building envelopes increases also their thickness. The possible integration of subtle columns in building envelope can thus save valued inner space. The construction of an experimental frame validates the feasibility of the project and production technology of elements and installation of frame structure.

ACKNOWLEDGEMENT

This outcome has been achieved with the financial support of the research project granted by Technology Agency of the Czech Republic grant TA03010501. Authors would like also to express thanks for all support provided by companies ŽPSV a.s., Peikko a.s. and AZS 98, s.r.o.

ABSTRACT

In Hong Kong, as of January 2013, 75.8% of commercial buildings and 90% of composite buildings were built before 1995 (ESP, 2015). The opportunities of energy consumption reduction for old existing buildings cannot be neglected to achieve deep energy saving target for Hong Kong by 2025 as per Energy Saving Plan launched by Hong Kong Special Administrative Region Environment Bureau. This paper presents a case study of adopting electronically commutated (EC) motor plug fan technology for replacing belt driven fan for AHU in an existing building.

EC motor plug fan technology offers high operation efficiency in HVAC air side system and be widely adopted in new building development in recent years. This advanced technology however was not common in existing building retrofit due to some hurdles such as initial cost, payback, spacing, installation approach and timing. This case study aimed to investigate the feasibility as well as performance of only replacing an old belt driven fan with external variable frequency drive (VFD) control by 4 nos. of EC motor plug fan with installed controlled electronics, but not involving the other operable components inside the air handling unit. It was estimated that more than 40% of fan energy reduction could be achieved, based on the hourly fan operation data via BMS, onsite fan power measurement and testing and commissioning (T&C) results of new fan installation. The life cycle cost and payback were also considered thus providing a full picture of this HVAC airside retrofit.

Keywords: existing building retrofit, electronically commutated motor plug fan, energy saving

1. INTRODUCTION

Fan uses nearly 40% of all electricity in HVAC systems of a commercial office building (Yik et al., 1998). Thus, adopting high efficiency fan technology is a good opportunity to achieve energy saving target for building. Recently, EC motor plug fan is one of the most effective fan improvement technologies available. There are some different types of EC motor plug fan available in the market, the most common one is a backward curved centrifugal impeller directly mounted on a brushless direct current (DC) motor. Its variable speed control can be achieved by varying the DC voltage delivered to the motor. This fan technology has significant advantage in terms of energy efficiency compared to alternating current (AC) motor belt driven fan, which is one of most typical HVAC applications in existing buildings, required on-going maintenance and frequent replacement of belts, pulleys and bearings. Failure to do so will lead to increased inefficiencies and motor and bearing failures which increase cost even further. For the purpose of improving energy efficiency and operation performance, this case study investigates the feasibility and effectiveness of adopting EC motor plug fans for replacing belt driven fan in an existing office building.

2. CASE STUDY

In this case study, a typical office floor (area: 1490 m^2) of a 22-year-old Hong Kong Island building was selected for fan retrofit. Air-conditioning system of variable air volume (VAV) powered by air handling unit (AHU) is adopted in this office floor. Static pressure control logic is applied for varying supply air volume. An old AHU belt driven fan of rated power 22 kW with external variable-frequency drive (VFD) control was replaced by 4 nos. of EC motor plug fan of rated power 5.05 kW (Figure 1). Table 1 lists the detail technical information of fans.

Figure 1: (a) Belt driven fan and (b) EC motor plug fan

	Rotation Speed Control	Rated Input Power (kW)	Design Air Flow Rate (l/s)	Design Static Pressure (Pa)
Belt Driven Fan	External VFD (Previously set 25Hz to 45Hz)	22	10500	1125
EC Motor Plug Fans	Embedded rotation speed control (Set max. 85% speed)	20.2 (4 × 5.05 kW)	11200 (4 × 2800 l/s)	1200

Table 1: Technical information of fans

The retrofit work was commenced in early November of 2015. The old fan motor, fan blower, and its associated supporting frame were removed. The 4 nos. of new backward curved centrifugal EC motor plug fan were installed with new supporting steel frame, and an electrical panel for power supply to 4 nos. of fan was newly installed. The original building management system (BMS) control signal (0-10V) was split into 4 nos. of signal with 4 wires connecting to the new fans. Synchronized rotation speed operation was adopted in new fan system. Differential pressure sensor for air flow measurement and Modbus connection for high level interfacing between the new fans and existing BMS were installed for this case study, which provide useful operation data for fan performance analyses. The maximum rotation speed control of 85% of full speed was set for new fan system to deal with the predicted cooling demand according to the previous operation experience.

To facilitate the performance analyses, the portable power analyser and sound pressure level meter were utilised for the pre-retrofit on-site measurements in July and August of 2015 and post-retrofit new EC motor plug fans T&C in early 2016. Operation data of belt driven fan (pre-retrofit) and new EC motor plug fan (post-retrofit) which includes AHU air flow rate, fan input power, VFD control frequency and fan rotation speed were collected from BMS. Different data sources are summarized in Table 2.

	Data Collected by BMS (Recorded every 15 minutes)	Data Measured by Portable Measurement Device (Measured every 5 minutes)
Belt Driven Fan	• AHU air flow rate • VFD control frequency	• Fan input power and Harmonics (by power analyser) • Noise (by sound pressure level meter)
EC Motor Plug Fans	• AHU air flow rate • Fan rotation speed • Fan input power	• Harmonics (by power analyser) • Noise (by sound pressure level meter)

Table 2: Data sources

3. RESULTS AND DISCUSSION

Performance of belt driven fan and EC motor plug fans are compared in three aspects: electricity consumption, Harmonics and noise. Payback analysis is also conducted in this part.

3.1. Electricity consumption comparison

Belt driven fan input power and VFD control frequency were measured on-site and collected from BMS before the fan retrofit. Control setting from 25Hz to 45Hz was adopted to suit the cooling demand of office floor. Figure 2 displaces the relationship between fan input power and VFD control frequency. Electricity consumption of belt driven fan in July and August of 2015 is calculated by this equation with the BMS data of VFD control frequency. Compared with the electricity consumption of belt driven fan in July and August of 2015, electricity consumption of EC motor plug fan measured in July and August of 2016 is approximately 40% lower (Table 3) without considering the variations of weather condition and user demand between year 2015 and 2016.

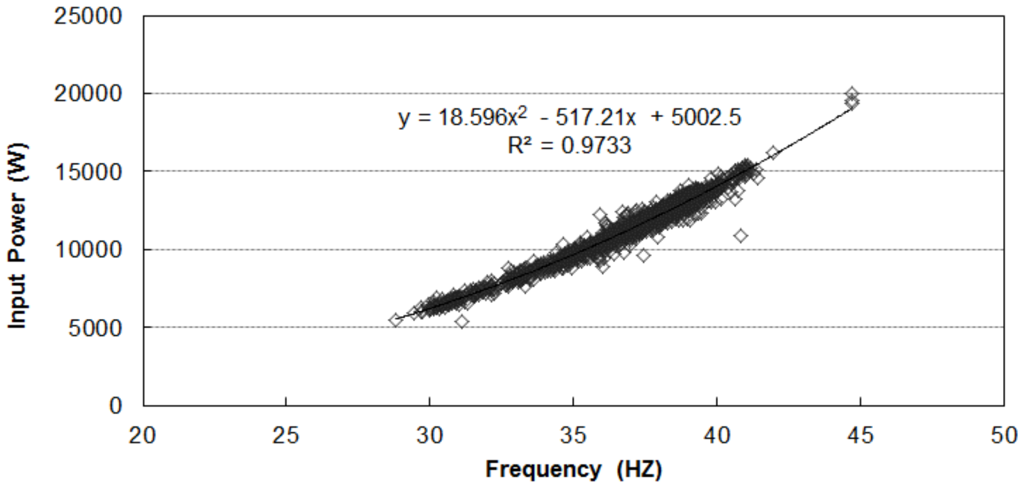

Figure 2: Belt driven fan input power vs frequency

Belt Driven Fan Electricity Consumption		EC Motor Plug Fan Electricity Consumption		Electricity Reduction after Retrofit
1 July 2015 to 31 July 2015	3595.99 kWh	1 July 2016 to 31 July 2016	2093.54 kWh	41.78%
1 August 2015 to 31 August 2015	3213.43 kWh	1 August 2016 to 31 August 2016	1936.71 kWh	39.73%
Total	6829.42 kWh	Total	4030.25 kWh	40.81%

Table 3: Energy consumption of fans

Based on data measured and collected from BMS in July and August of 2016, relationship between input power and air flow rate of EC motor plug fans is identified as shown in Figure 3. Annual consumption of belt driven fan and EC motor plug fans based on year 2015 operation profile were calculated by regression equations shown in Figures 2 and 3 respectively. Figure 4 shows the comparison result. It can be observed that, with the same quantity of air supply, EC motor plug fans require less energy in every month. This is mainly contributed by higher efficiency of EC motor plug fan. For belt driven fan with VFD, efficiency of VFD and belt drive can significantly influence the total fan efficiency. The VFD losses are typically 2% to 5% at the nominal torque and speed, and 10% to 30% at 25% torque and speed. The efficiency of a belt drive is 90% at medium power application (3 – 15 kW), but it can easily slip to 60% to 70% if the gear adjustment is incorrect (Brelih, 2012). For EC motor plug fan, the DC rotation speed control technology can maintain a relatively high efficiency from the rotation speed of 10% to 100%. The direct mounted impeller design can offer almost 100% of efficiency in transmission from motor to impeller.

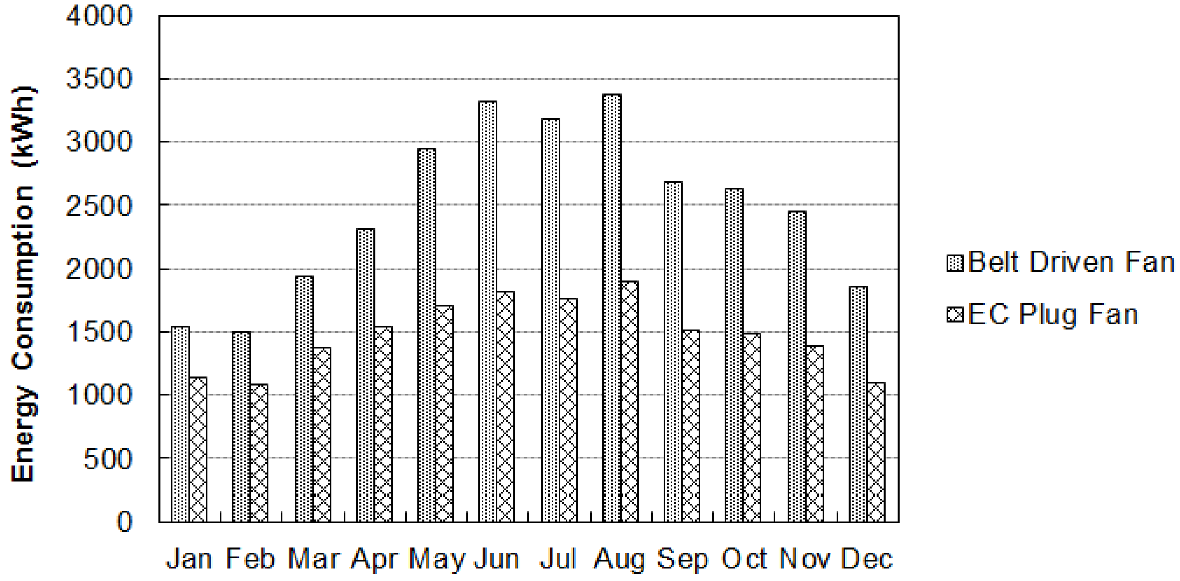

Figure 3: EC motor plug fan input power vs air flow rate

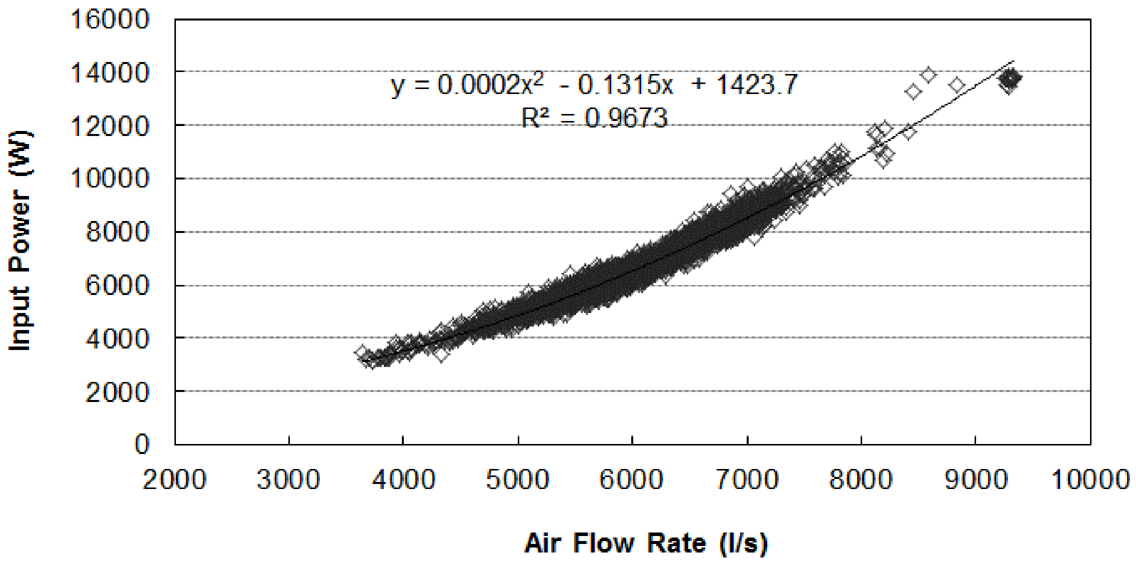

Figure 4: Energy consumption comparison: Belt driven fan vs EC motor plug fan

Based on year 2015 operation profile, electricity consumption estimation of fans in every month is summarised in Table 4. Adopting EC motor plug fans could save potential 40% of belt driven fan electricity consumption annually. This estimation assumes the both fan technologies operating under an identical real case operation profile (year 2015). These electricity saving estimations for July and August are slightly higher than that energy saving measurements identified in shown in Table 3 for approximate 4%.

Table 4: Energy consumption of fans

3.2. Harmonics comparison

Harmonics induced by belt driven fan with VFD and EC motor plug fan were measured by portable power analyser before and after the retrofit. The measured variation range of current and total harmonic distortion (THD) for different fans are shown in Figure 5 and Figure 6. As Code of Practice for Energy Efficiency of Building Services Installation suggested when the design THD of current for a circuit at or below 40 A, THD should be lower than 20% (BEC, 2015). Obviously THD of current for the measured three-phase circuit connecting to both belt driven fan and EC motor plug fan is out of recommended range. It is thus suggested to install a harmonic filtering device to mitigate the THD when VFD or EC motor plug fan is adopted. For the fifth harmonic which may cause a counter electromotive force in motors acting in the opposite direction of rotation, current distortion induced by EC motor plug fans maintains 35% or below when the motor operates under the loading of 50% or less (single phase current of 15A or less). This conditionally meet the requirement of Code of Practice for Energy Efficiency of Building Services Installation that the maximum fifth harmonic current distortion at the VSD input terminals during normal operation within the variable speed range is less than 35% (BEC, 2015), given condition that the normal operation is larger than 50% of design loading. Harmonic filtering device is again recommended for low loading operation.

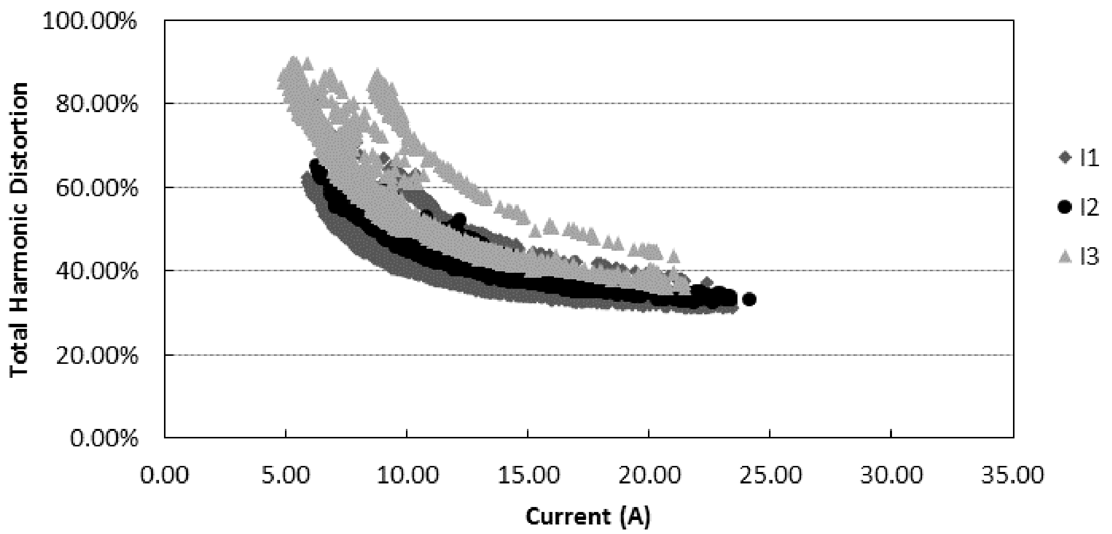

Figure 6: EC motor plug fan total harmonic distortion of current

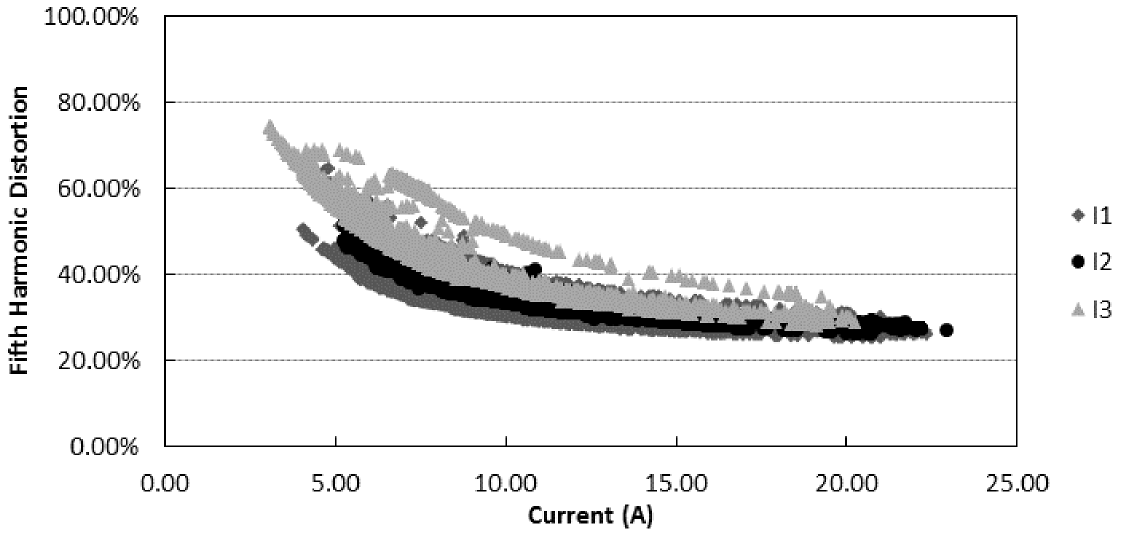

Figure 7: Fifth harmonic current distortion of EC motor plug fan

3.3. Noise test

To ensure the operation of EC motor plug fans will not affect office working environment, noise tests were conducted before and after the retrofit. Testing results are shown in Table 6. The highest sound pressure level under the normal air outlet was measured at a test point, which is located under one of the air outlets nearest to the AHU. According to BEAM plus Existing Building (version1.2, 2012), NC 40 is suggested for office type premises. For this AHU, air flow rate demand is in the range of 2500 - 8000 l/s during a year. Thus, the sound pressure level of office space can meet the requirement in most time of the year with EC motor plug fan.

	Belt Driven Fan			EC Motor Plug Fan		
Frequency	45Hz	30Hz	Off	-	-	-
Rotation Speed	-	-	-	2444rpm (94.0%)	1850rpm (71.2%)	1235rpm (47.5%)
Air Flow Generated	Approx. 8000 l/s	Approx. 4800 l/s	-	Approx. 9900 l/s	Approx. 7000 l/s	Approx. 2500 l/s
dB(A)						
Inside AHU Room (1m away from inlet)	71	62	48	74	71	50
Worst Case Test Point	46	41	37	48	45	37

Table 6a: Testing results

	Octave Band Center Frequency (Hz)								Noise Criterion
	63	125	250	500	1000	2000	4000	8000	
	Sound Pressure Levels (dB)								
Belt Driven Fan at 45Hz Worst Case Test Pt.	56.3	51.2	47.6	41.5	38.7	38.2	0.0	0.0	NC 40
EC Motor Plug Fans at 2444rpm Worst Case Test Pt.	59.7	55.3	49.1	45.0	41.0	37.0	0.0	0.0	NC 40

Table 6b: Testing results

3.4. Payback analysis

To answer the question whether the EC motor plug fan is worth the investment for building retrofit, a payback analysis was conducted. Table 7 shows the analysis result. Payback period for individual fan retrofit in this case study is relatively long (over 8 years). Weekend/ night-time installation, which aims to minimise the disturbance to office tenant, is also one of the reasons of high initial cost in this particular case. It is expected the cost of retrofit could be reduced by capturing the benefits of economy of scale, while engaging a large scale retrofit work with a significant quantity of fan replacement.

Item	Cost (HKD)
Fan and sensor supply	Approx. 80,000
Removal of belt driven fan	Approx. 20,000
EC plug fan installation	Approx. 80,000
EC plug fan control panel	Approx. 40,000
Test and Commissioning	Approx. 5,000
Total investment	Approx. 225,000
Electrical cost saving per year (1.4 HKD/kWh)	16,685
Maintenance cost saving per year (no belt and bearing replacement)	Approx. 9,000
Simple Payback	8.8 years

Table 7: Payback

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4. CONCLUSION

This study investigates the performance and feasibility of adopting EC motor plug fan technology for replacing belt driven fan in an existing office building. It is found that EC motor plug fan can achieve more than 40% energy saving over belt driven fan yearly. Its modular and compact design makes installation easy. Its maintenance cost is lower because it is not necessary to frequently replace belts and bearings. Thus EC motor plug fan could be a good choice for new buildings or existing buildings which targets to achieve high performance in energy efficiency.

Low Temperature Radiant Cooling Design and Application in Tropical/ Sub-Tropical Countries

Paul CHAN Yim-Cheong[a]

[a] *Wong & Ouyang (Building Services) Ltd., Hong Kong SAR, cyc@wobse.com*

ABSTRACT

Radiant cooling design has been practiced in many countries in the form of chilled beams or chilled ceiling and intakes chilled water temperature at around 16°C to avoid condensation under normal indoor conditions. With such 'high temperature 'radiant cooling equipment, it cannot meet the high cooling load requirements for tropical/sub-tropical countries like Hong Kong making this cooling design not popular in these countries.

Currently with the new emerging technology, a new breed of 'low temperature' radiant cooling products are now available in the market where intake chilled water temperature can be as low as 7°C without condensation problem when working with a special fresh air system. Indoor Environmental Quality (IEQ) is also much enhanced due to it's silent operation, capable of providing full fresh air to the indoor space, no draft and evenness of temperature distribution.

With this 'low temperature' design, performance of these radiant cooling products is greatly enhanced to meet cooling demand for hot and humid countries like Hong Kong. Cooling energy saving can be up to 40 % reduction compared to conventional convective air-conditioning design. Fan and pump power can also be greatly reduced since it is basically a passive system with much reduced chilled water flow rate.

This paper will discuss the design, energy performance, indoor Environmental Quality, E&M spatial advantages, cost, maintenance requirements and applications/ limitations of this range of 'low temperature' radiant cooling system compared to conventional AC design.

Keywords: adaptable design, energy saving, indoor environmental quality

1. CONVENTIONAL AC DESIGN

Heat transfer can be in the form of conduction, convection, radiation or a combination of all the three forms. In conventional air conditioning design, convection process has generally been adopted in that the air conditioning system absorbs heat by convection or circulating cool air in an indoor space. The cool air rises while it absorbs heat and returns through air ducts or plenum back to the cooling coils of the AC equipment where it is cooled down again before being re-circulated back to the space to repeat the cooling process.

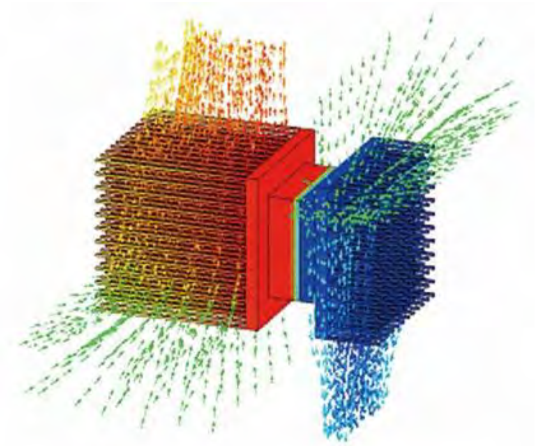

Figure 1: Convection air conditioning design

This convective heat transfer process uses the following equation:

$$Q = h \cdot A \cdot (Ts - Tf)$$

Equation 1

In conventional AC design the heat transfer between different fluids is more commonly expressed as:

$$Q = \dot{m}\,Cp \cdot (T1 - T2)$$

Where, Q = heat transferred per unit time; hc = convective heat transfer coefficient; A = heat-transfer area of the surface; Ts = temperature of the surface; and Tf , T2 = temperature of the fluid, $\dot{m}$ is the mass flow rate of the fluid, Cp is the heat capacity of the fluid.

Equation 2

This conventional AC design basically mixes cool supply air with the indoor air to form a cool reservoir of air where heat is absorbed and removed by the cooling process as mentioned above. Since invented by the famous American Dr Willis H Carrier more than 100 years ago, this AC design has widely been adopted by engineers and designers. However, nowadays with increasing demand of better IEQ and conservation of energy, the following disadvantages of this kind of convective AC design attract more and more comments:

- Over 80 % of indoor air has to be re-circulated that means odour, suspended dust particles, air contaminants, bacteria, virus, etc. will also be re-circulated back to the indoor space that deteriorate the air quality or put more reliance on air filter performances/ maintenance hence increasing life cycle cost;
- Air is a poor conductor and the whole indoor space has to be cooled down making this AC design method inherently energy inefficient;
- Large fan power is required to re-circulate and treat the bulk volume of air in the space;
- Very often air draft, uneven distribution of air and temperature, fan/ air borne noise, water dripping are experienced that cause nuisance to occupants;
- Large air handling equipment and air ducts are involved that occupy valuable indoor space.

2. RADIANT COOLING PRINCIPLES AND DESIGN

Radiant cooling however does not depend on circulating cool air but rather it uses differences in surface temperature of objects to effect heat transfer. According to law of radiation, any object with surface temperature above 0-degree K will continuously radiate and absorb heat energy via electromagnetic wave to/ from surrounding in the speed of light.

The convective AC design will also cool down ‘surfaces’ of the indoor area that will enable ‘radiant cooling’ to take place but the effect is minimal as heat absorbed through this process is very slow and limited.

We should also note that the media in which this heat transfer process is taking place does not have a direct effect of the process. For example sun ray travels through vacuum and the very cold ‘Outer Space’ before reaching our body but we still feel the ‘intense heat’ of the sun. We feel the ‘heat’ because radiation heat transfer takes place via the difference in surface temperature of the sun (around 5800 K) and our body (around 306 K).

Hence with the application of radiant cooling for indoor space, condition of indoor air can be seen as ‘transparent’ or it’s effect can be considered ‘minimal’ that gives this design much more rooms for indoor environmental quality (IEQ) control and energy performance improvements.

Radiant heat transfer equation:

$$\text{Stefan-Boltzmann law } Q = e \cdot \sigma \cdot A \cdot (Tr4 - Tc4)$$

where, Q = net radiated power; e = emissivity; σ = Stefan Boltzmann constant;

A = radiating area; Tr = temperature of the radiator; Tc = temperature of the surrounding

Equation 3

Emissivity for an ideal radiator (black body) has a value of 1.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Hence Q is proportional to the object surface area, emissivity and difference in surface temperature in the 4th order of power.

In radiant chilled ceiling design, metallic ceiling is preferred for more effective heat transfer. Chilled water temperature down to 7°C can be supplied to the cooling coil of the chilled ceiling panel to enable maximum evenness of ceiling surface temperature, more effective/ responsive performance under various load conditions. The following criteria and assumptions are adopted in this 'Low Temperature' chilled ceiling design:

- Supply chilled water temperature lowest is 7°C and chilled ceiling surface temperature to be maintained at 2 degree above dew point temperature of the indoor condition at all times (minimum ceiling surface temperature is 16°C)
- Indoor humidity shall be controlled at 55 % RH or below with fresh air at 11°C RH 100 % under an outdoor condition of 33°C RH 90 %
- Fresh air supply rate from 10 l/s per person to 20 l/s per person and indoor CO_2 concentration to be controlled below 800 ppm at all times
- Chilled ceiling area coverage from 40 % to 50 % depending on the building usage, population density, façade design, building orientation, and equipment load
- Fresh air will control the indoor humidity and CO_2 concentration through low pressure air ducts and variable speed drive PA fan unit. Chilled ceiling will handle most of the sensible heat loads including solar, equipment and people load.
- An air tightness test in accordance with CIBSE Technical Memoranda (TM23: 2000) should be carried out to ensure air tightness of the indoor environment

4. CASE STUDY OF A LOW TEMPERATURE CHILLED CEILING PROJECT IN HONG KONG

This is an existing 30-storeys office building in Hong Kong that was being renovated into a modern office. The existing building constraints are that the floor to floor height is only 3000 mm with flat slab structure and there is no further space on roof to accommodate additional chillers and cooling towers to increase chiller loading.

The client is Hong Kong Hang Seng Bank and it's brief is to create a modern work place with flexibility in staff mobility, an excellent IEQ and low energy performance to achieve a minimum LEED 'Gold' certification, a finished ceiling height of 2400 mm and a raised floor for power and IT cablings.

The Total Gross Floor Area of the building is around 30000 m^2 with population density in future of up to110 persons / floor (about 7 m^2/ person). The existing façade is single glazed with tinted glass where shading coefficient and energy performance are only up to standards some 25 years ago. The existing chiller capacity is 1100 TR and to meet future cooling demand the chiller capacity has to be increased to around1600 TR using conventional fan coil system.

In view of the low existing floor height, conventional fan coil system can only achieve a maximum of 2200 mm finished ceiling height that is largely below client's expectation for this modern office. To meet client's brief and to overcome the site constraints, an innovative low temperature chilled ceiling design was proposed.

Figure 6: Existing structural ceiling level

Figure 7: Original office (Fan coil unit)

Figure 8: New office (Chilled ceiling)

4.1 Design of chilled ceiling and fresh air system

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 9 below shows a typical chilled ceiling (in pink colour) layout plan used both in open plan office and meeting rooms. The chilled ceiling panel sizes can be standard 600x600 mm or made in different dimensions and shapes to suit interior designer's requirements.

The system is designed into different chilled ceiling zones to meet different user's requirement. Independent temperature sensors and humidity sensors are installed to control the room IEQ conditions by modulating supply chilled water temperature/ flow rate and fresh air supply temperature/ quantities. Dew point temperature sensor is incorporated in the chilled panel to cut off chilled water supply to avoid condensation.

Figure 9: Typical ceiling plan

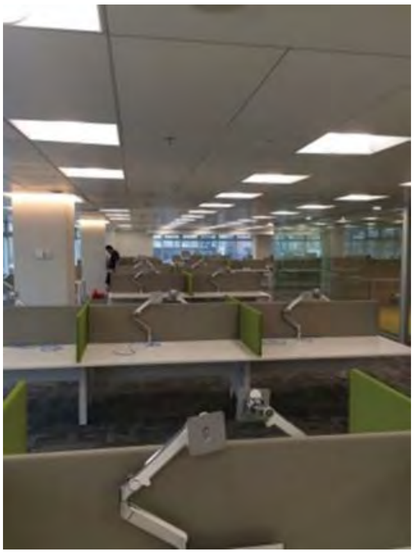

Figure 10: Open plan office

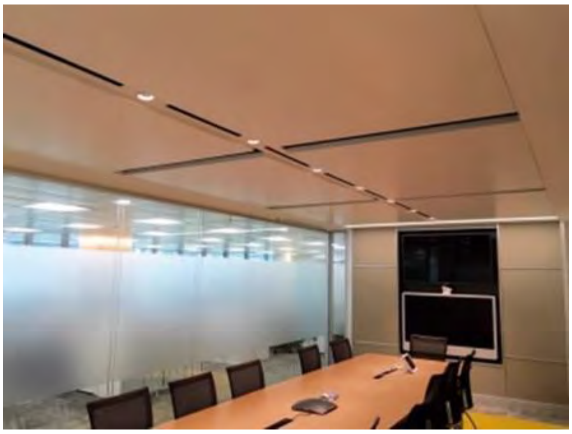

Figure 11: Meeting room

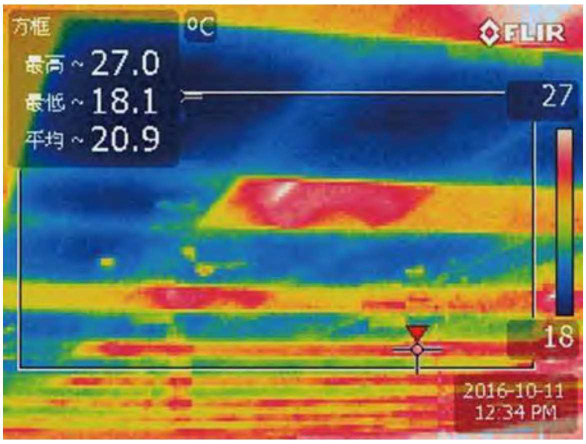

Figure 12: Thermal scan image of chilled ceiling

The above results show that performance of this chilled ceiling design can meet all requirements in the client's brief with satisfaction by most of the end users. Total chiller load is predicted to be around 900 TR upon full occupation such that additional chillers are not necessary to meet the new cooling load demand.

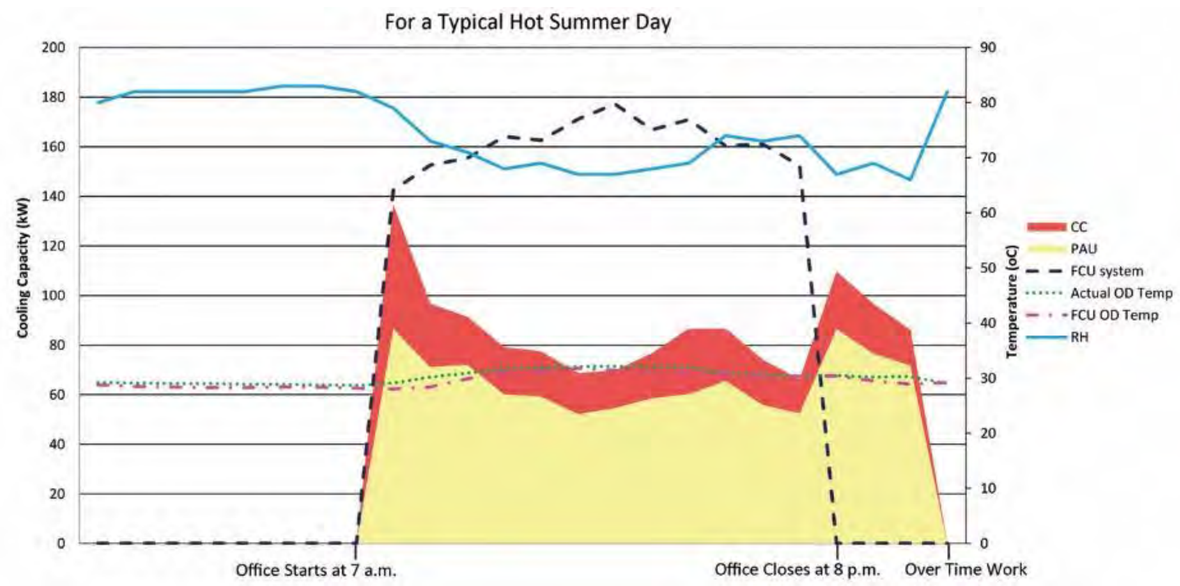
From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4.2 Merits of chilled ceiling versus conventional AC systems

	VAV/ AHU System	Fan Coil System	Chilled Ceiling System
1. IEQ			
• Space Temperature	23°C±1°C	23°C±1°C	23°C - 27°C
• Relative Humidity	55 % - 70 %	60 % - 75 %	50 % - 55 %
• Heating/ Cooling	Both but not common/ not well accepted	Both but not common/ not well accepted	Both and relatively comfortable so expected to be welcome by market
• CO_2 Concentration	Average 900-1000 ppm	Average 1000-1400 ppm	Average 600 ppm
• Recirculation Air	80 %	80 to 90 %	Flexible and can be full fresh air
• Acoustic	Medium NC 38	Noisy NC 40 average	Extremely quiet typically under NC 30
• Air Draft Problem	Exist	Exist	Very Minimum
• Temperature uniformity	Average	Fluctuating	Very Even
2. Energy Performance			
• Cooling Load	200 W/m²	180 W/m²	100 W/m²
• Water Pump Power	'A' kW	'A' kW	0.75 x 'A' kW
• Air Fan Power	'B' kW	0.4 x 'B' kW	0.25 x 'B' kW
3. Operation and Maintenance			
• Ease of Operation	Complicated	Less Complicated	Medium Complicated
• Maintenance Cost	High	High	Low
4. Plant Spatial Requirement			
• Requirement	High	Medium	Low
5. Cost			
• Capital Cost	High	Low	Medium (Due to limited suppliers)
• Running Cost	High	Medium	Low

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

5. COOLING LOAD PROFILE



It is noted that the cooling load profile for a Chilled Ceiling System is a reverse of a conventional VAV or Fan Coil System that can significantly improve the electrical demand profile of a building.

6. LIMITATIONS

The following limitations of this radiant cooling design are observed:-

- Suppliers of proven products in the market are few resulting that initial cost is relatively high. There are limited design professionals in the trade so that this design technology cannot be proceeded on a large scale basis.
- Unfamiliarity by the end users on the system further deters development of this low energy cooling design in the market. To ease this problem perception of thermal comfort as elaborated in Ole Fanger's Predicted Mean Vote (PMV) index can be used to holistically review this system to confirm level of thermal comfort should achieve very high score to most people.
- Due to complexity of the indoor radiation cooling process, no formulated or validated calculation is available at present to verify cooling load calculation such that most parts of the design have to rely on past project data and references.
- New control strategy is adopted so that FM team needs to adapt and be trained to avoid operation problems like condensation.
- There may be higher water spill risk as more water pipes are installed but this problem can easily be resolved by specifying a reliable pipe connection system.

7. CONCLUSION

This innovative low temperature radiant cooling design can save up to 50 % of the cooling energy, 30 % of the pump power and 75 % of the fan power compared with conventional AC system. Furthermore the IEQ provided by this system can be much improved as confirmed in our case study project. It's application can almost cover all types of building including offices, hotel, hospitals, health care/ elderly centres, transportation facilities, airports, exhibition spaces, theatre, concert halls, factories and luxurious residence.

Following recent signatory of the two world most powerful countries - China and USA for the 'Paris Accord', energy conservation will regain top of the agenda of most developed/ developing countries for years ahead. It is hoped that with the continual development of the product and support from the market, this innovative low energy radiant cooling system can become the most promising design for indoor environmental control system of most building projects in the near future.

Hybrid Air-conditioning System Efficiency for Districts in the Tropics

ABSTRACT

Hybrid air-conditioning systems in buildings have a high potential to utilize resources in an efficient and sustainable manner in districts. The goal of this study is to compare the performance of hybrid air-conditioning systems at building and district scale in the tropics. For this, we gather operational data of an office with a hybrid air-conditioning system in Singapore and analysed the energy saving potential of separating latent and sensible cooling processes at the district scale. The effect was quantified with a virtual case study composed of 11 office buildings in Singapore. We compared decentralized and centralized options for the supply of High-temperature and Low-temperature chilled water. For the case study, the cooling consumption per area at the district scale can be potentially reduced by 24% in comparison to the current supply system at the building scale. A further study is necessary to determine optimal operation strategies and associated costs of hybrid air-conditioning systems at the district scale.

Keywords: district cooling, hybrid air-conditioning systems, energy supply systems

1. INTRODUCTION

Conventional air-conditioning systems in hot and humid climates remove the latent and sensible heat of buildings with a low temperature of condensation close to 6 °C. By separating latent and sensible heat removal process, hybrid air-conditioning systems can increase the temperature of condensation to approximately 17.5 °C for sensible heat removal. This strategy increases the energy efficiency of cooling equipment (Chua et al., 2013) (Mujahid Rafique et al., 2015).

Various hybrid Air-conditioning systems are proposed and implemented in many recent studies (Kojok et al., 2016; Mandegari and Pahlavanzadeh, 2009). For example, Kojok et al. present a thorough review on five configurations of hybrid cooling systems. Within these, the combined desiccant-vapor compression cooling system is recommended for the hot and humid climate.

Ventilation units of hybrid air-conditioning systems could be either centralized or decentralized. A centralized ventilation system consists of centralized air handling ducts distribute the cooled and dehumidified air to the indoor spaces. Instead of centralized air distribution, a decentralized system consists of air handling units installed in the vicinity of the space to be cooled, the dehumified air is sent to indoor space directly. In the past, centralized and decentralized ventilation units of hybrid-air-conditioning have been proposed in office buildings in Singapore (Meggers et al., 2013; Rysanek et al., 2016), Hong-Kong (Fong et al., 2011) and Shengzhen, China (Zhao et al., 2011).

This paper explores the energy saving potential of hybrid air-conditioning systems for offices at the district scale. For this, we gathered real operation data of the hybrid air-conditioning system of (Schlueter, 2015) and compared configurations with decentralized and centralized options for the supply of chilled water in a district in Singapore. The district consists of 11 office buildings connected to a district cooling network of close to 2 km of length.

2. METHODOLOGY

2.1 Relative office cooling load

The decentralized hybrid air-conditioning system studied in this paper consists of decentralized air handling units (DOAS), fan coil unit (FCU), and passive chilled beams (PCB). The DOAS and FCU provide latent cooling to outdoor and recalculated indoor air respectively. The humidity target is 8 g/kg (Murray et al., 2015). While the PCB circulate cold water to remove sensible heat from the room. Chilled water for both latent and sensible heat removal is provided from the same chiller plant at around 7.6°C. The latent cooling coils in the DOAS and FCU use the chilled water directly from the plant, while the PCB runs water at ~17.5 °C, which the cooling energy is extracted from the chilled water stream (7.6°C) with heat exchangers.

The hourly thermal load of the system, Q_cooling, is acquired through the building management system (BMS) of an office of 550 m2 of gross-floor area for a period of 4 weeks in July.

2.2 Supply system energy consumption

The energy consumption of the cooling equipment is calculated with Equation 1, where Qcooling is the office cooling load. The result was normalized to the GFA to facilitate the further extrapolation of results to the district scale.

$$W_{el} = Q_{cooling} \times COP_{chillerplant}$$

Equation 16

In Equation 1. 〖COP〗_(chiller plant) represents the efficiency of the chiller plant or Coefficient of Performance. 〖COP〗_(chiller plant) is calculated according to Equation 2., where g is the exergetic efficiency. The second term on the right side of the equation is the carnot efficiency, where Te is the temperature from the chiller evaporator, and Tc = 26.5 °C is the temperature of the condenser assumed as constant throughout the day.

$$COP_{chillerplant} = g \times \frac{T_e}{T_c - T_e}$$

Equation 2

Beside the cooling energy consumption, the total energy consumption also consists the pumping energy consumption for district network, and energy used from fans for building ventilation. The total energy consumption is normalized to the Gross Floor Area (GFA) for further extrapolation of results to the district scale.

The fan power for building ventilation depends on the building level system control strategies, therefore, the fan power of the decentralized hybrid air-conditioning system studied in this paper is acquired from the BMS data.

The pumping power in the district cooling network is calculated with Equation. 3. The head of pressure is calculated with Darcy-Weisbach equation (Menon, 2011) assuming commercial welded steel with a roughness of 0.046 mm. The friction factor,f_D , is approximated with the Swamee-Jain equation (Menon, 2011). In Equation. 3., P is resulting pumping power requirement in W, v˙ is the volumetric flow rate in m3/s, ρ is the water density in kg/m3, D is the pipe diameter in m, and L_ Equation is the network length equivalent in m. The L_ Equation is approximated as 1.2 times of the network distance to account for other friction losses from bends, valves and other components. The shaft efficiency and motor efficiency is assumed to be 0.7 and 0.9 respectively.

$$P = \dot{v}\rho g \Delta h = \dot{v}\rho g \times f_D \frac{8}{\pi^2 g} \frac{\dot{v}^2}{D^5} \cdot L_{eq}$$

Equation 3

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.3 Supply system configurations

There are two ways to improve the efficiency of the cooling system from the cooling energy supply side according to Equation 2. One is to increase the chiller evaporator temperature, Te, and another is to use machines with higher exergetic efficiency, g. For this reason, we explore the efficiency improvement from supplying sensible cooling with chillers operating at higher temperature, and from using large scale centralized chillers in the district cooling network.

The chillers at the building and district scale are assumed to respectively operate at an exegetic efficiency of 0.3 and 0.6, since the large scale chillers could operate at higher exergetic efficiency (Meggers et al., 2012)

We decide to set up three configurations with combinations of high-temperature (HT) and low-temperature (LT) chillers at building and district scales to compare the energy efficiency of the current supply system (base case). Configuration 1 consists only building level chillers, these chillers supply cold water for sensible cooling at high temperature and latent cooling at a lower temperature. Moving to the district scale, configuration 2 has a district cooling connection with centralized HT chillers, and LT chillers in buildings. Configuration 3 is the opposite of configuration 2, centralized LT chillers are installed at the district scale and HT chillers are installed at the building scale.

The supply (Tsupply) and return (Treturn) temperatures in the base case are retrieved from the office operational data. For the other three configurations, the Tsupply and Treturn are determined with assumptions explained in the following. In configuration 1, the LT chillers are operating at the conventional temperature range for air dehumidification, while the HT chillers only supply cold water to the PCB for sensible cooling, which operates at an average temperature of 18 °C. District scale chillers have lower supply temperatures and higher return temperatures to account for cooling energy losses in the pipelines, therefore, imposing larger cooling loads to the chillers (Tredinnick and Phetteplace, 2016). 10% heat loss is assumed in this study.

	Building scale chillers			District scale chillers	
Base Case	LT				
Config.1 (Building)		LT	HT		
Config. 2 (HT DC)		LT			HT
Config. 3 (LT DC)			HT	LT	
COP*	6.2	5.3	10.5	8.6	17.0
T_{supply} / T_{return} [˚C]	7.6 / 17.2	7.6 / 11	16 / 20	6.6 / 14	15 / 21

LT: Low Temperature chillers, HT: High Temperature chillers, DC: District Cooling.

Assumptions:

1. The chiller plants are well modulated, therefore operates at constant COP in each hour.
2. The pipe hydraulic diameter is 1.58 m for HT DC network and 1.26 m for LT DC network, assuming water speed in the pipe is 3m/s.
3. Pump capacities are sized for the maximum flow rate, and the pumping energy is calculated assuming a Darcy's roughness coefficient of 0.046 mm (welded steel).

Table 1: Supply system chiller configurations and operational conditions of the current cooling system (base case) and three alternative configurations.

2.4 Case study

A case study with 11 office buildings in the central business district of Singapore is set up to assess the performance of the hybrid air-conditioning system at the district scale. Similar to the existing district cooling pipeline situated at the Marina bay area in Singapore, one centralized chiller plant supplies cooling load for all 11 office building. The building GFA ranges from 90,900 to 653,000 m2. The total district network length is 2.3 km. Since the district is situated in a tropical climate with steady patterns of temperature and relative humidity through the year, it is assumed that all of the office buildings has the same weekly load profiles. Additionally, the chillers are sized for the peak cooling load over a week.

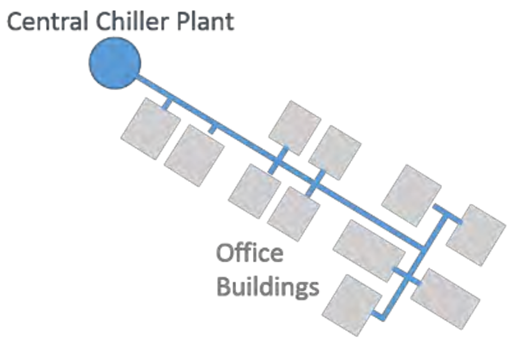

Figure 1: Case study site with 11 office buildings connection to a district cooling network with a centralized chiller plant.

	Building		District		
Chillers sizes [W/m2]	LT	HT	LT	HT	Total
Base Case	0.076				0.076
Config. 1 (Building)	0.038	0.049			0.087
Config. 2 (HT DC)	0.038			0.054	0.092
Config. 3 (LT DC)		0.049	0.042		0.091

LT: Low Temperature chillers, HT: High Temperature chillers

Table 2: Chiller size in each supply system configuration.

3. RESULTS

3.1 Relative cooling loads

The average weekly office cooling load acquired from 4 weeks of office BMS operational data is shown in Fgure 2. The latent heat ratio is 40%, with an average cooling load of 3.16 kWh/m^2 per week, which equals to 0.05 kWh/m^2 per hour of office operation.

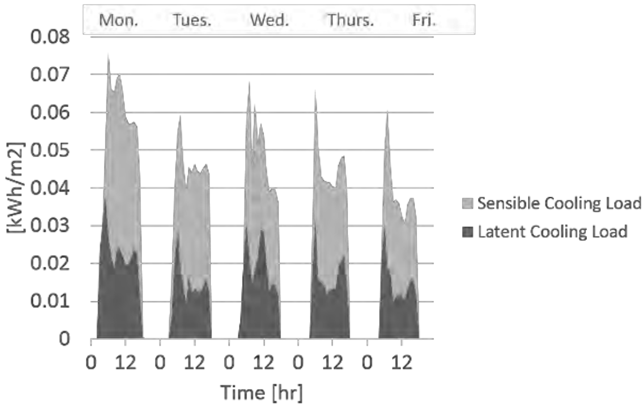

Figure 17: Average hourly office cooling load in July in Singapore.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.2 Cooling energy consumption

The resultsing total cooling energy consumptions for each configuration are calculated using the methods and assumptions described in section 2.2 and 2.3. The cooling energy consumptions of different supply system configurations are shown in Table 3. Figure 3 shows the hourly energy consumption over a week of the base case and configuration 3, the configuration with the lowest total energy consuption.

	Total energy consumption [kWh/m2/week]	Sensible cooling	Latent cooling	Pumping**	Fan
Base Case	0.72	42.8%	28.0%	-	29.2%
Config.1 (Building)	0.63	28.9%	37.7%	-	33.4%
Config.2 (HT DC)	0.59	19.9%	40.2%	4.4%	35.5%
Config.3 (LT DC)	0.55	32.8%	27.0%	2.3%	37.9%

Table 18: Cooling energy consumption of each supply system configuration

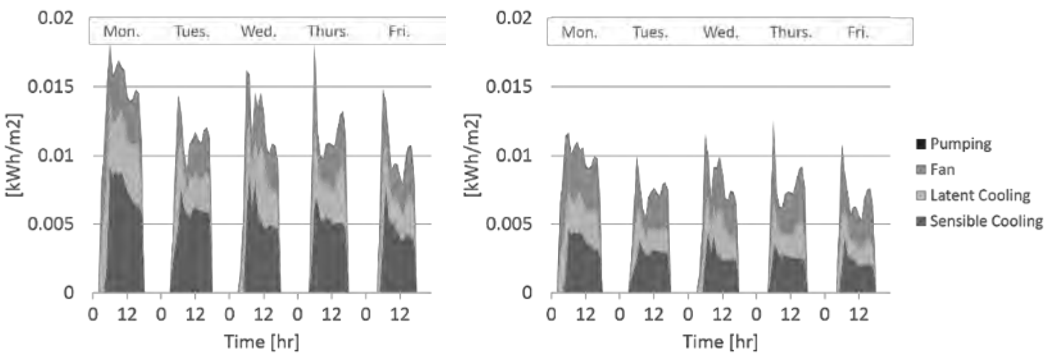

Figure 3: Hourly energy consumption of the base case (left) and configuration 3 (LT DC) (right).

4. DISCUSSION

The office building studied in this paper presents a latent cooling load ratio of 40%, which is higher than the conventional cooling system design capacity, which is around 25% (Mujahid Rafique et al., 2015). For the case study, the cooling energy consumption is reduced by 11% in configuration 1 (Building) comparing to the base case. Within the 11% reduction, the major part is coming from the 40% energy saving in sensible cooling load attended by HT chillers. The energy consumption for sensible cooling is lower than the energy consumption for latent cooling since HT chillers operate at better efficiency.

Besides, using high temperature chillers enables more renewable energy integration. As opposed to using electricity from grids as the main energy source, high temperature chillers could be supplied by various renewable sources with good efficiency, such as absorption chiller using solar thermal energy or waste heat (Udomsri et al., 2011).

When operating the supply system at the district scale, configuration 2 and 3 respectively reduce 19% and 24% of the energy consumption comparing to the base case. Configuration 3 with a LT network has lower consumption than configuration 2 with a HT network. The reason is that the benefit of replacing LT chillers in buildings with a LT network is slightly higher than replacing HT chillers in buildings. Also, the pumping energy requirement for LT network is lower because building latent loads are lower than sensible loads, therefore, the required flow rate is smaller.

The resulting centralized LT chiller plant of configuration 3 is equipped with 11.2 MW capacity. Since the district only consists of office buildings with identical load profiles, the LT centralized chiller plant operates most of the time at part load. If the district cooling network is connected to buildings with different load profiles, the chiller plant could operate at higher loads or operate outside the current operation periods. For example, the load profiles from

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

residential buildings, which the cooling demand starts from 5pm to 7am (Chow et al., 2004), could complement well with the office cooling load . The installed chiller capacities are better utilized when connecting buildings with different load profiles to a district network, this way, the cumulative chiller loads are increased but no additional capacity expenditures on chillers required. This load sharing benefit is not applicable to the building scale chillers since the current centralized district cooling scheme does not allow transferring surplus capacities from various buildings back to the cooling network.

On the other hand, central chiller plants could be complemented with thermal storages, which is normally not feasible at the building scale due to space restrictions and costs. Thermal storage could shift the peak cooling consumption away from the peak cooling load period, which provides system flexibility (Powell et al., 2013) and financial benefits when peak energy tariffs are high.

5. CONCLUSIONS

This study presents the energy efficiency improvement opportunities from the supply system side when sensible and latent cooling energy is utilized separately in the building operation systems. 11 % reduction in total energy consumption compare to the base case is achieved in configuration 1, which supplies cooling energy with HT and LT chillers at the building scale. Furthermore, the consumption is reduced by 26% when connecting buildings to district energy network. This is the advantage of utilizing large scale chiller with higher exergetic efficiency. Additionally, HT chillers could be powered efficiently from renewable energy sources, e.g. solar thermal, which enables more renewable energy penetration.

Beside better energy efficiency performances, centralized chiller plant also presents several benefits that normally are not applicable to building scale chillers. The first benefit is the opportunity to connect to more building types with different cooling load profiles (e.g. residential buildings), this way, more cooling loads could be produced from the same chiller plant without additional capital investment. The extra capacity in the building level chillers are not sharable in the framework of the current district cooling network with centralized production, however, it is possible when implementing a cooling network with bi-directional energy flows. Secondly, the possibility to utilize thermal storage to produce cooling energy at the period with lower tariff could reduce operational expenses. In addition to cost savings during operation, thermal storage could provide system flexibility and financial benefits.

Despite the advantages of hybrid air-conditioning systems, hybrid air-conditioning systems require specialized control systems to ensure efficient operation. Further studies could lie on determination of the optimal chilled water supply temperatures and quantification of benefits from the storage and load sharing schemes mentioned above. The first part could be done by pinch analysis, which is a process integration technique to determine the minimum amount of hot and cold utilities and temperature level requirements. The second part could be done by computational models, which can be used to perform a detailed dynamic simulation of control strategies applicable to the system's configurations addressed in this study. Key configurations of interest include integrating thermal storage units, residential buildings, renewable energy and bi-directional flows in a thermal network.

Evaluation of Saving Energy of SOFC and Battery Combined System

Takeshi SASE[a]

[a] *Building Research Institute, Japan, sase@kenken.go.jp*

ABSTRACT

Fuel Cells have been utilized for residential use recently. Because they are very effective saving energy, generating not only electricity but also hot water. Especially SOFC (Solid Oxide Fuel Cell) has been utilized because of its higher efficiency of generating electricity than PEFC (Polymer electrolyte fuel cell).

The authors have found that it has high efficiency 42% at full capacity but it decreases on smaller scale. To overcome this shortcoming, the authors have made the system, combining SOFC and battery. This system accumulates overflowed electricity into the battery, operating SOFC on the full scale, and emits electricity from the battery when the electricity load is beyond SOFC capacity.

The authors have evaluated its efficiency of generating electricity, saved energy compared with the traditional method, which provide electricity and hot water by the Commercial power and the gas boiler, and the only SOFC on various electricity and hot water scale patterns. They have found that it is more effective by generating electricity and accumulating overflowed electricity and emitting it generally. But it is not more effective than the only SOFC when it is operated on smaller electricity scale. The proposed system loses some electricity during accumulating it into the battery, emitting it from the battery, and translating it between direct and alternate current.

It is suggested its efficiency and effectiveness could be improved by reducing this electric loss.

Keywords: SOFC (Solid Oxide Fuel Cell), battery, saving energy

1. INTRODUCTION

Fuel cells have been utilized for residential use to save energy. At first PEFC (polymer electrolyte fuel cell) have been used, recently SOFC (Solid Oxide Fuel Cell), which have higher efficiency, have been introduced for not only for commercial use but also for residential use.

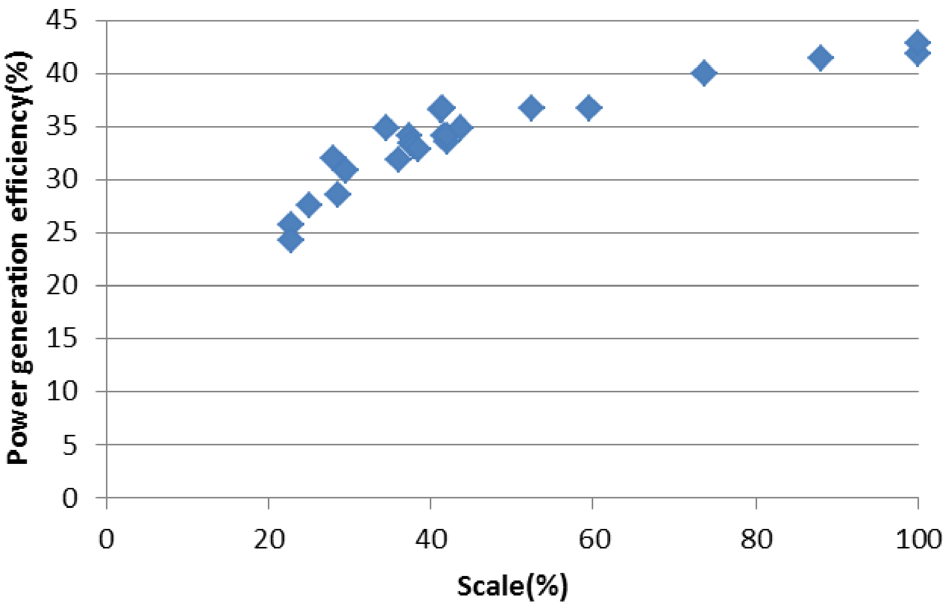

Figure 1: Power generating efficiency of SOFC

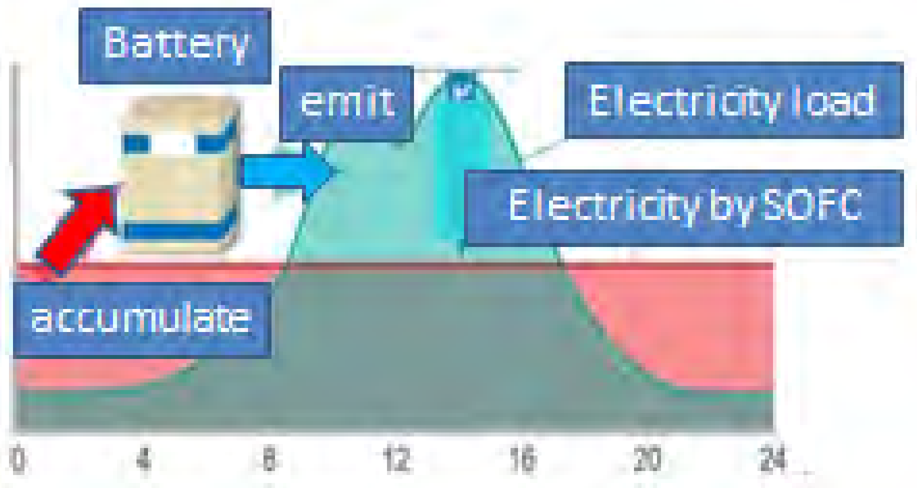

Figure 2: Operation of SOFC and battery

It is said that SOFC efficiency of generating electricity is high (about 42%) at the full scale but it decreases at small scale.

To overcome this shortcoming, the authors combined SOFC with battery. SOFC is operated at full scale if the battery is not full, accumulating overflowed electricity. On the other hand, Battery emits electricity when the electricity load is beyond SOFC capacity. The authors have examined efficiency and effectiveness of this system.

2. EVALUATING TESTS FOR EFFICIENCY System and loads for evaluating tests

Figure 3 shows the system combining SOFC (producing from 50 to 700W electricity, with hot water tank 90 Litter) and Battery (The full capacity 7.2 kWh, the Rated Voltage 2.5W) and locations of various sensors, such as electricity, gas, temperature and flow censors.

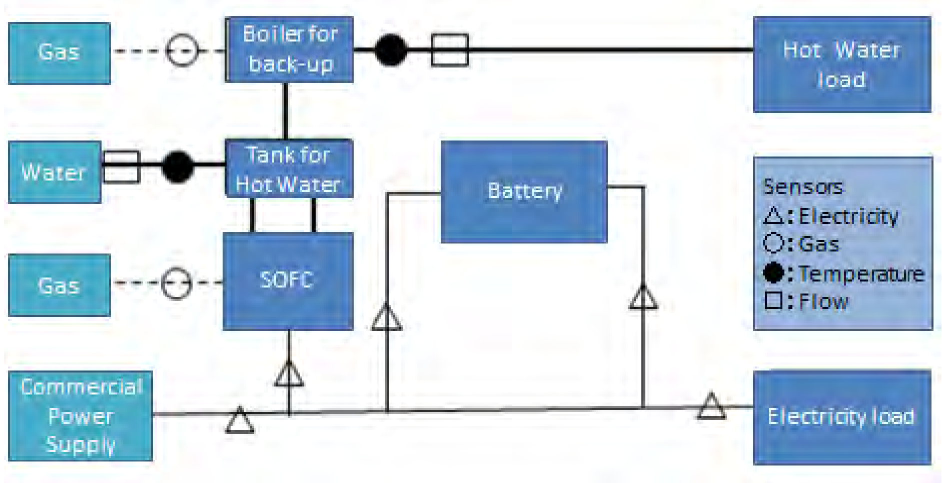

Figure 3: System of SOFC and battery

Test electricity loads are set based on the Japanese Standard Energy-Saving Building Guideline (10.96kWh/ day) and the full capacity of SOFC (16.8 kWh/ day). 4 Types of loads are set, which are large one with 2 peaks (16.27 kWh/ day), large one with gentle slope (16.27 kWh/ day), medium one (the Japanese Standard Energy-Saving Building Guideline 10.96kWh/ day) and small one (6.58 kWh/ day).

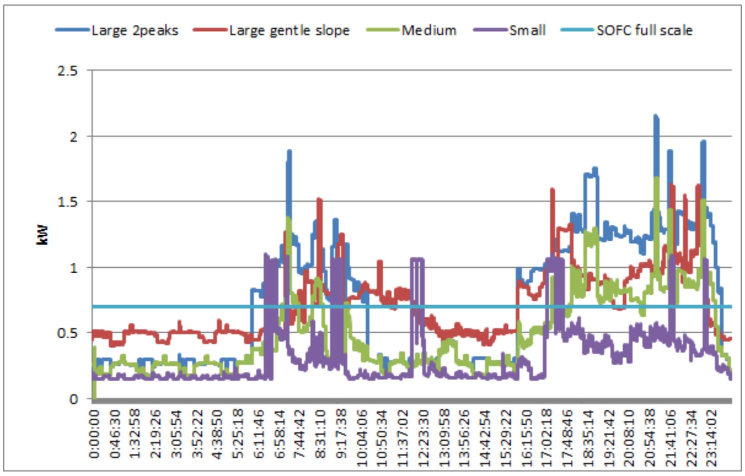

Figure 4: Test loads of electricity

Test hot water loads are set based on the Japanese Building Suppling Hot Water Guideline. Modified M-1 mode (650,550,470,380,380,240 Litter/ day) is allocated with 2 large electricity loads. Modified M-1 mode saving type (522,454,387,306,166 Litter/ day) is allocated with Medium and Small electricity loads. The Efficiency and effectiveness of this system are examined with various electricity and hot water loads in this way.

Hot water loads(L/day)	
Modified M1 mode	Modified M1 mode (Saving type)
650	522
550	454
470	387
380	324
380	306
240	166

Table 1: Test loads of hot water

2.2 Electric power supply of this system with various loads

The authors have examined efficiency and effectiveness of this system with various electricity and hot water loads mentioned on the above.

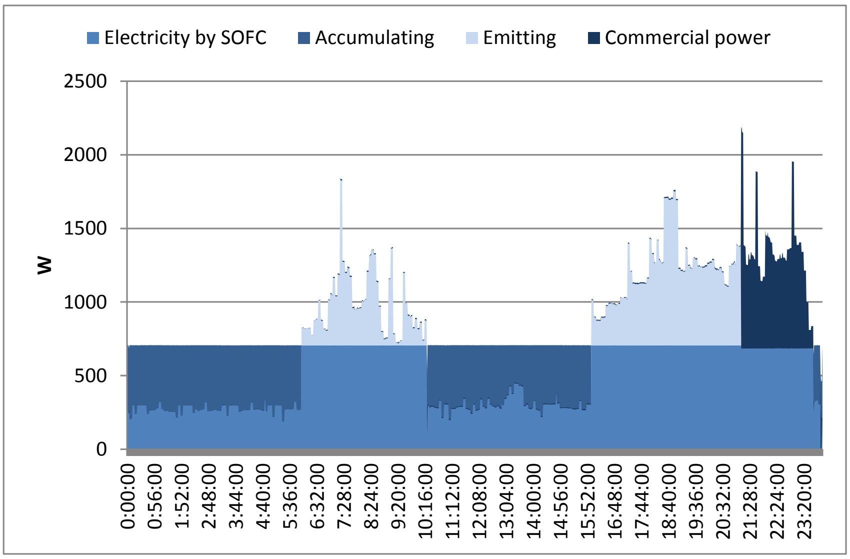

Figure 5: Supply of electric power (large 2peaks)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

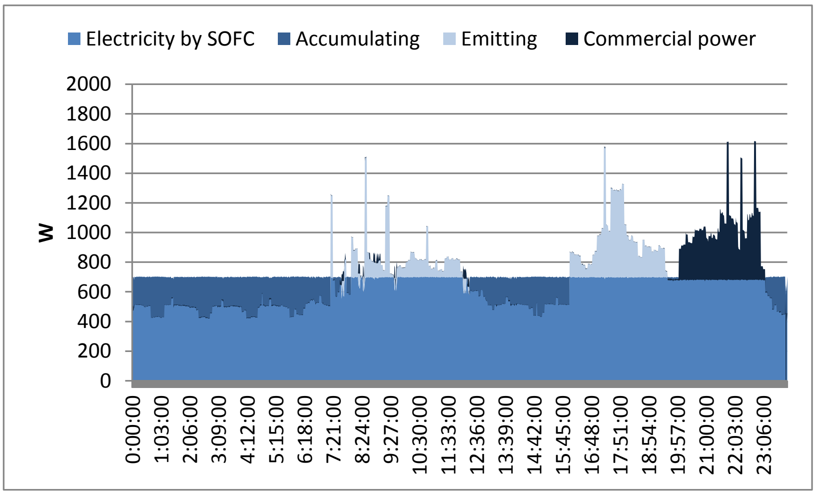

Figure 6: Supply of electric power (large gentle slope)

Figure 5 shows supply of electric power by this system with large electricity load with 2 peaks and Figure 6 shows that with large electricity load with gentle slope. In both cases, the batteries accumulate overflowed electric power while the load are low, operating SOFC on the full scale and emit electric power from the batteries while the loads are higher than the full capacity of SOFC. Also in both cases, the commercial powers are supplied after the batteries run out of accumulated electricity.

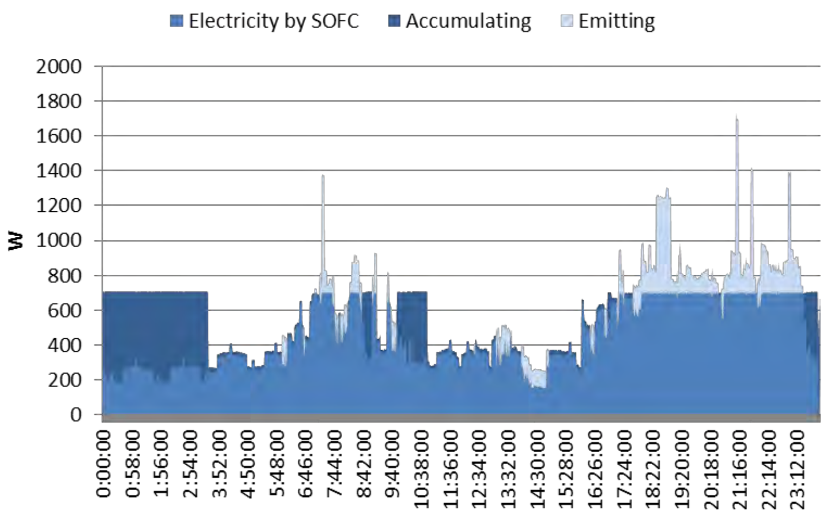

Figure 7: Supply of electric power (medium load)

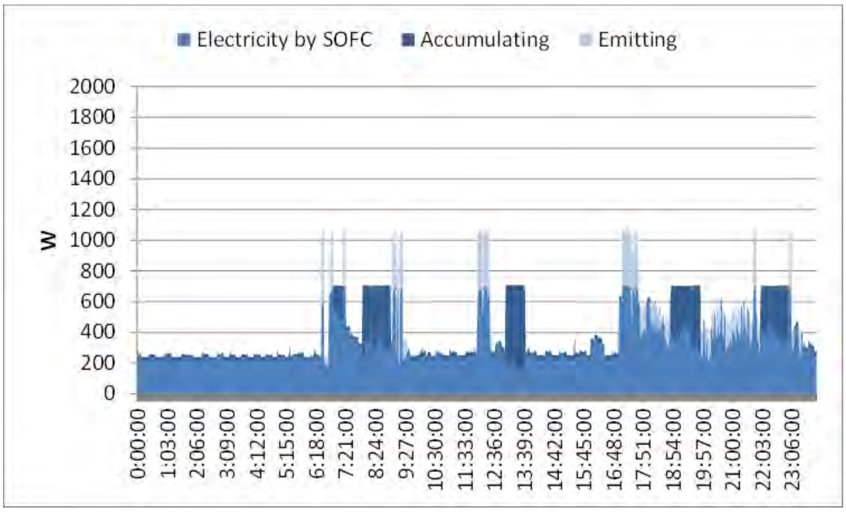

Figure 8: Supply of electric power (small load)

Figure 7 shows supply of electric power by this system with medium electric load and Figure 8 shows that with small electric load. As shown in Figure 5 and Figure 6, the battery accumulates overflowed electricity while the load is low and emits electricity from the battery while the load is higher than the full capacity of SOFC.

On the other hand, in Figure 7 and Figure 8, the batteries accumulate electricity until they get full. In both cases, the SOFCs operate according with the electric load after they get full, not on the full scale.

So the authors have seen different patterns of electric power supply between large electric loads and medium, small load.

2.3 Evaluation of energy saving of this system with various loads

The authors have evaluated the rate of energy saving of this system as below. The total load is provided as below.

Et = Ee + Ew
Et: Total load (kWh)
Ee: Electric load (kWh)
Ew: Hot water load (kWh)

The supplied energy to this system to provide the above load Et, is described as below.

$S_1 = G_1 + G_{1b} + E_1$
S_1: Total supplying energy to this system (kWh)
G_1: Gas usage by SOFC (kWh) (Gas calorific value 45MJ/ m^3)
G_{1b}: Gas usage by the back-up boiler (kWh) (assumed 85%)
E_1: Commercial power usage (kWh) (with The Japanese Guideline. Transferred as 9760kJ/ KWh)

The supplied energy to the traditional energy providing system, which is by the commercial power and the gas boiler, is described as below.

$S_2 = G_{2b} + E_2$
S2: Total supplying energy to the traditional system, which is by the commercial power and the gas boiler (kWh)
G2b: Gas usage by the traditional gas boiler (kWh) (assumed 85%)
E2: Commercial power usage (kWh) (with The Japanese Guideline. Transferred as 9760kJ/ KWh)

Energy saving rate is evaluated, comparing total supplying energy S1 with this system and S2 with the traditional energy providing system, which is by the commercial power and the gas boiler.

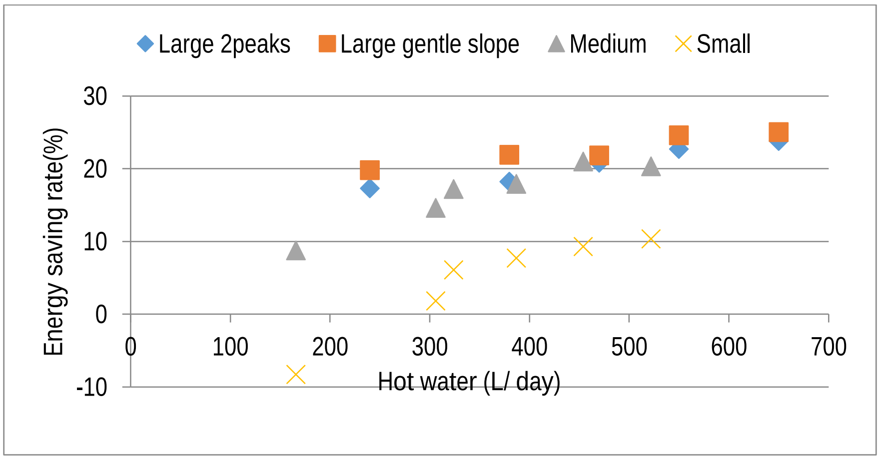

Figure 9: Energy-saving rates with various loads

Figure 9 shows energy saving rates with various loads. In all loads, energy saving rates are higher in larger hot water loads. It is typical with fuel cells. In general energy saving rates with large 2 peaks, large gentle slope and medium loads are beyond 15%, with small load are below 10%. So this system has advantage with more than medium electricity load.

2.4 Evaluation of energy saving of this system with only SOFC

The authors combined SOFC with battery to overcome the shortcoming that SOFC efficiency of generating electricity is high (about 42%) at the full scale but it decreases at small scale.

So the authors have evaluated energy saving of this system with not only the traditional providing system, which is by the commercial power and the gas boiler, but also with only SOFC.

The authors have known the general trend of energy saving of this system on 2.3. So the authors have compared energy saving of this system with only SOFC with not every type of load but only large electricity load with 2 peaks and medium load.

The supplied energy to only SOFC to provide the above load Et, is described as below.

S3= G3 + G3b + E3
S3: Total supplying energy to only SOFC(kWh)
G3: Gas usage by SOFC (kWh) (Gas calorific value 45MJ/ m3)
G3b: Gas usage by the back-up boiler (kWh) (assumed 85%)
E3: Commercial power usage (kWh) (with The Japanese Guideline. Transferred as 9760kJ/ KWh)

Energy saving rates are evaluated compared with the traditional energy providing system, which is by the commercial power and the gas boiler, both for SOFC with the battery and only SOFC.

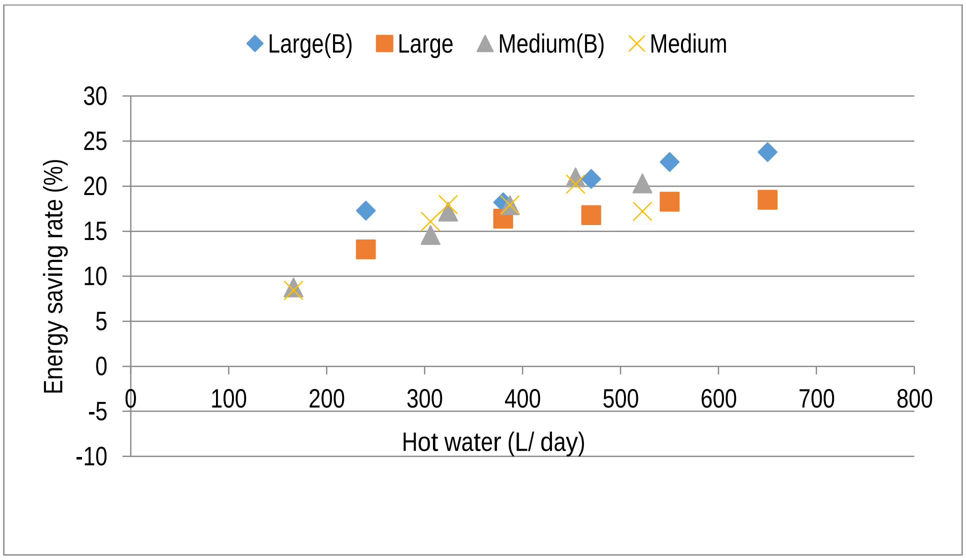

Figure 10: Energy-saving rates (SOFC + battery vs SOFC)

Figure 10 shows the results of this evaluation. This system, combining SOFC and the batter, has higher energy saving rate than only SOFC with large 2peaks electricity load, especially with heavier hot water loads. But it has no higher energy saving rate than only SOFC with medium electricity load.

2.5 **Battery's** traits

If this system, combining SOFC and the battery, could accumulate, emit electricity and translate it between direct and alternate current perfectly with no electricity lost, it could always have higher energy saving rates than only SOFC. But in reality, it always has some electrical loss during accumulating, emitting and translating electricity. So it is important to know the battery's traits and evaluate these losses to make this system more energy saving.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

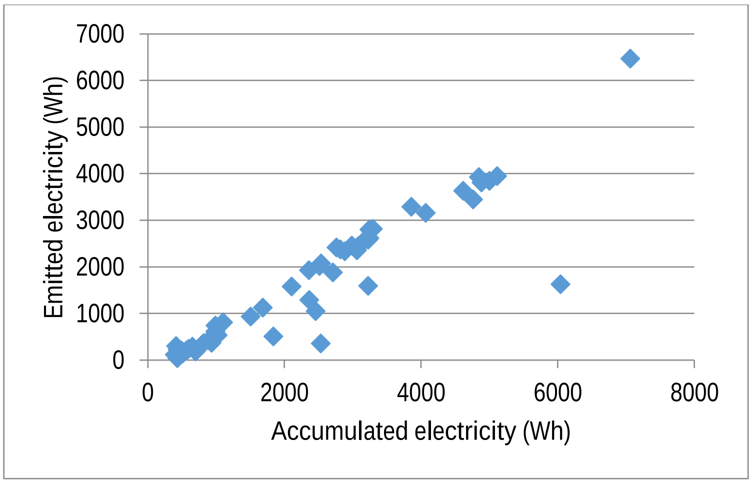

Figure 11: Battery's trait (emission vs accumulation)

Figure 11 shows correlation between accumulated electricity into the battery and emitted electricity from it. It is suggested they are proportional in general. But there are some exceptions, which are lower than proportional dots. Moreover, the direct line to connect dots does not pass the Zero point, crossing X line with positive. It suggests effective efficiency is low, where accumulated electricity is small.

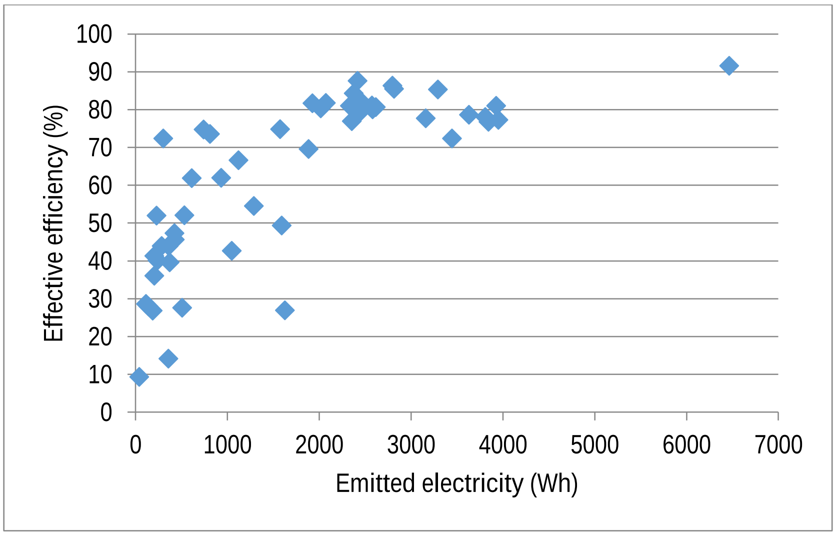

Figure 12: Battery's trait (effective efficiency vs emission)

Figure 12 shows correlation between emitted electricity from the battery and effective efficiency. The effective efficiency is stable, around 80%, where emitted electricity is over 2000. But dots are scattered and below 80% where is emitted electricity below 2000.

This means at least 20% electricity is lost during accumulating and emitting process. And it is suggested that more than 20% electricity is lost, where emitted electricity is below 2000. Moreover, it is suggested it is difficult how much electricity is lost in this part because dots are scattered vastly.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

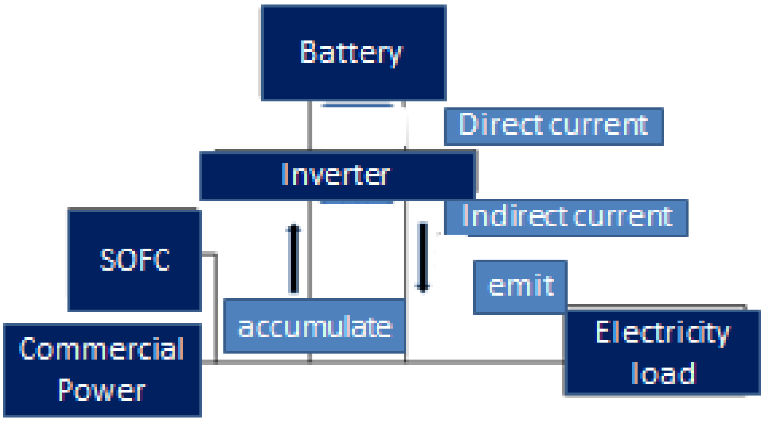

Figure 13: Mechanism of SOFC + battery system

Figure 13 shows the mechanism of this system, combining SOFC and the battery. This shows the flow of electricity from SOFC, the commercial power to the battery and it from the battery to the electricity load.

The electricity from SOFC, the commercial power is indirect current and it is converted to direct one in the inverter and accumulated into the battery as direct one. On the other hand, the electricity from the battery is direct current and it is converted to indirect one in the inverter and delivered to the electricity load.

It is suggested some electricity is lost during this converting process. This loss is included in Figure 9 and 10.

3. CONCLUSION

The authors have evaluated its efficiency of generating electricity, saved energy compared with the traditional method, which provide electricity and hot water by the Commercial power and the gas boiler, and the only SOFC on various electricity and hot water scale patterns. They have found that it is more effective by generating electricity and accumulating overflowed electricity and emitting it on larger electricity scale. But it is not more effective than the only SOFC when it is operated on smaller electricity scale.

The proposed system loses more than 20% electricity during accumulating it into the battery, emitting it from the battery, and translating it between direct and alternate current. Especially more than 20% electricity is lost, where emitted electricity is small. Moreover, it is suggested it is difficult how much electricity is lost in this part because dots are scattered vastly.

It is suggested its efficiency and effectiveness could be improved by reducing this electric loss.

Analysis of Fourth-Generation District Energy Systems with Renewable Energy Cogeneration by Using Rational Exergy Management Model

Birol KILKIS[a]

[a] *Baskent University, Turkey, email*

ABSTRACT

Recent 4th-generation district energy systems envision optimum bundling of different energy resources and conversion systems with main emphasis on sustainability and renewable energy use. Because renewable energy sources generally have low exergy and some of them are interrupted, they must be stored, time and exergy matched with low-exergy demands. The complex nature of the source and demand hybridization requires new exergy focused controls based on *Rational Exergy Management Model*. This need actually defines the main concept of smart metropolis. In this paper a new algorithm for optimizing the exergy bundling of renewable energy and conversion systems in cogeneration format with low-exergy metropolis demands is described with the objective of minimizing the CO_2 emissions. A second algorithm for the control of the hybrid system, which is tested in a smaller scale in a LEED Platinum building Ankara has been adopted and projected to typical metropolis. New definitions like Net-Zero Exergy Metropolis, Net-Zero Carbon Metropolis are also described. The paper concludes that the Second Law of thermodynamics leading to the exergy concept is the primary player in developing smart metropolis and minimizing their carbon foot print.

Keywords: sustainable neighbourhood, cogeneration, rational exergy management model

1. INTRODUCTION

Districts have several tasks to accomplish with highest reliability and best sustainability while facing time-dependent loads of different forms and exergy. Figure 1 shows typical hourly variation of thermal and power loads of a District. According to this figure, peaks of different loads are not coincident and every different load has a different profile. Consequently, not only the magnitudes but also the load proportions change with time. Large variations of different load proportions are particularly important for cogeneration systems, because they deliver heat and power almost at a constant ratio over their regular operational range. All these factors make it necessary to employ more than one energy conversion system and to bundle various energy sources, preferably by utilizing different sustainable systems. This makes it essential to extensively use TES (Thermal Energy Storage) systems and –if feasible to employ- electrical storage systems, besides grid exchange. One also needs to know the availability of renewable energy systems on an hour-by-hour basis for a sustainable and near-zero design and operation. In addition, controls, systems, and equipment primarily respond to comfort cooling and heating loads, which impose time-dependent temperatures: not only the magnitudes and proportions of loads change but at the same time demand temperatures for thermal equipment and systems change continuously. For example, in a HVAC system supply temperatures are proportionately controlled with respect to outdoor air temperature, which affect the system and equipment performance. Finally, the factors that affect part-load efficiency of the equipment must be also considered in order to yield accurate hourly equipment energy demand data.

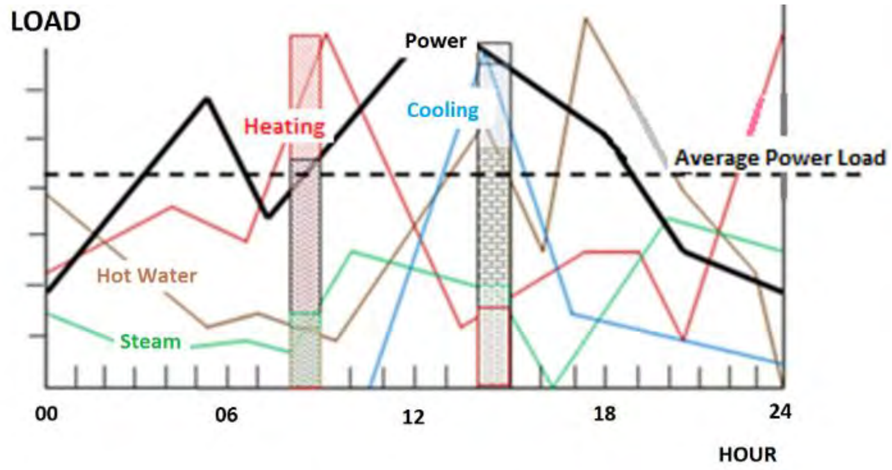

Figure 1: Typical Daily Load Profiles in a District

On the other hand, Districts are becoming a vital partner of the built environment and get multi-dimensionally connected to the cities forming a nexus of economy, energy (exergy), and environment. For example, Districts send their trash to biogas plants in the nearby cities and receive power and energy in return. For a sustainable future, the most recent trend is to connect Districts to 4DE (Fourth Generation) district energy systems in the built environment, where low-temperature heat (for DHW, LowEx heating), high-temperature heat (for conventional space heating, process heat), moderate-temperature cold (space cooling), low-temperature cold (process cold) and power generated with conventional and renewable energy systems and resources are exchanged at various exergy levels. Solar energy is used to generate power in the built environment widely. However, when it comes to harvest solar and wind energy, Districts face serious limitations due to air traffic safety. Generally new District construction and their operation may impose serious environmental risks. In spite of all these complexities, U. S. Department of Energy (DOE) has recently defined Zero-Energy Building (ZEB) in an over simplistic format by using only the First-Law of Thermodynamics. In their definition, energy supplied-received balance is simply based on an annual single cumulative basis of all kinds of energy with different exergy values without taking into account the exergy variations and associated CO_2 emissions, which are hidden in the Second-Law. This issue was first addressed by [5] by developing new definitions for net or near building in terms of exergy (NZEXB, nZEXB). In fact, according to Marszal and Heiselberg, the definition of net or near zero building is quite complicated.

2. THEORY

Several European countries are in the process of developing and implementing their road maps for near-zero energy buildings (nZEB) according to the relevant EU Directive for High Performing Buildings. There are several definitions for nZEB concept and all models, definitions, and implementations are based on the First-Law, which only deal with the quantity of the energy exchange between the building, grid, and the district. Current practice is primarily focused on electric power exchange. Today, Denmark is the only EU country that factors-in the thermal energy exchange. Thermal energy at different states and temperatures mean a wide variation of the thermal energy quality (exergy). Other shortcomings of the current NZEB or nZEB definitions, which may be inferred from Kılkış, Ş. are:

- Thermal energy exchange definitions must distinguish different forms of heat like steam, hot water, service water, cold water etc.
- Quality of energy exchange needs to be embedded in the nZEB definition.
- The quality of energy exchanged in calculating the harmful emissions must be taken into account by a new definition.

More importantly, the temperatures of the heat received from and supplied to a district system must be taken into account in determining the supply and demand exergy balance as shown in Figure 2. For example, an exergy exchange deficit occurs in the grid-connected building if the building delivers 30°C water to the district but receives 40°C water from the district in the same amount over a given period of time. A similar deficit occurs for cooling, because exchange temperatures of the chilled water are different.

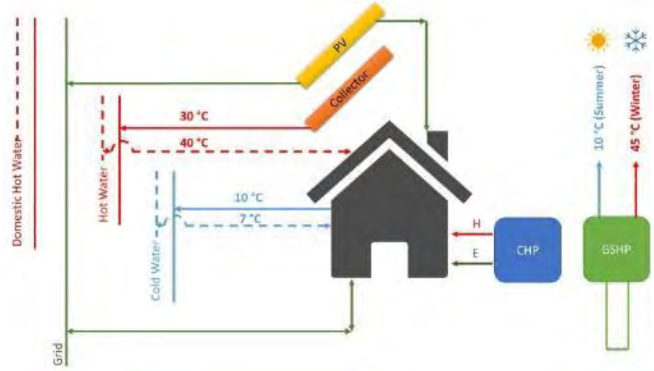

Figure 2: Supply and return temperatures between a sustainable building and de system

Therefore, the unit exergy of each 1 kW-h of the supply heat, ε_{sup} according to the ideal Carnot Cycle must be considered. Equation 1-a may also be used for destroyed exergy and demand exergy. Equations 1-a,1-b, 2, and 3 establish the energy, environment, and economy nexus, respectively.

Energy

$$\varepsilon_{\text{sup}} = \left(1 - \frac{T_{ref}}{T_{sup}}\right) \times (1\,\text{kW - h})$$

Equation 1-a: Unit exergy

$$E_x = \varepsilon_{\text{sup}} \times Q_{\text{sup}}$$

Equation 1-b: Energy and exergy

$$\psi_R = 1 - \frac{\sum \varepsilon_{des}}{\varepsilon_{\text{sup}}}$$

Equation 1-b: Rationality of energy use

Equation 1-a through 1-c establish the energy and exergy metric of the nexus. For a green district and subscribing building the annual average of ψ_R must be greater than 0,70.

Environment

$$\sum CO_2 = \left[\frac{c_l}{\eta_l} + \frac{c_m}{\eta_m \eta_T}(1 - \psi_R)\right] Q_H + \frac{c_m}{\eta_m \eta_T} E$$

Equation 2-a: Environment

Equation2-a, which is derived from the Rational Exergy Management Model (REMM) establishes the environment metric of the nexus. At below, *EDR* is the Ratio of Emissions Difference. The CO_{2base} term is the standardized emission rate calculated with practical defaults for 0,5 kW-h thermal and 0,5 kW-h electrical load per hour

(*C* =1). See Equation 2-c, where CO_{2base} is 0,63 kg CO_2/ kW-h, which is derived from Equation 2-a. *EDR* must be close to one.

$$EDR = 1 - [CO_{2on\text{-}site}/CO_{2\,base}]$$

Equation 2-b: Emissions are based on REMM

$$\sum CO_2 = \left[\frac{0{,}2}{0{,}85} + \frac{0{,}2}{0{,}35}(1 - 0{,}2)\right] 0{,}5 + \frac{0{,}2}{0{,}35} 0{,}5$$

Equation 2-c

Economy

$$PES = \left[1 - \frac{1}{\left(\frac{\text{CHPH}\eta}{\text{RefH}\eta} + \frac{\text{CHPE}\eta}{\text{RefE}\eta} \right) \times \frac{(2 - \text{Ref}\,\psi_R)}{(2 - \psi_R)}} \right] \times 100$$

Equation 3: Economy

Equation 3 provides the economy metric, where *PES* must be greater than 35% in order to qualify for a green status. In order to satisfy the above metrics, a complex design example for achieving NZEXAP status is shown in Figure 3 (Kilkis, B., 2012). In this design the combined heat and power system (CHP) is supported by renewable energy systems including solar collectors, PV systems, and their derivatives, and remote green electricity power from wind. Buildings and large complexes need to use radiant heating and cooling systems and thus may easily qualify for Low-Exergy Building status, while they employ moderate working temperatures. Thus solar energy may be directly utilized in their HVAC systems. Hot water, chilled water, and ice tanks shave the peak loads, shift the loads to converge to the supply profiles, and match the thermal exergy levels of various supplies and demands in the complex.

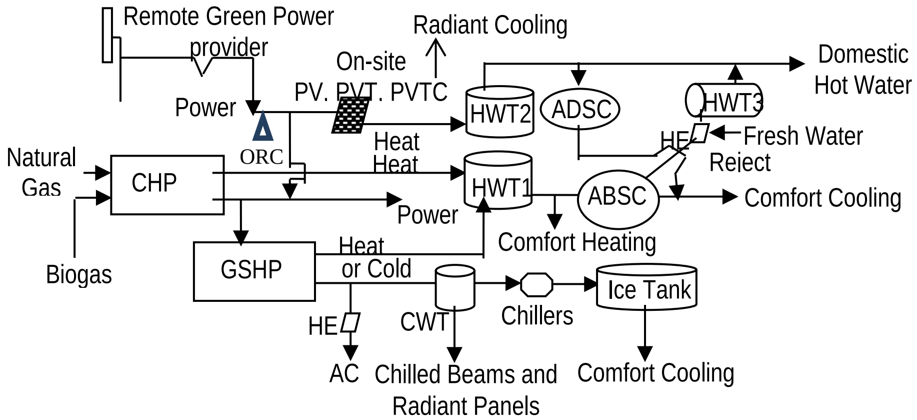

Figure 3: NZEXAP tri-generation plant design

3. OPTIMIZATION OF 4DE SYSTEMS

Figure 5 shows a typical daily power load profile at different (*c*) values with respect to P_P (Peak power load). (*c*) is the ratio of the selected capacity of a cogeneration plant to the peak power load. For example, if a tri-generation system in Figure 5 is selected with a capacity equal to P_P, then it will only operate for about only two hours at a capacity near to its full capacity. At the same time because most CHP engines are not allowed to operate below 40% capacity, it will remain idle for about 9 hours in a typical day. Unless cascaded, the CHP unit at part load will have reduced efficiency. It is obvious that NZEXAP or nZEXAP conditions may only be satisfied and energy, environment, and economy nexus be established by a careful selection of the tri-generation plant. Therefore, the capacity(ies) of CHP systems must be carefully optimized and cascaded, if necessary.

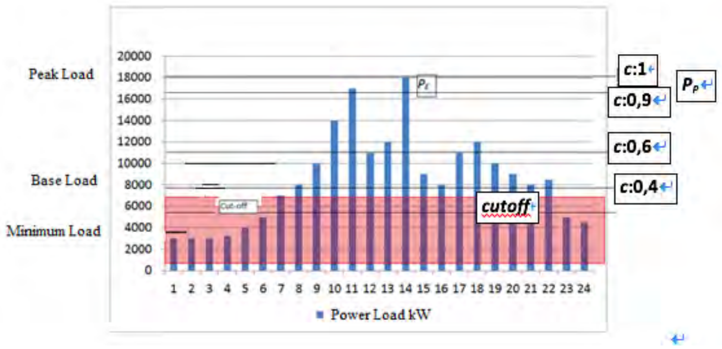

Figure 5: Typical hourly change of power demand

3.1 Objective function and its simplification

The primary objective is to maximize the performance of a CHP system under the energy, environment, and economy nexus. Main parameters are First-Law efficiency (η), (c) value, Operating Factor (IF), Rational Exergy Management Efficiency (ψ_R), CO_2 emissions, and economic return. Terms (j) and (l) are correlation parameters.

$$OF = f(\eta, c_i, IF, \Psi_R, CO_2)$$

Equation 4-a: Maximize

(c_i) for natural gas it is 0,2 kg CO_2/ kWh-h. IF depends on (c) that is shown in Figure 6, where $IF = f(c)$ [8].

$$OF = \left[\frac{0{,}6 + j(IF - 0{,}6)^l}{0{,}9}\right] + \left[\frac{IF)}{0{,}9}\right] + \left|\frac{0{,}088}{\left(\frac{c_i}{\eta}\right)(1-\psi_R)}\right|$$

Equation 4-b

Where,

$$\eta_I = \left[\frac{0{,}6 + j(IF - 0{,}6)^l}{0{,}9}\right]$$

Equation 5

After taking the upper limit of $\Psi_R \leq \eta_{EX}$ conditional inequality, assuming $C = 1$, and using the upper limit of the $\eta_{EX} \leq 0{,}9 \cdot \eta_I$ conditional inequality, Equation 4-b reduces to a single-variable expression.

$$OF = f^*(c)$$

Equation 6-a: Maximize

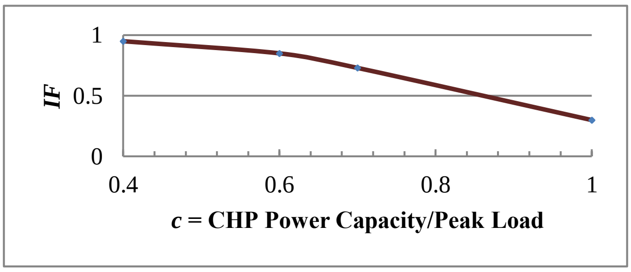

Figure 6: Approximate change of IF with (c)

Provided that for gas engines (c) must be greater or equal to 0,4, Equation 6-b gives the initial solution:

$$\frac{dOF}{dc} = 0$$

Equation 6-b

<u>Constraints of the nexus:</u>

$\eta_I \geq 0{,}80$,

$0{,}4 \leq c \leq 0{,}75$, $0{,}7 \leq IF \leq 1$,

$\Psi_R \geq 0{,}6$, $CO_2 \leq CO_{2base}$.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Once the optimal (*c*) value is determined, the CHP system may be cascaded, in optimal numbers and individual capacities depending upon the daily-averaged hourly load profiles. In general, the first cascade is allocated to the minimum continuous load (24 hours a day), the second one is sized such that it operates about 16 hours a day between its full capacity and 60% capacity, and the remaining one(s) are sized for peaking purposes such that they operate about 8 hours a day between full capacity and 75% capacity. Extreme caution must be exercised for these practical set of capacities and cascading schemes. Instead, they must be selected after an hourly load-based economic analysis, with an objective of achieving a simple return period of at most four years.

3.2 Automation

Without a dedicated general automation system, a 4DE system will not operate successfully. A novel automation system was developed for the ESER LEED Platinum Building in Ankara Turkey, keeping in mind that the same algorithm is expandable to the district level. A green and hybrid electromechanical system consists of several energy sources, energy conversion systems, and varying time based performance values, as a requirement of the system. Eser Green Building is also designed and constructed as a high performance green building and has various green and hybrid systems incorporated within its electromechanical structure. The building has platinum certification from LEED. Winter and summer operation diagrams of ESER Green Building are given in Figure 1 and Figure 2. It is almost impossible for these different systems to work together in harmony and supply various energy and power demands of the building and achieve the desired energy savings with the use of the existing Building Management Systems. An automation algorithm for high performance buildings, based on exergy balance between supply and demand was developed. This software is called as “Rational Exergy Automation (AEO) Program”. The main objective of the algorithm is to deliver exergy from on-site sustainable systems and other equipment to various demand points with maximum supply and demand exergy balance. Increasing the balance reduces exergy destructions and thus compound CO_2 emissions. The method is based on Rational Exergy Management Model (REMM).

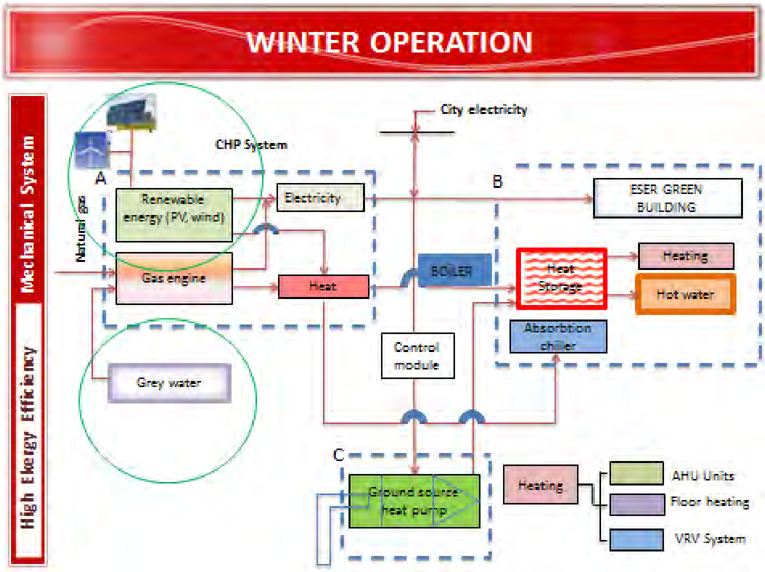

Figure 7: Winter operation scheme for the district

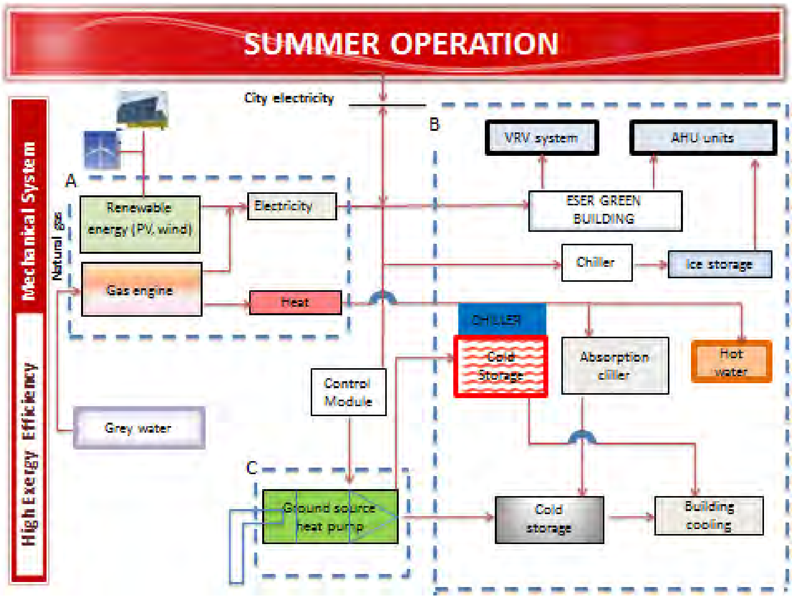

Figure 8: Summer operation scheme for the district

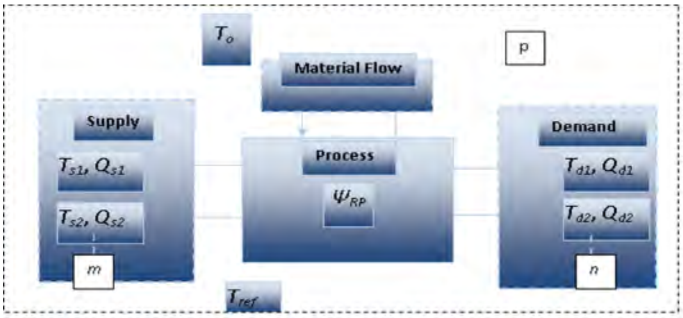

Figure 9: Basic REMM Block

$$\bar{\Psi}_R = \frac{\sum \Psi_{ij} \times \frac{Q_{ij}}{\eta_{ij}}}{\sum \frac{Q_{ij}}{\eta_{ij}}}$$

Equation 7

Equation 7 gives the overall REMM efficiency of the district with *m* supply points and *n* demand points. If there are a colocation of sub-districts, then *p* is the number of sub-districts.

4. CONCLUSIONS

n this paper the importance of exergy rationality in net-zero or near-zero buildings connected to 4DE systems was discussed and new definitions were made. It has been shown that net-zero or near-zero exergy building definitions are more realistic and definitive compared to the DOE definition. In the same token, CO_2 emissions need to be calculated according to both First and Second Laws of thermodynamics. In this respect a new zero carbon definition was also made, which supersedes previous definitions, being developed only in terms of the First-Law.

5. SYMBOLS

c	Ratio of the selected CHP power generation capacity to the peak power demand
c_i	Unit CO_2 emissions of any fuel combustion (*i*), kg CO_2/ kW_h-h
C	Power to heat ratio of CHP, dimensionless
CHPEη	Partial electrical power generation efficiency of CHP, dimensionless

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

$CHPH\eta$	Partial thermal power generation efficiency (including steam) of CHP, dimensionless
CO_2	Carbon dioxide emission, kg CO_2
EDR	Ratio of carbon CO_2 emissions difference to the base emission, dimensionless
E_x	Exergy, kW or kW-h
IF	Operating factor, dimensionless
OF	Objective function, dimensionless
PES	Primary energy savings percentage (According to Rational Exergy Management Model, REMM)
Q	Thermal load, kW-h
$RefE\eta$	Reference value for partial power generation efficiency of CHP, dimensionless
$RefH\eta$	Reference value for partial thermal generation efficiency of CHP, dimensionless
T	Temperature, K

<u>Greek Symbols</u>

Refψ_R	Reference value of ψ_R, 0,2
η	First-law efficiency, dimensionless
η_{EX}	Second-law efficiency, dimensionless
η_T	Power transmission and distribution efficiency (Equation 2-a)
ψ_R	Rational exergy management efficiency, dimensionless
ε_{dem}	Unit demand exergy, kW/ kW, or kW-h/ kW-h
ε_{des}	Unit destroyed exergy, kW/ kW, or kW-h/ kW-h
ε_{sup}	Unit supplied exergy, kW/ kW, or kW-h/ kW-h

ABSTRACT

Organic waste has been a major concern in Hong Kong in terms of environmental aspect. Waste-to-Energy system might be an effective solution. By using the bio-gas generated by the Waste-to-Gas system as fuel for SOFC-TG, most of the organic waste could be recycled. The solid oxide fuel cell-based trigeneration energy system (SOFC-TG) is a promising energy solution for green residential buildings. Cooling, heating, and electricity generating can be achieved at a high efficiency with SOFC-absorption cooling trigeneration configuration in the context of Green building and high performance building. The fuel flexibility is a distinguished advantage of SOFC system operating at high temperature, making the bio-gas produced from wastes an attractive alternative to commercial naturel gas (e.g. TownGas. Inc) as the fuel for SOFC-TG system in residential building application. This study focuses on the integration of SOFC-TG system with the Distributed Waste Treatment (DWT) system for simultaneous waste treatment and energy recovery. A case study is used for systematic energy analysis to evaluate its feasibility in HK. Series of surveys were arranged to discuss the potential development and constraints for the system.

Keywords: solid oxide fuel cell, tri-generation, waste-to-energy/ waste-derived energy

1. INTRODUCTION

The environmental problem and energy crisis are recognized as the serious global issues after 2015 United Nations Climate Change Conference. Hong Kong, as one of the most densely populated regions, creates 14,300 tons landfilled waste per day (AU, 2015), and consumes 162,356 tera-joules electric power ("Hong Kong Annual Digest of Statistics," 2016). Establishing the building integrated Distributed Waste Treatment (DWT) and Distributed Energy Resource (DER) system offers a promising method for effective waste treatment and energy generation simultaneously.

The organic waste such as food waste contributes to 37% of total landfilled waste but only 6.9% of the food waste was recycled (AU, 2015). Sending the organic waste to the landfill stations not only increases the environmental burdens, but also waste the valuable organic components, as they can be used as useful resources for energy generation or other products. The distributed anaerobic digestion system can treat the organic waste and generate biogas which can be used as a fuel for Solid Oxide Fuel Cell (SOFC) (Chen and Ni, 2014). SOFC is a promising energy conversion device with an efficiency (about 50%) higher than conventional heat engines (typically below 40%). The SOFC-based multi-generation system combining electrochemical power generation and waste-heat recovery can achieve a much higher energy efficiency (i.e. 70 - 95%). The biogas-and SOFC-based tri-generation system with heating, cooling and electricity generation is recognized as one of possible building integrated energy system for its high energy efficiency, low operating cost, quiet operation and low noxious-gas emission.

Although Waste-to-energy (WtE) is an active research area, the building-integrated WtE (BIWTE) system for Distributed Waste Treatment (DWT) and energy generation has rarely been studied to fill this research gap, this study focuses on the integration of SOFC-based trigeneration system with the DWT system for simultaneous waste treatment and energy recovery. The power consumption data of Hotel Icon is used as a case study for systematic energy analysis to evaluate its feasibility in HK. In addition, series of surveys were arranged to discuss the potential development and constraints for the system.

2. WASTE-TO-ENERGY SYSTEM

The proposed BIWTE system consists of a waste-to-gas DWT system and an SOFC-based tri-generation sub-system proposed by Chen et al (Chen & Ni, 2014). The waste-to-clean biogas system consists of the adapted waste-to-biogas system (Curry and Pillay, 2012); and the biogas treatment system (De Arespacochaga et al., 2014), as shown in Figure 1. The two main sources of waste in the system proposed are food waste (FW), from restaurants such as Green or The Market at Hotel ICON, and the hypothetical sludge in anaerobic digestion from an on-site wastewater treatment.

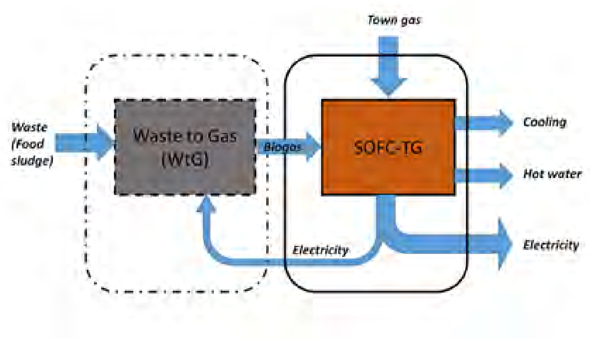

Figure 1: Schematic of the waste to power system based on SOFC-trigeneration

The waste-to-biogas system refers to the anaerobic digestion system for the urban environment by Curry and Pillay (2012). Yet, some modifications were integrated from the original design, such as the excess liquid from the dewatering process is aerated and solely sent to the sewage urban system instead of being recirculated or being used as fertilizer. In addition, the H_2S removal system proposed by the author will be substituted by the system of De Arespacochaga et al. (2015). The biogas treatment system is taken as the original one; including the polishing system configuration based on adsorption technologies by De Arespacochaga et al. (2014).

2.1 Waste-to-Gas (WtG) system

Food waste management has been of great concern for Hong Kong authorities. In 2013, Hong Kong generated 1.36 million tonnes of food waste, of which 1.33 million tonnes (98%) were disposed of at landfills (Audit Commission 2015). Hong Kong is a densely populated city with limited land resources. Thus, alternatives for food waste treatment have been encouraged by Hong Kong Government. The idea of the hypothetical sludge, in anaerobic digestion from an on-site wastewater treatment, is based on existing systems in high performance buildings [e.g. Solaire in the USA (ASHRAE 2008), Business Complex (Kimura and Funamizu, 2012), OHSU Center for Health and Healing (SPU and USMB, 2008), Ikebukuro Sunshine City, and Tokyo Dome (Udagawa 1994) in Japan]. In general, the buildings with on-site wastewater treatment use septic tanks to contain the sludge till a mobile sludge removal vehicle takes it out from the building (Matsuo 2000); or sent back to the city through the sanitary system (ASHRAE 2008). Yet, some buildings in Japan stabilize the sludge in night soil treatment facilities where biosolids are recycled for biogas yield for energy, compost, agriculture, and cement manufacturing (Gaulke, 2007). In this system both types of waste are utilised for anaerobic digestion due to their biogas yield potential.

2.2 Waste-to-Gas (WtG) system

Curry and Pillay (Curry & Pillay, 2012) studied food waste as a sole substrate for anaerobic digestion. The study reviewed the technologies for biogas production from food waste, from which the experimental estimation of 367 m3/tonne volatile solids (VS) was recommended by the Environmental Protection Agency (EPA) for mixed food waste biogas generation (65% CH4 and 35% CO_2). In other study, the biogas generation could reach1063 m^3/tonne VS (Prabhu & Mutnuri, 2016). Additionally, the energy value for food waste biogas with 65% methane is considered as 6.25 kWh/m^3 (Curry & Pillay, 2012).

This study proposes the co-digestion of food waste with sewage sludge for biogas generation. Anaerobic co-digestion is a process where two or more substrates with complementary characteristics are mixed for combined

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

treatment. Prabhu and Mutnuri (Prabhu & Mutnuri, 2016) studied the co-digestion of food waste and sewage sludge. The results of the study showed that for pilot scale digestion a mixing ratio of 1:2 and loading rate of 1g VS/Ld gave the maximum biogas production of 742 ml/gVS Ld with a methane content of 50%, followed by 2 g VS/Ld with biogas yield of 539 ml/gVS Ld. The loading rates are within the range recommended in literature review of 1-5 kgVS/m^3 (Curry & Pillay, 2012).

Co-digestion of FW with sludge has several advantages such as higher CH4 yield at a proper mixing ratio, an accelerated methane production rate, handle two different waste streams, and reduce the costs of food waste management (Prabhu & Mutnuri, 2016; Schiettecatte, Tize, & De Wever, 2014). For example, the FW co-digestion in the pilot project of East Bay Municipal Utility District (EBMUD) in California, USA experienced a three-fold CH4 yield, better performance from the machines, and costs savings from on-site electrical and thermal generation (Gill-Austern, 2011).

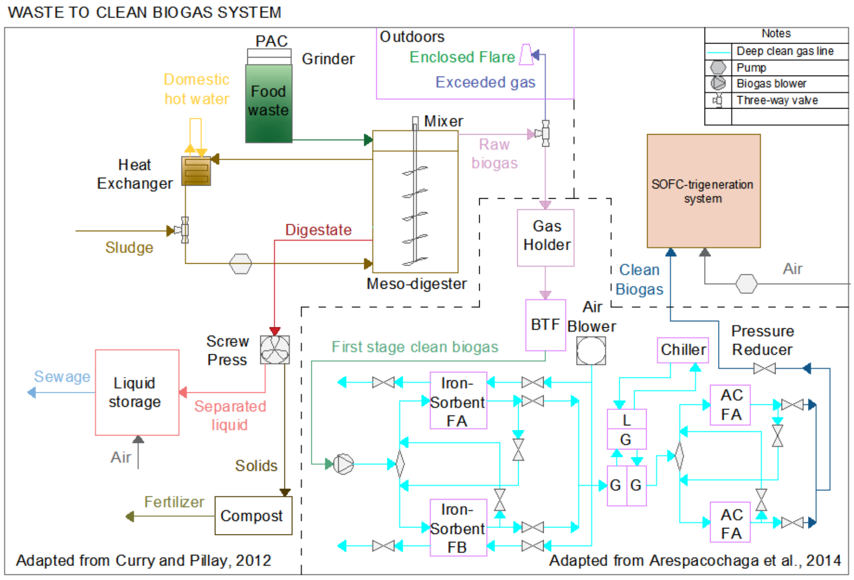

Figure 2: Schematic of the Waste-to-Energy (WtE) system

Researchers (Heo, Jeon, Lee, Kim, & Lee, 2003) studied different food waste and activated sludge co-digestion ratios in a single-stage anaerobic co-digester. The food waste used by the author was simulated Korean food waste which is similar in characteristics with Hong Kong food waste (Zhao & Deng, 2014). The highest methane production rate, with hydraulic retention time (HRT) of 10 days, was present for the ratios of 50:50 and 30:70 with 1.150 and 0.601m^{3}CH$_4$/m^{3}day, respectively. The organic loading rate varied from 3.14 to 2.60 kgTVS/m^3 day. The design of the anaerobic digestor in this paper is based on the considerations mentioned above, the daily amount of food waste generated by the hotel is 4300 kg, assuming the food waste mainly comes from 528 consumers (5 kg per person per day) and 1,100 staff (1.5kg per person per day). The required activated sludge for co-digestion ranges from 6.02 Ton/day to 4.3 Ton/day. Ideally the mixing ratio should be kept 50:50, but the food waste supply might fluctuate at the Hotel ICON. Thus, the anaerobic digester is designed with maximum flow allowed, while the methane production rate considers a range of the probable mix ratios possible. The volume of the reactor considers a maximum flow of 8.6 Ton/day and HRT of 10 days. The total working volume with a maximum flow would be 86 m^3 ~90 m^3. The methane production rate ranges from 98.9 to 51.7 m^{3}CH$_4$/day. The methane content ranges from 63.3 to 70.4%. Thus, the total biogas production rate varies from 156 to 73.42 m^3 biogas/day.

The space required for the installation is based on Tsang et al 's calculations (Tsang, 2013) of a 70 m^3 anaerobic digester. The system in this paper is about 22% larger than the system in Tsang's work. Thus, the space required for the anaerobic digester is 44 m^2, biogas holder is 31 m^2, food waste tank is 7.5 m^2, enclosed flare is about 6m^2, and auxiliary equipment around 10 m^2. The total space required would be around 100 m^2 including indoor and outdoor components.

2.3 Biogas treatment system

The biogas produced by the waste-to-biogas system includes several gases that could affect the performance of the SOFC. In particular, H_2S concentration should be reduced to avoid any SOFC deterioration. The biogas treatment system based on Arespacochaga's work (de Arespacochaga et al., 2015), is a previously studied option to clean the biogas and make it more compatible for SOFC. The results showed that after the polishing system the clean CH_4 concentration ranged around 55.1-57.8%. Thus, based on that assumption, the biogas treatment system with the best conditions can provide 108.33 L biogas/min with 62.62 L CH_4/min, and with the less optimum conditions it can provide 51 L biogas/min with 28.09 L CH_4/min to the SOC system. An important consideration for the performance of the SOFC is that the cleaned biogas might include around 7.5-12.5% of N_2 and 1.8-2.9% of O_2.

2.4 SOFC-TG system

Solid Oxide Fuel Cells (SOFCs) as an efficient energy converter, are superior over other types of fuel cells, in case of biogas feeding operation. Its fuel flexibility benefits from its ability of internal reforming at its high operating temperature (600-800^oC), with proper catalysts such as Nickel.

Biogas produced from waste treatment, compose of about 60% CH4 is a good fuel option for SOFC, with necessary pre-treatment such as desulfuration and drying process. Compared to other biogas exploitation systems such as direct combustion systems (Bruno, Ortega-López, & Coronas, 2009), stationary/mobile internal combustion engines (Basrawi, Yamada, Nakanishi, & Katsumata, 2012; Colmenar-Santos, Zarzuelo-Puch, Borge-Diez, & García-Diéguez, 2016), upgrading system to natural gas grid, SOFC has advantages such as high energy efficiency, low carbon emission, silent operation, etc. These features make the SOFC suitable for distributed cogeneration system for residential applications.

Pilot biogas-powered SOFC plants were installed and demonstrated to be successful. In Chabloz, Switzerland, farm biogas was used to power a 1 kWe SOFC, for more than 5000 hours starting from 2001 (Basrawi et al., 2012). In 2008, Acumentrics (Westwood, USA) launched two 5 kWe biogas-fed SOFCs (BIOSOFC project, LIFE06 ENV/E/000054) in Barcelona and Stockholm ("Laymen's Report,"). Another biogas-powered SOFC pilot plant was installed at Mataró which collected wastewater from different towns and villages in the Maresme region of Barcelona, Spain (de Arespacochaga et al., 2015).

Bloom Energy, the leading SOFC power module supplier, claim that their SOFC system can directly fed with natural gas, or even biogas for 10 years life-span (Devlin, 2013). The electricity efficiency can reach 56 - 60%, while the overall energy efficiency can be improved to over 80% for cogeneration.

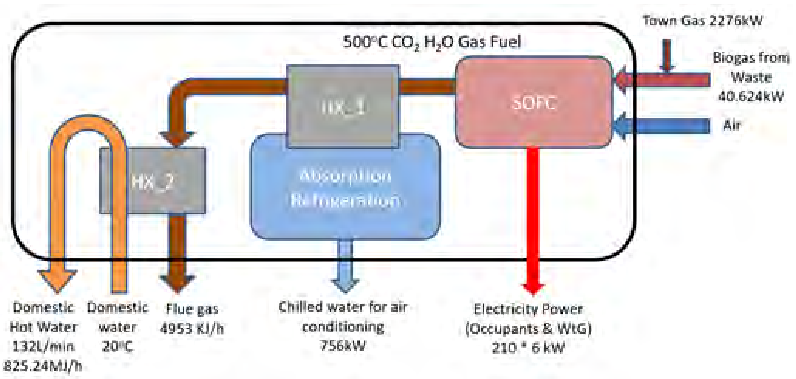

Figure 3: Schematic of the GtE system (SOFC-trigeneration)

In distributed systems, the high temperature waste heat from SOFC can be recovered by refrigeration cycles, turbine, or hot water generators, to achieve a higher system efficiency (even above 90%). Besides, in distributed applications, the need for cooling, hot water and electricity can be partly fulfilled by the tri-generation system at the most time. In this study, a tri-generation system is developed based on 6 units of 210KW SOFC server (ES-5700) from Bloom Energy. The fuel gas to power the SOFCs are the cleaned biogas produced from the Waste to Gas process as introduced in Section 2.1. The configuration of the Gas to Power process are partly adapted from Chen et al 's work, as shown in Fig. 3 to briefly described bellowed.

According to the energy utility analysis from HOTEL ICON's management data, a nominal 1210KW electricity power is in demand with a conservative regard to its monthly fluctuation see Figure 4 (ICON, 2016). The SOFCs mainly use the Town gas (a heat value at 17.27MJ/m3) from commercialized pipeworks of Town gas. Inc as the fuel to provide an equivalent 2276KW energy flow into the SOFCs. The composition of Town gas can be referred to Table 1 ("Gas Production of Towngas,").

Figure 4: Hotel ICON's electricity demand report, with a monthly average 1210 KWh (ICON, 2016)

Town Gas Characteristics	CO_2	CH_4	H_2	N_2+O_2
Volume fraction	16.3% – 19.9%	1.0% – 3.1%	28.2% – 30.7%	46.3% – 51.8%

Table 1: Town gas characteristics ("Gas Production of Towngas,")

It is important to note that the by-product of waste treatment process: biogas could be another option to power the SOFCs at an optimistically estimated flow rate of 108.33 L/min. The equivalent energy inflow of biogas can be calculated as 40.62 KW. In view of the small amount of biogas production compared to the overall fuel demand by SOFCs, the biogas here only act as an assisting fuel (1.75% of the total fuel heat value), due to the enormous electricity demand by the hotel. The authors hold the view that the waste treatment of residential buildings could be distributed by the combination of WtG and GtE process as demonstrated by this study, though the waste amount cannot fully sustain the hotel power operation, even when the high efficiency SOFC is used. However, in this concept of distributed waste treatment, implicated waste treatment issue are expected to be cut, such as labour cost in waste collection, transportation cost, land source in high density cities where landfill is the prevailing solution to waste treatment, i.e. Hong Kong.

In this study, an absorption refrigeration system (Broad X Non-electric Chiller) manufactured by Broad Group ("Broad Air Conditioning, Borad X Non-electric Chiller (Model Selection & Design Manual),") is chosen to server for the first stage waste heat recovery of the SOFC flue gas. The 500oC flue gas consists of H_2O and CO_2 would exchanging heat with the absorption chiller, leveraged a 756KW cooling capacity in form of chilled water. Consequently, HOTEL ICON's cooling demand can be relieved with 756KW using this absorption chiller. The outflow temperature of flue gas after this first stage heat recovery would be reduced to 160oC. Then the second stage heat recovery will further cools down the temperature to 60^{o}C, generating domestic hot water at a rate of 132L/min.

3. POTENTIAL DEVELOPMENT AND CONSTRAINTS

To investigate the feasibility of combing system in Hong Kong, series surveys are conducted involving experts and potential users. The viewpoints of respondents are noted to discuss technical and legal constraints and the potential market in Hong Kong business environment.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.1 Technology obstacles and potential market

Some technical defects obstacles limit the actual performance of Waste-to-biogas system combining with the SOFC-TG system. Extra-supports should be provided to control the concentration of sulfide to maintain normal operation and realize satisfactory lifespan of the system. In addition, the fluctuation of power supply and consumption should be considered seriously. Further study is requisite in the simulation tests of combining system.

Moreover, space limitation and unaffordable reinstallation cost extend pay-off period, which might reduce the clients' interest. Majority of respondents prefer projects with short pay-off period (less than five years) due to the lucrative purpose and insufficient supporting funds. On the other hand, the development of DER has raised the importance of waste-to-biogas and new generation fuel cells. Considering the optimistic prospect, majority of respondents have indicated their interests in the application of this system.

3.2 Government supporting and legal constraints

With the advancement of environmental awareness, series of ordinances such as Building Energy Efficiency Ordinance, Building (Energy Efficiency) Regulation, and BEAM-Plus standard were established by Hong Kong government to ensure the rational energy utilization. The Waste Reduction Framework Plan is introduced to encourage the Waste-to-energy. It is agreed that this system could improve energy efficiency and waste recycling performance of buildings and it might obtain financial support funds from the government and social organizations.

Power generation in private sector is cramped by legal restrictions in Hong Kong (Chen and Ni, 2014). Nevertheless, the progressive liberalization of private power generation has achieved a desirable result in mainland China and some European Countries, where established policies to support the BIWTE. Respondents suggested that the operators of this system should obtain the permission from the government in the current legal environment.

4. CONCLUSION

The SOFC-TG and Waste-to-Gas (WtG) system is a possible contribution for remitting environmental and energy crisis. This study is set to investigate the potential development of the combing system from both technical and social concern in hope of searching for availably solutions of food waste problem and resource exhaustion. Hotel is selected as the main object of this study for its stable organic waste output and energy demand and the Hotel ICON is analysed as a case study to investigate the application condition in Hong Kong. Based on the current situation, the waste-to-gas system can treat around 4300kg daily organic waste and product 108.33 L/min biogas, the equivalent energy inflow of biogas can be calculated as 40.62 KW. With the fuel of biogas and town gas, the system can realize satisfactory efficiency (50%-80%). However, within the surveys with potentials users and technical experts, the overcoming of technical, legal and social constraints of the combing system is indispensable. If the above aspects are addressed, the SOFC-TG with WtG system is promising for building integrated application in Hong Kong and even around the world.

ABSTRACT

This paper presents a modelling-led approach applied to low carbon innovative housing retrofit practice in Wales, UK. The research has investigated the implementation of combinations of existing and emerging low carbon technologies through a system based approach to optimise the use of energy at the point of generation at both building and community scales. A performance prediction model has been developed to examine the effectiveness of different strategies in relation to energy and carbon reduction. Simulation results of individual building have shown, the retrofits with a net carbon reduction by up to 110% indicating a zero-energy or energy positive performance. Based on this, further investigation is carried out in retrofitting the whole community towards a 'zero-energy' or 'energy positive' community through a micro-grid connection and storage. The simulation results show an energy positive performance can be achieved for community 1 under the proposed retrofit scenarios.

Keywords: building energy simulation, energy positive community, renewable energy supply

1. INTRODUCTION

To meet the target of an 80% reduction in the UK's carbon emissions by 2050 (HM Government, 2008), it is crucial to reduce the carbon emission associated with the domestic sector, which accounts for some 29% of the UK's total energy consumption (DECC, 2014a). The housing stock in the UK is replaced with a proportion of only around 1% a year (TRCCG, 2008), it is estimated that 70% of the UK's housing stock that will exist in 2050 has already been built (Wright, 2008). Therefore, it will be necessary to retrofit existing housing, as the CO2 emission target reductions will not be achieved through new build alone. A growing interest in nearly zero energy or zero energy housing (NZEH or ZEH) has been shown in the past decade, where a number of cases studies worldwide have demonstrated the feasibility. Norton et al. present the design, construction and performance of a three-bedroom Habitat for Humanity net-zero energy home in a cold climate, which generate 24% more energy than it consumed in the first year of operation (Norton et al., 2008). Musall et al. summarizes the research of the International Energy Agency's Annex 52 "Towards Net Zero Energy Buildings", including a comprehensive collection of more than 280 zero energy buildings worldwide, with both existing and new build (Musall et al., 2010). Serghides et al. report that the refurbishment of an old Single Family House in Cyprus into a nearly Zero Energy Building is financially viable (Serghides et al., 2015). In general, the idea is to minimize the need for building energy use through effective energy-efficient strategies before adopting renewable energy technologies to meet the reduced energy requirement, to achieve a nearly zero or zero energy balance between demand and supply, import and export. Energy positive performance could be achieved when more energy is exported compared with that imported over a whole year.

However most near-zero or zero performance has been investigated for new build housing. This paper presents an energy modelling-led approach to investigate energy retrofit housing in Wales, UK, for individual buildings, and community scale with the integration of a micro-grid connection and battery storage. The investigation considers combinations of existing and emerging low carbon technologies through a system based approach, combining reduced energy demand, renewable-energy supply and energy storage.

2. LOW CARBON RETROFIT TECHNOLOGIES

Through proper retrofit strategies, energy use and the resulting carbon emissions of the houses can be reduced significantly. Energy retrofit technologies are designed to reduce energy demand, especially space heating, which comprises around 66% of the domestic energy usage in the UK (DECC, 2014b). Fabric insulation is generally considered to be the most effective strategy. A large number of domestic houses in the UK were built with cavity walls, 60% of which did not have thermal insulation by 2004 (EHCS, 2004). Cavity wall insulation can reduce up to 40% heat loss through the walls (EST EEBPH, 2003). Older houses have solid walls and require external or internal wall insulation to improve their performance. It is estimated that upgrading an old poorly insulated house to post-1990 standards through roof and wall insulation can reduce heat loss by 50%-80% (Roberts, 2008). However, there are concerns that the insulated wall performance may not be achieved in practice due to construction details and poor workmanship (HM Government, 2015). Insulating existing ground floors can prove disruptive and is only likely to be viable during major refurbishment programmes (Shorrock et al. 2005). Loft insulation is generally easy to apply as a cost-effective measure. Although many lofts already have some level of insulation, loft 'top-ups' can cost effective, bringing them to a minimum of 270mm loft insulation, the level required to meet the current Building Regulations in the UK for new build (DECC, 2014c). Improving air tightness can also reduce heat loss from ventilation (Everett, 2007), and can be an ancillary benefit from upgrading the building fabric, particularly windows and doors. Ideally, upgrading the building envelope should be accompanied by improving the heating system, either downsizing the current system, or switching to a more energy-efficient system, with modern boilers achieving over 90% efficiency (Everett, 2007).

Other popular technologies to reduce energy demand include LED lighting, energy-efficient appliances, and Mechanical Ventilation Heat Recovery (MVHR). Most LED light lamps can save over 80% electricity compared to conventional incandescent lamps do (DoE, 2014), and last longer with less maintenance. A notable improvement of energy efficiency has been shown in the appliance market due to technical progress. For example, the average electricity use of an A+++ Panasonic fridge freezer is only 175kWh/yr, while that of an A+ fridge freezer of the same size is 313 kWh/yr. However, the energy use of appliances can vary greatly with occupant behaviour. Mechanical Ventilation Heat Recovery (MVHR) has the potential to reduce heating losses by pre-heating supply air using heat recovered from stale air leaving the property, and improve indoor air quality by providing constant fresh filtered air. It works well in an airtight house, however, for a property with poor airtightness, or if the system is not correctly installed or commissioned, it can increase heating and auxiliary energy demand (White, 2016).

Renewable energy supply can be used to meet the reduced energy demand. The current average annual solar resource in the UK is estimated to be 101W/m^2 (Burnett et al. 2014), or 2.4 kWh/m^2/day. The electricity generated from Solar PV can be stored using batteries, maximising its use onsite, and only surplus power exported to the grid.

3. METHOD

A series of energy retrofits have been studied in Wales (Jones et al. 2016). At the start of each retrofit, a survey was carried out to investigate the current conditions of the property. A combination of energy saving measures were then proposed, combining fabric measures, renewable energy and energy storage, through a systems based approach. A low carbon design approach will firstly reduce internal heat and power loads, followed by passive design, and finally applying efficient heating, lighting and ventilation services, combined with the integration renewable energy supply and storage. Energy simulation models were developed for three houses in order to predict the optimised performance of the houses with appropriate packages of energy saving measures. The best option for each house was identified, in terms of energy consumption, carbon emission and operating cost savings.

These models were then expanded to a community scale, in order to examine their performance in relation to further reducing energy use through micro-grid connection and community scale energy storage. At a community scale, the average household energy performance could be better or worse than that of single build due to a combination of different building types (terrace, semi-detached, detached) and orientations according to the layout. However, there are advantages of sharing renewable energy supply and storage systems, compared to individual building integrated systems, especially where some building may not have an optimal orientation in relation to solar energy systems. Installing PV on both sides of a pitched roof with east-west orientation may even lead to increased energy generation due to the larger PV area.

The simulation tools employed in the research include HTB2 and VirVil SketchUp (Jones et al., 2013). Both HTB2 and VirVil SketchUp were developed at the Welsh School of Architecture, Cardiff University. HTB2 is typical of the more advanced numerical models, using as input data, hourly climate for the location, building materials and construction, spatial attributes, system and occupancy profiles, to calculate the energy required to maintain specified internal thermal conditions (P.T. Lewis, D.K. Alexander, 1990). Due to its advantages of flexibility and ease of modification, it is well suited for use in the field of energy efficiency and sustainable design of buildings, which is rapidly evolving. The software has been developed over thirty years, and has undergone a series of extensive testing and validation, including the IEA Annex 1 (Oscar Faber and Partners, 1980), IEA task 12 (Lomas,

1994) and the IEA BESTEST (Neymark et al., 2011). VirVil SketchUp is an extension development of HTB2 for urban scale modelling. By linking SketchUp with HTB2, it can carry out dynamic thermal simulation for multiple buildings in a community or urban scale, with consideration to overshadowing impacts from the neighbourhood. Based on the output from thermal simulation, hourly energy models were developed to integrate energy demand, supply and storage at both building and community scales.

4. SIMULATION RESULTS

The retrofits are all located in South Wales, UK. Table 1 summarizes the energy saving technologies employed in the retrofits of three houses (Retrofits 1, 2 and 3), which formed part of the Low Carbon Research Institute (LCRI) SOLCER Retrofit project (funded by the European Regional Development Fund (ERDF)). Table 2 summarizes the proposed optimisation strategies for the three communities. The three communities are based on existing layouts for Retrofit House types 1, 2 and 3.

	Retrofit 1	Retrofit 2	Retrofit 3
			
Basic information	2000's, 3-bed filled cavity wall 86m² semi-detached, southeast facing, with gas heating.	Pre-1919, 2-bed 74m² solid wall, mid-terrace south facing, with gas heating.	1950's, 3-bed 80m² cavity wall semi-detached southeast facing, with gas heating.

4.1. Retrofits 1, 2 and 3 results

Figure 1 presents the overall annual savings of the three retrofits. The electricity savings are between 55% and 90% with the higher saving associated with more electricity demand met by PV supply. Gas savings are highest for retrofit 2, where insulation has been applied to solid wall pre-1919 houses. CO2 emission reductions are in excess of 70% for all three retrofits, and exceeding 100% for retrofit 3, indicating an energy positive performance. All retrofits have high cost savings indicating an income generation from exporting electricity to the grid. The results also indicate the reduced contribution to (gas) heating from lighting following the application of LEDs. Where the PV is used to contribute to DHW (immersion) heating for retrofit 1 which has a hot water tank, further gas savings of 17% are predicted (the other two retrofits have combi-boilers with no hot water storage). Table 3 summarizes the predicted annual performance of the retrofitted properties. An electricity self-sufficient ratio of more than 85% can be achieved by retrofit 1 and 3, indicating their majority of electricity use can be met by PV energy supply and storage.

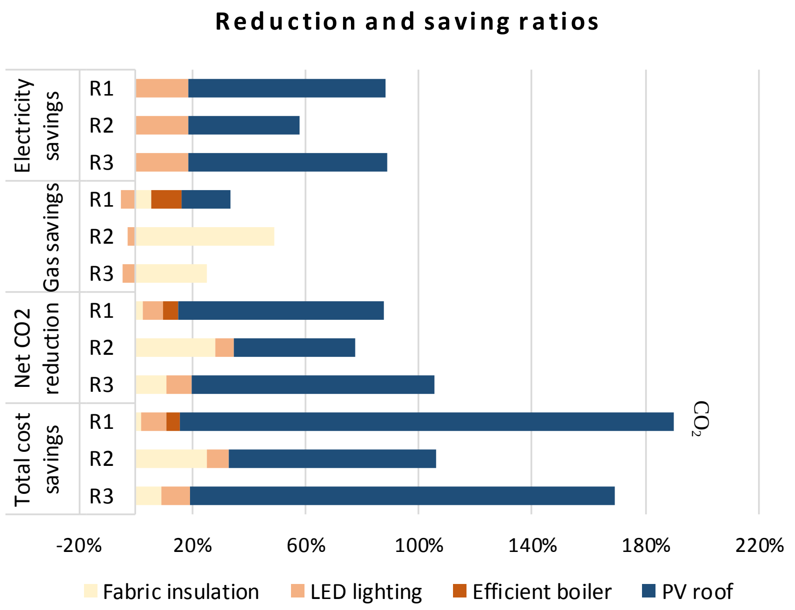

Figure 1: Summary of the predicted performance optimisation of the three retrofits

	Retrofit 1	Retrofit 2	Retrofit 3
Total electricity generation by PV	4493 kWh/yr (52 kWh/m²/yr)	2572 kWh/yr (35 kWh/m²/yr)	3916 kWh/yr (49 kWh/m²/yr)
Electricity generation by PV per kW_p	998 kWh/kW_p/yr	989 kWh/kW_p/yr	986 kWh/kW_p/yr
Electricity from grid	281 kWh/yr (3 kWh/m²/yr)	1021 kWh/yr (14 kWh/m²/yr)	268 kWh/yr (3 kWh/m²/yr)
Electricity to grid	1279 kWh/yr (15 kWh/m²/yr)	1519 kWh/yr (21 kWh/m²/yr)	1992 kWh/yr (25 kWh/m²/yr)
Electricity export to import ratio	4.55	1.49	7.43
Electricity self-sufficient ratio	90%	49 %	86%
Electricity demand	1983 kWh/yr (23 kWh/m²/yr)	1983 kWh/yr (27 kWh/m²/yr)	1983 kWh/yr (25 kWh/m²/yr)
Heating demand	4245 kWh/yr (49 kWh/m²/yr)	3856 kWh/yr (52 kWh/m²/yr)	3201 kWh/yr (40 kWh/m²/yr)
Gas supply	3798 kWh/yr (44 kWh/m²/yr)	4284 kWh/yr (58 kWh/m²/yr)	3557 kWh/yr (45 kWh/m²/yr)
Net operating carbon emission	302 kg/yr (4 kg/m²/yr)	667 kg/yr (9 kg/m²/yr)	-126 kg/yr (-2 kg/m²/yr)

4.2. Community scale results

Table 4 presents the predicted energy performance of the communities. The potential of PV generation is shown through the visualisation of solar radiation on the roofs, with red indicating the most solar radiation, orange the second most, and green the least. Both red and orange roofs have been considered for PV installation. This explains why there is more electricity generation per household in community 1, compared with the single case in table 3, as PV is considered on both sides of the pitched roofs for almost half the number of buildings, i.e. those with an east-west orientation. Community 1 is 90% self-sufficient in electricity use, and with an annual net CO_2 emission of 588kg/household, indicating an energy positive performance over the year. For community 2, there is an increase of PV generation compared to the performance of the individual Retrofit 2, as a result of the increased PV area per household from further optimisation (see Table 2), contributing to a smaller average net carbon emission. For community 3, it generates proportionally less electricity per household, but uses more electricity and gas, compared with the single build Retrofit 3 (see Table 3). This is due to most buildings in community 3 without an optimal orientation as that of the single build, and only a couple of buildings have both sides of roofs considered for PV installation (see red and orange roofs in Table 3).

	Community 1	Community 2	Community 3
Visualisation of solar potential on the roofs  1200 kWh/m^2 900kWh/m^2 700 kWh/m^2			
Total electricity generation by PV	5319 kWh/household/yr (61 kWh/m^2/yr)	3103 kWh/household/yr (42 kWh/m^2/yr)	3377 kWh/household/yr (43 kWh/m^2/yr)
Electricity generation by PV per kW_p	980 kWh/kW_p/yr	991 kWh/kW_p/yr	940 kWh/kW_p/yr
Electricity from grid	315 kWh/household/yr (4 kWh/m^2/yr)	1021 kWh/household/yr (14 kWh/m^2/yr)	790 kWh/household/yr (10 kWh/m^2/yr)
Electricity to grid	2444 kWh/household/yr (28 kWh/m^2/yr)	2055 kWh/household/yr (28 kWh/m^2/yr)	2059 kWh/household/yr (26 kWh/m^2/yr)
Electricity export to import ratio	7.76	2.01	2.61
Electricity self-sufficient ratio	90%	49%	60%
Electricity demand	1983 kWh/household/yr (23 kWh/m^2/yr)	1983 kWh/household/yr (27 kWh/m^2/yr)	1983 kWh/household/yr (25 kWh/m^2/yr)
Heating demand	3281 kWh/household/yr (38 kWh/m^2/yr)	4682 kWh/household/yr (63 kWh/m^2/yr)	4162 kWh/household/yr (52 kWh/m^2/yr)
Gas supply	2394 kWh/household/yr (28 kWh/m^2/yr)	5203 kWh/household/yr (70 kWh/m^2/yr)	4625 kWh/household/yr (58 kWh/m^2/yr)
Net operating carbon emission	-588 kg/household/yr (-7 kg/m^2/yr)	587 kg/household/yr (8 kg/m^2/yr)	340 kg/household/yr (4 kg/m^2/yr)

Table 4: The predicted energy performance of the communities

5. CONCLUSION

The paper has described case studies of a systems approach to low carbon innovative housing, including three retrofits in South Wales, UK. The results indicate that, the combination of reduced energy demand, renewable energy supply and battery storage could reduce net carbon emission by 88%, 78% and 110% for the three retrofits, demonstrating that a near-zero energy and for one case energy positive performance, can be achieved.

There can be added benefits from a community performance compared to an individual house performance due to the increased area of PV applied to different orientations and building type variations (detached, semi-detached, terrace). For some east-west oriented houses, PV applied to the whole roof rather than the south facing side can significantly increase the total electricity generation. Community 1 has the potential to achieve an energy positive performance.

ABSTRACT

Presented in this paper is our investigation on the potential of usingexisting natural gas and oil wells in the USA to provide high quality geothermal heat. Geothermal heat is renewable energy that can be used from higher temperature sources for direct heating. In the USA and other less thermally active regions, it is most commonly harvested from shallow ground heat exchangers leveraging seasonal average seasonal temperature to maximize heat pump performance. Drilling deeper would provide higher temperatures, but for most projects the drilling and heat pump are significant costs - up to 90% of the total cost of a geothermal system for wells beyond 600m. The state of Pennsylvania has 66,000 active natural gas and oil wells with depths typically greater than 1000m, so how much might we harvest from these wells? Analyzing the recently released data from National Geothermal Data System (NGDS), we found bottom temperatures of 17,467 Pennsylvanian wells with 95% having depths from 1000m to 2500m and 70% having temperatures above 80 ˚F (26.6˚C) that could be used in low temperature, low exergy, district heating systems. In this context, linking them to a district heating system would therefore be providing essentially free heat without any drilling costs. This study aims to characterise the geothermal potential that can be exploited and identify potential locations for pilot projects. This is done using criterias including spatially varied demographic profile, heating demand and variable heat loss through possible distribution pipelines. We identified a possible 10% of the heating demand in the state of Pennsylvania could be covered by the 17,476 oil/gas wells should they all become dedicated to geothermal post active-production stage. Cities like Pittsburgh could have a substantial portion of their heating demand supplied. Finally, upon decommissioning, many of these wells often become pathways for methane leakage as sealing is required, but not well incentivised - which would be addressed by further utilisation in our proposed district concept.

Keywords: *geothermal, district heating, distributed energy systems*

1. INTRODUCTION

Our attention towards geothermal systems is very polarized in the current mar- ket. There are emphasis on harvesting the geothermal energy in the form of power generation, eliciting Enhanced Geothermal Systems (EGS) that only counts at the depths deeper than 2km, or on the other side, Ground-source heat pump(GSHP) systems for residential purposes that rarely goes beyond 600ft(182.88m). The in-between is rarely addressed since it is in an awkward area where the temperature recovered is relatively warm while the costs can be exceedingly high. At a depth beyond 600 feet, the majority of the costs can be attributed to drilling, which can make up to 90% of the total costs of the system, mounting to a total of $500,000 for a system with 1000 feet system. A possible way of reaching the desired depth without investing heavily on the capital cost for geothermal systems is to enlist the boreholes that are out-of commission. This paper sets out to provide an estimate of such geothermal potential from existing oil/gas wells that have been recently made public by the National Geographic Database System(NGDS).

2. BACKGROUND

The state of Pennsylvania has a long history of harvesting oil and gas from the underground. The Marcellus Shale basin was, in fact, found among the conventional boreholes that were thought to have been depleted once. First recognized by the USGS in 2003, the actual capacity of Marcellus Shale basin is expected to reach a mean undiscovered natural gas resource of 84,198 billion cubic feet according to the USGS fact sheet, essentially helped achieving the longed energy independency for the United States.

It is also known, however, that abandoned/depleted wells, despite being plugged with concrete, can be the source of fugitive emissions. This was brought to the attention of researchers when first identified by a PhD thesis in

Princeton University. Her research indicated that even wells that are considered sealed can still have emissions coming out from the bottom of the wells.

Many studies have been done to ensure the proper sealing of the aban- doned/inactive boreholes, mostly treating them as a problem to be fixed. But what about taking an active step back and looking at the problem proactively and try to harvest the heat that is available at the bottom of the boreholes? Similar thoughts were pursued by [13] in 2006 using mine water to cool buildings, exploiting the underground mine water's temperature for better performance of geothermal heat pumps.

3. METHODOLOGY

3.1 Visualizing geothermal potential

To visualize the potential that is available from the 17,467 boreholes, a simple extrapolation of the temperature at different depths using linear regression and a resolution of every 100m and plotted in Figure 1.

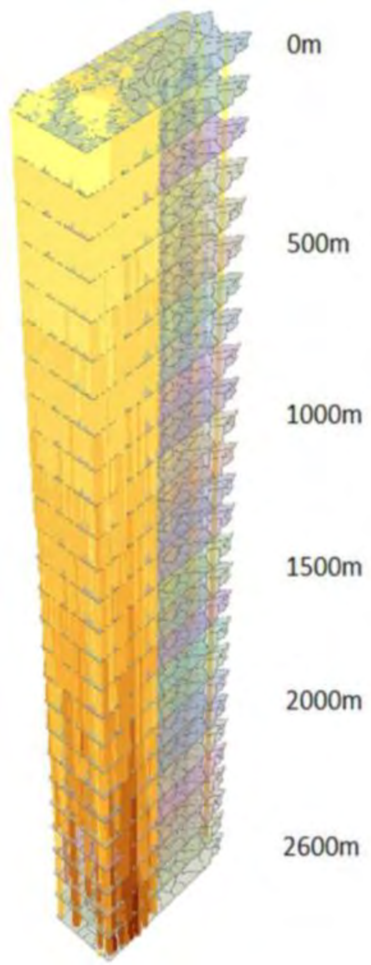

Figure 1: Geothermal potential visualization from 17,467 boreholes through linear extrapolation in ArcScene in Pennsylvania, United States

As the geothermal potential is visualized in three dimensions in ArcScene, aside from the quantitative results that could have been obtained from the data analysis of the temperature profiles in the well logs, the increase of temperature along depths of the boreholes became qualitatively more apparent as the general temperature increase beyond 1,000 meters beyond 20 Celsius can be easily observed - not enough for enhanced geothermal system (EGS), but more than adequate for considering using the geothermal heat for heating rather than power generation. But exactly how much heat can be generated from the 17,467 wells? It is important to identify the available heat that can be harnessed from the boreholes.

3.2 Identifying the available heat

To estimate the supply temperature from boreholes, three cases were established based on different assumptions were used to cover the industry convention, academic estimation and ideal production conditions: For Case 1, the heat extraction rate from the boreholes was assumed to be 50W/m, which would allow the calculation of the flow rates for different boreholes. Case 2 builds on the estimation of the heat extraction from the geothermal heat flow estimation from Pollack et al. at 87 MW/m 2 to obtain the temperature available from boreholes with the flow rates obtained from Case 1. Case 3 then combines the assumptions from Case 1 and 2 with the 2Sol Coaxial Borehole Heat Exchanger from 2Sol and propose an idealized model that idealize the temperature extracted from the boreholes. The accumulated resulting available heating power can be found in Table 1.

	Case 1	**Case 2**	**Case 3**
Heat Extraction Rate	50W/m	87W/m^2	87W/m^2
Heat Exchanger Type	Double U-Tube	Double U-Tube	2Sol CoAxial
Flow Rate (L/s^{-1})	7	7	7
Total Heating Power Available (Q_{tot} in GW)	2.47	0.61	0.05

Table 1: Assumptions used to estimate supply distances for three different cases

The available heat numbers are then put into ArcMap for spatial analysis to identify the suitability of the different estimation methods as well as the temperature availability at ground surfaces using the volumetric flow rate and return water temperature as suggested by[7]. We may therefore obtain the heat map of Pennsylvania for the three different cases under the scenario of supplying different temperatures across different counties as shown in Figure 2. This can be used to further analyze the potential of heat supplied to specific households using the overlap with demographic map. To estimate the supply distances, a number of assumptions were made to obtain reasonable accuracy of estimations. As the boreholes would provide up to 13.25 kW of heat, the distribution pipes were assumed to be of a medium sized 80 mm nominal distribution pipes buried with a ground temperature of 8 Celsius. The media pipes are assumed to be placed vertically with the return pipe located closest to the group surface, giving lower heat loss comparing to having the forward pipe on tops or horizontal setup. Assuming the thermal conductivity to be 0.0265 W/(mK), which would give an average heat loss of 18.08W/m according to [4] from Danfoss, which is consistent with [5].

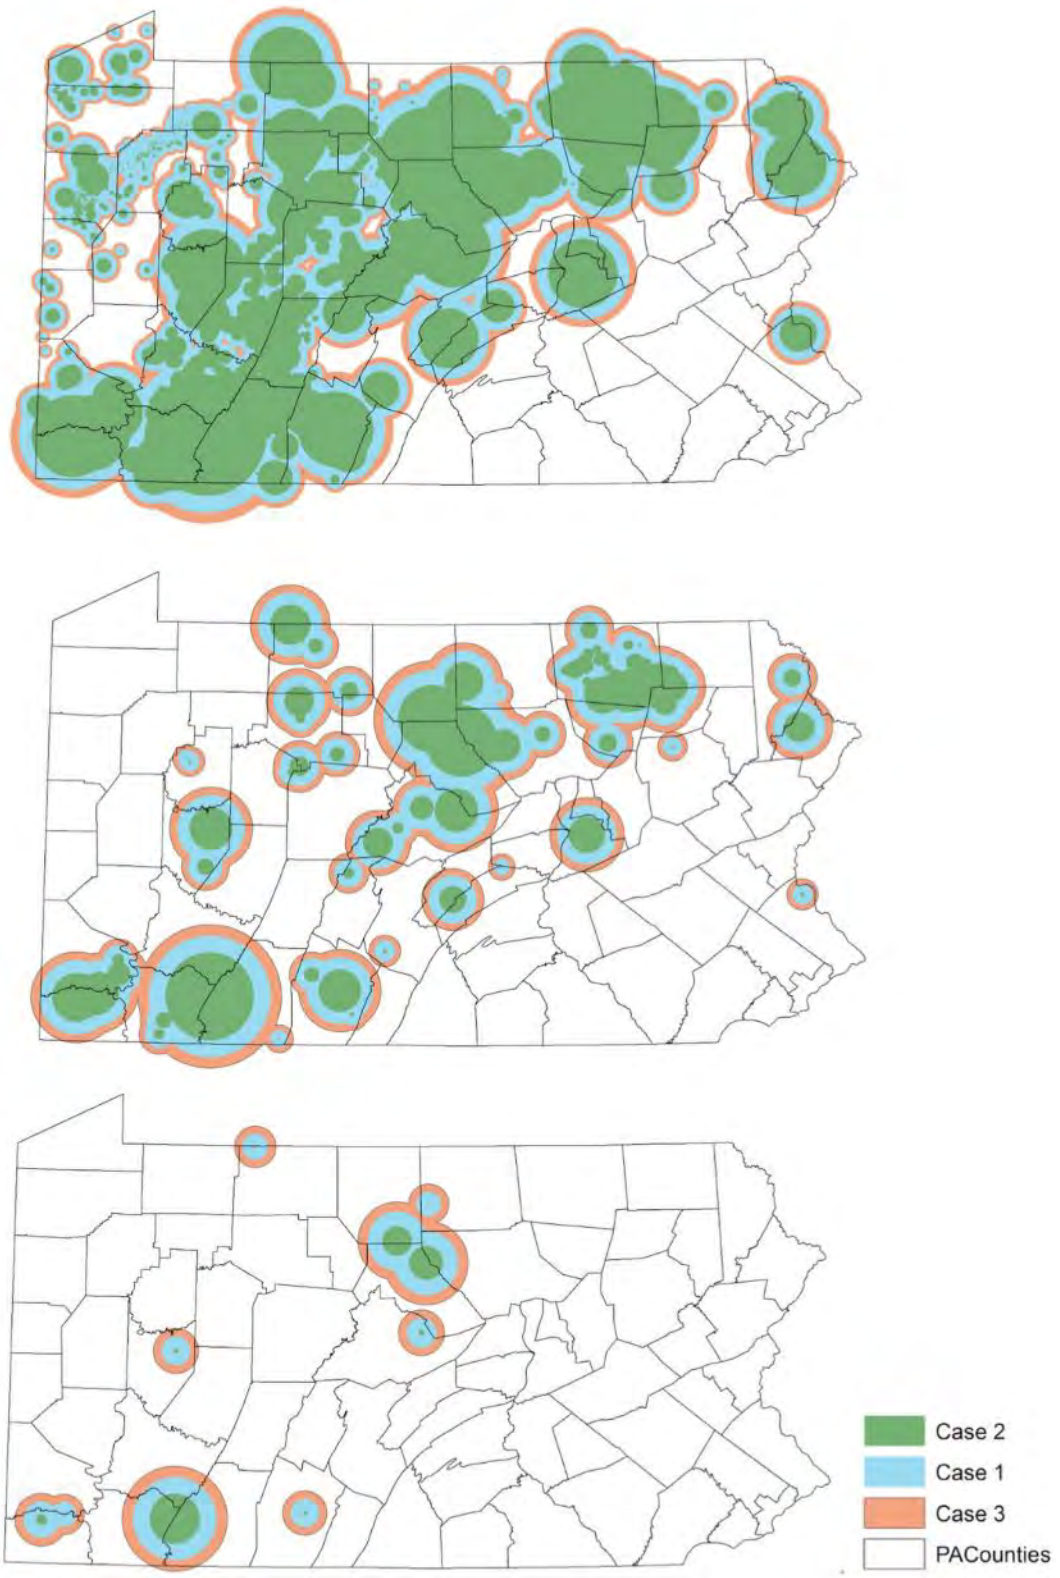

Figure 2: Coverage of supply temperature at 17 ˚C for heat pump assisted heating (top), 30˚C for LowEx direct district heating (middle) and 45 ˚C for direct district heating(bottom)

3.3 Estimating households covered

To better understand the scope of the problem, the demographic profile of Pennsylvania from the 2010 US census is used to compare against the supply distances from Case 2 to determine the possibility of coverage of the supplied areas. Of the total households of 4,777,003 in Pennsylvania, the total amount of house- holds that can be supplied with different temperature availabilities are therefore determined as indicated in Figure 3:

Figure 3: Potential households coverage map using different supply criteria assuming Case 2 scenario.

To put it into a more quantitative interpretation, the information in Figure 3 can be summed up into Table 4.3 as the following:

Supply Temperature (˚C)	17	30	45
Percentage of Total Households (%)	858,487	199,019	15,043
Primary Energy Saved (TBTU)	30.3584	6.78	0.53
Million Dolalrs Saved (Million US$)	632.458	141.25	11.04

Table 2: Comparison of performance under three supply criteria assuming Case 2 scenario.

4. RESULTS AND ANALYSIS

Using simplified assumptions on the power output from the boreholes and the heat loss along assumed distribution lines, it is estimated that using one-fifth of the boreholes (once they are depleted of oil/gas) available in Pennsylvania, up to 17% of the population of Pennsylvania can be supported using small-scale heat pumps, or a 5% of households can be heated without any additional costs of electricity using LowEx district heating. This is a preliminary investigation done to estimate the scope of the project so a few assumptions were made to sim- plify the analysis, and require further analysis. Further research would include and not limit to: More refined modeling of the distributional losses along the pipelines to provide better power generation and electricity costs estimates such that better return of investment (ROI) can be obtained; better sub-surface ex- traction estimation techniques that is more tolerant towards different subsurface geological conditions. It would also be valuable to include considerations of the costs that will incur to layout the distribution pipelines to obtain a reasonable ROI for the consideration of investors as well as local authorities.

Despite these limitations, the supply range that was achieved in this paper does come from a mere fifth of all boreholes that are currently active in Pennsylvania. With the increasing number of boreholes that are to be developed in the Marcellus Shale, this number could be continuously on the rise. It is important that we continue to look for means to benefit from the wells beyond production and estimate the potential that is buried underground to gain access to free heat while ensuring no fugitive emissions are escaping from the abandoned wells.

ABSTRACT

The present study deals with the performance assessment of a building integrated photovoltaic (BIPV) system through exergoeconomic analysis method. The system was installed at Yasar University in Izmir, Turkey within the framework of a EU/ FP7 funded project, the so-called REELCOOP (REnewable ELectricity COOPeration). Some preliminary experimental, modelling and numerical simulation studies have been performed by a research team from the University of Reading, which is one of the partners. Accordingly, the best design was chosen for the BIPV system to be installed at Yasar University. The PV glass was designed and manufactured by another partner, Onyx Solar, with glass/ glass configuration and mono-crystalline PV technology, through 6"(156 mm) pseudo-square cells. The BIPV system consists of a total of 48 Crystalline Silicon (c-Si) modules in 4 rows and 12 columns, with a gap of 150 mm between the modules. The façade area is totally 57.6 m^2 with a cell area of 42.8 m^2 while the total peak installed power is 7.44 kW with a peak power per PV unit of 155 W_p. Exergoeconomic evaluation methodology is a combination of exergy analysis and economic aspect analysis. Based on the literature survey, some limited studies on exergetic assessment of BIPV/ T (PV/ Thermal) systems have been done while no studies on exergoeconomic analysis and evaluation of a BIPV system using long term actual operational data have appeared in the open literature to the best of the authors' knowledge. This was the primary motivation behind this contribution.

In this study, the BIPV system was introduced first. The exergy, cost, energy and mass (EXCEM) method was then applied to the BIPV system considered. Finally, the results obtained were presented. Exergoeconomic parameters based on energetic and exergetic terms range from 0.001 to 0.714 W/ €, and 0.001 to 0.664 W/ €, with daily average values of 0.315 and 0.293, respectively.

Keywords: exergy, exergoeconomic, building integrated photovoltaic, BIPV, sustainability

1. INTRODUCTION

Photovoltaic (PV) technology is rapidly-growing compared to other renewables. There are various organizations worldwide, which support the research and development of PV technologies for improving efficiency and reliability and lowering manufacturing costs in order to make solar electricity cost-competitive with other sources of energy.

According to the International Energy Agency, the share of renewables in electricity generation is expected to rise up to 25% of the total power generation in 2018. PV generated electricity is also estimated to double its share by 2018 compared to 2011. In this regard, Building Integrated PV (BIPV) systems play an important role in generating electricity. BIPVs are defined as PV modules, which can be integrated in the building envelope (into the roof or façade) by replacing conventional building materials (tiles e.g.). Therefore, BIPVs have an impact of building's functionality and can be considered as an integral part of the energy system of the building.

Performing exergy analysis of various energy-related systems has been very popular in recent years. Exergy may be defined in various ways and indicates the maximum work potential of a system under certain conditions. All systems with different conditions from the environment contain exergy. Exergy analysis aims at quantitatively evaluating the exergy destructions and losses within a system. Instead of energy analysis, exergy analysis results in a more clear and true values when examining thermodynamic systems. It should be noticed that exergy is always evaluated with respect to a reference (dead) state, which is arbitrary.

Exergoeconomics (thermoeconomics) is a combination of exergy analysis with economic constraints). The main aim of exergoeconomic analyses is to provide cost-effective ways for improving the performance of energy systems. In the scientific literature, different exergoeconomic approaches can be seen while exergy, cost, energy and material (the so-called EXCEM) method proposed by Rosen and Scott in 1987 is one of them. Within the framework of a European Commission project, the so-called REELCOOP, it is aimed at significantly enhancing research cooperation and knowledge creation on renewable electricity generation, involving Mediterranean partner countries, while at the same time developing and testing new renewable electricity generation systems. One of three novel prototype systems to be developed and tested in the project is prototype 1, which is related to a BIPV system. In this context, based on some preliminary experimental, modeling and numerical simulation studies done at the University of Reading, the best design was chosen for the BIPV system to be installed at Yasar University. The PV glass was designed and manufactured by Onyx Solar with glass/ glass configuration and mono-crystalline PV technology, through 6“(156 mm) pseudo-square cells.

In this context, the main objective of this contribution is to analyse a BIPV system considered here by using the EXCEM method, which is used to investigate costs and thermodynamic losses for devices in energy systems.

2. LITERATURE REVIEW

Since the study deals with the exergoeconomic analysis, which is a combination of exergy and economics, previous exergetic and exergoeconomic studies on BIPV systems are briefly reviewed in the following.

As far as studies on exergetic analysis and assessment of BIPV systems are concerned, Joshi et al. studied the performance characteristics of a PV and PV/T system based on energy and exergy efficiencies, respectively. They proposed relations for the energy, power conversion (electrical), and exergy efficiency of a PV system. Abid and Hepbasli assessed the exergetic performance of PV modules of a PV-wind hybrid system installed on the roof of Mechanical Engineering Department, King Saud University Riyadh, Saudi Arabia. There were twenty polycrystalline PV panels with a dimension of 0.9 m x 1.48 m and a rated power output of 200 W at a rated voltage of 24 V. The energy efficiency values varied between 34.09% and 52.14% while the corresponding exergy efficiencies ranged from 0.16% to 15.23%, respectively. Vats and Tiwari evaluated energetic and exergetic performance of a building integrated semitransparent photovoltaic thermal system integrated to the roof of a room. They compared six different PV modules through energy and exergy efficiencies. They concluded that the crystalline silicon (c-Si) PV modul was suitable for producing electrical power while the thin amorphous silicon (a-Si) PV cell was suitable for space heating. Saloux et al. analyzed PV and PV/ T systems using the exergy method. They defined electrical current and voltage reduction factors and used to express the exergy as well as its destruction in a PV/ T system. Shukla et al. assessed the performance of building integrated semitransparent photovoltaic modules for roof and facade in terms of energy, exergy and power generation. The experimental setup consisted of two modules, each of 75W rating, which was conducted on a clear sky day at roof and façade of Energy Centre building, MANIT Bhopal, India. The energy efficiency varied between 11- 18% at roof and 13-18% at facade throughout the day. The maximum electrical efficiency values of the modules were 85% on the roof and 72% at the façade. Shukla et al. also reviewed studies on energy and exergy analyses of building integrated photovoltaic modules to evaluate the electrical performance, exergy destruction and exergy efficiency with photonic method. They concluded that exergy assessment of BIPV systems was highly dependent on the daily solar radiation and radiation intensity while the building integrated photovoltaic module temperature had a great effect on the exergy efficiency.

As far as exergoeconomic analysis of BIPV systems is considered, no study utilizing the actual operational data has appeared in the open literature to the best of the authors’ knowledge although there is only one study on the exergoeconomic and enviroeconomic analyses of semitransparent and opaque PV modules based on different kinds of solar cells. In this regard, Gaur and Tiwari proposed the modified EXCEM method. They calculated annual electricity and net present values for the composite climatic conditions of New Delhi, India. It was reported that irrespective of the solar cell type, the semitransparent PV modules shown higher net energy and exergy loss rates compared to the opaque ones. Among all types of solar modules, the one based on c-Si had minimum energy and exergy loss rate values.

3. SYSTEM DESCRIPTION

The BIPV system installed at Yasar University, Izmir, Turkey has a total peak power of 7.44 kW and consists of a total of 48 Crystalline Silicon (c-Si) modules in 4 rows and 12 columns, with a gap of 150 mm between the modules and the wall, as illustrated in Figure 1. There are shading effects that were considered, as the Southeast façade lies on the lower part of the building. The façade area is totally 57.6 m^2 with a cell area of 42.8 m^2 while the total peak installed power is 7.44 kW with a peak power per PV unit of 155 W_p. The peak power is reduced after the inverter and the balance of the system losses to 6.8 kW.

The installation of the BIPV system was completed on 8 February 2016 and since then, the performance of the system has been monitored through Sunny Portal while a total electrical energy of 3103 kWh has been produced as of 21 August 2016.

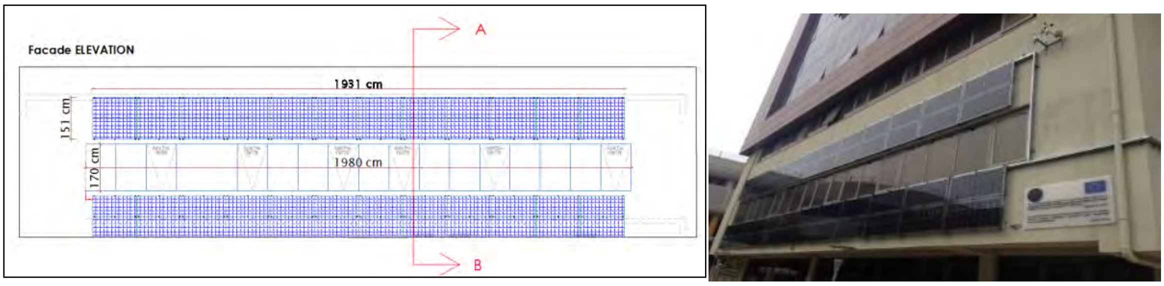

Figure 1: A schematic and picture of the BIPV system installed

4. ENERGY, EXERGY AND EXERGOECONOMIC ANALYSES

4.1 Energy analysis

Solar cell (or module) power conversion efficiency (η_{pc}) can be defined as follows [14,17]:

$$\eta_{mod} = \frac{V_{max} I_{max}}{GA} \qquad (1)$$

Equation 1

where V_{max} is the voltage at the maximum power, I_{max} is the current at the maximum power, G is the global irradiance (or solar radiation intensity), and A is the surface area.

The traditional linear expression for PV electrical efficiency is given as [17-20]

$$\eta_{T,elec} = \eta_{ref}[1 - \beta_{ref}(T_{mod} - T_{ref})] \qquad (2)$$

Equation 2

with

$$\beta_{ref} = \frac{1}{(T_0 - T_{ref})} \qquad (3)$$

Equation 3

where η_{ref} represents the efficiency of the PV module under standard test conditions, T_{ref} is the reference temperature (°C), T_{mod} is the PV module temperature (°C) and T_0 is the high temperature at which the PV modules electrical efficiency drop to zero. According to the manufacturer information, the temperature coefficient ($ß_{ref}$) is equal to 0.0045 K^{-1}.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

In addition, the influence of the total irradiation level on the electrical efficiency of the PV modules is considered using the following equation.

$$\eta_{irr-A} = \alpha\eta_{ref} \qquad (4)$$

Equation 4

where η_{irr-A} stands for the electrical efficiency of the module under irradiation level equal to 'A' (W/ m^2) and the PV module temperature equal to 25 °C. According to the manufacturer information, the irradiation coefficient (α) values are as follows: 92, 97, 99, 102 and 100% for irradiation levels of 100, 200, 400, 700 and 1000 W/ m^2, respectively.

4.2 Exergy analysis

In the literature, there are various approaches to exergetic assessment of the BIPV modules, as reviewed in Ref. while the relations used in the calculations are presented as follows [8,9,17,18]:

Since electricity and work are the same on energy and exergy bases, the overall energy and exergy efficiencies for such devices are the same.

The exergy efficiency of a system can in general be given as

$$\psi = \frac{\dot{E}x_{PV}}{\dot{E}x_{sol}} \qquad (5)$$

Equation 5

where $\dot{E}x_{PV}$ is the exergy rate of the BIPV system, which is mainly electrical power output of the system. Since the thermal energy gained by the system during the operation is not desirable in case of PV system, this becomes a heat loss to the system and hence needs to be subtracted in order to calculate the exergy of a PV system.

$$\psi = \frac{V_{max} I_{max} - \dot{E}x_Q}{\dot{E}x_{sol}} \qquad (6)$$

Equation 6

with

$$\dot{E}x_Q = \dot{Q}_{c,r}(1 - \frac{T_{amb}}{T_{mod}}) \qquad (7)$$

Equation 7

$$\dot{E}x_{sol} = GA\Psi_{ex,sol} \qquad (8)$$

Equation 8

where $\dot{E}x_{sol}$ is the exergy rate from the solar irradiance in W/ m^2, $\dot{Q}_{c,r}$ is the convective and radiative heat transfer coefficient from photovoltaic cell to ambient, which is found using

$$\dot{Q}_{c,r} = h_{ca}A(T_{mod} - T_{amb}) \quad (9)$$

Equation 9

with

$$h_{ca} = 5.7 + 3.8V_{wind} \qquad (10)$$

Equation 10

where V_{wind} is the wind velocity (m/ s).

$\Psi_{ex,sol}$ is the exergy of solar radiation (thermal radiation) and may be calculated by using one of the following relations, respectively [21-24]:

$$\Psi_{ex,sol,Petela} = 1 + \frac{1}{3}\left(\frac{T_0}{T_{sol}}\right)^4 - \frac{4}{3}\frac{T_0}{T_{sol}} \qquad (11a)$$

Equation 11A

$$\Psi_{ex,sol,Spanner} = 1 - \frac{4}{3}\frac{T_0}{T_{sol}} \qquad (11b)$$

Equation 11B

$$\Psi_{ex,sol,Nobusawa} = 0.95 \qquad (11c)$$

Equation 11C

$$\Psi_{ex,sol,Jeter} = 1 - \frac{T_0}{T_{sol}} \qquad (11d)$$

Equation 11D

where T_{sol} is the solar radiation (sun) temperature with 6 000 K.

By substituting $\dot{E}x_Q$ in Eq. (7) (along with Eqs. (9 and (10)) and $\dot{E}x_{sol}$ in Eq. (8) (along with Eq. (11a)) into Eq. (6), the exergy efficiency of the BIPV system becomes

$$\psi = \frac{V_{max} I_{max} - A(5.7 + 3.8V_{wind})(T_{mod} - T_{amb})[1 - (T_{amb}/T_{mod})]}{GA[1 + \frac{1}{3}(\frac{T_0}{T_{sol}})^4 - \frac{4}{3}\frac{T_0}{T_{sol}}]} \qquad (12)$$

Equation 12

4.3 Exergoeconomic analysis

For a thermal system operating normally in a continuous steady-state steady-flow process mode, the energy and exergy loss rates can be obtained through the following equations [7,25]:

$$\dot{L}_{en} = \sum_{inputs} \dot{E} - \sum_{products} \dot{E} \qquad (13)$$

Equation 13

and

$$\dot{L}_{ex} = \sum_{inputs} \dot{E}x - \sum_{products} \dot{E}x \qquad (14)$$

Equation 14

where the summations are over all input streams and all product output streams. For the BIPV system considered, the following energy and exergy loss rates may be written [15]:

$$\dot{L}_{en} = \Sigma \tau_{glass} \alpha_{mod} \beta_{mod} G(t) A_{mod} - \Sigma \eta_{mod} G(t) A_{mod} \qquad (15)$$

Equation 15

$$\dot{L}_{ex} = \Sigma \tau_{glass} \alpha_{mod} \beta_{mod} G(t) \Psi_{ex,sol,Petela} A_{mod} - \Sigma \eta_{mod} G(t) \Psi_{ex,sol,Petela} A_{mod} \qquad (16)$$

Equation 16

where τ_{glass} is the transmitivity of the glass, the absorption factor of the module and β_{mod} is the packing factor (the fraction of absorber plate area covered by the solar cells) of the module.

Another parameter, $\dot{R}$ is defined as the ratio of thermodynamic loss rate $\dot{L}$ to capital cost K as follows:

$$\dot{R} = \dot{L} / K \qquad (17)$$

Equation 17

The value of *R* generally depends on whether it is based on energy loss rate (in which case it is denoted $\dot{R}_{en}$), or exergy loss rate ($\dot{R}_{ex}$), as follows:

$$\dot{R}_{en} = \dot{L}_{en} / K \qquad (18)$$

Equation 18

and

$$\dot{R}_{ex} = \dot{L}_{ex} / K \qquad (19)$$

Equation 19

Values of the parameter $\dot{R}$ based on energy loss rate, and on total, internal and external exergy loss rates are considered. In investigating sets of $\dot{R}$ -values, maximum ($\dot{R}_{max}$), minimum ($\dot{R}_{min}$), mean ($\dot{R}_{m}$), standard deviation (SD($\dot{R}$)) and coefficient of variation (CV($\dot{R}$)), which is the ratio of standard deviation to mean, are considered.

5. RESULTS AND DISCUSSION

The daily power generation distribution of the BIPV system on 23 July 2016 is illustrated in Figure 2 with respect to irradiation. As can be seen from the figure, the daily power generation is in accordance with the irradiation profile.

Variations of the average BIPV surface temperature and the ambient temperature during the day are plotted in Figure 3 where the maximum power of 434 W/ m² is obtained at 10 p.m while a power of 2864 W is seen at 10.15 p.m.

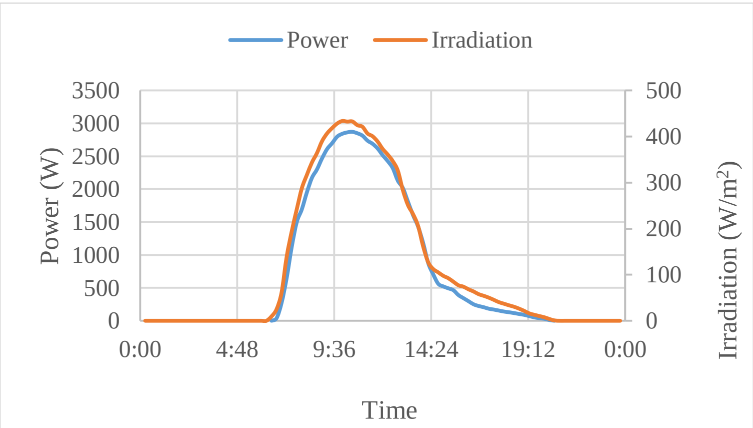

Figure 2: Daily power generation and irradiation distribution on 23th of July

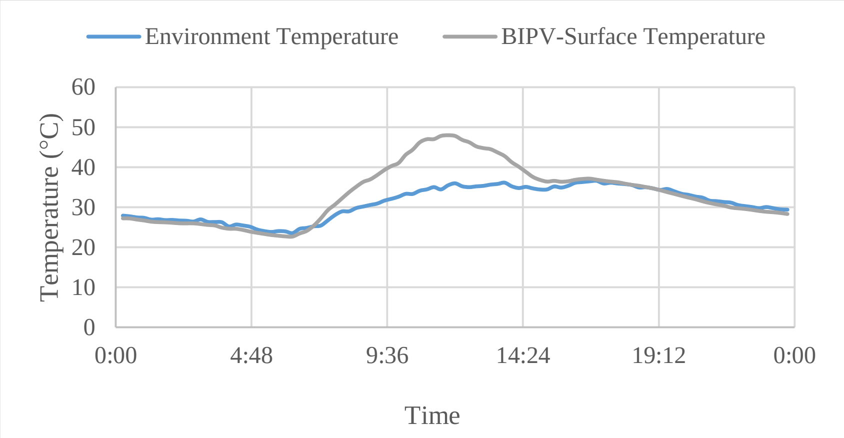

Figure 3: BIPV surface temperature vs. ambient temperature

Figure 4 shows the variation of power conversion and exergy efficiencies based on cell and module (total) areas. It is clear from the figure that there is a good agreement between the power conversion and exergy efficiencies while the difference in the efficiencies based on cell area and module area are about 4%. Exergy efficiency values range from 7.26% to 12.91% and 9.78 to 17.37 based on total and cell areas over a period of 7 a.m. to 8 p.m., respectively.

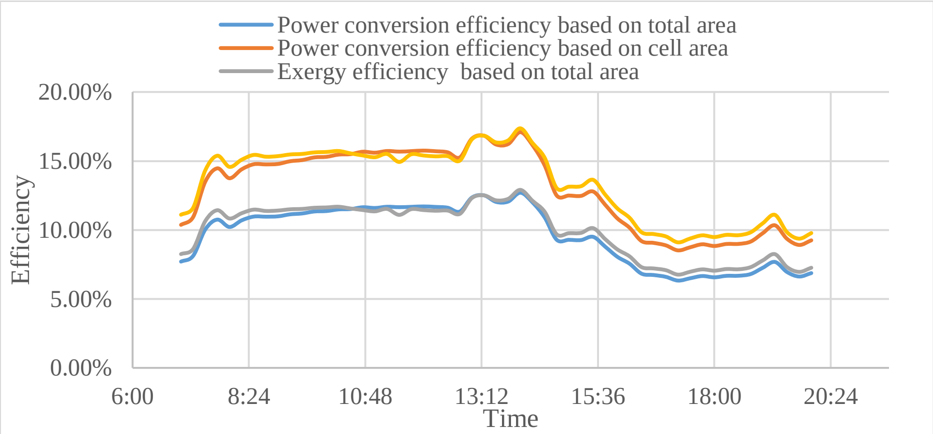

Figure 4: Energy and exergy efficiency distributions

Exergoeconomic parameters based on energetic terms ($\dot{R}_{en}$) and exergetic terms ($\dot{R}_{ex}$) are calculated and the results are shown in Figs. 5 and 6. As can be seen from the figures, $\dot{R}_{en}$ lies in the range of 0.001 – 0.714 W/ € with a daily average of 0.315 W/ € while $\dot{R}_{ex}$ varies between 0.001. and 0.664 W/ €, with a daily average of 0.293 W/ €.

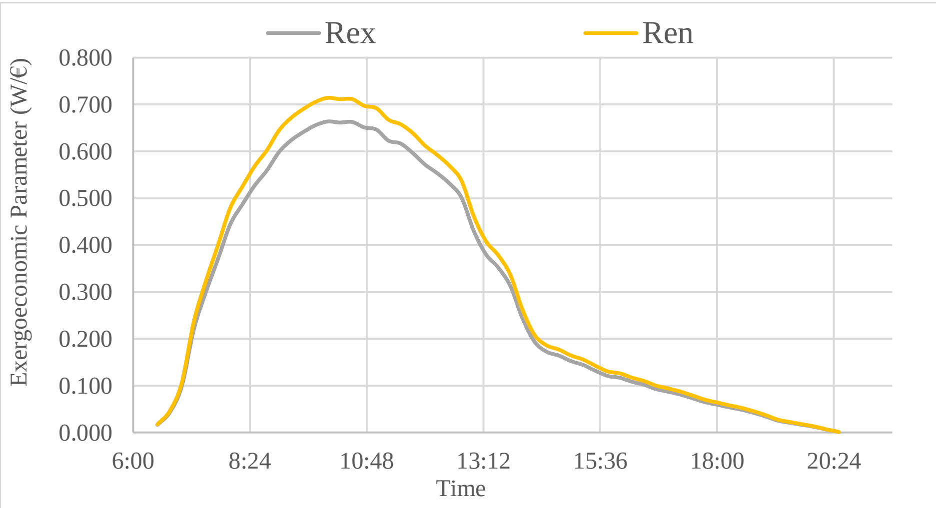

Figure 5: Daily variation of exergoeconomic parameter based on energy and exergy terms

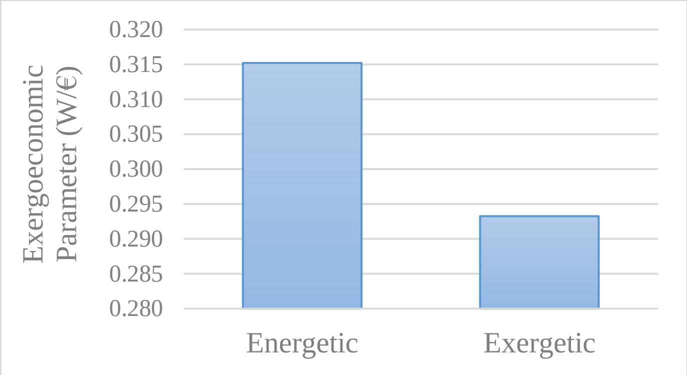

Figure 6: Comparison of the daily averages of energy and exergy based exergoeconomic parameters

6. CONCLUSIONS

In this study, a BIPV system installed at Yasar University, Izmir, Turkey, which also achieved TS EN ISO 50001:2011 (Energy Management System Standard) certification as the first university in Turkey on 5 January 2016, was considered. The performance of the BIPV system was evaluated using an exergy-based economic analysis methodology, which is based on the quantities exergy, cost, energy and mass (the so-called EXCEM method).

The main conclusions we have drawn from the results of the present study may be summarized as follows:

- Exergy efficiency values are obtained to be in the range of about 7.3% to 12.9% and 9.8 to 17.4 based on total and cell areas over a daily period considered, respectively.
- Exergoeconomic parameters based on the energetic terms are calculated to vary between 0.001 and 0.714 W/ € with a daily average of 0.315 W/ € while those based on the corresponding exergetic terms are in the range of 0.001 to 0.664 W/ €, with a daily average of 0.293 W/ €.
- The authors expect that this study would be beneficial to the researchers, designers and manufacturers, who are interested in applying exergy-based economic analysis methods to BIPV systems.

ACKNOWLEDGMENTS

The presented work was developed within the framework of project "REELCOOP-Research Cooperation in Renewable Energy Technologies for Electricity Generation", co-funded by the European Commission (FP7 ENERGY.2013.2.9.1, Grant agreement no: 608466). The authors would also like to thank Prof Andrew Baldwin for his kind invitation to publishing this paper under the title "*SBE16 Top Papers*" in the Conference Proceeding of WSBE17 Hong Kong.

ABSTRACT

Purpose - Our research purpose is developing the Small Commercial Building Design Model (SCBDM). Our design model should be adopted for small-scale commercial stores (24-hour convenience store) in order to achieve to find efficiency of all installed technologies, energy use and demand, energy conservation and energy creation. Our research target of small size buildings have different environmental situations, so every project must select some common and different technologies.

Development/ Methodology / Approach - All of the developed and designed projects have already been built and their operations are running without facility manager at each location. All of the pilot sustainable stores have visualization systems and AI control systems that provide optimized indoor temperature and humidity, IAQ, the control of HVAC devices, lighting, and their 24-hour optimization by machine learning. This paper displays both the common and locally integrated sustainable technologies implemented in the pilot projects, illustrating their economic benefits through actually monitored energy conservation and degrees of the usage of renewable energy.

Findings -

- Developed SCBDM (small commercial building design model) could be arranged to give conditions and scope of sustainable technologies. The model needs a feedback information system as EMS.
- We show three EMS (energy management system) levels for energy conservation and energy creation.
- Key developed technologies include information feedback EMS, AI control systems, and selection of design models arranged and organized by sustainable technologies.

Originality/ value - Designed and developed AI control system achieves energy reduce and unman system control.

Keywords: sustainable, IoT (internet of things), machine learning, AI (artificial intelligence), EMS (energy management system), energy conservation, environment efficiency, optimized control, CO_2 reduction

1. INTRODUCTION/ TECHNICAL AND SOCIAL BACKGROUND

There are a large number of small-scale commercial buildings, ranging in size from 200m^2 to 300 m^2 in Japan and in Asia. In addition to these, the number of 24-hour operating stores are increasing in large cities as well as in small suburban towns. However, most of these stores do not use sustainable technologies, renewable energy or control systems that are suitable to their environmental contexts.

For example, in regards to existing EMS most large-scale buildings have some sort of EMS, but most small-scale buildings do not. However the importance of BESM (building energy management system) is quickly being recognized, and the market for these systems is expected to grow to 155,300,000,000 Japanese yen by 2020. This prediction[] is a growth of 70.8% (2013 ratio) for the market scale.

1.1 Research questions and purpose/ Design and development pilot model buildings in Japan

Our research questions the applicability of sustainable technologies to small buildings with large energy consumptions, aiming to develop a “Small Commercial Building Design Model (SCBDM)” that achieves high-economic performance and high-efficiency energy use through integrating to various locations.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The development of SCBDM has been planned and built over a nine-year collaboration between the construction division of Lawson- s Japanese convenience store company that operates about 9000 24-hour stores in Japan - and the University of Tokyo.

All of the developed and designed projects have already been built and are running without facility manager at each location. All of the pilot sustainable stores have visualization systems and AI control systems that provide optimized indoor temperature and humidity, IAQ, the control of HVAC devices, lighting, and 24-hour optimization by machine learning. This paper displays both the common and locally integrated sustainable technologies implemented in the pilot projects, illustrating their economic benefit through actually monitored energy conservation and the degree of usage of renewable energy.

2. RESEARCH PURPOSE

Our research purpose is developing the Small Commercial Building Design Model (SCBDM). Our design model should be adopted to small-scale commercial stores and achieve to grape efficiency of all installed technologies, energy use and demand, and energy conservation and energy creation.

2.1 Arranging each attribute related to energy conservation and energy creation

Before comparing the design modeling, we arranged the conditions for each sustainable store and each attribute that relate to energy conservation and energy creation. All equipment and systems are optimized for energy efficiency by using visualization and AI control systems that we have developed. The targets that should be optimized for energy efficiency are HVAC, refrigerator units, and energy creation equipment and system (PV, solar heating panel, biomass generator, etc.) Table 1 is giving conditions and attribute for our sustainable store design model.

Items		contents
Giving conditions of each site	Climate area code for energy conservation	I-VI areas code (old codes) 1～8 areas code (new codes) Cold and hot district
	Store building type	Tenant type
		Independent type
	Direction	Front direction
	The surrounding circumstances	The physical relationship of the neighborhood
	The store area	The total floor area (the air conditioning area), the parking area
	Business hours	24 hours per 365 days
	energy classification	Electricity (gas and others)
Energy conservation and Energy creation	Building technologies of building	Insulation (envelope)
		Solar radiation control (canopy)
		Solar radiation control (window)
		Daylight utilization

		Optimized cleaning and maintenance
	User's actions	User actions for energy conservation

Table 1: Related giving conditions and attribute for sustainable items

2.2 Research themes and solution policies

Almost all typical small commerce buildings are not related to sustainable items. Most buildings only focus on cold district style. Table 2 shows three R & D items and solutions for sustainable energy conservation and energy creation.

NO	Main R & D items	Solutions (Methodology)
1	Information of given conditions is not utilized for energy conservation and creation technologies	R & D, EMS for feedback Information about adoptable technologies in variable location and operation conditions
2	Nobody finds M & E system condition and efficiency in operational time.	R & D, monitoring energy conservation and evaluating efficiency
3	Stake holders don't have about external environmental information, maintenance information and building user information.	R & D EMS grasps external environmental information, maintenance information and building user information for steak holders.

Table 2: R & D items and solutions

3. RELATION BETWEEN ATTRIBUTES OF THE STORE AND THE ENERGY SAVING EFFECT OF ENERGY CONSERVATION AND THE ATTRIBUTES OF ENERGY CREATION

Table 3 shows the differences of given conditions, attributes of energy creation, and the energy saving effects. The leftmost line describes 'the typical store'. The next column describes 'the typical store with visualization,' which includes existing stores that have installed visualizations systems. 'The typical store with visualization and optimized control' includes existing stores that have installed both visualization systems and optimizing systems for existing typical equipment. Finally, 'the sustainable developed store' column describes new stores that are planned and designed to include installed sustainable technologies. All projects and the design models ware developed between 2008 to 2015.

3.1. Energy conservation effects through visualization systems in existing stores

The visualization system gives us real time information about energy use, outdoor and indoor temperature and humidity, the operation condition of M & E equipment and systems situation. We understand by installing a visualization system to a typical existing store, we were able to reduce the total energy use by ▲ 3～5%.

Every stuff member has control of the settings for indoor temperature. Cleaning the filters of the air-conditioning system reduces air-conditioning energy by ▲ 9%. Controlling the indoor and equipment lighting illuminance is found to reduce lighting energy by ▲ 42% (about ▲ 17kwh/day). Controlling daylight and lighting shows us an important technology for energy conservation.

3.2. Energy conservation effects of using a visualization system and an optimizing control system

In order to observe the effects of a visualization system and an optimized control system (AI control system), we installed the systems in an existing store and its M & E equipment. We targeted the interior and exterior lights, HVAC, settings of AC temperature, refrigeration temperature, and demand control of electric power. The optimized controlling of M & E in an existing building is able to reduce total energy use by ▲ 10.3%. In addition, controlling

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

the solar radiation, and natural ventilation gives us a ▲ 14% reduction of total energy use. This process includes analyzing information from sensing data and feedback control.

3.3. Sustainable store effect

Location, circumstance, district, site area, and direction for architecture is very important for energy conservation and creation. Our R & D and design model achieve efficiency and a reduction of ▲ 30～70% of total energy use.

All existing small commercial stores and small 24-hour stores do not have maintenance staff, necessitating our design model and AI control system.

4. THE NECESSITY OF A MULTI-PURPOSED INFORMATION MODEL

Our visualization system as an information system could get variable information from buildings by using local sensors. The sensor cost and data storage cost become much cheaper after one decay. We can monitor and control the building despite being far from the control center. The most important information is related to each building's targets and how to get high quality information for our management and stakeholders. Table 4 shows us EMS scope, targets, and purpose.

All store level EMS are able to compare the amounts of energy use daily, monthly, and annually. The construction division member of headquarters could understand and control the average levels of energy. Store level EMS is able to compare the energy use of each store as it relates to characteristics of the space, operation, maintenance conditions. The EMS for each technology is also able to understand energy use and efficiency of each equipment and systems under real site operation.

Scope and Level of EMS	Targets and purpose
EMS for management of All store in Japan	Compare operation efficiency and amount of energy
EMS for each Stores	Information below Space/ service/ operation/ maintenance/energy use environmental issues
EMS for each technology	Electric equipment and systems/ HVAC equipment and systems/ Energy creation equipment and systems/ Control system/ Aging degradation

Table 4: Scope and level of EMS relate to each targets

4.1 Information model of the small commerce store and its design model and decision making model by using real time data

Figure 1 shows the basic information model and the flow (process).

First, we retrieve the real data (data collection) by using sensors. Using this information, we form an analysis.The quality of the interpretation is highly relevant to the quality of information gathered. Action and control are automatically selected.

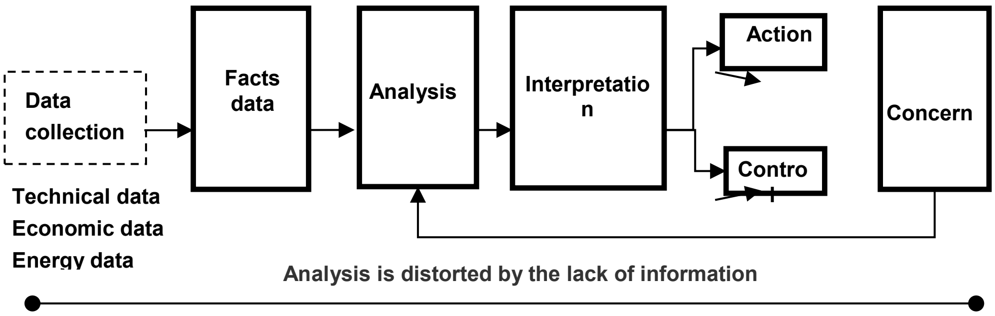

Figure 1: Well informed decision making model by using quantitative information

5. THE OUTCOME OF THIS RESEARCH AND DEVELOPMENT

5.1 The case study of sustainable store in cold direction (No.1)

This building was completed in November of 2013, and is the first of its kind. It has a storage system for snow, which generates air-conditioning energy. It achieved a 50% reduction in energy use compared to a typical store of similar size. Table 5, Figure 2 shows us the main sustainable systems.

Figure 2: Installed design system (description)

NO	Items	Contents
1	Snow storage cold and hot air-condition system	In winter. The snow storage the local snow in storage tank and use the energy in summer. The storage tank is a recycle container
2	Solar heating system for hot water supply	Hot water is using floor heating near in the cushier area.
3	Geothermal heat pump system	Geothermal heat pump is for radiation panel and FCU system.
4	PV panel on the roof	Generation and energy storage, and disaster prevention electricity
5	High insulation glass	Low-E glass windows in the front the store
6	The high insulation of the roof	High performance insulation for roof and wall materials
7	LED lighting and illumination control	LED and AI day light and schedule control
8	Energy saving type design refrigerator	High insulation, protect freezing control, window heater control
9	Refrigerator with natural ventilation	Developed refrigerator system using natural ventilation in winter
10	Water splay for refrigerator outdoor compressor	Storage snow water use as cooler splay for refrigerator in summer
11	Frozen case use CO_2 refrigerant	Non-Freon CO_2 refrigerant and high efficiency system
12	AI control and energy management system	Automatic optimized control energy management system by using environmental sensors

Table 5: The main technologies and systems of sustainable store in cold direction

5.2 The case study of sustainable store (No.2)

This building was completed in November of 2014. It achieved a 60% reduction in energy use compared to a typical store of similar size (2010 average energy use ratio). Table 6, photo1～3 show us the main sustainable systems.

Photo 1: Designed technologies, the exterior of front side

Photo 2: Designed technologies, the interior

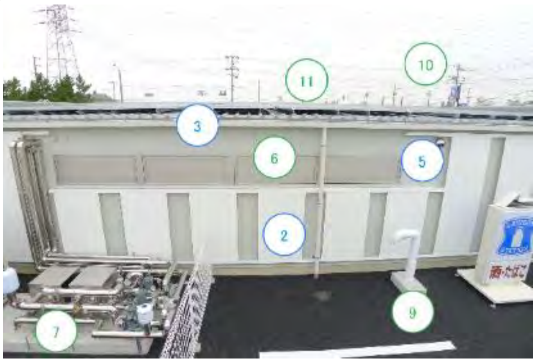

Photo 3: Designed technologies, the exterior of back side

NO	Items	Contents
1	Duplication of store front glass	Pair glass front and double skin with exhaust air system
2	Tent film style double skin system on the wall	Double skin is made from white tent texture. The developed double skin reflects solar radiation and cooling wall surface temperature.
3	PV panel and double skin protection solar radiation system on the roof	PV generator and double skin effect for the roof
4	Wall planting	The parts of envelope are planting with water splay. The wall temperature become cooling.
5	The high insulation of the roof and wall Prefabrication methodology	High performance insulation for roof and wall materials
6	Natural ventilation and optimizing air condition operation	AI control seasonal, outdoor temperature and humidity by opening and closing the windows for ventilation
7	Geothermal heat pump and air-condition system	Under grand temperature become almost 17℃. Geothermal heat pump system made cooling and heating energy for FCU and radiation panel.
8	Storage type radiation panel system	Heat storage type radiation cooling and heating system.
9	Earth tube system	Earth tube system getting outdoor air and under grand heating as fresh air for control indoor air quality.
10	Gravity ventilation system	Outside store signage pole became gravity ventilation system for natural ventilation.
11	PV and battery system	PV and battery is used with energy storage and electric power demand control.
12	Frozen case use CO_2 refrigerant	Non-Freon CO_2 refrigerant and high efficiency system
13	Dehumidification air conditioner	Dehumidification air conditioner control indoor air humidity.
14	LED lighting and illumination control	LED and AI day light and schedule control
15	AI control and energy management system	Automatic optimized control energy management system by using environmental sensors

Table 6: The main technologies and systems of sustainable store in cold direction

6. CONCLUSION/ FUTURE ISSUES

- Developed SCBDM (Small Commercial Building Design Model) could be arranged to give conditions and scope of sustainable technologies. The model needs a feedback information system as EMS.
- We find three EMS levels for energy conservation and creation.
- Key developed technologies include information feedback EMS, AI control system, and the selection of a design model arranged and organized by sustainable technologies.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

7. FUTURE ISSUES

- Showing our EMS feedback model technologies and its open protocol software.
- Getting as much information as possible about a store, and return the benefits to the building service, user services, and other stakeholders services.
- Reporting of the applied example to other building types.

Study on the Potential of Converting Former Military Bunkers into Energy Storage Facilities

Joachim SCHULZE[a]

[a] *Technical University Darmstadt, Germany, schulze@stadt.tu-darmstadt.de*

ABSTRACT

Building a sustainable future calls for a strong re-evaluation of energy production and consumption patterns. With the release of the so called 'energy concept' in 2010, the German government has made a clear commitment to sustainability, by officially anticipating a future energy supply system depending almost exclusively on renewable energy and utterly turning away from fossil energy carriers. The remodeling process involved will take decades and a number of defined issues are yet to be solved. Among others, dealing with the fluctuation of renewable forms of energy, such as sun and wind power, is one of the key challenges. Apart from the extension of the power grid, it is inevitable to provide capacities for energy storage to face this problem. These are able to buffer times when energy production exceeds or falls beneath the current demand. A more or less unnoticed approach is the possibility of reactivating unused building complexes to serve as medium scale storage units, in this case former military bunkers going back to the Second World War and the Cold War. Altogether about 3000 of these facilities still exist in Germany, of which many are vacant to the present day inter alia because their specifications don't match the requirements of residential or office use. Nevertheless, it is worthwhile to take effort in finding solutions to preserve these buildings since demolition is an elaborate task when dealing with walls up to three meters thick. Apart from that, the construction of new buildings can be prevented, which results in less energy consumption. The research covers the historical background of the bunkers in Germany and continues by defining relevant bunker types using cluster analysis. Finally, these bunker types are evaluated in terms of how their structural properties fit the requirements of two selected systems of energy storage.

Keywords: *conversion, military bunker, energy saving*

1. INTRODUCTION

For the next decades the German energy supply system will be undergoing a fundamental remodelling process. The so-called "energiewende" has officially been underway since the turn of the century and was further boosted by the nuclear catastrophe of Fukushima. The main goal is to become fully independent of fossil energy carriers like coal, gas or nuclear power and to rely solely on renewable forms of energy. This is a major step stone on the way to a sustainable future and the reason why the German government is taking great effort to support this endeavour. Amongst others, targeted funding is supposed to accelerate and support research in topics regarded as substantial for the success of the overall project. One of these thematic fields is energy storage. As stated in the abstract, energy storage facilities are needed to handle the discontinuous energy production of the renewable energy carriers, notably wind and sun power. A great deal of research in this field deals with raising the efficiency and the capacity of existing systems or developing new types of storage. In terms of size, the focus lies primarily on large-scale units in the range of several megawatt hours. But also small to mid-size plants can contribute to the overall need for storage capacity. In this case, apart from the option of constructing new buildings, it is worthwhile to examine the possibility of building conversion. Generally speaking, this can save resources, energy and help maintain buildings that are culturally or historically worth preserving. For a number of reasons the military building sector is of interest for this type of building transformation. First of all, Germany has a large stock of military facilities predominantly bunkers dating back to the Second World War and the Cold War. Numbers range at about 3000 preserved buildings. Secondly, these bunkers are equipped with a series of special structural properties such as exterior walls with a width of several meters, closed shell or large volume capacity that could meet the requirements of certain systems of energy storage. Finally, an existing conversion project in Hamburg demonstrates how a large-scale "flakbunker" erected in 1943 can be transformed into a thermal energy storage unit. It was part of the International Building Exhibition in Hamburg dedicated to the topic of future sustainable city development. Since completion in 2013, the bunker has been supplying up to 3000 households in the quarter with heating energy. Apart from being an interesting case study, this project proves that the basic approach discussed in this paper has the chance of being realized.

2. HISTORICAL GENESIS OF BUNKERS IN GERMANY

2.1 The second world war

As an introduction, it is necessary to sum up the historical events, which led to the construction of such a great number of bunkers in Germany. This is helpful for comprehending the different types of bunkers that are described and evaluated later. Although bunker construction can even be traced back to the First World War the initial impulse for bunker construction was given in the summer of 1940. In this year the first British bombardment of Berlin took place. Due to this incident the National Socialists ruling over Germany proclaimed a large-scale bunker construction program that was suppose to provide safety for the civilian population, military facilities and important traffic hubs in case the bombardments should continue. This program had top priority and the construction of the first bunkers almost immediately began in 1940. Officially the program was subdivided into three phases with the first phase lasting from 1940 to 1941 and completing 839 bunkers. The subsequent second phase lasted from summer 1941 to summer 1943 and the third phase basically continued until the end of the war in 1945. Beside the official program a number of bunkers where constructed for specific military or propaganda purposes. These are of particular interest because of their comparably large size and will be discussed in section 4.3.

2.2 The cold war

After the end of the war in 1945 many bunkers had resisted the bombardments and were supposed to be demolished by order of the Allies. But due to the fact that many refugees in the destroyed cities had no other choice but to use the bunkers as living space the so-called directive 22 was often not followed. Many bunkers were left untouched or simply made unsuitable for warfare purposes by cutting holes in the walls. With the dawning of the Cold War paradigms shifted again. Because the threat of nuclear war was omnipresent, the German government set up a civil defence program, which also included the use of bunkers. In comparison to the construction program carried out during the Second World War the civil defence initiative did not bring about many new bunkers. Instead, approximately 600 existing bunkers were retrofitted and then maintained. Furthermore, some special purpose large-scale underground bunkers were constructed, which are also worth mentioning and will be covered in section 4.6. After the end of the Cold War and the German unification the civil defence program was officially terminated in the year 2007. As a result, many bunkers maintained or constructed during the civil defence program lost their function and are vacant up to this day.

3. BUNKER TYPES AND ENERGY STORAGE SYSTEMS

3.1 General approach

When thinking about determining the potential of bunkers regarding their suitability for the conversion into energy storage facilities, two key elements are of importance. On the one hand, there is the existing building structure of the bunker defined by parameters like space, material and construction and on the other hand, there are the requirements of a technical system of energy storage addressing these properties in one way or another. Qualitatively one can evaluate the suitability of a selected bunker by simply confronting the existing structure with the requirements of an energy storage system. As a result the potential of a chosen bunker is dependent on to what extent requirements and conditions match. This procedure is meant to be applied on the level of bunker types. The goal is to point out those types within the bunker typology, which have the highest degree of suitability and are worthy of further inspection e.g. in a case study.

3.2 Bunker typology

The first step in the potential analysis is to set up a bunker typology and thereby to get an overview on the existing types. Methodologically, cluster analysis is applied, grouping or distinguishing types by architectural / constructive features that are measured by nominal[1] as a well as ordinal[2] scales. The starting point is an existing typology defined by Foedrowitz, who just differs between two very basic types: bunkers constructed above (overground bunkers) and bunkers constructed below (underground bunkers) the surface. Cluster analysis then goes by divisive analysis technique, building up the typology hierarchically, but in reverse order. This means that the two predefined bunker types are gradually split up into a number of sub-types. The outcome of this method is a typology consistent of eight bunker types, which can be subdivided into two layers (Table 1). Each layer represents a step of clustering. The precision of the defined bunker types increases with each one of these steps. Essentially layer two originates bunker types that are precise enough to commence with the evaluation method mentioned in the previous section, naming those types that have the highest potential.

overground bunkers	1 small-scale serial bunkers of phase one
	2 mid-scale and partly standardised bunkers of phase one and two
	3 large-scale bunkers with extraordinary features
underground bunkers	4 embedded underground bunkers
	5 exposed underground bunkers
	6 tunnel-like underground bunkers

1 Nominal scales measure whether a certain feature exists or not. E.g. types one, two and three are differentiated whether they are associated to phase one or phase and two or not and if they are serial, partly standardised or not.
2 Ordinal scales enable a rank order that is based on the degree of a certain feature. E.g. types one and two and three are ranked as small-, mid- and large-scale according to their size.

Table 1: Bunker typology [source: author]

3.3 Energy storage systems

Apart from knowing the properties of the bunker types it is essential to be aware of the demands laid down by the energy storage systems. This paper focuses on two selected systems of electrical energy storage: flywheel and compressed air storage. Both are relevant, since flywheels are already in use for saving renewable energy and compressed air storage is predicted to evolve to one of the leading systems in this field in the near future. Flywheels are prefabricated cylindrically shaped modules with an overall weight of about 2 t, a diameter of approximately 1 m and a height of 2 m (manufacturer data) that rotate a mass at high speed to store energy kinetically. Usually they are deployed in large numbers to increase storage amount and performance. Compressed air storage systems save energy by compressing and decompressing outside air up to 72 bars. Currently there are only two existing plants in service: one in Elsfleth, Germany and one in Alabama, USA. Both rely on artificial salt domes voids that are located beneath the facility to act as storage space for the compressed air. As stated in section 3.1, each storage system has a set of substantial structural requirements. These are derived from a thorough system analysis based on literature review and then assigned to four categories, dependant on the way they affect the building. These are dimensions, spatial structure, load-bearing structure and shell. Essentially, flywheel storage installation is dependent on the spatial structure and the dimensions of a building. First of all, sufficient space on ground floor level is mandatory to place a significant numbers of units. Secondly, the designated space should at best be free of columns or the like and, to ensure maintenance, the clear room height must at least be twice the height of the flywheel. In addition, the ground floor level should be equipped with adequate openings to allow the flywheels modules to be brought into the building. In contrast, the demands of compressed air storage revolve around all four categories. To begin with, the basic precondition is ample volume capacity and dependent on building dimensions. It determines the amount of potential energy that can be stored. Next are the requirements associated to the load-bearing structure, which are somewhat challenging. They result from the extraordinary surface loads induced by air compression ranging between 800 kN/m^2 (8 bars) and 3200 kN/m^2 (32 bars). Therefore, in any case, the load-bearing structure ought to be designed for surface loads. Furthermore, it should be constructed of reinforced concrete and preferably be form active, e.g. circular cross-sections. Especially form activity can substantially increase load-bearing capacity and is the main reason why newly built storage tanks are usually cylindrically or spherically shaped. Linked to this aspect is the favouring of sub-terrain buildings. Not only shape but also earth pressure can help compensate surface loads. Furthermore, this can buffer the heat, which inevitably arises during the air compression process. The last aspect concerns air leakage. Either way, the building shell should have little to no openings at all. Air tightness is a different issue. Very likely it will have to be ensured subsequently by taking measures in the course of the conversion. One possibility is airtight foils, which are commonly used in the field of passive house construction.

4. POTENTIAL OF BUNKER TYPES

4.1. Small-scale serial bunkers of phase one

Bunker 1		Bunker 2	
size		size	
17 * 20 * 12	[m]	18 * 18 * 39	[m]
volume capacity		volume capacity	
app. 4100	[m³]	app. 12 000	[m³]
shell thickness		shell thickness	
2	[m]	2	[m]

Table 2: Bunker specifications referring to section 4.2 [source: author reference to [10]]

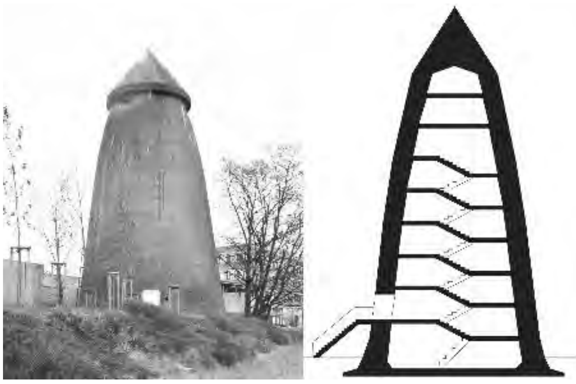

Figure 1: Outside view [source: author] and section of a variant "winkel" bunker [source: 11]

This type of bunker is of interest for two reasons: standardisation and high quantity. There are three versions named "winkel", "zombek" and "dietel". Variant "winkel" is shown in Figure 1 and totals to a number of 200 built. Regulations at the time limited it to 500 people and a diameter of just 10 m, which results in an estimated volume capacity of merely 1000 m^3. Regarding potential, this bunkers properties do not fit any of the necessary system requirements. First of all, the small volume capacity negates compressed air storage, especially because other WW II bunker types have greater capacities up to 12 000 m^3. Secondly, the lack of space on the ground floor combined with insufficient clear room height and access possibilities excludes flywheel systems.

4.2. Mid-scale and partly standardised bunkers of phase one and two

A great deal of the bunkers situated in Germany can be assigned to this type. All are multi storey buildings and constructed of reinforced concrete. In the most cases they are equipped with two opposite entrances, two separate staircases and basically have no windows. Overall size gradually increased from 1941 to 1945, whereas the thickness of the shell continuously ranged between 1 m and 2.50 m. Table 2 lists the specifications of two selected bunkers shown in Figure 2, which can be considered as representative for this type of bunker. Taking these characteristics into account, flywheel storage can be excluded due to the same reasons named in the previous section, whereas the considerable increase in volume capacity up to 12 000 m^3 makes compressed air storage a conceivable option. Moreover, there is a very durable and more or less closed shell, which contributes to the level of potential. The decisive question is the amount of pressure that the bunker shell can withstand. Technically, the energy density achievable ranges from app. 0.35 kWh/m^3 (8 bars) to 0.75 kWh/m^3 (32 bars), totalling in 2.5 MWh to 5.2 MWh of electrical energy that could be stored. This corresponds to the daily energy consumption of 250 to 520 single-family houses. Ultimately, only a case study can clarify this issue, which would also include the evaluation of material samples from walls and ceilings. Nevertheless, two aspects can give some indication. First of all, research shows that the concrete strength of the bunker walls has gone from level C30 to C55 due to 70 years of subsequent hardening. Secondly, the amount of steel reinforcements used at the time is significantly higher than what the German DIN norm requires today. Table 3 demonstrates that bunkers walls with a thickness of two meters contain up to six times more steel reinforcement.

Factor: 2 / 1 = 6.4		

Table 3: Comparison of steel reinforcement [source: author reference to [14][15]]

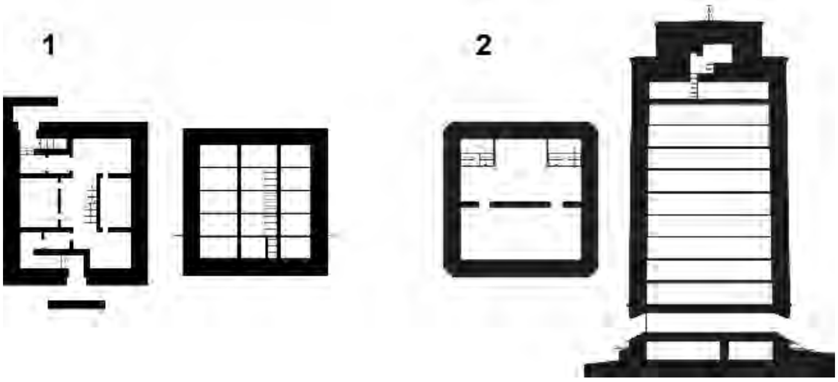

Figure 2: Standard floors plans and sections of bunkers [source: author reference to [10]]

4.3. Large-scale bunkers with extraordinary features

Good examples for this type of bunker are the so-called "flakbunkers", which were already mentioned in the introduction. Altogether, eight slightly different variants were built in Hamburg, Berlin and Vienna. Today only five remain. The others were torn down after the war. In terms of spatial structure they are comparable with the other phase one and two bunkers but are much larger and have a shell up to 3.50 m in thickness. As a result, the suitability for compressed air storage is somewhat higher when compared to the mid-scale bunkers. Analogous to the previous bunkers flywheels can be excluded.

4.4. Embedded underground bunkers

This is the first bunker type covered that originates from the cold war. These one or two storey bunkers were always integrated in the basement of another building e.g. a public school or an administration office, not least on account of protection and camouflage. The floor plans are subdivided into a rather large number of small sized corridors and rooms and can most likely be compared to those of a hospital. Walls and ceilings are not as thick as those of WW II facilities and often only the ceiling slab was exceptionally heavy. Due to their ordinary spatial structure, the comparably slim ceilings respectively walls and the fact that they are connected to another building make these bunkers incompatible with the two energy storage systems portrayed.

4.5. Exposed underground bunkers

The so-called "warnamt" bunkers are one of the few examples for this bunker type. Altogether ten were newly built during the Cold War period. The office for public warning was established as a part of the civil defence program and had the task to alert the public and to carry out safety measures prior to, during and after an attack. The bunkers acted as control centres. From a structural point of view and considering size they are comparable with the mid-scale bunkers described in section 4.2. The main difference is that the shell was constructed with a thickness of three meters. This aspect and the sub-terrain position increase suitability for compressed air storage. Again, flywheel storage cannot be applied.

4.6. Tunnel-like underground bunkers

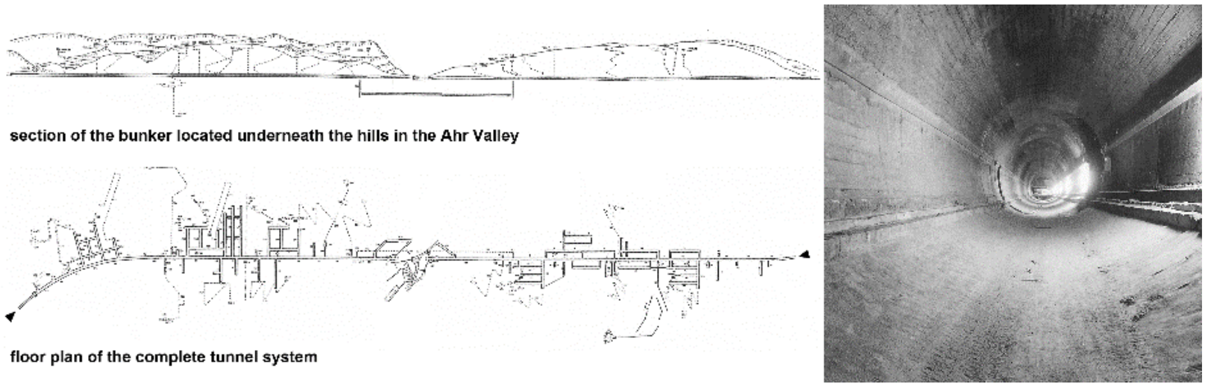

Figure 3: Plan of the government bunker and indoor image after disassembly

The tunnel-like underground bunkers are a very divertive type. On the one hand, there are facilities dating back to the WW II, which were built during the third phase of the construction program initiated by the National Socialists. Generally, these bunkers are more or less ruinous today because resource use was strictly limited at the end of the war. This can be verified by a study done on a number of such bunkers located in and around the town of Salzgitter. On the other hand, there are bunkers constructed during the Cold War period. Until this day, information concerning these facilities is rather scarce because they were highly confidential and not open to public. Many served military purposes and acted as depots for ammunition, fuel or other supplies. One example for a bunker that is sufficiently documented and accessible is the German government bunker built between 1952 and 1972. It was fully protected and was suppose to serve as a retreat where government service could continue in the case of nuclear warfare. Constructed in the tube of an uncompleted railway tunnel it consisted of 19 km of tunnels after completion. Today the bunker is almost entirely disassembled with only the naked concrete tunnel walls remaining (Figure 3). This bunker type has the highest degree of suitability. The ovoid profile of the main tunnel is app. 8 m in height and app. 6 m in width, which enables the deployment and maintenance of flywheel units. The overall length of 19 km also allows a very large number of modules to be placed. But especially for compressed air storage conditions match such as sub-terrain position, ample volume capacity, closed shell and form activity. With a usable volume capacity of app. 250 000 m^3 and applied pressures ranging from 8 bars to 32 bars it would be possible to store app. 87.5 MWh to 187.5 MWh of electrical energy.

5. CONCLUSION

Initially, this paper demonstrates that former bunkers have a potential for the conversion into energy storage facilities. Altogether, four of the six defined types are equipped with a series of structural features that favour this task. In the most cases these are limited to compressed air storage. Put into order, the degree of suitability gradually increases from the mid-scale and partly standardised bunkers of phase one and two, to the exposed underground bunkers, to the tunnel-like underground bunkers, which have an exceptionally high degree of suitability and can provide comparably large storage amounts. Regarding application, a bunker storage unit could save the midday surplus production of photovoltaic systems and provide this energy in the evening when household demands reach a peak. Thereby, not only the quantity of renewable energy used is increased but also the load on the power grid can be relieved, contributing to the energy independence of neighbourhoods. But the approach shown in this paper is not limited to bunkers. It can also be applied on other types, e.g. industrial buildings. Especially from a global perspective this could be of interest, since brownfield conversion is a reoccurring question in urban planning worldwide and is associated to many aspects essential for the development of sustainable cities.

ABSTRACT

Microgeneration of energy is one of the major research areas in the sustainability field. While there are multi-faceted benefits in the generation of energy locally, the scales of economy and underestimation of difficulties in practical application hinders the uptake. Microgeneration through wind energy is no exception. While the history of wind energy proliferation shows an increasing trend of bigger and higher capacity installations in remote locations, architects and planners kept on envisioning the integration of single miniaturized turbines on buildings as the future of smart cities. Including few iconic examples, the application of wind turbines on building roofs has not proved success. In this paper, a review of microgeneration issues and potential technologies for a breakthrough will be presented. The authors aim to propose a distributed wind energy harvesting system embedded in building facades that also works as a ventilation device at different modes.

Keywords: high performance buildings, wind energy, microgeneration

1. INTRODUCTION

When the electrical energy distribution was at its infancy, the power stations were all located close to the demand, i.e., Bankside Power Station in London (currently Tate Modern Gallery), Silahtarağa Power Station in İstanbul (currently santralistanbul Modern Art Gallery). These industrial buildings were an important part of the cityscapes at that era, dominating the skies with their tall chimneys and long spanning voluminous interior spaces. Exclusively running on fossil fuels, these power generation stations were serving a rather limited demand (of only illumination and basic appliances). Increasing populations and ever-expanding uses of electricity led to higher demand, requiring higher capacities. In addition, sustainability issues regarding the supply of energy source (i.e., coal), and increasing pollution within city boundaries caused inconvenience and discomfort. As a result, the power stations were moved closer to the sources of energy, such as coal mine regions, hydro/wind potential locations, and later custom build nuclear power plants at strategical locations. Such move brought the cost of energy loss (up to 10%) during transmission to the demand. However, throughout the 20th century this issue was not much of a concern until the awareness of Global Warming has become an influential matter. During the search for a sustainable energy generation method, harvesting wind power for electricity has become one of the major strategies. Basic concepts of wind energy can be seen in Herbert et al.'s work, and the history in Kaldellis and Zafirakis's work.

Microgeneration is the small-scale generation of heat and electric power by individuals, small businesses and communities to meet their own needs. It came out of a need, when distant locations and communities were yet to be connected to the main energy grid. Most small towns and villages had their own microgeneration strategy based on local resources and skills. Ever-reaching network of the energy grid has led to the demise of microgeneration throughout 20th century, until its re-birth just at the turn of 21st century. The current take on microgeneration is focused on its increased efficiency (via reduced transmission lines, and more efficient conversion technologies, i.e., co-gen, tri-gen) and reduced carbon dioxide (CO_2) emissions (due to higher use of renewable energy sources, i.e., solar, wind, bio-mass).

It is possible for a building to supply/produce its own energy without the need to be supported by fossil fuels. For this, first of all, the energy demand has to be reduced. Green buildings or zero energy buildings (ZEB) are two of the recent initiatives that help designers reduce the energy demand. These incentives support the use of energy from renewable resources including building integrated energy generation solutions.

Microgeneration applications of solar energy as a building integrated solution is a straightforward one, i.e., covering roof surfaces, utilizing backyards, and creating temporary structures. However, the integration of wind energy solutions has always been problematic. While the wind energy in urban areas has a sensational enigma to it with its relatively large installations (i.e., visually dominant and attractive revolving turbines), it has yet been proven that these solutions are worth the effort. There are few iconic examples for integrating the wind turbines to the building

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

architecture (i.e., Bahrain WTC, London Strata Building, etc.), but these are one-off and problematic applications. Nevertheless, governments are still subsidizing these microgeneration initiatives via grants and tax returns.

The issue with wind energy microgeneration integration into buildings stems from the fact that conditions required for conventional horizontal axis wind turbines are difficult to satisfy in urban areas since these conditions are mutually exclusive with the needs for user comfort. In addition to that, these wind turbine installations generate vibration and noise, cause structural loads, and pose risk to the surrounding environment. Many major building integrated wind power turbines are plagued with user complaints, under-performance, and technical problems. These issues stem from the fact that earlier proposals were trying to import scaled down versions of industrial wind turbines onto building tops. However, it is reported that building tops have chaotic wind regimes with strong turbulence, leading to failing applications. Research shows that due to this situation such investments rarely pay-back within their lifetime. Also it was shown that majority of micro wind turbines installed in the UK did not receive sufficiently high wind resource to make them economic.

In this paper a sea-change in the integration of wind turbines to buildings in urban environments is called for. The authors would like to call this new approach nano-generation. While urban environments do not provide the necessary conditions for conventional horizontal axis wind turbines, there are still wind energy harvesting opportunities that can be exploited via other methods. High rise buildings in dense urban environments create a chaotic, turbulent flow of air between large vertical surfaces. Contemporary building technology and architecture calls for separate building skins that improve the internal conditions of facilities. The authors claim that it is possible to create complex building skins with embedded airfoils that generate small amounts of energy, continuously. Harvesting from a distributed network of such energy generators, building façades can be a positive contributor to a facility’s energy ledger book. The inspiration for this application was taken from the emerging re-generative braking technology applied in most hybrid and electric vehicles. This technique converts the kinetic (or potential) energy of the vehicle to electrical energy via existing drivetrain and motor, and stores it in battery. In reality, all wind turbines can be considered some sort of regenerative brake devices which brake the wind. However, the analogy of the buildings to electric vehicles stems from the fact that in buildings the existing ventilation infrastructure can be re-thought and utilized to allow both the intake of air into spaces, and generate energy when possible. In a similar fashion to electric vehicles, a building façade can be designed to have a distributed network of ventilation devices, which in certain modes (i.e., when they are not active, or diverted) can be used for generating energy by letting the airflow pass through. The façade and the integrated distributed nano-generation technology can be developed using parametric design tools and also become a reflection of creative architectural concepts.

2. CURRENT STATE IN BUILDING INTEGRATED WIND ENERGY

Microgeneration through wind turbines mounted on buildings has serious issues due to the fact that calculation of actual wind patterns is a difficult and expensive task. According to Walker this is particularly important since these installations reside within the surface roughness layer, thus being under strong influence of the surrounding buildings. Urban wind patterns have a complex structure, which is investigated by researchers mostly for pollution dispersal and pedestrian comfort reasons. Investigation of wind speed calculation methods in urban environments for wind energy purposes was done previously. Moreover, due to a continuous development in urban environment, the wind patterns change character in time. Therefore the exploitation of wind power in urban environments is very different in comparison to rural or off-shore implementations.

Wind energy microgeneration strategies in urban environments almost exclusively rely on scaled down applications of conventional wind turbines used in remote wind farms. These turbines inherently rely on constant and sustained flow of air, thus well researched and executed wind farm investments in rural or off-shore implementations. The rooftop wind turbines do not have the efficiency of remote wind farm installations due to turbulence and chaotic behavior of air movement in urban areas, leading up to ten-fold reduction in their efficiencies. Research points at the need for the investigation of low-speed wind turbines for urban areas.

There are several studies previously done, focusing on the urban wind energy generation problem. For instance Sharpe and Proven proposed an “innovative ‘true’ building integrated wind turbine” based on Darrieus turbine form. While horizontal axis wind turbines have proven higher efficiencies at constant and relatively high wind speeds; vertical axis wind turbines can fulfill the energy generation purposes at high wind turbulence, wind fluctuations, and high directional variability Vertical axis wind turbines had been widely used since 2nd century BC until the 20th century in Iran and Afghanistan and their suitability of urban wind energy generation was investigated by Müller

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

et al. Castelli et al. and Balduzzi et al.. These analyses showed that for higher efficiencies, the installations require to be on the highest buildings in the urban environment Grant et al. proposed a ducted wind turbine that used pressure differentials created by wind flow around a building, increasing the efficiency and reducing risks via safety enclosures.

The common element for these studies are their insistence on installing miniaturized but still relatively large wind turbines on buildings. It has been many times proven that the wind regime on building surfaces has a chaotic and unexpected nature. These findings support the proposed solution which aims to utilize the whole building surface for harvesting the wind energy.

3. A PROPOSAL: 'REGENERATIVE' VENTILATION

One of the highest energy cost items in medium-large buildings stem from heating, ventilation, and air conditioning systems (HVAC). These systems take fresh air, condition it to achieve the correct temperature and humidity, and mix it with the indoor air. Most of these systems are composed of large and centralized equipment, carrying the air into spaces via ducts. Carrying of air into spaces is called ventilation, which uses electric power 4.1% of whole energy consumption. While the other energy cost items (such as heating and cooling) have a decreasing trend for the next decades (see Figure 1), the ventilation energy costs are predicted to linger. This is due to the fact that the technology for ventilation has already achieved maturity and no major changes are expected in its efficiency. An investigation of ventilation types and their efficiencies are discussed . A major criticism of centralized HVAC systems is that it is difficult to adjust the local climatic conditions. These installations are designed with the assumption of full occupancy. However, most buildings operate much below their full occupancy targets. As a result, most of the building spaces are ventilated for no useful reason. This is one of the major reasons for the wasted energy in medium-large buildings. A new trend in building technology aims to detect the presence and movements of users and condition the environments locally. This trend sets the case for the focus of research on ventilating buildings locally.

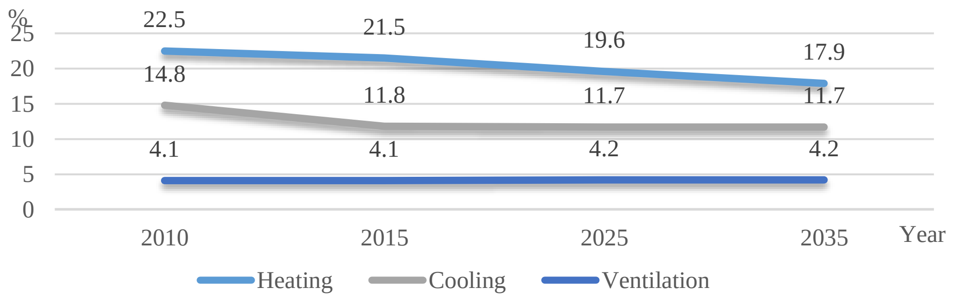

Figure 19: Projection of building services energy loads – data from DOE

In this study an analogy between electric vehicles and buildings is offered. In a hybrid/ electric car, the energy stored in batteries is used to power the drivetrain and create movement. During slow-downs, instead of conventional braking (which convert kinetic energy to heat), the drivetrain motors are used for charging the batteries by creating resistance on the wheels due to induction load. This is called re-generative breaking. The use of regenerative braking in transportation predates hybrid/electric vehicles. Studies show the use of regenerative braking in railway locomotives as early as 1970s. An important advantage of regenerative braking is due to the ability to use existing drivetrain and hardware that moves the vehicles to slow them down and generate energy. One of the most difficult technical hurdles in regenerative braking is the ability to store the generated energy quickly and efficiently. Super capacitors are a partial solution for this problem since they can be charged with high currents and offer a virtually maintenance free storage option for regenerative braking systems. Automotive manufacturer firm Mazda invented a simple regenerative braking technology on gasoline engine cars based on super capacitors. This technology eliminates the need for large batteries for such a system and increases fuel efficiency since the load of alternator is reduced by the utilization of energy stored in super capacitors (see Figure 2). However, super capacitors store only a limited amount of burst energy, which can be directed to other systems and relieve the load of alternator and main batteries in these cars, thus achieving fuel efficiency.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 20: Super capacitor integrated automotive regenerative braking system overview

Another innovative application of regenerative braking is proposed by Volvo, where a high-mass flywheel in vacuum is connected to rear wheels of a car (Flybrid® KERS - Kinetic Energy Recovery System). The flywheel is accelerated during slow-downs and continues to spin for a long time due to lack of friction and high-mass. When needed, the kinetic energy stored in the device is transferred to the wheels to improve acceleration performance. This system is more complex and costly since it requires extra hardware and controllers for operation. While it is a regenerative braking technology, it sets itself apart from the rest of the solution provided by other makers. Regardless of their implementation methodology, most of the regenerative braking technologies improve the energy efficiency performance of vehicles at a fraction. However, these techniques are still investigated and there are continuous research and development activities ongoing for their improvement.

A similar relationship can be created between buildings ventilation and naturally occurring winds around building façade. The winds around building facades has a temporal and chaotic character. The pressure zones around a building changes according to season, time of day, or temporary climatic events. Regardless of the existence of wind around buildings, centralized ventilation systems continually use energy to divert fresh air indoors. In this paper it is proposed that the ventilation inlets can be spread throughout building facades and operated on a need-base. These ventilation inlets can be integrated to each façade such that they can (1) run on electrical energy and provide air indoors, (2) make use of positive outdoor pressure and let air in while generating power via ventilation fans, and (3) shift the air route, bypassing indoors and generating energy via ventilation fans. This system can potentially reduce the energy wasted on building ventilation via the reduction of overall ventilated areas, positively generated energy in suitable conditions, and excess energy generation in no-ventilation scenarios.

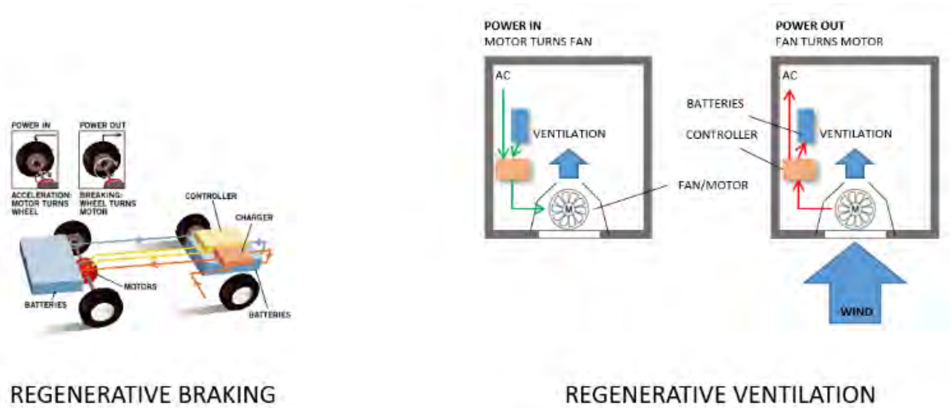

Figure 3: The regenerative braking analogy

The whole system can be devised as a contained solution, where the wind turbine, gearbox, and energy storage device can reside as a single field replaceable unit. Excess energy generated by the units can be fed back to building via purpose-built lines, or transferred across a closed circuitry which is connected to each ventilation unit throughout the building. This way the naturally occurring winds around the building can be utilized for continuously running the localized ventilation systems across the building.

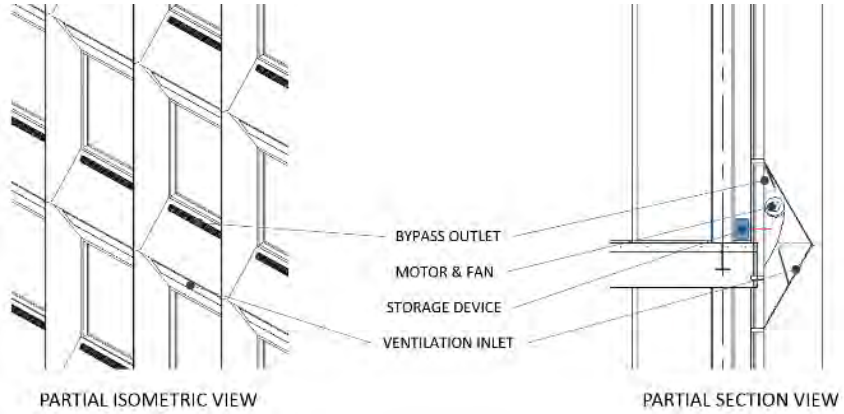

Figure 4: A partial isometric and section views of the proposed façade

As seen in the Figure 4 the proposed system is a façade skin that embodies the ventilation and energy generation device as a single unit. At each floor these units are matched to the windows, letting the façade wind in (through operable ventilation inlet) and ventilating the indoors or just letting the wind out through bypass outlet. According to different operating conditions, energy is generated or used by the system according to the availability of façade wind conditions or internal ventilation needs (Figure 5). The whole system should be controlled by a central building management system (BMS), which collects and interprets data from a sensor network spread throughout the building. According to user occupancy data and interior air quality, the BMS can operate the integrated diversion flaps in these units to either ventilate indoors by means of wind energy or electricity, or to let the air bypass the system to generate energy.

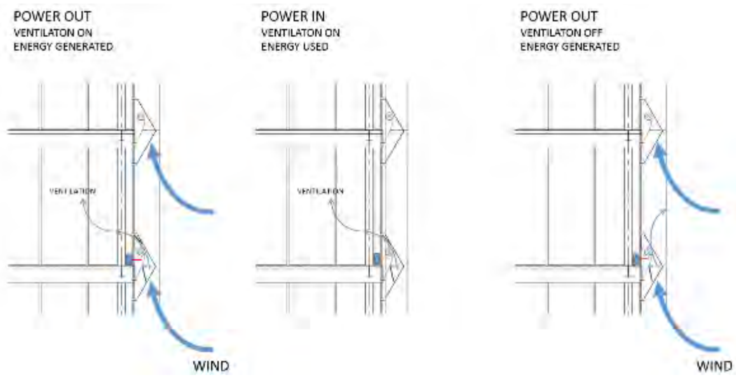

Figure 5: Three states of regenerative ventilation device

The proposed solution allows the conditioning of the external air by means of local heating and cooling coils and also micro-humidifiers. This is not a finished/complete design, but only a tool to describe the need and the potential. There is more research that needs to be done to investigate the practicality of the approach via the investigation of the suitability of the temporal wind conditions and the influence of units on air flow through the building surface as a whole system.

The researchers intend to have a design proposal for the integration of nano-generation into building façades and other elements for distributed energy generation at the end of this research project.

4. CLOSING REMARKS

This research project is an exploratory study aiming to investigate the possibility of harvesting wind energy from whole building surface by means of small distributed wind turbines which also work for the ventilation of indoors. There are no results yet; the project is still at its literature review stage. The proposal needs to be discussed further and more research related efforts need to be investigated. The upcoming tasks are determined as further literature review, collecting data on surface wind patterns from case buildings, and investigation of computational fluid dynamics for further role in the test of this proposal. With the aid of these efforts the study will focus on developing a prototype device and calculate its effectiveness at a built environment setting. The results from these experiments will identify the performance characteristics of the proposed solution.

ABSTRACT

Cities are the habitat of the knowledge-based economy. Cities produce and attract human capital and are today giant interface of communication, cities possess the critical mass for production and diffusion of knowledge, innovation and integration of human networks, which enable sustainable growth. At the same time cities are the true heart of innovation. The aim of this paper is to create architectural interventions on these new cities for the creation of spaces that all human beings can felt comfortable as they are inside old cities and with modern and sustainable contents. The new type of city concept focus on not develops only buildings and beautiful construction. They will produce concepts of community for inhabitants and not only a network with technologies. All the data from these spaces will be incorporated inside an Open Community Data, where the citizens participate actively on decisions, and empowering citizens in a construction of a participatory e-society. According to Jeff Speck “a walk has to be useful, safe, comfortable, and interesting if you're going to get people out of their cars and into the sidewalks”. Architecture has to produce feelings and sensations to inhabitants. A city is not an object as a simple “fridge”. The focus on public spaces and common areas inside buildings, how they connect with each other it is an objective and the technologies that we use, we apply, we see and we find are points that we can´t forget. The aim of this research is to determine some architectural concepts that will help cities, but especially planners and architects, their role, their tools and their strategies. The paper argues the future sustainability of spaces maintenance and their strategic plan applied on these New Smart Climate Smart Cities where will be produce outcomes on techno-economic scenario analysis and on the socio-economic impacts.

Keywords: climate smart cities, green architecture, cities.

1. INTRODUCTION

“Smart Cities” are part of our modern society and are strong models on our generation, but as everything, we have the positive face and the negative face, it always depends on how spaces are used. These spaces are a reflection of the enormous technological advances provided by years and years of studies promoted by the human being, that in certain actions go beyond the physical barrier allowing the people to live in a space at the beginning of virtually, without borders. Like many inventions changed the history, the Smart Cities are revealed as a tendency for new generations marking determining and creating a new type of culture.

At the end, what are real Smart Cities? What are Smart Cities? Across the world, the stride of migration from rural to urban areas is increasing. By 2050, about 70 per cent of the population will be living in cities, and India is no exception. It will need about 500 new cities to accommodate the influxaccording to this statement human beings are trying to react to the law of supply and demand, and trying to find a way to be able to solve a future problem. Cities are modern creations …where information technology is the principal infrastructure and the basis for providing essential services to residents. The origins can be at some especial lines. The concept of smart cities originated at the time when the entire world was facing one of the worst economic crises. In 2008, IBM began to work on 'smarter cities' concept as part of its Smarter Planet initiative. By the beginning of 2009, the concept had captivated the imagination of various nations across the globe…” On article of November 11th of 2014, on the SustainableCitiesCollective, Nina Bianchi and Kat Hartman, describe Smart Cities as a skeptical image of a “remote-control city…” The definition says A city can be defined as ‘smart’ when investments in human and social capital and traditional (transport) and modern (ICT) communication infrastructure fuel sustainable economic development and a high quality of life, with a wise management of natural resources, through participatory action and engagement…”

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Smart City means efficiency, but efficiency is where human beings are also involved in its development. Smart Cities are characterized as «innovation ecosystems» could offer ample opportunities for sustainable, user-driven «intelligent services»…" If these spaces are well designed, they can become multicultural areas and knowledge zones and development where citizens will want to live with quality of life. However, the economic pressures have led some errors in planning and management. A city cannot provide only this feeling No other city in South Korea, has attracted more attention than Songdo, the skyscraper-intensive, apparently eco-friendly 'smart city' built along reclaimed waterfront land in Incheon, home of the country's largest international airport called Songdo International City, so called because of the 'ubiquitous' data-gathering technology".

In recent centuries, and from 70's by Michael Graves and his concept of Re-design cities, or even the city model of Corbusier and several authors as Paolo Portoghesi were big influences on urban design. Colin Rowe also has been present as another influential but more focused on the American's city design. Léon Krier, Rodrigo Perez, Peter Eisenman, Daniel Libeskind and recently Norman Foster, are major influencers in these new concepts of Smart Cities.

Maria Teresa Bilotta expose on her article on December 22th of 2014 that Songdo is the first Smart City in the world. It is a sustainable city, Green and full of technology and innovation." Songdo is a city that contains a Central Park as a mark point, a semi imitation New York Central Park and with 10 years of development. However, according Antony M. Townsend, in his Smart Cities book Songdo was originally conceived as «a weapon for fighting trade wars» the idea was «to entice multinationals to set up Asian operations at Songdo»… with lower taxes and less regulation…". It is true that Songdo since its inception introduced the concept of a Free Economic Zone, an area with different regulation of the rest of the country, but it's not working like was planned and it presents many different problems, but at the end it is trying to arrive to a green space more Korean than international.

2. METHOD

The first and new theory is based on logic with the concept and the implementation of Green Architecture and elements that create the Quality and Happiness inside cities and logic of Sustainable Urban and sustainable Energy applications. This initial question arises a sub - question to identify response that is characterized by knowing which the limit it has to be present on the sustainable design method to be used. On December 17th of 2014, the Guardian, by Steven Poole said, "…The truth about smart cities: 'In the end, they will destroy democracy…" and further underlines also "…The smart city is, to many urban thinkers, just a buzz phrase that has outlived its usefulness: 'the wrong idea pitched in the wrong way to the wrong people'. So why did that happen – and what's coming in its place?..." This research is in direction of the improvement of these cities to be projected and built today, improving its existence, its sustainability and the type of intervention with a new systems. There are situations that are not identifiable, as Alain de Botton described Beautiful houses not only fail as guarantee of happiness, as can also be accused of failing to improve the character of those who live there…", may not only be the image of buildings but can describe the development of a city. Nerveless, Alain de Botton identifies a reality. We have to ask what should be exactly the look of beautiful building …" and this is a concept that goes in different scientific directions that has to be developed in another study case.

Zygmunt Bauman, on his book Trust and Fear at the Cities says submit ourselves to the limits of our faculties: we know very well that we will never come to dominate completely the nature and our body also will never be immortal or also immune to the relentless course of time. Thus, we do not have, because another remedy that is not content with what exists. This is a finding that has no reason to discourage us or break the will to live, but rather should serve us encouragement and infuse us energy. While we cannot completely extirpate the pain, we can, in some cases, eliminate it in part and in others relieve it. The question is to know about it persist, again and again, without faint…" in cities opinions can be diverse and at the same time opposite as well.

These new Smart Cities provide 'proxemics' levels that are identified and can be supported by the planning. Proxemics studies the spatiality behaviour of man, the relationships between individuals in a spatial frame and between individuals or groups and the space itself… In the theoretical-methodological frame of ethology, there is a series of central concepts as space, spatiality, distance, contact, territoriality, aggressiveness and defence. The biggest part of conceptual tools of the discipline builds on the fundamental ideas of space and distance." by Ciprian F. Ardelean in The Grammar of social space: An Anthropological approach to human Proxemics.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The third theory is focused in "Netizen" people, the concept of Net addiction As many as 10 per cent of Internet surfers are pathologically addicted to the Web, and although it can disrupt their lives, many doctors and mental health practitioners are unaware of the dangers, according to an article by psychiatrists at the Be'er Ya'acov Mental Health Centre and Tell Aviv University…". This is a global problem that the planners have responsibility since the beginning of the projects. Excessive connection can be harmful to the human being when the objective is to be a helpful tool. The centralized waste treatment systems remove waste storage on the streets and reduce spending fuel expenses. Touch screens within the housing and the information energetic spent on mobile applications indicative of productivity and consumption alert inside homes, services and are productive but when this pass the proxemics level, "shut down" the real results.

The third concept theory is that inside a city need to exist an improvement of non-standard urban elements. As time goes by, people start looking for unique things, handmade, special places and mysterious places. WCCD the new international standard on city data, published in May 2014, create a database of indicators for City Services and Quality of life by the International Organization for Standardization (ISO). The ISO 37120 defines and established definition and methodologies for a set of indicators to steer and measure the performance of city services and quality of life in 17 different themes. This new data analysis could create a positive approach in some cities but could create a negative approach and give more emphasis to the Standard level.

2.1 Sample preparation

A list of questions and analysis at experts ideas connected with the Smart Cities State of Art create this new type evaluation to apply in existing cities and in Future Cities.

Figure 1: Songdo building at night Sharp I - transformed image by the author, Ana Oliveira

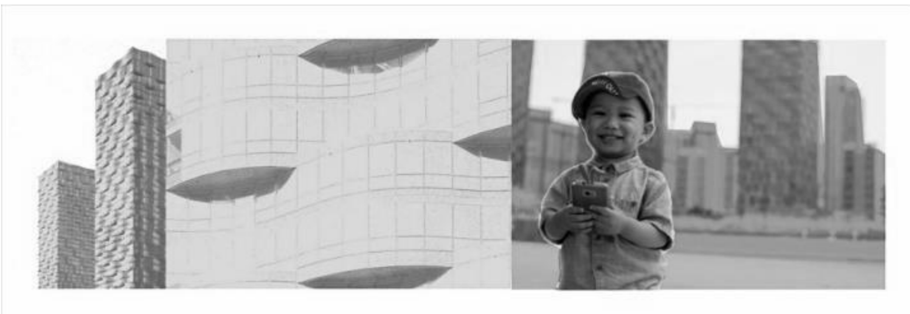

Figure 2: Songdo building Sharp I - transformed image by the author, Ana Oliveira

A daily analysis was developed during two years and a questionnaire was integrant part of this study complemented by a direct focus at the territory.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.2 Experimental procedure

This idea was based on interviews on experts, where were identified needs on Smart Cities and the influences of the technology on Smart Cities. Experts: CIKUTOVIC, Marco - AES Gener, Engineering Manager – Chile; DIAS, Solemain - Chadwick International School - support Director, Brazil, DUMELIE, Geoff - Chadwick International School - Village School Counselor – Canada; HAN, Jisop - Opus Design and KPF - Director design – South Korea; JACKSON, Emma - Metroland Media Group - Canada-; KIM, May - Collins International - Real State advisor – Korea; MORE, David G. - Gale International - Project Manager – England; Polycarp, Clifford - Green Climate Found - Director Manager – India, helped to create this analysis. Different ways of knowing the city and different ways of living the city were identified.

In general, everyone accept that the results from the Data are very important, but the extreme of not giving space for Nature, off line status or shut down options are inside the needs of the population. Green was the selected colour to implement on Equipment's, Green is a Sustainable colour in all opinions.

An orientation basis on the demonstration of how architecture on city's can be changed according to the real importance and action in which the Green Architecture can produce big results in our days was another conclusion. People need a connection between life and real Nature. For a sustainable intervention, and a sustain-able business this level of thought is an integrant part of the Project Plan Implementation.

Interviews

State of ART

Conclusions

Figure 3: Flowchart illustrating the sample process.

2.3 Results and discussions

As a base on good results, all inhabitants need to be informed and guided to produce results from the initial planning of interventions inside Smart Cities. The solutions pass on improvements on the communication with universal language because cities are not static they are Organic. People expect that cities focus on Quality and not turn into ghost towns. All this concepts with Green Architecture can be applied in Old Cities without the needing a total demolishment.

For choosing a new technology implementation it's important to know how people live and how people relate to cities. Jan Gehl explain "... Cities are the places where people meet to exchange ideas, trade, or simply relax and enjoy Themselves ... The compact city - with development grouped around public transport, walking, and cycling - is the only environmentally sustainable form of city... the city must Increase the quantity and quality of well-planned beautiful spaces are human in scale, sustainable, healthy, safe, and lively ... Cities ... They provide the structure that Enables cities to come to life, and to Encourage and accommodate diverse Activities, from the quiet and contemplative to the noisy and busy. The human city ... Creates pleasure for visitors and passers-by, as well as for those who live, work, and play there every day ... "Jan says: "We shape cities, And They shape us ... " At the end, technologies are used for creating more quality on the way of living, if we create the opposite we are not arriving to the objectives. Symbols in a city are an automatic human reaction…" Jan Gehl also notes the following walking, stopping, resting, staying and conversing. Unpredictability and un-planned, spontaneous actions are very much part of what makes moving and staying in city space such a special attraction."

Figure 4: Home Touch Panel – South Korea – Songdo – by the author Ana Oliveira

Figure 5: Home Touch Panel – South Korea – Songdo - by the author Ana Oliveira

What is inside the buildings in the interior or in the exterior spaces produces influence on human beings. The architect Peter Zumthor also transmits in his book Atmospheres. I enter the building see the room and - in the fraction of a second - have this feeling about it. We have perceive atmosphere through our emotional sensibility - a form of perception that works incredibly and Which We humans evidently need to help us survive ... I have no idea why that is so, but it's like that with architecture too ... ".

Population, cities, governments, companies will benefit with this new concept of planning and using the city with more quality, more health and more happiness. Could Happiness be measured by data results? In the future we will have this answer and this new theory will help in some results.

3. CONCLUSIONS

All of the Smart Cities are not following the original sustainable spaces concepts, it is important to change that. To transform and create a Sustainable City, the amount of money needed pass the Private Sector level and demand the Government intervention. A project like this, will work only with a strong Community involvement and it has to be very productive. All Smart Cities have to improve and to maintain inhabitants, because only with this focus, the space will be prepared to make and produce results to create mechanism with new technologies or ether to transform Spaces into Sustainable and autonomous areas. The importance of the proxemics, the limits of communication, the constant “ALWAYS ON LINE” status and the search for non-standard urban elements are problems to solve on the next ten years.

ABSTRACT

The Electrical and Mechanical Services Department (EMSD) of the Government of the Hong Kong Special Administrative Region provides operation and maintenance engineering services for electrical and mechanical systems in various government venues and public transport infrastructures.

To enhance manpower utilization, optimize building services system performance, and to achieve greater energy saving, various building management systems (BMS) of government venues are being integrated and connected to a Geographic Information System (GIS) platform, which will map all the critical assets being operated and maintained by EMSD.

Critical traffic infrastructures such as traffic signal systems, footbridge lifts and escalators, ventilation and lighting systems in public transport interchanges, and submersible pumps in subways/underpasses will also be mapped onto the GIS via remote monitoring units (RMU). The integrated BMS/GIS/RMU platform enables real time detection of equipment fault and prompt alert to maintenance staff, and provides a user-friendly geographical interface to facilitate quick deployment of technical workforce.

This paper gives an overview of the use of the integrated BMS/RMU/GIS platform which helps reduced fault response time and fault rectification time, achieve energy saving, and improve reliability of critical transport infrastructure for the benefits of the general public.

Keywords: integrated building management system, geographic information system, green building management

1. INTRODUCTION

Hong Kong is a densely populated cosmopolitan city with the urbanized areas covering less than 30% of this small city of 1,100 square kilometre. The city is characterized by sophisticated infrastructure systems and tall buildings, both of which rely on reliable operation of modern electrical and mechanical (E&M) systems. The Electrical and Mechanical Services Department (EMSD) of the Government of the Hong Kong Special Administrative Region provides operation and maintenance engineering services for E&M systems in various government venues and public transport infrastructures.

2. OPERATION AND MAINTENANCE OF E&M SYSTEMS IN GOVERNMENT VENUES

Building management system (BMS) is widely used in modern buildings to control and monitor the E&M systems such as air-conditioning systems, mechanical ventilation systems, lighting systems, security systems, lifts and escalators, etc. BMS substantially improves the efficiency of building management and reduces the operation and maintenance cost as it provides an easy way to assess the performance of the various systems, simplifies the operation, helps in planning operation and saves energy via more accurate control and operation schedule.

Though BMSs are providing a lot of benefits, they are scattered in a variety of buildings. For property maintenance agents who maintain a large number of buildings, monitoring such scattered BMSs is still time and manpower consuming, as a resident maintenance team is required for each building or the team needs to travel between buildings to operate and maintain the BMSs. On the other hand, continuous monitoring of the E&M systems is usually only possible at the consoles of the BMSs usually located in the control rooms of the buildings. Alarms identified by BMSs have to reach the management staff and repair teams via some reporting mechanism. For

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

maintenance agents with a large portfolio of buildings, this may cause delay in responding to alarms occurring concurrently in different buildings.

EMSD is maintaining a large number of government buildings which are widely distributed all over Hong Kong. Many of these buildings are equipped with BMSs. The work load to cater for BMSs in these buildings is quite heavy. As an example, the headquarters of a government department consist of a cluster of four buildings, each with their own BMS. Consoles of the BMSs are located in BMS rooms of the four buildings. The maintenance staff, particularly those on night shift, have to travel between buildings which is manpower consuming and very often the response to alarms is not as prompt as desired.

2.1. Integrated Building Management System (iBMS)

In view of this, EMSD developed an integrated BMS (iBMS) in order to enhance the efficiency and performance of operation and maintenance work and to relieve staff work load. The iBMS enables control and monitoring of the E&M systems of the four buildings within the headquarters complex via a single platform using either computer, tablet, smart phone at any location by operators with proper authority.

The major challenge to the integration was to exchange massive real time data of commands and system status between the central iBMS and the BMSs smoothly. To address this issue, optic fibre network was installed to connect the iBMS with the four BMSs. The second issue to be solved was that the four BMSs were using different protocols. Thus, a BMS upgrading work was conducted. BACNet communication modules were installed so that all the BMSs will work with the same protocol. As BACNet is an open protocol, it enables future integration of other systems. With optic fibre and the open protocol of BACNet, an iBMS server was installed and the connection with the BMSs were established in 2015.

All the E&M equipment including air-conditioning system, mechanical ventilation system, lighting control system, electrical system, lift system, emergency generator, etc. can be monitored and controlled via the console of the iBMS. Energy consumption of the systems is also monitored and recorded. In addition to the integration, the iBMS also provides web based access. With proper authority, operation and maintenance staff can use the iBMS anywhere with Internet access. Management staff and repair team can also monitor the system to obtain information of system performance and alarms directly. Furthermore, as a further step towards a smart city, the iBMS is integrated with a GIS platform installed in the headquarters of EMSD for map-based asset management. System status and alarms are visualized on the GIS platform. Management staff can get an in-depth understanding on the system performance which enables prompt and accurate decision making. The system architecture diagram is shown in figure 1.

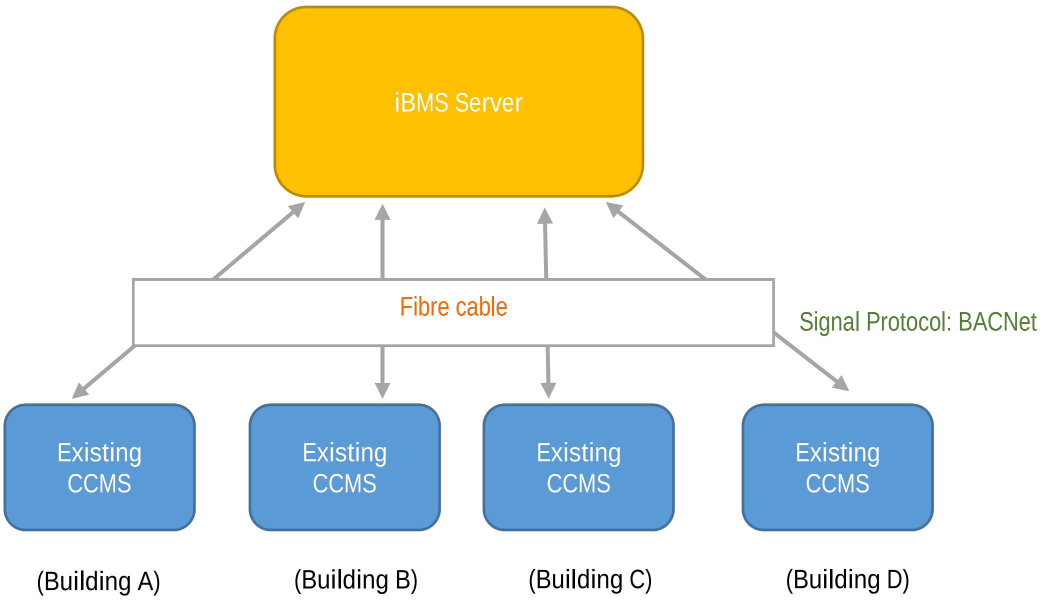

Figure 1: System architecture of the integrated BMS (iBMS)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Since the implementation of the iBMS, the operation and maintenance work has become more effective. As the control and monitoring of the E&M equipment can be carried out through one central console, the maintenance team does not need to travel between buildings. Manpower is saved and staff can carry out maintenance work more efficiently and effectively. Operation and control of E&M systems of the four buildings become easier as these can now be done using the same interface.

The iBMS also enables a faster response to equipment faults and even allows pre-diagnosis to be carried out. By setting the auto escalation mechanism, alarms can be sent directly to management staff and repair team whenever they are triggered. Alarms will be shown in iBMS, the GIS and alarming SMS will be sent to mobile phones of the maintenance staff. Reporting time is saved. As the iBMS can be accessed anywhere, the repair team can check the system status and conduct a pre-diagnosis. Proper manpower, parts and tools can be well prepared which significantly enhance the efficiency of repair work.

iBMS also helps in energy saving. With the iBMS, energy consumption is monitored and recorded continuously. The trend analysis provides data-driven insight to optimize E&M system operation. On the other hand, the energy consumption data also helps identify abnormal energy consumption pattern due to equipment failure, e.g., a faulty control valve which cannot be properly closed wastes energy and causes overcooling.

The remote monitoring provided by the iBMS also helps in maintenance management. With the understanding of the system status and load, management can suitably mobilize maintenance workforce and prioritize the work.

3. OPERATION AND MAINTENANCE OF PUBLIC TRANSPORT INFRASTRUCTURE

Over 90% of Hong Kong's 7.3 million population use public transport regularly. Every day, over 12.6 million passenger journeys are made on the public transport systems which include railways, buses, minibuses, trams taxis and ferries. The efficient mobility provided by the public transport systems, and also to the users of around half a million of private cars, depend on a well-developed and properly maintained transport infrastructure and its associated road side facilities, enabling people in Hong Kong to move around and reach their destinations easily, quickly and safely despite its high density.

3.1. Traffic signal control system

A central traffic signal control system covering over 1,800 signalized junctions is operating round the clock throughout the year for the allocation of the right-of-ways properly at road junctions for safe movement of vehicles and pedestrians.

The planning, upgrading and replacement of all traffic signal systems are initiated and undertaken by the Transport Department of Government of the Hong Kong Special Administrative Region, whilst EMSD looks after their maintenance.

Apart from equipment aging and system expansion, traffic signal systems and associated equipment distributed throughout the roads of Hong Kong are exposed to all kinds of weather phenomena – from the dry, cool winters to the wet and hot summers, from tropical cyclones to torrential rain and thunderstorms. They are also prone to direct damage by traffic accidents. Underground cables are sometimes damaged by road excavation works. With a view to improving the reliability and performance of the equipment, which is of paramount importance in ensuring road safety, EMSD started to implement in 2013 an asset management system, and has subsequently accredited under the ISO 55000 series of international standards in 2014. Under the ISO 55001 asset management system, critical analysis of past failures/complaint cases and associated risk analysis were performed. The maintenance team identified and implemented a number of improvement measures, including the implementation of a two-tier monitoring system to ensure timely feedback of repair status to complainants, enhancement of fault data collection and analysis, taking immediate action to investigate repeated junction controller failures, etc.

3.2. Geographic information system

As there are a huge number of traffic signal assets distributed over the territory of Hong Kong, a geographic information system (GIS) platform was developed for better management of the asset information. All asset information of traffic signal system was converted into a manageable database. A live monitoring feature with three condition levels was developed for indicating the equipment status. The integration of the asset databases

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

with GIS has greatly improved the user-friendliness and life cycle maintenance of the asset management system, enabled faster response to equipment failure and enhanced the effectiveness in maintenance management and replacement planning of these assets.

3.3. Remote Monitoring Unit (RMU) for transport infrastructures

Upon the successful use of GIS for asset management of traffic signal system, EMSD has extended the GIS-AM protocol to other transport infrastructures under her maintenance. Unlike traffic signal system, most of these infrastructure systems are operating in standalone mode without any remote monitoring tools. To acquire the desired information from the remote facilities, we have adopted wireless solution as mobile network technology is very mature nowadays.

EMSD has developed a remote monitoring unit based on customized System-on-Chip (SoC) module with mobile network module integrated to enable mobile transmission of the equipment operation data. The RMU has different interface ports for various monitoring purposes, and can monitor on/off status and measure analogue signal. The measured signal is digitized for transmission to the server via mobile network.

The RMU is now applied to transport infrastructures including footbridge lifts and escalators, ventilation systems at public transport interchanges, and submersible pumps in subways and underpasses.

4. INTEGRATION OF iBMS/RMU/GIS

Live equipment status from iBMS and remote conditions of transport infrastructures are now integrated under a single GIS platform, as shown in figure 2. Different types of systems or infrastructures are displayed in different layers of the GIS. Staff responsible for different systems can select individual layers of interest, while management staff or staff in the fault call centre can select multiple layers for territory-wide overview of the infrastructure conditions.

The integrated iBMS/RMU/GIS platform enables real time monitoring of system healthiness, and sends early warning of equipment fault to maintenance staff. This integrated platform also provides a user-friendly geographical interface to facilitate quick deployment of technical workforce to resolve problems. All these help reduce the fault response time and fault rectification time and improve the reliability of critical infrastructure systems. Furthermore, the integrated platform also facilitates optimization in energy usage in building and infrastructure systems.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

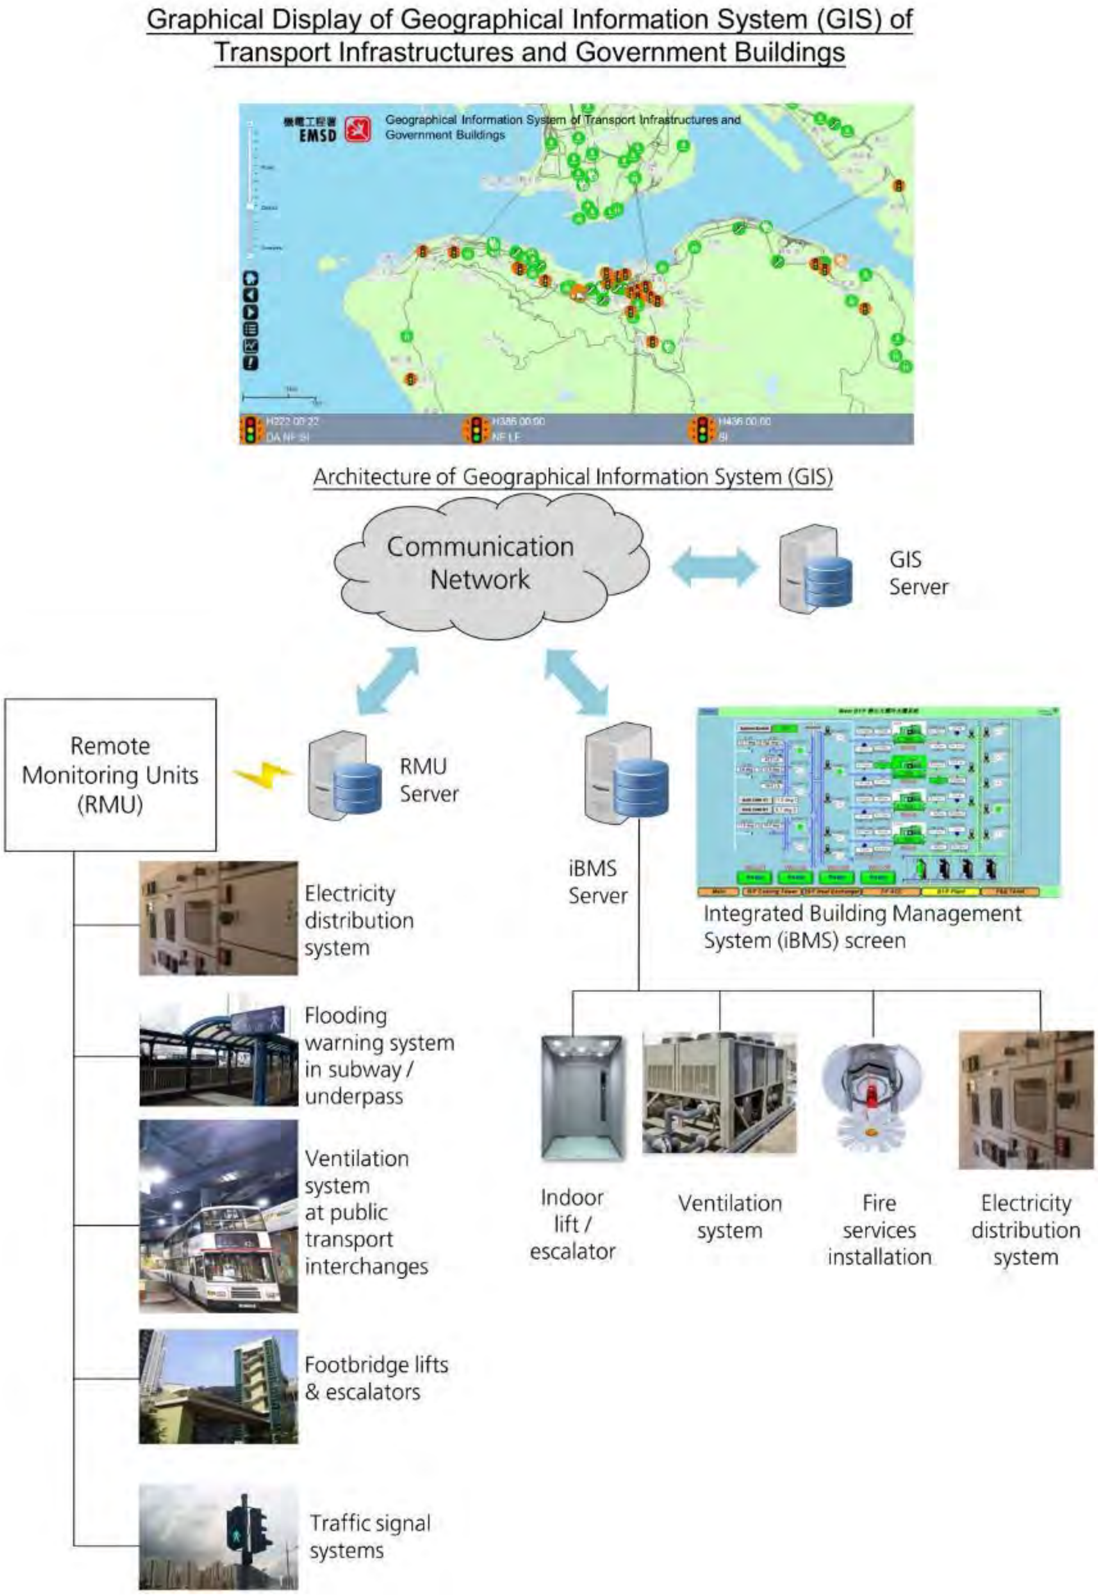

Figure 2: Integration of iBMS, RMU and GIS

5. CONCLUSION

As a positive step in transforming Hong Kong towards a smart city, EMSD has built an integrated iBMS/RMU/GIS which enables easy visualization of the real-time status of a wide range of E&M systems distributed around Hong Kong; provides critical information to facilitate decision making and quick deployment of suitable workforce and support to resolve problems; as well as facilitates optimization in energy usage in buildings and infrastructure systems.

ABSTRACT

With the prevailing global challenges facing energy providers to provide secure, affordable, profitable, resilient and sustainable forms of energy a trend towards finding the optimum solution is developing.

In response to these challenges the concept of Microgrids supplied by distributed energy resources has seen steady increase in research and development funding, technological advances and real world adoption. With this trend towards the adoption of Microgrids for distributing power there also exists the opportunity to harness the energy cascade principle to provide co and tri-generation, providing Heating and Cooling in a district configuration to provide a Micro Energy Grid (MEG). When controlled as a single entity with real time feedback and control to respond to the local consumption, large savings in carbon emission associated with the generation of energy are possible alongside reductions in peak energy demand leading to reduced reliance on centralized energy generation.

This paper sets forth the opportunities and barriers for implementation through technical, regulatory and business case analysis of large scale, smart distributed energy resources drawing on experience from large scale projects across Asia

Keywords: smart micropower generation, distributed energy system, decarbonisation

1. INTRODUCTION

Carbon dioxide emission is widely recognized as the major contributor to global climate change. Whenever fossil fuel such as gas, coal, oil are burnt, carbon together with other greenhouse gases are released into the atmosphere creating a cascading effect leading to climate change.

Climate change has progressed rapidly with the urbanization of the developed countries since a city is major contributor of carbon emissions such that urban activities constitutes over 80% of anthropogenic carbon dioxide emissions produced globally each year due to the enormous consumption of energy resources (While & Whitehead, 2013).

Recently steps have been taken to ‘decarbonise’ the supply of electricity, that is in essence to reduce the amount of carbon produced for each Kilowatt-hour (kWh) of electricity produced. Moves towards renewable energy sources, natural gas and nuclear energy away from cheap and polluting coal are being undertaken globally.

At the recent Conference of Parties 21 held in Paris (‘COP 21’) over 190 nations put forward their commitment to reducing carbon emissions with the stated goal of limiting global temperature rise to less than 2 degree. Amongst these China has committed to a reduction in energy intensity (as a unit of Gross Domestic Product (GDP)) of 15% whilst the carbon intensity reduction target announced in the 13th 5 year plan calls for an 18% reduction, thusly it can be concluded that the 3% gap will be made up primarily of a growth in renewable (and nuclear) energy sources.

Naturally, as China moves towards a service economy with a continued targeted GDP growth of 6.5-7%, away from the previous manufacturing led growth engine a reduction in energy intensity is foreseeable. However, alongside the issue of carbon emissions is a further pressing concern, namely the current environmental challenges of air, water and soil pollution. Air pollution in particular presents a challenge which can be directly correlated to the generation of electricity. A recent study by Greenpeace found coal fired power plants to be responsible for over 250,000 premature deaths in in 2011 (Greenpeace, 2013) alone.

A further factor influencing development of the energy business in China is the increased rate of urbanisation, such that 53% of Chinese citizens lived in urban areas in 2013, compared to 22% 30 years earlier (Climate Nexus, 2015). It is expected that 68.6 % of china’s estimated population will live in urban areas by 2050, causing the development of new cities with an expected 221 new cities by 2020 (Worlds Resource Institute). Increasing population and new cities development calls for the idea of sustainable urban development. China's National Development Reform Commission (NDRC) announced a National Pilot Program on Low-Carbon Provinces and Cities. In addition to these pilot regions, many other cities, such as Qingdao, Wuxi and Suzhou have also undertaken a variety of approaches to building low carbon cities.

As a response to the need to develop a low-carbon, less polluting solution for the provision of energy against the backdrop of growing urbanisation and the emergence of new technologies, ours is a world moving towards a smarter (in the technological sense) society, driven by real time information and decisions made based upon data and information gathered from interactions. With these drivers, there exists the opportunity to revisit our thinking on how we provide and use energy in our cities, one such approach is the application of Micro Energy Grids.

For this study a community expected to be developed in China was selected. Buildings in the community were categorized in terms of functions and annual demands were computed for individual building types. Sustainable energy supply strategies were selected to form a micro energy grid for the community. Cost-effectiveness study was performed by varying the system capacity, development size and discount rate and subsidies. This study is based in the China, but the community micro energy grid model is generic enough to be applicable to other countries.

2. DEFINING A MICRO ENERGY GRID

A microgrid is defined as development or district scale distribution system containing distributed electricity generation (DG) and loads, which is controlled to balance supply and demand within the microgrid, the operation of which can be separated totally from the main distribution systems (i.e. the utility grid) or connected to it. A Micro Energy Grid (MEG) is where the concept of an electrical microgrid are expanded to further capture the improvements in efficiency through the harnessing the by-products of generation (namely heat) to produce cooling and heating for distribution to the district.

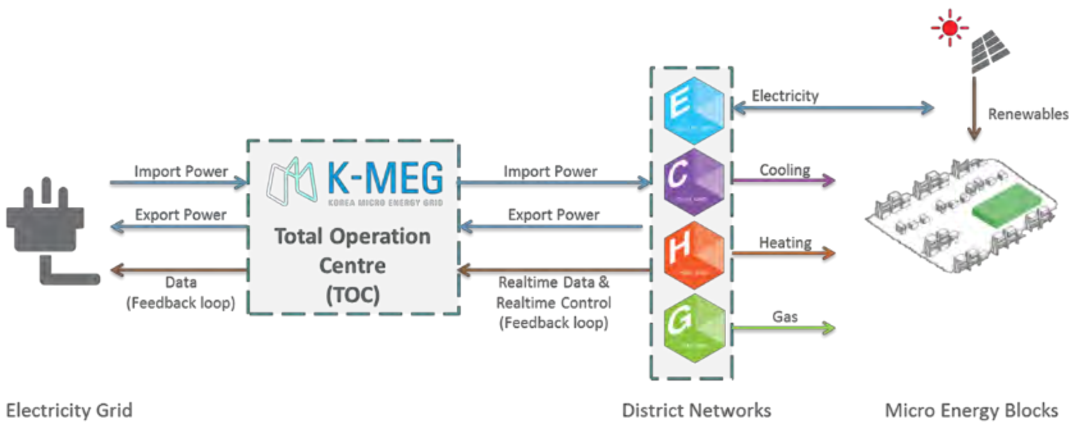

Figure 1: Micro energy grid (MEG) concept schematic

3. BENEFITS OF A MICRO ENERGY GRID

There are a number of benefits realized through the development of MEG:

- Improved efficiency against traditional power supply: The process of generating electricity in a thermal power plant generates large amounts of waste heat. In a typical power plant this heat is rejected to the atmosphere via cooling towers or via the use of sea water. Further, large centralised thermal power plants tend to be located away from urban centres (and therefore the main loads) due to impacts on local air quality, this leads to large transmission networks across which electricity is lost. Given these limitations, a typical utility grid supply only delivers around 40% efficiency for each unit of fuel input.
  Through locating DG sources within a development, making use of cleaner fuels to reduce air quality issues and the 'energy cascade' principle whereby waste heat from the process of electricity generation is utilised, the overall system efficiency can be increased to upwards of 80%, a sizable improvement over the traditional approach. A further consideration is the ability to reduce water stress, as water used to remove

heat from the steam cycle can be harnessed and reused within the MEG for space heating or heating of hot water for domestic or industrial use.

Depending on the types of building to be sited in a particular development, there exists the opportunity with MEG to share resources, for example utilising roofs of residential buildings to site PV panels which feed into the grid and power office buildings. This sharing of resources, coupled with control of the supply infrastructure allows the optimisation of operations.

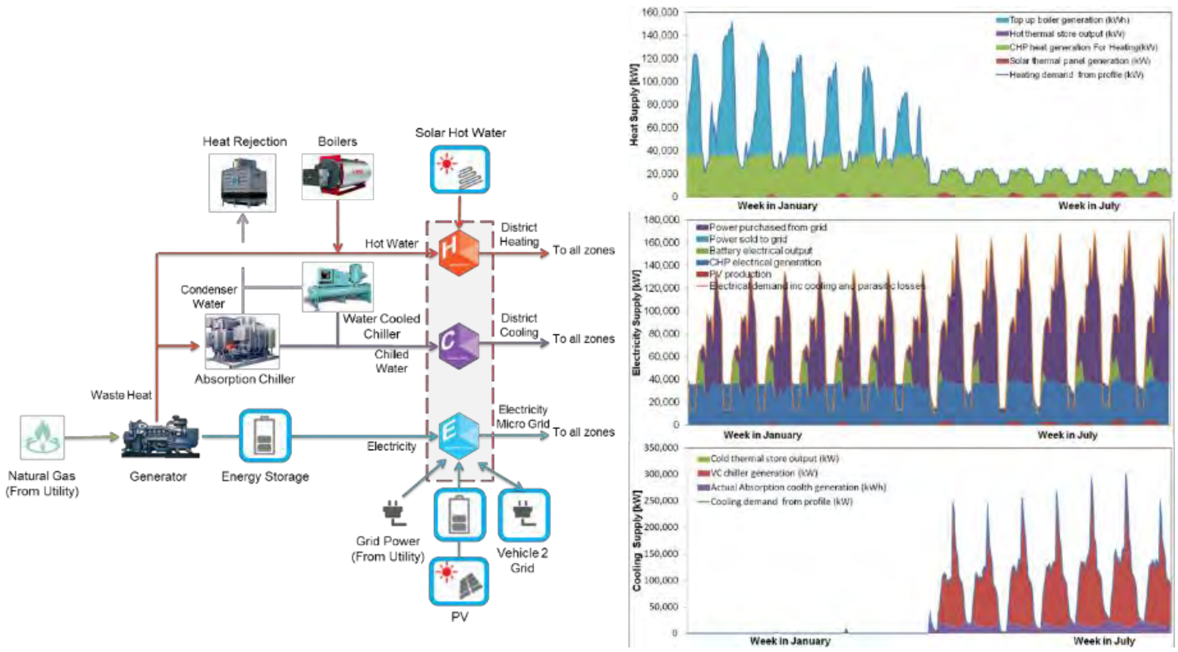

Figure 2: Typical MEG system schematic showing energy cascade (l), Flows of energy in a reference project during peak winter and peak summer weeks (r)

- Reduced installed utility capacity: Each building within a development will have a distinct operating schedule, for example when combining the schedules of a hotel and office it is fair to assume that whilst one is occupied, the other shall be less so. This variance in scheduling is reflected in the energy demands of each building type. When considering multiple building types as a combined entity, as is the case with a MEG, the concurrent demands of each space total less than the combined peak demand of each. By sizing the required equipment to serve the district based upon these concurrent loads, the amount of plant, distribution etc. to be installed can be significantly reduced.

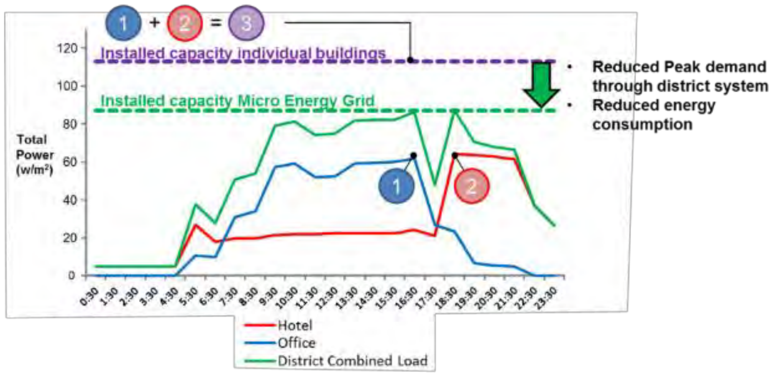

Figure 3: Reduction in installed utility capacity

- Support distributed energy including waste-to-energy, industrial process etc.: When planning district developments there are a number of infrastructure elements which must be considered, including how to deal with waste (organic, inorganic, sewage etc.) and in certain cases whether industrial type buildings will be provided. Where these elements are to be provided the MEG concept offers benefits. The benefit is derived from generating energy from waste, for example Anaerobic Digestion of organic waste to produce

Biogas which can be used for electricity generation, thus increasing the ability of the MEG to be self-sufficient.

- Enables demand response: Demand response (DR) is the ability to control the loads, or demand for energy from an end source to reduce the total amount required at a given time. The concept of DR is one which although possible with a centralised, traditional system is trickier as it involves the retrofitting of Smart meters and the means to control end uses. The process becomes easier to install and importantly to manage on smaller scales, where control over loads and the ability to respond to changes in demand is faster given the smaller distribution network and lag times on signals and response.
- Embraces the smart city, empowering users: A core principle of the MEG approach is the use of real time data to inform the operation of the system and to provide detailed information to end users. An important aspect of the Smart city is educating users through information, allowing them to better understand their behaviour (in this instance, their consumption) and providing them with options and recommendations to adapt, potentially saving energy, carbon and money.
- Resiliency of supply: A key feature of a microgrid and by extension a MEG is the ability to operate in 'Island' mode. This would occur when the utility network is unavailable and the MEG would switch to being fully serviced by its own interconnected supplies. Referencing the ability to control the demand of the MEG, if required loads may be shed across the MEG to balance supply and demand. This feature comes in to its own when availability of the local utility supply is not guaranteed or in areas where natural disasters are liable to impact upon power supply.

4. CASE STUDY

The micro energy grid model was applied to a community in Qingdao, China to identify the benefits of the micro energy grid compared to the conventional energy supply model and to evaluate the business feasibility of the micro energy grid model. The community is composed of 18 zones and comprised of 76 separate building plots located in Shandong province, China. Each zone is designated as a distinct building type including residential, education, office, retail, healthcare, community and hotels. The total floor area of the community is 3.2 million m^2 to be constructed in 2 phases. Based on the study of the energy and carbon emissions related regulations, three KPIs were identified and targets were set to align with the national and local government's overall target; 1) Energy consumption reduction of 25%; 2) Carbon emission reduction of 26%; 3) Renewable Energy Generation of 2%.

4.1 Technical analysis and carbon emissions savings

Extensive energy modelling was performed to determine the demands of electricity, heating and cooling over the course of the year. To cater for these loads and meet these sustainability targets a new approach was sought, namely the development of the MEG concept. Numerous technologies were assessed against 6 key criteria, technical and environmental performance, commercial viability, occupant satisfaction, proven technology, space required, and applicability.

The selected technologies included the use of a 36MW natural gas fired tri-generation system which would provide base power, heating (in winter) and cooling (in summer) to the district. The tri-generation system would be supplemented with 20 MW of batteries (for electrical storage), 5MW of distributed PV's and 6,700 m^2 of solar hot water panels, in turn connected to the district networks. The renewables systems were designed to allow sharing of resources across building types, for example power from PV's would be fed back to grid from residential blocks during the day for use in commercial blocks. Figure 2 above shows the MEG system schematic and energy balance.

The combined carbon emission factor (including power from grid, natural gas and MEG generated) for the MEG system was calculated to be 0.64 kgCO_2/kWh, a 25.7% reduction when compared to traditional energy supplied from local utilities in Shandong Province.

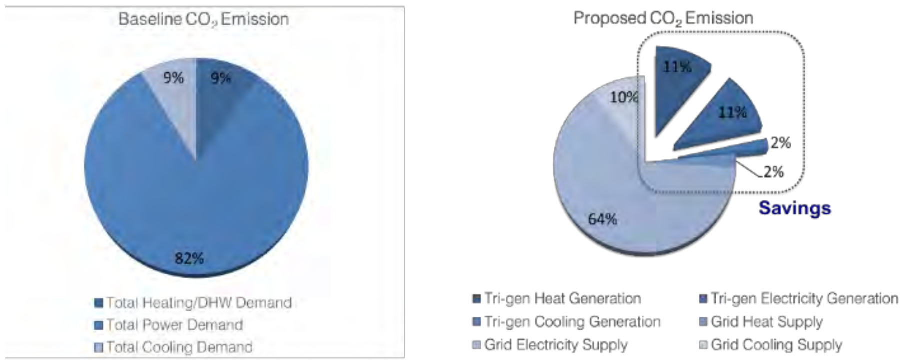

Figure 4: Carbon emissions savings for the project

4.2 Economic analysis – providing the business case

In order to review the business case of the MEG masterplan, lifecycle economic analysis was developed. This analysis takes into account the costs and revenues associated with the MEG including development, replacement, operation and maintenance and energy cost; set against, government subsidies (in the form of feed in tariffs or direct subsidy) tariff revenues which including avoided costs of not needing to install individual building level system equipment. The objective of the MEG to be a viable business relies on the basis that the end users shall not be paying an excessive cost for energy. As such, the basis of analysis was to maintain the tariff levels similar to existing utilities, however allowing for the avoided system costs as outlined above. Inflation and increase in fuel costs were both taken to reflect the China average of 3% for the purposes of analysis.

The economic analysis is performed considering three different aspects of factors impact; financial conditions, system capacity and development size. Financial conditions considered in this study are the government incentive and the investment discount rate of the project. The baseline discount rate used to calculate net present value (NPV) and payback time was 10% as this is a typical interest rate for large scale infrastructure development projects. A range of 3 ~ 15 % was used as part of a sensitivity analysis. To consider the impact of system sizing, three different tri-generation capacities and three different battery sizes were simulated in the micro energy grid model. In summary, the simulation was carried out for multiple combinations of each parameter shown in Table 1.

Scenario	Discount Rate [%]	Government Subsidy [cents/kWh]	NPV [US million $]	IRR [%]	Discounted Payback [Yrs]
Scenario 1.1	3%	0.0	1082.96	10.4	16
Scenario 2.1	5%	0.0	445.28	10.4	18
Scenario 3.1	7%	0.0	173.07	10.4	23
Baseline case: Scenario 4.1	10%	0.0	10.66	10.4	51
Scenario 5.1	12%	0.0	-34.98	10.4	>60
Scenario 6.1	15%	0.0	-68.17	10.4	>60
Scenario 1.2	3%	3.7(0.25)	1291.45	12.3	13
Scenario 2.2	5%	3.7(0.25)	579.65	12.3	14
Scenario 3.2	7%	3.7(0.25)	265.90	12.3	16
Scenario 4.2	10%	3.7(0.25)	69.50	12.3	22
Scenario 5.2	12%	3.7(0.25)	10.63	12.3	38
Scenario 6.2	15%	3.7(0.25)	-35.34	12.3	>60
Scenario 1.3	3%	5.2(0.35)	1374.85	13.4	12
Scenario 2.3	5%	5.2(0.35)	633.40	13.4	13
Scenario 3.3	7%	5.2(0.35)	303.04	13.4	15
Scenario 4.3	10%	5.2(0.35)	93.04	13.4	18
Scenario 5.3	12%	5.2(0.35)	28.87	13.4	24
Scenario 6.3	15%	5.2(0.35)	-22.21	13.4	>60

Table 1: Economic sensitivity analysis

The results of the economic analysis showed that the project could satisfy the clients' requirements for a feasible project and as such could be further developed.

5. IMPLEMENTATION CHALLENGES FACED

Throughout the development of MEG projects, a number of challenges have been faced. In particular the allowable scale of distributed energy was encountered as a potential roadblock, with local codes and requirements of State Grid limiting on- site power generation to 6 MW, which would in many cases directly impact the viability of deploying a MEG as generating capacity is capped. To overcome this limitation close negotiation is needed with State Grid (or local electrical grid provider), for which the support of the project sponsor is key.

A further challenge faced is the uncertainty of subsidies and feed in tariffs provided by national, provincial and local governments. For the project to be economically viable an element of Government support is required, as with any nascent technology. Securing agreement and long term commitment to rates is something which must be considered and negotiated on a project basis.

6. CONCLUSION

The following conclusions are made for this study.

- The micro energy grid for a community is very effective on reducing peak energy demand and carbon emissions by optimizing energy supply to meet the energy demand in real time. The micro energy grid is financially feasible with the combined use of a tri-generation system, energy storage, and renewable energy sources applying demand response strategy.
- The sizing of the tri-generation and energy storage plays an important role in the micro energy grid concept, since the majority of the energy and carbon savings and revenue are generated from the tri-generation. The operation mode of tri-generation shall be determined considering the size and stability of base load as well as load types to maximize its energy efficiency and carbon reductions.
- Demand response is an effective means for the peak shift in the micro energy grid which reduces power generation and optimizes power balance. The size of demand response is determined by the load profiles of peak to base load ratio and energy storage capacity.
- The discount rate and government subsidy are the key factors affecting the financial feasibility of the community micro energy grid since they affect the operation cost and revenues. For the micro energy grid in China to be financially viable, the government subsidy is a necessity. Therefore, negotiation of tariff of purchased power and maintenance cost of utility network are important for the successful implementation of the community MEG.

ABSTRACT

This paper intends to illustrate the importance of integrating built environment, business environment and human environment for developing a sustainable neighbourhood where smart mobility, smart economy and smart living would be realized. Global concepts of Transit-Oriented-Development (TOD) and Smart City would be applied for developing Hong Kong's Kowloon East District into a second central business district (CBD2) where an integrated live-work-play thriving domain will act as a complementary to the existing Central Business District (CBD) in Hong Kong Island. Afterwards, a comparative study on Singapore Marina Bay Project is conducted to validate this multi-disciplinary approach. The Importance of TOD and virtual infrastructure in value-added of Hong Kong's local economy and culture will be mentioned. In this pursuit, economic growth plays an initiative agent for energizing social and environmental sustainability. This study aims to provide local decision makers including private, public and academic sectors an overview of a productive chain of collaboration among different operational sectors after assessing and discussing and studying the case, so that they will gain a better notion of the possible need for integrating different forces to reach a common goal benefiting to all the stakeholders.

In the community scale, the objective is to regenerate the old industrial district where new business, entertainment and international culture (food, youth and festival), entrepreneurship and sustainable built environment activate the development of this dynamic and prosperous district.

In the regional scale, due to Hong Kong's recent decline in world competitiveness ranking, the agenda of KEDP acts as a pilot test for transforming Hong Kong into a Smart Human E-City and for strengthening her competitiveness in the world at the same time.

In the global scale, as stated by the United Nation, global warming and rapid urbanization leading inequity in society which are the global city problems everyone is facing now and onwards. By adopting this recommended integrating framework, it is going to create a new vision in Hong Kong's city planning practice to build an active and liveable environment for the locales to master a sense of belongings with the end goal for enhancing quality of urban life.

Keywords: transit-oriented-development, smart neighbourhood, sustainable neighbourhood, quality of life, integration of urban system

1. INTRODUCTION

Hong Kong is an important trading and financial hub in the global economy. Thus, the current Hong Kong competitive economic model heavily relied on the four industries: finances, trading, logistics and tourism. Some have questioned the ability of Hong Kong to shift toward innovation and entrepreneurship from its current key industries. On the other hand, the rise of other world cities, and especially Singapore, have been threatening the competitiveness of Hong Kong in recent years. However, we firmly believe the development of the new East Kowloon District (CBD2) can offer a unique opportunity to enhance the attractiveness and competitiveness of Hong Kong as "Asia's World City". The character of the CBD2 will be incorporated through the built environment, business environment and human environment in order to create a vibrant, dynamic and multi-functional district catalysed by these effective components: 1) TOD and information technology; 2) local-international economic growth; and 3) entrepreneurship and E-Youth culture. In such case, this CBD2 is going to provide a dynamic and fresh environment for local and non-local young at heart and global-minded people to foster creativity and entrepreneurship via physical (TOD) and virtual (ICT) connectivity and robust economic activities. We stress on using the space smartly with an orientation towards social, economic and environmental sustainability.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Transit-oriented development (TOD) is defined as a high-density, mixed-use development within walking distance (a 1/ 2 mile) of a transit station. TOD provides a range of benefits including increased transit ridership, reduced regional congestion and pollution, and healthier, more walkable neighbourhoods where economic and social capital would be flourished also. Therefore, in this paper, Mass Transit Rail (MTR) stations of Kwun Tong, Ngau Tau Kok, Kowloon Bay and Kai Tak are the transit stations regenerated, invigorated, connected and sustained by this multi-disciplinary environment. Whereas, virtual connectivity such as Information & Communication Technologies (ICT) is employed in various aspects of the city management and services delivery in order to connect and integrate those relevant systems effectively and smartly for enhancing quality of life in the context of social, economic and environmental sustainability. In addition, the concept of smart city is being used. According to Boyd Cohen, "Smart City has six aspects: smart economy, smart mobility, smart environment, smart governance, smart people, and smart life. He also stated that a "smart city" is one that exploits technology and innovation to make efficient use of resources and reduce the size of the ecological footprint, and still a people-oriented city.

2. CBD2 CONCEPT: INTEGRATION OF BUILT ENVIORNMTN, BUSINESS ENVIRONMENT AND HUMAN ENVIRONMENT

We propose a plan of dividing the East Kowloon District (former Kai Tak Airport: 320 hectares; Kwun Tong and Kowloon Bay: 168 hectares) into 5 function zones (Figure 1). They are 1) Low-Carbon Green Zone; 2) Industrial Heritage Rehabilitation Zone; 3) Modern Residential Commercial Zone; 4) Multipurpose Sports Centre; 5) Premium Tourist, Residential and Commercial Business Zone supporting by well-connected MTR transit nodes including Kowloon Bay, Ngua Tau Kok, Kai Tak and Kwun Tong, ride sharing services and walkable green foot bridges/ green decks, universal accessible biking paths and sustainable green public open spaces. Here TOD is the major connectivity linking all the created function zones in order to harness their complement among each zone in the CBD2 and even to other CBDs in terms of cultural, social, economic and environmental performance. In the urban scale (Figure 2), local ferry route is added at Pier 1 to connect workforce from CBD2 to the CBD in central (HK Island). At Pier 2, new ferry route is added for connecting tourists and workforce to the CBD and shopping centres at Tsim Sha Tsui (Kowloon Island). For another serious consideration, along the promenade from Kwun Tong all the way to Tsim Sha Tsui, a walkable, bikeable and rideable (mini e-car) sustainable green lane is an effective activity-based sustainable development plan. For connecting Kowloon Bay (Low-carbon Green Zone) to the Kai Tak International Cruise Terminal (Premium Tourist Residential and Commercial Business Zone), a green deck (a hybrid of public open space and fly bridges) is built for pedestrians to enjoy a walking journey full of cultural exhibitions and creative street performance.

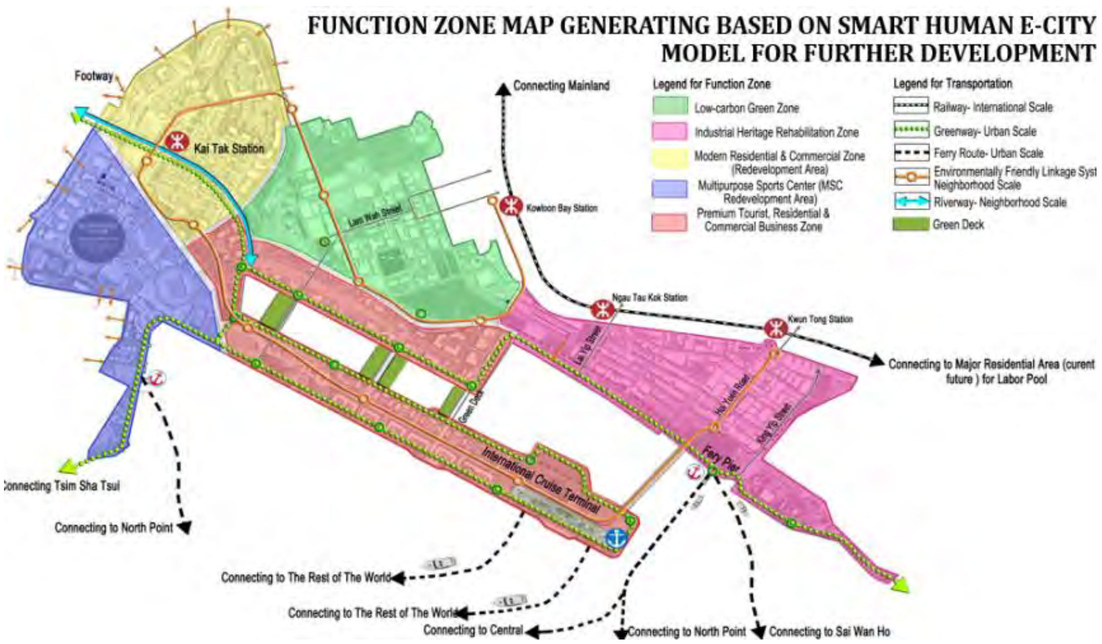

Figure 1

Figure 2

In the international scale (Figure 3), multiple cruise ship routes linking to the world by sea, MTR nodes linking to the inter-city-train to Mainland China all the way to Europe and South East Asia on land, and international airports nearby Hong Kong to the World by air.

Figure 3

At the same time, in order to achieve economic growth sustainably in the area and strengthen the competiveness of Hong Kong's economy in the world vigorously, a dynamic and sustainable virtual infrastructure would be in formation where technology, information, knowledge, monetary and internet of things data can be accessible and shared easily so that this proposed function zones can interact and work with the world 24/ 7 and enhance the utmost capacity of the physical environment significantly and swiftly. With this efficient communication media where value-added youth culture and international cultural accessibility will add fresh energy and diversity in nurturing sustainable human environment. At its best, smart mobility, smart economy and smart living would be reachable, and tourism and retail-wholesale-oriented economic activities would be fostered and robust in the CBD2 for the purpose of sustain its business environment.

3. CURRENT PREFERABLE CONDITIONS FOR THE CBD2

- Physical environment
  - Convenient connectivity in different scales: International scale, Urban scale and Neighborhood scale.
  - Wi-Fi infrastructure is well developed in HK with high speed.
  - Storage and manufacturing buildings provide vast space for building data center and facilitate international trade.
- Business environment
  - Free trade and investment policy
  - Well-implemented rule of law with strong enforced rules and regulations
  - Free capital inflow and outflow
  - Low taxation policy and a simple tax system
  - Well-functioning financial markets
  - Close proximity to markets in Asia
  - Gateway to mainland China for business
  - Labour market of highly-skilled workers
  - Well-developed infrastructures
  - Large pool of advanced producer services
  - International lifestyle and diversity
- Human environment
  - The studied area has a large portion of young people
  - Most of the residents are relatively well-educated
  - The distribution of the wealth is relatively equal

4. TIMELINE FOR IMPLEMENTATION

In light of the above preferable conditions, this CBD2 is loaded with many of the necessary factors to overcome its current disadvantages as an old industrial town. Whereas, the old industrial town outdated characters might be just the reason for revitalizing the out-dated industrial area and lies the opportunity for a prosperous future in the long run. Below is a timeline for illustrating how this multi-disciplinary approach is implemented (Figure 4).

Figure 4

5. COMPARATIVE STUDY: (SINGAPORE VS HONG KONG)

Items	Singapore New CBD 2030 (Marina Bay Development:360 hectare)	Hong Kong CBD2 2030 (Kowloon East Waterfront Development:488 hectare)
Historical Background	Singapore is a city-state, a British colony and then a state of Malaysia before its independence to become the Republic of Singapore in1965. A prominent international financial centre and a port city lived by 74.1% Chinese, 13.4% Malay, 9.2% Indian and 3.3% others. With close tie to adjacent Malaysia and neighbour of Indonesia.	Hong Kong SAR is a special region of the People's Republic of China (PRC), a British colony before its handover back to the PRC in 1997. A prominent international financial centre and a port city lived by 93.6% Chinese and 6.4% others. With close tie to adjacent PRC and neighbour of Guangdong cities of PRC (one country two system)
Population (Million)/ Area (2016)	5.6/ 719.2 square km	7.3/ 2,755 square km
Literacy Rate	96.8 (2015)	95.7 (2014)
Density	7,797/ square km	6,544/ square km
GDP at current market price (US$ Million) GDP/ capita (2015)	$402,457.9 $72,711	$307,300 $42,100
Transportation	A TOD-Led City, transporting people by Land: MTR and BRT (Regional), by Air and by Sea (International).	A TOD-Led City, transporting people by Land: MTR and BRT (Regional), by Air and by Sea (International).
Project vision/ goal	Becoming a world winning global city with connectivity to the world. Creating a new iconic CBD (adjacent to the existing CBD), an international investment hub featuring tourism, state-of-the-art-infrastructure, parks and cultural venues, contemporary high-rise commercial towers.	Becoming a global city connecting to the world efficiently. Transforming Kowloon East into the CBD2 of Hong Kong to support economic growth and to strengthen global competitiveness.
Issues/ strength*	- old shipping ports with filthy open sewer. - resource-poor (natural and human). - land-scarce: by comparing to HK, more land has been developed which reflected on the density figure. * Efficient internet accessibility (internet users: 82.1/ 100 person; secure internet servers: 932/ 1 million persons: mobile subscriptions: 146 plans/ 100 persons.	- outdated built environment including the filthy open sewer and inefficient connectivity - old industrial-oriented business environment - low skill labour human environment needs to be upgraded to meet the challenge of the digital world. * plenty of natural and human supply from the cities of PRC. - land-scarce for development because 75% of the land are zoned for preservation (nature). * Efficient internet accessibility (internet users: 84.95/ 100person; secure internet servers: 905/ 1 million persons: mobile subscriptions: 229 plans/ 100 persons.
Function zone	Marina South: as the new CBD extension for office and some residential developments, a new lively and mixed-use residential district. Marina Centre (Marina Bay Sand) for commercial, tourism, retail malls, convention and cultural development. Marian East for residential use mostly. A true green, walkable and bikeable sustainable urban living	Area including Kwun Tong (old industrial area), Kai Tak (new development) and Kowloon Bay (commercial section): 1) Low-Carbon Green Zone; 2) Industrial Heritage Rehabilitation Zone; 3) Modern Residential Commercial Zone; 4) Multipurpose Sports Centre; 5) Premium Tourist, Residential and Commercial Business Zone
Performance	- Marina Bay Sand has become the major tourist point of interest and a new icon of Singapore. - in recent years, Singapore has gained more world recognition than Hong Kong - the ranking of quality of life organized by different world institutes positioned Singapore over Hong Kong.	- not available yet because this is only a proposed idea as a pilot test.

Table 1: Urban development project in Asia (case study for comparison)

6. EXECUTIVE SUMMARY

After examining the two new water-front development projects in Asia, one can easily find the similarity of the two: especially the goals of the development projects and their local constraints. They both use a multi-disciplinary approach to integrate their business environment, physical environment and human environment through sectioning the total development area into different function zones in order to achieve the project goals. The vision of the Marina Bay Development is an inclusive, highly liveable, economically vibrant and green home, with the six key focuses in housing, economy, recreation, identity, transport and public spaces, for all the Singaporeans. In this regard, the business environment, built environment and human environment are addressed. So far, Singapore's Marina Centre has gained excellent review by those world organizations which shows Singapore's world ranking leaping over Hong Kong for the past years. Frankly, the success of Marina Bay Sand Project at the Marina Centre sets as a valid justification for the multi-disciplinary function zone planning framework suggested in this paper. The CBD2 would become the sustainable community where entrepreneurs, small business enterprises (SME), the government and the value-added international culture would be fully developed to their utmost capacity. If Hong Kong envisions to become the "Asia's World City" and continue to lead not only in economic and social in Asia, but also culture, technology and environment, this notion of developing an integrated multi-function-zone will serve the trajectory for guaranteeing her world competitiveness in future.

Sy(e)nergies Between Mega Event Buildings and The Surrounding Neighbourhoods

Simone MAGDOLEN[a]

[a] *Munich University of Applied Sciences (MUAS), Germany, simone.magdolen@hm.edu*

ABSTRACT

Hosting major sports events such as Olympic Games is an ambivalent topic in today's society. In the last years there have been several examples for a rejection by the residents for hosting such Games. Taking this into consideration the paper focusses on the role of the constructions for major sports events, stadia and arenas in particular. Despite the fact that the organizers of mega sport events are more and more under pressure to report on the sustainable performance of their venues, they indisputably have a high resource and energy demand and therefore high costs. At the same time the events lead to numerous successes for the construction sector of the host cities. Additionally, the venues are identity donors and have iconizing effects on the cities and specifically the immediate vicinity. The potential for benefits and sy(e)nergies with the surrounding neighbourhood is diverse but so far less exploited. Up to now, most stadia are isolated, individual buildings. In fact they offer an enormous potential for the use of renewable energy sources and could be both, energy provider and energy storage for the surrounding neighbourhood. Therefore, a case study analysis has been conducted to identify potentials in terms of urban planning and energy. Moreover the study involves an investigation about the ability to connect a stadium with the surrounding neighbourhood to benefit from sy(e)nergies.

Keywords: smart neighbourhood, green infrastructure, energy saving

1. INTRODUCTION

Hosting major sports events such as Olympic Games is an ambivalent topic in today's society. In the last years there have been many examples for a rejection by the residents for hosting the Games. The most recent example is the city of Hamburg where 51.6% voted against a bid for the 2024 Olympic Games in a referendum. It puts Hamburg in a growing line with European and American cities such as Oslo, Stockholm, Krakow, Canton of Grisons, Munich as well as Boston to shun an Olympic campaign [AFP, 2015; Eberts, 2015].

Taking this into consideration the paper focusses on the role of mega event buildings in the neighbourhood. Despite the fact that the organizers of mega events are more and more under pressure to report on the sustainable performance of the venues, they indisputably have a high resource and energy demand and therefore high costs. At the same time, the constructions in combination with mega events such as Olympic Games or Football Championships, lead to numerous successes for the construction sector of the host cities, such as the introduction and improvement of environmental laws and building standards in the field of energy efficiency and sustainability as well as the promotion of energy-efficient and ecological technologies in construction [Essig et al., 2012]. Additionally, the venues are identity donors and have iconizing effects on the cities, specifically on the immediate vicinity [Preuss, 2004].

Back to one of the examples for a rejection of the Games, the city of Hamburg: The highest percentage of rejection is in the immediate vicinity of the planned event locations. It came from the nearby residents in the centre of the city where most of the sports facilities should have been situated (see Figure 1). This can be ascribed to the formally known "Not in my Backyard" (NIMBY) phenomenon, the opposition by residents to a proposal for a new development because it is close to them.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

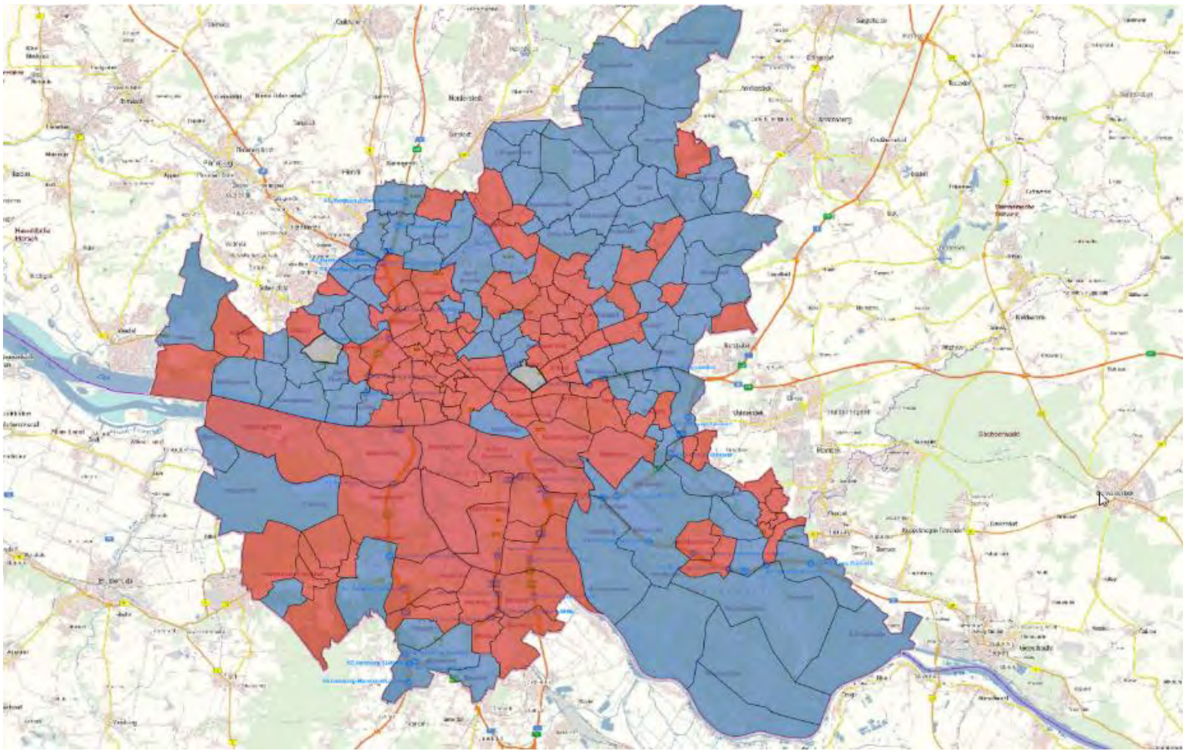

Figure 1: Result of the referendum on hosting the Olympic Games in Hamburg 2024 [Statistisches Amt für Hamburg und Schleswig-Holstein, 2015]

Consequently, the following questions arise: Is having a major sports arena in your neighbourhood so bad? What are the positive aspects and benefits for the surrounding neighbourhood and how can they been strengthened? Far too little attention has been paid to the potential for sy(e)nergies of a stadium with the surrounding neighbourhood which is diverse. Unfortunately up to now, most stadia are isolated, individual buildings. In fact, due to the large roof and facade surfaces and mainly massive construction, stadia offer an enormous potential for the use of renewable energy sources and could be both, energy provider and energy storage for the surrounding neighbourhood.

Therefore, a case study analysis has been conducted to identify potentials in terms of urban planning and energetic aspects. Moreover the study involves an investigation about the ability to connect a stadium with the surrounding neighbourhood to benefit from sy(e)nergies. The goal is to develop a broader understanding of the building typology (stadium) and its role in the neighbourhood. From the point of view of sustainability a stadium should be more than a venue for large sport events, the typology also offers a lot of potentials for improving the social and energetic qualities in the neighbourhood.

2. FROM STADIUM TO NEIGHBOURHOOD

2.1 Status quo: Stadia today

Unlike the ancient Greeks who hold major sport events on earth walls [Essig, 2010], we are hosting them today in big stadia and arenas. A stadium in the modern sense describes a venue of sporting competitions in the form of a playing field or swimming pool surrounded by a stand for the spectators [Karch, Höf, 2008]. As in the early 20th century the athletes had played on uneven lawns with two makeshift goals without nets, the current requirements changed completely. The first stages usually only offered standing places. Covered stands were initially extremely rare, so most competitions were organized under the open sky. In Europe, stadia were characterized by the 400 m running track whereby the stands were a few meters away from the pitch. Over time sports such as handball, basketball, volleyball and hockey tended more and more to move to closed halls. At the same time stadia with 400 m running track increasingly disappeared and there were more and more pure football stadiums built. With the age of television as well as in line with the increase in commercialization of sports events, luminous installed floodlights and the stadium itself increasingly gained importance [Adam, 2010]. In contrast to the stages of the 70's buildings now arise "whose close envelopes capture the visitors 90 minutes, directly adjacent to the pitch" [Karch, Höf, 2008].

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Since an accident due to mass panic in Brussels (1985) single seats are prescribed. As with bigger arenas the operating costs explode, big VIP areas are forced more and more. Because of the size as well as more and more functions the building covers, the requirements for infrastructure regarding catering, plumbing, space, etc., increased immensely [Adam, 2010].

Today's stadia are more than just a venue for hosting sports competitions, they are meeting points in today's society, places of action, of exchange, the encounter of different cultures and much more.

2.2 Sustainability of mega event buildings

Undeniably, mega event buildings have a high resource and energy demand. In terms of sustainability, it is still a long way to go before you can consider mega event arenas as sustainable buildings. But the green lights are there: Non-governmental organizations like UNEP (United Nations Environment Programme), Greenpeace or WWF (World Wide Fund for Nature) as well as the organisation committees of sport events have demanded for sustainability impact assessments for venues for a couple of years in order to reduce the impact on the environment and the climate. As a result different sustainable planning concepts and the use of sustainability assessment methods have been adopted by the host cities and organisation teams.

Examples are the venues of the Vancouver 2010 Olympic Winter Games, London 2012 Olympic Summer Games or the Football World Cup of Brazil 2014. In the case of the Games in Vancouver and London the organising committees have certified their new and existing competition venues as well as non-competition facilities by applying existing national assessment schemes to build and operate the buildings to ensure a minimal environmental footprint. Vancouver, for instance, has used the North-American system LEED Canada (Leadership in Energy and Environmental Design) to assess its Olympic sports facilities. For the London Games 2012 the label "BREEAM for Olympic Park and Venues" was developed by BRE (Building Research Establishment) within the national sustainability method BREEAM (BRE Environmental Assessment Method) to assure the ecological implementation of the Olympic venues [Essig, 2010]. Considering that the IOC is only demanding for assessing the sustainability performance of the facilities, but not giving out common mandatory indicators and benchmarks, the host cities have fulfilled the assessment with different approaches. Due to the applied diverse tools and instruments, the evaluation results of the venues are not comparable at all.

In addition, by the public rejection of mega events the societies in first world countries stress that the present procedure, exceeding prior arenas with newly built bigger and full service mega event buildings, is not tolerated any more. In particular the nearby residents in the centre of the city where most of the sports facilities should have been situated are the most sceptics.

For this reason this study raises the questions about how a mega event building – a stadium or arena – changes the surrounding neighbourhood and how advantages can be derived from the adjacent location. Accordingly the present study attempts to demonstrate stadium-neighbourhood relationships and synergies as well as their inter-linking considering urban planning, infrastructure and energy.

3. ANALYSIS: STADIA AND NEIGHBOURHOODS

3.1. Locations

First step was to categorize the locations of stadia as there are different scenarios for planning approaches as well as possible synergies: It should be differentiated between in-town and out-of-town stadia. So far the locations of first league football stadia in Germany, England and Spain were analysed (Figure 2).

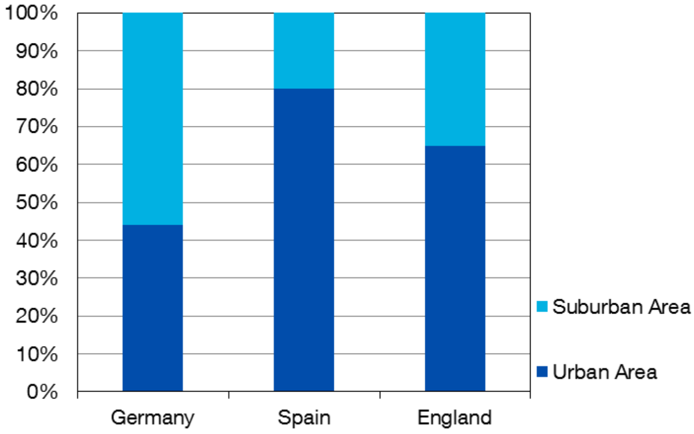

Figure 2: Characteristic location of stadia in Europe

Furthermore, the surroundings can be characterized as mixed/ urban areas, residential or commercial areas. In Germany, most stadia can be found in close vicinity to commercial areas. Moreover, a majority of stadia is located in suburban areas, which is mainly due to the high rate of new constructions for the Football World Championships hold in Germany 2006. While in England most stadia are situated in urban, mixed areas followed by residential areas, in Spain they can most likely be found in mixed areas with urban characteristics (Figure 3).

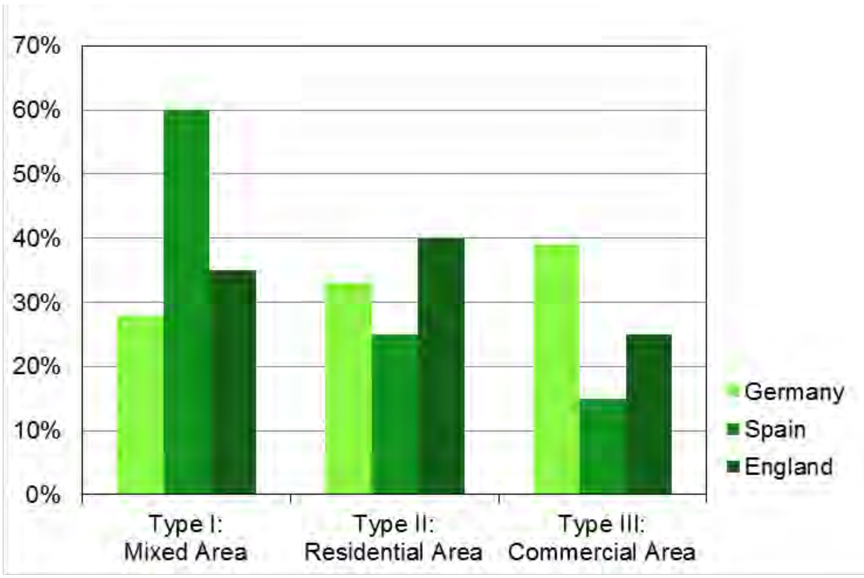

Figure 3: Characteristic surrounding of stadia in Europe

3.2. Neighbourhood related aspects

For identifying the stadium-neighbourhood relationships, case study neighbourhoods are investigated in terms of urban planning characteristics. Exemplary criteria for the study are as follows: Local supply, green spaces as well as the image and density of the district, noise, light pollution, mobility etc. In a following step potentials and synergies will be derived and presented.

3.3. Energy related sy(e)nergies

As was pointed out in the introduction to this paper, a main focus of the study are energy related synergies. Therefore, the energy demand of the case study neighbourhoods is investigated in terms of cumulated energy of the different uses, load profiles as well as share of renewable energy. Notable examples for producing energy in a stadium - for instance through integrating photovoltaic modules in the building shell - are "Mineirão" stadium in Belo Horizonte, Brazil or Weserstadion in Bremen, Germany. However, little is known about the potentials of integrating a stadium in a local smart grid so far.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Thus it will be analysed to which extent energy can be saved by the cross-linkage with the surrounding neighbourhood with the help of intelligent power distribution and renewable energy. The typical energy profile of a stadium shows a high peak load in terms of an event and a lower, but constant base load (see example Figure 4). An example of the stadium Letzigrund in Zurich shows that this base load shouldn't be neglected: 73% percent of the annual energy consumption of the stadium results from times without an event [Stadion Letzigrund Stadionmanagement, 2012]. Therefore, simulations will be performed analysing energy efficiency measures for stadia, for example to proof whether and how energy can be produced on the site of the stadium. Can energy be stored in the neighbourhood in times of no event and reversed to cover the peak loads in times of an event?

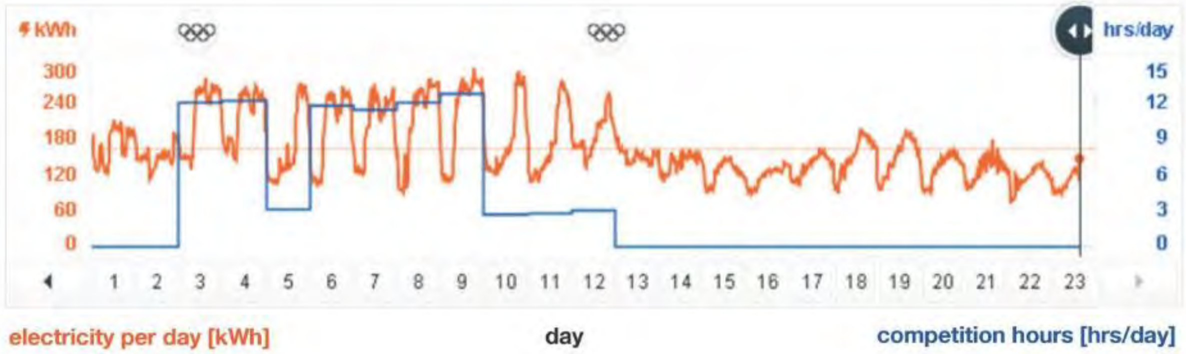

Figure 4: Energy load curve of the Olympic Stadium London 2012 [EDF Energy, 2012]

4. CONCLUSION

This study has raised the questions about how a mega event building – a stadium or arena – changes the surrounding neighbourhood and how advantages can be derived from that. Therefore, stadium-neighbourhood relationships are analysed with a major focus on energy related sy(e)nergies. As stadia are expanding more and more to massive constructions and becoming important meeting points in today's society, it is a crucial part to integrate the buildings into the surrounding and to connect them socially, ecologically and economically.

ABSTRACT

Building Information Modelling (BIM) technology has rapidly emerged in recent years in architecture, engineering and construction (AEC) industry to reduce design and construction efforts through enhanced multi-disciplinary coordination, however, its application in the long building lifecycle of operation and maintenance (O&M) stage is little investigated. Whilst research studies and real-world applications of BIM in building facility management (FM) and asset management (AM) have put emphasis on data exchange between BIM and FM/AM software, this paper presents a novel system framework and our development works for transforming BIM to sustainable building asset management by seamless integration among BIM model, AM system and multiple electronics systems/tools.

Furthermore, the proposed framework provides a visually intuitive way to access heterogeneous O&M information of assets such as photos, attributes, equipment relationships, manuals, drawings, maintenance records, live view of Closed Circuit Television (CCTV) System, real-time sensing data from a Building Management System (BMS) and wireless ad-hoc sensors, as well as location information from a Real Time Location System (RTLS) in one single integrated mobile platform. All these information is accessible simply by asset repository, manoeuvring throughout a BIM model, or even a handheld Radio Frequency Identification (RFID) scanning tool.

Having selected our headquarters building as a showcase project, an integrated BIM-AM System with four key generic user models has been developed to implement the proposed framework. The results have successfully demonstrated the system capabilities in not only facilitating daily O&M works and effective asset management but also responsive incident handling, thus enhancing building sustainability.

Keywords: asset management, smart building, information integration

1. INTRODUCTION

Tracing and identification of building facilities using 2D computer-aided design (CAD) drawings are complicated and inefficient particularly where there are overlapping layered services. Inconvenient cross-reference among different 2D CAD drawings also hinders a clear visualisation of concerned service like duct and pipe works of Heating, Ventilation, and Air Conditioning system. A better visualisation of service drawings is therefore always desirable from O&M perspective. In recent years, BIM, a digital model and process being conceived as an object-oriented CAD system supporting the representation of building elements in terms of their geometric and functional attributes as well as their inter-object relationships, has rapidly emerged in AEC industry to facilitate early coordination among different disciplines, leading to significant shrink of construction schedules and project costs.

However, the approach and application of adopting BIM for sustainable building asset management is yet to be investigated. Whilst there are many research studies and real-world applications of adopting BIM in FM/AM, most of them focus on data population from BIM to FM/AM software [1,2,3,4] either by proprietary add-ins, open BIM standard in IFC format [5], or a spreadsheet / an XML file for Construction Operations Building Information Exchange (COBie) [4,6,7]. Albeit that there are researches involving information exchange between BIM and FM/AM system with BMS integrated [8] and integrating RFID technology with BIM [9], they are in essence not considered as full and seamless integration among BIM, FM/AM software and multiple O&M systems in terms of their integration diversity and extent, as compared with our developed BIM-AM System. Owing to the utmost importance of information accessibility for efficient O&M, asset related information that can be obtained by maintenance engineer should not be limited to static asset attributes of each building element residing in the BIM model. To close the gap between direct adoption of BIM and day-to-day O&M practice for sustainable asset management, we have investigated the appropriate approach for integrating/interfacing BIM with a variety of O&M systems/tools.

This paper aims to show that, by leveraging the underlying principle of BIM in facilitating effective information exchange and storing in an interoperable and reusable way, a novel framework exploiting BIM in integrating AM and a variety of O&M systems/tools has been successfully implemented with a view to streamlining building O&M. Such a BIM-AM System has been piloted in our headquarters building to evaluate its O&M effectiveness. The pilot results have broken new ground in the application of BIM and could potentially fill a void in the market. The BIM-AM System features multiple O&M tools in a single integrated application, offering real-time O&M information sharing/retrieving and exchange capabilities, thus making system handover and O&M much more efficient and effective. It is envisaged that the BIM-AM System would be an enabling tool for sustainable building asset management.

2. SYSTEM FRAMEWORK

As far as our knowledge goes, full and seamless integration of BIM with an AM system as well as a variety of O&M systems/tools including BMS, CCTV system, RFID scanning tool, and RTLS has not been realized. Figure 1 depicts the proposed system framework in which the dotted line indicates the integration that may have been implemented in some other FM/AM software applications whereas the solid line indicates the full and seamless integration that was first implemented by us in 2014.

Under this framework, AM system is considered as an O&M software application for building asset management, preventive maintenance and corrective maintenance management including workflow for fault reporting, handling and monitoring. One of the most distinctive differences is that the AM system in the proposed framework serves as a middleware to integrate/interface with other systems/tools whereas other research works take BIM as a middleware for information exchange with other systems/tools, thus increasing the integration complexity. This is because direct integrations between BIM and other systems/tools would result in high complexities in the Application Programming Interface (API) developments on BIM software and the systems/tools. Moreover, BIM cannot replace the role of AM system in storing and upkeeping AM-related information as well as performing other comprehensive AM features. Another distinctive difference between our works and other researches is that the visual integration between BIM and AM system is in a seamless and intuitive manner, in the sense that the BIM-AM System allows locating and visualising any particular asset with its real-time asset information by maneuvering freely throughout the BIM model in one single integrated system, instead of mere data exchange between BIM and AM system.

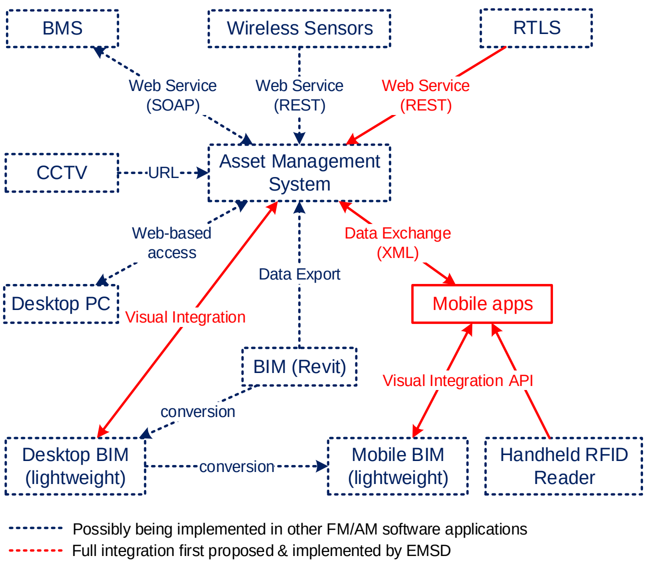

Figure 1: The novel framework for BIM-AM System

2.1. Visually intuitive cross-reference among real-world, BIM model, and static asset information

The BIM-AM System enables visually intuitive cross-reference of real-world physical objects to BIM model and even to asset attributes, maintenance records, asset relationships, system topologies, manuals (including animated repair manuals, if any) and system drawings at a mobile terminal. As shown in Figure 2, a VAV box can be visualised and quickly located in its approximate real-world physical location, enabling easy cross-reference to a BIM model for pre-diagnosis.

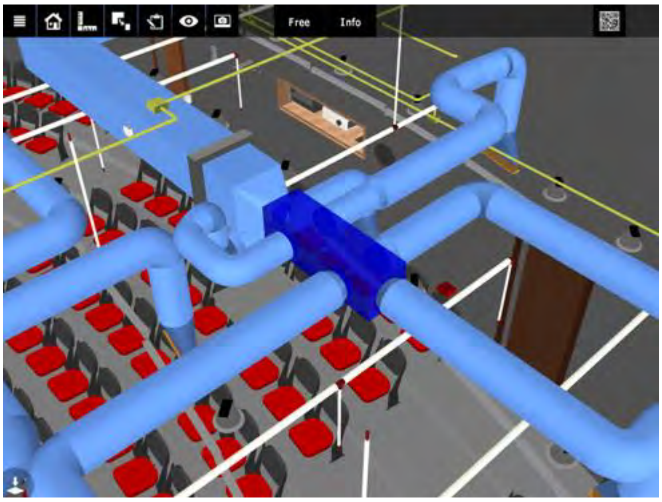

Figure 2: Georeference of a VAV box in a BIM model

System topology generation was purposely developed to visualise the asset relationships within a particular system for further cross-referencing among assets information during fault locating. The system topology as shown in Figure 3 provides a graphical view of the asset relationships of the VAV box within the overall system.

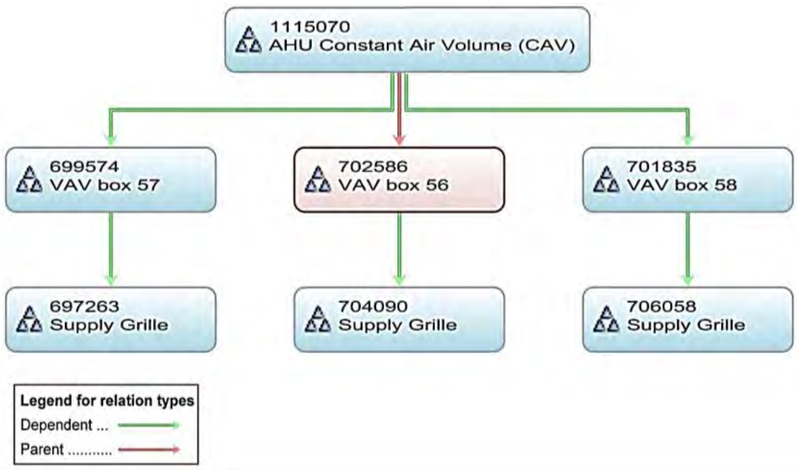

Figure 3: System topology visualising the asset relationships of a VAV box within the overall system

In addition, we have established our BIM-AM asset templates for Mechanical, Electrical, and Plumbing (MEP) installations. Apart from typical system specific attributes, the standardised asset templates also contain the information of asset relationship, wireless tag ID and geometric related attributes for system topology generation, RFID/RTLS application, and BIM visualisation respectively.

2.2. Pre-diagnosis and condition monitoring based on real-time asset information from BMS, wireless ad-hoc sensors, and CCTV system

Integrating BIM-AM System with BMS and fixed CCTV system for accessing real-time remote site information with control functions at a mobile terminal could facilitate efficient offsite pre-diagnosis and possible rectification. Based on the pre-diagnosis, maintenance engineer would be able to bring necessary tools / spare parts to the site in one go. Figure 4 is the mobile screen capture showing the real-time BMS monitoring sensor values of an Air Handling Unit (AHU).

1028834	VAV7F_55FLW, VAV Flowrate	16/12/2015 21:23	0

Figure 4: BMS monitoring interface of an AHU in the BIM-AM system

In addition, wireless ad-hoc sensors, such as temperature sensor, humidity sensor, power metre, and wireless camera over WiFi, Bluetooth, and cellular networks, were developed for prompt installation and monitoring. These wireless ad-hoc sensors are considered useful in incident handling, condition monitoring, generation of pre-fault alerts, or energy management. Figure 5 shows the live feed of a wireless camera available at the mobile terminal for monitoring the subject plant room area. In this pilot, web services have been employed for the data communication from BMS and wireless sensors to the AM system and vice versa.

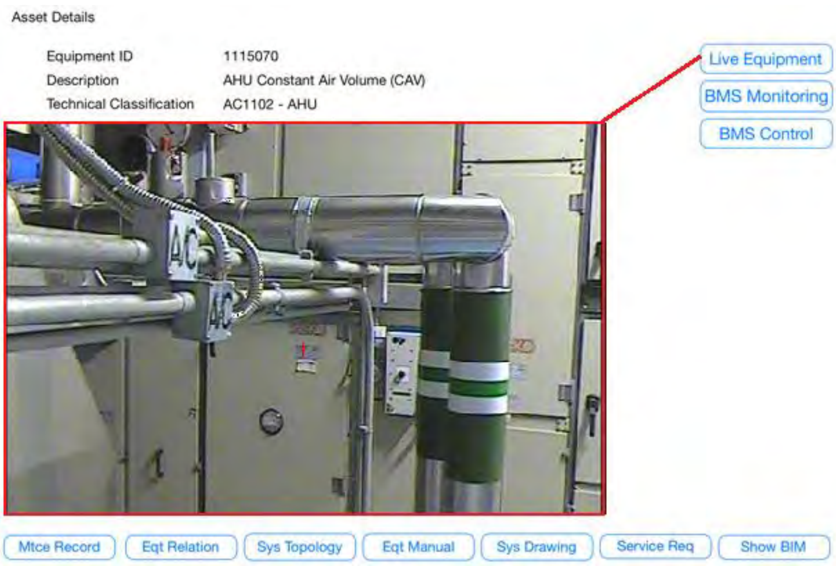

Figure 5: The live feed of a wireless camera in the BIM-AM system

2.3. Efficient locating of fixed and movable assets

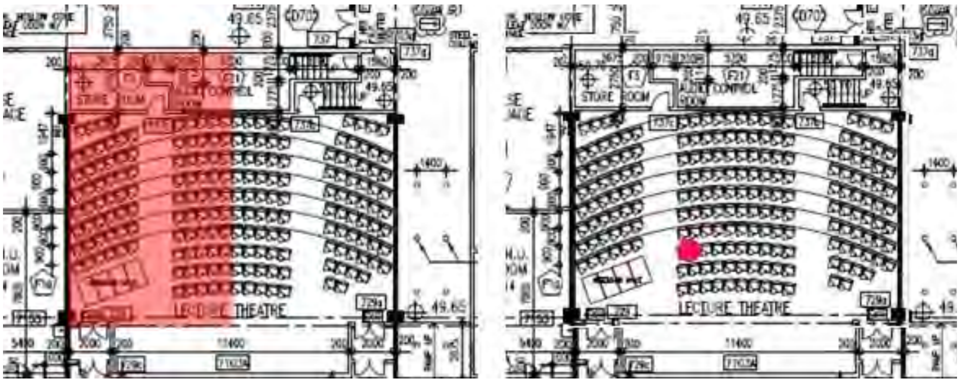
Having integrated the mobile terminal platform of BIM-AM System with a handheld RFID scanning tool, maintenance engineer could efficiently and effectively locate critical equipment for further enquiry of asset information even if the equipment is hidden above a false ceiling or underneath a raised floor. Figure 6 shows a mobile screen capture of RFID scanned results listing nearby assets.

ScannerName HW SW Battery 0%
29 Scan Search By ID

Equipment ID	Description	Location	System Type	Signal
000258	AHU supply 1.4 - 2.8 m3/s	LOBBYZone 1	HVAC	90 %
000244	Airco Unit	AHU RoomZone 4	HVAC	80 %
000243	Emergency lighting decentrally fed	Common AreaZon...	LIGHT	70 %
000253	Splitting system VAV	Hub RoomZone 5	HVAC	60 %

Figure 6: RFID scanned results listing nearby assets

To extend the locating feature from fixed assets to movable assets such as working platform and biomedical equipment, RTLS over WiFi and Ultra-Wide-Band (UWB) technologies, as shown in Figures 7(a) and 7(b) respectively, were piloted in EMSD HQs building. The latter was adopted and installed because of higher positioning accuracy.



(a) (b)

Figure 7: (a) RTLS over WiFi; (b) RTLS over UWB

2.4. Efficient and effective O&M workflow management

Coupled with four key generic user interfaces for client, helpdesk, supervisors and frontline, the BIM-AM System can facilitate efficient and effective O&M workflow in fault reporting, handling and monitoring not only for in-source but also out-source arrangement. As shown in Figure 8, the user interface for the maintenance engineer provides readily accessible asset information, such as asset attributes, maintenance record, equipment relationship, system topology, manual, and system drawing as well as creating service request and cross-referencing to BIM model. Additionally, the System can timely notify users to fill in an electronic pre-work safety check form such that the safety compliance can be easily achieved.

Moreover, the System can cater for highly dynamic and versatile interactions among different parties in the client, maintenance contractor and our organisation by assigning respective features to different parties to facilitate efficient and effective O&M services, supervision and communication at all times.

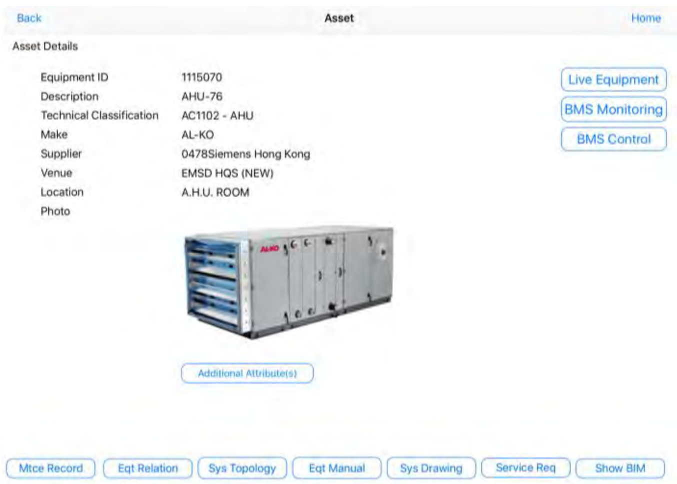


Figure 8: User interface for the maintenance engineer at the mobile terminal

3. DEMONSTRATION

Simulated maintenance showcases using an AHU model, a fire sprinkler system model, an emergency lighting model, and a general lighting model in the BIM-AM System were recorded in videos for demonstration purpose [11]. The results demonstrate that the BIM-AM System can improve productivity in fault response, workflow

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

management, safety compliance, retrieval and appending of maintenance record, access of asset details, relationships and manuals, and so on. Significant time-saving of more than two hours can be achieved on fault localization in a typical air conditioning fault situation as compared with the current practices. In fiscal year 2015/2016, the total number of maintenance orders was about 639,000 in all buildings maintained by the EMSD. Projecting the potential time-savings without real trials would lead to inconclusive findings, but the benefits of the full rollout are foreseeable.

4. CONCLUSION

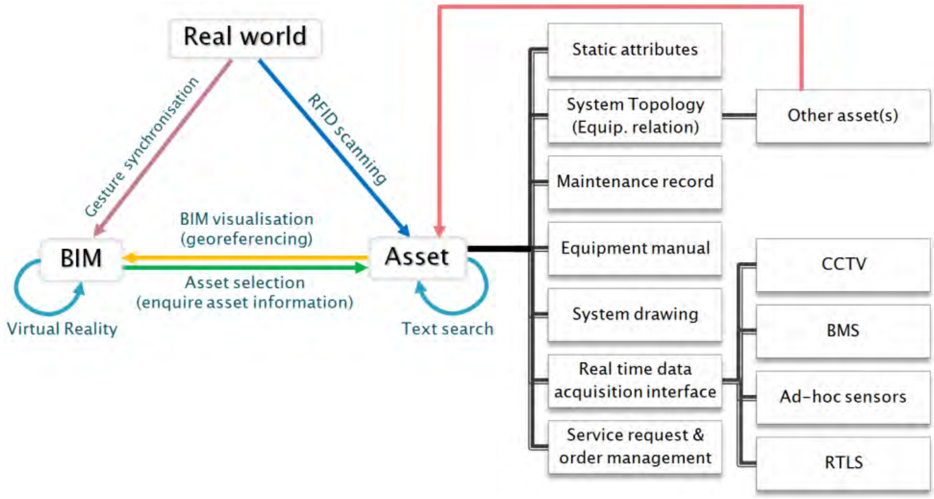

Figure 9: A graphical summary of BIM-AM System features

We have proposed a novel system framework exploiting BIM in asset management and realized the concept in an integrated BIM-AM System featuring multiple O&M systems/tools in one single platform. A graphical summary of the System features is exhibited in Figure 9. The integrated platform has proved effective in streamlining workflow, facilitating responsive incident handling and sustainable asset management. The tool has great potential to bring major benefits including long-term cost savings in the O&M building lifecycle. Though the successes arising from the framework and pilot BIM-AM System are only on a limited scale, we hopes the integrated BIM-AM System would not only benefit our services in operating and maintaining about 5,800 government buildings, but also encourage and facilitate the construction industry in Hong Kong to better deploy this new technology for sustainable building asset management, particularly O&M services, ultimately benefitting the public.

ABSTRACT

The rising need for reducing building energy use has continued to grow over the world. In Hong Kong, various measures have been developed for curbing energy use and a target has been set to reduce 30% of building electricity consumption by 2030, as compared to the level of 2005. Towards this goal, a range of efforts have been made, including those in practice and on the academic side. A review of the relevant literature, however, reveals that research showing how the use of online energy consumption forecast information could drive changes in occupant or user behaviour is limited. Reported in this paper includes a case study, which was conducted on a residential clubhouse in Hong Kong. Using the Meter Online (MOL), a system developed by CLP Power Hong Kong Limited (CLP) to provide energy consumption forecast information to commercial and industrial customers, the facilities management team of the clubhouse is pre-informed of the energy use of the clubhouse. The challenges in implementing energy saving actions for the clubhouse include the worry of attracting complaints from users about the air conditioning and the lack of technical knowledge of the frontline staff responsible for taking the energy saving actions. In addition to describing how the challenges were tackled and the various steps taken during the implementation process, the case study shows that 5% of the clubhouse's energy use was successfully saved through changes in the user (operator) behaviour.

Keywords: energy use, forecast, occupant behaviour

1. INTRODUCTION

The need for saving energy use in buildings, which is a goal of the global community, has continued to rise. In Hong Kong, a range of measures have been developed for curbing energy use and a target has been set to reduce the city's carbon intensity by 50-60% by 2020 (Environment Bureau, 2015). In parallel, the Hong Kong Green Building Council (HKGBC) launched the HK3030 Campaign, which aims to reduce 30% of building electricity consumption by 2030, as compared to the level of 2005 (Hong Kong Green Building Council, 2014).

In fact, a wide spectrum of efforts, including those in practice as well as those on the academic side, have been devoted over the years in order to achieve the goal of energy reduction. The ensuing section, which is a review of the recent literature, highlights some key research studies on occupant behaviour in relation to building energy use. Then, an empirical case study is reported. It shows how the energy consumption forecast of a residential clubhouse, which was provided by an online system of the power company, was used to inform decisions on energy saving actions. Not only the process of executing the actions and the hurdles encountered during the process are described, but the efforts made in surmounting the hurdles are also reported.

2. PAST STUDIES

Forming part of the research activities of the International Energy Agency Energy in Buildings and Communities Program Annex 66 (Definition and Simulation of Occupant Behaviour in Buildings), the review of Hong et al. (2016) introduced the recent advances in modelling occupant behaviour (OB) and assessed the impact on building energy use imposed by the barriers to the modelling. The challenges in OB modelling, as identified, include collection of good and adequate data for behaviour understanding and modelling, and quantifying the impact of energy-related occupant behaviour on building energy performance. Using building simulations, Barthelmes et al. (2016) demonstrated the potential impact of occupant behaviour lifestyles and different household compositions on energy use and thermal comfort conditions in a nearly zero energy building. EnergyPlus simulations were carried out, and three different levels of behaviour lifestyles and six types of interactions between inhabitants and building envelope/systems (e.g. regulation of air-conditioning set-points, ventilation rates, etc.) were considered. The study found that the occupant behaviour lifestyles significantly affect the energy performance of the building; the urgent need of reference models related to human behavioural issues was also revealed.

To develop simulation models for evaluating the energy impact of occupant behaviour (especially occupant presence), Duan and Dong (2014) used occupancy sensors to collect occupancy data from four low income test beds in Texas, compared the data with the American Time Use Survey (ATUS) data, and integrated the real-life data into a validated EnergyPlus house model. The simulations found that instead of monitoring single zone all the time, using the occupancy pattern to determine which room to be controlled can reduce the energy consumption for cooling by 7%. The result indicated that integrating detailed occupant behaviour information into facilities' control systems could achieve significant energy saving. In South Africa, Masoso and Grobler (2010) used energy auditing equipment to audit the energy use of six randomly selected commercial buildings. Sub-hourly electricity consumption data were logged, with breakdowns of heating, ventilation and air conditioning (HVAC), plug load (office equipment) and lighting. The consumption amounts were also divided into two periods: working hours and non-working hours. It was found that more energy was consumed during the non-working period (56%) than the working period (44%). This dark side of occupant behaviour was largely due to occupants leaving lights and equipment on during off-duty periods.

To statistically determine occupant behaviour patterns associated with energy use for heating and to identify building characteristics that could contribute to the development of energy-user profiles, Santin (2011) used paper questionnaire to obtain detailed data on occupant behaviour and paired them with data on building characteristics obtained from municipalities and architects' firms. Five underlying groups of behavioural variables were identified for use in defining the occupant behaviour patterns and user profiles. While the relationships between occupant behaviour and household characteristics were made clear, the study found it hard to establish relationships between energy consumption and behavioural patterns. In a bid to assist in tailoring interventions to the specific characteristics of building occupants, Azar and Menassa (2015) carried out computer simulations and scenario analysis on a typical commercial building. Using an agent-based model and data gathered from the Commercial Building Energy Consumption Survey (CBECS) in the US, the study revealed that extremism have a high impact on building energy performance and could revoke the energy saved from traditional occupancy interventions. The proposed solutions, including increasing social connectivity of occupants and increasing extremists' acceptance of new energy use behaviours, are promising.

In the UK, the study of Mulville et al. (2014) explored the energy consumption patterns across the workstations in two office spaces and the potential effect of using feedback to encourage energy reduction through behaviour change. With the use of energy-monitoring devices and field surveys, the baseline data were compared with industry benchmarks to understand the impact of small power. Through the provision of comparative feedback, monitoring was also made to determine the effect of behaviour change interventions. It was concluded that even simple interventions such as an awareness of being monitored can have an impact on end user behaviour. Behind the variation in energy consumption, the key driver was occupant behaviour rather than technical considerations.

The above review, covering some recent and prominent studies, is by no means exhaustive. But a consensus of the studies' outcomes is that occupant behaviour plays a vital role in energy use of buildings. Research showing how the use of online information could drive changes in occupant or user behaviour, which has emerged recently (e.g. Cheung et al., 2016), is still limited. In the following, a case study on a residential clubhouse in Hong Kong is reported. It illustrates how appropriate actions could be taken to save energy by referring to predicted energy consumption.

3. ENERGY CHARGE REDUCTION: A CASE STUDY

The clubhouse investigated under the case study is located in a large estate which comprises 32 residential blocks, with a total of over 5000 flats. The final phase of the development was completed in 2011. The daily operating period of the clubhouse is from 7:00 a.m. to 11:00 p.m. Being the person-in-charge of the operations of the whole clubhouse, the facilities management (FM) team comprises an Estate Manager overseeing two branches of staff members, as shown in Figure 1.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

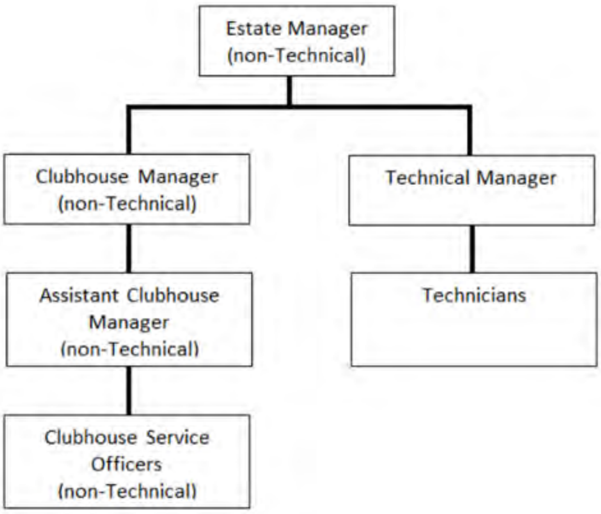

Figure 1: Organization chart of the clubhouse

Air-conditioning systems, lighting installations, lifts and the all-season swimming pool contribute to the major electricity consumption of the clubhouse. Between 2011 and 2014, T5 fluorescent lamps (FLs), compact fluorescent lamps (CFLs) and various types of LED lightings were used to completely replace all the original T8 FLs, halogen lamps, and non-LED lit exit sign. Variable refrigerant flow (VRF) units, split type air conditioners with 'grade one' energy label, and window blinds were used to reduce the chiller's load. Variable voltage variable frequency (VVVF) motor drives were used for the lifts to reduce their energy consumption. Heat pumps were used to replace the original electric water heaters for the all-season swimming pool. Energy saving reminders were widely posted at prominent areas to remind users to switch off unnecessary lightings and encourage the use of daylight as far as possible. All air conditioning plants are set to maintain the indoor air temperature at 24.5 – 25.5°C. Furthermore, capacitors were also added to improve the power factor so as to reduce the demand charge of electricity.

After the completion of all the above measures, the total annual saving in energy consumption of the whole estate was over 15%. But the Owner Committee (OC) of the estate continued to ask the Estate Manager to further reduce the electricity consumption in order to curb the rise in management fee. Since all the major plants had been replaced with energy efficient ones, very limited energy saving could be achieved by further hardware change. Technically, raising the air conditioning temperature set-point of the clubhouse could be a possible way for energy saving, but less comfort for the clubhouse users is a price to pay and thus it is difficult to get all the users support this energy saving measure. An alternative measure is to replace the existing air cooled chillers with water cooled chillers, but it entails a large capital investment and very complicated modification would be required. Obtaining the support from the OC members to this measure, likewise, would be difficult. In a bid to explore other viable energy saving alternatives, the Clubhouse Manager met with his Account Manager of CLP Power Hong Kong Limited (CLP) - the company supplying electricity to the clubhouse.

The Account Manager initiated to conduct a joint Meter Online (MOL) power consumption forecast experiment with the Clubhouse Manager. The essential part of the experiment was to use MOL power consumption forecast function (i.e. MOL kWh Forecast) to justify extra energy saving actions. In principle, for each day with high forecast consumption, the Clubhouse Manager should reduce the air conditioning supply to the clubhouse, unless there were special bookings. The experiment was carried out from 1 September to 31 October 2014, and CLP helped to do the associated energy saving analysis.

The experiment was an innovative trial that made use of big data to save energy. Showing a great interest in it, the Clubhouse Manager organized a meeting, during which CLP explained to the Estate Manager about the concept and operation of the experiment. The expected outcomes include: the Clubhouse Manager could save energy consumption of the clubhouse, and CLP could learn any practical challenge in establishing a model to drive the implementation of energy saving actions without additional manpower. Realizing this win-win initiative, the Estate Manager agreed to proceed with the experiment.

3.1. Challenges encountered and solutions

Although making swift decisions was a critical success factor to realizing the advantages of the MOL forecast function, the Clubhouse Manager soon recognized that he might not be always available to visit the MOL system and order energy saving actions. Therefore, he delegated his authority to the Assistant Club Manager with the following simple decision rules: (a) If there is no special booking, implement special energy saving actions on all high consumption days as forecast by the MOL (Figure 2); (b) If customer complaint about air conditioning is received during the experiment, terminate all the energy saving actions and resume the air conditioning setting to normal.

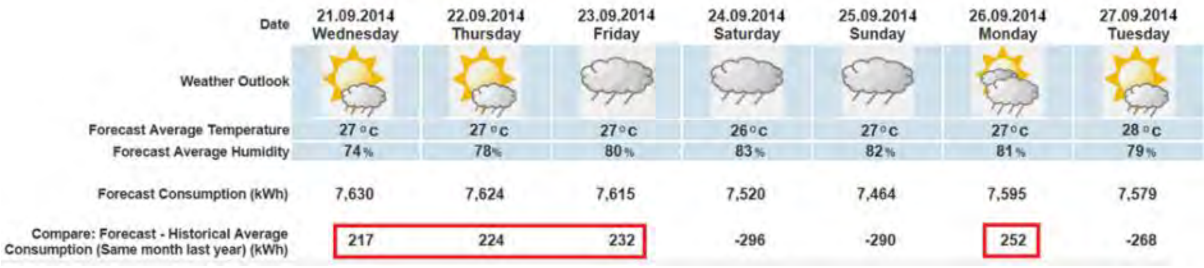

Figure 2: MOL 7-day energy forecast (Arbitrary figure is used for illustration purpose)

Then, the Clubhouse Manager arranged CLP to meet the Technical Manager for introducing the operation concept of MOL kWh Forecast to save energy and the necessity of adjusting the air conditioning plants in due course in order to realize the desired energy saving. The Technical Manager expressed that his technicians might not be available to do the extra plant switching because they had been occupied with their normal duties. He suggested that it would be more efficient if he prescribes the list of plants to be switched off and assign somebody to do the switching. The Clubhouse Manager appreciated the suggestion and agreed with it.

Afterwards, the Clubhouse Manager organized a meeting for CLP to introduce to the Clubhouse Service Officers the concept of using MOL kWh Forecast to save energy and the expected roles of the officers in dealing with the plant switching on high consumption days. The officers worried about their ability to do the switching and the potential customer complaints about insufficient air conditioning for the Clubhouse. In order to relieve their worries: (a) The Clubhouse Manager demonstrated the plant switching works by a joint site meeting with the technicians and the officers; (b) The Clubhouse Manager promised to ignore all the customer complaints associated with the extra energy saving actions when performance appraisals of the officers are made.

The Clubhouse Manager also reiterated the pressure of energy saving to the Clubhouse Service Officers and reminded them that it was a new way of energy saving with free-of-charge technical support offered by CLP. Touched by the enthusiasm and effort of the Clubhouse Manager, the officers indicated their support to the experiment. The Clubhouse Manager further promised that the experiment would be terminated if any customer complaint about the clubhouse's air conditioning is received during the experiment.

The technicians also supported the experiment. Several primary air units (PAUs) were selected to be switched off on high consumption days. They labelled the relevant switches of the PAUs for easy recognition by the Clubhouse Service Officers. The sequence of energy saving actions is summarized by the flowchart in Figure 3.

3.2. Result

The experiment was successful. Almost 7800kWh was saved during the experiment, which was equal to 5% of the total energy consumption in the same period (see Table 1). No customer complaint about the air conditioning for the clubhouse was received throughout the experiment period. The Estate Manager appreciated the innovative spirit of the Clubhouse Manager, Technical Manager and Clubhouse Service Officers, and their keen support to the experiment. The Clubhouse Manager was invited to share his experience in this experiment in a subsequent technical talk, which was attended by professionals in the building industry.

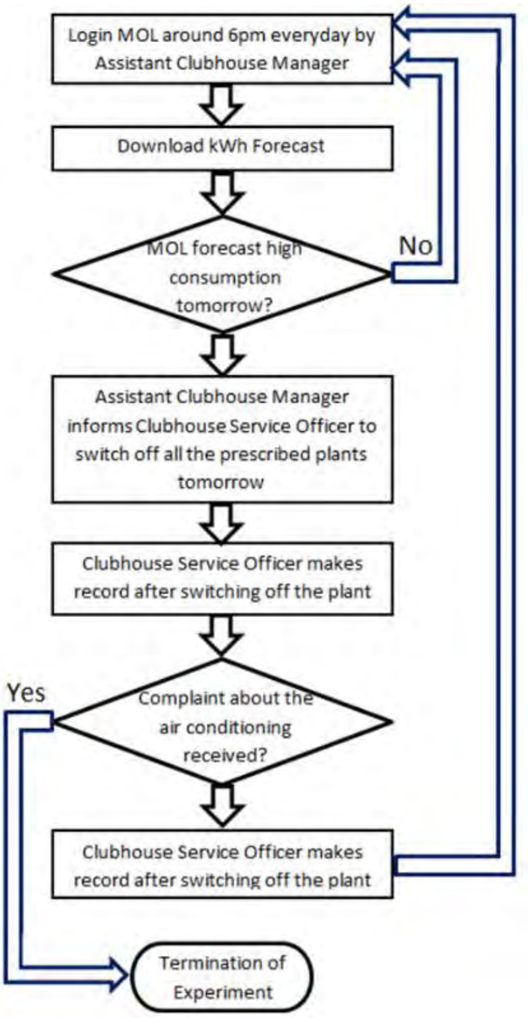

Figure 3: Sequence of energy saving actions

Electricity Account	Result	Forecast Saving by the Energy Saving Actions (Note 1)	Actual Saving by the Energy Saving Actions (Note 2)
Account Number 123456	Successful	6082 kWh	7779 kWh

Table 1: Energy saving result of the experiment (1 Sep – 31 Oct 2014)

Notes: (1) Forecast Saving by the Energy Saving Actions = ∑All Action Days in the whole experiment period (Forecast Consumption without Actions – Actual Consumption after Actions). (2) Actual Saving by the Energy Saving Actions = Total Energy Consumption during the Test Period – Total Energy Consumption of the same period in 2013.

4. CONCLUSION

Many energy saving measures are widely known. The literature review found that although occupant behaviour has a crucial role to play in saving building energy, research on how online energy consumption forecast could drive users to save energy was very little, if not none. The above case study, centred on a residential clubhouse, illustrates the use of the MOL - an online system that can forecast energy consumption for energy saving purposes. It shows not only the process of putting energy saving measures into actions but also how the problems encountered during the process were overcome. With the concerted efforts of the whole FM team and the energy supply company, a significant amount of energy was saved for the clubhouse. MOL not only provided a scientific means for justifying the energy reduction measures but also effected a genuine behavioural change of the team members in implementing the energy saving actions.

Energy Efficient Optimal Controls and Smart Energy Management of Buildings and Their Energy Benefits in Real Applications

WANG Shengwei[a], SHAN Kui[b]

[a] The Hong Kong Polytechnic University, Hong Kong SAR, beswwang@polyu.edu.hk
[b] The Hong Kong Polytechnic University, Hong Kong SAR, shan.kui@connect.polyu.hk

ABSTRACT

This paper provides a summary on the energy efficient optimal control methods developed and the actual energy benefits when implementing these optimal control strategies in real buildings over the last ten years. The control optimization methods cover most of sub-systems in commercial HVAC systems as well as special indoor environment control systems such as that serving cleanrooms, industrial processes and underground stations.

The various optimization methods implemented in a high-rise building in Hong Kong have achieved an annual saving of about 10 million kWh, of which about half is the contribution of optimal control. The energy savings of implementing optimal control strategies in the buildings of Hong Kong PolyU are projected to be between 15% and 30%.

Beside of the control strategies for commercial buildings, control methods and strategies are also developed for cleanrooms and other special spaces, which often have high or specific requirements on temperature and humidity controls and pressure and airflow balances. To control these variables, the counteractions between different processes often occur in practical applications, resulting in huge amount of energy waste. The implementation of proper and optimal control strategies in a pharmaceutical factory in Hong Kong achieves an annual energy saving of about 40% (around 5 million HKD).

Control and smart energy management methods are also developed for the building demand limiting control for electricity cost saving under current pricing and the demand response (DR) control to the requests of smart grid in the near future. Investigations show that peak power demand limiting in very few hours (2 - 5 hours) within a month could achieve very significant electricity cost saving in certain buildings (up to 25% of demand charge and up to 5% of total building electricity cost).

Keywords: energy saving; optimal control, smart energy management

1. INTRODUCTION

Building energy consumption increases rapidly in recent years due to global climate changing, increasing demand for healthy, comfort and productive indoor environment, etc. The contribution from buildings toward global energy consumption was approximately 40% (Omer 2008). According to the buildings energy data book (2012) provided by the U.S. Department of Energy, buildings account for 73.6% of electricity consumption, 41.1% of total energy use, and 40% of carbon dioxide emissions in 2010. In China, the building sector consumes nearly 20% of China's total primary energy consumption in 2006, in which electricity occupies 44%. While in Hong Kong, the proportion of the energy consumption of buildings occupies nearly 91% of the total electric energy consumption in 2009.

Most of energy used in buildings is for the provision of heating, ventilation and air conditioning (HVAC), which takes over 50% of building energy consumption on an average (Pérez-Lombard et al 2008). High-level performance of HVAC systems in building lifecycle is critical to building sustainability. However, excessive energy is consumed in buildings and HVAC systems because they often fail to operate as intended.

Generally, energy saving in buildings can be achieved by three approaches: (1) Reduced heating/cooling loads, e.g. passive design of building envelops; (2) Use of energy efficient components and technologies, e.g. using chillers, pumps, and fans of high efficiency; (3) System Optimization and optimal control.

Proper operation of building energy systems can lead to improved occupant comfort and health, improved energy efficiency, longer life cycle of equipment, reduced maintenance costs, and reduced unscheduled equipment shut down time, etc. This paper provides several real case studies aiming at saving energy in buildings using optimal control techniques.

Remaining of this paper is organized as follows: Section 2 describes the energy saving efforts for the tallest building in Hong Kong. Section 3 provides a briefing on the energy saving project for a clean room factory in Hong Kong. Section 4 shows the energy saving programme in the campus. Section 5 presents a summary on these energy saving projects.

2. CASE 1: THE TALLEST BUILDING IN HONG KONG

2.1. The building and its air-conditioning system

The International Commerce Centre, a 118-storey and 490m super high-rise commercial building, is currently the tallest building in Hong Kong. It has a gross floor area of approximately 321,000 m2 except the hotel at the top of the building. It serves as a commerce centre involving commercial offices (mainly occupied by international financial firms), shopping arcades and a six-star hotel.

The central chilling plant consists of six identical centrifugal chillers (each with cooling capacity of 7,230 kW). Plate heat exchangers are employed to deliver cooling from low levels to high floors to avoid extremely high static pressure. Each chiller is interlocked with a constant condenser water pump and a constant primary chilled water pump. Taking into consideration the winter plume abatement purposes, two different types of evaporating cooling towers (named CTA tower and CTB tower, respectively) are used in this building. Each of the CTA towers (total of six) without heating coils has a heat rejection capacity of 5234 kW and each of the CTB towers (total of five) equipped with heating coils has a heat rejection capacity of 4061 kW at the design condition. All cooling towers are an in house type and are equipped with variable speed axial fans. All pumps in the secondary chilled water distribution system are equipped with variable frequency drivers for energy efficiency except that the primary chilled water pumps dedicated to the heat exchangers in Zones 3&4 are constant speed pumps. Each office floor in this building is served by two AHU systems. In each zone, the outdoor air is centrally supplied by several primary air units (PAU). The outdoor air is supplied to each AHU system through a VAV system. VAV dampers are installed to connect the main supply air ducts to deliver supply air into the ventilated zones with diffusers. Return air was drawn back through the ceiling plenum.

2.2. Energy efficient optimal control methods

The major challenge faced in this project is how to reduce building energy consumption and environment impacts while still providing satisfied indoor environment. Since HVAC system design stage (2005) and after the first stage of occupation in 2008, the research team, together with the developer, consultant, facility management team and contractors, has made serious efforts to develop innovative solutions for enhancing the energy efficiency and improving environmental performance. The actual annual saving is about 10 million kWh, of which about half is the contribution of optimal control. Figure 1 shows the total electricity consumption of the building in recent four years. The reduction was about 10.2 million kWh if comparing year 2015 with 2012, with an estimated 8.6 million kWh savings from the air-conditioning system. It shall be mentioned that the average outdoor air temperature in 2015 was 0.7 °C higher than that in 2014, which should have caused an increase in electricity demand.

The optimal control methods that had been applied to this large and complex system covers nearly all sub-systems, including air side sub-systems, chilled water delivery sub-systems, cooling system, and the chiller plant.

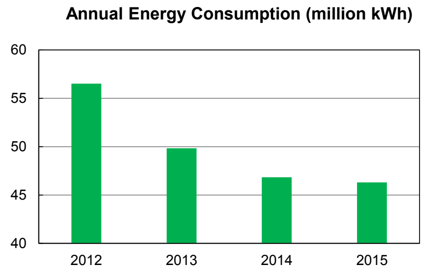

Figure 1: Annual energy consumption in the past four years

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.3. Air side optimal control methods

- Demand Controlled Ventilation (DCV) and free cooling

To solve the over-ventilation or under-ventilation problem in the conventional ventilation controls, a robust DCV control strategy using limited number of sensors based on ASHRAE standard 62.1 was developed and implemented to all office floors in the building (Shan et al 2012). Additionally, a model-based free cooling outdoor air control strategy was combined with the DCV strategy. The test results in operation confirmed that the energy consumption of the PAU can be saved up to 50% under part load compared with the original two stage control and the energy consumption for cooling outdoor air can be reduced by 65% at most. With the CO2 concentration being maintained below 800 ppm, the excellent indoor air quality was ensured.

- Robust supply air static pressure control for AHUs

Conventional optimal control strategies reset the supply air static pressure based on the opening degrees of all the VAV dampers. However, such methods are not robust because the supply air static pressure set-point will gradually increase to its high limit in case some VAV terminals are abnormal, or with extremely low temperature set-points. A practically applicable fault tolerant control strategy was developed for pressure independent VAV systems (Shan et al 2015). Supported by the test data, the new control strategy is compared with the conventional strategy which was originally implemented in the building. The supply air static pressure is reduced significantly resulting in 33.6% power saving while the space thermal comfort was still maintained (Figure 2).

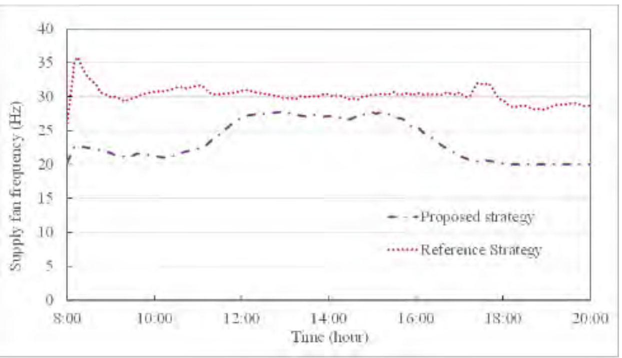

Figure 2: The proposed strategy reduced supply air fan speed significantly

- Other air side control methods

Some other optimal control methods had also been applied to the system, such as robust supply air static pressure control for PAUs, optimal control of AHU supply air temperature, etc.

2.4. Water side optimal control methods

- Optimal control of the secondary water pumps

A cascade controller, as shown in Figure 3, is used to control the operating speeds of pumps distributing water to heat exchangers (fully open the control valves) instead of using the modulating valves while keeping a fixed differential pressure (Wang and Ma 2010). The fully opened valve in the cascade control minimizes the water loop resistance and therefore saves the energy of pumps. The test results proved good control reliability of the strategy as well as the annual energy saving up to 250,000 kWh.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

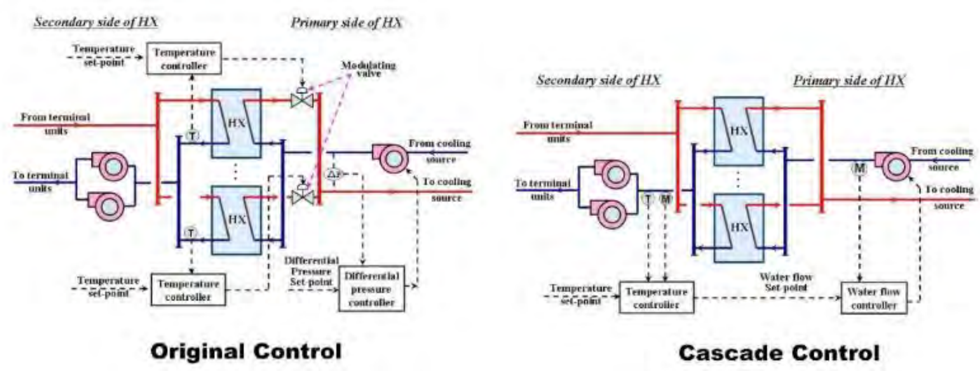

Figure 3: Comparison of the original control and the cascade control

2.5. Chiller plant optimal control methods

- Robust chiller sequencing control

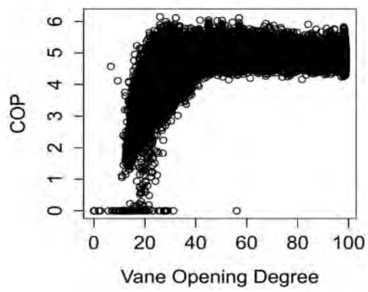

Figure 4: Van Opening is a robust indicator when chiller is of high COP

Chiller sequence control significantly affects the efficiency and operation stability of plants with multiple chillers. However, in real practice, the energy efficiency is commonly sacrificed to avoid uncertainties. Also, the strategies found in literature may be too complicated to be used practically. An effective and robust strategy for centrifugal chiller plants is therefore developed (Shan et al 2016). The strategy innovatively utilizes chillers inlet guide vane openings as the load, and more particularly the energy efficiency indicator (Figure 4). A validation of the use of such an indicator is conducted using the in situ measurements from the chiller plant in a high-rise building. The strategy is compared with two other commonly used strategies through tests. In the ideal condition (no measurement errors), the proposed strategy saves 3% of the energy comparing to the original strategy. When systematic errors exist in the cooling load measurements, energy performance of the plant is not affected when controlled by the proposed strategy.

- Optimal cooling tower control

Usually, the fixed approach control method and fixed set-point control method are used to determine the cooling water supply temperature set-point while the operating number of cooling towers is simply determined based on the operating number of chillers. The conventional method is hard to achieve energy saving under low partial load conditions.

A hybrid quick search method is developed and implemented to minimize the instantaneous total power consumption of the chillers and the cooling tower fans (Ma et al 2009). The required operating number of cooling towers and the water temperature entering the condensers are continuously reset based on the weather conditions and system working conditions. The method also uses a fussy approach to predict uncertainties in chiller and cooling tower models to enhance the accuracy of model predictions (Zhu et al 2013).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

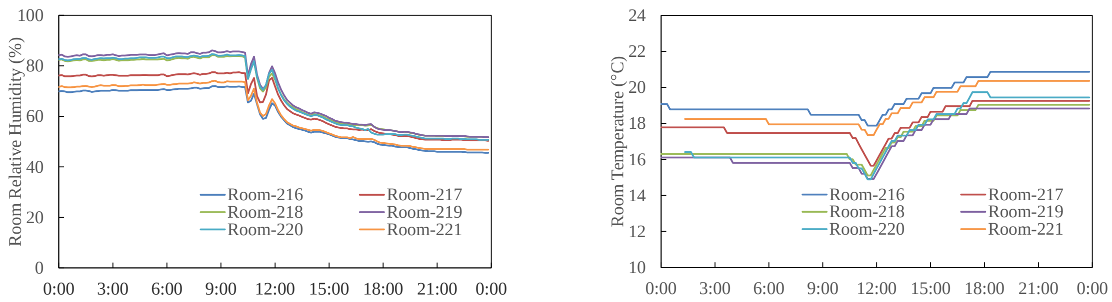
- Other optimized control strategies

Flow-limiting control for eliminating deficit flow, avoiding low delta-T syndrome and saving pump energy, chilled water supply temperature optimization (Ma and Wang 2009b), differential pressure set-point optimization in the secondary pumps (Ma and Wang 2009a).

3. CASE 2: A CLEAN ROOM FACTORY IN HONG KONG

Comparing with spaces air-conditioned for thermal comfort, cleanrooms often have special requirements on dry bulb temperature, relative humidity, static pressure, or air flow rates. It is a challenging task to achieve those requirements with minimum energy consumption, especially when different parameters interfere with each other. Specifically, the counteraction between cooling and heating often happens in the field, resulting in significant waste of energy.

A method was developed to solve this problem. The concept is to move dehumidification process into from AHU to PAU, so that no hardware modification is required. A trial test was conducted to evaluate the concept of the proposed method prior to detailed development of it. The heating system was all off during the entire test day, and the test started at around 11:00 in the morning. When the test started, the RH started to decrease and the DBT began increase but still within the required limitation. Figure 5 shows the progress in psychrometric chart. Although the progress is slow, the two parameters could be controlled within the required range without the use of heating during the trial test.



(a) Room relative humidity *(b) Room dry bulb temperature*

Figure 5: Trial test result of the proposed method to control room RH and DBT with no heating

The full control method was then developed and tested in an air side subsystem in the factory and compared with the original method used. The test was conducted when the ambient dry bulb temperature and relative humidity were 21.8 °C and 75.2%, respectively. Results indicated that the developed method saved 60.2 kW (74.4%) and 62.2 kW (89.8%) in cooling load and heating load, respectively. The annual energy saving was estimated to be about 40% (about 5 million HKD).

4. CASE 3: BUILDINGS IN A UNIVERSITY CAMPUS

We are also engaging in the campus (Hong Kong polytechnic University) energy saving programme to provide energy performance assessment and optimization. Phase 7 buildings being studied consists of a biology clean room lab which has strict requirements on humidity, temperature and air change rate. Great energy saving potential was identified during energy assessment. About 1.0 - 1.5 million kWh energy might be saved by changing the existing operation and control mode as variable speed control, while has no adverse impact on lab environment.

An other assessment on the electricity profile of one campus building indicate that cutting the power demand peaks (Figure 6) in very few hours (2 - 5 hours) in a month could achieve very significant electricity cost saving in certain buildings (up to 25% of demand charge and up to 5% of total building electricity cost).

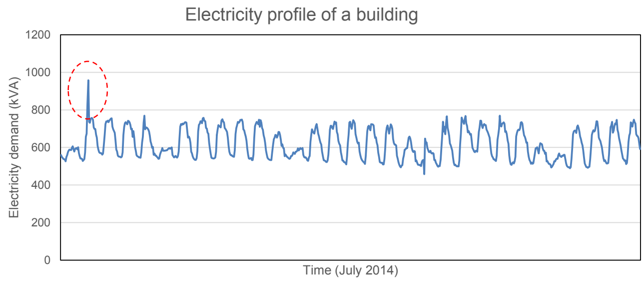


Figure 6: kVA profile in one month

5. SUMMARY

This paper provides a summary on the developed energy efficient optimal control methods and the actual energy benefits of implementing the optimal control strategies in real buildings over the last ten years. These control optimization methods cover most of sub-systems in commercial HVAC systems, as well as special indoor environment control systems for cleanrooms, industrial processes and underground stations, etc.

A set of optimal control methods have had been implemented in the tallest building in Hong Kong. The methods address almost all sub-systems of the large and complex air-conditioning system. According to the electricity bill, the methods applied in the building achieved an annual saving about ten million kWh.

By eliminating the counteraction between heating and cooling, the developed method for a clean room factory had significantly reduced cooling and heating load. The estimated annual energy saving is about 40% (about 5 million HKD).

The control methods are also being applied in several buildings in a campus. During the energy saving assessment stage, the saving potentials of the A/C systems in the buildings studied range between 15-30%. And there is also a potential in reducing electricity bill by cutting power demand peaks.

ABSTRACT

The main deficiency with the Post-Occupancy Evaluation (POE) method discussed in this paper is that feedbacks collected are delayed and exert limited influence on the building being surveyed. Another drawback with this approach is that it fails to take the technological updates, such as ICTs, Web 2.0, big data, etc. into account due to the fact that the POE system is rooted from the 1980s but methods to carry out POE surveys remains almost same recently. Therefore, it is necessary to look beyond POEs and to promote direct e-participation of building users with regard to advanced ICT technologies.

Previous studies have figured out that user-led innovations with the purpose to deepen the level of user controllability of indoor environments are able to improve user perception of comfort and increase the quality of their daily life. The study presents a literature survey on how different factors influence human comfort in indoor environments with respect to user controllability. An app running on iOS and Android is introduced as a platform to display information, to make suggestions about actions can be taken, to collect feedback from users. The concept, the gap, challenges and determining factors of interactive building systems will be discussed.

Keywords: Human-oriented Buildings, Real-time buildings, Interactive building-user system, Behavioral change

1. INTRODUCTION

Post-Occupancy Evaluation (POE) has been applied as a systematic framework to evaluate the built environment according to responses of occupants in the buildings (Brand 1994), which indicated that POE surveys aimed to collect user responses at the operation stage and provide evidence-based design knowledges for the next generation of buildings. The main deficiency with this method is that feedbacks collected are delayed, sometimes simply ignored and exert limited influence on the building being surveyed. Another drawback with this approach is that it fails to take the technological updates, such as ICTs, Web 2.0, big data, etc. into account. The POE system is rooted from the 1980s and methods to carry out POE surveys are normally questionnaires, interviews, observations, recording, etc. (Preiser & Vischer 2005), which remains almost same recently. Meanwhile, conflicts among findings from POE surveys caused by various human behaviors or environment-related factors demonstrated the lack of universality, adaptability and flexibility. Therefore, it is necessary to look beyond POEs and to promote direct feedbacks of real-time, dynamic e-participation of building users with regard to advanced ICT technologies.

With the changing concept of green buildings, the green building rating systems have gradually evolved from tools for buildings to tools for humans. Previous studies has figured out that user-led innovations with the purpose to deepen the level of user controllability of indoor environments are able to improve user perception of comfort and increase the quality of their daily life (Frontczak & Wargocki 2011). Comfort could be enhanced in the perceived built environment by deeper user-building communication and user controllability of buildings.

2. LITERATURE REVIEW

The definition of Post-Occupancy Evaluation (POE) is given by Preiser in 1988 is "the process of evaluating buildings in a systematic and rigorous manner after they have been built and occupied for some time". Evidence gathered in POE is used to identify human-oriented design strategies and to provide feedback for further research, design and evaluation of green buildings (Gou 2012). Generally, the purpose of POE surveys is to test the appropriateness of a design approach, to offer an optimized spatial solution, to understand human perceptions of environment related behaviors, and to provide evidence-based knowledge of the effectiveness of approaches and investments in practice (Wolfgang Preiser 2002). The significance of POE is because of the gap and the fact that, firstly even all the requirements and demands of green building rating systems are met, not all occupants are

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

satisfied with the working environment (Humphreys 1994; Brager & Dear 1998; Heerwagen 2001; Zhao et al. 2016; Brager & Baker 2009; Gou et al. 2013); secondly, green building certification is a one-time activity, fine-tunings or major renovations of design decisions are given very few opportunities for buildings-in-use (Moezzi & Goins 2011); Moreover, POE surveys are significant to identify the adaptable ranges of comfort differs due to numerous factors such as hours worked per week, time pressure, job stress, psychosocial atmosphere at work, relationship with colleagues, job satisfaction, type of job, education level, pattern of coffee drinking, pattern of smoking, health, menstruation cycle, fitness, self-estimated environmental sensitivity, height and weight, gender, age and country of origin, etc.

However, among all the POE surveys, there are only two systematic POE studies concerning green buildings' occupants: one is the Occupant Indoor Environmental Quality (IEQ) Survey and Building Benchmarking by the Center for the Built Environment (CBE) at the University of California Berkeley in North America (Abbaszadeh et al. 2006); the other is the Post-occupancy Review of Buildings and their Engineering carried out by BUS (Building Uses Studies) Ltd. in the U.K. (Leaman & Bordass 2001).

Furthermore, since the intervention of POE surveys are post occupancy, these approaches are not related to architectural design stages of the buildings researched and information gathered from feedbacks are delayed and sometimes simply ignored. In fact, the building being surveyed is not able to react according to the results of user feedbacks. Complaints might de facto only be taken into consideration for further green buildings to some extent rather than influencing the building at the operation level. This traditional POE and feedbacks are too passive for building occupants to be directly involved. In addition, the link between POE researchers and architects is week and the results from POE survey fail to get enough attention to guide design strategies (Hadjri & Crozier 2009).

3. DISCUSSION

3.1 The mechanism to encouraging pro-environmental behaviors

Socio-environmental psychology has gained notice by academia since the 1960s when environmental psychology and a variety of disciplines started to intervene in the research field of environmental behavior of human beings, seeking answers to questions such as "are human behaviors predictable?", "how do human behaviors change?", etc. However, findings from empirical research do not support the presupposition (Redclift & Woodgate 1997) which hypothesized that behaviors were determined by environmental attitudes (Maloney & Ward 1973; Maloney et al. 1975), hence environment-related knowledge - attitudes - behaviors had a linear relationship. As a result, inconsistency between attitudes and behaviors has become one of the emergent focuses in academic research, directing at the relationship among other factors such as norms, values and external factors. In architecture, researches on user behaviors and behavioral changes at the building level has emerged as a new frontier due to the fact that user behaviors have impacts on building performance and addressing the interaction between human factors and green building systems are complementary with market-driven systems in search of sustainability (Kats et al. 2010).

The core of this discussion is the added value of human-oriented buildings, which indicates that the encouragement of pro-environmental behaviors would not place a burden on occupants' reducing energy consumption at the cost of less comfort. In addition to green building whose aims are to reduce loads and enhances efficiency, (Yudelson 2008), the concept of human-oriented buildings paves the way, through a holistic integrated approach, for sustainable development at the personal level (International WELL Building Institute 2016).

The study defines those with pro-environmental behaviors as "green users". How to create green users via behavioral changes is one of the main research questions. The study proposes a model that one of the contributing factors for green buildings to create green users is a technology-enabled, human-building interaction platform (see Figure 1) based on a participatory mechanism of a e-platform of smart phones and a vote system. The preliminary interdisciplinary model of technology-enabled empowerment on the behavioral change of occupants proposes that behavioral change can be trigged by either the technology-enabled platform directly or via cognitional change triggered by a technological-enabled means. There is a substantial list of theories and models to reveal those contributing factors of environmental behaviors, including the Theory of Planned Behavior (Ajzen & Fishbein 1980), Responsible Environmental Behavior (Marcinkowski 1988; Hines et al. 1987), Value-Belief-Norm (VBN) Theory (Stern 2000), Multi-factor integration model (Bamberg & Möser 2007), Attitude-Behavior-Conditions (ABC) model (Guagnano et al. 1995), Context model for analyzing environmental consciousness and behavior (Brand 1997), etc. Of these, the VBN theory was put forward by Stern in 2000 (Stern 2000) on the basis of the Norm-activation Theory, which claims that social norms could be converted into pro-social and pro-environmental behaviors of individuals only when it is personized. The activation of individual norms is influenced by two factors: the awareness of the consequences of the action (AC), and the assumed responsibility for these consequences (AR). When AC and AR are high, individual norms will be activated, leading to the implementation of pro-environment behavior. VBN theory combined this idea with the Value Theory and the New Environmental Paradigm (NEP) in order to explain environment-related behaviors and how they are formed. The starting point of the VBN Theory is that generic values would activate individual norms, resulting in personal (environmental) responsibility through environmental 'beliefs' (NEP), recognizing the relationship between the outcomes of individual negative behaviors and the "beliefs' in reducing threats and consequences through behavioral changes. The VBN theory has been proven in many precedent studies (Nordlund & Garvill 2003; Ã et al. 2006; Scherbaum et al. 2008). Other contributing factors to trigger green-intent behaviors are wider collaboration and engagement, design-driven strategies, incentive-driven strategies, etc. For example, in order to create green users, the WELL system (International WELL Building Institute 2016) highlights not only individuals, but more so employers. The concept behind WELL is that eventually it is people (employers) who is managing people (employees), as well as people's behaviors. That is why WELL tends to manage people (employers) who are administrators at the operation level of buildings. Similar trend and development can be noticed in the latest version of the Green Mark rating system where a Green Mark Pearl Award was launched in 2015 to encourage green promises from building owners and tenants.

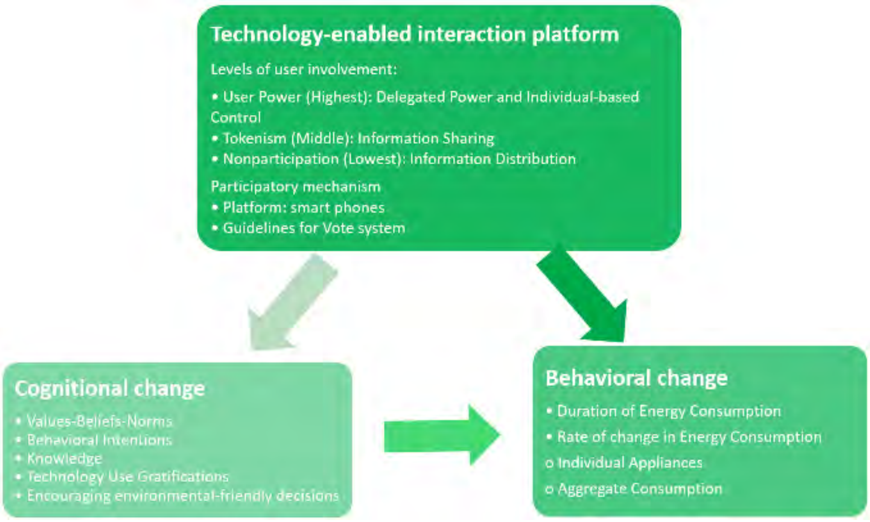

Figure 1: A preliminary interdisciplinary model of technology-enabled empowerment on the behavioral change of occupants

3.2 The "soft" (human-centric) challenges of environmental-responsive building

The shifts in the attention on the "soft" (human-centric) aspect in architectural design are due to the fact that human beings' understanding and cognition on environment, ecology, sustainability, human factors, etc. are subject to dynamic changes, and these thought waves influence green building as an evolving concept. According to a research on the financial benefits of green buildings (Kats et al. 2010) , it is indicated that the main return of green buildings are the enhancement of productivity and health benefits. Since enhanced user satisfaction, comfort and productivity will contribute to increased economic benefit, addressing human factors in green buildings would lead to the motivation that drives the green market. Under this circumstance, attitude changes have been made in various building evaluation systems. However, green building certification is a one-time activity, fine-tunings or major renovations of design decisions are given very few opportunities for buildings-in-use (Moezzi & Goins 2011). In response to the questioning of "How about buildings in use? How about user responses?" the concept of Post-occupancy evaluation (POE) was introduced. Post-Occupancy Evaluation (POE) has been applied as a systematic framework to evaluate the built environment according to responses of occupants in buildings (Brand 1994), which indicated that POE surveys aimed to collect user responses at the operation stage and provide evidence-based design knowledge for the next generation of buildings. The main deficiency with this method is that feedbacks collected in the occupancy stage are delayed, sometimes simply ignored and exert limited influence on the building being surveyed. Another drawback with this approach is that it fails to take technological updates into account due to the fact that POE system is rooted from the 1980s and methods to perform POE surveys are normally

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

questionnaires, interviews, observations, recording, etc. (Preiser & Vischer 2005), which remain almost the same despite the advent of advanced technologies, such as Building Informatics and ICTs. The critique is that the POE paradigm barely changes its methodology and core concept. Another drawback of POE is that conflicts among findings from POE surveys widely exist due to varied human behaviors or diverged environment-related factors, which demonstrated the lack of 'universality, adaptability and flexibility' as evidence-based design guidelines. Therefore, it is necessary to look beyond POEs by promoting direct feedbacks and communication with real-time, dynamic e-participation of building users with regard to advanced ICT technologies. For example, the control center reacts instantly by switching ventilation modes in mixed-mode buildings, changing the room temperature, lighting levels, etc. as occupant vote system via mobile and real-time management are realized by collecting quantitative indications to realize human-building interaction. This vote informed real-time building is an active system, which is turning POE from a problem-finding process to a problem-solving process, i.e. to close the loop

Human-centric, or human-oriented is the same concept as people-oriented, which is defined as "skilled at or focused on interaction with people" in the Oxford Dictionary. Potentials of POE as an ideology and means for improving operational benefits lie on the evolved concept of POE surveys with the intervention of updated technologies with a promising human-building interactive scenario. Concerns of building occupants should be comprehensively collected, demonstrated, analyzed and discussed via interactive mechanism. Previous studies have figured out that user-led innovations with the purpose to deepen the level of user controllability of indoor environments are able to improve user perception of comfort and increase the quality of daily life (Frontczak & Wargocki 2011). Comfort could be enhanced in the perceived built environment by deeper user-building communication and user controllability of buildings.

3.3 The significance of user participation in architecture

The relationship between man and machine and how they could cooperate interactively to contribute to the welfare of humanity continues to be one of main and interdisciplinary topics and challenges of the new era. In building science, "active" and "passive" have been endowed with different meanings under different contexts. For a building mechanism, passive design approaches and strategies taking advantages of natural resources and elements while an active system is employed with energy consumption (Tang 2013a; Tang 2013b). For occupants, when a building is "active", they are generally given limited or no controllability and adapt to the indoor environment "passively"; when the building is "passive", occupants have to respond "actively" to acclimatized with the indoor environment. The proposed interactive scenario, a real-time building, aims to break the boundary between passive and active, and to achieve a dynamic balance of "interactive" instead by the intervention of user e-participatory processes with interdependent individual-based control by users via Internet of Things (IoT) and ICTs.

Citizen participation has been long and widely discussed in planning, public policy and public administration literature (Davidoff 1965; Arnstein 1969; Fagence 1977; Day 1997; Healey 2006; Forester 1999). The proposed study aims to apply the citizen participation theories at the urban scale in the occupant participation at the building level. Deduced from "public participation" (Cai 2010), "occupant participation" for buildings-in-use refers to building occupants involved in building operations and maintenance through direct interaction with building systems. Occupant participation is thus empowered by the interactive vote system introduced in the real-time mechanism. Similarly, occupant participation shall become one of the soft powers of green-intent and human-oriented buildings. The Sherry Arnstein's "ladder" theory (Arnstein 1969) of public participation divides public participation into eight different steps within three levels from shallow to deep, i.e. non-participation (Manipulation, Therapy), tokenism (Consultation, Placation, Informing) and citizen power (Partnership, Delegated Power and Citizen control). Traditional collective-based POE surveys are regarded as "nonparticipation" in this research due to the fact that information from feedbacks are delayed, sometimes ignored, and even when the feedbacks contributes to the database of empirical evidences, the actions and updated design approaches do not have effects on the building being surveyed. The proposed individual-based real-time buildings may reach the "user power" level by empowering occupants to control specific buildings via the vote system. Moreover, based on the Communicative Theory by Jurgen Habermas (Habermas & Habermas 1984), John Forester pointed out that in the process of a design process, designers widely ignored the key content, listening (Forester 1989). Vote system is such a platform that enables buildings to listen to their occupants and communicate directly. Recently, citizen participation theories are trying to adapt new technologies (Foth et al. 2009) such as e-planning and e-participation (Silva et al. 2013; Silva 2010).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The application of the participation theory as a research methodology is combined with the backcasting methodology and the POE methodology to promote user controllability via the direct vote system based on previous research outcomes that individual control of building occupants over the indoor environment has been proven to have a strong positive effect on the overall satisfaction with IEQ (Frontczak & Wargocki 2011), the acceptance of a wider range of conditions (Paciuk, 1990; Leaman and Bordass, 1993; Williams, 1995, de Dear and Brager, 2002) and higher "forgiveness" (Deuble & de Dear 2012). The forgiveness factor defined in the Building Use Studies Occupant Survey and Reporting Method (Leaman & Bordass 2001), is hypothesized to be a function of the power of control, constitutes an important aspect of the research. Employing participation theory in architecture could overcome one important barrier of POEs, that of inconsistencies and conflicts which present architects with a dilemma in making a choice (Frontczak & Wargocki 2011). These inconsistencies are caused by the size of surveyed samples to a certain extent. People are individually different but collectively same. However, 100 to 1,000 occupants can be regarded as an individual compared to the entire population. Thus, findings from occupants of several buildings are more like opinions and perceptions from several "individuals" and they are "individually" different. The intervention of direct user participation is to turn collective-based feedbacks into individual-based control in buildings at the operation level, and to let occupants speak for themselves.

4. CONCLUSION

User-led, real-time controllability communication and controllability enabled by networked building components with the changing roles of buildings, users and architects could lead to a wider range of perceived comfort and wellness of building users in built environments. Furthermore, levels of user involvement in building controllability, technology-enabled interaction platform, inclusive involvements and user trust are key contributing factors in the human-building interaction.

An app run on iOS and Android to display information, to make suggestions about actions can be taken, to collect feedback from users, is an elegant solution to meeting the goal. An advanced option is to integrate iBeacon to provide location information and help researchers in identifying where (which classroom/ studio/ office/ restroom and so on) the events occurred.

ABSTRACT

Demand-controlled ventilation (DCV) has become research hotspot in recent years with quality of the air inside building and associated energy use attracting increasing attention. Previous studies put insight into CO2-based demand-controlled ventilation in which the CO2 concentrate is used as a parameter indicating indoor air quality (IAQ). It's questionable with respirable particulate matter (PM) being the primary pollutant in China. It's unscientific to introduce outdoor air in occupied space without comparing the air quality of indoor and outdoor.

Thus a new strategy about DCV has been developed in which the control indexes are indoor VOC concentration, indoor PM concentration, indoor CO2 concentration, indoor humiture, outdoor PM concentration and outdoor humiture. The set points of indoor control indexes comply with the requirements of IAQ and energy saving, because the closer between actual design ventilation and the ventilation required for good IAQ, the more energy saving. To implement the strategy, a direct digital control (DDC) along with the location of indoor sensors mounted in the return air duct and the outdoor sensors in the supply fresh air duct. The controller output is determined by comparing these measured concentration with corresponding set point. In this strategy, supply air value will be modulated for more outdoor air if the indoor concentration of VOC and CO2 exceeds the set point. Especially, as indoor and outdoor PM concentration exceed the set point, other measurement, such as purifier, must be taken. This strategy offers great benefit in terms of IAQ, because it has considered the influence of outdoor pollutants to indoor.

Keywords: IAQ, demand control ventilation, control strategy, pollutants' concentration

1. INTRODUCTION

1.1 Indoor air quality

Indoor air quality (IAQ) is a term which refers to the air quality within and around buildings and structures, especially as it relates to the health and comfort of building occupants. IAQ can be affected by gases (including carbon monoxide, radon, volatile organic compounds), particulates, microbial contaminants (mold, bacteria), or any mass or energy stressor that can induce adverse health conditions. A major source of indoor air pollution in developing countries is the burning of biomass (e.g. wood, charcoal, dung, or crop residue) for heating and cooking. The resulting exposure to high levels of particulate matter resulted in between 1.5 million and 2 million deaths in 2000.

Human-generated indoor pollutants and building-generated indoor pollutants can be divided from various buildup pollutants which affected IAQ according to generation source. In non-industrial building, CO_2 levels severe as a proxy for building occupancy and the rate of human-generated indoor pollutants, since the only generation source of CO_2 is human indoor. Building-generated indoor pollutants refer to fumes from copiers and printers, out-gassing from building materials, carpets and furniture, and vapours from cleaning supplies.

1.2 Ventilation design

Two options are offered to maintaining adequate ventilation: the ventilation rate procedure and the indoor air quality (IAQ) procedure. The ventilation rate procedure uses the traditional prescriptive method, i.e. a minimum quantity of cfm per person based on maximum occupancy. In contrast, the IAQ procedure allows designers to vary outdoor air ventilation rate (from 0% to 100% of the design outdoor air) if the pollutant concentration remains below a recommended level.

The specific environment of the building and corresponding ventilation demand must be considered in the traditional ventilation design of HVAC. While the air supply rate is ensured at the beginning of design rather than make changes with the actual indoor personnel load and the actual demand of building, as a result of insufficient

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

ventilation or overdraft. It not only increase the energy consumption of building, but also cannot ensure IAQ. Similarly, the outdoor flow rate in most of air conditioning system are according to the standards or people number.

The addition of the IAQ procedure to the standard allows for demand control ventilation (DCV) in buildings. If a DCV strategy needs less outdoor air in the heating and cooling seasons than dose the traditional prescriptive method, then the annual energy required to heat or cool decreases. In addition, lower flow rate decreases the fan energy spend on introducing and transporting the air through building. Available data suggest that DCV reduces ventilation, heating, and cooling loads by 10% to 30%. Buildings and spaces with large swings in occupancy, e.g., movie theatres and conference rooms, tend to realize the largest savings. It can save almost 60% energy consumption if the fresh air can vary from the minimum to entire outdoor airflow rate especially in the transition season, and the cooling capacity utilizing variable air volume can be less 20% than constant air volume during all year.

In the following paper, author will describe research status and resisting problems of DCV, then present a novel strategy based on the research findings of previous studies.

2. RESEARCH STATUS

2.1 Literature review

There are 19 test indexes about IAQ covering the physical, chemical, biological, radiological aspects. Temperature, relative humidity, airflow rate are included in physical indexes, while the rest about health are shown in the *Table 1*. To control these contaminants in the limit value is the requirement of good IAQ, while the first investment and maintaining fees will increase sharply because various sensors and control strategy are needed. Persily has studied the relation between CO_2 level and IAQ, proving that the CO_2 concentration can be used as a parameter indicating IAQ.

Parameter type	Number	Species	Reference value	Note
Chemical	1	SO_2(mg/m^3)	0.5	1h mean value
	2	NO_2(mg/m^3)	0.24	1h mean value
	3	CO(mg/m^3)	10	1h mean value
	4	CO_2 (%)	0.1	Day mean value
	5	NH_3 (mg/m^3)	0.2	1h mean value
	6	O_3(mg/m^3)	0.16	1h mean value
	7	HCHO(mg/m^3)	0.1	1h mean value
	8	C_6H_6(mg/m^3)	0.11	1h mean value
	9	C_7H_8(mg/m^3)	0.2	1h mean value
	10	C_8H_{10}(mg/m^3)	0.2	1h mean value
	11	B(a)P(mg/m^3)	1	Day mean value
	12	PM10(mg/m^3)	0.15	Day mean value
	13	TVOC(mg/m^3)	0.6	8h mean value
Biological	14	Colonies number (cfu/m^3)	2500	Instrument measurement
Radiological	15	Rn (Bq/m^3)	400	Year mean value

Table1. IAQ control indexes about health

CO_2 concentration in outdoor airflow is lower than occupied space indoor in common situation, so that outdoor airflow dilutes indoor pollutants and enhances IAQ in air-conditioned zones. From this aspect, a high outdoor should be maintained. However extra outdoor airflow requires extra energy for hanging it. From this aspect of energy consumption, a low outdoor airflow is prefered. In orde to compromise the requirement of acceptable IAQ and energy savings, outdoor air flow in an air-conditioning system should be properly controlled. Then, how to control the CO_2 concentration in limit values with the least outdoor airflow rate, as well as CO_2-DCV, is critical. In most cases, the CO_2-DCV strategy is applied by detecting the CO_2 contrentration in return air or based on flow rate per person. In the first condition, it may result in poor air quality inside certain zones in a multi-zone building.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

To solve the poor air quality in a multi-zone building, many scholars have made great efforts. Nabil Nassif proposes a robust CO_2-based DCV strategy to maintain the CO_2 concentration in supply air a low enough to meet the new ventilation requirements of ASHRAE Standard 62.1 2010 in all zones and improve energy efficiency, and provides insight into the performance of a typical VAV system under different operating and ventilation requirement conditions, as shown in Figure 1. The results show that it can save 23% energy consumption compared to the traditional design, and the saving will be lower as the actual occupancy is getting closer to the design value.

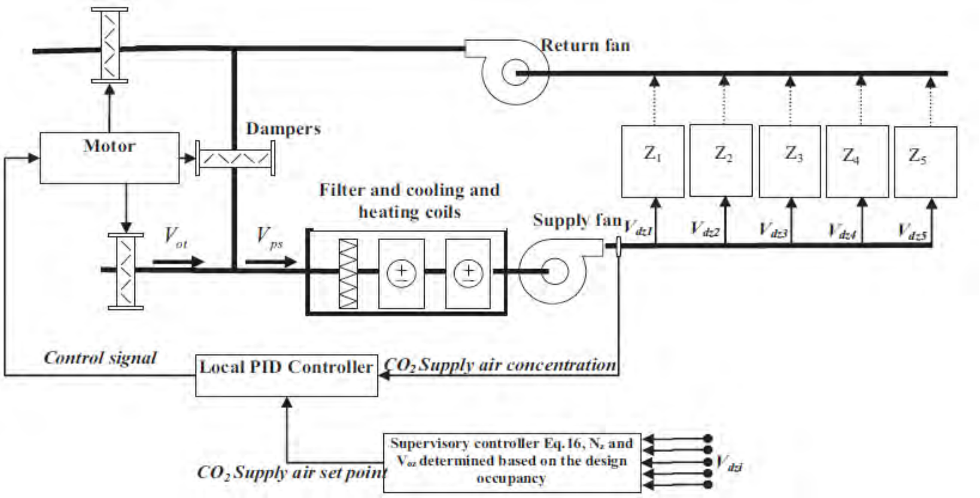

Figure 1. Control strategy with a typical VAV system

Tao Lu, Xiaoshu Lü, Martti Viljanen have presented a novel and dynamic control strategy for hourly scheduled buildings which utilized schedules by setting a base ventilation rate for unoccupied periods and calculating ventilation rate dynamically at each occupied period by solving the CO_2 mass balance equation to keep indoor CO_2 near the set point during the occupied period, as shown in Figure 2. The result proves that it can save about +26% of energy related to ventilation air compared to proportional control.

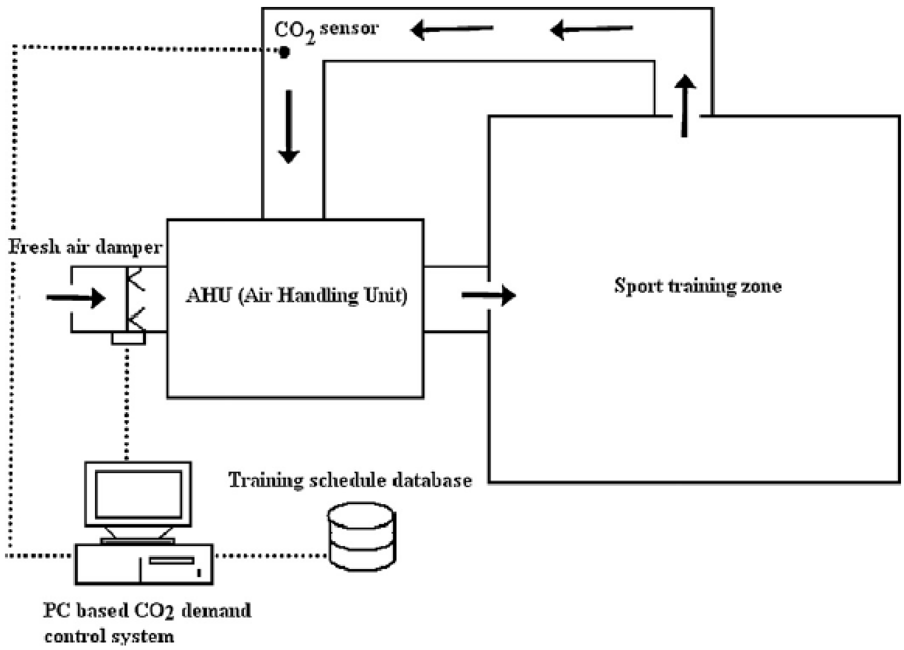

Figure 2. New strategy of DCV-CO2

As mentioned above, the CO_2-DCV strategies have proved effective. While these strategies require many sensors. In a large building, the number of CO_2 sensors and flowmeters needed could be huge. That may significantly increase the initial investment considering the price of the sensors and meters as well as the cost for installation, maintenance and integration into a building management system. Kui Shan, etc presents a new strategy using a limited number of sensors for (DCV) of multi-zone office buildings.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

As we know, the control algorithm affects directly the quality of the control system as well as the success or failure of the whole system. In CO_2-DCV system, proportional, exponential controls and genetic algorithms are the most discussed and popular ones among control algorithm. In terms of proportional and exponential controls, both approaches modulate ventilation between a lower set point of indoor CO_2 and an upper set point that represents the equilibrium concentration of CO_2 corresponding to the target per-person ventilation rate of a space, the difference between two lies in the modulation of ventilation rate which is proportionally for proportional control but exponentially for exponential control. Exponential control is able to adjust ventilation rate more quickly to changes in CO_2 concentration by using a standard proportionalplus- integral (PI) or proportional-integral-derivative (PID) control algorithm. From the energy conservation point of view, exponential control adds little additional benefit compared to proportional control generally. Congradac and Kulic set genetic algorithms to optimize the return damper position uch that indoor CO_2 concentration can be kept close to the desired level as possible and at the same time the lowest value of the valve (the lowest energetic use) can be accomplished.

2.2 Exsisting problems

CAI Kun presented three mainly reasons by investigation and study which cannot get extensive application of CO_2-DCV: 1) it cannot reflect the air volume requirement of building-generated indoor pollutants, 2) it will result in energy waste that inaccuracy in control leads to over-ventilation, 3) it is too expensive about sensor maintenance and calibration. Steven has present multi-parameter DCV strategy to control the concentrations of TVOC, PM, CH4, and relative humidity. So it must maintain lower air volume rate at low concentration of CO2. While in this condition, it must add sensors to detect other parameter's concentration.

In practice, the design ventilation rate is calculated based on the assumption of a CO_2 equilibrium condition (steady state) and occupant density that might be different from actual one, which could distance indoor CO_2 concentration from the CO_2 set point. While the potential energy saving is affected by the factor how closely the actual design ventilation rate achieves the ventilation required for the actual occupancy in the space.

So far, all strategies are operated under the assumption that it's enough clean for outdoor air, while with the economic development, concentrations of some contaminants in outdoor air, such as particulate matter (PM), SO_2 and NO_2 are higher than indoor air. In practice, introducing outdoor air only decrease the large PM concentration, e.g. PM10 rather than PM 2.5 by low efficient filter. So, it's necessary to make compare between indoor and outdoor air, then design control strategy to maintain IAQ.

3. NEW STRATEGY ABOUT DCV

3.1 Control indexes

In recent studies, VOC is the major factor of sick building syndrome (SBS) so that the VOC can represent the building-generated indoor pollutants. As mentioned above, IAQ control indexes can be VOC concentration, CO_2 concentration, humiture. As for office and residential building, outdoor PM is the main source of indoor. So PM concentration and humiture outdoor must be tested. So the control indexes are indoor VOC concentration, indoor PM concentration, indoor CO_2 concentration, indoor humiture, outdoor PM concentration and outdoor humiture.

The set point of control indexes must comply with the requirements of IAQ and energy saving. The closer between actual design ventilation and the ventilation required for good IAQ, the more energy can we saving. It's worth to study in making the limit value of control indexes' concentrations. These limit values are Refer to Table 1.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.2 Implication of strategy

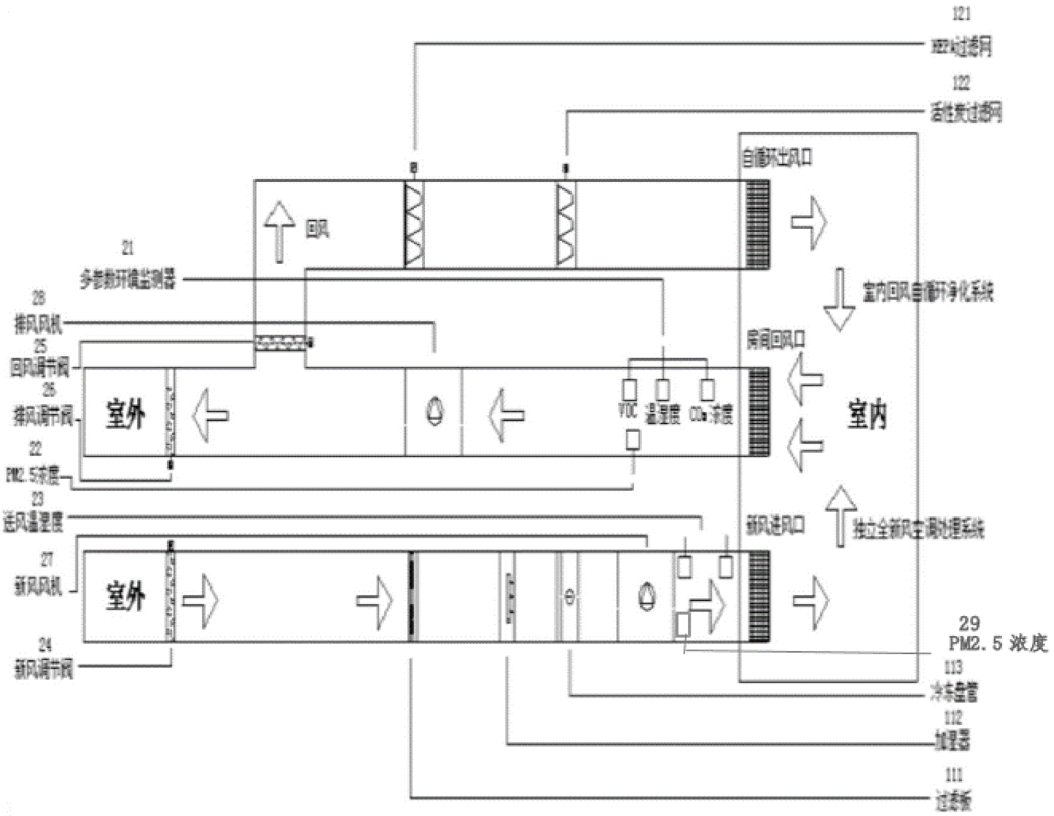

Figure 3. Implication of strategy

As shown in Figure 3, the location of indoor CO_2 sensor, PM sensor, VOC sensor and humiture sensor can be mounted in the return air duct, while the outdoor PM sensor and humiture sensor in the supply fresh air duct. To implement the strategy, a direct digital control (DDC) along with these sensors should be installed. The controller output is determined by comparing these measured concentration with corresponding set point.

The control flow chat is as shown in Figure 4. As we know, the humiture mainly to control the return water temperature as well as the air-conditioning's mainframe. The humiture control is no longer illustrated on the flow chat, to highlight the DCV's requirement. The set point of CO_2 and VOC are consulted about the IAQ standard as mentioned above. In this flowchart, PM_{in} is the indoor PM concentration, PM_{out} is the outdoor PM concentration. While PM is composed of different size particles, e.g. PM10 and PM2.5, PM10 is specified in the standard rather than PM2.5. In recent years, PM2.5 has been found that it is harmful for personal health. So set point of PM_{in} is subjected for further discussion and research.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

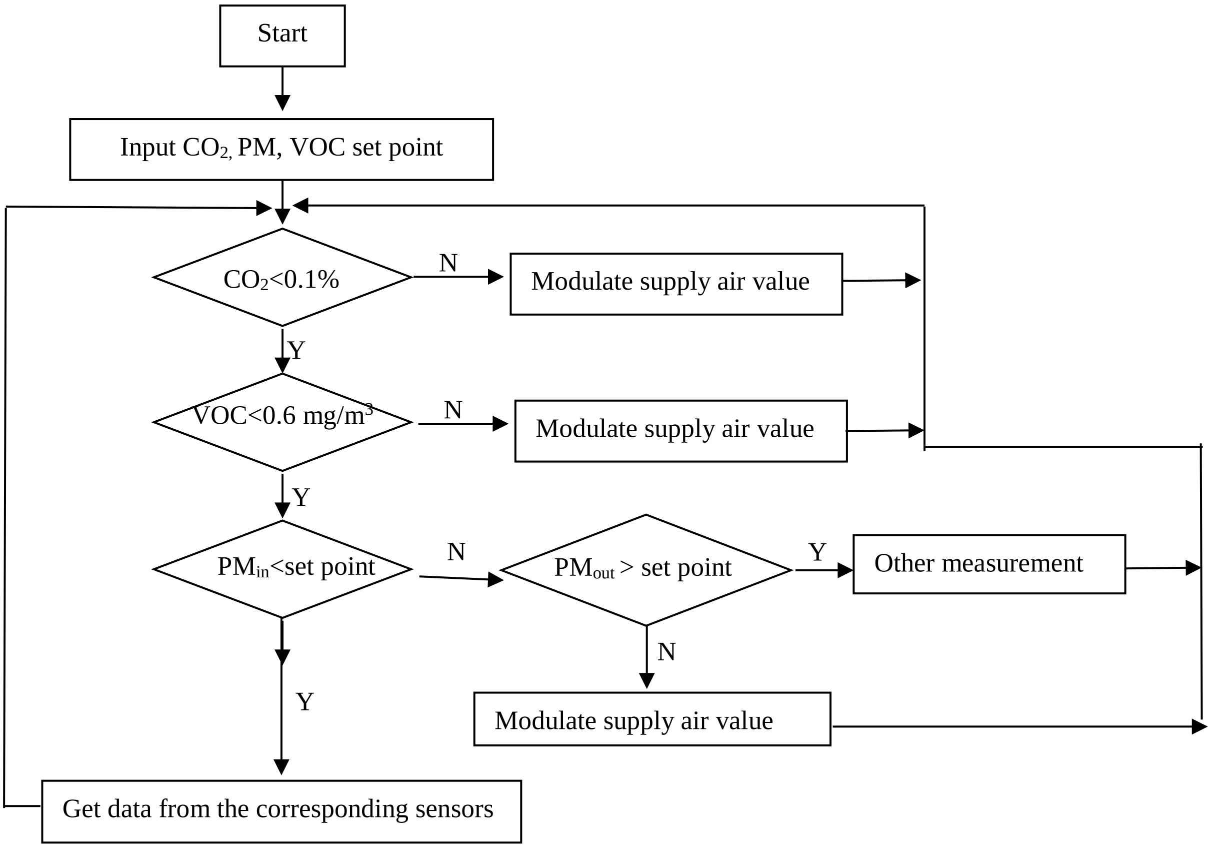

Figure 4. Control flow chart

It is easy to reason out that the relationship between PM_{out}, PM_{in}, PM_{set} has 6 situations: 1) $PM_{out} > PM_{in} > PM_{set}$, 2) $PM_{out} > PM_{set} > PM_{in}$, 3) $PM_{set} > PM_{out} > PM_{in}$, 4) $PM_{set} > PM_{in} > PM_{out}$, 5) $PM_{in} > PM_{set} > PM_{out}$, 6) $PM_{in} > PM_{out} > PM_{set}$. The 2) 3) 4) situations are the desired result after processing. The 1) 6) situations mean that the indoor and outdoor PM concentrations exceed the limit value, which is not conformity with the requirements. The outdoor air supply system may operate with the requirement of concentration of CO_2, VOC below corresponding limit value, so the PM pollutant cannot be diluted because transports from atmosphere to buildings. Other measurement, e.g. purifier, must be operated to control the PM concentration under set point. The 5) situation means that the outdoor air supply system is required to decrease the concentration of PM.

3.3 Summary

The strategy presented above is based on the assumption that the data detected by sensor is accurate and effective. However, it's difficult to achieve higher precision with development of sensor technology at present. It is necessary to develop a new type of sensor for measuring the concentration of VOC, PM and other pollutants.

Single factor analysis is made for various pollutants with the consideration that they don't effect each other. However, the various pollutants are mutually influenced in fact, and the impact on the human has not been analyze completely. The comprehensive index of air pollution needs to be further studied.

The strategy are based on the requirement of IAQ rather than energy saving, so the set point of pollutants is need to be discussed.

Using Advance Thermodynamics and Online Big Data Analytics to Maximize the Chiller Plant Performance

Rafael NAVARRO[a], Glen ANDERSON[b]

[a] *ETC Group, Macau SAR, rafaelnavarrobarraza@gmail.com*
[b] *ETC Group, Macau SAR, ganderson@etcgrp.com*

ABSTRACT

It comes as no surprise; chillers are often the largest consumer of power in a building, accounting for 15-30% electric use. Just because a chiller is operating, does not mean it is efficient. Most chillers do not function efficiently resulting in higher energy costs and increased CO2 emissions. Building owners looking for ways to better operate their facilities are paying more attention to their chillers.

This paper examines how advanced thermodynamic monitoring combined with big data analytics has advanced chiller plant performance in commercial buildings. This new Online Chiller Performance Evaluation technology (OCPE) supports high-performance buildings through accurate thermodynamic evaluation of chiller operation. This paper is based on real-world OCPE cases and will show:

- The typical % of savings achieved in chillers installed in commercial buildings such as clinics, hospitals and offices.
- The most common saving opportunities identified with the technology.
- The Return on Investment (ROI) of applying the OCPE technology.

This document also explains the importance of independent chiller performance monitoring, and defines the typical architecture (hardware, software and network) of an online OCPE system, its integration with an existing BMS, the involved cybersecurity concerns and how to overcome them. Finally, it explains the next steps of this technology towards Dynamic Chiller Performance Optimization: DChPO, that will lead to the next generation of high-performance Buildings.

Keywords: high-performance building, energy saving, smart building

1. INTRODUCTION

Air Conditioning (AC) systems are a central focus in the climate change challenge, as they play a double role in the problem. On one hand, AC systems have become a basic need, not only for developed countries, but also for the rest of world. To mitigating rising global temperatures, air conditioning systems have become necessary to keep adequate conditions for occupants of both residential and office environments.

On the other hand, AC systems are energy intensive, meaning they consume large amounts of energy over their lifetime, until the point that the acquisition cost is sometimes 5 to 20% of the net present value (NPV) of the energy consumption. It is important to note that AC systems are, by far in residential and commercial sectors, the highest energy consumer.

In much of the world, increase in energy demand occurs among the developing non-OECD (Organization for Economic Cooperation and Development) nations, where strong economic growth and expanding populations lead the increase in world energy use. Non-OECD demand for energy is expected to rise by 71% from 2012 to 2040. In contrast, more mature energy-consuming and slower growing OECD economies, total energy use is expected to rise by only 18% from 2012 to 2040 (U.S. EIA, 2016).

Multi-country studies of the effects of urbanization on energy use have shown two opposing effects: improvements in energy using equipment (e.g. air conditioning units) associated with an urban lifestyle increase efficiency, but higher numbers of households and increased penetration of air conditioning increase overall energy use (U.S. EIA, 2016).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

It is evident that AC systems, specifically large units like those served by chiller plants, are suitable for optimization. The optimization process is not easy. This paper details a real-case of chiller plant optimization project, improving energy efficiency, by applying advance thermodynamics and data analytics. This document also presents the identified improvements of the Online Chiller Performance Evaluation (OCPE), which a commercially-available technology (but still unknown) and its next steps.

1.1 Barriers to chiller plant optimization

Chillers (unlike electric motors, engines, pumps, etc.) are susceptible to inefficiency since they are composed of many sub-components that transform energy from different sources (not only electricity) to several services (generally cooling and in some cases heating, when heat recovery process are part of the equation). Chiller plants, comprised of at least one chiller, cooling tower (and/or heat exchanger) and pipelines, have even more complex sequences of operations than chillers alone and are more prone to inefficiency.

Chiller plant optimization requires understanding of electricity conversion, turbomachinery, refrigeration cycle, thermodynamics and advanced thermodynamics, and psychometrics. Knowledge of statistics is also required in order to convert large amounts data into actionable information to support the decision-making process.

As can be expected, this intricacy leads to a several challenges that need to be identified in order undertake an optimization process on chiller plants. These barriers to Chiller Plant Optimization are:

- Lack of specialised professionals:

Given the technical background required to understand the chiller plants, its optimization process implies a specialized understanding of several diverse study fields, postgraduate studies and operational experience which are required before undertaking a chiller plant optimization project, or even a simple performance evaluation.

- A business model focused on reliability rather than efficiency:

Due to requirements for continuous operation, chiller manufacturers (and owners and facility managers) are more concerned with reliability and longevity rather than efficiency.

In addition, it is common to find that manufacturer staff (post-sales professionals) are more knowledgeable on chiller's design specifications rather than with the complexities of chiller performance evaluation or optimization process. In this regard, it is possible that the business model (manufacturer/owner) fosters a conflict of interest, as chiller optimization might show evidence of poor chiller performance and with current chiller capacity capable of future cooling demands thus negating new equipment purchase.

- Lack of a comprehensive method and tools:

As was presented above, chiller plant performance is complex and multivariable, depending on the following variables: outside air temperature (OAT), outside air relative humidity (OARH), condenser entering water temperature (CEWT), condenser entering water flow (CEWF), evaporator entering water temperature (EEWT), evaporator entering water flow (EEWF), refrigerant charge (RefCh), compressor isentropic efficiency (CompIE), Power Factor (PF), voltage (Volt), workload (WL), sequence of operation (SOO), chilled water set point (CWSP) and chilled water inertia.

As such, chiller plant optimization requires a well-structured method that takes into account all variables. Usually, chiller controller (control system) only consider half of these variables, those that are easy to measure and critical for chiller reliability.

1.2 Online chiller performance evaluation technology

To facilitate insight into chiller plant operation, an "Internal Method" was developed which offers a cost-effective way to determine overall performance with detailed component level information (Berglöf, 2013).

This Internal Method helps overcome barriers to Chiller Plant Optimization, as it incorporates several types of analysis to evaluate chiller performance. It is a huge advance providing for thorough performance evaluation.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The advantage with the Internal Method is that it is based on thermodynamic analysis of the refrigeration process. Additionally, it does not require any pre-installed sensors and can often be installed without stopping the compressors (brief interruption may be needed when opening the electrical housing to connect current clamps). Figure 1 shows sensor locations and how they are linked to the refrigeration cycle.

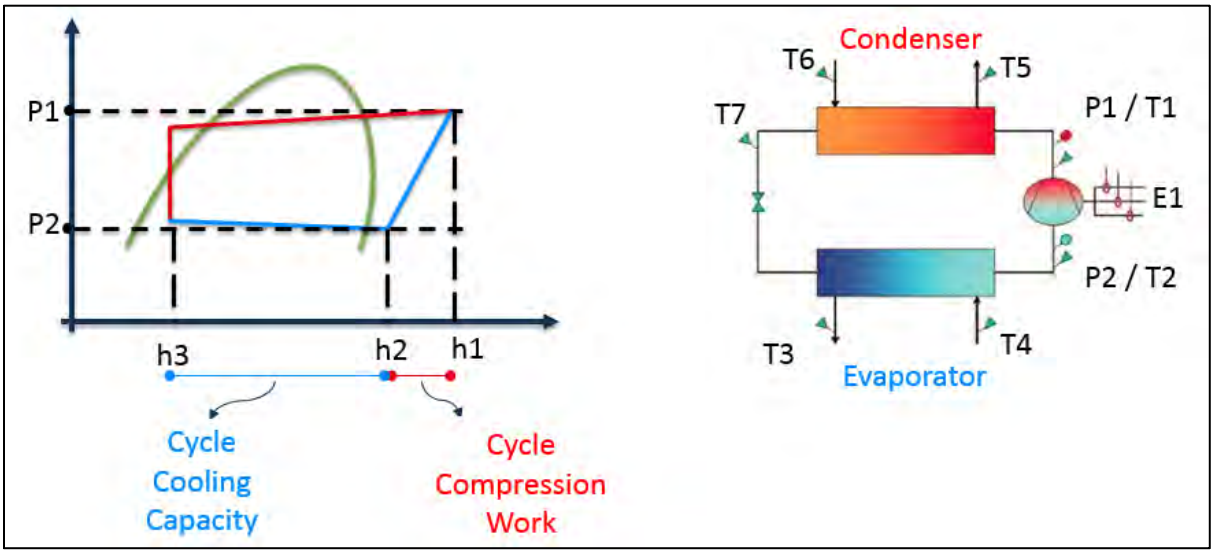

Figure 1: Location of "Internal Method" sensor and their equivalence on refrigeration cycle

The following are typical sensor locations: Pressure of Refrigerant in the Condenser (P1), Pressure of Refrigerant in Evaporator (P2), Temp. of Refrigerant at leaving compressor (T1), Temp. of Refrigerant at entering compressor (T2), Temp. of Chilled Water pipe at leaving the Evaporator (T3), Temp. of Chilled Water pipe at entering the Evaporator (T4), Temperature of Cooling Water at leaving the Condenser (T5), Temperature of Cooling Water at entering the Condenser (T6), Temperature of entering pipe to expansion valve (T7), and Power Demand of Chiller Compressor (E1).

This method is based on well-defined properties of the refrigeration cycle and reduces measuring errors while generating information about dynamic systems that cannot be achieved using other methods. It accurately determines a working system's (Berglöf, 2013):

- Coefficient of performance (± 5%)
- Cooling and heating capacity (± 7%)
- Power input (± 2 %)
- Compressor isentropic efficiency

As the method has been successful, specialised software and hardware has been developed to increase productivity and accuracy where a portable unit can be installed on almost any chiller and connected to the Internet for multiple purposes: big data analysis, monitoring and remote assistance. The method (patented in 1986 and commercialised since 1990) has a large database of chiller models and refrigeration cycles that support analysis and deliver insightful results.

These advances have led to Online Chiller Performance Evaluation technology (OCPE) which can be integrated with controls systems for chiller plant optimisation and consequently better building efficiency.

Since 2004, hardware and software were developed in a cost-efficient way to allow the method deployment and commercialization to "early adopters" (via a few specialized consultants and technology providers), however the large majority of the market potential is far away of being reached.

2. CASE DESCRIPTION

This paper is based on a real-world success case of a chiller plant evaluation developed in 2016. Findings are supported by 16 chiller plant evaluations and optimizations conducted on hospitals, medical centres, manufacturing plants, universities and supermarkets conducted in USA, China and South America.

The project-host company is located in Suzhou (China) while the energy consulting company (contractor) is located in Macau SAR, China with headquarters in UTAH, USA.

The project-host company plans to expand its operation which is composed by production buildings, administrative offices and other facilities where air conditioning is required.

The air conditioning system is composed of a central chiller plant (ChP) a chilled-water distribution system and 25 air handler units (AHUs).

Due to the host company's commitment to sustainability, the chiller plant optimization project was started. This paper uses this chiller plant optimization study to illustrate the OCPE technology.

2.1 Chiller plant description

The existing central chiller plant has two 500 ton Trane chillers. Figure 2 shows the ChP schematic.

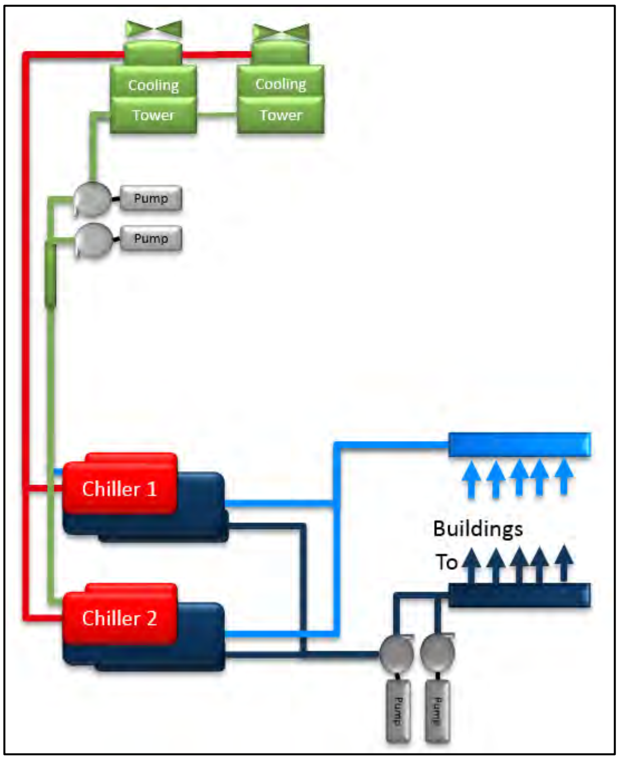

Figure 2: Chiller plant schematic

There is a plate and frame heat exchanger used for water side economization. The primary only chilled water plant has two chilled water pumps with Variable Speed Drive (VFD). The condensing water side of the plant has two condenser water pumps with VFDs and two counter flow cooling towers with VFDs fans.

As the production plant is being expanded to increase production a new 400-RT chiller was budgeted for 2017.

2.2 Installation of OCPE unit

The OCPE technology was developed in two formats: portable unit and permanent installation. In this case, a portable unit was installed due to budget limitations. Figure 3 depicts how the portable unit is connected to the chiller plant to gather the data for analysis. The Appendix A shows more detail about sensor placement.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

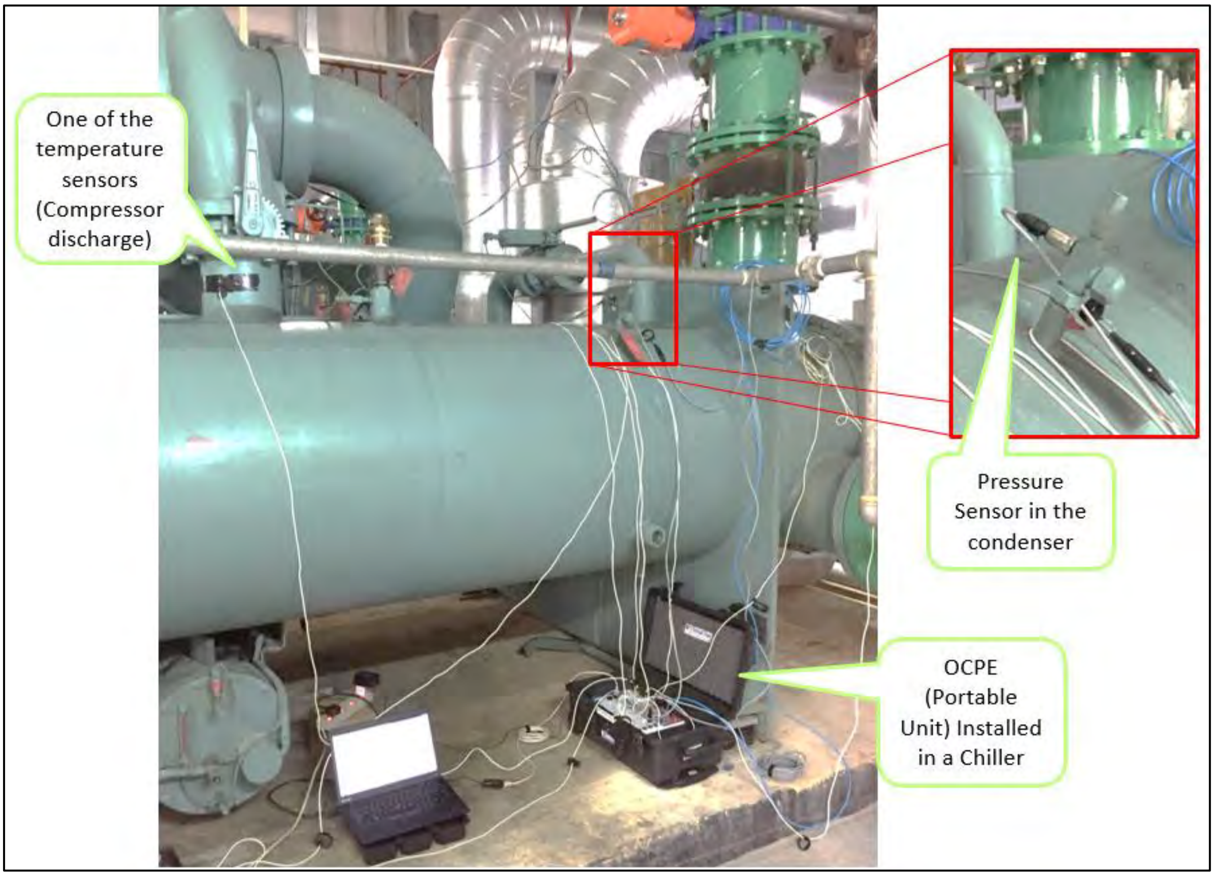

Figure 3: OCPE portable unit installation

2.3 How the chillers are operating

The sensors, data collection and calculations of the OCPE technology establish the chiller operating points. The Figure 4 depicts the operational conditions of both chillers.

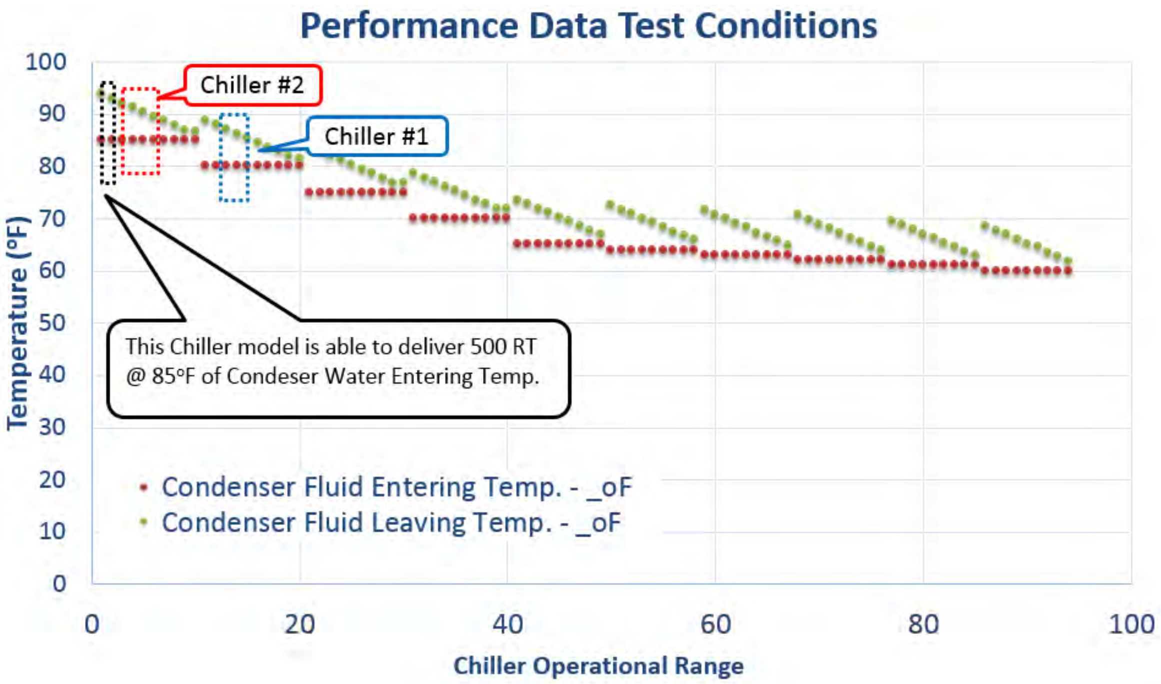

Figure 4: Chiller operational conditions

The OCPE technology shows current operating conditions which are compared to design specifications to determine if the chiller is able to operate at full capacity. In this case, both chillers were working under less stringent conditions and were able to deliver design capacity and performance.

2.4 Chiller performance design vs. actual

The OCPE technology calculates actual chiller performance based on the thermodynamic properties of the refrigerant and the refrigeration cycle, together with the measurement of power consumption. The Figure 5 shows that Chiller 1 and 2 have higher kw/ton than design data which is less efficient.

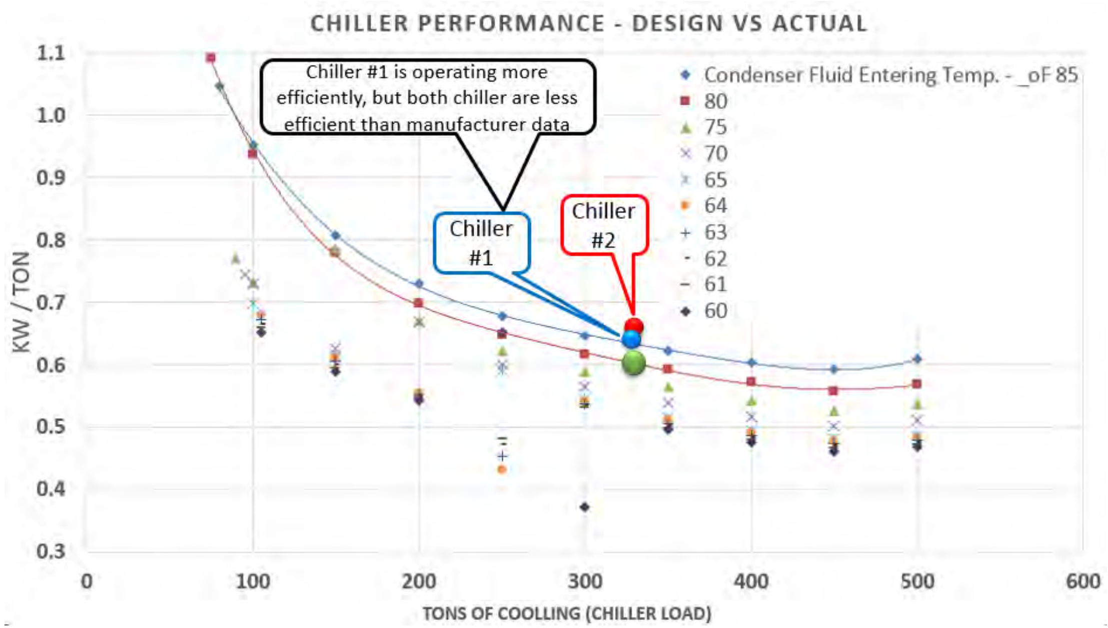

Figure 5: Chiller performance – design vs. actual

2.5 Cooling demand profile

Since OCPE technology calculates the chiller load, it was also possible to determine the chiller plant cooling demand profile. The Figure 6 shows cooling demand together with other key variables.

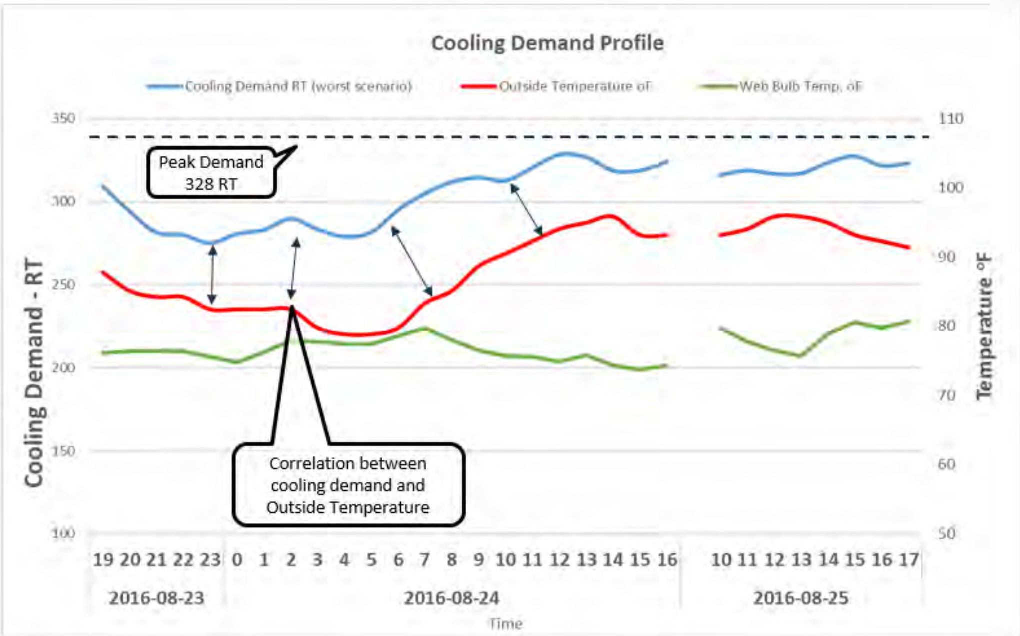

Figure 6: Cooling demand profile

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

A trend analysis of the cooling demand profile, showed a potential correlation between Outside Air Temperature (OAT) and cooling demand. This led to a regression analysis which is shown in Figure 7.

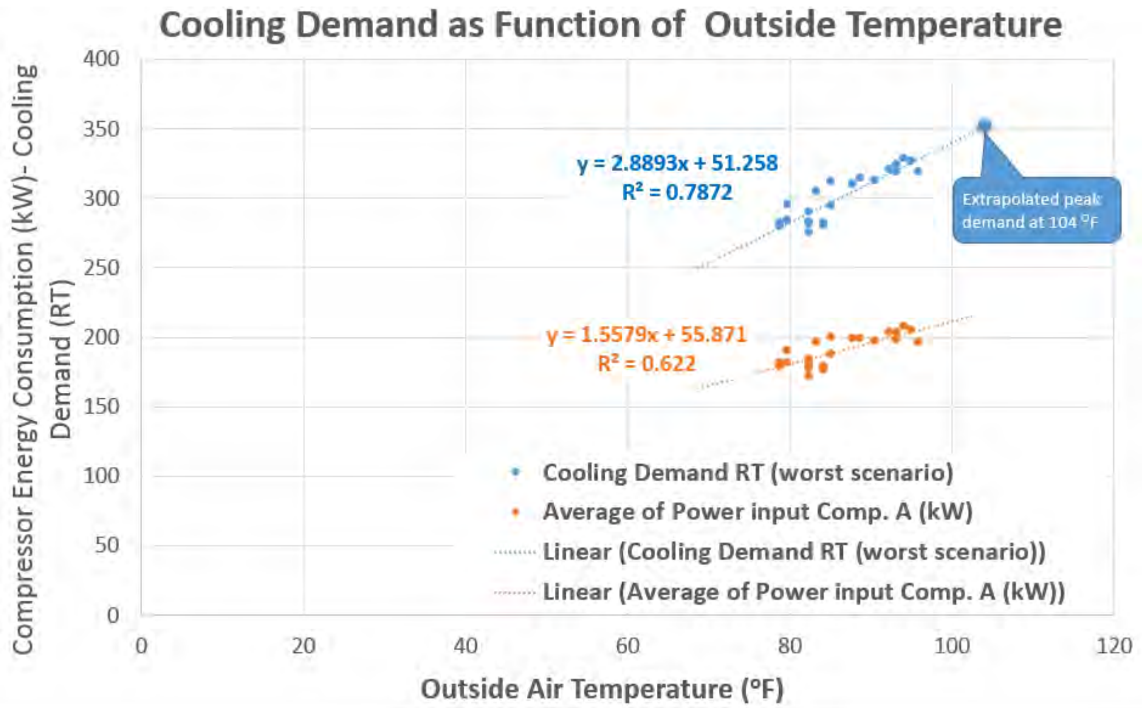

Figure 7: Cooling demand and chiller compressor consumption as function of OAT

2.6 Cooling demand forecast

The regression analysis allowed to develop a cooling demand forecast establishing the peak demand as a function of OAT and based on historical records of extreme weather conditions. The forecast provided insight into the current ChP workload and planning for optimization projects in two phases to keep the cooling demand under 500 TR, under one single chiller capacity, as it is shown in the Figure 8.

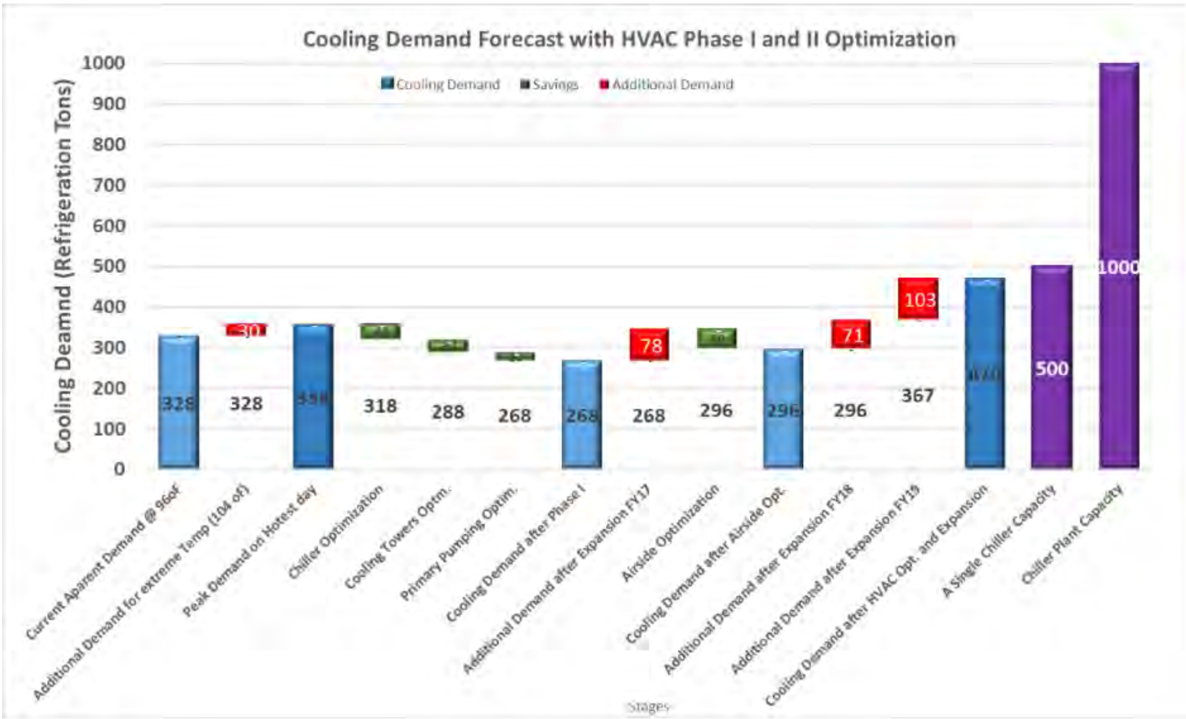

Figure 8: Waterfall chart of cooling demand forecast

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. IDENTIFIED IMPROVEMENTS

The following improvements were identified as a result of the OCPE:

Optimizing chillers and associated plant equipment will permit chillers to achieve their design capacity of more than 500 RT, each or 1000 RT together.

There is an opportunity to avoid a new chiller purchase if the recommended energy saving measures are implemented.

Current HVAC issues are not caused by of lack of chiller capacity, but could be related to chilled water distribution issues.

Chiller Plant improvement will “free up” electrical infrastructure capacity. The electrical capacity to be released is from 40 to 80 kVA.

3.1 Return on investment

The main energy-saving opportunities identified are:

- Increase condenser water flow by 20% and modulate it as a function of the chiller workload and efficiency.
- Modulate cooling tower fans to reduce condenser water temperature as a function of chiller efficiency.
- Optimise Air Handler Units by installing VFDs to modulate air flow to rooms and reduce outside air infiltrations.
- Install capacitors to increase electric motors power factor.
- Reduce condenser water flow to chiller when they are not in operation.
- Clean condenser tubes.

The typical % of energy savings achieved by implementing the above measures is from 20 to 30%. The following Table show the financial analysis for the above improvements:

Improvement Area	**Total Project Cost**	**Annual Energy Savings**	**Annual Energy Cost Savings**	**Chiller Capital Savings**	**Chiller Maint. Savings**	**Electrical Infrastructure savings**	**Total Savings first year**	**Net Annual Recurrent Savings**	**Simple Payback Period**
	[USD]	kWh / year	[USD] / Year	[USD]	[USD] / year	[USD]	[USD]	USD / Year	Years
HVAC Waterside	$ 141,715	287,000	$ 34,440	$ 160,000	$ 13,000	$ 75,000	$ 282,440	$ 47,440	**0.50**

Table 1: Financial analysis.

3.2 Common saving opportunities identified with the OCPE

OCPE technology has been applied in 16 chiller plants with the following common saving opportunities:

Inadequate refrigerant charge, low condenser water flow, Low chilled water flow, Faulty expansion valve and Inefficient cooling tower function.

3.3 Next steps for OCPE

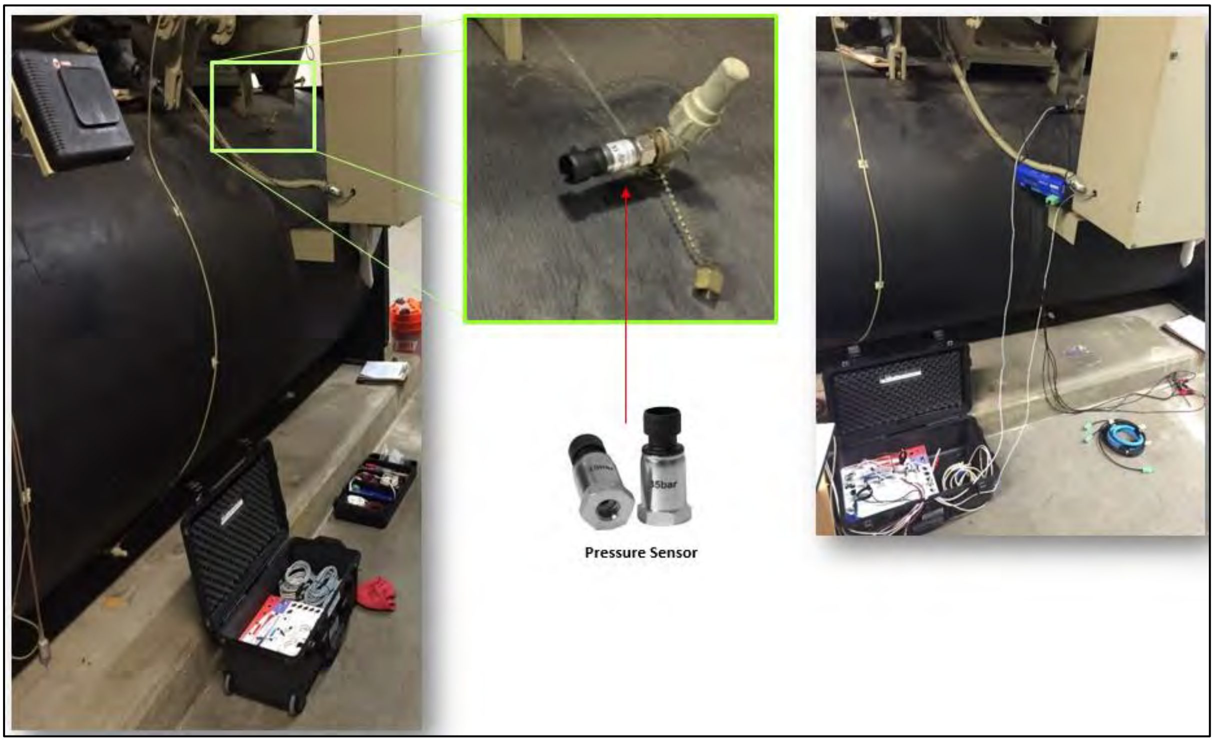
OCPE technology has represented a huge advanced in chiller plant evaluation and optimization, however developments such as internet of thing and monitoring and analytics will assist towards Dynamic Chiller Performance Optimization: DChPO, which will lead to the next generation of high-performance Buildings. This new technology will incorporate elements such as:

- Predictive Maintenance
- Net present value optimization, including variables such as: maintenance cost, energy and water tariff, environmental taxes or incentives, etc.

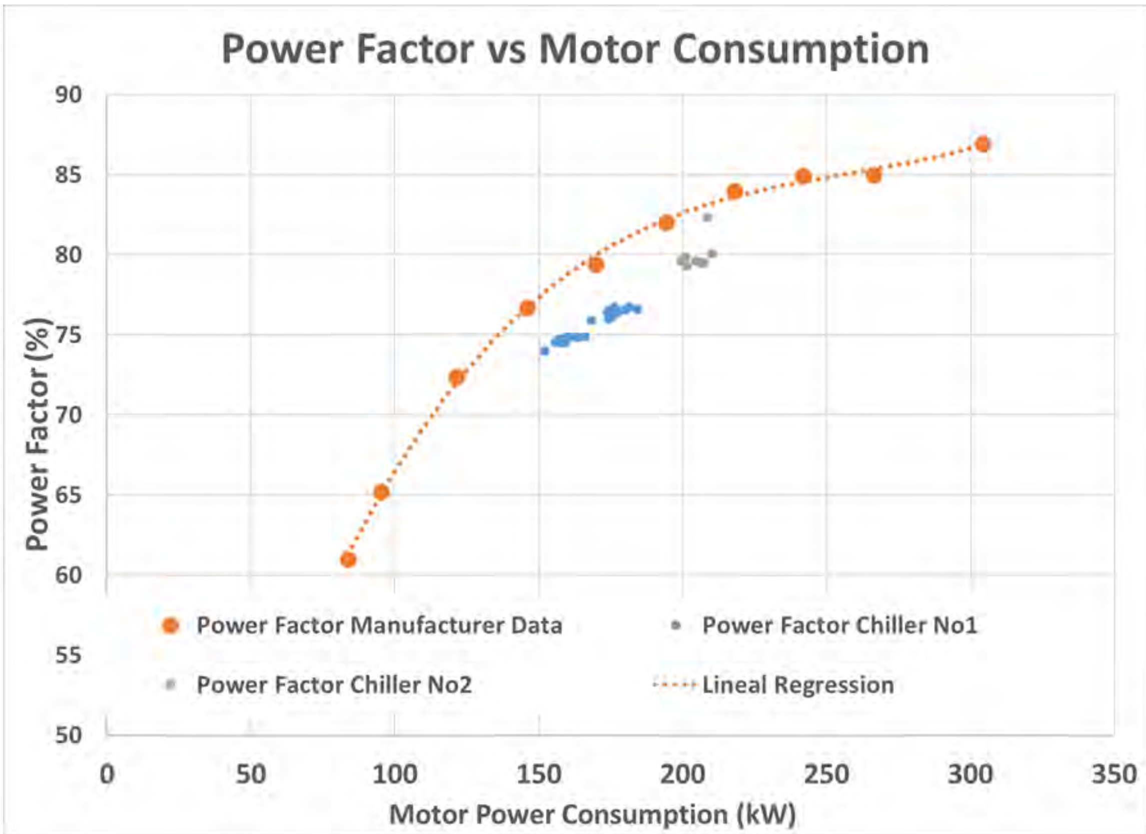
The incorporation of these elements will allow an optimization at a higher level, towards to maximise building performance throughout its lifespan with more comprehensive information.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4. APPENDIX A: INSTALLATION OF OCPE SENSORS



APPENDIX B: EFFECT OF LOW POWER FACTOR IN CHILLERS RLA



Project-host-company maintenance staff was confused by using Rated Load Amperage (RLA) in chiller 2 as an indicator of the chiller workload, this indicator had reached 80%, but the workload was not at 80% for the following reasons:

Chiller 2 is not operating in an optimum point.

Its Electric Motor is operating at a lower Power factor than the manufacturer performance conditions. This situation makes the motor consume more apparent current than it should be. In this case, when the chiller 2 reached 80% of the RLA at 79% of power factor only 62.3% is active Amperage against 65.6 % that it should be. This means the motor was loaded 3.7% less than it seems. Thus, the motor reached only 76.3% of its maximum load. As Chiller 2 is less efficient than Chiller 1 by 15%, the actual chiller load was not 80% but 71.3% when both effect are considered: Efficiency + power factor.

ABSTRACT

The Paris Agreement highlights the objective of holding the increase in the global average temperature to well below 2oC compared to pre-industrial levels, recognising that this would significantly reduce the risks and impacts of climate change. The building, which accounts for 40% of global energy consumption, represents a major opportunity to reduce greenhouse gas and combat climate change. By cohering smart technologies and energy-efficient initiatives into a building, people are enabled to raise building energy performance and enhance the sustainability of the built environment in their daily lives.

To motivate building management and users' participation in saving energy, Building Energy Management System (BEMS) can be built for turning data into actions. BEMS is formed by interfacing and integrating various control systems and legacy meters in the building and applying innovative data analytical techniques. It provides energy profile of a building which enables building management to achieve energy performance improvement through raising building users' energy awareness, analysing the energy and system data for enhancing green operations and benchmarking the energy usage for planning and prioritising energy management opportunities (EMO).

A BEMS comprises 4 core elements: (1) Energy Dashboard, for visualizing the building energy consumption and the contribution from renewable energy; (2) Energy Performance Analysis, for providing a comprehensive perspective on energy utilization and composition; (3) System Performance Analysis, for providing a holistic view on systems usage and efficiency; and (4) Benchmarking and Reporting, for measuring and verifying energy performance in accordance with ISO 50001 standards and energy audit requirements.

This Paper will illustrate how BEMS promotes green operations to actualize sustainable built environment and revitalises an existing building into a smart building. By transforming data into action, we perceive that the BEMS would contribute in developing Hong Kong into a sustainable smart city to be admired.

Keywords: energy use. energy measurement and verification, smart building

1. INSUFFICIENCY TOWARDS AN ENERGY-SAVING SOCIETY

About 90% of total electricity in Hong Kong is consumed by buildings. Through enhancement of building energy efficiency, a significant saving of electricity energy can be achieved and greenhouse gas emissions can be effectively reduced. The Buildings Energy Efficiency Ordinance (BEEO) in Hong Kong came in full operation in 2012. Different building stakeholders, including developers, building owners, occupiers, etc. should ensure key building services installations in new buildings fully comply with the energy efficiency standards of the Building Energy Code (BEC).

As at 2016, about 75% of Hong Kong's private commercial buildings have been operating for more than 15 years (Rating and Valuation Department, the Government of the Hong Kong Special Administrative Region, 2016). Therefore, initiatives in unleashing energy saving potentials of existing buildings are as important as designing a new building with energy efficient design. The revised BEEO requires the commercial buildings owners to carry out an energy audit on the key types of central building services installation every 10 years. (Electrical and Mechanical Services Department, The Government of the Hong Kong Special Administrative Region, 2012). The energy audit inevitably requires resources from building stakeholders in order to fulfil the legislative requirement, and the adoption of an effective BEMS can help them effectively carry out the energy audit and maximise the energy saving benefits.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

1.1. Lack of plan-ahead features in legacy building control systems

Building Management System (BMS) has been deployed in commercial buildings for many years for purpose of centralised monitoring and scheduled control. Power Quality Management (PQM) System is also commonly used to check and manage the stability of the electrical power supply. However, these systems focus on how to achieve the optimum value by finding the best-fit parameters and loading profile to suit the best comfort and/or efficient operations. To achieve improvement for higher achievements, stakeholders should also continuously review and respond to what they have done, including extrinsic factors beyond the hardware limitation of building installations, so that they know what they can do next for greener operations under multiple perspectives As existing buildings play a major role in electricity consumption as a whole, it is time to check what we can do better in a strategical way, achieve the most with least impact to existing operations.

1.2. Technical parameters are not transformable to business decisions

Metering facilities and mimic panels are not new technologies. But thanks to advanced metering facilities and communication networks, “smart meters” have been installed in more buildings in this decade, in which the interconnected sensor networks enable real-time central analysis and control for more efficient building operation and management. With sufficient operation data, building owners should be able to plan better than before (advancement in sensor and system level in Figure 1). However, as data representation in most BMS and PQM System are usually tailor made from a technical management perspective, that means there exists a gap between technical details and the layman understandable terms, unable to tell the subsequent steps to take. In order to mobilise stakeholders to take action, we should not underestimate the importance of common language and communication, and make use of BEMS to translate and propagate the key message to the key decision makers for establishing the directives, manage and hence push forward the green initiatives. (advancement in building level in Figure 1).

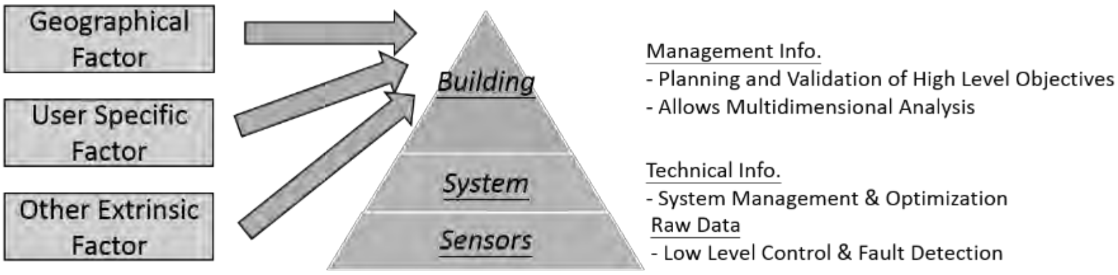

Figure 1: Hierarchy of building information collection and analysis

1.3. Hurdles to arouse and encourage public engagement

Some market barriers were identified in a previous study towards implementing energy efficient measures and some of them align with the situation in Hong Kong, including (1) misplaced incentives, (2) decision influenced by custom, (3) lack of information, etc. (Golove and Eto, 1996). For situations where residents are not billed for individual energy use, studies recommended to focus on continued awareness, education, and visualise incentives to achieving a long-term, sustainable effect, which is a matter of social-psychological domain rather than engineering discipline (McMakin, Malone, and Lundgren, 2002). In Hong Kong, the public is still focusing on the “reliability” level, and we have to move one step forward to “efficiency”. To encourage them to change, especially to visualise those indirect or intangible benefits, BEMS is helpful in providing accurate and up-to-date information, and facilitate in drafting plans and boosting incentives. Through regular review, proactively notified by energy alerts and passively by reading reports, BEMS is expected to help stakeholders to closely monitor building energy efficiency and address the barriers above.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2. ESSENTIAL FEATURES – HOW BEMS BOOST MOTIVATION

2.1 Less is more – Regrouping data to suit stakeholder capability

By adopting more smart meters in buildings, we are more accessible to the actual building performance. However, studies demonstrated that perceived information overload is associated with decreased performance. To balance the reader's satisfaction and confidence to make decisions, we need a careful dissemination of information even within the organisation (O'Reilly, 1980). Also, studies suggested that specific and challenging goals lead to higher performance than easy goals, "do your best" goals or no goals. Goal setting is likely to improve task performance when the goals are specific and sufficiently challenging, and sufficient feedback is provided to show progress in relation to the goal, rewards, supportive management, etc. (Locke et al., 1981). The adoption of push notification is also expected to reduce information the overload (Edmunds and Morris, 2000), thus should also be considered. This suggests that BEMS should avoid information overload, select only the particular information and make target that actually matters to the particular reader groups nor beyond what they can perceive to encourage for action to save energy within their capacity.

Facility owner and management are usually responsible for analysing the building energy consumption. Central facilities like air-conditioning and pumping are maintained by facility management instead of individual tenants. In the case of system ageing and malfunctions, they should take lead in recommending a more energy efficient machinery. From tenants' perspective, the focus would be narrowed down for a comparison amongst themselves. For example, if Area A consumes more electricity per floor area than Area B, the usage pattern in Area A should be reviewed. As the usage patterns among similar tenants should be comparable, the review can help find out the abnormalities and/or rooms for improvement. If geolocation factors are considered, the "aspect effect", e.g. west-facing vs. north-facing apartment, can also be determined quantitatively.

2.2 Planning by setting target and verification by benchmark

Rewards can effectively encourage energy conservation, but with rather short-lived effects, yet frequently feedback has proven its merits in previous studies (Abrahamse et al., 2005). We have discussed the importance of setting challenging but achievable targets, and it is critical for management to set targets and endorse the representatives to take action. Setting a target will be the first step to do better, and then we could move forward and discuss how BEMS can assist in selecting the most efficient option and verifying the result

No two buildings can be completely identical, geographical locations and many other factors will affect the energy consumption and usage patterns. Therefore, the best yardstick to evaluate the changes would be the building itself, using the past performance data. To further analysis the performance, we can exclude those extrinsic factors like increase in outdoor temperature, and focus on intrinsic only.

For a qualitative comparison, green building project information is available online after green building certification like using the BEAM Plus assessment tool in Hong Kong. The public can understand more about the green features and the environmental performance of their buildings through the assessment for further advancement, and recognise the effort by the building owners. (The Hong Kong Green Building Council, 2016). For end-use energy data analysis, the Hong Kong Government has developed selected energy-consuming groups in various sectors in Hong Kong since 2001. The energy utilisation indices, benchmarks and benchmarking tools are available online for information and use by the public (Electrical and Mechanical Services Department, The Government of the Hong Kong Special Administrative Region, 2016).

No matters which grading and standards are taken for comparison, it is often good for builder users to share the fact for mutual learning. Although the standards and levels of detail could be different owe to different focus and various reasons, in the era of big data, we have to believe these scattered data could finally turn into useful advice, only when we have a sufficient information gathered for analysis.

2.3 All information at a glance – energy dashboard

An effective BEMS should provide different dashboard views which suit the needs of stakeholders. In the adoption in EMSD headquarters, there is three major view developed. For example, a view for public and general tenants may focus on the overview of green features; The breakdown view by system is for central management, while the breakdown view by floor suits the tenants' representatives. The system view and floor view design another for decision makers and action takers can focus on benchmarking and trending analysis, to identify EMOs and setting targets to achieve. There will be two key ideas for the views: (1) keep it simple to understand, and (2) know the current performance against target.

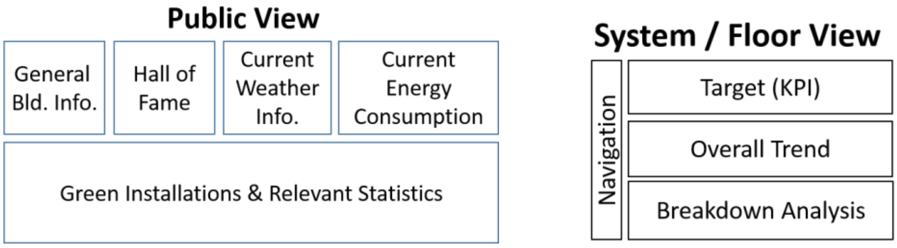

Figure 2: Different design of dashboard

To further arouse readers to get an idea how well they have done against the pre-defined target, the BEMS should provide a graphical interface with easily understandable charts to illustrate the intentions and achievements. For example, Key Performance Indicator (KPI) Gauge is introduced to visualise the target comparison rate by comparing the target and the up-to-date usage (Figure 3). The baseline used is derived from last year's electricity usage with adjustment accordance to the saving target , for example, 1% saving in the coming year, and the target is normalised in a shorter period in this implementation to further emphasise the possibility of meeting target while eliminating the fluctuation owe to daily patterns.

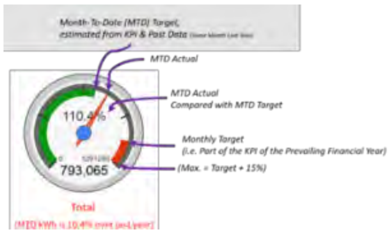

Figure 3: KPI gauge, show the target completion rate in a single chart

2.4 Take action proactively and passively – energy alerts and reports

If a system fault or abnormal energy pattern is found, a BEMS should be able to detect and provide energy alerts. The clues could be a combination of (1) Past Data (e.g. last day, last year same month, etc.) (2) Current Weather (e.g. against the pattern of same Cooling Degree Day loading) and (3) Usage patterns in different part of the building (e.g. against all west facing area of the building). The detection algorithm can be adaptive to the actual deployment, but instead of dashboard which focuses on providing a direction and overview, these alerts should be presentable to the user in a mixed "push" (system notify the user actively, e.g. by sending notification via emails) and "pull" (system allows user to filter and analyse only on the data they are interested) approach, to suit the users' dependency on BEMS.

BEEO requires an energy audit to be carried out for commercial buildings once in every 10 years, and other standards, e.g. ISO50001 can require a more frequent check. An efficient BEMS should feature an Energy Audit report functions which meet both the statutory law and ISO requirements, incorporate the general management methodology, e.g. KPI to help users easily understand the latest achievement.

Although these audits and checks are means to be conducted by registered professionals, it is still good for building management to establish the practice of internal audit as a quick check to know on the interim results towards the set targets. With smart meters' deployment and BEMS, report generation process could be fast and fully automatic. The simplicity allows a more frequent check and review, which then raise the awareness in management levels with faster and effective response based on the feedback. The report should also show and compare the data against the past performance with detail breakdown so as to identify the possible EMOs. The EMOs can be discussed in regular management review meeting, and members can define the next year's plan in order to achieve the targets, and channel the message to the frontline staff with motivation scheme for the frontline building users, so as to boost the atmosphere for executing energy saving initiatives.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. IMPLICATION AND EFFECTIVENESS – HOW WE CAN BENEFIT

3.1 Systematic review of building performance

BEMS allows building owners and users to keep track the status of the building installation, and thus enables a systematic and quantitative review for detail analysis. With the data retrieved, we could better determine if a previously conducted campaign success or not, or in what ways we could replicate the success or learn from the failure. In addition, we can focus the activity on the potential improvement areas other than simply by the try-and-error approach.

3.2 Prioritisation of energy and system retrofit and the breakeven point

It is difficult and time-consuming to save energy by a try-and-error approach, especially from a financial perspective to building owners. However, as every electrical and mechanical installation system needs regular maintenance and replacement, BEMS can serve as a tool to find out the break-even point, in which the additional cost for a replacement to more energy efficient equipment might be payback through energy cost saved.

In 2016, an energy saving campaign had been carried out in EMSD Headquarters, in which non-essential lighting at particular areas were turned off during lunch time. Comparing the figures of 2015, the light-off campaign contributes 1% of saving solely, while the overall electricity consumption decreased for 3%, which means there are other factors also leads to energy saving. The result demonstrate energy measurement and breakdown is important to verify the effectiveness of an energy saving campaign, which will be useful in planning the next campaign, while further analysis can be applied to identify the cause of additional 2% saving by categorization the usage

3.3 Execute retro-commissioning for subsequent upgrades

Retro-commissioning of energy consuming building installations can restore them to the optimum operation level after years of usage. It shows how closely the building comes to operating as intended, helps to identify improper equipment performance, what equipment or systems need to be rectified or replaced, identifying EMOs and strategies for improving the performance of various building systems. As the actual usage pattern may have shifted in comparing with the original, execute retro-commissioning will be the best fit for existing buildings. As Hong Kong Government mentioned, some EMOs are simple housekeeping practices that require little additional cost, and they can and should be undertaken today (Electrical and Mechanical Services Department, The Government of the Hong Kong Special Administrative Region, 2015), the systematic analytics provided by BEMS makes it a cost-effective option to help building owners identify and justify the suitable measures for retro-commissioning.

4. DISCUSSION AND PROJECTIONS – WHAT WE CAN DO NEXT

As BEMS can quantitatively measure the consumption data, it gives rise to a new engagement model for owners to manage their buildings.

4.1. Energy performance contract

A typical building services maintenance contract includes materials cost and labour cost for repair of malfunctioning equipment. But when we come to maintenance or repair, ones may seldom measure if the energy usage is out of the expected range or not. If we take this into accounts, we will further correlate the equipment status with the long-term support pledge. Related energy saving and contract requirements have proved to show improved operational and plant efficiency gains in several studies (Davies and Chan, 2001). Instead of simply put the fault to maintenance body if the target cannot be met, an incentive can be established to encourage the maintenance body to upkeep the equipment in good and energy efficient condition. For example, a fixed amount of remuneration can be issued if the target is meet, similar to the practice of gratuity, with an additional bonus corresponds to the saved energy cost within the contract period; in return, the cost for overshoots can be shared by both building owners and the maintenance party, to raise the awareness and motivation on both side.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4.2. From scheduled maintenance to predictive maintenance

The deployment of massive sensor network keeps tracks of energy consumption, which also serves as means to measure equipment's healthiness. Abnormal energy consumption often correlates with faulty equipment or improper energy usage pattern, analysis of sensor data gives chances to derive a new maintenance model for "predictive" maintenance. For example, the maintenance agent may alter the preventive maintenance schedule for checking the high-risk equipment with an abnormal profile at a higher frequency and priority to better align the actual practical performance. The arrangement can be actualized by adding a fixed rate for onsite inspection service when setting the contract requirement, keeping the service in higher availability with minimum contract variations.

5. CONCLUSION

There are plenty of ways in saving unwanted energy consumption, but building management requires professional advice and tools to identify what they can do and how much they can do. It is crucial to effectively motivate and enable everyone to take action, which involves ideas beyond technical know-how. BEMS serves as a platform to let everyone do their part and take action together. Data analysis do matters, but how we take actions changes the environment, every little bit of efforts count.

Telecommunications Infrastructure for High Performance Buildings

Philip TAI[a]

[a] *Swire Properties Ltd., Hong Kong SAR, philiptai@swireproperties.com*

ABSTRACT

Easy access to full range of voice, ultra-high-speed broadband Internet and terrestrial & pay TV services, and full spectrum of mobile coverage everywhere have become "must have" for high performance buildings. Security and resilience are mandatory requirements from banking, finance and high-tech sectors who cannot afford any service unavailability. This paper addresses how these needs from Tenants and visitors can be catered given limited space.

We introduce a copper Cat 5-fiber hybrid blockwiring system, supplemented with a bi-directional coax SMATV system, for delivering full range of fixed network and TV services. Choice of services, security and resilience shall be taken into account. We also propose an indoor common antenna system which supports full spectrum of mobile services, and can be expanded to include Wi-Fi and walkie-talkie systems if needed. Space requirement can be optimized with common equipment rooms, and proper interconnection arrangement (on the shared use of blockwiring, SMATV and common antenna systems) with services providers.

The remaining of this paper is organized as follows. Section 1 addresses Tenants' needs for different kind of communications services. Section 2 introduces a hybrid blockwiring and bi-directional coax backbone for wireline and TV services. Section 3 describes mobile common antenna system and Wi-Fi provision. Section 4 projects the future trends of communications services and how our proposed infrastructure can cater for future requirements. Section 5 provides a conclusion remark.

Keywords: high performance buildings, telecommunications, security and resilience

1. INTRODUCTION: TENANTS' NEEDS & CONSIDERATIONS IN TELECOMMUNICATIONS SERVICES

Telecommunications services can be categorized into wireline and wireless services, both are critical to everyone including building managers, hotel operators, tenants, visitors, occupants, shoppers as well as hotel guests.

Office tenants expect easy access to full range of (both local and international) wireline services including voice grade, ultra-high-speed data and TV services. Free choices of service providers and hassle-free services provisioning are important. Security and network redundancy are mandatory requirements of banking, finance and high-tech sectors who cannot afford any service interruption. Nowadays, almost everyone carries smart phones. Mobile coverage everywhere has already become a necessity. In addition, courtesy Wi-Fi services in main lobby, cafes/food & beverage area provides convenience to office tenants and visitors who are tablet and notebook users, and helps to create cyber community sentiment. Tenants and visitors of shopping malls expect the same telecom services provision as office tenants except network redundancy may not be critical.

Broadband Internet, terrestrial & pay TV and telephone services are must-have in residential buildings. Occupants always expect reliable services, free choice of service providers as well as quick service provisioning time. Good mobile coverage within residential flats is desirable. Coverage inside lift cars is nice-to-have but not critical. In addition, free Wi-Fi service is usually provided in residents' club house.

Telecom provision for hotels is another story. Hotel guests always expect a very user-friendly & easy-to-use telephone system with IDD services (reasonably priced), speedy broadband services (both wireline and wireless), plenty of popular satellite TV channels around the world, pay TV and video-on-demand services in their rooms. All these services shall be managed by the hotel's hospitality system for better guest experience, market analysis and billing purposes. Furthermore, comprehensive mobile coverage of all domestic mobile operators (for roaming services to visitors) and free Wi-Fi everywhere in hotel are must.

2. WIRELINE INFRASTRUCTURE

Wireline infrastructure includes fixed network, TV services and some shared facilities facilitating tenants to operate their own private networks within the building or campus.

2.1. Fixed network Services Provision

Fixed network facilities consist of 3 components: lead-in cable, equipment room (i.e. TBE room in Hong Kong terminology) and blockwiring system. Building managers shall facilitate as many fixed network operators as possible to deliver their services in their buildings for the sake of choices of services. To achieve better space utilization, building managers shall mandate share use of lead-in cable ducts, TBE rooms and telecom risers among all services providers.

Fixed network operators connect a building (i.e. their customers within the building) to their networks via their own fiber cable contained in lead-in ducts. Two different lead-in routings connecting to the TBE rooms are strongly recommended for the sake of network security and availability.

TBE room accommodates the access equipment of fixed network operators who deliver their voice, data and multi-media services to tenants. Each building shall be provisioned with at least one TBE room, for the shared use among all fixed network operators. Dual TBE room is highly recommended for office towers whose tenants demand for secure and truly resilient fixed line services. The size of TBE room(s) usually relates to the total floor area of the building, and the OFCA guidance provides a good reference on this subject.

Blockwiring system (i.e. the “last mile”), including cat 5 copper and single mode fiber cable, is usually the hindrance for fair competitions among fixed network operators. To ensure free choices of services for occupants, building managers can build and lease out their own blockwiring to all services providers with a non-discriminatory terms. In addition, dual telecom riser, a standard provision in high-end office towers, is recommended for network redundancy and resilience. Figure 1 illustrates that buildings can achieve “no single point of failure” in fixed network provision by deploying dual lead-in, dual TBE room and dual telecom riser.

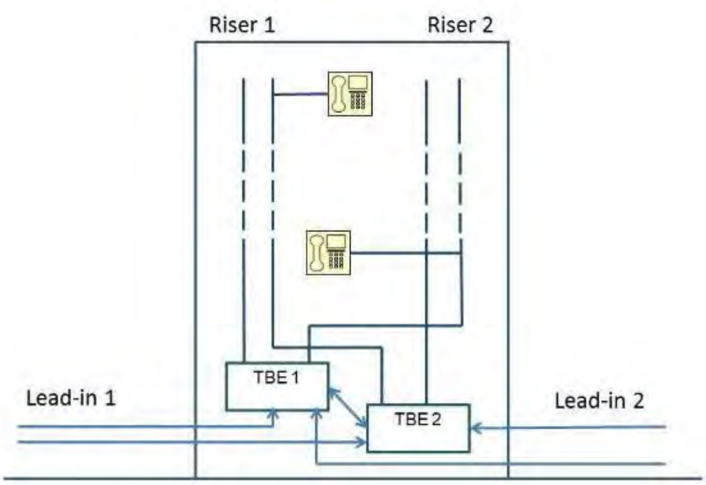

Figure 1: Fixed network provision with no single point of failure

2.2. Private connectivity solution for office tenants

Some office tenants may occupy two or more premises at different floors within a building or across buildings within a campus. They always need to build their own private network connecting up all their premises. Conventional fixed network service is an obvious solution but can be very costly. Private fiber is a cost-effective solution for these tenants who want to build their own very high speed private network connecting up two premises. Building managers can reserve a “Tenant’s Trunking” in telecom risers for the shared use of tenants who want to lay their own telecom cables across floors.

Alternatively, building managers can maintain their own fiber network within the building (and across buildings for a campus of buildings), and lease out dark fiber to tenants. This kind of private dark fiber network within a building and a campus of buildings also offers other benefits including dedicated high speed access to common facilities within the building or campus such as satellite farm (i.e. to support tenants' own satellite dishes), data centres etc. Building managers can also utilize their own fiber network for better support of their own system such as surveillance CCTV, building management systems, energy management systems, walkie-talkie etc.

2.3. SMATV System

Coaxial cable based SMATV system is another basic infrastructure in every building. It consists of terrestrial TV antenna, satellite dishes, headend (i.e. receivers and combiner) and a tree-like coax distribution network. In Hong Kong, OFCA has specified a bi-directional coaxial cable based backbone system, which supports reception of various TV services such as terrestrial TV (including both analog and digital), satellite TV and cable TV (HFC based) services, and broadband Internet services (cable modem based).

For a campus of buildings, a single SMATV system with a centralized communal TV antenna and satellite reception dish, as shown in Figure 2, is desirable. Individual buildings are provisioned with a coaxial backbone, which connects to the headend via single mode fiber. Cable and pay TV operators can deliver their services to the whole campus by interconnecting to the headend. This communal system approach minimizes space requirement as only one set of headend in a single equipment room plus one set of satellite dishes is needed for serving the whole campus.

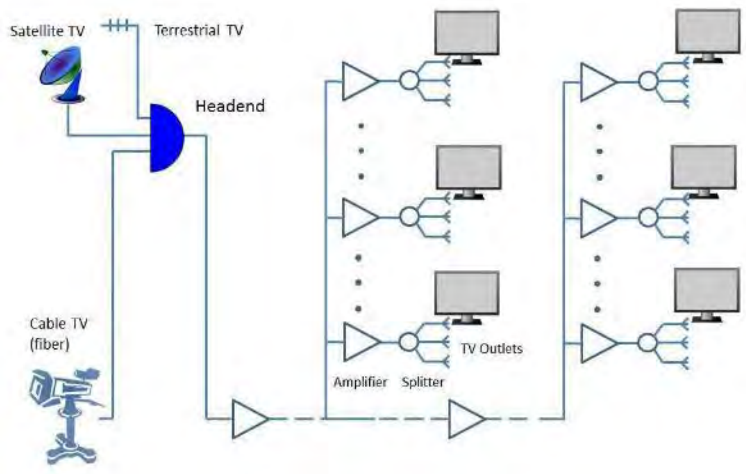

Figure 2: Communal SMATV system

3. WIRELESS INFRASTRUCTURE

Public mobile communications, including voice and data, has become a necessity for everyone nowadays. Wi-Fi services, which can be operated by either service providers or building managers, is considered as a supplementary wireless services to mobile services.

3.1. Mobile communications

One challenge for building owners is to facilitate tenants and visitors to enjoy full range of mobile services (i.e. 2G, 3G & 4G) and free choices of services from all mobile operators given limited space.

Common antenna system is the only solution for this challenge. A tree topology, as shown in Figure 3, consisting of a point-of-interconnect (i.e. combiner) and a mobile backbone with horizontal cables extending mobile overage in each floor, is adopted. All the joining mobile operators shall install their own base station equipment inside the Common Mobile Equipment Room and connect to the common antenna system via the point-of-interconnect. Dual cable design is usually adopted for the sake of maximized system capacity i.e. the quantity of mobile networks to be connected to the common system.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

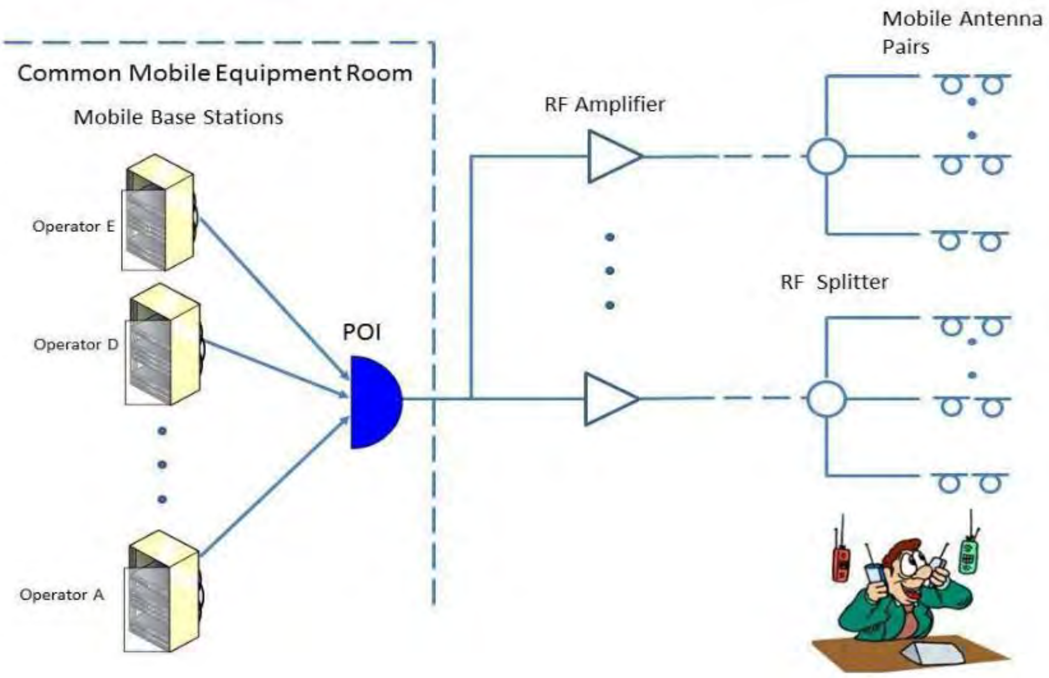

Figure 3: Mobile common antenna system

Indoor mobile antenna is the most common and cost-effective transmission element. Leaky coax is another option of providing mobile coverage particularly for indoor or confined area (e.g. tunnels) with very limited space but it is more costly. To provide mobile coverage inside lift cars, mobile antenna can be installed inside lift cars and connects to the mobile backbone with a travelling cable. Alternatively, mobile coverage inside lift cars can be achieved by installing small panel antennae along the lift shaft and a mobile repeater covering lift cars.

Wi-Fi signal can also be transmitted through mobile common antenna system. The biggest advantage of this approach is capital cost saving, and can be adopted in hotels and shopping malls where guests and shoppers expect comprehensive mobile and Wi-Fi coverage within the whole premise.

3.2. Wi-Fi

Wi-Fi services, being a “must have” facility in most buildings, allows handheld devices to connect to Internet and virtual private network (VPN) via a wireless local area network (LAN), mainly using the 2.4GHz and 5GHz radio bands. The current Wi-Fi, confirming to the IEEE802.11ac standard, can supports data speed up to 1,300 Mb/s. Wi-Fi services can be offered via hot spots within around 100m from wireless router(s) owned by the establishment. Hot spots are common in airports, libraries, coffee shops and beverage outlets. Another approach is comprehensive Wi-Fi coverage which is common in shopping malls and hotels who want to provide high quality services to their visitors and guests. Normally, users must connect manually to Wi-Fi services by checking the Wi-Fi connection option, selecting the correct network (i.e. the SSID), and entering authentication information, usually a simple password. Most shopping malls encourage visitors to register as a member of the shopping mall so that they can enjoy free Wi-Fi services in the mall.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

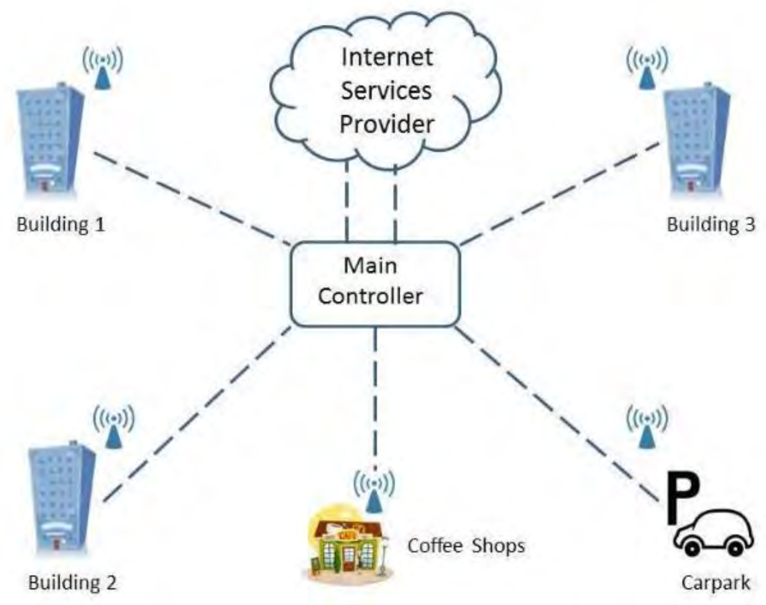

Figure 4: Campus-wide Wi-Fi system

Wi-Fi services can be offered by either telecom service providers or building mangers. Operating a self-own Wi-Fi system brings the following benefits to building managers.

- Courtesy Wi-Fi services which is a great convenience to visitors particularly tourists or foreign visitors
- Better understanding on visitors/guests behaviour in terms of usage pattern, footfall etc. (more precise marketing analysis is possible when combined with visitors and guests profile data)
- Wireless data connections for all activities in Atrium or public hall area
- Wireless data connections for building facilities or systems (which eliminates the needs of cable laying and related builder work and cable containment)

4. FUTURE OUTLOOK

The fifth generation (5G) mobile and Hotspot 2.0 are emerging new wireless technologies which aim to enhance user experience in terms of speed and connectivity.

4.1. 5G Mobile

5G mobile, operating in the 5GHz band, is the next generation mobile services which shall support higher data speeds (i.e. up to 1 Gb/s or 100 times of the current 4G mobile) and larger network capacity. The market expects the first 5G mobile services to be commercially available after 2020. We anticipate that tenants and visitors will expect indoor 5G mobile coverage when new 5G mobile handsets and devices come into market.

The dual-cable common antenna system as described in section 3.1 has already catered for future expansion for 5G mobile support without the needs for substantial cable alternation or installation work. The upgrade work shall include replacement of point-of-interconnect, antennae and RF components (such as fiber amplifiers, splitters, couplers etc.) by wideband ones supporting 900MHz to 5GHz. Additional antenna points and/or fiber amplifiers may be needed as 5G mobile signal propagates at shorter range than 4G/3G signals. We need to identify some equipment space in the common mobile equipment room for additional 5G base station equipment. Mobile equipment has reduced their physical size due to rapid advancement in semi-conductor technology, and thus extra space in common equipment room may not be critical. The biggest challenge of 5G upgrade is probably agreeing outage windows with tenants for the replacement of mobile antennae/splitters/couplers inside tenant premises. Opening and re-instatement of tenants' false ceiling will be involved. The upgrade work can be delayed due to the difficulties in convincing tenants to allow for the replacement and associated false ceiling work.

4.2. Hotspot 2.0 (IEEE802.11u)

Hotspot 2.0 (HS 2.0), also called Wi-Fi Certified Passpoint, is a new standard for public-access Wi-Fi that enables seamless roaming among Wi-Fi networks and between Wi-Fi and mobile networks. HS 2.0 was developed by the Wi-Fi Alliance and Wireless Broadband Association to enable seamless hand-off of traffic without requiring additional user logon and authentication.

The HS 2.0 specification, introduced in 2012, is based on a set of protocols called 802.11u, which facilitates cellular-like roaming, increased bandwidth, and service on demand for wireless-equipped devices in general. When a subscriber's 802.11u-capable device is in range of at least one Wi-Fi network, the device automatically selects a network and connects to it. Network discovery, registration, provisioning, and access processes are automated, so that the user does not have to go through them manually in order to connect and stay connected.

Major objective of HS 2.0 is to support automated roaming between HS 2.0 certified Wi-Fi networks so that users, once connected to a Wi-Fi network or even mobile network, can enjoy seamless connection to Internet when they travel from place to place. Traffic offload for mobile operators is possible with HS 2.0 and can become a potential revenue stream which is a partial subsidy for venue owners who operate their own Wi-Fi services.

5. CONCLUSION

We have introduced the fiber-cat 5 cable based fixed network infrastructure and mobile common antenna system/Wi-Fi system which can support full range of fixed network and wireless services nowadays as well as choices of services and network resiliency. In addition, our proposed dual-cable mobile common antenna system can be upgraded easily to support future 5G mobile without major rewiring work.

ABSTRACT

During the 21st session of the Conference of the Parties (COP21) in Paris, 177 countries agreed on reducing their greenhouse gas emissions. The COP21 is just the start of a long path towards sustainable development. The next step is to identify and implement projects to efficiently increase energy performance in industrial, commercial and residential processes. This paper describes how big data analytics and continuous building monitoring are used to reduce the capital cost and implementation time of energy projects, while increasing the ROI of facility's sustainable performance: higher comfort at lower or lowest footprint.

This paper examines how the Energy Efficiency industry is changing and how these changes can help project formulation and make implementation easier and less risky for investors and decision makers. This paper will use a real-world success case of a Deep Building Renovation (technological upgrade in control and monitoring system) project to describe how data analytics led to a reduction in capital cost and implementation time while improving project return and overall success. It examines continuous monitoring enabled energy waste identification along with saving verification, and how these two technologies worked together to overcome typical sustainable project barriers.

The paper will explain:

- The key factors for success in Deep Building Renovation projects:
  - Change Management: Cultural change and training.
  - Quality of the Solution: The most efficient hardware / software architecture for both Cloud-base continuous monitoring systems and local-server oriented facilities
- The streamlined roadmap that guarantees the highest ROI.
- Operational tangible benefits:
  - Maintenance management
  - Energy efficiency
  - Compliance and verification

Keywords: high-performance building, smart building, deep building renovation

1. INTRODUCTION

While it is widely known that sustainable development is the only sound and viable pathway for humankind's future, its attainment remains elusive despite intensive efforts and some successes. The current industrial society approach, based on product and process innovation in a variety of fields, is not providing the expected results in addressing this important issue (Morioka, 2006). There have been various studies regarding improvement on the efficiency of several industrial, commercial and residential processes and technologies but a few in Energy-Efficiency industry itself.

The Energy Efficiency industry, as other industries, has been highly impacted by IT development, making industry processes cheaper and less time demanding. As a technological field highly dependent on exact science (such as Mathematics, Physics and Thermodynamics), the automation of its process it has been possible thanks to advances in data storage, telecommunications and computing. Behind are the days when it was necessary to manually collect large amounts of data, which might not make sense due to lack of synchronization, unstable processes or simply uncalibrated instruments, or could not be identified because data was insufficient for trend analysis or inadequate instruments to crosscheck the accuracy of the in-field readings.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Those early days were very hard for energy professionals who had to fight with several challenges: a new field of study, lack of literature, unreliable instruments, manual work for data gathering and computing, cost-efficient technology, etc.

Fortunately, those days are gone and technology has advanced, allowing a streamlined process for energy audit and project formulation. Energy efficiency is a proper study field and many universities around the world offer degrees for professional careers. Today data collection is very easy and the analysis is done instantaneously via servers connected to internet providing information that allows industrial, commercial and residential processes to be analysed by hour, minute, second, or even before problems occur.

This paper describes a real-world project that used big data analytics and continuous monitoring to identify, define and implement energy efficiency improvements in order to increase building performance and sustain this performance for the long run. These technologies also allowed a fast and reliable project formulation and made implementation more cost-efficient and less risky for investors and decision makers.

The main objective of this article is to describe the evolution of the energy efficiency industry pillars (tools, process and people) key factors for success in this Deep Building Renovation project, and the streamlined roadmap that guarantees the highest ROI.

The project was executed by an international energy efficiency services company with an Asia regional office in Macau and headquartered in Utah, USA. The project-host company is a healthcare products manufacturer located in Singapore. The main objective of the project was to increase building HVAC system efficiency, thus reducing environmental impacts and the operational cost. This project is also a real-world success case of a Deep Building Renovation (technological upgrade in control and monitoring system) that describes how data analytics led to a reduction in capital cost and implementation time with improved project return and overall success. It examines how continuous monitoring enabled energy waste identification along with saving verification, and how these two technologies worked together to overcome typical sustainable project barriers.

1.1 Evolution of energy-efficiency tools

Energy efficiency diagnostic tools have advanced significantly in past 50 years, passing from fully-manual to online-automatic based approach. This huge leap has brought cost and time reduction to energy efficiency process, especially savings identification, quantification and verification. And with this, the project capital cost has been reduced, as well as the associated risk.

The newest monitoring and analytics technology allows energy professionals to identify and evaluate energy efficiency opportunities in existing buildings by analyzing trends of different variables in systems such as: air conditioning, heating, ventilation, lighting, etc. This type of study can be executed on-site or remotely via an internet connection. As a result, projects no longer require an energy professional's physical presence for data collection or monitoring. This has brought two direct benefits: lower cost and implementation time.

The technology brought new challenges, as large amounts of data need to be processed, requiring more complex algorithms, software and data storage. Fortunately, the Internet offered a solution, cloud data storage and processing. This implies the following benefits:

- Lower capital investment: local server data storage is no longer required
- Lower operating cost: cloud services are significantly cheaper than in-situ data centres
- Higher flexibility: cloud data storage can be contracted monthly with long term contracts not required.
- Less administration: Software as a Service (SaaS) model can be deployed by specialized energy efficiency companies.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

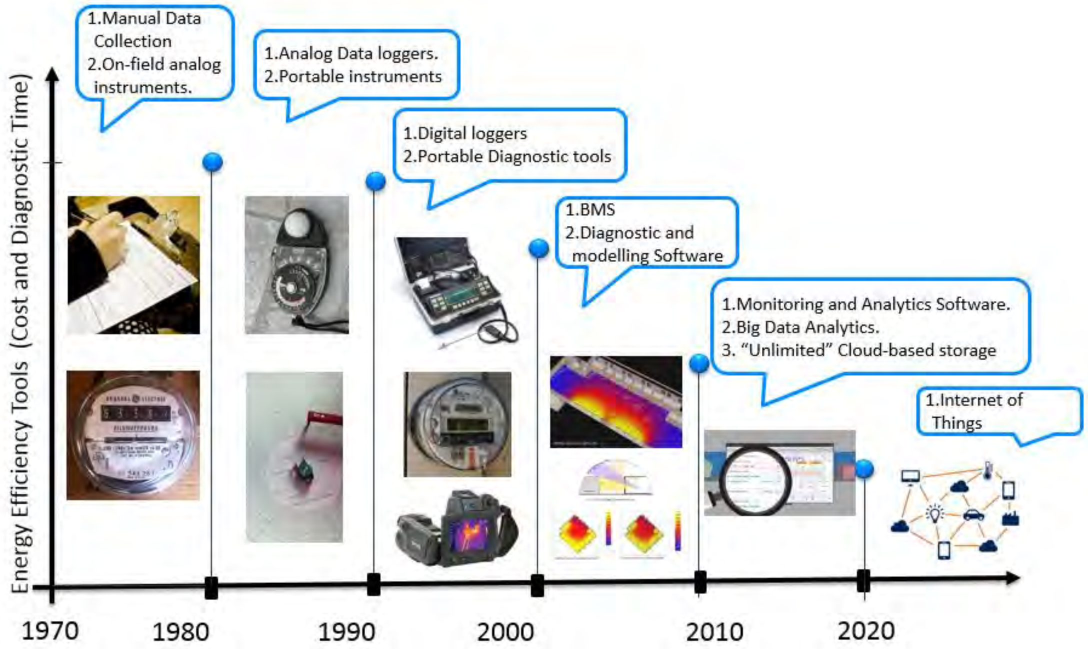

Figure 1: Evolution of energy-efficiency tools

1.2 Evolution of energy efficiency industry pillars

A project manager increases the probability of a project successfully meeting its business objectives by applying the most effective combination of people, process, and tools to solve the problem and providing the essential leadership to guide the project in the right direction for it to be successful, (Cobb 2016).

It is necessary to review the evolution of the other two pillars, as not all the advances have been developed on the tools side, there has also been progress in the energy efficiency study field (process pillar) itself. In this sense, a large and robust knowledge base has been developed with proven best practices in several energy systems. These best practices are not only improvements to energy systems, but also enhancement to the process of how energy savings calculations are made. This, of course, facilitates the work of the energy efficiency professionals and technicians.

Similar to process and tools, the third pillar (people) has become an important component of the energy efficiency industry. Energy managers are now a very common position in different industries such health care, commercial building, and large hotels, etc. From an academic point of view, it is now possible to find master and doctoral degrees in energy efficiency. The increase in the number of professional certifications offered has allowed for industry growth in commercial and public institutions around the world.

When these three pillars (people, process and tools) of the project development converge, the factors for a successful energy-efficiency project can be deployed, the key factors that were identified in this paper case study were: Change Management and Quality of the Solution.

2. PROJECT METHODOLOGY CHANGES

The advances in data monitoring and analysis have impacted the development of energy efficiency projects in a positive way. With the recent advances in energy efficiency tools, large amounts of data are processed and converted into valuable information which reduce uncertainties which affect project risk and cost. The result is a streamlined roadmap.

This is explained by to the following:

First, traditional project methodology is based on a manual data collection, a limited knowledge base and less specialized human resources. As a result, the learning curve to understand the system takes longer in comparison to the new approach. The streamlined roadmap is simplified version of the traditional one.

Second, traditional data collection with multivariable analysis was difficult to perform. With a streamlined road map, data collection is a continuous process, multiple variables are recorded at the same time, making it easy to find correlations, especially with help of computational tools.

Third, data collection records different conditions and scenarios of the process. The decision-making process is based on robust and diverse scenario analysis which reduce the risk of investing in an energy saving opportunity that is a result of a data-driven analysis rather than a pure deterministic study as the traditional approach was.

The Figure 2 shows how the project development path has been simplified.

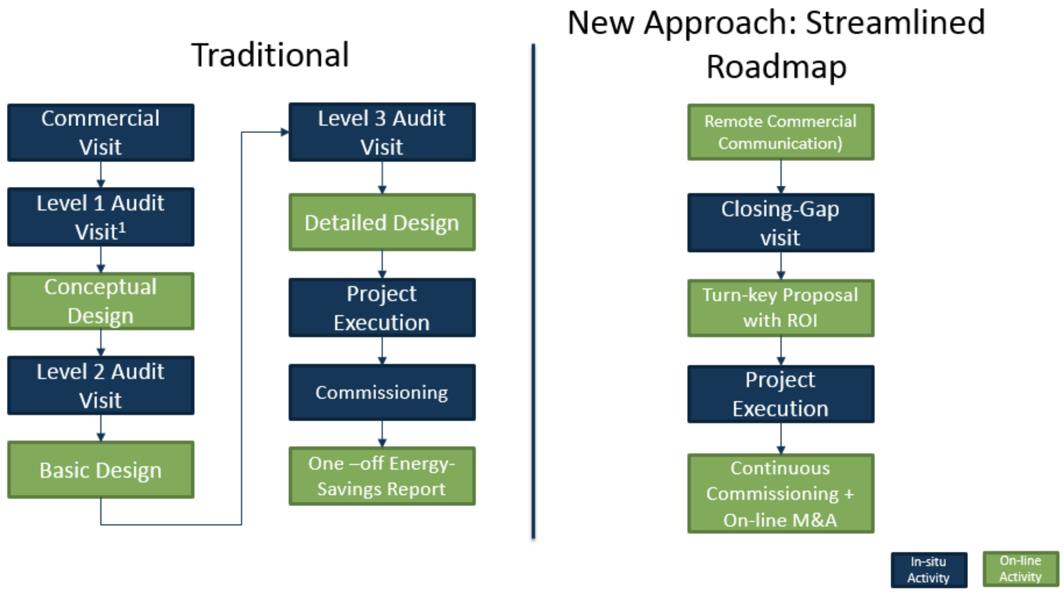

Figure 2: How traditional project methodology has changed

3. PROJECT DESCRIPTION

This paper uses a real-world success case of a Deep Building Renovation (technological upgrade in control and monitoring system) project which was developed from 2014 to 2016.

The project-host company is located in Singapore while the energy consulting company (contractor) is located in Macau SAR, China with headquarters in UTAH, US. Singapore-based contractors also participated in the project development.

The project-host company is dedicated to manufacture and commercialize health care products which production processes require controlled air conditions for temperature, humidity, pressure and cleanliness. Therefore, the HVAC system is a fundamental element in the building where production occurs. The scope of the project included production buildings, administrative offices and other facilities where air conditioning is required.

The air conditioning system is composed of a central chiller plant (ChP) a chilled-water distribution system and 70 air handler units (AHUs). The Table 1 shows the main characteristics of this system.

Chillers Power Peak Demand	Served Area	Peak Cooling Demand
Kilo Watts	Square Meters	Refrigeration Tons
1146	Production – 14,600	2,000
	Office – 5,900	
	20,500	

Table 1: Basic description of the HVAC system

3.1 Project Scope

The project scope was to identify, select, define and implement energy-saving improvements to the HVAC system by designing a monitoring and analytics platform that provided the right data to drive the system optimization. Project-tasks breakdown included the following:

- Monitoring hardware, installation and Integration
  - Furnishing and installation of electric sub-meters
  - Network hardware
  - Integration Hardware
  - Data Integration
- Analytics software programming and integration
  - Monitoring and Analytics (M&A) software license
  - Analytics software programming
  - System mapping, classification and investigation
  - Development and installation of customized analytics software
  - Findings summary
- Implementation of recommended measures
  - Control Logic changes
  - Hardware refurbishment were required
  - Measurement and Verification
- On-going M&A maintenance
  - Software updates
  - Configuration Management

3.2 Monitoring and analytics platform

The project deployed a M&A platform (platform is the combined infrastructure of hardware, software, telecommunication, internet, cloud service, and human support) which allowed identification and visualization of energy-efficiency opportunities via trend analysis and sequence of operation rules. When the M&A application detects an energy efficiency opportunity, it creates a notification called a "Spark" and visualize the problem by send an email or text message with the relevant information required to fix the problem in the HVAC system. Some examples of these rules as follows:

AHU - Supply Temperature Not Met: Identifies when supply air temperature consistently does not match the set point. This is an indication of energy waste due to either over heating or cooling, as well as lack of comfort.

Boiler & Chiller Cycling: Detects when the boiler or chiller status is cycling on and off, and determine equipment status by preferencing points.

AHU - Valve Leak: Measures entering and leaving temperature from each coil individually, taking advantage of any temp sensors available and accommodating for different AHU designs.

Flow Through Offline Equipment: Detects flow through offline equipment have been deployed. This is measured by the temperature drop through equipment that is off, with support for temperature preferencing. These have been deployed on chiller plant equipment.

The project deployed the following rules for AHUs and TUs:

AHU - 100 rules

Terminal Units – 40 rules

However, the M&A application has rules for the following systems as well:

Boilers – 30 rules

Chiller – 50 rules

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Meters – 10 rules

Pumps – 5 rules

3.3 Project results in energy-efficiency

The project-host maintenance staff is using the Sparks to increase the efficiency of the HVAC. Figure 3 is an example of the Spark: “Supply AHU Temperature Not Met”.

Figure 3: Issue detected by M&A application.

In this case, further investigation on the AHU identified a problem with the actuator that operates the chilled water valve. The valve was kept always open even though the controller commanded it to close. As expected, the fix of this issue led to save energy as chilled water started to be properly supplied.

This project successfully implemented changes in control and corrected equipment deficiencies that saved 152 kW power demand and 1,331,520 kWh/year of consumption, which represents $170,340 (USD) per year in operating cost saving. The optimization of AHU workloads led to a reduction in chiller load by 10%.

With these actual benefits, the project pay-back period is 1.8 years, only considering tangible and measurable energy-saving benefits and based on an electricity tariff of 0.128 USD/kWh. If other maintenance and operational benefits are included (such as: releasing chiller capacity and electrical infrastructure), then the pay-pack period would be less than one year. In some companies, it is difficult to include in financial analysis of benefits that are not supported by a meter. The decision-making process is very critical for company success, thus a well-defined process, such as TCA , is recommended in order to include those benefits that are not easily measurable (Navarro, 2012).

Additionally, significant effort was made to document and clarify equipment inconsistencies and gain vision for future improvement.

3.4 Project results in maintenance management

Although most of the Spark algorithms are oriented to identify energy-efficiency opportunities or issues, they also identify equipment failures due to the close relationship between equipment performance and efficiency. For instance, the Spark for AHU - Valve Leak is intended to save energy (a leaking valve might allow cooling in a room that is not required, therefore wasting energy).

At the same time, the Spark also detects a maintenance issue since the leak may get worse. The AHU may become inoperable which or more expensive to repair. Even worse, the leakage may lead to a catastrophic damage if the AHU is part of a critical air conditioning system such a gateway or data centre where moisture level has low tolerance.

The M&A application has led to significant benefits in maintenance management and equipment reliability. Using the M&A application, the maintenance staff is able to schedule work in advance in a way that has moved HVAC system maintenance from corrective to predictive as equipment failures can be identified in an early stage.

Furthermore, given the historical data storage, some maintenance teams have been able to conduct root cause analysis and highlight common issues in some types of equipment, such as valve models with design defects or those not appropriate for the application where installed.

3.5 Key factors for a successful energy-efficiency project

This paper case study identified the following key factors for a successful energy efficiency project:

Change Management

An energy-efficiency project is not only the deployment of a new technology; it is a profound change in the organization where the technology is being deployed. A well-managed project deploys a change management approach in order to facilitate the knowledge transfer.

From client company to contractor/ consultant, thus the contractor captures the right information at the right time, mainly during the steps of energy saving measure identification, business case development, design review, build and commissioning, amount others.

From the contractor/ consultant to client company, the technology is well-understood in a way that the users are able to:

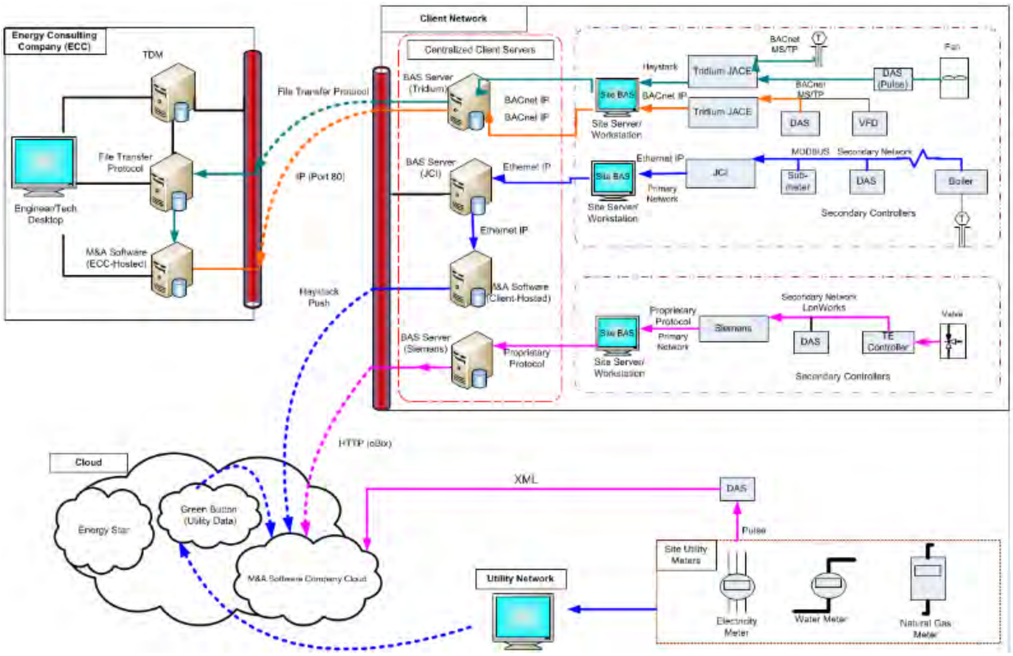
- Utilize the technology to realize the benefits as per the business case
- See how these benefits impact both the client company goals and themselves

Quality of the Solution

As M&A infrastructure is integrated into the existing hardware and software, it is critical to define the minimum software and hardware requirements to guarantee a low-cost solution that will be able to paid via energy savings. At the same time, the solution must be high quality with flexibility (able to connect to different protocols) and scalability for future expansions. Appendix A shows the different options for data transfer to a M&A platform.

4. APPENDIX A: DATA TRANSFER OPTIONS FOR A M&A PLATFORM

There are different options to connect a M&A system, the following diagram shows four proven ways of doing it. The efficiency and suitability of each option depend on each case based on: IT landscape, cybersecurity policies, cost, among others.



Option 1 (Teal ---):

- Meter pulse data acquisition device (DAS) to Site BAS.
- Primary Controllers transfer data to centralized BAS server

- Centralized BAS server transfers data by file transfer protocol (FTP) to M&A Software server (Energy Consultant-Hosted).

Option 2 (Orange ---):

- Meter secondary controllers and transfer data to primary controllers
- Primary Controllers transfer data to centralized BAS server
- Centralized BAS server transfers data to M&A Software (Cloud)

Option 3 (Pink ---):

- Pulse data acquisition from utility meter to M&A Software (Cloud)
- Primary Controllers transfer data to centralized BAS server
- Centralized BAS server transfers data to M&A Software (Cloud)

Option 4 (Blue ---):

- Meter secondary controllers and transfer data to primary controllers
- Primary Controllers transfer data to centralized BAS server
- Centralized BAS server transfers data to M&A Software (Cloud)
- Green Button transfers data to M&A Software (Cloud)

Vertical Farm: Integrating Multifunctional Microalgae Cultivation into the Sustainable Built Environment

LEE Tzan-chain[a]

[a] *Biodiversity Research Center, Academia Sinica, Taiwan, crane173@yahoo.com.tw*

ABSTRACT

The world's first algae-powered has been built in Hamburg, Germany. In the building, microalgae are cultivated in the glass elements that make up its "bio skin". Microalgae are sustainable energy source for biofuel production that can transfer solar energy to chemical energy by photosynthesis. Microalgae are known to exhibit 20-fold higher biomass production than agricultural crop plants. Microalgae can culture in glucose-contained culture medium in dark condition, it is similar fermentation culture and produce many commercial products, e.g. DHA, lutein, biodiesel and biomedical compound.

In this article, I would like to share an idea about "How to design a microalgae-powered sustainable building that can utilize microalgae more efficiency", including increase biomass of microalgae in light-culture condition, and produce commercial products in high cell-density culture in dark-culture condition. This idea might help microalgae sustainable building will be become a multifunctional building.

Keywords: microalgae, renewable energy, commercial products

1. INTRODUCTION

1.1 BIQ House--- The world's first algae-powered building

There are many sustainable building using biomaterials, e. g. plants and microalgae, to decorate or integrate into building structure. Microalgae cultivation is a photosynthetically driven system applied to architectural integration in last three years. BIQ house (building in Hamburg Germany; Image 1) project is completed in April 2013. In the building, microalgae are cultivated in the glass elements that make up its "bio skin". These bioreactors are used to produce energy, can also control light and provide shade.

Figure 1: The BIQ is setting new standards as the first building in the world to have a bioreactor façade. Microalgae are cultivated in the glass elements that make up its "bio skin"

1.2 Utilization of algae

Microalgae and plants are renewable energy source which can transfer solar energy to chemical energy by photosynthesis. They can capture and consume CO2 to produces many compounds, including oxygen, glucose, oil and other organic compounds in light culture condition. Algae have efficient conversion of solar energy to biomass and electricity (20-fold higher biomass production than agricultural crop plants). However, the cell densities can't higher than 66g L−1 in light culture condition. On the other hand, fermentation culture can significantly increase the culture density of microalgae (>100g L−1). Until now, there are some kinds of microalgae can use fermentation culture condition for a long time by supplied carbon source (e.g. glucose, acetic acid and glycerol), without light irradiation. In the culture condition, algae would be change their biochemical pathway, and can be use in waste water clearance, or produce high-value products: biodiesels, antioxidants, bioplastics, pigments, cosmetics compounds, etc. (Figure 2). Thus, it is important to increasing production efficiency of energy and foods.

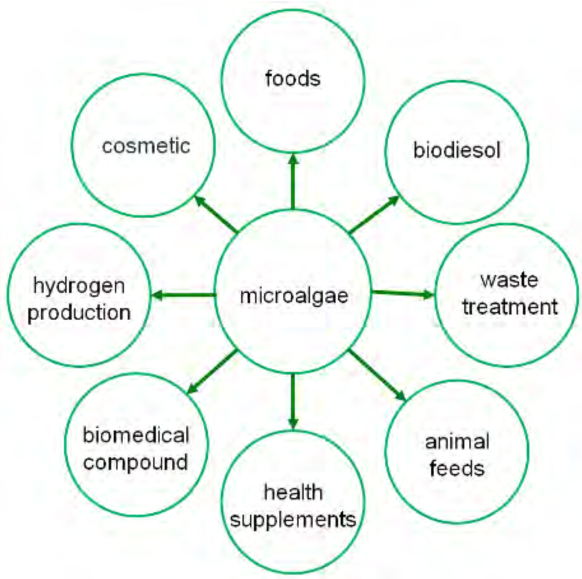

Figure 2: Microalgae are multifunctional organisms, as a powerful tool for the production of commercial biomolecules

1.3 Change culture conditions can modify physiological state and increase productive efficiency of the final products

Beside photosynthesis, algae can change their physiological characteristic with different culture conditions. For example, heat and light stress can increase antioxidants production. Haematococcus pluvialis can synthesis and accumulated astaxanthin when cells under conditions of cellular stress [4]. Many alga cells can synthesis GABA (γ-Aminobutyric acid), DHA and EPA in fermentation culture. In the article, I only share an opinion about how to use different culture conditions to increase the economic efficiency of microalgae to integrate into the sustainable built environment, but not showed experimental data.

Algae are photoautotropic organisms that carry out photosynthesis for maintain their life. However, the production of high-value products from microalgae using fermentation culture in the dark (heterotrophic production) has very successful to date. The final products were very different in two culture conditions, and these two conditions can be continued to recalculate. The characteristic of this two culture conditions as shown in below.

	Light condition	Dark condition
Energy pathways	Autotrophic	Heterotrophic (fermentation)
Carbon source	CO_2	Sugars (including glucose)
Growth rate	Fast	Slow
Cost	Low	High
Final products	O_2, H_2, glucose, and antioxydants.	CO_2, health supplements, biodiesol, biomedical compound.

Generally speaking, microalgae culture in light condition in glass elements. In the culture condition, algae can fix CO2 and utilize inorganic nutrition media. It would be growth fast during log phase and slow down the rate until stationary phase. In my suggestion, during stationary phase, collect 90-95% volume of the algae suspension medium as fermentation materials. The fermentation materials can influx into inorganic nutrition media and add sugars as carbon source. It is very important that fermentation culture must keep the concentration of nutrition media (the same with light culture) and sugar (1.5~0.8% w/v). Fermentation culture without light irradiation, and can maintain high culture density of microalgae. On the other hand, microalgae cells would be recovered to the log phase after add new inorganic nutrition medium into the glass elements.

Microalgae can storage glucose as starch in light culture condition. In dark condition, microalgae can hydrolysis starch to glucose during fermentation process and the added sugars can be transfer to highly productive, in terms of biomedical compound, oil (e. g. EPA and DHA), and CO2. Beside CO2 can be reused in light culture, the economics are greatly improved when considering the high amount of product on a per liter basis (high titer). The production cycles, and the high productivities are not attainable with autotrophic algae (culture in light condition).

As shown in Figure 3, the light-dark recirculate culture can enhance the economic values of microalgae-powered building.

Figure 3: A model system for light-dark recirculate culture

Grid Connected Photovoltaic System Potentials and Performance in 4 University Campuses

Chanikarn YIMPRAYOON[a]

[a] *Faculty of Architecture, Kasetsart University, Thailand, arccks@ku.ac.th*

ABSTRACT

Photovoltaic (PV) system installation has grown exponentially in the last few years because of growing concerns about the environmental impacts from fossil fuel and nuclear energy. Solar energy is abundant, especially in locations near the Equator. Grid-connected PV system prices are also decreasing, so many projects found it was affordable. Using renewable energy is also a key a project can use to demonstrate commitment to sustainable development. A common problem in Thailand in promoting the use of grid-connected PV systems is the unpredictable incentive program from the government and the lack of confidence in the system with a few demonstration case studies. Universities as educational institutes could be pioneers in successful large installation demonstration projects.

Kasetsart University is the largest public university in Thailand with four teaching campuses across the country and several research stations, mostly in agricultural fields. This study aimed to evaluate the potential of each campus in accommodating rooftop PV. The results demonstrate the maximum PV installation potential of each campus, as well as the specific installation location for each building, the predicted annual electricity production, and the feasibility of the installation. However, more incentive programs or the integration of PV systems into building envelopes could make the investment return more favourable. The results could help other similar university campuses evaluate their potential, moving toward self-sustainable energy production as demonstration projects in the communities are successful, and encourage more PV installation in the country.

Keywords: grid-connected photovoltaic system, sustainable neighbourhood, green university

1. INTRODUCTION

Thailand imported more than 80% of its fuel from outside the country—mostly crude oil and natural gas—resulting in country energy insecurity. The country actually has a lot of sunlight due to its location at 14°N of the Equator. Despite the monsoon seasons and frequently overcast sky, the average solar energy received per day is approximately 5 kWh (Department of Energy Development and Efficiency and Department of Physics, 1999) which is high, compared with other leading countries in photovoltaic (PV) installation. PV systems have a very low environmental impact compared to other sources of energy for electricity production, especially fossil fuels. PV systems can be easily installed on building rooftops without the need for land. Its modulation characteristic makes the system size and shape flexible. Solar energy has the highest capacity compared to other energy sources: it is free, unlimited, and available everywhere. When the system is in operation, there is no noise, no pollution, and it requires very low maintenance.

Electricity peak demand in Thailand occurs during the day, especially in the afternoon in summer when the temperature is high from strong solar radiation resulting in heavy use of air conditioning systems. At the same time, solar energy is the primary source of PV electric generation. The amount of electricity generated from PV has a strong correlation to the electricity peak demand. PV has high potential to be used for peak load mitigation during heavy electricity demand periods. Many studies have demonstrated that PV systems could help reduce grid peak load stresses (Perez and Collins, 2004, Perez et al., 2004, Perez et al., 2009).

Institutional buildings such as those in university campuses or commercial building complexes have plenty of unused rooftop area free of shading. These available areas can be used for green roof, collecting rain water, or installing PV systems that can provide electricity both for the buildings and to help relieve grid stress due to peak demand (Yimprayoon and Navvab, 2011).

UI Green Metric, the green university ranking initiated by the Universitas Indonesia in 2010, assigned the highest score proportion to the energy category in all of the rating versions. The latest version, 2016, has increased the score related to renewable energy from 3/100 to 5/100 which emphasized the importance of renewable energy

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

awareness in this building type. Kasetsart University was ranked number one in Thailand for the UI Green Metric in 2011, the rating inception year. The university has continued to participate in the ranking process since then. However, renewable energy is not yet implemented much because of the lack of information and the lack of confidence in such a technology. This study demonstrates the potential of Kasetsart University's four campuses for implementing PV systems on their building rooftops in a tropical climate, thus increasing the university's UI Green Metric score and encouraging similar projects for more PV installation.

2. KASETSART UNIVERSITY

Originally an agricultural based educational institute, Kasertsart University (KU) owns many lands and is the biggest public university in Thailand, both in terms of area and enrolled student numbers. The university has seven campuses, four student training facilities and 16 research stations in various agriculture fields across the country. The four main campuses with study activities, Bangkhane, Si Racha, Kampangsan, and Sakon Nakhon locations are shown in Figure 1. There are currently more than 67,000 enrolled students. With its missions and context, the university has many advantages in promoting sustainability development.

Figure 21: Locations of four Kasetsart University campuses

2.1 Kasetsart University: Bangkhane campus

Bangkhane Campus is located in the northern part of Bangkok. It is the oldest KU campus established in 1887. The campus has more than 36,600 enrolled students and 1.41 km2 land area and more than 250 buildings. There are 16 schools: Faculty of Agriculture, the Faculty of Agro-Industry, the Faculty of Architecture, the Faculty of Business Administration, the Faculty of Economics, the Faculty of Education, the Faculty of Engineering, the Faculty of Environment, the Faculty of Fisheries, the Faculty of Forestry, the Faculty of Humanities, the Faculty of Science, the Faculty of Social Sciences, the Faculty of Veterinary Medicine, the Faculty of Veterinary Technology, and the Graduate School.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.2 Kasetsart University: Kampangsan campus

Kampangsan Campus is located in Nakorn Pathom Province, 90 kilometers east of the Bangkhane campus. The campus has more than 13,000 enrolled students and 12.72 km2 land area—mostly agricultural lab areas—and more than 350 buildings. There are six schools: the Faculty of Agriculture, the Faculty of Engineering, the Faculty of Education and Development Sciences, the Faculty of Liberal Arts and Science, the Faculty of Sports Science, and the Faculty of Veterinary Medicine

2.3 Kasetsart University: Sakon Nakhon campus

Sakon Nakhon Campus is located in Sakon Nakhon province in the northeastern region in Thailand. The campus has more than 6,800 enrolled students and 7.52 km2 land area with more than 35 buildings. There are four schools: the Faculty of Natural Resources and Agro-Industry, the Faculty of Science and Engineering, the Faculty of Liberal Arts and Management Sciences, and the Faculty of Public Health.

2.4 Kasetsart University: Si Racha campus

Si Racha Campus is located in Rayong Province in the eastern region of Thailand. The province is famous for Pattaya beach, and the industrial estate Maptaphut. Sitting on the hillside, the campus has more than 10,000 enrolled students and 0.32 km2 land area with more than 40 buildings. There are five schools: the Faculty of Management Science, the Faculty of Engineering at Si Racha, the Faculty of Science at Si Racha, Faculty of Economics at Si Racha, and the International Maritime College.

3. METHODOLOGY

3.1 Roof potential survey

Basic data of building names, locations, sizes, and floor areas were obtained from the university facility offices at each campus. Field site surveys, together with satellite images obtained from Google Maps were used to update or correct the basic data. The potential of each building was determined by surrounding shades, structure conditions, working possibility, and obstructions on the roofs. Aerial maps using an Unman Aerial Vehicle (UAV) were produced for two campuses, Bangkhane and Si Racha.

3.2 PV systems

PV systems used in the calculation were 250 W crystalline silicon modules, size 2 m x 1 m. The modules would be mounted on the structure attached to the roof away from obstructions at the actual roof orientation and tilt angle. Space between PV arrays and roofs is no less than 0.10 m to allow proper ventilation to reduce heat accumulation.

Electricity produced from PV systems was estimated using PVwatts Calculator (http://pvwatts.nrel.gov/). The inputs were as follows:

- Weather data source: IWEC BANGKOK, THAILAND
- Latitude and longitude:13.92° N 100.6° E
- Module type: Standard polycrystalline silicone
- Array type: Fixed (open rack)
- System losses: 14%
- Inverter efficiency: 96%
- DC to AC size ratio: 1.1
- Capacity factor: 15.4%

The highest PV potential was 1,351 kWh/year when the module was tilted 14 degrees from the ground and oriented toward the south. Other orientations and tilt angles potential proportional to the highest potential tilt angle and orientation are shown in Table 1.lectricity produced from PV systems was estimated using PVwatts Calculator (http://pvwatts.nrel.gov/). The inputs were as follows:

Tilt angle

Azimuth*	0°	15°	30°	45°	60°	75°	90°

Peak reduction (MW)	10.94	10.98	1.64	2.01
Investment (Mbaht)	937.32	941.21	140.60	172.32
Payback period (Year)	10.43	10.76	11.39	10.41

Table 2: Rooftop PV potential, investment and rate of return for KU Four campuses.

Bangkhane and Si Racha campuses are located in urban areas. They have many large buildings, many big trees, and limited open spaces. Fifty-five to 70% of the buildings have PV rooftop potential; however, the electricity produced could account for only 32-33% of the campus' total electricity use. Energy saving measures are recommended to be implemented intensively to reduce energy use and increase percentages that renewable energy can account for.

Kampangsan and Sakon Nakhon campuses, on the other hand, have many open spaces mostly used for agricultural labs, livestock farms, and dry dipterocarp parks. The majority of buildings are small and use passive cooling or small air conditioning systems, resulting in much less electricity use intensity compared to the Bangkhane and Si Racha campuses. Kampangsan campus roofs have the potential to accommodate PV systems that can generate electricity more than the amount that the campus needs in one year, while the Sakon Nakhon campus can have PV systems produce electricity almost equal to the amount that the whole campus uses in one year. The two campuses could then be made net zero energy campuses.

The university can invest in PV systems one building at a time. The payback period is approximately 10 to 12 years without subsidy. There are two other possible investment options which are 1) Loan money from Kasetsart University Cooperatives Bank (KU Coop) with a very low interest rate, and 2) Sign solar power purchase agreements with a private company. Both options could result in large-scale solar rooftop investment which could reduce the investment cost by approximately 20%. The income each year would need to be shared, 66% with KU Coop for option 1 and 50% with the private company for option 2. The university could then possess the systems after the loan has been paid (25-30 years - option 1) or the contract has ended (21-25 years – option 2).

Installing PV systems on all roofs that have potential in PV system installation at four campuses could provide approximately 53% of the electricity demand. This will increase points for KU in UI green metric rating assessment as well; however, grid system improvement might be needed. The university would need to work closely with Thailand's Metropolitan Electricity Authority and Thailand's Provincial Electricity Authority to make the project possible and successful.

Track 2: Practices & Policies for High-Performance Buildings

Session 1.4: Practices Review of High-Performance Green Buildings

When will Hong Kong build its first Passive House? : Concepts and Case Studies around Asia show great possibilities for Energy Savings

Anne JACOBS[a]

[a] *BASF, Hong Kong SAR, anne.jacobs@partners.basf.com*

ABSTRACT

The Paper explains the history and basic technical principles of the Passive House Concept in the context of the need for more energy efficient buildings. Several pilot projects around Asia are introduced. These projects show the wide adaptability of the concept, with examples of a single family home, an office, a hotel and a multi-family high-rise. As all projects are located in different climate zones, they also offer insights into adaptation to the climates.

The paper evaluates the possibility to use the Passive House Concept for Hong Kong. It explains why the concept could work very well for this city where energy consumption in buildings is one of the highest worldwide. In addition to significant energy savings, a Passive House also contributes to healthier indoor air quality due to its ventilation system with energy recovery.

Keywords: energy efficiency, indoor air quality, Hong Kong

1. BACKGROUND

It is well known that worldwide, buildings account for about 40% of global energy use and for about one third of energy-related GHG emissions. (UNEP, 2017).

In Hong Kong the figure is even more extreme: buildings consume an incredible 90% of all the city's electricity and emit more than 60% of the city's GHG. (HKGBC, 2014).

Much of the rise in energy use by buildings can be attributed to increased demand for cooling and heating. Whereas some time ago people were happily using open windows or fans to cool their apartments or work spaces in summer, now ever-growing numbers of people live in air-conditioned dwellings. Mobile heating units replace warm clothes in winter time, and dehumidifiers run around the clock in the humid season. More and more people strive for comfortable dwellings, which are no longer regarded as luxury. This is a worldwide trend: with advancing urbanization, comfort levels are rising, too.

Yet it is possible to provide the comfort people are longing for and at the same time reduce the energy consumption of buildings to a more sustainable level. Widely used in Europe and America, a "Passive House" can provide exactly the comfort wished for - at a fraction of the current energy consumption of buildings

2. SHORT HISTORY OF THE PASSIVE HOUSE CONCEPT

The first Passive House was constructed in Germany in 1991. This single family, row house proved the feasibility of an idea evaluated academically in previous years by Wolfgang Feist during his research in Sweden, together with his host Professor Bo Adamson. The two men followed up on the concept and Feist later founded the German Passive House Institute (PHI) to promote and facilitate the idea. In the early years, the Passive House concept attracted mainly visionaries, but it soon became more mainstream. With the increasing demand for technology suitable for this type of buildings, prices for improved building elements began to drop, and it became more and more affordable to construct this way. Reduced energy costs quickly offset higher investment at the construction phase.

The concept began to be applied to non-residential buildings like schools, offices, hotels and special use buildings; the projects also became bigger in size.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. THE BASIC PRINCIPLES OF PASSIVE HOUSE

The Passive House is not a new concept, and the name is not protected by copyright. The concept is open to anybody who understands its principles. It is basically a comfort-improved, low-energy building brought to a new level. Its energy demand has been reduced so significantly that traditional heating or cooling systems are unnecessary. The official definition of a Passive House given by the German Passive House Institute reads as follows:

"A Passive House is a building, for which thermal comfort (ISO 7730) can be achieved solely by post-heating or post-cooling of the fresh air mass, which is required to achieve sufficient indoor air quality conditions – without the need for additional recirculation of air." (Passipedia.org, 2017)

To achieve good thermal comfort without a standard heating or cooling unit, some principles need to be observed (see Figure 1 and Figure 2):

- The building needs to be insulated very well. This will help to keep the indoor comfort steady. Typical thickness of insulation would be between 4 and 30 cm – depending on material and climate.
- The building needs to be airtight, in order to hinder unwanted air exchange with outdoor air - if the outdoor air is too cold, too hot or too polluted.
- An external shading system needs to be installed to prevent the sun from heating up the building in summer time.
- Thermal bridging needs to be reduced. This also contributes to a high quality construction standard.

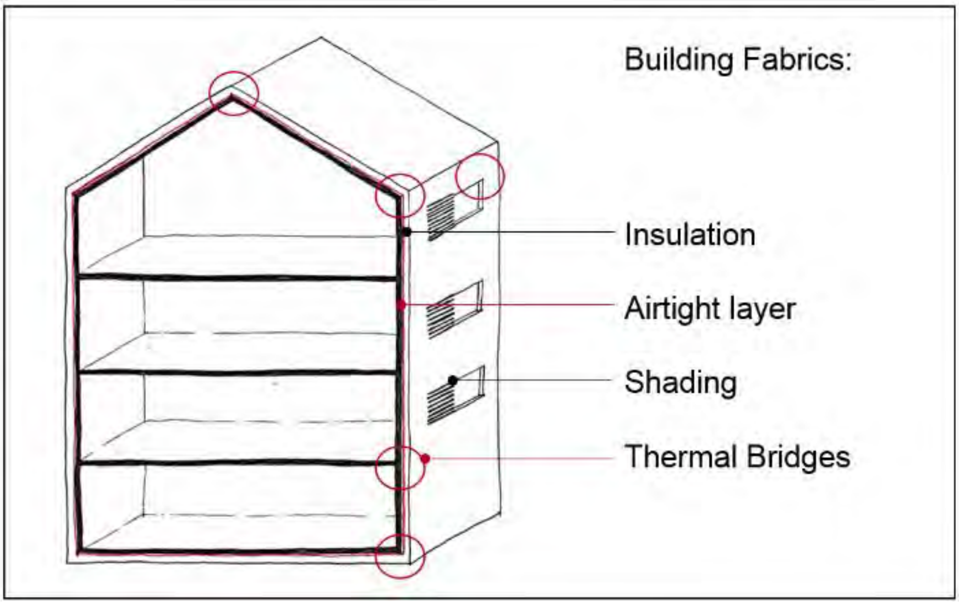

Figure 1: The passive house principles: improved building envelope (Source: BASF)

- The building services need to include a mechanical ventilation unit with energy recovery and filters for most climate zones. This is to ensure best indoor air quality at lowest energy consumption.

Innovative hot water production or further energy recovery solutions help to further improve the performance of the building.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

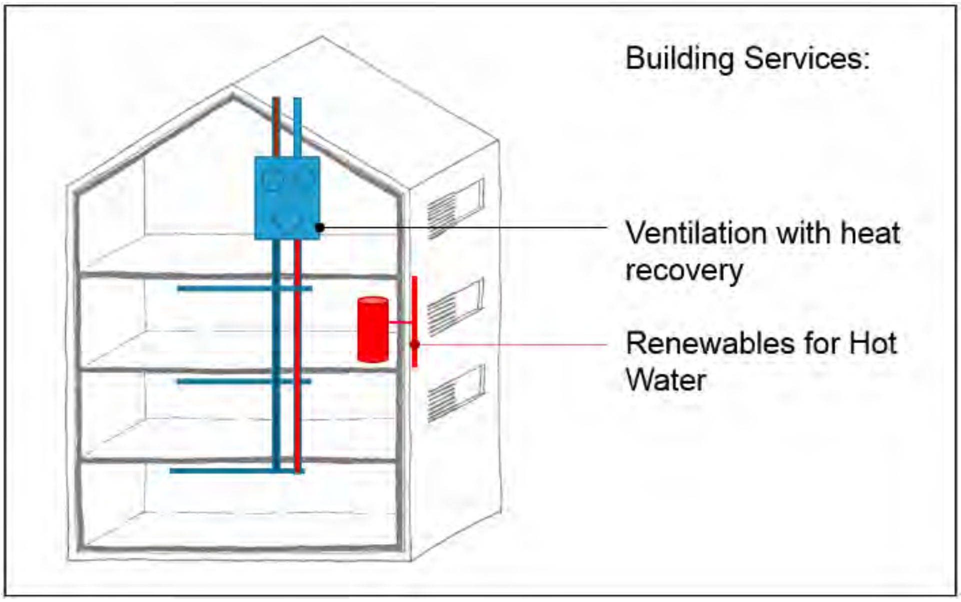

Figure 2: The passive house principles: ventilation with heat recovery (Source: BASF)

A Passive House can be certified by PHI or their certification partners worldwide to ensure the quality standards are met. For example, this certification helps to make sure that it reaches the required energy standard, and indirectly also provides assurance of the construction quality. Because reaching Passive House standards requires extreme dedication to every detail in construction, Passive House buildings achieve excellent construction quality standards, which often also result in reduced maintenance costs.

4. EXAMPLES IN ASIA

While the first examples of Passive Houses were all small buildings, constructed in northern European climate zones, the concept is now spreading all over the planet and is used for large-scale buildings, too. The PHI, among others, has conducted studies on adapting the concept to all climate zones, and several examples have already been constructed and are being monitored.

4.1 Korea and Japan

As most of the South Korean and Japanese climate zones are very well suited for this standard, the concept was quickly adopted there, and several Passive Houses have been registered with PHI. Passive Houses are viewed as highly desirable: One Japanese company for prefabricated houses recently extended their portfolio to include this building concept (see Figure 3).

Figure 3: Design for the new pre-fabricated passive house (Source: Hokushu)

To not lose any indoor area due to higher insulation standards, they are using one of the thinnest insulation materials available (see Figure 4).

Figure 4: Aerogel insulation for space saving (Source: BASF)

4.2 Chinese passive house projects

In China, the Passive House concept was explicitly recommended in the 13th Five Year Plan, leading to high interest in the topic and several pilot projects. The additional benefit of very good indoor air quality has also created interest in the Passive House construction method.

The first ever certified Passive House in China was the Hamburg House in Shanghai, which was constructed in 2010 as an office building (see Figure 5). This showcase building used innovative insulation materials, high performance windows, airtight layers and efficient building services, none of which were standard in the Chinese market. Therefore, the building also served as a learning project for all of the building experts involved.

Figure 5: The hamburg house: thin and efficient insulation for the external walls and healthy indoor air (Source: BASF)

The first certified Passive House for the hot summer and cold winter climate of the Yangtze River Delta region in China was a hotel (see Figure 6). In addition to being constructed according to the Passive House principles, the building was also certified according to three sustainability standards - China Three Stars Green Building Evaluation Standard, DGNB (German Sustainable Building Certificate) and LEED (Leadership in Energy and Environmental Design).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 6: The passive house hotel, innovative neopor® insulation, efficient spray foam insulation for the roof (Source: BASF)

As there is a high demand for Passive House construction, due to energy efficiency targets as well as due to improved indoor air quality, there are currently many projects in the planning phase.

A very interesting example will be the first high-rise Passive House, currently under development in Tianjin (see Figure 7). This project recently received Pre-Certification by the PHI. This building will highlight the adaptability of the Passive House concept to standard building archetypes. It will most likely lead the way from showcase houses to standard construction on a larger scale.

Figure 7: Planning for the first certified Chinese high rise passive house (Source: BASF)

With the growing numbers of buildings constructed according to Passive House principles, the availability of innovative construction solutions is also increasing and the costs for these solutions are dropping.

5. WHEN WILL **HONG KONG, ASIA'S WORLD CITY, BUILD ITS FIRST PASSIVE HOUSE?**

Although Hong Kong is seen as a technology and innovation leader in many areas, the city has yet to construct its first Passive House. Even though there are sustainable buildings being constructed in Hong Kong, none meets the Passive House standard. Considering the extremely high electricity consumption of the building sector, the savings potential is compelling. Adding the advantage of good indoor air quality, it can only be a matter of time until the first Passive House will be constructed in Hong Kong – which will serve as a showcase for others to come.

The conditions are right: there is a high demand for comfortable, high-quality dwellings; rising awareness of sustainability is making people look for energy-efficient buildings; and the construction sector is technologically ready to take on the task.

Hong Kong's climate is suitable for constructing a Passive House. Even a typical Hong Kong high-rise building in a dense neighbourhood could implement the standard, as in contrast to other climates, the building would not require significant solar gains to heat it up in winter. The few cold days in winter could easily be covered in a well-insulated building by the heat recovering unit. In summer, shading in a densely-inhabited area could help the building keep cool, and in combination with good insulation and the energy exchange of the ventilation system, the air inside the dwellings would stay comfortably cool.

So why has this concept been so well received in mainland China, but not in Hong Kong? Do construction experts believe that insulation works only to keep out the cold? Many examples worldwide prove the opposite. If Hong Kong really wants to position itself as a leader in sustainable construction, it is time for Hong Kong to build its first Passive House.

Insights into Energy Efficiency of hotels Constructed as Green Buildings

Duygu ERTEN[a]

[a] *TURKECO Consulting, Turkey, derten@turkeco.com*

ABSTRACT

Global climate change has already had observable effects on the environment. Hotel industry has a role to play mitigating climate change by reducing carbon emissions. This article explores the energy saving potentials in hotels by simulating several currently available scenarios at different climates by using methodical and iterative processes to evaluate potential decisions and achieve long-term goals. The information provided in this research work is based on a review of relevant literature and the results of EQUEST simulations for 3 hotels certified with LEED V3 across Turkey. Three locations were selected to represent the three climate zones in Turkey. Green criterias are evaluated according to LEED V3 certification system. Based on the findings presented in this paper, it is suggested there exists significant energy savings potential for the Turkey's hotel industry if hotels are designed and built with sustainability principles. The main finding after compairing the three hotel designs is that it is technically feasible to increase energy efficency more than 60% without compromising guest comfort by using green technologies. Because the number green design and construction of new constructed hotels is low, implementing a new green building code with strict energy requirements is recommended for those developers who do not want to certify their hotels.

Keywords: green hotels, energy simulation, CO_2 reduction, LEED, DGNB, sustainability

1. INTRODUCTION

Glaciers have shrunk, ice on rivers and lakes is breaking up earlier, plant and animal ranges have shifted and trees are flowering sooner. Taken as a whole, the range of published evidence indicates that the net damage costs of climate change are likely to be significant and to increase over time. The Second Assessment Report (SAR) of the Intergovernmental Panel on Climate Change (IPCC), published in 1996, is an assessment of the then available scientific and socio-economic information on climate change. Working Group I, dealing with the scientific aspects of climate, stated that carbon dioxide remains the most important contributor to anthropogenic forcing of climate change. According to US Green Building Council, with buildings accounting for up to 30 percent of global emissions, a commitment to the rapid transformation of the global built environment seems to be one solution that the entire world can get behind.

United Nations declared that, emissions generated directly from the tourism sector account today for 5 per cent of global CO_2 emissions but may be higher. Due to similar facts, energy consumption and conservation in hotels received growing attention globally in recent years. Hotel facilities rank among the top five in terms of energy consumption in the tertiary building sector (minor only to food services and sales, health care and certain types of offices). Among non-domestic buildings, hotels belong to one of the highest emitting sector. According to US EPA, for a study that was carried out in the United States for both hotels and motels on their practices and operating costs energy represented roughly six percent of all the operating costs. The CHOSE project estimated that European hotels – which are reported to provide nearly half of the world total hotel rooms – used a total of 39 TWh (terawatt hours) in 2000, half of which is in the form of electricity. Most of this energy is derived from fossil sources, and the hotel sector's contribution to global warming and climate change, is estimated to include annual releases between 160 and 200 kg of CO2 per m2 of room floor area, depending on the fuel mix used to provide energy. Global hotel-based CO2 emissions were assumed to be at the level of 55.7 Mt in 2001, while the estimated annual energy consumption for European hotel of 39 TWh, would result in emissions of more than 10 Mt of CO2 each year.

	COST OF ENERGY/COST OF TOTAL SECTOR
Other services	18,90
Other mining	12,40
Precious Metal Mining	9,80

Balance	3,4

Table1: The ratios of total gross value added (right) and cost of total sector (left) to the cost for total energy. Source: Calculations prepared by Deloitte based on EU Commission Tables on Turkey data

According to Turkey's National Energy Efficiency Plan, energy costs for hotels have a considerable portion among total industry costs. Looking from this framework, as seen from the Table 1 data, the increase of energy efficiency in hotels will not only drop the cost of energy, but will contribute lowering the energy density and increase the competitiveness. The hotels designed and built according to sustainabilility principles and certified with green building certification systems can contribute to this national goal.

According to USGBC rankings, Turkey has made the top 10 Countries for LEED certification list, and was able to make this year's list on the strength of the 258 percent increase in the amount of year over year. Maintaining this form of commitment to transforming Turkey's national built environment holds enormous potential for the country's long term economic and environmental future since 42 percent of Turkey's net electricity consumption comes from the country's building sector.

Rank	Nation	GSM of LEED certified space (million)	Total GSM of LEED-certified and registered space (millions)	Total number of LEED-certified and registered projects
1	Canada	26.63	63.31	4,814
2	China	21.97	118.34	2,022
3	India	13.24	73.51	1,883

2. STATUS OF HOTELS WİTH GREEN BUİLDİNG CERTİFİCATİONS

In US alone, hotels represent more than 5 billion square feet of space, nearly 5 million guest rooms and close to 4$ billion in annual energy use. Hotels and hospitality venues have significant opportunity to reduce negative environmental impacts associated with guest rooms, event space, an general facility use through measures such as enerfy and water efficiency, waste reduction and management, sustainable and local purchasing, and the use of alternative transport. Hotels can also contribute to human health by providing healthy, comfortable, and productive indoor environments with improved indoor air quality, access to daylight and views, and occupant control of the lighting and thermal environment]. Leadership in Energy and Environmental Design (LEED) is a set of rating systems for the design, construction, operation, and maintenance of green buildings. Developed by the U.S. Green Building Council (USGBC), LEED is intended to help building owners and operators be environmentally responsible and use resources efficiently. Since 1993, it has been a popular system all around the world. In LEED, credits are all organized under the following seven categories: location and transportation, sustainable sites, water efficiency, energy and atmosphere, material and resources, indoor environmental quality, and innovation. Len Foote Hike Inn in Dawsonville, Georgia became the first LEED certified hotel in the world. Since 2004, though practitioners and advocates have been promoting LEED certification, hospitality industry was shy about using LEED. One reason maybe was the LEED criterias were not initially directed specifically at hotels. Since 2004, hotels started seeking green building certification systems.

Available studies seem examine the benefits of LEED from a cost perspective, with a focus on whether certification will reduce energy costs or empirically examine the impact of LEED certification on revenue performance on a substantial sample of hotels. The LEED certification system’s new v4 has criterias specifically designed for the hospitality industry and is intended to create incentives for new lodging construction that meets sustainability criteria.

A recent study of 93 LEED certified hotels found that the certified hotels displayed better financial performance than a larger sample of non-certified ones. These researchers analyzed the financial results of hotels that had received the Travelocity eco-friendly hotel designation, which is based on any of a dozen different certifications. They found that the “green” hotels recorded higher resource efficiency for both hotel operations and customer activities, as compared to those that had not earned the designation. Thus, it may be that regardless of the certification, hotels that are involved in sustainability activities are operated more efficiently than typical properties.

DGNB is relatively a new system by German Sustainable Building Council. The DGNB has developed the CORE 14 system for international use. It is based on international standards and requirements and can be adapted to local requirements in different countries. As of August 2015, there are 17 hotels in Germany certified with DGNB and an additional project certified by ÖGNI in Austria with the DGNB System other than the one pre-certified hotel project in Turkey.

2.1 Status of hotels with green building certifications

Turkey’s energy demand is increasing so does the number of new hotels built. Out of 477 buildings in Table 2, only 36 of them are hotels registered to be certified at some level of LEED. The author used the three hotel projects in Turkey for this research, aiming to be certified with LEED.

The Fairmont Hotel in Mecidiyeköy, İstanbul received a DGNB-Gold pre-certification but the project has not been completed and received the final certification yet.

Even though BREEAM as well as LEED and DGNB is a widely used green building certification system in Turkey especially for retail projects; there are no BREEAM certified hotels in Turkey as of August 2015.

From 2007 to 2015, the number of hotels aiming to get certification in Turkish market give us an indication that hotel industry has started appreciating the benefits of certification. The hotels aiming for green building certification in Turkey are among top-tier foreign hospitality brands, offering environmentally friendly features and practices including solar panels, green roofs, electric vehicle charging stations, rainwater collecting systems and VIP parking for electric and hybrid vehicles. The hotel buildings themselves incorporate many sustainable design and construction features, while the hotel teams include sustainability professionals to oversee environmental practices throughout the buildings.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. STATE OF ART

According to USGBC, energy efficiency is a key strategy for reducing building-related pollution and greenhouse gas emissions, which are possibly the most important negative environmental consequence of building operation. Production of electricity from fossil fuels is responsible for air pollution and water pollution. Building systems including electrical, lighting, HVAC, and others can be designed to significantly reduce energy consumption compared to conventional designs and practices. The real estate industry started using green building certification systems to demonstrate that their design and construction since early 1990s. Several Cornell Hospitality Reports have demonstrated the importance of green certification in gaining favorable guest notice, including ISO 14001 and LEED. A study of over 2,000 independent hotels in Spain by Segarra-Oña, Peiró-Signes, and Verma found that hotels that have implemented the ISO 14001 environmental standards displayed stronger sales and earnings before taxes and depreciation than those that were not certified.

Constructing hotels green is one of the great strategies to combat climate change for the hotel industry. Greening the hotels help building managers, investors, owners and occupiers reduce the running costs and improve the environmental performance once the hotels start operation. Independent certification process provides a clear and credible route map for sustainable design and construction. Green design and energy simulation results help to optimize the building envelope and mechanical and electrical systems as well as fullfilling the pre-requisite requirements of green building certification systems.

4. METHODOLOGY

This research is conducted on 3 hotel projects in Turkey. These hotels are: Rixos Bademlik Hotel in Eskişehir (certified with LEED-GOLD) and CARYA Hotel at Belek (certified with LEED-GOLD) and HILTON Güneşli in İstanbul (certified with LEED-GOLD). The author was the LEED Process Manager of the three projects and was involved from the design to end of construction of the every step of the integrated project management process including performing the energy simulations with a team of experts for each hotel. In LEED, energy performance is a key component of sustainable design. Accordingly, in both of these systems it is the energy consumption category EA is the the most influential in terms of its impact on the overall assessment score. The most influential sub-categories in LEED is: EA Credit-1 Optimize Energy Performance (19 available credits). 'EA Credit-1' sub-category grant credits for buildings that demonstrate a performance improvement over a specific target. For LEED this target is associated with ASHRAE performance standards. To enable this, the performance of the 'Designed building' is compared to that of a generated 'Base case' building by using any of the approved simulation tools according to each standard. The 'Base case' building shares some characteristics with the 'Designed building' (shape, size, activities etc.), but includes adjusted specifications for building fabric and service systems. For LEED V3 standard: The 'Base case' building is known as the 'Baseline building' and is defined in accordance with the specifications outlined in ASHRAE 90.1-2007. The LEED 'performance improvement' is a cost savings calculation.

For LEED EA Credit-1 calculations, USGBC approves the qualified simulation program must follow a list of specification that includes requirements that the tool must be able to • Calculate 8760 h of building operation to simulate annual energy use. • Model hourly variations in occupancy, lighting power, miscellaneous equipment power, thermostat set points, and HVAC system operation.

Energy modelling was performed for each hotel to predict the annual hotel energy usage and to investigate the energy savings. Performing energy simulation is a prerequiste in order to get most green building certifications but energy modeling predates certification systems like LEED, BREEAM and DGNB. Energy modelling proved to be a powerful tool in all projects since it was part of the integrated design process from the beginning. Energy efficiency measures in each projects are diverse and have different interactions with other components of the building and it was necessary to evaluate their effectiveness using some sort of modelling approach.

There are many energy modelling softwares available in the market. A fundamental issue that has been highlighted in various studies is the predictive variability found between energy simulation tools. For the design and selected HVAC equipment, the research team decided to select eQUEST. eQUEST, used for all 3 projects demonstrates the percentage improvement in the proposed building performance rating compared to the baseline building performance rating as per ASHRAE/IESNA Standard 90.1-2007 for a whole building project simulation using the Building Performance Rating Method in Appendix G of the standard. The proposed design model is based on the actual parameters and actual design considerations and architectural details.

During schematic design phase a simplified model of building is used to test site and basic design features. For the values not available at the pre-design stage, default values are utilized. After several runs, alternative scenarios are compared. During design development stage inputs like, building characteristics, occupant characteristics, system characteristics are used to model. The outputs show us what the monthly consumption by end use will be as well as equipment type. Once the design development is completed the exact location, size and material characteristics for the envelope, windows, doors, roof and foundation are plugged into the model. During the preparation of construction and bid documents the complete energy model outputs are used. Construction management team is asked to install the designed features. Modelling also helped us to examine the life cycle costs.

There are 35 possible points and 3 Prerequisite requirements for energy requirements in LEED V3. The prerequisites are: 1. Fundamental Commissioning of Building Energy Systems 2. Minimum Energy Performance 3. Fundamental Refrigerant Management. The document states that the minimum energy performance in Prerequisite 2 is 10% improvement in the proposed building performance rating for new buildings compared with the baseline building performance rating. Other credits are:

- Credit 1 Optimize Energy Performance 1-19
- Credit 2 On-site Renewable Energy 1-7
- Credit 3 Enhanced Commissioning 2
- Credit 4 Enhanced Refrigerant Management 2
- Credit 5 Measurement and Verification 3
- Credit 6 Green Power 2

4.1 Case studies

A total number of 36 major hotel developers in Turkey were contacted for the study. 35 of these hotels aimed to receive LEED certification at some level while 1 aimed to receive DGNB. All 3 cases under this study received LEED GOLD certifications.

4.2 **Bademlik Rixos Hotel at Eskişehir, Turkey**

The Hotel consists of 5 basements, ground floor and 3 Guest Room floors. Boilers are designed to meet the heating energy demand of the building. Principal heating source is natural gas. According to function of the zones different heating systems are used. 4-piped Fan Coil system is used ballroom, back stage retail areas, foyer. Water cooled VRF system is used in guest rooms; café, restaurant and gym are heated by PTACs. Water cooled chillers are installed for cooling; FCU indoor units are used to meet the cooling energy demand of the building. Geothermal water is used as domestic hot water and laundry process demand. In addition to heating and cooling systems;

provided fresh air rates are designed according to ASHRAE 62.1-2007. In order to predict and compare the energy performance of the project with respect to the LEED NC requirements, Energy Analysis is done using eQUEST. This program simulates the energy performance of a building using hourly time steps for all 8760 hours in a year and by using Meteonorm Hourly Interpolated Values for Eskisehir weather file. The analysis and modeling methodology is in line with the LEED requirements. The energy model results show that the actual design for the building performs 30 % better than ASHRAE 90.1-2007 requirements using the LEED performance rating method.

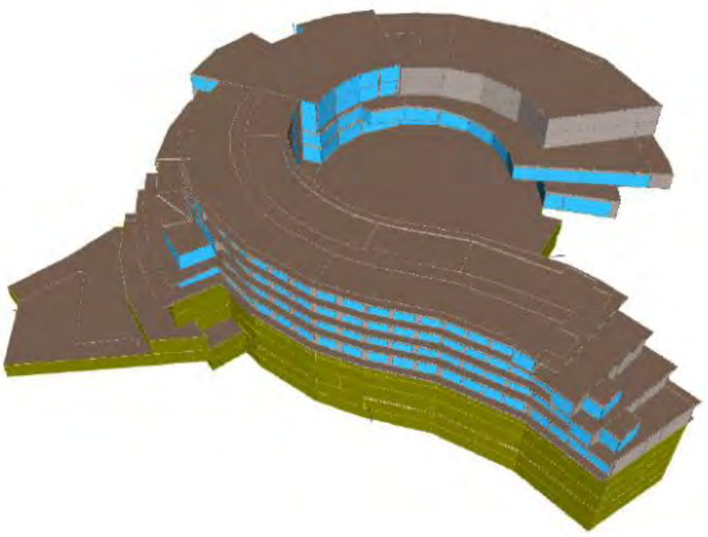

Figure 1: The 3D geometric model output of Bademlik Rixos Hotel for eQuest

4.3 Carya Hotel in Antalya, Turkey

Carya Hotel consists of one basement, Ground floor, one Mechanical Floor, and 4Guest Room floors (including Attic Floor). Boilers are designed to meet the heating energy demand of the building. As a fuel type natural gas is used. According to function of the zones different heating systems are used. 4-piped Fan Coil system is used office, hotel rooms and circulations. Unitary Heaters are used in technical areas; café, restaurant and gym are heated by PTACs. Chillers are installed for cooling; FCU indoor units are used to meet the cooling energy demand of the building. Tri generation unit installation is the most important point for energy efficiency and improvement in the building. In addition to heating and cooling systems; provided fresh air rates are designed according to ASHRAE 62.1-2007.

eQUEST is used to simulate the energy performance of a building using hourly time steps for all 8760 hours in a year and by using TUR_Antalya_MN6.bin weather file. The analysis and modeling methodology is in line with the LEED requirements.

The proposed design model is based on the actual parameters and actual design considerations and architectural details. The key measures of an efficient design are: improving glazing, improving exterior wall Thermal Energy conductivity, using Heat Recovery Wheel; etc. The energy model results show that the actual design for the building performs 20 % better than ASHRAE 90.1-2007 requirements using the LEED performance rating method.

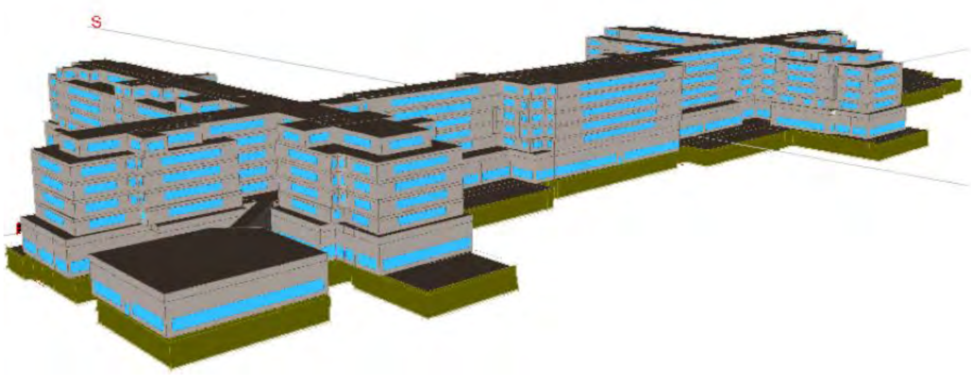

Figure 2: The 3D geometric model output of Carya Hotel for eQuest

4.4 **GÜNEŞLİ HILTON, ISTANBUL, Turkey**

Güneşli Hilton Hotel consists of 4 basements, ground floor and 22 Guest Room floors. Boilers are designed to meet the heating energy demand of the building. Principal heating source is planned to be natural gas. According to function of the zones different heating systems are used. 4-piped Fan Coil system is used in restrooms, changing rooms, ballroom, boardrooms, offices, fitness room, guest rooms and corridors. Variable air volume with under floor static heating is modelled for the pool area. Air cooled chillers are installed for cooling; FCU indoor units are used to meet the cooling energy demand of the building. In addition to heating and cooling systems; provided fresh air rates are designed according to ASHRAE 62.1-2007. In order to predict and compare the energy performance of the project with respect to the LEED NC requirements, an energy analysis is completed using eQUEST. The proposed design model is based on the actual parameters and actual design considerations and architectural details. The energy model results show that the actual design for the building performs 26,9 % better than ASHRAE 90.1-2007 requirements using the LEED performance rating method.

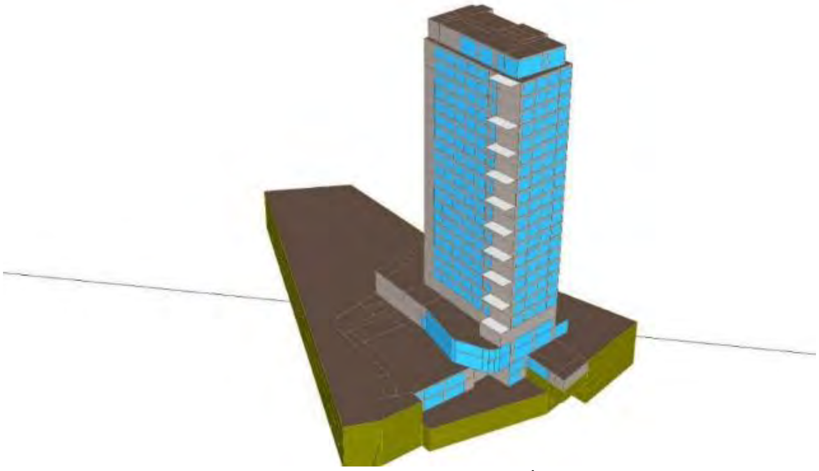

Figure 3: The 3D geometric model output of GUNEŞLİ HILTON hotel for eQuest

5. RESULTS

Green building rating systems like LEED, aims to give benchmark and rank buildings within a specific frame. LEED considers a broad range of categories for reducing the environmental impact. The certification process requires a substantial modelling work. Building Energy Modelling helps determine the most cost effective solutions. Balancing the long-term payback of energy improvements, against critical capital costs, defines the building decisions. It is beneficial for hotel designers to utilize modelling as part of their design plan since modelling helps to optimize the building envelope and mechanical and electrical systems. Based on the findings presented in this paper, it is suggested there exists significant energy savings potential for the Turkey's hotel industry as in the case for the 3 green hotel projects from three different climate zones in Turkey. The main finding was that it is technically feasible to have 67 % energy cost improvement over baseline without compromising guest comfort by using green technologies used in Carya Hotel in Antalya.

Category	DATA	CARYA	BADEMLIK	HILTON
ENERGY	Standard of Simulation	ASHRAE 90.1-2007 App. G	ASHRAE 90.1-2007 App. G	ASHRAE 90.1-2007 App. G

Table 4: Comparision of sustainability criterias

6. CONCLUSİONS AND RECOMMENDATİONS

Turkey has a favorable economic environment for foreign direct investment and construction market has a compound annual growth rate (CAGR) of 19%, while investment in the sector is increasing with a CAGR of 10%. Every year 100 thousand construction permits are granted for new buildings and 1,2% of these permits are for hotels. That corresponds to approximately 1200 hotel construction per year where only 3% of these hotels are aiming to receive green building certification systems. Based on the analysis of the three hotels which received LEED-GOLD certification, there exists significant energy savings potential for the Turkey's hotel industry if hotels are designed and built with sustainability principles. The main finding after compairing the three hotel designs is that it is technically feasible to increase energy efficiency over 60% without compromising guest comfort by using green technologies. From the LEED registered hotel list in Turkey, a high percentage of hotels receiving green building certifications are found to be foreign brands. Turkey, in order to develop its local hotel brands in a sustainable way, has to create a green code for the hotels. Turkish NGOs in the real estate sector are on the verge of creating a new national code for buildings. Since the ASHRAE 90.1 Energy Standard is being widely used by international green building certification systems, the new building code to be developed for Turkey can embed the requirements of ASHRAE 90.1 Energy Standart into the new code. Designers can use the building energy modelling to efficiently meet the new building code standard. This way, developers can evaluate energy saving potential of several possible solutions and pick the one suitable to meet the requirements of the code.

ABSTRACT

Hong Kong currently has over 42,000 existing buildings that account for over 90% of the total electricity consumption in the territory. The Energy Saving Plan by the Hong Kong Government and the "HK3030" Campaign by the Hong Kong Green Building Council ("HKGBC"), both put forth an electricity consumption reduction target of buildings. Expediting green building adoption with better energy performance is identified critical to achieve the target. To advocate low carbon sustainable built environment, Business Environment Council ("BEC") has undertaken a Transformation Project which aims to upgrade its Headquarters (with building age of around 20 years) to an energy wise green building with BEAM Plus Platinum rating. This paper presents the details and major findings of the project.

Since 2013, a number of energy-retrofit measures has been implemented, which including lighting system upgrade, installation of variable speed oil-free air cooled chiller, light and motion sensors, smart metering, and commissioning of building services equipment. These implementations aim to reduce electricity consumption of the building, future replacement, maintenance cost, and to enhance the energy efficiency of different building facilities. Meanwhile, driving behavioural changes of the occupants is also an important element for energy conservation. Stair-Days was one of the adopted measures which contributed to approximately 5% reduction in daily electricity consumption of lift. As an overall result, the electricity consumption of BEC Headquarters was reduced by 24% from 2013 to 2015. Together with other green features and environmentally friendly operational practices introduced, the BEC Headquarters has achieved the Platinum Rating of Provisional Assessment under the BEAM Plus Existing Buildings. It is the first commercial building in Hong Kong which has achieved the highest level of recognition under the BEAM Plus assessment for existing buildings. This project showcases how a 20-year-old building could contribute in energy saving and green building transformation in Hong Kong.

Keywords: existing buildings, BEAM Plus, energy consumption

5. INTRODUCTION

Hong Kong currently has over 42,000 existing buildings that account for over 90% of the total electricity consumption in the territory. To enhance the public awareness of energy saving, the "HK3030" Campaign was initiated by the Hong Kong Green Building Council ("HKGBC"). The objective was to reduce the electricity consumption of buildings in Hong Kong by 30% by 2030, compared to 2005 level. In 2015, the Energy Saving Plan by the Hong Kong Government also set a target to reduce energy intensity by 40% by 2025, compared to 2005 level. Expediting green building adoption with better energy performance is identified critical to achieve the target. To advocate low carbon sustainable built environment, Business Environment Council Limited ("BEC") has undertaken a Transformation Project which aims to upgrade the BEC Headquarters (with building age of around 20 years) to an energy wise green building with BEAM Plus Platinum rating.

This paper presents the narrative of the Transformation Project and energy performance achieved to demonstrate that it is feasible for existing buildings to make themselves green and energy efficient.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

1.1 BEC headquarters

BEC Headquarters ("BEC-HQs") is situated at 77 Tat Chee Avenue, Kowloon since September 1996. It is a low rise commercial building. The building consists of 3 floors and a car park area on the lower ground floor, totalling an area of about 4,000 m2. Apart from offices, auditorium and classrooms are also provided in the building. The building, when constructed in 1996, achieved "Very Good" rating under Hong Kong BEAM for New Office Designs Version 1/96.

1.2 Transformation project of BEC-HQs

Since BEC-HQs is almost 20 years old, the installed hardware became out-dated and inefficient in energy. Therefore, a Transformation Project was carried out and it commenced in 2013. The objectives of the Transformation Project were a) To provide optimum energy savings, better indoor environment quality, and more importantly greater connection to the community; and b) To provide environmental and green building related education and information to different community segments and create a large scale impact. A number of measures, relating to energy use, waste management, plumbing and drainage installation, have been implemented in order to improve building performance.

This paper focuses on the measures related to energy use. The measures are divided into two categories: a) Energy-retrofit and b) Driving behavioural change, and they are listed in the tables overleaf. The detail of these measures are discussed in the following sections.

Designation	Item
a)	Installation of variable speed oil-free air cooled chiller
b)	Upgrade of lighting system
c)	Installation of daylight and occupancy sensor
d)	Installation of power meters and energy meters
e)	Commissioning of building services installation

Table 1: Energy-retrofit measures in BEC-HQs

	Item
a)	"Stairs Days"
b)	Setup of Lighting zones
c)	Switching off lights during lunch hours
d)	Energy Saving Reminder

Table 2: Driving behavioural change measures in BEC-HQs

6. ENERGY-RETROFIT MEASURES

2.1 Installation of variable speed oil-free air-cooled chiller

The old air-cooled chiller was installed since the building completion. In other words, the operation time was almost 18 years in 2014. Its performance deteriorated from its original. To improve the energy efficiency of air conditioning, this chiller was replaced by an oil-free variable speed air-cooled chiller in July 2014. The new chiller consists of high energy efficiency compressors with magnetic bearings and variable speed permanent magnet motors. In addition, on the operation side, maintenance cost of the new chiller will be significantly reduced due to the maintenance free compressors.

The advantage of the oil-free chiller is its better COP and part load performance. Considering the thermal load of BEC-HQs is relatively low compared to a commercial building due to its scale, allowing part load operation of chiller could achieve energy conservation. According to the meter reading, the energy consumption of chilled water system (i.e. including chilled water pump) reduced by approximately 29.9%.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.2 Upgrade of lighting system

Apart from the air-conditioning system, lighting system is also dominant in the building energy consumption, and hence, the lighting system was also upgraded since 2014. The lighting system originally adopted in BEC-HQs was mainly T8 fluorescent tubes. The system was firstly saved by de-lamping of the lighting panels by reducing the number of fluorescent tubes. In 2014, to further enhance the saving, LED panels were installed in the building. There were mainly three features to achieve energy conservation:

- The rated power of LED panel is much lower than T8 lighting panel (3 T8 fluorescent tubes in one panel), where approximately 40% of energy can be saved.
- Due to the luminance of LED panel is higher, the required amount of fittings is less than original plan. For instance, for the BEC office areas, totally 207 nos. of lighting fittings were originally installed, but it only requires 111 nos. of LED panels to provide satisfied working environment for staff members, which is in compliance with CIBSE.
- The heat generated from the LED panel is much lower than that of T8 fluorescent tubes. This can reduce the cooling load of the air-conditioning system.

By calculation, the replacement of lighting system contributed approximately 54.9% reduction in the consumption of lighting system.

It is targeted to install LED panels/ tubes for the whole lighting system in the building. At the current stage, office areas, common corridors, lift, back of house corridor, external staircases and floor lights, exit sign were all replaced.

2.3 Installation of daylight and occupancy sensor

To enhance energy saving, both daylight and occupancy sensors were provided for light fittings at common area (essential lighting is excluded). Inside the building, totally 5 daylight sensors were installed at perimeter zones at 1/F and 2/F, including corridor and offices. The light fittings at the controlled area were pre-set to provide at maximum 80% of lux level of the rated performance. The light fittings are dimmed when there is sufficient lighting level at the controlled area. There were totally 9 occupancy sensors installed at toilets and corridor at lower ground floor. The light fittings are switched on when there is occupant in the sensed area, and switched off if no occupant is detected within the certain time interval.

2.4 Installation of power meters and energy meters

In order to enable better monitoring and measuring the energy performance of the building engineering systems, 20 power meters and 12 energy meters were installed in 2014.

The installed power meters could separately monitor the power consumption of chillers, air handling units, lighting system, lift installation and small power. By checking metering record, the management office could take prompt and targeted actions to improve energy efficiency of specific facilities.

Energy meters were installed at the areas occupied by tenants in order to evaluate their respective amounts of energy consumption associated with air-conditioning. The data is targeted to be adopted as a factor to implement green lease in the future.

2.5 Commissioning of building services installation

Re-commissioning has been carried out since 2014, covering air conditioning system, water pumps and pressure vessels, and electricity system. The property manager has set up a schedule to maintain and inspect the systems regularly. Regular inspection and adjustment of building services installations optimise system performance throughout the lifetime of the equipment.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

7. DRIVING BEHAVIOURAL CHANGES

Driving behavioural changes of the occupants is also an important element for energy conservation. As mentioned, several campaigns has been introduced and implemented since 2014. These campaigns were initiated by the Green Office Team of BEC. The team members meet regularly for discussing if any campaign can be held for engaging building occupants to live and work greener.

3.1 **'Stairs Days'**

'Stairs-Days' encourages building occupants to take the stairs instead of lift for the purpose of health and energy conservation. It commenced in March 2015 and was originally proposed for Friday only. With the support of the building occupants, the campaign was extended to Monday. With increased idling time of the lift, this campaign contributed to a 5% reduction in daily electricity consumption of lift.

3.2 Energy saving reminder

To promote energy saving and influence the building occupants to have better habit, the energy saving reminders were allocated around the office, near the switches of lighting system, computers, air-conditioning system. The users are always reminded to switch off the equipment or lights that are not in use, and to keep the air-conditioning set point at 25°C or above.

3.3 Energy saving measures of lighting

Considering it is a waste of energy when only a few staff member is working but with all lights are on in office, lighting zones were setup in BEC offices to allow individual control from BEC staff member. A lighting zones map is posted to draw staff's attention. BEC staff member who is the last one leaving the zone is responsible for turning off the light.

Apart from setup of lighting zones, lunch hour is also an opportunity to achieve energy saving. In BEC, staff members are recommended to switch off the lights during lunch hour. By estimation, if the lights are turned off 1 hour, approximately 2.2kWh could be saved daily, which may contribute to over 570kWh reduction in annual consumption.

Meanwhile, the measures not only benefit the reduction of lighting power consumption, but also indirectly help for reducing the thermal load, implying that less energy is required for air-conditioning system.

8. ENERGY PERFORMANCE OF IMPLEMENTED MEASURES

To study the effect on the energy performance of the adopted measures, the electricity consumption of the BEC-HQs from 2013 to 2015 is considered and presented in Figure 1. It is found that the consumption decreased year by year. As mentioned in Sections 2 and 3, most of the measures, especially the hardware upgrade, were implemented in 2014. Over 14% of electricity consumption was saved in this year; while the total electricity consumption of 2015 was further reduced by 10%, reaching 424,330kWh. In other words, approximately 24% of electricity consumption has been reduced since the commencement of transformation project (compared with 557,696kWh in total in 2013).

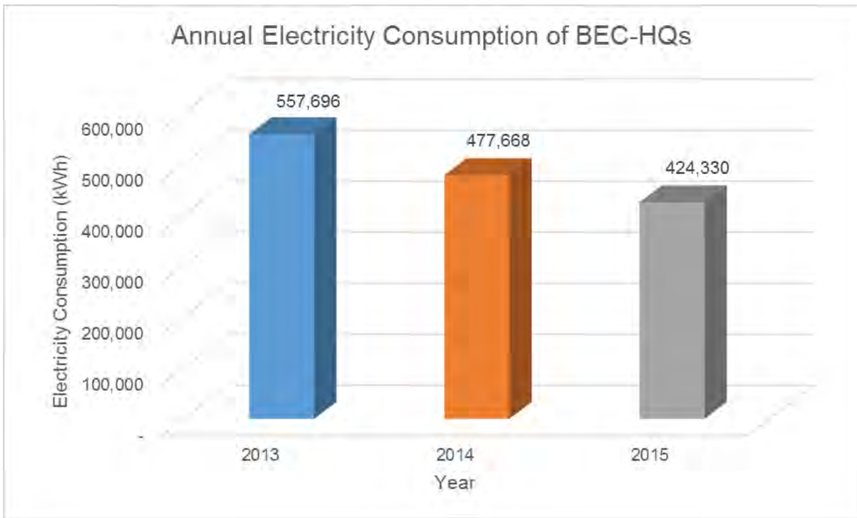

Figure 1: Annual electricity consumption of BEC-HQs

9. BEAM PLUS ACHIEVEMENT

BEC-HQs has achieved the Platinum Rating of Provisional Assessment under the BEAM Plus Existing Buildings (Version 1.2), as a result of the green features and campaigns adopted. Table 3 shows the credits achieved in different categories under BEAM Plus Provisional Assessment. The measures described in Sections 2 and 3 contribute to Energy Use category, which has the largest weighting among all categories in the assessment tool.

Category	Weighting (%)	Credits Achieved
Site Aspects	18	16
Materials Aspects	12	4.4
Energy Use	30	24.4
Water Use	15	10.7
Indoor Environmental Quality	25	19.2
Innovations and Additions	-	5
	Total	79.7

Table 3: BEAM Plus credit achievement

10. CONCLUSION

A series of hardware upgrade and campaign have been implemented to improve the energy performance of BEC-HQs. In 2015, the overall energy consumption was approximately 24% lower compared with that of 2013. Both energy retrofit and driving behavioural change measures are essential to achieve this accountable energy saving performance.

BEC-HQs has achieved the Platinum Rating of Provisional Assessment under the BEAM Plus Existing Buildings. With the achievement of the first commercial building attaining the highest level of recognition under the BEAM Plus Provisional Assessment for Existing Buildings, BEC-HQs is a successful case for industry to learn from. This is not the end, continual improvement in energy performance is essential for existing buildings. It is believed that there would be more opportunities in the future for making existing building more green and energy efficient.

ABSTRACT

Embodied Carbon (EC) in buildings is increasingly becoming an important factor in carbon management. There are numerous tools and methods to estimate EC right from the beginning of a construction project. However, each tool has its own pros and cons. One such approach is to estimate EC using Element Unit Rates (EC-EUR) and Element Unit Quantity (EUQ). This is made possible by identifying carbon hotspots in buildings in the first instance and developing EC-EURs for different specifications of the carbon hotspots. Development of elemental EC-EUR benchmarks and its application in the proposed elemental approach for predicting EC is presented in the paper. Carbon hotspots of office buildings were identified using a sample of 28 office buildings in the UK where Substructure, Frame, Upper Floors, External Walls and Services were identified as the carbon hotspots. EC-EUR benchmarks were developed for different specifications of the hotspots by statistically modelling the sample for Frame. However, EC-EURs of the rest of the hotspots were not developed due to lack of specification information. The key outcomes of the research include the carbon hotspots of office buildings leading to the development of an early design stage EC prediction model and the concept of developing EC-EUR benchmarks which are not established at the moment and hence, fill the knowledge gap in the literature.

Keywords: carbon hotspots, Embodied Carbon Element Unit Rate (EC-EUR), Element Unit Quantity (EUQ), office buildings

1. INTRODUCTION

A hotspot may mean different things to different people from different discipline. RICS (2014) defines 'carbon hotspot' as the carbon significant aspect of a project which can be building elements or other aspects in supply chain. However, carbon hotspots in this research refers to the carbon critical or significant building elements. RICS (2014) further extends that carbon hotspots are not only carbon intensive but also easily measurable and carbon reduction is possible. Pareto Principle defines that 80% of the results (or consequences) are attributable to 20% of the causes which implies unequal relationship between the inputs and the outputs (Koch, 2011, Delers, 2015). According to 80:20 Pareto rule, it can be assumed that 80% of embodied emissions are caused by 20% of building elements (yet to be proved). These carbon hotspots may vary from one building to the other depending on the type or function of the building (Ashworth and Perera, 2015).

Monahan and Powell (2011) highlighted the importance of identifying hotspots in buildings by modelling a two storied residential building (in the UK) in three different scenarios – timber frame and larch cladding, timber frame and brick cladding, conventional masonry cavity wall. The substructure (including foundation and ground floor) accounted for 50% of embodied carbon in timber frame and larch cladding building and substructure, external walls and roof were identified as the carbon hotspots in the building (elements responsible for 81% of embodied carbon, however, not all the building elements were included in the accounting). Further, the same building (timber frame with larch cladding) substituted with timber frame and brick cladding and conventional masonry resulted in additional embodied carbon of 32% and 51% respectively. The majority of difference in embodied carbon was found to be attributed to the difference in foundations and external walls. The findings of the study (Monahan & Powell, 2011) reveal substructure and external walls as 'carbon hotspots' in the particular residential building and highlight the potential for embodied carbon reduction.

Shafiq et al. (2015) studied a two storied office building in Malaysia by modelling six different scenarios for structural composition using Building Information Model (BIM). However, Shafiq et al. (2015) used UK databases to estimate embodied carbon due to lack of embodied carbon databases in Malaysia. Different grades or classes of concrete and steel were combined to generated different composition which resulted in different material quantities producing varying embodied carbon impacts. Only few elements were studied including foundation, beams, slabs, columns and staircases which can be related to substructure, frame, upper floors and stairs as per NRM element classification. Shafiq et al. (2015) found that it was possible to reduce up to 31% of embodied carbon by designing these elements with different classes of concrete and steel to meet the given design criteria. However, it should be noted that only the elements that consititute concrete and steel are considered because concrete and steel are considered as the main structural building materials and emit high embodied carbon during production. Particulalry, upper floors were identifed as the key carbon hotspot followed by substructure, frame and stairs.

It is clear that embodied carbon studies in different types of buildings highlighted above (Monahan & Powell, 2011; Shafiq et al, 2015) has different focus and hence, limit the analysis to few elements. However, analysis of the whole building will provide a holistic picture of the embodied carbon contribution of each element and will highlight the potential areas for carbon reduction. Generally, floors (ground and upper floors), frame, external wall and roof are identified as carbon hotspots in building case studies (Clark, 2013, Davies et al., 2014, Halcrow Yolles, 2010). However, the knowledge of carbon hotspots is still obscure and there is a need for research in this area especially to facilitate early design stage EC estimating as proposed by Victoria et al. (2016).

2. THE METHOD

Historical data were obtained from a QS consultancy practice which include embodied carbon estimates of twenty-eight (28) office buildings prepared in an NRM compliant element standard. Carbon hotspots were analysed using the Pareto principle which suggest that 80% of the results (or consequences) are attributable to 20% of the causes which implies unequal relationship between the inputs and the outputs (Koch, 2011, Delers, 2015). The same 80:20 theory was used to identify the carbon hotspots in the buildings due to its popularity and applicability in especially, economics, business and management related areas. Consequently, it was deduced that 80% of the EC is coming from 20% of the building elements. These 20% of the building elements are named as the 'carbon hotspots' in the context of the research. Even though 80:20 is accepted as the universal ratio, Pareto Principle neither dictates that the 80:20 ratio is applied to all the situation nor should the two figures add up to 100 (say, it could be 90:10 or 80:30) (Business Balls, 2016). Therefore, this ratio is also tested in the case of the relationship between embodied carbon (and cost) and building elements.

The elements contributing up to 80% of the EC were identified as shown in Error! Reference source not found.. irstly, embodied carbon of individual elements was estimated and the percentage contribution was calculated. Then, the elements were arranged in descending order based on the EC intensity. Then, cumulative percentage was calculated to draw a cut-off point at 80% as shown in Error! Reference source not found..

Building Elements (NRM compliant)	Embodied Carbon % (in descending order)	Cumulative Embodied Carbon%
2A Frame	38.54	38.5
2E External walls	20.30	58.8
5 Services	13.82	72.7
1A Substructures	9.90	82.6
2B Upper floors	6.71	89.3
2C Roof	3.94	93.2
2D Stairs	2.44	95.7
2G Internal walls and partitions	1.66	97.3
3B Floor finishes	1.50	98.8
4A Fittings and furnishings	0.43	99.2
3A Wall finishes	0.34	99.6
2H Internal doors	0.32	99.9
3C Ceiling finishes	0.09	100.0
2F Windows and external doors	0.01	100.0

Table 1: Identifying carbon hotspots of a building – an example

According to the example presented in Error! Reference source not found., Frame, External Walls, Services and ubstructure are the identified as the carbon hotspots of the particular building and 28% of the building elements (4 of the 14 elements) are being responsible for the 80% of the embodied carbon emissions form the example building. The carbon hotspots of the sample (28 buildings) were calculated in this manner by using the average EC values of the elements. In addition to that, descriptive statistics (mean, minimum, maximum and standard deviation) were also presented to convey the dispersion of the sample analysed.

The identification of the carbon hotspots lead to the development of the early design stage EC prediction model for office buildings based on the idea proposed by Victoria et al. (2016). The proposed concept of Victoria et al. (2016) suggest that the sum of the product of EUQ and EC-EURs of the carbon hotspots and the residuals will yield the EC of the building. Consequently, EUQs of the carbon hotspots were defined using BCIS and EC-EURs were also calculated using 'mean' while minimum, maximum and standard deviation were also presented to enable the readers to understand the data dispersion.

3. FINDINGS

3.1 Carbon hotpots

Carbon hotspots of the sample were analysed using 80:20 Pareto Rule as described in the method. Accordingly the carbon hotspots (building elements contributing up to 80% of the EC emissions in descending order) were identified and plotted in a table as shown in Error! Reference source not found.. Accordingly, each row epresents a building and the elements that were identified as carbon hotspot in the respective building were marked with a 'x'. Last row of the table presents the probability of each element being identified as a hotspot in the sample. Accordingly, Frame found to be a hotspot in all the buildings; Substructure and Services found to be a hotspot in 90% of the buildings; and External Walls found to be a hotspot in 80% of the buildings in the sample. On the other hand, elements like Stairs, Internal Doors, Wall Finishes, Ceiling Finishes and Fittings and Furnishings were not found as hotspots in any of the buildings in the sample. Rest of the elements were found to be hotspots in some of the buildings.

Building ID	1A Substructures	2A Frame	2B Upper floors	2C Roof	2D Stairs	2E External walls	2F Windows and external doors	2G Internal walls and partitions	2H Internal doors	3A Wall finishes	3B Floor finishes	3C Ceiling finishes	4A Fittings and furnishings	5 Services

#D1002	x	x				x								x
#D1003	x	x	x			x								
#D1004	x	x				x								x
#D1005	x	x				x								x
. . . .														
#D1028	x	x	x			x								x
Probability of occurrence	0.9	1	0.6	0.1	0	0.8	0.11	0	0	0	0.2	0	0	0.9

Table 2: Example of identifying carbon hotspots of the sample buildings

Descriptive statistics of EC per GIFA of the sample for each element are presented in Error! Reference source ot found.. Elements are presented in a descending order according to their EC intensities. Further, cumulative EC percentage was also calculated to identify the elements responsible for 80% of the EC emissions. Frame, Substructure, External Walls, Services and Upper Floors (highlighted in greyscale) were identified as carbon hotspots in the sample. Findings suggest that 36% of the elements are responsible for 80% of the EC emissions. Also, it can be noticed that the standard deviation is comparatively high for the hotspots which implies EC-EUR range is wide for these elements.

Element	Average EC per GIFA (kgCO_2 per m^2)	Minimum	Maximum	Standard Deviation	Cumulative EC %
2A Frame	236.72	98.00	486.41	101.13	30.1
1A Substructures	137.20	33.21	320.72	65.31	47.5
2E External Walls	111.24	8.37	265.80	63.35	61.6
5 Services	106.81	6.63	192.88	50.16	75.2
2B Upper Floors	75.99	1.72	191.08	38.68	84.8
3B Floor Finishes	37.69	0.39	97.77	28.82	89.6
2C Roof	25.05	2.88	103.25	19.69	92.8
2G Internal Walls and Partitions	20.14	1.19	64.37	15.97	95.3
2F Windows and External Doors	15.20	0.02	157.64	35.20	97.3
3C Ceiling Finishes	8.55	0.65	24.62	6.05	98.3
2D Stairs	7.00	2.47	21.46	5.01	99.2
3A Wall Finishes	3.65	0.22	18.47	4.23	99.7
2H Internal Doors	1.50	0.12	7.32	1.79	99.9
4A Fittings and Furnishings	0.86	0.02	3.39	1.15	100.0
EC of the building	785.31	431.61	1,368.17	215.92	

Table 3: Descriptive statistics of the sample

3.2 The proposed EC model

Based on the carbon hotspot analysis of the sample, the proposed idea by Victoria et al. (2016) for an early stage EC model can be presented as follows for office buildings:

$$EC = EUQ_{Fr}.EUR_{Fr} + EUQ_{Sub}.EUR_{Sub} + EUQ_{EW}.EUR_{EW} + EUQ_{Ser}.EUR_{Ser} + EUQ_{UF}.EUR_{UF} + k$$

EC - EC of the Building
EUQ_F - Element Unit Quantity of Frame
EUR_F - Element Unit Rate of Frame
EUQ_{Sub} - Element Unit Quantity of Substructure
EUR_{Sub} - Element Unit Rate of Substructure
EUQ_{EW} - Element Unit Quantity of External Walls
EUR_{EW} - Element Unit Rate of External Walls
EUQ_{Ser} - Element Unit Quantity of Services
EUR_{Ser} - Element Unit Rate of Services
EUQ_{UF} - Element Unit Quantity of Upper Floor
EUR_{UF} - Element Unit Rate of Upper Floor
k - Minor EC components of the rest of the elements (20% of EC emissions)

Equation 1

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

According to the proposed EC model for office buildings, EUQs have to be defined in a standard way and EC-EURs need to be developed for the identified elements in the model. NRM compliant Building Cost Information Services (BCIS) defines the measurement rules for EUQs of the elements which is adopted as the standard definition of the EUQs of the identified hotspots. However, in the case of Services, each type of service is measured in different unit of measurements. For instance, Sanitary Installations are measured in Nr while Water Installations are measured as floor area serviced by water installations (m2). However, details such as number of appliances and service equipment are less likely available during early design stage. Hence, GIFA was selected as the appropriate EUQ for Services. Error! Reference source not found. presents the definitions adopted for EUQs of he selected carbon hotspots.

Elements	EUQ
Frame	GIFA - area of a building measured to the internal face of the perimeter walls at each floor level (m^2).
Substructure	Area of lowest floor measured to the internal face of the external wall (as for GIFA) (m^2).
External Walls	Area of external walls measured on the inner face (excluding openings) (m^2).
Services	GIFA – same as for Frame (m^2).
Upper Floors	Area of upper floor measured to the internal face of the external wall (as for GIFA) (m^2).

Table 4: Definitions of EUQs for the identified carbon hotspots from NRM compliant BCIS

3.3 Developing EC-EURs

The next step in using the model is to develop EC-EURs for possible alternative design options of the identified carbon hotspots. Based on a survey of 41 buildings from BCIS online database, the design options which were found to be predominant in the office buildings are presented in Error! Reference source not found..

Elements	Design options
Frame	Concrete, steel and hybrid
Substructure	Pile, raft, pad and strip
External Walls	Cavity and curtain walls
Services	Non-air-conditioned, air-conditioned – with and without BMS or lift installations
Upper Floors	In-situ concrete floors, pre-cast concrete floors, metal decking and timber floors

Table 5: Typical design options for the identified carbon hotspots

Consequently, EC-EURs were developed for the identified design options using the available EC data. Frame EC-EURs of the sample (28 buildings) are presented in Error! Reference source not found. where the sample size f each design option is indicated in parentheses. It can be noted that the EC-EUR of the concrete frame is derived from one (1) building which cannot be considered as a representative of the population. Similarly, hybrid frame EC-EUR is also calculated from three (3) buildings which is also unsatisfactory. In comparison to concrete and hybrid frames, steel frame EC-EUR has been derived from a larger sample with fourteen (14) buildings though the sample size is not statistically significant. Hence, a larger sample is required to benchmark EC-EURs.

Frame	Average EC per GIFA	Minimum EC per GIFA	Maximum EC per GIFA	Standard Deviation
	kgCO$_2$/ m^2			
Concrete (1)	108.51	-	-	-
Steel (14)	242.86	98.00	486.41	104.87
Hybrid (3)	230.36	191.49	291.38	53.50

Table 6: EC-EURs for the possible design options of frame

Further, EC-EURs of the other elements could not be developed due to the unavailability of specification information of the rest of the elements of the sample buildings.

4. CONCLUSIONS

Application of a proposed EC estimating method is presented in this paper using the concept of carbon hotpots. Carbon hotspots in this research context is defined as the carbon critical building elements. Frame, Substructure, External Walls, Services and Upper Floors were identified as the carbon hotspots of the selected sample whose EC-EUR range is wider than the other elements. Also, 80:20 Pareto Rule was not supported in the research context instead the findings propose an 80:36 ratio for EC of office buildings which implies that the 80% of EC emissions in office buildings are attributable to 36% of the building elements. However, the findings are based on a sample of 28 buildings and hence, are not generalised which is a limitation of the study. However, the study can be repeated with a larger sample to attain statistically significant results. Further, there is also a need for a larger sample to benchmark EC-EURs for alternative design options of the identified carbon hotspots. Developing such EC-EURs will facilitate EC estimating during early stages of design which has the potential for huge emission reductions.

ABSTRACT

The transition to the offsite construction and manufacture of buildings stands to create a lucrative opportunity for the global building sector. The shift to the manufacture of buildings stands to generate numerous benefits including economic benefits (such as construction times for major commercial construction projects substantially, social benefits (significantly improving workplace occupational health and safety by bringing the majority of building construction indoors), and environmental benefits (through reduced materials wastage, reduced materials transportation, greater inclusion of energy and water efficient elements, and the potential for greater use of recycled materials). This paper explores a range of factors that affect the attractiveness of such benefits along with the perception of the associated risks related to the fact that for instance in order to provide the access to capital needed to significantly upscale building manufacture long standing financing structures need to be redesigned in the building sector related to providing progress payments and dealing with completion risk.

The paper is informed by an industry workshop held by Sustainable Built Environment National Research Centre (SBEnrc) in Australia, in collaboration with the EU Centre for Global Affairs at the University of Adelaide and prefabAUS, on the topic of "Capturing Opportunities from Financing Offset Building Manufacture". The workshop was held as an official partner event as part of the European Union's Green Week 2016. The workshop was well attended with 25 representatives from banks, builders, government agencies and researchers. In-line with the Green Week theme of "Investing in the Future" the workshop focused on how the banking community perceived risks and rewards from investing in the manufacture of buildings in Australia.

Keywords: building manufacture, construction risk, innovation

1. INTRODUCTION

The transition to the offsite construction and manufacture of buildings stands to create a lucrative opportunity for the global building sector. The shift to the manufacture of buildings stands to reduce a number of impacts including economic (reducing the time homebuyers rent while their home is constructed), social (significantly improving workplace occupational health and safety by bringing the majority of building construction indoors), and environmentally (through reduced materials wastage, reduced materials transportation, greater inclusion of energy and water efficient elements, and the potential for greater use of recycled materials).

In 2012 the economic output from the manufacture of buildings globally was estimated at just over US$90 billion, up from $60 billion in 2011. Asia-Pacific was the largest regional market in 2012, worth just under $60 billion, outperforming all other regional markets, and set to rise to some $100 billion by 2020. In 2014 the largest regional market was Asia-Pacific valued at US$44.4 billion, followed by Europe at US$31.5 billion, and North America at US$10.2 billion. China constituted the largest share of the Asia-Pacific market with just over 60% in 2012, followed by Japan at 22%, Australia at 7%, and Indonesia at 5%. The growing number of case studies and examples of manufacturing buildings provides quantifiable data that can inform efforts to capture the opportunities by providing strong evidence to developers, investors, and homebuyers.

There is great potential for the manufacture of buildings to be harnessed to significantly strengthen both the building and manufacturing sectors. Domestic building industries around the world will face strong international competition in the near future, especially as the quality of imported prefabricated and manufactured building offerings is increasing and the price is decreasing. If not considered as part of a strategic transition such competition can have significant impacts on domestic construction industries with an Australian study suggesting that Australian imports

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

of buildings are anticipated to reach a value of $30 billion by 2025, which could displace as many as 75,000 jobs nationally. Hence the transition to manufactured buildings needs be undertaken in such a way as to harness a nations existing pool of skills and trades so as to allow workforce transitioning in a manner that strengthens industry.

A leading example is the 'Little Hero Apartments in Melbourne Australia that demonstrated the savings possible, from time to safety improvements. Built by Hickory for Delphine Holdings, Little Hero Apartments is an eight storey building, comprised of 75 prefabricated modules which were able to be assembled on site in just 10 days – significantly reducing the interruption to traffic in the CBD of Melbourne associated with onsite construction methods. The total project time was 9 months, which reduced the construction time by at least 6 months when compared to an onsite build, fast tracking the return on investment.

2. BENEFITS OF OFFSITE CONSTRUCTION

Research by the Australian Sustainable Built Environment National Research Centre has shown that building manufacture allows for cost savings, faster delivery times, and the reduction of a number of impacts associated with on-site building construction methods, such as:

- Cost savings

The shift to prefabrication of buildings stands to deliver a range of cost savings to developers, builders, and owners. The greatest cost benefits are achievable in projects where replicable structures are used, such as apartments, housing developments, hotels, student accommodation, classrooms, prisons, and mining accommodations. Direct costs savings are achieved from the faster delivery of buildings using prefabrication methods, along with reductions in construction waste both from design and higher reuse of materials, weather damage of materials, damage caused from onsite handling in often restricted sites with multiple trades, and the elimination of vandalism and site theft during construction. The potential for such savings opens up the opportunity for the greater provision of affordable and social housing along with the provision of a higher level of quality and non-standard inclusions in residential and commercial buildings. In particular it would make 'sustainability' related inclusions that can deliver lower operating costs to occupants and owners more economically feasible at the construction stage (especially energy related inclusions).

- Faster delivery

The shift to the manufacture of buildings stands to significantly reduce construction times, along with reducing onsite delays often caused by waiting for materials delivery, coordinating service providers and subcontractors, and from inclement weather. Reducing construction times can lead to a range of benefits such as reducing the cost of fees on land taxes, equipment hire, fuel bills, and staff on-costs. The shift will also allow a greater volume of buildings to be delivered as not only is the construction time shorter it can be carried out at the same time as site preparation (i.e. footings, retaining walls, and landscaping). This is important as the shift is likely to reduce the labour requirement of individual buildings so it will be important to compensate with a growth in building output.

- Improved work place conditions

The shift to the manufacture of buildings in dedicated facilities will provide a number of improvements to workplace conditions, including:

  - Protection from weather and other hazards for both workers and materials, along with the provision of appropriate lighting levels 24 hours a day,
  - Provision for use of central power tool facilities rather than the reliance on hand tools or portable power tools onsite, and
  - Greater ability to provide elevated platforms, mini cranes, roped harnesses, and other safety equipment due to construction undertaken in a fixed facility with flat floors and overhead beams.

Furthermore, the shift to a centralised facility leads to a number of benefits such as greater flexibility in supplier choice as materials can be stockpiled rather than being needed on demand at multiple sites across a city or region, a regular delivery location with dedicated loading bay facilities reducing transportation costs of supplies, and the assurance that there will be someone to sign for materials at the facility.

On the 24th of July the Sustainable Built Environment National Research Centre (SBEnrc), in collaboration with the EU Centre for Global Affairs at the University of Adelaide and prefabAUS, held an Industry Stakeholder workshop in Perth, WA, at the WA Club on the topic of “Capturing Opportunities from Financing Offset Building Manufacture”. The workshop was held as an official partner event as part of the European Union’s Green Week 2016. The workshop was well attended with 25 representatives from banks, builders, government agencies and researchers. In-line with the Green Week theme of “Investing in the Future” the workshop focused on how the banking community perceived risks and rewards from investing in the manufacture of buildings in Australia.

- Reduced risk of delays

Faster construction times and a focus on greater quality construction will reduce the risk that the project will be delayed, especially from supply issues or weather related delays. This reduces a number of risks, such as delayed mortgage payments, delayed rental payments, and delayed occupancy dates for hotels.

  - When asked how valuable the reduced risk of delays was to lenders and investors just over 35% responded ‘Very High’ with a further 35% responding ‘High’ and 25% responding ‘Moderate’, suggesting that this provided tangible value.

- Reduced risk of variations

A manufacturing approach shifts focus from assuming that variations can be undertaken onsite, to getting it right the first time. This is achieved by eliminating defects and ensuring consistent quality in design, workmanship, and materials, hence avoiding costly variations.

  - When asked how valuable the reduced risk of variations was to lenders and investors some 28% responded ‘Very High’ with a further 34% responding ‘High’ and 24% responding ‘Moderate’.

- Increased construction safety

A factory environment for building construction allows improved workplace occupational health and safety that will reduce the number of work place accidents and injuries and the associated impacts.

  - When asked how valuable the reduced risk of variations was to lenders and investors just under 32% responded ‘Very High’ with a further 25% responding ‘High’ and 44% responding ‘Moderate’ (with no respondents indicating ‘Low’ or ‘Very Low’).

- Greater return on equity

The faster construction times mean that return on equity can be increased by completing a project sooner and re-investing the capital in subsequent projects, especially on commercial projects. Given the faster construction time the initial capital could be invested into multiple subsequent projects in the same time that it would take to deliver an onsite construction project.

  - When asked how valuable the greater return on equity was to lenders and investors some 20% responded ‘Very High’ with a further 60% responding ‘High’ and 20% responding ‘Moderate’ (with no respondents indicating ‘Low’ or ‘Very Low’).

- More attractive to home buyers

Given faster construction times, homebuyers are likely to be interested in reducing the time they wait for their home to be built, which not only reduces the amount paid in rent or alternate accommodation but also sees them occupying the property sooner and hence paying the mortgage.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

  - When asked how valuable the potential for greater appeal to homebuyers was to lenders and investors just over 22% responded 'Very High' with a further 56% responding 'High' and 17% responding 'Moderate'.

- Less theft, vandalism or damage of materials

Given the construction is undertaken in a factory environment materials and tools can be better protected from weather conditions and from theft. Such costs can increase the construction cost and cause delays.

  - When asked how valuable the potential for less theft, vandalism or damage of materials was to investors/financiers just under 18% responded 'Very High' with a further 30% responding 'High' and 42% responding 'Moderate'.

- Reduced materials costs

A central facility allows for 24 hour receipt of bulk orders with secure storage which will reduce costs and delays. Further materials can easily be reused which can reduce waste by 30-40%, reducing wasted materials and dumping costs.

  - When asked how valuable the potential for reduced materials costs was to lenders and investors just under 12% responded 'Very High' with a further 53% responding 'High' and 35% responding 'Moderate' (with no respondents indicating 'Low' or 'Very Low').

- Land value unaffected until completion

As construction is offsite the land value of the intended site is not affected should the construction be interrupted, postponed, or abandoned. Rather the near complete building is delivered to site, maximising the lands utility and worth throughout the construction phase.

  - When asked how valuable it would be to lenders and investors that the land value was unaffected until close to completion just over 6% responded 'Very High' with a further 38% responding 'High' and 44% responding 'Moderate'.

- Greater security on completion risk

Given the construction is undertaken in a centralised facility the majority of the tools and equipment are owned by the manufacturer and can be used as security for loans, rather than these assets being owned by independent trade contractors.

  - When asked how valuable it would be to lenders and investors to have greater securing on completion risks no respondents indicated its importance was 'Very High', 23% responded that it would be 'High' and 46% responding 'Moderate'.

3. WHAT IS HOLDING UP PROGRESS?

The workshop explored the premise that in order to increase the market penetration of offsite construction and building manufacture a number of key challenges need to be addressed related to finance, insurance, and warranty structures with the following findings:

- Negative perceptions

There is a need to shift perceptions of the industry and consumers around manufactured buildings being simply temporary reloadable structures to recognising them as high quality precision built buildings; this may be through independent quality verification, demonstration buildings, community education programs, and qualifying the specific benefits to consumers.

  - When asked how much of a risk the issue around negative perceptions was to lenders and investors nearly 40% responded 'Very High' and a further 40% responded 'High'.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Quality and lifespan

There is a need for a clear and accountable process for the rectification of defects, especially when sourcing building modules from overseas, along with insurance and warrantee structures that support offsite construction and onsite erection. The allocation of responsibility for defects is complicated by the nature of the offsite delivery model in that it can require multiple contractors to undertake offsite construction, module transportation, and onsite preparation and assembly, with each stage able to identify defects and warranty issues.

  - When asked how much of a risk the issue around quality and lifespan was to lenders and investors nearly 30% responded 'Low' and just under 45% responded 'Moderate'.

A key element in ensuring the quality of buildings constructed offsite using prefabrication and/or manufacturing based processes is the provision of associated design codes and standards that can be assessed for compliance. In the USA, the U.S. Department of Housing and Urban Development can created a construction and safely standard for offsite construction and building manufacture, the 'Manufactured Home Construction and Safety Standards'. This standard classifies a manufacture home as one that is 'constructed on a permanent chassis' and provides standards for design, construction, and installation of manufactured homes to assure the quality, durability, safety, and affordability. The standards include a dispute resolution component along with the provision for inspections and record keeping.

A second key way to provide assurance of quality is through the provision of a warranty or assurance scheme. For example in Japan building owners are provided with a standard 20 year warranty which entails strong after sales service. In the UK efforts to increase the viability of securing construction financing have focused on providing independent certification of the processes used in offsite construction and building manufacture in collaboration with the Council of Mortgage Lenders. The 'Build Offsite Property Assurance Scheme' (BOPAS) seeks to provide assurance to lending institutions that buildings constructed offsite are sufficiently energy efficient and durable and will be readably saleable for a minimum of 60 years.

- Completion risk

There is also uncertainty around managing completion risk, such that the building is in the possession of the manufacturer up until delivery and may not be able to be easily completed should the manufacture halt operations (this may be affected by issues related to intellectual property of manufacturing methods hindering a shift in manufacturer if required). This also presents a risk to the builder or manufacturer as clients many not provide purchase confirmation until the building is delivered and able to be used for collateral for loans, leaving open the potential to withdraw part-way through the offsite construction or not being able to secure a loan at time of delivery.

  - When asked how much of a risk the issue around completion risk was to lenders and investors nearly 65% responded 'High' and just under 12% responded 'Low' or 'Very Low'.

- Progress payments

In order to provide the access to capital needed to significantly upscale building manufacture, and capture the associated benefits, long standing financing structures need to be redesigned in the building sector that are on progress payments at different stages of onsite construction rather than being able to support factory style construction prior to transportation to site of completed product for erection. Issues related to the lack of a standardised quality assessment process for offsite construction along with gaps in current building standards and codes complicate matters.

  - When asked how much of a risk the issue around progress payments was to lenders and investors nearly 70% responded 'High' (25%) or 'Very High' (44%) and no respondents indicated the risk was low.

Considering the progress payments related risk, lending institutions are however accustomed to releasing funds for buildings constructed offsite after the building has been placed on site. The stage at which funds are released varies between lenders from when the building is installed on approved footings to when a certificate of occupancy has been issued. Hence the issue of progress payments is currently being overcome by developers, or even the

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

building manufacturers, providing the funding required for the construction phase to then allow customers to seek purchasing finance based on the completed building. Although this model allows for the client or owner to secure traditional loan products based on a completed building there are two draw backs that are hindering the growth of the industry. Firstly it lends itself to large companies who can afford to provide construction phase financing, with smaller operators having to mortgage their own assets (or requiring customers that have appropriate assets to leverage), and secondly it means that the risk is carried by the builder or manufacturer until payment is made. Since the purchase finance cannot be secured prior to the construction stage this leaves the builder open to risks like the customer not being able to secure funding after the building is complete, or having the client change their mind before the building is completed.

4. CONCLUSION

At a project level there are numerous economic, social, and environmental benefits associated with building manufacture or offsite construction. According to research by the Australian Sustainable Built Environment National Research Centre (SBEnrc, 2014), new approaches to design, materials, and expanding the use of modular techniques can take advantage of faster fabrication times, lower costs, less waste, high quality standards, and shorter onsite construction periods. These enhanced outcomes provide benefits to both the builders and the financiers.

In order to capture the potential of building manufacture the building sector needs to quickly develop the infrastructure for the construction of buildings in centralised facilities and their transport and erection on site. This may involve a transition strategy that includes an initial push for the use of panelised onsite construction to build momentum in the manufacture and erection of prefabricated components and modules. It is particularly important to develop the sector in a manner that takes advantage of the cost effectiveness of sourcing building modules off-shore, otherwise such offerings may compete with domestic construction. Hence, if countries slow to invest in this new sector do not seize the opportunity, offshore interests will certainly continue to bring them to market, which if not harnessed as part of the sectors overall development could lead to job losses across the building sector and its supply chain.

ABSTRACT

Ambitious climate change targets are transforming how new and renovated buildings are designed and constructed. As the industry seeks to significantly reduce built form energy use, carbon emissions and, ultimately, strive for net-zero - or better yet, net-positive - the professionals engaged in meeting these challenges must grasp a new way of thinking about energy use and design. ecoMetrics was developed to reveal the energy modelling data for a portfolio of projects and thereby inform decision making. It also seeks to expose the key integrated passive and active systems that drive energy use down. The goal is to present data gleaned from energy modelling results that can be understood by non-energy experts in graphic, accessible terms.

The architects and engineers who developed ecoMetrics believe improving energy literacy and transparency is a necessary and fundamental step in advancing the outcome of the challenges we all face to realize the urgency of significant energy use and carbon emission reduction in building design.

Keywords: architecture 2030, big data, energy metrics

1. ENERGY LITERACY

The sharing of information is a key tenet of the integrated design process (IDP) that drives most of today's energy-efficient building projects. Energy metrics are complex, difficult to understand and opaque for most non-engineers, which limits the conversation and exploration of deeper energy reductions. There is a vast array of energy reduction programs and benchmarks - Building Codes based on ASHRAE and MNECB, LEED and the 2030 Challenge all have different energy use approaches and metrics.

During the design phases of a project, energy simulation modelling informs decision-making. Energy simulation models are typically developed and submitted for review for LEED projects and more recently for building permits. Quick access to energy use in our portfolio of buildings has been elusive until we created an internal data bank. We strove to frame modeled data in a way that is meaningful to the architectural profession. Simply, we unpack the energy simulation models for our projects and reveal the data in accessible graphic terms. If we can understand it, we can explain it. Similarly, if we can understand it, we can manage it. To this end, we created a series of custom templates or lenses through which to view the enormous amount of data contained in energy models; data that we typically never see. The result is ecoMetrics an in-house tool that democratizes the energy-use conversation and decision-making.

ecoMetrics is a live, interactive database that currently showcases building energy simulation model results for over 50 completed Diamond Schmitt Architects' projects. It contains templates for various purposes: energy literacy, benchmarking, design and data management.

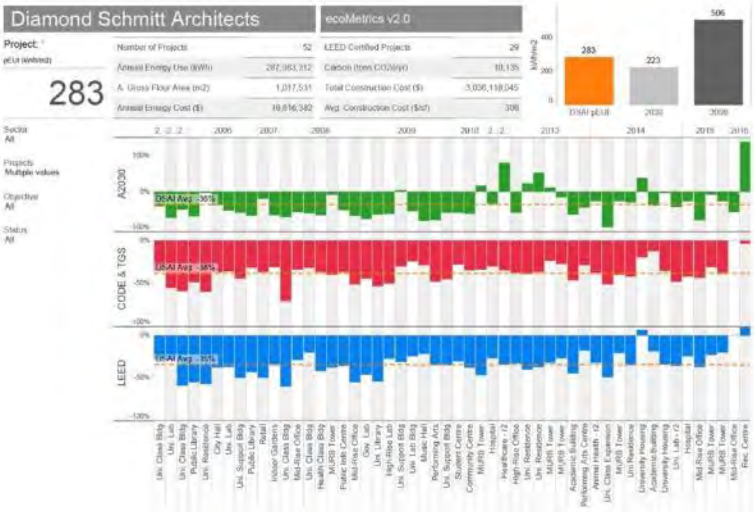

Table 1: The Benchmark Comparison template highlights differences between prevailing energy metric systems. The 2030 Challenge is based on kWhr/m²/year as compared to a building of its type in its region. Canadian codes and LEED are compared to a reference building of identical configuration as the design building. Codes assess energy while LEED assesses cost of energy. The comparison template shows greatest divergence between the 2030 challenge and the code / LEED methods.

The following Tables 2, 3 and 4 highlight several of the databanks key templates:

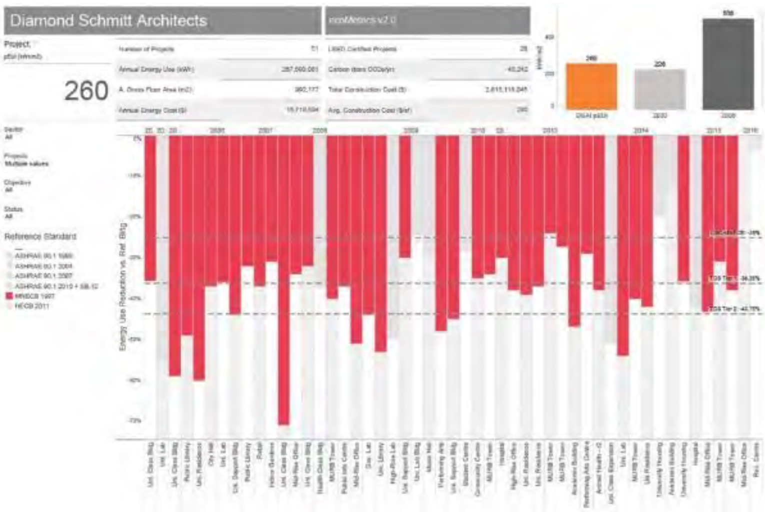

Table 2: The Building Code Template shows 51 uploaded projects. Red bars represent those projects modelled as compared with the MNECB (Model National Energy Code for Buildings). Grey bars represent projects modelled as compared to ASHRAE; these are carried on a separate template. The longer the red bar the greater the energy reduction of the building. The upper dashed horizontal line indicates the OBC-SB-10 25% energy reduction, which is a mandatory reduction required to obtain a building permit in Ontario. The middle dashed line represents Toronto Green Standards (TGS) Tier 1, which has a 36.25% energy reduction requirement for building permit in Toronto. The lowest dashed line represents TGS Tier 2, which is a voluntary, and incentivised 43.75% energy reduction target. This template instantly allows us to see how our building portfolio performs relative to these code requirements and to each other.

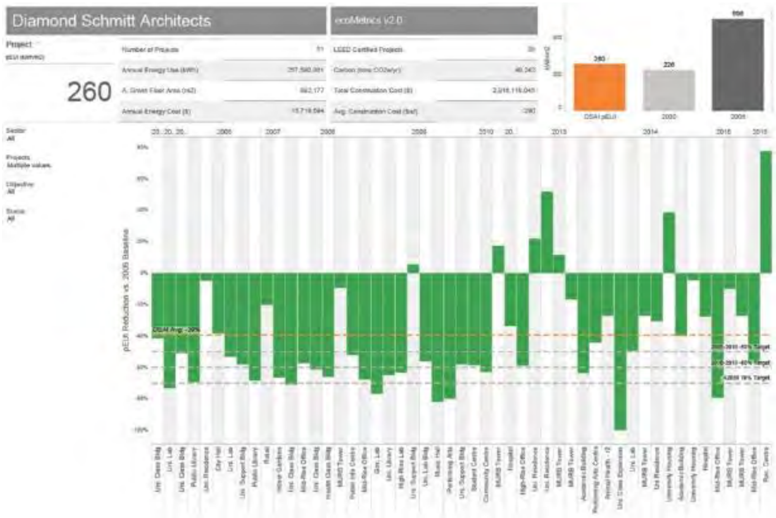

Table 3: 2030 Challenge Template shows 51 uploaded projects. Green bars represent modelled energy reductions relative building type as set out by NRCAN. The longer the green bar below 0% line, the greater the energy reduction. The orange dashed line is the portfolio average. The top grey dashed line indicates a 50% reduction, the target for projects tendered before 2010. The middle dashed grey line indicates a 60% reduction, the target between 2010 and 2015. The lowest dashed grey line indicates a 70% reduction, the target for projects tendered between 2015 and 2020. Those projects with green bars above the line are predominantly MURB (Mixed Use Residential) Towers and Student Residence towers. These projects all meet code but not the baseline carried by 2030 Challenge.

The energy metric approach set out in the 2030 Challenge led us to explore the comparison of energy uses as chronicled in the following template which focuses on Energy Use Intensity (EUI).

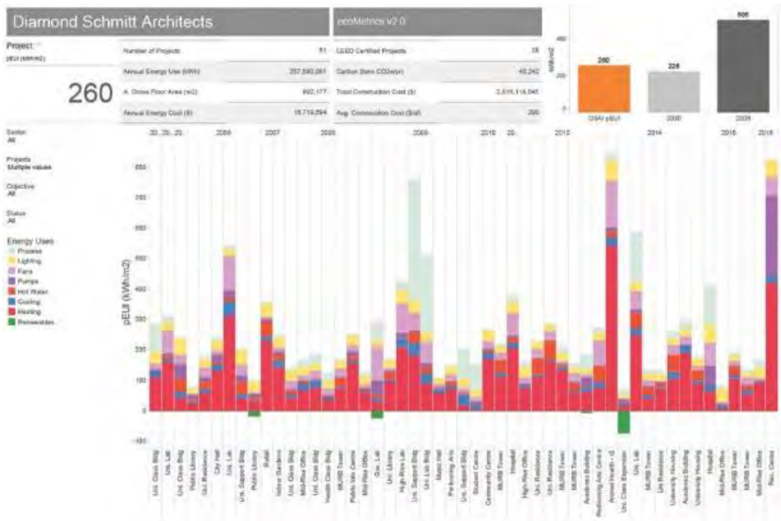

Table 4: The Energy Use template reveals modeled kWhr/m2/yr statistics for the main categories of end energy uses (heating, cooling, pumps, domestic HW, fans, lighting, process loads) and exposes energy use as an apples to apples comparison between projects. Colours represent major energy uses above the 0 line and renewable energy in green below. The light blue tone at the top of each column represents the process (or plug) loads. These process loads are influenced by building function and client expectations. On a few projects, the process loads are equal to the building operation loads, highlighting the importance of client participation when striving towards zero energy. The Uni. Class Expansion project (13th column from the right) is a net-zero energy and carbon project; renewable energy matches energy use.

The data contained in these templates increases our understanding of the prevailing energy use methods and how our projects perform within each framework.

Energy literacy and access to key data from the portfolio can form a foundation for new design projects. Fully integrated design, where architecture and engineered systems are designed in lockstep for optimal energy performance, is essential for high performance and net-zero buildings. Gaining insight into the architectural (passive) parameters is a useful starting point for early design modeling.

Table 5: The Architectural template has been developed to capture passive (non-system) model inputs such as building envelope thermal performances, window-to-wall ratios, floor-area-to-perimeter ratios, which provide valuable insight into correlations between building EUI (Energy Use Intensity) and strategies to reduce energy use through built form and design. The template below shows Educational Building Types sorted with most efficient EUI to the left. This provides a data set to inform the design of new projects and guide early stage shoebox massing model comparisons.

Curiosity to explore the integration of passive and active systems has led to the vital signs template that is described further in section 6 below.

The ecoMetrics databank is visually accessible and interactive; this data empowers us, our design teams and clients with a foundation for decision-making during design; it raises our collective understanding of energy targets and provides access to the methods used for deep energy reductions using our portfolio of projects as reference.

2. BENCHMAKING AND SETTING TARGETS

As we strive towards designing net-zero and net-positive or regenerative buildings, we incrementally work towards increasingly high performance buildings. We have recognized that setting an energy reduction target is a powerful driver for the team that focuses effort and improves results.

Evolving code requirements are also a potent driver for change as building permit issuance is subject to design compliance. OBC-SB10 increased energy performance requirements for the province of Ontario. Toronto Green Standards Tier 1 further increased the requirement for metropolitan Toronto. In both cases obtaining a building permit is contingent on following a prescriptive path or demonstrating compliance through an energy simulation model submission.

Energy reduction incentives provided in programs such as the Toronto Green Standards Tier 2 encourage clients to aim for greater reductions. The modelled performance of past projects is a valuable resource for both client and the design team to make decisions about the appropriate energy reduction target. Precedent high performance projects engender confidence for clients to aim as high or higher.

Case study: When Version 2 of the Toronto Green Standard (TGS) was launched ecoMetrics provided Diamond Schmitt Architects the ability to reassure their clients that the enhanced performance targets that TGS v2 presented were an achievable step forward, not an insurmountable leap. With the development of TGS v3 is in the works we anticipate ecoMetrics being similarly useful when it is released.

Table 6: Code Template selection set to educational and lab buildings. A search selecting academic buildings allows us to instantly see that 100% meet OBC SB-10, 77% meet TGS Tier 1 and 61% meeting TGS Tier 2. Note that Animal Health meets TGS Tier 1.

The 2030 Challenge views energy reduction through another lens based on kWhr/m²/year. This energy reduction program has been adopted by the AIA, RAIC and the OAA and its strength is that it focuses on energy and incrementally increases the energy use reduction by 10% every 5 years to 100% by 2030, with an allowable 20% contributed by renewables. Building performance is adjusted to a baseline for building type and region. We have discovered that projects that do well based on code targets may perform poorly relative to the 2030 challenge. Viewing projects through both lenses helps flag issues and identify opportunities to improve energy performance.

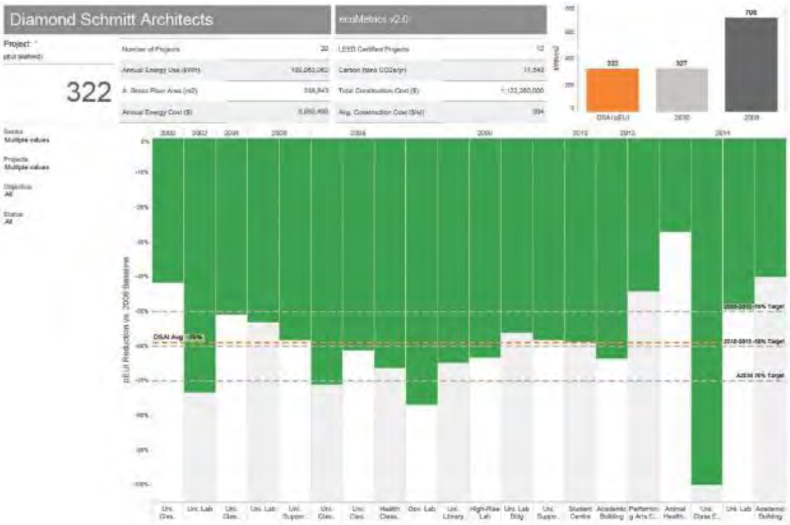

Table 7: 2030 Challenge Template selection set to educational and lab buildings. Note that Animal Health does not perform well relative to 2030 Challenge. The most recent projects to the right show data for several non-LEED projects.

Code officials are taking note; increasingly we are seeing an array of metrics being established to meet minimum program requirements. In Ontario for example, peak electricity demand (kW), carbon intensity (eCO^2/m^2) and energy use reduction vs. a reference building are all required to be reported and meet minimum performance benchmarks. We anticipate this trend to continue as programs that are seen to be on the leading edge, such as Passive House, introduce new metrics such as Thermal Energy Demand Intensity, and infiltration limits. Interpreting and contextualizing metrics will be a critical skill for future building design and we believe tools such as ecoMetrics have great potential in this regard.

The 2015 Paris Climate Change Summit focused on GHG emission reduction. Canada, Ontario and Toronto now have carbon reduction targets, although not identical, they are all ambitious. Across the country there are various approaches being developed that will drive market change, finance significant incentives and penalize large carbon emitters. Carbon is an important new metric and has been included in the ecoMetrics databanks.

Net-zero, net-zero ready and net-positive buildings are emerging within our portfolio, demonstrating that a no carbon future is possible. However, like our LEED Platinum projects, these projects rely on fully integrated passive design and systems design to drive energy use down.

3. LEVERAGING DATA

Many predict that data will be leveraged to provide much needed direction as the green building movement continues to advance. ecoMetrics presents Diamond Schmitt Architects' effort to utilize data from completed projects to advance the work produced by our studio.

In his recent book, The Industries of the Future, Alec Ross, an Innovation Advisor to Hillary Clinton, outlines the current and future technological trends that will be drivers of disruptive change. Mr. Ross identifies 'Big Data' as one of six technologies that will have a broad reaching impact on many, if not most, industries in a similar fashion to the impact of the Internet in the late 1990s. How is the building design, construction and operations industry readying itself to leverage big data?

To date, existing operational buildings are leading the way in the development of large data banks of building energy performance information. For example, since 2011 the Green Energy Act has required all of Ontario's Broader Public Sector (BPS) buildings to report their annual energy use and Greenhouse Gas emissions. Other examples include Local Law 84 in New York City that requires all public and private buildings greater than 50,000 sq. ft. to disclose their energy use and the City of Philadelphia, whose mandatory energy-reporting program has been in place since 2012.

The data banks being developed in Ontario, New York, Philadelphia and by other municipalities around the world are based on data reported from operational 'existing buildings'. The collection of existing building energy performance data is tremendously important and will undoubtedly begin to inform buildings codes, incentive programs, green building standards and carbon reduction strategies. However, the wealth of information available in 'new construction' building design documents presents a large, rich and underleveraged opportunity.

Data such as predicted levels of energy performance, building geometric characteristics, mechanical systems performance, amongst many other metrics, are data points that can be harvested from design information available from new construction projects in a relatively easy fashion. Diamond Schmitt Architects' ecoMetrics provides an example of the data that can be harvested from new construction projects and how graphic representations can be developed to gain insights into the data set.

4. CHECKS AND BALANCES

The role of the architect as the prime consultant often requires taking an oversight role of specialty consultants who are responsible for the completion of studies such as energy models. ecoMetrics provides Diamond Schmitt Architects with a powerful tool to vet energy models prepared by sub-consultants through a quick comparison to other completed projects in the Diamond Schmitt portfolio.

Through growing adoption and rollout of voluntary programs such as LEED, energy codes and regulations and incentive programs, the use of energy modelling to inform design decision-making has become commonplace. As a result, energy modelling and consulting as a discipline has moved from being a niche service performed by specialists to an exercise that is now being completed by designers without the years of experience necessary to interpret the validity of results produced by energy performance software. Programs such as LEED require a third party review of energy models to be completed by experienced experts prior to granting approval. However, such review processes are not typically in place when energy models are being submitted for regulatory purposes such as code compliance. The result is energy models that are of questionable quality and a growing divide between predicted and measured energy performance as a result. ecoMetrics allows for quick, inexpensive screening level reviews of energy models to be completed through a comparison to similar completed projects. If municipalities were to create accessible data banks of submitted energy models, a similar approach could be taken, with the potential to significantly raise the quality and accuracy of energy models.

There is a trend towards completing an early energy model at the concept stage of design to support preliminary decision-making. However, preliminary models are typically based on broad assumptions that can produce

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

misleading results if not checked by an experienced professional. The availability of a data bank of previously completed energy models has the potential to aid in solving this challenge by allowing design teams to compare their results to aggregated results from like projects. Designers at Diamond Schmitt are using ecoMetrics in this fashion to inform Sefaira energy simulations that are being completed at the concept or schematic stages of design.

Case Study: On a recent project, the project's design progress energy model was uploaded to ecoMetrics to find that the proposed energy use intensity far exceeded that of any other project in the tool. Upon further investigation it was noted that the "Vital Sign" (see Section 6) for outdoor air was one of the highest in the portfolio. Identifying this outlier triggered a conversation with the mechanical engineer about the project's approach to ventilation. Through a rezoning exercise and the addition of demand control ventilation in critical spaces the design team was able to reduce the projects total predicted energy use intensity by over 25%.

5. VITAL SIGNS

ecoMetrics has raised the understanding of performance benchmarks such as Energy Use Intensity (EUI) and reduction targets vs. energy codes within the Diamond Schmitt studio. This collective understanding brought forth the next logical question – what do we do about it? Inspired by this question and a paper by Dr. Ted Kesik, Diamond Schmitt Architects and RWDI set out to develop a set of next level indicators that are intent on identifying the architectural and engineering systems that are driving the performance of a given project.

In a 2015 paper, 'Vital Signs: Towards Meaningful Building Performance Indicators' University of Toronto professor Dr. Ted Kesik suggests that the root of the emerging problem with energy simulations is 'a failure to correlate measureable and/or observable physical attributes with key indicators that concisely reveal the critical performance characteristics of buildings'. Dr. Kesik further suggests that there should be a set of building performance indicators, which designers could use to diagnose building performance issues in a similar fashion to how physicians use indicators such as a patient's heart rate and blood pressure to diagnose human health concerns.

Building upon this concept, RWDI and Diamond Schmitt worked to analyse the data set resulting from the ecoMetrics tool to identify and propose a set of 'vital signs'. In this context, vital signs are a set of performance indicators that are intent on identifying the architectural and engineering systems that are driving the performance objectives of a given project. The ecoMetrics "Vital Signs" template is presentation below as Table 8.

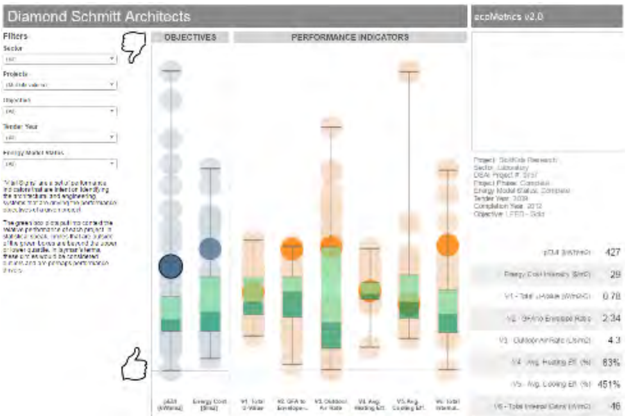

Table 8

The objectives or performance indicators for each project are displayed along a spectrum as blue or orange circles, respectively. The green box plots put into context the relative performance of each project. In statistical speak, circles that are outside of the green boxes are beyond the upper or lower quartile. In layman's terms, the circles outside the typical range for each vital sign would be considered outliers and warrant further exploration.

The hypothesis is that successful management of these six key metrics throughout the design process should result in improved energy use and energy cost performance. The following performance indicators are the "vital signs" that we have proposed:

- Total Envelope U-Value: the weighted average thermal resistance of all above grade envelope components
- GFA-to-Envelope Ratio: an indicator of the architectural efficiency of the built form

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Outdoor Air Rate: the average rate at which outdoor air is being introduced into the building
- Heating Efficiency: the weighted average of heating equipment efficiencies
- Cooling Efficiency: the weighted average of cooling equipment efficiencies
- Internal Gains: the sum of major sources of internal heat gain including: lighting, people and process equipment normalized by the building gross floor area

These individual vital signs do not necessarily provide much insight to designers without a background in building energy performance consulting. However, when compared to a set of like buildings from a data bank of completed projects, the vital signs become compelling design tools that reveal performance indicators that are often buried in the appendices of energy reports or never extracted from digital simulation files.

The efforts to date by RWDI and Diamond Schmitt Architects present a starting point. Further work is required to increase the size of the data set, which will allow for regression analyses to be conducted to statistically test the strength of the correlation between the vital signs and the desired outcome.

ABSTRACT

Hong Kong is a densely populated metropolitan city crowded with more than 7 million people. The erection of high-rise buildings is thus essential for accommodating the residents of this small stretch of land. These buildings and the activities therein are the energy terminators which consume about 90% of the city's total electricity use. Of the 50,000 buildings and facilities in Hong Kong, commercial sector and residential sector account for around 66% and 26% respectively of the electricity share. Thus, energy saving in commercial and residential buildings is a key factor in addressing climate change and associated environmental issues of Hong Kong.

HKSAR Government has been pursuing various energy efficiency policies and initiatives to reduce energy use in buildings. In 2012, the Buildings Energy Efficiency Ordinance, Cap 610 (BEEO) came into full operation. It requires new buildings as well as existing buildings undergoing major retrofitting to comply with the energy efficiency standards and requirements specified in the Building Energy Code (BEC). Such "built-in" approach is able to regulate nearly 80% of electricity consumption in commercial buildings. Meanwhile, by specifying the energy performance of 5 types of "plug-in" domestic electrical appliances under the Energy Efficiency (Labelling of Products) Ordinance, Cap 598 (EE(LP)O) since its full implementation in 2009, about 60% of electricity consumption in residential sector can be regulated. These two pieces of legislation govern the "built-in" system and "plug-in" appliances in buildings, which together constitute over 70% of electricity consumption in Hong Kong.

An overview of the BEEO and the EE(LP)O will be given in this paper. The latest update since their full implementation, including progress of enforcement, tightening of energy efficiency standards and issuance of new Codes, will be highlighted. Besides, the way forward in enhancing energy efficiency of existing buildings through operational optimization and retro-commissioning will be addressed.

Keywords: building energy code, Buildings Energy Efficiency Ordinance, Energy Efficiency (Labelling of Products) Ordinance, energy saving

1. INTRODUCTION

Hong Kong consumed 289,160 TJ (about 80,000 million kWh) of energy in 2014, in which around 55% energy end-use is in form of electricity consumption. With more than 7 million people squeezed within small stretch of 1,100 km land, the fulfilment of living needs and city operation has indeed resulted in making Hong Kong the most vertical city in the world. It is thus not surprising that buildings take up about 90% of our total electricity consumption, and is roughly 50% of total energy end-use. When comparing to the global energy use in buildings of 40% of the total energy consumption, the energy footprint for buildings in Hong Kong is affirmatively on the high side. It is imperative to reduce the use of electricity in buildings to help mitigate climate change. Commercial buildings and residential buildings are the major sectors which share 66% and 26% of electricity use respectively.

To this end, the Electrical and Mechanical Services Department (EMSD), HKSAR enacted two Ordinances respectively to govern those "plug-in" electrical appliances in residential buildings and "built-in" major building services installations in commercial buildings.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 1: BEEO and Energy Label under MEELS

2. THE BUILDINGS ENERGY EFFICIENCY ORDINANCE

The BEEO gives a legislative foundation to continuously save energy use in both new and existing buildings through the mandatory compliance of its BEC and Energy Audit Code (EAC). For building design, the BEC governs the minimum energy efficiency standards for "built-in" central building services installations, including air-conditioning, lighting, electrical as well as lift and escalator systems, which are about 80% of electricity consumption in buildings. Meanwhile, EAC sets out the technical guidance and details in conducting energy audit for commercial buildings.

2.1 Certificate of compliance registration

The BEEO requires the developers of newly constructed prescribed buildings to engage Registered Energy Assessors (REA) to certify and submit "stage one declaration" at design stage to declare all the major building services installations (BSI) in buildings have been designed and will be completed according to the specified standards and requirements under BEC. Subsequently at occupation approval stage, the developers are further required to submit "stage two declaration" certified by REA to declare those BSI have been installed and completed in accordance with the BEC requirements, and apply for Certificate of Compliance Registration (COCR) which will be valid for 10 years.

Figure 2: BEEO applicable to newly constructed buildings

2.2 Major retrofitting works

When Major Retrofitting Works (MRW) are involved, irrespective of newly constructed buildings or existing buildings, the owners or responsible persons are required to obtain a Form of Compliance (FOC) from REA certifying the MRW's compliance with the BEC. MRW refers to the addition or replacement of BSI covering a works floor area aggregated to 500m2 or above, or the addition or replacement of a CBSI component, including an electrical circuit at rating 400A or above, a chiller/ air-conditioner at 350 kW cool/ heat capacity or above, or a motor drive plus mechanical drive of a lift or escalator.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 3: BEEO applicable to major retrofitting works in existing buildings

2.3 Energy audit

Owners of commercial buildings are required to engage REAs to conduct energy audits for the CBSI of their buildings once every 10 years. The energy audits should be carried out in accordance with the requirement of EAC. After the audits, energy audit forms which contain the energy utilization index (EUI) of buildings must be exhibited in conspicuous positions at the main entrance of the buildings. Energy Management Opportunities (EMO) should be included in the energy audit report for building owners to realize the possible savings of the building and to consider further the implementation plan in the future.

Figure 4: BEEO requires commercial buildings to carry out energy audit

2.4 Implementation of the Building Energy Efficiency Ordinance

Upon full implementation of the BEEO in Sep 2012, around 1,200 "stage one declaration" have been received and over 220 COCR have been issued. As for major retrofitting works, about 5,200 FOC have been recorded for completion of work in prescribed buildings. It is also expected that about 4,000 commercial buildings are required to comply with the energy audit requirements. In respect of enforcement actions against any non-compliance with BEEO, prosecution action will be instigated if relevant parties fail to comply with the statutory requirements. On the other hand, briefings and presentations have continuously been conducted for all stakeholders including developers, building owners and tenants etc. to promote the statutory requirements of BEEO.

2.5 Continuous review of the codes

The BEC and EAC will be reviewed at a 3-year interval since the initial edition was issued in 2012 so as to further tighten the energy efficiency standards. In each review, reference will be made to the latest worldwide technological development as well as the updated international standards and public aspirations. The review was conducted by a Technical Taskforce with members drawn from the relevant professional institutions (including green groups), trade associations, consultant or contractor associations, university academia, and government departments. Six Working Groups were formed under the Technical Taskforce to help provide expert advice on the possible improvements to the energy efficiency standards and requirements under BEC and EAC.

The first comprehensive review was conducted in Sep 2014 and completed in mid-2015. The updated version of the BEC and EAC (i.e. BEC 2015 and EAC 2015) were gazetted with a press release in Dec 2015. Having taken into account the past practice and the operational need of relevant trades, grace periods of six-month and nine-month respectively have been provided for COCR and FOC submission respectively. The revised energy efficiency standards are expected to bring around 10% energy saving in buildings as compared to those under BEC 2012.

Figure 5: BEC 2015 Edition

3. ENERGY EFFICIENCY (LABELLING OF PRODUCTS) ORDINANCE

3.1 The Ordinance

The Mandatory Energy Efficiency Labelling Scheme (MEELS) was introduced through the Energy Efficiency (Labelling of Products) Ordinance (Cap. 598) [EE(LP)O] which was enacted in May 2008. The MEELS was implemented in phases. The initial and second phases were fully implemented on 9 November 2009 and 19 September 2011 respectively. Currently, five types of prescribed products, namely room air conditioners, refrigerating appliances, compact fluorescent lamps, washing machines and dehumidifiers are covered that altogether account for about 60% of the annual electricity consumption in the residential sector.

Figure 6: Five types of prescribed products regulated under MEELS

Under the EE(LP)O, the manufacturers or importers are required to submit relevant forms, test reports and associated product information to EMSD for assignment of reference number for the product models and attach energy labels in the prescribed formats as specified in the EE(LP)O before supplying these products in Hong Kong. All local suppliers (including wholesalers and retailers) cannot supply the specified products without any energy labels.

As at the end of August 2016, over 7,800 product models have been listed under the MEELS. Consumers can check the information of these product models in the thematic website namely Energy Label Net.

Since the enactment of the EE(LP)O, the MEELS has been effective in –

- Promoting energy saving by informing potential customers of the energy performance level of the products and facilitating customers in choosing the more energy-efficient models;
- Encouraging product suppliers to make available more energy-efficient products to meet customers' demand; and
- Increasing the penetration rate of energy labels through the introduction of legislation to mandate the display of energy labels.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.2 Review of MEELS

Any regulatory system has to move with times. The scope and grading standards of MEELS are kept under regular reviews to ensure that the grading standards will not lag behind technological advancement. The scope of MEELS is also regularly reviewed to cover more products and hence increase the penetration rate of products bearing energy labels.

3.2.1 Review of grading standards

A review of the grading standards of room air conditioners, refrigerating appliances and washing machines was completed in late 2014. In reviewing the grading standards of these products, due consideration has been given to the distribution of the appliances among various existing grades; grading systems adopted overseas; development of testing standards; technological development and potential energy savings arising from further tightening of the grading standards, etc.

The energy efficiency grading standards of these 3 products have been tightened and promulgated through issuance of a revised Code of Practice on Energy Labelling of Products (CoP). The revised CoP stipulating the new grading standards was published by gazette in October 2014. Full implementation took place on 25 November 2015, after which the three products to be supplied into the market must bear energy labels under the new energy efficiency grading standards.

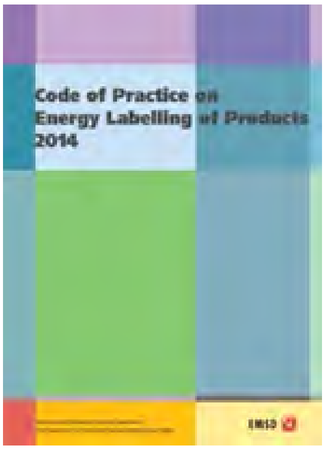

Figure 7: CoP on Energy Labelling of Products 2014 Edition

3.2.2 Proposed third phase of MEELS

In order to capture further energy saving potential, a review of the scope of the MEELS has been conducted with a view to expanding the coverage of the scheme. Having considered the comments received during a 3-month consultation conducted in the second quarter of 2015 and other factors such as overseas practices, availability of test standards and testing laboratories, as well as energy consumption and energy saving potential of the products, it was proposed to include more products such as televisions, storage type electric water heaters and induction cookers in the MEELS. In addition, the existing coverage of room air conditioners and washing machines will also be extended. The Legislative Council Panel on Environmental Affairs was consulted in January 2016, and was supportive of the proposal. The preparation of legislative amendment of the EE(LP)O is underway.

4. PROMOTION OF ENERGY SAVING IN BUILDING – GOING FORWARD

With the full implementation of BEEO and EE(LP)O, 80% of electricity consumption of "built-in" central building services installation in commercial buildings as well as 60% of electricity consumption of "plug-in" domestic electrical appliances can be effectively regulated. By combining the effect of these Ordinances, over 70% of electricity consumption in Hong Kong can be governed.

While the energy intensity and carbon intensity of Hong Kong has been the lowest among the APEC economies, we should continuously strive for further improvement towards energy efficiency to help mitigate climate change. To this end, a first-ever “Energy Saving Plan for Hong Kong’s Built Environment 2015 ~ 2025+” was launched in May 2015 by HKSAR to address the necessity on reducing energy consumption in Hong Kong and a new target

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

of reducing Hong Kong's energy intensity by 40% by 2025 has been set. With this ambitious vision, the whole community has to endeavour further effort to achieve energy conservation with concrete supporting measures.

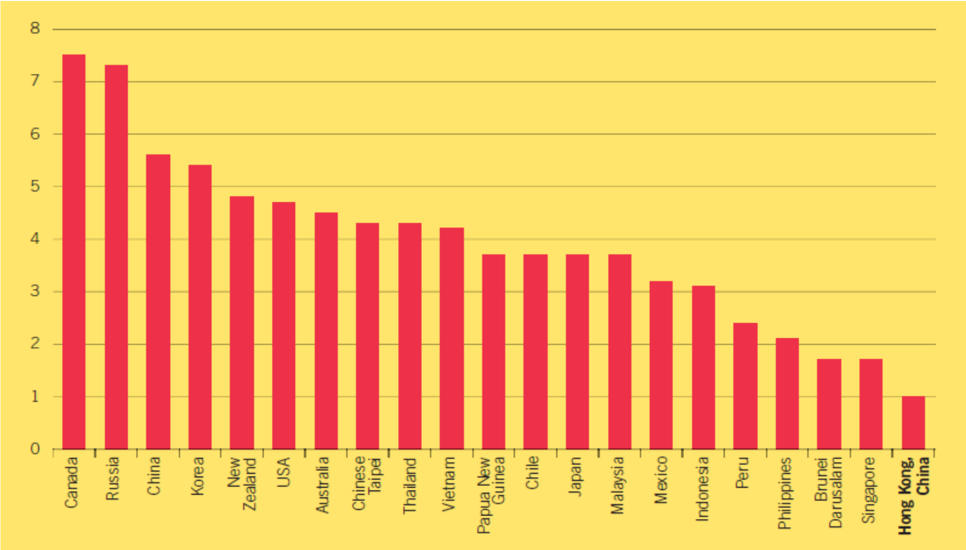

Figure 8: APEC energy intensity ranking, 2012

The Government is leading by example. In particular, we have set a new target of 5% saving in the electricity consumption of government buildings in the next five years from 2015/ 16 to 2019/ 20. With other green building initiatives being rolled out in full steam and relevant energy efficiency regulations being continuously enforced with further tightened requirements, various energy saving initiatives have been readily in place. However, there will still be a gap to achieve the energy saving target. It is therefore important to trigger contribution from private sector towards the energy saving target. A dialogue platform has been established to forge closer partnership with key stakeholders to foster energy efficiency in the community, especially for the private buildings, as foreshadowed in the Energy Saving Plan. Other initiatives including Retro-commissioning (RCx) will be promulgated by developing a Technical Guidelines for RCx and taking the lead to conduct pilot RCx projects in government and private buildings.

5. CONCLUSION

HKSAR has made a very deliberate move to regulate the energy performance of buildings and electrical appliances. Through the implementation of BEEO and EE (LP)O on "built-in" central building services installations in commercial buildings and "plug-in" domestic appliances in residential buildings, over 70% of electricity consumption in buildings can be regulated. Since the implementation of the EE(LP)O and BEEO, which serve as the key drivers of product and building energy efficiency, Hong Kong has taken the very major step forward in addressing to the impacts of climate change by the reduction of energy consumption of electrical products and buildings. This mandatory approach reinforces the roothold of the energy efficiency of electrical appliances in MEELS as well as minimum energy efficiency standards in the BEC, and paves the way for further enhancement in energy efficiency and relevant energy efficiency standards by means of periodic review.

While the Government has put lots of effort by tightening the regulations, enhancing the codes and reducing government energy consumption, the gap to achieve the energy saving target would require the collaboration with the private sector and the community. Therefore, to mobilise stakeholders and the entire community to understand energy efficiency issues better and thus contribute in energy saving is of paramount important. Through the implementation of RCx to trigger private stakeholders to gauge the energy saving potential in existing buildings, we are on the right track to reduce the total electricity consumption in buildings and hence to meet the target of 40% energy intensity reduction by 2025.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

6. ACKNOWLEDGEMENTS

Sincere thanks are extended to members (including representatives from ASHRAE, CIBSE, HKIE & PolyU) of the Technical Taskforce on Mandatory Implementation of the BEC and its working groups in offering their expertise advice and support in the development of the BEC and EAC, as well as the members of the Taskforce on the MEELS in offering their advices and support in the development of the new grading standards as well as proposed new product types.

How Sustainable Are the Quality Control Procedures for Constructions in Europe?

Frits MEIJER[a]

[a] *TU Delft / Faculty of Architecture and the Built Environment, The Netherlands, f.m.meijer@tudelft.nl*

ABSTRACT

Requirements on the sustainable quality (e.g. energy performance) of new and existing buildings are one of the pillars building regulatory systems of European countries are founded on. The influence of EU policy goals and contents of EU Directives in the energy regulations of the Member States is clearly noticeable. The European Union has set the ambitious goal that all newly built constructions must have a zero energy level by 2020. The total building stock must furthermore be energy neutral by 2050. The Energy Performance of Buildings Directive and the Energy Efficiency Directive have given Member States the tools and direction to develop and strengthen their regulations. There are doubts if the current requirements are sufficient to realise these goals. There is common agreement that the goals only can be reached by more strict and supportive policy instruments. This does not necessarily mean that the technical requirements must be formulated in more severe terms. Probably the big-gest challenges could be found in the way the construction process is organized, the regulations are enforced and way the roles and responsibilities of constructors (builders and installers) are defined. On the basis of a comparative research project in seven European countries, this paper analyses to what extent the current frameworks for the quality control of constructions are adequately organised to meet the current and future sustainable demands.

Keywords: policy and regulation, quality control, energy saving

1. INTRODUCTION

From way back quality control of construction work in Europe has been a governmental responsibility. In most European countries local authorities have been responsible for plan approval, site-inspections and checks on completion of constructions. During the last decades however these building control tasks have been outsourced more and more to private parties. The main driving force behind this development has been the wish of governments to deregulate. The shift of responsibilities to private parties should not only improve the quality of construction works but it could also streamline administrative procedures and processes. The idea is that less regulation leads to a qualitative better building stock through cheaper and faster quality control procedures. It is because of these reasons that the Dutch government is on the brink of changing its quality control system of constructions towards a more private model (MBZK, 2015).

Simultaneously with the strong wish to deregulate new quality goals have emerged that require regulatory governmental intervention. The reduction of energy use and environmental impact of construction have been the most important new policy goals the last decades. The European Union and its Member States have implemented regulations that should ensure very energy efficient new buildings and have introduced instruments to improve the energy performance of the existing building stock. The Energy Performance of Buildings Directive and the Energy Efficiency Directive have been the dominant frameworks for the Member States to fit in their national regulations. This growth of energy performance requirements seems to be at odds with the deregulation trend. Furthermore recent studies show that the (energy) regulations are probably inadequate to realize the ambitious energy saving goals (summarized in Visscher et al, 2016). To reach the goals more strict and supportive governmental regulations are needed. That does not only mean formulating more stern demands. It also poses new challenges to the way the quality control process of constructions is organized and the regulations are enforced. The roles and responsibilities of (private) quality controllers and builders are an essential part of this. This paper explores if the regulations and the quality control processes in the ´average´ European building regulatory system are fit for the task that lies ahead. Section 2 characterises the essentials of the systems in seven European countries. In the closing sections 3 and 4 the results are discussed and the main conclusions are drawn.

2. OUTLINES OF THE CONTROL SYSTEMS

For many years we have been involved in studying alternative visions on building regulatory systems in international comparative projects. Recently we have been involved in studies for the DG Internal Market (Ecorys and Delft University of Technology, 2015) and for the Dutch government (Meijer et al, 2016). For the latter we compared the quality control system for constructions in the Netherlands, England and Wales, France, Germany, Ireland, Norway and Sweden. In these countries the tasks and responsibilities of public and private building controllers were analysed. The study was based on our existing dataset on building regulatory systems. Additional and updated information was inventoried via desktop research. Relevant regulatory documents and other sources were analysed. Within the framework of this paper only the essentials of the systems can be touched upon.

2.1 England & Wales

For the technical quality control of constructions requiring approval, applicants can choose between local authority building control or a private Approved Inspector. Approved Inspectors have to be certified and must be registered. No legal demands are made about the way in which quality control should take place. Nonetheless both public, as well as private controllers, have voluntarily committed themselves to the Building Control Performance Standards. These standards give guidelines how qualitative good building control should be performed (DCLG, website). Builders have to comply with the general rules concerning materials and workmanship. There are no general recognition or certification schemes for contractors or builders. However specialist installers can join a Competent Person Scheme. These installers can self-certify certain types of building work (e.g. glazing, heating systems), It is assumed that the work meets the requirements. In practice many installations are being placed by these competent persons. Although there is no certainty that all these competent persons deliver adequate work, the certification frameworks in which they have to operate give certain basic assurances about their workmanship, capabilities and experiences. Obligatory demands on indemnity and warranty insurance schemes are in place to protect the building owner. There are no regulations that apply to a post occupancy testing of for instance if the regulations are being met.

2.2 France

For technical control a public-private construction supervision system has been in operation in France for almost forty years (Meijer et al, 2016). The complexity of the construction defines the quality control procedure. For relative uncomplicated works (e.g. dwelling) a registered architect must declare that the plan meets the demands. In practice these works are hardly being controlled during construction (De-man, 2013). For complex construction works with a higher risk quality control by private control organisations is obligatory. Control starts in the phase of plan approval and continues until completion. After plan approval the control organisation has to a deliver an initial technical report and an inspection plan. Private controllers are obliged to control the structural and personal safety. Site inspections are held at random. After completion the private controller must deliver an end report. Public and high-rise buildings must have a user permit before they can be used (MLHD, website). Private controllers have to be certified and accredited and must be independent of the applicant/building owner. Organisations can be certified for various control scopes. A decisive factor behind this system is the French insurance and guarantee system for building works (Meijer et al, 2016). The relevant law dictates that every building professional involved with a construction project must have appropriate guarantee insurances. Builders and contractors have to be registered otherwise there is no certainty that they can meet the guarantee provisions.

2.3 Germany

The German model is a mix between public and private quality control. Municipalities are responsible for issuing the (building and completion) permits. Recognised or registered building professionals however play an important role in the system. Certified and registered architect and/or structural engineer must submit the permit application and usually take care of plan approval. In addition -– depending of the construction type and control scope – state recognised experts must be involved in the quality control process. These experts have to be independent and comply with strict demands on education and practical experience (Building Code of NRW, 2015). The building application for constructions that are eligible for a regular building permit procedure must be signed by a qualified architect or engineer. Normally state recognised experts verify compliance with demands on structural stability and fire safety). For the construction phase a contractor and a – independent- site manager has to be appointed. Both the builders as the other building professionals have to meet statutory insurance requirements regarding liability.

During construction, building control is exercised by local authority building control and the site manager. After the construction is finished and local authority building control is satisfied the requirements have been met a completion certificate. Is issued (Meijer et al, 2016)..

2.4 Ireland

Ireland has recently (2014) changed its system to an almost entirely private quality control system, in which competent private building professionals are responsible for the quality control of construction works.. Applicants for works that need building approval must submit a Commencement Notice that needs the inclusion of a certificate of design compliance and proof that an Assigned Certifier is going to inspect and certify the works and a builder has been hired to carry out the works. The Notice must also be accompanied by an inspection notification framework and an inspection plan. After completion of the project, both the certifier as the builder must certify that the completed construction complies with the demands of the Building Regulations (DECLG, 2014). Shortly after the introduction of the new regulations it became clear that for the construction of one-off dwellings and extensions on existing houses. the control costs were highly disproportionate. This has led to an amendment to the system. Owners and self-builders got the choice to opt-out of the statutory certification and are allowed to demonstrate compliance with the demands by other means. At the same time the government announced the development of a new local authority quality control process for single dwellings and residential and commercial buildings (Meijer et al, 2016). For building professionals inclusion on statutory registers is the primary means of establishing competency. For architects and engineers these registers already are in operation. The register for builders should be in place shortly. Furthermore building professionals must ensure that they are adequately covered for liabilities (DECGL, website).

2.5 Netherlands

In April 2016 the new law on Quality Assurance of buildings has been sent to the Dutch Parliament (MBZK, 2015). The law is going to be discussed in Parliament this autumn. If the bill will be adopted, it will change the quality control system fundamentally. All control activities on compliance with the technical building regulations will be transferred from public authorities to private parties. Construction works eligible for the quality control procedure will be classified in three groups according to their complexity and possible consequences in case of failure. Class 1 contains for instance one family housing. Hospitals and high rise buildings are assigned to class 3. The technical quality control of these construction works will be carried out by private parties. An independent Admission Organisation is going to assess and recognise these private quality controllers and their quality control instruments. In the intended new system an applicant must notify the municipality about his plans and the way quality control is going to be arranged. The appointed private controller carries out plan approval and makes an inspection plan and takes care of the control during the construction phase. At the end of the process the quality controller declares that the building meets the technical demands (IBK, 2014). To strengthen the position of the 'building consumers' the liability of builders (e.g. for hidden faults) will be sharpened in the Civil Code.

2.6 Norway

In the 1990's Norway changed its public quality control system drastically. The new system was largely based on self-certification by approved building professionals. These enterprises could self-certify their own construction works and that of others. In practice it quickly appeared that this new model proved to be highly ineffective. Self-certification proofed to be inadequate and local authorities failed to supervise the private parties (World Bank Group, 2013). From 2012 on a new regulatory framework has come into force. The checks and balances to assure the quality of the quality control process have been sharpened considerably. The demands and supervision on both quality as independence of control have become stricter. Building professionals have to meet demands on education and practical experience. For construction works that are eligible for quality control all parties involved have to be approved by the central government as (KoRD, 2015),. All roles have to be filed in properly before the authority issues a building permission (DiBK, website). The process starts with an obligatory consultation meeting where an inspection plan must be established. This plan is used during the construction and completion phase. For critical building elements (e.g. structural components, fire safety, energy efficiency and the building envelope) in complex constructions independent private control is obligatory (Meijer et al, 2016). At the end of the construction process the controller/applicant has to make a completion report. At completion the applicant and builder has to supply the user or occupant of the building with an user and maintenance manual of the building.

2.7 Sweden

For works needing building approval in Sweden at least one private person/party must be involved that controls the quality during construction. Quality controllers must be certified before they can operate in practice (Boverket, website). When private quality control is necessary it is obligatory to make an inspection plan and to organise a technical meeting (Deman, 2013). If the municipal building committee agrees with the inspection plan the building permit is issued. The municipality controls the essential elements (structural and fire safety, sustainability, insulation and health issues) of the intended construction plan during plan approval. During construction a certified independent quality controller takes care of the inspections. No specific demands are made on the builder with respect to registration or practical experience. The building regulations expect that a builder complies with the regulations. Liability-issues of building professionals are usually arranged in standard contracts. After completion an end meeting is held that establishes if all the agreements and commitments have been met that were stipulated in the approved inspection plan. If the municipal building committee is satisfied a written notice is issued to the applicant/owner.

3. DISCUSSION

The main goal of a quality control system is to assure that buildings – after they have been constructed - meet the regulatory quality demands. Traditionally the countries studied, focussed their attention on the beginning of the process. In the meantime they all have developed systems where the checks and balances have been more evenly distributed throughout the building process. During the process qualified architects and engineers (e.g. Germany and France), qualified builders (e.g. Norway, France, Ireland) and qualified controllers (all countries) have to make sure that constructions meet the demands. After completion controllers, and some-times builders too, have to report their experiences and the results of the inspections before local authority building control issues a completion certificate. With these kind of procedures in place the chances are fair that buildings meet the intended minimum quality.

At the same time all countries have been trying (and still are trying) to streamline and simplify their quality control procedures for construction works. Without exception the countries thought that deregulation and privatisation was the way forward. This has led to a greater emphasis on the responsibility of building owners and the transfer of actual quality control from municipalities to private parties. As we have sketched above the emphasis of quality control has moved from the design phase to the as built situation. Strict regulatory demands are made on the requirements that should be tested and sometimes the way it should be controlled. These demands always focus on the control and inspection of the structural and fire safety requirements. What is more, these statutory demands on control and inspection always apply to complex constructions. In most countries dwellings are outside the centre of the quality control attention. An example of this is France, where due to the insurance and guarantee system, the structural and fire safety of complex constructions is inspected thoroughly and adequately. Dwellings are hardly controlled by professionals, because the insurance risks are lower. In a more broader sense one can argue if a regulatory system that is heavily funded on insurance regulations is helpful in the face of climate change. The height of the energy use and the sustainable quality of construction probably hardly affect insurance heights and is no driving force to realise a better environmental quality.

The high potential and expected energy savings in buildings increases the need for accurate quality control. This theme still does not get the attention it deserves in the control systems. However the regulatory infrastructure is already available and more attention for energy and sustainable requirements can be easily incorporated in the current framework. The first step would be to give energy requirements the same status as currently is being done with structural or fire safety requirements. Private quality controllers should be made explicitly responsible to check these requirements.

Other interesting developments are the growing demands on the quality and workmanship of builders and installers. All countries have incorporated various forms of guarantees in their systems to make sure that builders and contractors de-liver what they are supposed to do. In England individual installers can certify their work when they are certified as competent persons. In France builders have to be registered before they can be qualified for insurance and can operate in practice. Ireland is working on a voluntary register of builders. In Norway persons and parties who want to perform construction work and building control tasks can be approved and in all cases have to declare that they are fit for the task. In Sweden the builder must appoint a certified site manager who is responsible for the quality control. On top of this, all countries have strict rules for building defects insurances. With these developments a step can be made to a further professionalisation of builders. How-ever for a successful transition to energy neutral constructions more stern demands must be set on the knowledge and skills of the building professionals. They will have to use new techniques and improve the quality and accuracy of the work. The Competent Person Scheme in England could be an example how to deal with the growing need for accurate quality control. This scheme specifically focuses on construction elements that matter regarding the energy performance of buildings (e.g. windows, glazing and installations). Further study will be needed to determine the accuracy and effectiveness of the scheme.

Regulatory attention for post occupancy monitoring is completely absent in the countries studied. Some countries have had in the recent past some regulations and guidelines relating to the user phase of constructions. Currently only Norway makes regulatory demands with respect to a user and maintenance manual. Besides that building owners all over Europe have to provide an Energy Performance Certificate because of European regulations. It is not foreseeable in the near future that post occupancy monitoring will be incorporated in the building regulatory system of any European country. In view of the growing big datasets with the actual energy use in buildings, one can question if the lack of regulatory post occupancy monitoring mat-ters much. The datasets provide, although indirectly, a wealth of information about the effects of the energy regulations on the actual use of occupants.

4. CONCLUSIONS

This paper pictures the state of the art of quality control systems for constructions in seven European countries. What can be noticed in the countries is that the balance slowly shifts from public control and enforcement towards a more dominant role of private parties and building professionals. This development goes hand in hand with the materialisation of more robust and reliable certification and accreditation schemes to guarantee the quality and qualifications of building professionals. With respect to the scope of quality control we see a strong focus on control of the design to monitoring of the building process and testing of the quality of the final building. Post occupancy monitoring is nowhere an established part of the building regulatory system. With respect to the contents it can be noticed that statutory demands on control (when present) usually are focussed on structural and fire safety issues. The priority to check the energy performance requirements in general does not seem to be high. All along the line more simple constructions (e.g. dwellings) are controlled to a far lesser extent. The leading question in this paper was if current quality control frameworks are adequately organized in the light of the regulatory needs related with the expected climate change. In organizational terms the frame-work looks adequate enough to make the regulations more climate proof. What is needed is the political will and determination to give the energy and sustainable requirements the same status as for instance the demands on structural or fire safety. The last decades the themes energy saving and climate change have been dominating the political agenda. It seems merely a question of time before the desired changes in the regulatory framework will be implemented. In the end however it is also about the question how the systems function in practice. In our future research we intend to lay emphasis on these practical experiences. Only then a more definite and more balanced judgement can be made about the “sustainability” of quality control systems for constructions.

Policy Scenarios of Zero Carbon Building for Hong Kong: To Survive or To Lead?

PAN Wei[a], PAN Mi[b]

ABSTRACT

During the past decade 'zero carbon' building policies have been formulated in a number of countries. In Hong Kong, despite the over 20 years of evolution of building energy codes, there is still no policy agenda of achieving possible zero carbon for buildings. General perception exists on the infeasibility of high-rise buildings particularly in the subtropical climate such as Hong Kong. This paper aims to develop policy scenarios of zero carbon building (ZCB) for the high-rise context of Hong Kong. The research was conducted through the integration of a questionnaire survey, follow-up interviews, series of focus group meetings, and a policy forum, which together engaged over 600 professionals and stakeholders in Hong Kong over a 15-month period. A definition of ZCB for Hong Kong is developed and so is a socio-technical systems ZCB policy framework, elaborating four technical components, i.e. definition and scope, measure and indicator, target and timeline, and renewable energy, within their social, regulatory and geographical contexts. Policy scenarios are developed for different building types and sectors from the status quo towards the UN's 2050 carbon neutrality target. Important opportunities are identified for addressing climate change as well as re-shaping energy and infrastructure planning in Hong Kong, whilst significant risks are also discovered with technological constraints and reluctant behavioural changes. The opportunities are found to outperform the risks. To realise the policy scenarios requires the adoption of the recommended strategies, aiming a leading model rather than survival. Key to that is to strengthen the partnership between government, industry, universities and communities. To survive or to lead for Hong Kong in the strategic future of high-rise ZCB is not a policy decision per se, but a socio-technical debate provoking an institutional paradigm shift.

Keywords: zero carbon building, energy policy, carbon emission, carbon policy

1. INTRODUCTION

During the past decade 'zero carbon' or 'zero energy' building policies have been formulated in a number of countries. In Hong Kong, despite the over 20 years of evolution of building energy codes, there is still no policy agenda of achieving possible zero carbon for buildings. In addition, research on ZCB policy and its associated opportunities and risks in Hong Kong has been limited. In 2011 the Council for Sustainable Development in Hong Kong launched a public engagement process on energy saving and carbon emission reduction in buildings, and provided recommendations of 'systemic enhancement' and 'facilitation of behaviour change' to help engage the community, but did not explore the opportunities and risks of possible strategic movement towards zero carbon. As observed by Crawley et al., a common language in defining and measuring ZCBs is lacking, which contributes to significant ambiguity when setting targets and procedures to achieve carbon reduction.

This paper aims to develop policy scenarios of zero carbon building (ZCB) for the high-rise context of Hong Kong. A definition of ZCB for Hong Kong is developed and so is a socio-technical systems ZCB policy framework. Policy scenarios are developed for different building types and sectors from the status quo towards the UN's 2050 carbon neutrality target. The opportunities and risks associated with the formulation and implementation of this ZCB policy are identified, including their relevant technical, regulatory, social and geographical aspects. These provide evidence of the potential benefits of this policy to inform the HKSAR Government's policy decisions. Recommendations are developed to realise the opportunities and mitigate the risks identified.

2. RESEARCH METHODOLOGY

The research was conducted through the integration of a questionnaire survey, follow-up interviews, series of focus group meetings, and a policy forum, engaging professionals and stakeholders in Hong Kong over a 15-month period.

The questionnaire survey approached over 1000 informed professionals and stakeholders in Hong Kong industry and society. In total 260 questionnaires were returned, of which 235 were properly completed, thus yielding an overall response rate of 235 for analysis. Followed by the questionnaire results, semi-structured interviews, four focus group meetings and one discussion forum were conducted to further explore and verify the results. Table 1 illustrates the number of participants involved in each research activities. The participants cover all eight stakeholder groups including developers, clients and investors, estate and facilities managers, contractors, professional advisors, manufacturers and suppliers, government and its departments and agencies, financers, bankers and mortgage lenders, and universities and professional bodies.

3. RESULTS AND ANALYSIS

The proposed ZCB policy for Hong Kong has drawn on the socio-technical systems policy framework of our previous research, which highlights a ZCB policy as a complex socio-technical system. The technical system of a ZCB policy consists of four components: definition and scope, targets and timelines, measures and indicators, reliance on renewable energy. This technical system should be embedded into the regulatory, social and geographical contexts. Stakeholder engagement is an important mechanism for formulating and implementing the policy. The four components of the technical system of the ZCB policy, in addition to the regulatory, social and geographical contexts and the mechanism of stakeholder engagement, form the core of the proposed ZCB policy for Hong Kong.

3.1 Policy scenarios of Zero Carbon Building for Hong Kong

3.1.1 ZCB definition and scope

The ZCB definition developed for Hong Kong regards ZCBs as complex socio-technical systems, and recognises the multidimensional boundaries of the ZCB systems and the wide-ranging stakeholder group engagement. The generic definition of a ZCB (or a LCB) is a building within its defined systems boundaries with net-zero (or very low) carbon emissions on an annual basis during the operational stage of the building. The systems boundaries should be defined in terms of the technical components of the definition within the relevant regulatory, geographical and social contexts (for a detailed explanation see [5]).

3.1.2 ZCB policy target and timeline

Different ZCB policy targets and timelines were proposed for different building types and sectors in Hong Kong, using the policy targets and priorities adopted in the UK as a point of reference. Considering three variables, namely, building type, sector and status, eight combinations of policy targets were considered in eight typologies, and preliminary timelines for these targets were also proposed (Figure 1). Their feasibility was examined through the stakeholder questionnaire survey and interviews.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

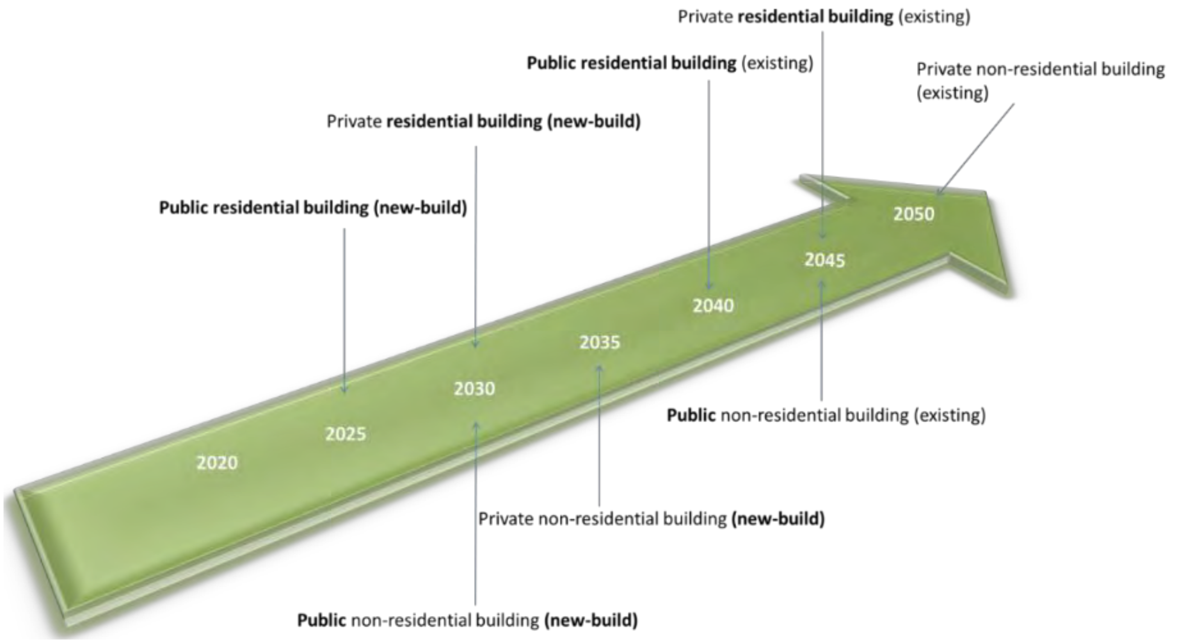

Figure 1: Possible ZCB policy targets and timelines for study

All buildings in Hong Kong were proposed to achieve net zero carbon as defined above by 2050. To enable a progressive approach, all newly built public residential buildings were prioritised to achieve net zero carbon from 2025. The other policy targets were proposed to follow up, with a five-year period of catching up, and with existing private non-residential buildings as the last target by 2050.

3.1.3 Measures and indicators

Performance measurement is important to ensure the effective implementation of the proposed policy. Use of kgCO2e/m2/year was suggested as a measure of carbon emission intensity (CEI) and kWh/m^2/year to measure energy use intensity (EUI), as these are common measures both worldwide and in Hong Kong. For consistency, the gross floor area (GFA) of a building was proposed for calculating the EUI and CEI, denoting the area contained within the outer surface of the external walls and measured at each floor level, with any portion of this area not floored over also included. Both regulated and unregulated operation energy should be counted.

3.1.4 Use of renewable energy

The energy supply is a major contributor to carbon emissions in Hong Kong, with 53% of the fuel mix from coal, 23% from nuclear energy, 22% from natural gas and remaining 2% from others. The increased adoption of renewable energy is crucial to reduce reliance on fossil fuels and reduce carbon emissions. Hong Kong has abundant sunshine, and solar energy has the greatest potential for use, such as solar thermal systems for water heating or refrigeration and PV systems for electricity generation . Wind power has been proposed as an alternative, but its low efficiency and effect on the natural environment have generated substantial debate about its applicability in Hong Kong. Energy from municipal solid wastes (MSW), particularly the organic fraction, has also been emphasised as a valuable source of electricity. The HKSAR Government has proposed targets to reduce carbon intensity by 50–60% of the 2005 level by 2020, and to utilise renewable energy at about 3–4% of the fuel mix in ways of two wind farms and integrated water management facility.

Given the limited use of renewable energy in Hong Kong, it was proposed that the required renewable energy for a ZCB may be generated on- or off-site and directly connected with the building and/or off-site and indirectly connected with the building.

3.2 Perceptions of the ZCB definition and policy scenarios

Overall, most participants recognised that Hong Kong should initiate a ZCB policy, or at least set relevant energy-reduction targets to facilitate the sustainable development of the city. The majority of questionnaire respondents agreed or strongly agreed that Hong Kong lacks a strategic policy leading to zero carbon emissions, that Hong

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Kong needs to develop such a policy and that this is a global trend (71%); and that a ZCB policy is important for Hong Kong (80%). However, opposed views still exist. These attitudes were explained through the follow-up interviews and focus group meetings by a perception that the existing building energy policies and ordinances were capable of reducing building energy use and carbon emissions; and a perception that achieving zero carbon in Hong Kong lacked feasibility due to the high-rise, high-density nature of its buildings. Some also argued that many steps are required before achieving zero carbon emissions and thus a low-carbon or low-energy building policy may be more practicable.

During the survey, focus group meeting and discussion forum, there was a consensus on the proposed measures and indicators, but much division and discussion of other parts of the technical system of the policy, including definition and scope, timelines and targets, and renewable energy.

Over two thirds (67%) of the questionnaire respondents agreed or strongly agreed with the proposed definition, while others held a neutral or disagree attitude. Possible reasons were identified through the follow-up interviews and focus group meetings as uncertainty about a true definition; lack of clarity about the definition of system boundaries in the definition; whether embodied energy should be considered; and different ZCB considerations for different types of building.

There was a division of views on the timeline and target, most respondents (61%) agreed that public buildings should be prioritised over private ones, but more than half (52%) disagreed with prioritising residential over non-residential buildings. Interviewees and focus group participants explained that although many other countries or cities prioritises residential buildings over non-residential, this may be unsuitable for Hong Kong due to the high-rise, high-density characteristics of residential buildings. In addition, the user behaviour factor of residential occupants (generally perceived as reluctant to change) may make it more difficult to achieve zero carbon in residential buildings in Hong Kong. In the follow-up interviews, most agreed that policy targets and timelines should set the same pace as the international approach, but that it was unlikely the target would be achieved by the proposed time. This perceived low possibility of the target fulfilment was attributed mainly to the high-rise, high-density building, difficulties with renewable energy, political uncertainty, and lack of industry and public willingness for zero carbon in Hong Kong.

While renewable energy is one of the most important strategies for achieving ZCB, the feasibility of applying many technologies in Hong Kong has long been doubted. The achievability of renewable energy like solar energy, combined cooling, heat and power (CCHP) plant was considered high from the questionnaire survey, but doubted during follow-up interviews and focus group meeting. One participant suggested that the results of questionnaire survey may not be useful as the general public lack technological knowledge, and it would reflect their misunderstanding of the use of some forms of renewable energy, the associated power generation and the potential benefits and risks.

Not surprisingly, most questionnaire respondents (65%) agreed that implementing the possible ZCB policy in Hong Kong would be difficult. Through follow-up interviews and focus groups, possible reasons that emerged were that the difficulty lies in industry not trying because the policy is not compulsory. The questionnaire survey results also demonstrate the view that the willingness of both industry and the public to support the ZCB policy is neutral or even weak, and that to gain such support the government should take the lead with more incentives.

3.3 Opportunities, risks and recommendations

The importance of possible opportunities to formulate and implement the proposed ZCB policy, as well as the potential risks, was examined in the technical, regulatory, social and geographical aspects. Raising public awareness of sustainable living was considered the most important opportunity, followed by promoting strategic urban planning for long-term city development, and cutting building energy consumption. The major hurdles were identified in the geographic and technical aspects, particularly the geographical difficulties for domestic renewable energy generation, heavy reliance on fossil fuels, and resistance of practitioners to support the policy due to uncertain benefits. To realise the opportunities and mitigate the risks, the important recommendations were recognized as the encouragement of energy and carbon reduction through urban planning, the demonstration of life cycle economies and cost benefits of ZCB, and including zero carbon/energy targets in public project procurement.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4. DISCUSSION

Drawing on a critical literature review and desk study of ZCB policies, initiatives, demonstrations and the like worldwide and the evolution of policies on building energy and carbon emissions in Hong Kong, a potential ZCB policy for Hong Kong was proposed. This proposed policy adopts the socio-technical systems framework which regards ZCB policies as complex socio-technical systems as presented by Pan and Ning [4]. The technical system of the proposed ZCB policy consists of four components and embedded in the relevant regulatory, social and geographical context of Hong Kong. Critical to the context is the high-rise, high-density, hot-and-humid urban environment of Hong Kong. Policy scenarios are developed for different building types and sectors, supported by a technology roadmap in a progressive manner towards net zero carbon. Stakeholder engagement is an effective mechanism for the formulation and implementation of a ZCB policy.

However, despite recognising the importance of such a ZCB policy for Hong Kong, the majority of the participants perceived limitations to the proposed policy centred on whether the policy targets can be achieved in the proposed timeline, whether zero carbon can ever be achieved for high-rise buildings in Hong Kong, and whether substantial renewable energy can be developed. Debates within the policy scenarios are illustrated in Figure 2, and the future direction could be manifold.

Although a ZCB definition for Hong Kong was proposed, concerns were raised over specific details and the applicability of this definition to different contexts. Taking energy scope as an example, some participants believed embodied energy should be included for 'true' ZCB, others disagreed over whether the energy scope should follow the EMSD scope or include others. These findings echo the differing definitions of ZCB and the like in other countries and regions. For practicality, the proposed definition should have explicit boundaries, particularly in relation to Hong Kong's context, building types and user behaviour.

Regarding the proposed policy targets and timelines, the participants appeared pessimistic and suggesting the timeline was too aggressive. In addition, the lack of a detailed blueprint contributes to policy and business uncertainty. Most participants believed that non-residential buildings could achieve net zero carbon more easily than residential buildings. This finding is in disagreement with the policy priorities for residential buildings in the UK, US, and EU. However, residential buildings in those countries tend to be low-rise and easy to measure, and energy consumption in residential buildings depends on user behaviour while for commercial buildings it is more dependent on energy systems.

Focus group meetings raised a wide range of recommendations regarding renewable energy. Some suggested solar power should be the main focus and it is the most developed energy technology, while others argued that critical learning is needed and that heavy reliance on solar power may not be appropriate for Hong Kong's high density with tens of thousands of high-rise buildings. Some suggested the use of power generation from waste, but shared uncertainties due to the current underdeveloped technologies and client preferences.

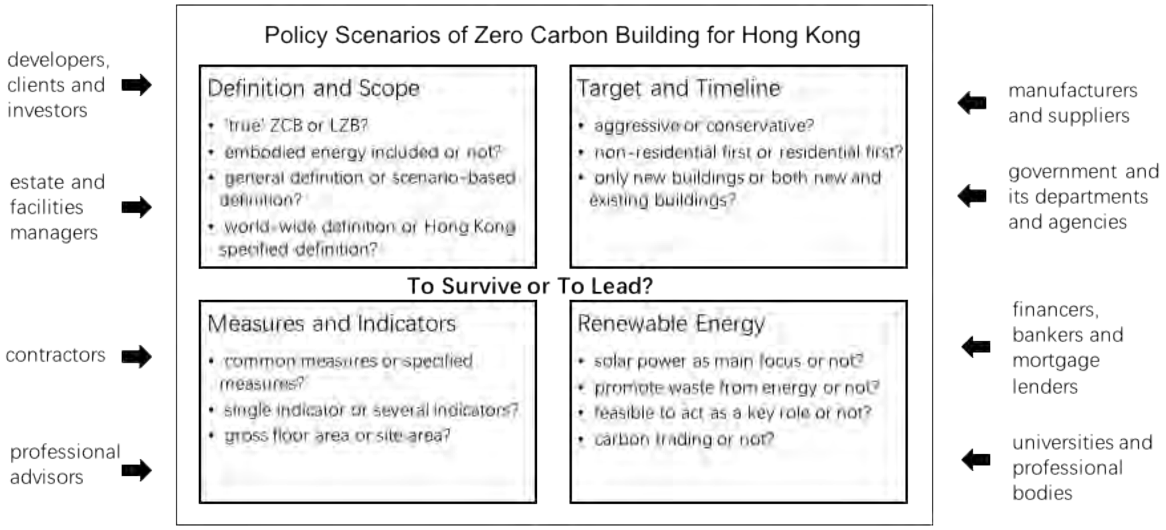

Figure 2: Debate on details of policy scenarios of ZCB for Hong Kong

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

5. CONCLUSIONS

This paper develops policy scenarios of ZCB for the high-rise context of Hong Kong. A definition of ZCB for Hong Kong is developed and so is a socio-technical systems ZCB policy framework, elaborating four technical components, i.e. definition and scope, measure and indicator, target and timeline, and renewable energy, within their social, regulatory and geographical contexts. Policy scenarios are developed for different building types and sectors from the status quo towards the UN's 2050 carbon neutrality target. Important opportunities are identified for addressing climate change as well as re-shaping energy and infrastructure planning in Hong Kong, whilst significant risks are also discovered with technological constraints and reluctant behavioural changes. The opportunities are found to outperform the risks. To realise the policy scenarios requires the adoption of recommended strategies, aiming a leading model rather than survival. Key to that is to strengthen the partnership between government, industry, universities and communities. To survive or to lead for Hong Kong in the strategic future of high-rise ZCB is not a policy decision per se, but a socio-technical debate provoking an institutional paradigm shift.

ABSTRACT

"Urban Heat Island" effect leads to high temperature in the urban climate, increased rainfall, reduced wind speed and air pollution as well as other effects. According to "International Association for the Evaluation of Educational Achievement," average carbon dioxide emission in Taiwan is 11.26 tons in 2008, while the building structures are the third source of carbon dioxide emissions. Taiwan' is ranked to have the 18th highest carbon dioxide emissions in the world. In view of this, for the new buildings, the Kaohsiung City Government actively promotes the transformation plan for "Green Building • Sustainable Environment", presenting the local culture, green architecture and the concept of public participation, and promotes Taiwan's first "green building autonomous regulations in Kaohsiung" , "the policy for design and encouragement reward for Kaohsiung building " and other innovative design policies. Kaohsiung implements existing buildings through “Improvement on Kaohsiung Buildings" action, prioritizing public buildings that are frequented by the people of Kaohsiung. Buildings will be elevated with the suitable solution based on integrated physical environment quality testing and data analysis (including sound, light, warmth, air).

Therefore, this study used the analysis of relevant policies of Kaohsiung city prompted by innovative green building. With the "Building (New) Sustainable Environment” of Kaohsiung City Government, practical benefits and the target completion of the policies will be discussed. From the point of view of environmental health diagnostic, existing buildings are examined for their achievement in actual practice. The aim of this study is to provide hope to enhance the quality of life in Kaohsiung, and to add to Taiwan's research reference.

Keywords: *Kaohsiung buildings, green buildings, innovative design policy*

1. INTRODUCTION

In 2015, Paris Climate Conference （COP21）performed protocols regarding the topic of restraining the global warming, which was aimed at reducing the emission of greenhouse gases and controlling the global temperature would not increase more two centigrade degree in 2100 with the global warming speed. The conference also advocated the concepts of think locally, act globally. To respond the changes of global climate and the trend of international energy conservation and carbon reduction, the central government promotes the policies of "Sponge City" and “Million Solar Roofs”. Faced at the problems of high carbon emission, alternations of floods and droughts, the air pollution of PM 2.5 caused by urban island effect and difficult to diffuse, more than 120,000.00 unauthorized buildings and Aging Population with too Few Children and other problems, Kaohsiung City is in need of thinking about how to transform into the healthy and sustainable Southern Taiwan metropolitan district from the image of industrial city to develop the local architectural features and living cultures of Kaohsiung region.

2. TO PROMOTE STRATEGIES AND CREATIVE ACHIEVEMENTS

In order to solve the environmental studies of Kaohsiung and effectively plan and make reformation on sustainable construction environment of Kaohsiung, the countermeasures, “Kaohsiung House Plan” is created. To more properly adapt to the sustainable construction movement, the three cores of the plan are consist of global Environmental Sustainability, the Identity of Reflecting the Local in line with the local conditions of Kaohsiung, and Healthy Residence closed to the populaces’ life, which conclude the following creative achievements:

2.3 Twelve creative policy tools

Kaohsiung House Plan has constantly made twelve policy tools initiatively nationwide, and conducts the reformations on sustainable construction environment by away with a higher standard.

2.4 Vertical forests: roof greening and landscape balcony

The landscape balcony with the depth of three meter is initially built in line with the local conditions to create green landscape in metropolis, which seems as a 3-D vertical forest park, creating the unique architectural features and brand, and promoting the construction to the international construction with high quality.

2.5 The universalization of design space

The elderly population in Taiwan will reach to more than 20% in 2025. In response to the upcoming super-aged society, the universal design is further introduced by the laws so that the children, the elderly and disabled person, etc., can conveniently use all sorts of building environments.

2.6 The solar photovoltaic facilities set on buildings

By making full use of Kaohsiung's abundant sunshine to facilitate the renewable energy of solar photovoltaic to develop local characteristics, and to standardize the setting of the solar photovoltaic facilities in the roofs of buildings, the regulations of central government's laws and decrees are broken, and the restrictions on the height of the solar photovoltaic on the roofs are broaden so that those with the height fewer than 4.4 meters are excluded from the volume and height of the building.

2.7 The self-creation of financial resources-the sustainable operating fund of green buildings

The financial resource is self-created by handing in the giving back money of Kaohsiung adjacent. Apart from giving back to sustainable environmental construction, the operation of the innovation policy's mechanism can also be constantly rolled. The operating fund of sustainable green construction of this city is co-managed by experts of industry, government and science.

3. RELEVANT OUTCOMES

3.1 Motivate cities to study from typical example

"Kaohsiung house plan" has motivated more than 10 other cities in Taiwan to learn all sorts of innovation policies of Kaohsiung City, which has become the typical example of green and sustainable city and become the dialogue basis for diplomacies between international cities.

Figure 1: Vertical forests –landscape balcony and transformation of unauthorized buildings - green energy facilities

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.2 Rainwater storage facilities

The disaster prevention of small flood detention: when the rainwater storage amount has reached to 223,920 cubic meters, equivalent to capacity of 119 swimming pools with international standard, then the delay time of the flood peak's arriving is set at about 30 minutes to reduce the disaster of heavy rain's impact.

The rainwater tank: the processed amount of recycled rainwater has reached to 2,761,365.24 litters/ day, which means 1,007,898 tons of water is saved per year, and 156,224 kg of carbon is reduced per year.

3.3 The set amount of solar photovoltaic

The set amount of solar photovoltaic in newly-built construction has reached to 54,446 KWP, equivalent to the amount the set amount of solar photovoltaic of 53 Kaohsiung World Games Main Stadium. It can create 700 million degrees of electricity consumption in one year, and the carbon reduction can reach to 430 million kg/ year.

3.4 The of lighting and energy saving

To standardize 97% of existing buildings in the city, the high-energy lamps and interior decorations shall not be used when applying for interior decoration for the buildings and changing the use of buildings. So far the energy-saving lamps applied in the case have reached to 2,861,768 watts, which can reduce the electricity consumption of 2,862/ hour. Calculated by using 16 hours one day, then, the reduced electricity consumption is 16,714,080 kWh/ year, and the reduced carbon amount is 10,228,188 kg / year.

3.5 The creation of universal space suit for All-Age

The universal design of the bathroom: the moving lines of the passageways are smooth and the net width of the door should reach 80 cm so that wheelchair users can be in and out smoothly and steadily, and the area has reached 12,406 square meters.

The universal design of social hall: Extending the traditional construct concept of "courtyard" space to create spaces of social hall for all-ages in the community, of which the area has reached 1,369 square meters.

3.6 To create the business opportunity for green building industry

By supporting green energy industry, increasing more than 2,500 job opportunities per year and newly- increasing 500 high-standard green buildings in four years to motivate the green business opportunity with about more than 700 billion of total industries, and to improve the job opportunity and wishes of returning the hometown to provide services for the people of Kaohsiung.

3.7 Verticals forest

The green area on the roof is 160,921 square meters.

The area of landscape balcony is 70,360 square meters, of which Green area 23,453 square meters. The balcony landscape with the depth of 3 meters, breaking the laws and decrees, is combined with more than 1/3 shrubs and arbors to afforest. By adjusting the micro environment, and creating a healthy rest space to promote the plane surface greening to become the vertical forest. By replacing the former frozen cement and iron sheet to transform the image of industrial city into Kaohsiung garden city.

The total green area has reached 184,374 square meters, equivalent to the areas of about 28 football fields, and the reduced carbon is 3,687,480 kg.

Figure 2: The landscape balcony that can be used for sun shading and rest

3.8 The total amount of reduced carbon

The execution of the "Kaohsiung house plan," can reduced the annual carbon amount of 13,500 tons, equivalent to the carbon amount stored by 13.5 ten thousand arbours. So far the total reduced carbon amount has reached to 47,250 tons, equivalent to carbon amount stored by 4,725 ten thousand arbours.

3.9 Cross-border action and social participation

"Kaohsiung house plan" is a cross-domain construction action studied and participated by citizens and experts from industry, government and science. Now 100 green building awarding brands of Kaohsiung houses has been awarded certificates, 100 outstanding creative design works of Kaohsiung houses has been selected, 45 ACCD of Kaohsiung house has been cultivated, and more than 12,000 people have participated in the relevant activities. The plan emphasizes the public participation and empowerment of community, and is driven by the units of metropolis, economy, education, agriculture and marine division dividedly. Having launched the responses of 348 schools, and 95 agricultural and fishery facilities, the plan has got 144 buildings of construction license of Kaohsiung house, a total of 11,950 households.

4. THE FUTURE KAOHSIUNG GREEN BUILDING 3.0 VERSION DEVELOPMENT ASPECT

4.1 Orange construction planning

The most important element of orange technology is H2O, which stands for health, happiness and offering. Its correlative calculation is orange computing models are health model, happiness model and offering model. The details are as follow:

- Health Technology: senior medical care and old timers living technology are becoming increasingly important. Medical prevention of illness has become a crucial issue. To advance and develop senior living quality and green-orange health care is the challenging issue.
- Happiness Technology: in order to promote happiness indicator, engineering technology and social science and humanity can be used to advance public safety, anti-stress, pleasure, social relationship, education, energy, financial wellbeing.
- Offering Technology: other than establishing personal health and happiness, orange technology also promotes happiness in others. Offering technology uses technological innovation to better interpersonal relationship.

4.2 Intelligence: disaster prevention

Cloud technology can provide designers to directly on Web-GIS cloud system to design site development, install and control various water tanks in order to set and measure the precipitation.

4.3 Life box

Newly built residential households have to install a family emergency shelter. It is about 1.6~3.4 m^2 (determined by the surface area of the house). The door is made of steel board, and the four walls, ceiling and floor are made

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

of concrete with steel foundation that are thickened to 200~300mm (determined by the height of the house). The inside has one or two vents and has electricity, internet and radio.

5. SUSTAINABLE DEVELOPMENT AND CONCLUSION

The city plan shown by Kaohsiung sustainable construction on its local culture, sustainable nature and friendly environment is: under the pluralistic development of the overall Kaohsiung city, not forgetting the traditional geographic landscape, architectural features and ethnic culture to show respects to different ethnics, cultures and regional characteristics by Kaohsiung house plan.

Figure 3: The field surveys on Kaohsiung house

Kaohsiung house case is integrated by project management, from which benefits of Kaohsiung house is studied and analysed. Inviting and getting the scholars and experts from industry and government to jointly study, analyse and discuss the case to formulate the basic standard of the sophisticated direction for Kaohsiung house plan's policy tools. Establishing the database of Kaohsiung house's newly-built cases to track application case progress of Kaohsiung houses which have got the licenses for the construction, and to build the databases of photos, decrees, construction methods, cost analysis on the basis of the weekly field surveys. Meanwhile the wind environment, ambient heat, light environment or user satisfaction will be studied and analysed by simulation software and questionnaires, and the benefits of industry, the economy and reduced carbon will be quantified.

To promote the sustainable environmental feedback mechanism, the financial resource should be self-created by paying agent money, fees for regulations and giving back money, besides which shall be executed by the management mechanism of sustainable green construction's operating funds. Apart from the direct giving back to sustainable environmental construction, the operation of the innovation policies' mechanism should be constantly scrolled.

ACKNOWLEDGMENTS

Full gratitude paid toward Public Works Bureau of Kaohsiung City Government for its support in this research.

ABSTRACT

More than a thousand buildings have been certified as green buildings using this evaluation system since 1999 when the green building evaluation system of Taiwan was first applied. It provides policy makers as a form of positive feedback from the quantitative effects of water conservation efforts. The present study offers a calculation process for estimating the quantitative volume of water saved by practical green buildings. The baseline water usage for all kinds of buildings was determined to serve as the criterion for determining the water saving efficiency of individual buildings. An investigation of the average water saving rate from 2000-2013 for 1,320 buildings certified as green buildings was conducted to validate the estimation results. This research used 568 cases of green buildings which involved the rainwater harvesting system design and operation to be the validation as well. The evaluation result shows average 48% water saving rate in these cases involved rainwater harvesting system. Water savings will inevitably follow from the use of water-saving appliances or water-saving designs for buildings. The investigation on the difference between the actual water consumption of the building awarded with green building certification and the general building had been verified. Through the field survey, the water efficiency from rain water harvesting operation was evaluated and confirmed. It is proved the significant contribution to water efficiency from adoption of saving water design and rainwater reuse system in green buildings.

Keywords: design process, green rating tool, high-performance building

1. INTRODUCTION

The green building evaluation system used in Taiwan was first applied in 1999 and initially utilized a building's water efficiency as the threshold index for determining the building's environmental impact. More than a thousand buildings have been certified as green buildings using this evaluation system since then. It provides policy makers as a form of positive feedback from the quantitative effects of water conservation efforts. Theoretically, water-saving designs and the adoption of water-saving facilities should benefit buildings in terms of their water usage efficiency . However, actual real-world water usage is complex, being affected by a wide range of human behaviors and other factors .Regarding the issue of the effective use of water resources, the actual water consumption of a building with a green building certification should be different from those of buildings without water-saving designs. Relatedly, the question of whether substantial water-saving effects are achieved by such designs, as well as questions regarding their energy-saving and carbon-reduction benefits, are widely discussed. Therefore, it is requested with various investigations had to be undertaken to answer them.

To date, however, there are still no solid means of verifying or providing clear evidence to determine the quantitative effects of various water conservation strategies. A model for estimating water-saving benefits in order to clarify the effective use of water resources was established in previous research. To that end, an empirical investigation of buildings with green building certification was conducted to verify the values estimated by the model after statistical analysis. More specifically, quantified values of reasonable water-saving benefits for Taiwan for every year were derived to examine the effects of water conservation and to validate the proposed model. In this study the actual cases awarded by green building certification since 2000 to 2013 are taken as the research subjects [9]. This study would focus on the water conservation measures for green buildings in Taiwan with the aim of providing a quantitative procedure for proving water-saving efficiency.

2. WATER INDEXES AND EVALUATION

The water conservation index is a ranking system for the adoption of water-conserving items, including water closets, urinals, faucets and baths, and for the reuse of rainwater and grey water. As a practical process of the assessment of the water index of a green building's water resource indicator system WI value, the applied building should submit the proof documents about the saving water design items; then, the referee committee would confirm and determine the final rating value of the WI index. This rating system focuses on the saving water design and the adoption of water efficiency facilities for green buildings. The evaluation consideration engages the design and facility, not including usage patterns or behavior styles. Therefore, the rating value of saving water is a conceptual assessment for the water efficiency parameter without real water saving volume.

To more precisely estimate the quantity of water actually consumed by a given green building, the factor of operating time was added to the building categories when estimating the baseline for the quantity of water consumed. After the water consumption per unit of the floor area of a building with green building certification was acquired, this study used statistical quantitative methods and an empirical investigation for comparison and analysis, determining the actual gross water consumption as a basis for estimating the quantity of a building's annual water conservation. Accordingly, the baseline for annual water consumption for each category of building Wty (m^3/year) was established, and the formula for the estimated quantity of annual water conservation Wst (m^3/year) is provided as Equations 1–4.

$$W_{ty} = A_f \times WUI$$

Equation 1

$$W_{st} = W_{ty} \times (WI \div 9)$$

Equation 2

$$R_{sw} = W_{st} \div W_{ty} \times 100\%$$

Equation 3

$$R_{rs} = W_{rs} \div W_{ty} \times 100\%$$

Equation 4

W_{ty}: Annual water consumption for each category of building (m^3/year).

A_f: The floor area of a building (m^2).

WUI: Water consumption density per unit area of a building ($m^3/m^2 \cdot$year).

WI: Water index of a green building's water resource indicator system ($0.0 \le WI \le 9.0$).

W_{st}: Annual water saving of building (m^3/year).

W_{ty}: Annual water consumption of each category of building (m^3/year).

R_{sw}: Annual water saving rate of building (%).

R_{rs}: Annual rainwater substitution rate of building (%).

The score for the water resource indicator system for a green building's rating assessment system, WI, is the key parameter for estimation. This study used the real cases with green building certification, and each case has a certified rating value of the WI index. The average values of the water resource indicator rating scores for 2007–2013 (WI) were, for the most part, normally distributed between 3.0 and 5.0. According to the survey green building certificated cases, the annual water saving rate Rsw and rainwater substitution rate Rrs would be estimated.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. BUILDING CATEGORY AND WATER USAGE BASELINE

The water demand and the actual water consumption of buildings are actually quite complex, not only because of the difference in building types, but also because even among buildings of the same type, individual buildings may differ substantially due to factors, such as building age, occupancy, density, etc. Moreover, a building's usage and demand patterns will change after the actual construction is completed. All of these factors cause considerable difficulty in accurately estimating water consumption. Therefore, in order to more accurately estimate the actual consumption of green buildings to serve as the basis for assessing water-saving efficiency, the operating time factor was added to the factor of building types as one of the water consumption estimation criteria [10]. Herein, the water unit intensity (WUI) formula is defined by the parameters of occupancy density, yearly water usage and occupancy rate, shown as Equations (5)–(8).

$$WUI = P_{di} \times Q_{wi} \times F_{ri}$$

Equation 5

$$P_{di} = \prod_{i=1}^{12} P_{di} \text{ ; } 0.03 \le P_{di} \le 1.2$$

Equation 6

$$Q_{wi} = \prod_{i=1}^{8} Q_{wi} \text{ ; } 1 \le Q_{wi} \le 130$$

Equation 7

$$F_{ri} = \prod_{i=1}^{5} F_{ri} \text{ ; } 0.4 \le F_{ri} \le 0.8$$

Equation 8

WUI: Water consumption density per unit area of the building ($m^3/m^2 \cdot year$).

P_{di}: Person density (person/m^2).

Q_{wi}: Yearly water usage (m^3/person/year).

F_{ri}: Occupancy rate (%).

This study proposes WUI as the definition of building water usage density and to serve as the baseline of building water usage to evaluate the water efficiency of building water consumption. Due to the various categories of buildings, this study, in accordance with existing literature and relevant research and investigations, divided the buildings according to 52 different types of water utilization based on the building's utilization time characteristics in order to estimate the baseline for water consumption more precisely. After estimating the parameter levels for the standardized building water consumption and water consumption parameters, the baseline for each type of water consumption was estimated.

Overall, other than accommodation or medical buildings, which involve everyday-life water demands, the per-capita water demand per unit of buildings in general is mainly determined by the use of toilets and for cleaning activities. The water demands of accommodation buildings, on the other hand, include the water needed for cleaning and bathing, toilet flushing, cooking and other purposes. Based on the unity and efficiency principle of the estimation formula and for the sake of consistency in our assessments, water consumption was translated into average per-capita water consumption per unit for all building types. A building's total water consumption is mainly influenced by the two factors of per-capita consumption per unit and user density, and basically, these two factors are independent variables. With regard to the building category, spatial contrasts were computed by referring to 52 types of space according to building categories A–I under the building code of Taiwan.

4. INVESTIGATION AND VALIDATION

In this study the actual cases awarded by green building certification since 2000 to 2013 are taken as the research subjects with totally 1224 cases, the rainwater harvesting system is the focus of this research. Through the field survey, the water efficiency from rain water harvesting operation of 568 cases was evaluated and confirmed which involved the rainwater harvesting system design and operation to be the validation. The adoption rate of rainwater harvesting system design and operation in green building certificated cases is around 50% in general since 2000 to 2013, as shown in Figure 1.

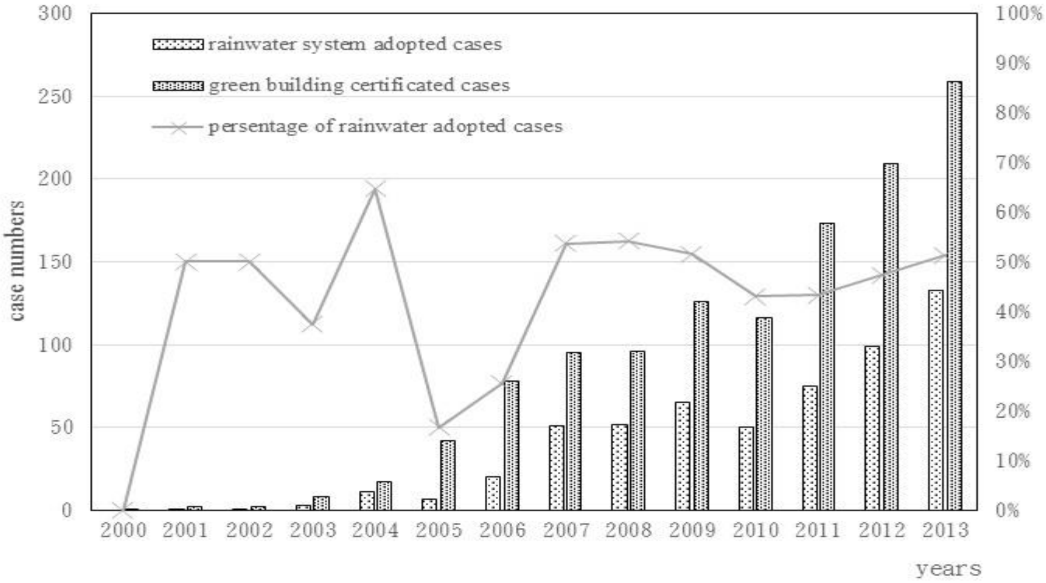

Figure 1: Green building certificated cases with rainwater system design

It is not possible to survey all green building certified cased with water consumption data. Thus, limited real cases of green building certification with confirmed data were selected to validate the efficiency of rainwater system. Due to the water quality standard and utility needs, the water saving rate was limited under 60% in evaluation system. Meanwhile, the rainwater substitution rate has maxima for different building type and utility needs. Herein, three groups of building types were defined from the 52 categories as residential, commercial and productive usage.

The residential use is daily usage for life including drinking, bathing, washing and etc.. The commercial use is daily usage for working area mostly is for toilet, washing, cleaning and etc.. The productive use is the usage for production area and the utility is vary and comprehensive including factory, restaurant, sport center, hospital and etc.. The usage includes producing process, toilet, washing, cleaning and etc.. Therefore, each category has maxima rainwater substitution rate for calculation from 20% to 55%. According to the reasonable limitation of maxima substitution rate, the green building certificated cases could be evaluated from water saving rate to rainwater substitution rate which the contribution framework of rainwater system adoption could be identified and recognized.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

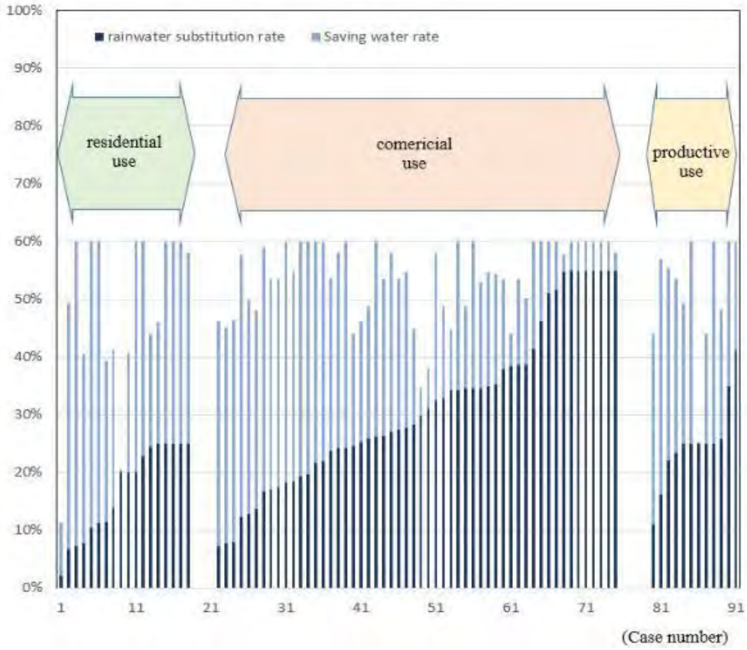

Figure 2: Distribution of rainwater substitution rate and water saving rate

This study used 91 cases of green buildings which involved the rainwater harvesting system design and operation to be the validation. Figure 2 shows the distribution of rainwater substitution rate and water saving rate of three group's buildings. It reveals that the rainwater substitution rate of residential use has lower rate of average 17%. As a result, the evaluation result shows average 54% water saving rate in these cases involved rainwater harvesting system. Initially, the average rainwater substitution rate is 28% as shown as Figure 3.

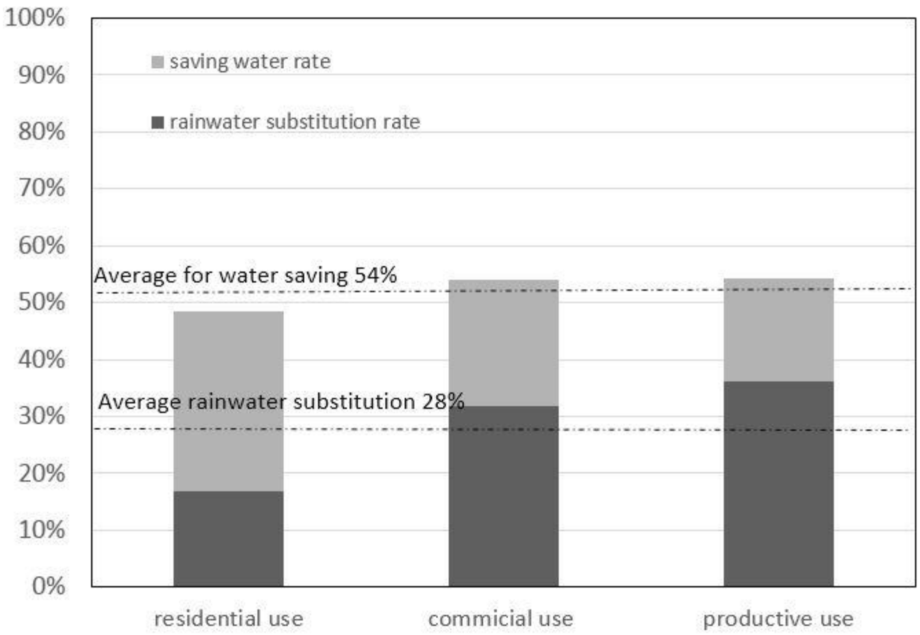

Figure 3: Comparison of rainwater substitution rate of three group's buildings

5. CONCLUSION

In this study the real cases awarded by green building certification since 2000 to 2013 are taken as the research subjects. WUI is proposed as the definition of building water usage density and to serve as the baseline of building water usage to evaluate the water efficiency of building water consumption. This conception is used to evaluate the water conservation in green building as the index to improve the water efficiency. The results are adopted by carbon footprint calculation model and link to low carbon evaluation system in Taiwan. Through the field survey, the water efficiency was evaluated and confirmed. This research used 91 cases of green buildings which involved the rainwater harvesting system design and operation to be the validation. The evaluation result shows average

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

54% water saving rate in these cases involved rainwater harvesting system. Initially, the average rainwater substitution rate is 28%. It is proved the significant contribution to water efficiency from adoption of water saving design and rainwater reuse system in green buildings.

ABSTRACT

The amount of solid waste generated in construction and demolition (C&D) processes is massive. Therefore, many countries and cities have established various economic policies to reduce C&D waste, which include waste disposal charge, deposit-refund scheme, tax on materials, and fine scheme. Appropriate economic policies can motivate the construction industry to minimise C&D waste. There are differences in economic policies adopted by various countries and cities. However, studies that compare the economic policies for C&D waste minimisation in various countries and cities are currently lacking. Therefore, this paper aims to quantitatively and qualitatively compare the economic policies implemented for C&D waste minimisation in Hong Kong, South Korea, the US, the UK, Ireland, the Netherlands. To understand the impacts of the economic policies on C&D waste minimisation, C&D statistical data are also analysed. Based on the comparative study, this paper will discuss the relationships between the economic policies and C&D waste. Recommendations on economic policies for C&D waste minimisation will also be provided.

Keywords: construction and demolition (C&D) waste, economic policy, waste management

1. INTRODUCTION

The amount of solid waste generated in construction and demolition (C&D) processes is massive. For example, C&D waste contributes 25% of solid waste disposed of at landfills in Hong Kong (HKEPD, 2015), 26% in the US (USEPD, 2009), and 47% in South Korea (ME and KECO, 2014). Therefore, many regions such as Hong Kong (HKEPD, 2015) and the US (ESD, 2012) have established various economic policies to reduce C&D waste. Appropriate economic policies can motivate the construction industry to minimise C&D waste (Li, 2013). Economic policies include waste disposal charge, deposit-refund scheme, tax on materials, and fine scheme (Li, 2013). There are differences in economic policies adopted by various countries and cities. For example, a high landfill tax is charged at USD 176 per tonne in Germany, which is 11 times as expensive as the construction waste disposal charge in Hong Kong. However, studies that compare the economic policies for C&D waste minimisation in various regions are currently lacking. Therefore, this paper aims to quantitatively and qualitatively compare the economic policies implemented for C&D waste minimisation in the Asia Pacific, North American, and European regions because they are the largest construction markets (IHS, 2013). Specifically, Hong Kong, South Korea, the US, the UK, Ireland, and the Netherlands were studied in this paper. The details of economic policies to be investigated include establishment and modification years of economic policies, waste disposal facilities, classification of waste types, and charges for each waste type. To understand the impacts of the economic policies on C&D waste minimisation, solid waste and C&D waste generated per capita and C&D waste generation rates are analysed as well.

The next section introduces the economic policies for C&D waste minimisation in the six regions, and investigates and compares them quantitatively and qualitatively. Section 3 compares previous and current C&D waste statistical data of each region. Section 4 discusses the findings, followed by conclusion in Section 5.

2. ECONOMIC POLICIES FOR C&D WASTE MINIMISATION

This section introduced and compared the economic policies for C&D waste minimisation in Hong Kong, South Korea, the US, the UK, Ireland, and the Netherlands.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.1 Economic policies for C&D waste minimisation

The economic policies cover deposit-refunded scheme, fines scheme, charging scheme (or landfill levy), and tax on raw materials (Li, 2013). Deposit-refunded scheme means that the deposit is refunded when the specific requirements are fulfilled. The scheme reduces the incentive to illegal dumping and stimulates reuse and recycling of waste streams. In construction and demolition diversion deposit (CDDD) in the US, the deposit is based on construction type, project size, and project value. Fines are charged for non-compliance such as illegal dumping and low recycling rates. The charging scheme charges construction waste generation in order to reduce the amount of C&D waste disposed of at landfills. Many countries and regions have adopted this scheme. Tax on raw materials is a financial measure by shifting the price differential against raw materials and in favour of secondary materials, in order to reduce resource extraction, to increase recycling rates, and to make full use of secondary materials.

2.2 Comparison of economic policies

Establishment and modification years of the four types of the economic policies were investigated and compared in this study. Data on the economic policies for C&D waste minimisation in the six regions were collected from previous studies (Oosterhuis et al., 2009, EIONET, 2009, HKEPD, 2012, ESD, 2012), as shown in Table 1. Although there are no economic policies for C&D waste management and minimisation in South Korea, the waste management law introduced for solid waste in South Korea in 1986 was used for C&D waste as well (KECO, 2016).

A deposit-refunded scheme (in 2001) and fines scheme (in 2006) were established in the US. In terms of the deposit-refunded scheme, CDDD of the County of San Diego (ESD, 2012) was effective in 2007 with the requirement of 90% of inert waste and 70% of other waste diverted from landfill. Four regions such as Hong Kong, the US, the UK, and the Netherlands established tax on raw materials. Moreover, tax on raw materials is also adopted by most of European countries such as Denmark, Sweden, Belgium, and Italy (Eunomia et al., 2009).

Region (reference)	Economic policies (year)			
	Charging scheme	Deposit-refunded scheme	Tax on raw materials	Fines scheme
Hong Kong (HKEPD, 2012)	2006	-	2001	-
South Korea (KECO, 2016)	1993[a)] (2008[a)b)])	-	-	-
US (ESD, 2012)	1989	2001 2007 (San Diego)	1998	2006
UK (EIONET, 2009)	1996	-	2002	-
Ireland (EIONET, 2009)	2002 (2008[b)])	-	-	-
Netherlands (Oosterhuis et al., 2009, EIONET, 2009)	1996	-	1997	-

a) Denotes the establishment or modification year for solid waste
b) Denotes the modification year

Table 1: Comparison of economic policies for C&D waste minimisation in six regions

Interestingly, the UK has a progressive landfill tax, which means the tax rate rises each year, to enhance the awareness of waste reduction and divert waste from landfill (Tojo et al., 2006). Since there are big differences in the charging schemes adopted by various countries and cities, C&D waste charging schemes in the six regions are quantitatively compared in the next sub-section.

2.3 Comparison of C&D waste charging schemes

C&D waste charging can be categorized by waste type and waste treatment facility type according to charging schemes, as shown in Table 2. For example, in Hong Kong, C&D waste is classified into inert waste and non-inert waste by waste material. Inert construction waste contains rock, rubble, boulder, earth, soil, sand, concrete, asphalt, brick, tile, masonry, and used bentonite (HKEPD, 2013). In other regions such as South Korea and the Netherlands, C&D waste is categorized into combustible and non-combustible waste (Gritten, 2007). In the Netherlands,

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

combustible waste that can be recovered is prohibited to dispose of in landfills. Depending on the C&D waste types, C&D waste is disposed of in other types of facilities, including landfills, public fills, sorting facilities, and incineration facilities. Table 2 shows the comparison results of charging schemes in the six regions, including C&D waste types, facility types, charging fee, and ratios of charging fee.

C&D waste disposal cost at landfills in the UK (USD 107.7) is the most expensive, followed by the US (USD 74.0), the Netherlands (USD 70.8), South Korea (USD 46.1), and Ireland (USD 26.0). The C&D waste disposal cost at landfills in Hong Kong (USD 16.4) is the cheapest among the six regions, which is 15.2% of that in the UK. On the other hand, the disposal cost at public fills in the UK and Hong Kong are cheap. The incineration of construction waste in South Korea is the most expensive method.

Country (Reference)	C&D waste type	Facility type	Charing fee (USD/tonne)	Ratio (%)
Hong Kong (HKEPD, 2012)	Less than 50% inert waste	Landfill	16.4	15.2
	Inert waste	Public fill	3.5	3.2
	More than 50% inert waste	Sorting facilities	12.9	12.0
South Korea (Lee and Dong, 2016)	Mixed waste	Landfill	46.1	42.8
	Recyclable waste	Sorting facilities	67.3*	62.4
	Combustible	Incineration	134.5*	124.9
US (ESD, 2012)	Mixed waste	Landfill	74.0	68.7
	Recyclable concrete	-	10.0	9.3
UK (UKGov, 2006)	Mixed waste	Landfill	107.7	100.0
	Sorted waste (rock or soil)	Public fill	3.2	3.0
Ireland (Li, 2013)	-	Landfill	26.0	24.1
Netherlands (Van Dijk et al., 2001)	Non-combustible	-	13.9	12.9
	Combustible	-	70.8	65.7

* Is the average value of charging fee

3. ANALYSIS OF C&D WASTE STATISTICS

In order to understand the current status of C&D waste generation and the impacts of the economic policies on waste minimisation in the six regions, their C&D waste statistical data were collected, analysed, and compared. This paper analysed data on (1) the amount of generated solid waste per capita, (2) the amount of generated C&D waste per capita, and (3) C&D waste generation rates.

In order to analyse the amount of generated solid waste and C&D waste per capita in each region, data on the amount of generated solid waste and C&D waste and population in each region should be collected. In this paper, data on the amount of solid waste and C&D waste were obtained from database of HKEPD (2015), ME and KECO (2014), and Eurostat (2016) for Hong Kong, South Korea, and the UK, Ireland, and the Netherlands, respectively. However, since Eurostat has provided waste information during the period from 2004 to 2012, this paper analysed trends of generated C&D waste per capita for 12 years. Population data in South Korea, the UK, Ireland, and the Netherlands were collected from the Organization for Economic Co-operation and Development (OECD) Structural Analysis (STAN) database (OECD, 2016). Population data in Hong Kong were collected from the database of the Census and Statistics Department of Hong Kong (HKCSD, 2016).

Figure 1 shows the trends of (a) Generated solid waste per capita, (b) Generated C&D waste per capita, and (c) C&D waste generation rates in the six regions during the period from 2004 to 2012. However, since data on the amounts of solid waste and C&D waste in the US were not officially provided, the results of the US could not be investigated and compared. As a result, the amount of generated C&D waste per capita in the Netherlands (average: 3,930kg) was generally larger than those in Ireland (2,033kg), Hong Kong (2,011kg), the UK (1,674kg), and South Korea (1,279kg), in spite of high recycling rates of C&D waste (around 99% in the Netherlands (Gritten, 2007)). The amount of generated C&D waste per capita increased in the Netherlands (159%), Hong Kong (203%), and South Korea (121%) during the periods from 2004 to 2012, while those in the UK (95%) and Ireland (3%) decreased during the period. Interestingly, generated C&D waste per capita in Hong Kong has rapidly increased since 2008, while that in Ireland has rapidly decreased since 2006 although generated C&D waste per capita in Ireland in 2006 was the highest among the six regions. The C&D waste charging schemes in Hong Kong and

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Ireland were released or modified in 2006 and in 2008, respectively, and they had positive impacts on C&D waste reduction at the time the schemes were released or modified in each region. Especially, generated C&D waste per capita in Ireland in 2012 was around 2 % of that in 2006. On the other hand, although generated C&D waste per capita in Hong Kong in 2008 was 77% of that in 2004, that in 2012 increased by 2.6 times as compared with that in 2008. According to previous studies (Lu, 2013, Lu and Tam, 2013, Yu et al., 2013, Hao et al., 2008), the C&D waste charging scheme in Hong Kong helped to reduce the amount of C&D waste generated for the first three years (2006 to 2008); however, the impacts of the charging scheme was low since 2008 because of low C&D waste disposal cost. The most expensive cost for disposal of C&D waste in the UK can be a reason of the slight decrease in the amount of C&D waste generation in the UK. Another reason is the annual increase of C&D waste disposal cost in the UK year by year.

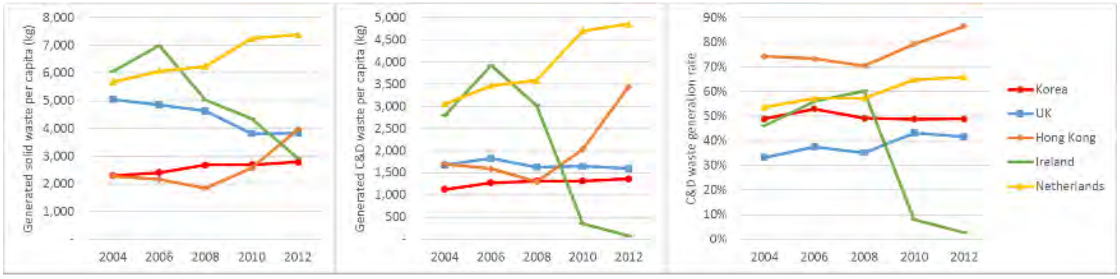

Figure 1: Trends of solid waste and C&D waste generation per capita in the six regions (2004, 2006, 2008, 2010, and 2012)

Although time-based trends of the amount of generated C&D waste per capita in the six regions were similar to those of generated solid waste per capita and of C&D waste generation rates, the orders of C&D waste generation rates in the six regions were slightly different from that of generated C&D waste per capita. In terms of C&D waste generation rates, Hong Kong (average: 77%) was the highest, followed by the Netherlands (60%), South Korea (48%), the UK (38%), and Ireland (35%). The C&D waste generation rates in the UK (125%), the Netherlands (123%), and Hong Kong (127%) increased unlike those in South Korea (100%) and Ireland (6%).

4. DISCUSSION

According to the results of this study and previous studies (Li, 2013), disposal cost of C&D waste had positive impacts on C&D waste reduction. Therefore, appropriate adjustment of disposal cost of C&D waste can motivate practitioners to efficiently minimise and manage C&D waste on site. Referring to the policy in the UK, an annual increase of the disposal fee year by year helps to decrease the amount of C&D waste generation. In Hong Kong, the charges for C&D waste disposal will be increased with effect from April 2017 to reduce the amount of generated and disposed C&D waste. Public fill charge, sorting charge, and landfill charge in Hong Kong are proposed to be increased to USD 9.2, 22.6, and 25.8 (263%, 175%, and 160% of charges of the current C&D waste disposal charging scheme in Hong Kong), respectively (HKEPD, 2016)

In order to efficiently minimise C&D waste, quantified goals, such as setting limits on the amount of total C&D waste being sent to landfills, setting recycling rates for C&D waste, etc., are required. The Department for Environment, Food, and Rural Affairs (DEFRA) in the UK has attempted to achieve zero construction waste to be disposed of at landfills by 2020 (Ismam and Ismail, 2014). The UK already exceeded the 2020 reduction target of recovering at least 70% by weight of inert C&D waste (DEFRA, 2013). Additionally, the impacts of economic policies on C&D waste reduction should be continuously monitored by investigating time-trends of C&D waste generation and disposal.

A comprehensive C&D waste composition study should be conducted so as to be aware of the current quantities of each C&D waste material type. Not only sorting inert and non-inert materials or combustible and non-combustible materials, a more detailed breakdown is necessary to identify which material type is in majority and which type should be mainly managed. The study should be carried out periodically in order to keep the data most up to date so that it can reflect recycling performance of different C&D waste materials as well as changes of disposal patterns because of established and modified economic policies for C&D waste minimisation. The collected data could also help the government to propose possible future scenarios and required capacities.

5. CONCLUSIONS

This paper quantitatively and qualitatively investigated and compared the economic policies for C&D waste minimisation in Hong Kong, South Korea, the US, the UK, Ireland, and the Netherlands. Four types of economic policies, namely deposit-refunded scheme, fines scheme, charging scheme (or landfill levy), and tax on raw materials, were compared. In terms of charging schemes, there are big differences among the six regions. Tax on raw materials and charging schemes are used as economic policies for C&D waste minimisation in the investigated regions. The disposal cost at landfills in Hong Kong is around 15% of that in the UK. Comparing results of C&D waste statistics in Hong Kong, the UK, and Ireland, this study finds that high disposal cost, annual increase of disposal cost, and establishment or modification of C&D waste charging schemes have positive impacts on C&D waste minimisation. However, impacts of low disposal cost for C&D waste in Hong Kong on C&D waste reduction did not last for a long period, but in Ireland, generated C&D waste per capita in 2012 decreased by 2% of that in 2006.

However, due to the limitations of data collection in this study, relationships between the economic policies and the amount of C&D waste were not analysed quantitatively and other factors can affect the C&D waste statistics as well. Therefore, in the future, the relationships will be analysed using statistical methods.

Using Supply Chain Management for Sustainable Public Procurement

Johannes WALL[a], Jörg KOPPELHUBER[b], Christian HOFSTADLER[c]

[a] Graz University of Technology, Austria, johannes.wall@tugraz.at
[b] Graz University of Technology, Austria, joerg.koppelhuber@tugraz.at

ABSTRACT

In recent years, interest in the cross-disciplinary area of sustainable procurement has increased in both academia and research. A main driver of this development is the rising number of policies and regulations dealing with these issues of procurement (e.g. COM (2008) 400; Directive 2014/24/EU). There are various strategies available for including sustainability aspects in the procurement of construction works.

However, the consideration of sustainability aspects in the tendering and awarding stage has only been implemented to a limited extend (insufficient criteria and weighting). In addition, a holistic approach is still missing.

This contribution presents a review of existing evaluation approaches in public tendering and awarding of construction works. This helps to provide evidence of connections between sustainability policy goals included in public procurement tenders and how public contracts are awarded (especially in Central Europe).

Furthermore, the paper focuses on supply chain management and how these processes of criteria setting, especially from the private (automotive) sector, can be considered and transferred to public procurement procedures. Therefore, not only product related aspects are examined, but also process related issues, e.g. information exchange and workflow management.

The goal is to identify and evaluate useful supply chain management criteria development methods, which could be adapted for construction and building projects in order to focus on a more holistic consideration of sustainability aspects.

Finally, a more performance-orientated approach is intended, with the aim of working towards a more cooperative procurement. Joint specification, selected tendering, performance-based bid evaluations and collaborative tools particularly influence the success of a construction project during its life cycle.

Keywords: green procurement, design process, green economics

1. INTRODUCTION

Based on the latest climate initiatives, there is increasing awareness of the construction industry and their contribution to fighting climate change. In addition to the COP 21 taking place in Paris in 2015, a global alliance for building and construction has been launched to emphasize the implementation of ambitious actions towards the below 2°C pathway in the building and construction sector (cf. UN, 2015). The sector offers crucial potential for resource and energy efficiency; 30% of global CO_2 emissions are related to construction activities. Current developments such as rapid urbanisation, in particular in emerging economies, highlight the need to use the procurement of goods and services in the building sector to consider these sustainable development issues. This contribution targets the use of supply chain management to enable and promote sustainable public procurement.

2. METHODOLOGY

In order to assess the state of the art in sustainable public procurement, an extensive literature review (Wall and Hofstadler, 2016a) has been performed. In a second step, the ongoing situation has been investigated using an expert questionnaire with the aim of investigating current implementation of sustainable construction (Scherz, 2016). The questionnaire explored the perception of different parties and stakeholders involved in sustainable construction from an AEC point of view. The experts were chosen based on their experience in this field. These are people with a certain specific knowledge and expertise in a field (based on reference projects). Experts (in general) are responsible for the design and implementation as well as for checking/monitoring a certain solution and have privileged access to certain information such as decision-making processes (cf. Bogner et al., 2009).

This contribution shows the important role of supply chain management in achieving sustainable procurement. The findings stated in the following sections provide an overview focussing on the building sector. But most of these issues are relevant to the whole construction industry. There are several patterns, especially in procurement, that target the use of supply chain management.

3. SUSTAINABLE PUBLIC PROCUREMENT

The procurement process sets up legal boundaries, based on the conditions within which a project is developed. Several European and national initiatives proposed policies for considering additional aspects during the tendering procedure. These started with the white paper on public procurement in the EU and COM 96 (583) final as well as COM 98 (143) final, which concluded with COM (2001) 274 focusing on "Commission interpretative communication on the Community law applicable to public procurement and the possibilities for integrating environmental considerations into public procurement". They resulted in the directive 2004/18/EC, which supports the awarding of contracts based on the most economically advantageous tender and enables a more life cycle orientated perspective in tendering with the European directive 2014/24/EU.

3.3 Current implementation of sustainability issues

The current procurement process within harsh and competitive markets in the construction industry is characterized by a strong focus on financial issues. The building sector has a fluctuating demand cycle, uncertain production conditions and segmented production processes with competitive relationships among the involved stakeholders. In order to focus more on life cycle oriented sustainable development, it is important to take into account a holistic approach, therefore the most economically advantageous tender could be suited best.

In the current implementation of sustainability aspects in the design and procurement of buildings, there is a strong focus on individual aspects, especially environmental issues. They may also be linked to certain energy-related performances of buildings, and building certification schemes are used to communicate these ambitions in practice. Therefore, data is required to transport this information and communicate certain aspects during the planning and construction stages of a project. For instance, in terms of environmental qualities, there are two different approaches available. One is on using normative issues, such as indications of toxic components and harmful influences, as limitation criteria in the procurement process. This information is gathered in online databases such as WECOBIS (German platform on ecological building products) and baubook (containing similar ecological information and offering services for implementing text blocks into calls for tenders).

Otherwise, a material selection process based on life cycle assessment according to EN ISO 14040 for determining the ecological performance of certain products and building components can help certain design targets to be reached. Relevant information can be communicated using environmental product declarations (EPDs) throughout the supply chain as an information tool for business-to-business clients/customers. Due to their standardized information, EPDs can be used in the procurement process to indicate the consideration of sustainably aspects and as an appropriate tool for documentation and quality management during the planning and construction stages (cf. Passer et al., 2015).

In an empirical study (cf. Scherz, 2016), different expert views from AEC industry have been assessed, not only taking into account the current implementation of sustainable construction but also future potential and action needed. The experts agreed that extensive demand planning is indispensable for the definition of specific stakeholder aims, especially for the consideration of sustainability aspects.

However, when the current situation is considered, the barriers result from reduced and limited financial and organisational capabilities of the clients. This is often combined with an insufficient understanding of integrated project deliveries and information workflows across the stakeholders. In addition to financial issues (price), current selection criteria take into account evidence of environmental policy, the supply chain network of subcontractors as well as the health and safety performance of main contractors. Furthermore, limited environmental information on products leads to look-alike criteria, which aim to consider life cycle orientated issues, but, due to their reduced weighting in the awarding procedure, are not relevant or do not contribute to a life cycle optimization.

Following the idea of holistic optimisation, it is important to target not only single normative aspects, but also an integrated project delivery.

When these findings are viewed in the context of the fragmented relationships between clients, contractors, subcontractors, and the building products and components manufacturing industry, the topic of supply chain management becomes of clear relevance.

4. SUPPLY CHAIN MANAGEMENT

Supply chain management (SCM) is a concept that flourished in manufacturing. It originated from Just-In-Time (JIT) production and logistics, taking into account the interdependency of supply chains (cf. Vrijhoef and Koskela, 1999). Recent developments in the field of SCM include the expansion of traditional performance measures (time, cost, and quality) including environmental and social aspects. In the automotive industry, factors affecting suppliers are identified as cost, technical capability, quality assessment, organisational profile, service levels, supplier profile as well as risk factors. Furthermore, suppliers' sustainability performance is becoming increasingly important as a key issue of tender selection criteria. Sustainable supply chain management (SSCM) has become a major issue in many industries, with the construction sector lagging behind (cf. Adetunji et al., 2008).

Green and sustainable supplier selection adds to the complexity of the decision and modeling process. The criteria are less specific and sometimes not easy to measure as they include aspects such as collaboration and project culture. Therefore, the operationalization of these criteria into meaningful and practical measurable variables presents a challenge to both suppliers and purchasers (cf. Igarashi et al 2013)

The following Figure 1 illustrates a general overview of a supply chain, with its dependencies in building construction (according to Vrijhoef and Koskela, 1999).

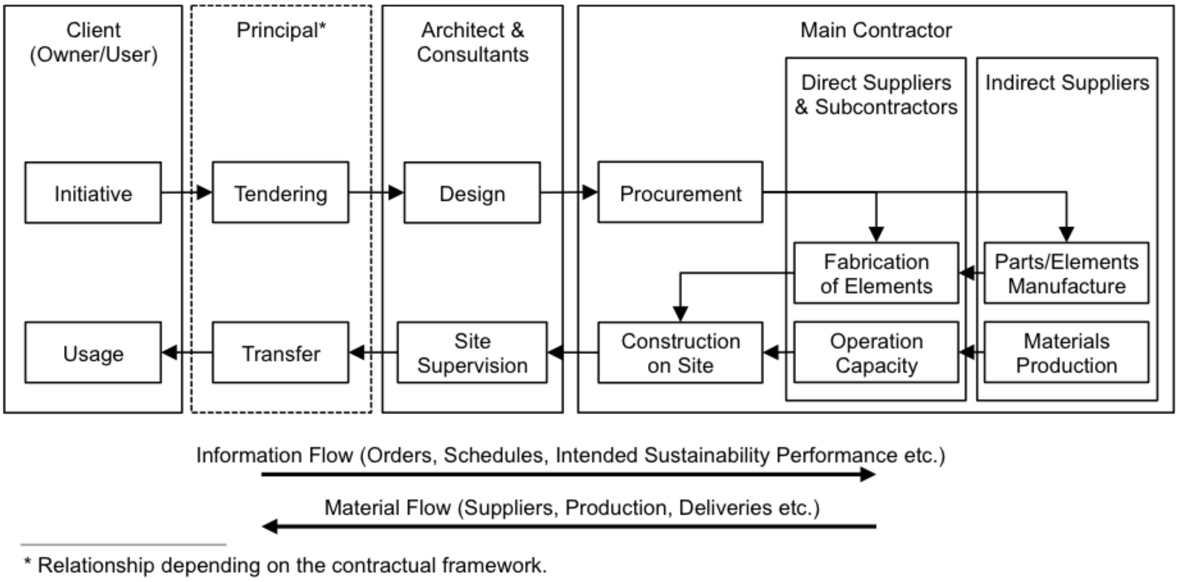

Figure 22: Generic overview of a building supply chain

A major challenge is to communicate information targeting sustainable performance, not only of certain products and materials, but also of overall achievement. Problems occur due to information asymmetries and losses though the supply process, affecting the interdependencies. This causes delays in earlier stages, resulting from myopic understanding and control of single processes missing out the impact on other related processes. In many cases, the actors are not willing/prompted to consider the effects of their activities.

4.1 Supplier selection methods

When procuring complex services and products, there is a need to evaluate and select qualified suppliers. The supplier selection process is often reduced to purchasing risks and maximizing the overall value of the purchase. The methodology evolved from the manufacturing industry, where selecting the right suppliers is crucial for business and represents a major opportunity for companies to reduce costs across its entire supply chain. However, emphasis changed from selection just based on price and has turned into a multi-criteria approach, with various qualitative and quantitative evaluation criteria.

There are plenty of sources introducing different approaches based on a categorical method, data envelopment and cluster analysis, such as case-based rating system decision modes for supplier selection. They follow a multi-criteria approach divided into multi-criteria decision-making tools, focusing on evaluation criteria, and sensitivity analysis (cf. Pal et al. 2013).

In this context, it is important to point out that the weighting aspect of additional criteria in supplier selection can vary depending on the specific project conditions.

4.2 Classification of project parameters

An increasing awareness of environmental issues due to clients' green procurement policies has led to a focus on a more comprehensive implementation of sustainability aspects, which depends on the type of building and its usage e.g. housing, office and public service buildings (hospitals, schools). Following this diversification, there are different key issues that occur in the context of a specific project and are necessary for providing a certain type of usage. Such parameters can be divided into: project goals, resources of the client, specific importance of the project, project duration, costs and number of involved experts and professionals form different disciplines managing the planning and construction tasks. Such issues are important in the selection of a supplier in terms of adapting requirements in specific project classes.

4.3 Supplier selection criteria

Despite the importance of sustainable supply chain management, there are several gaps in the research on how to implement sustainable issues into the procurement process within the frameworks of several policies (e.g. COM(2008)400) and directives (e.g. Directive 2014/24/EU). Literature reveals various criteria for supplier selection, such as cost, delivery quality, warranties, client policies and especially environmental product properties (cf. Pal et al., 2013).

The focus is often purely on product issues and material properties. Setting up selection criteria, it has to be considered that building products and the overall performance of the building are strongly influenced by the planning and building processes.

A life cycle optimized building can only be achieved using an integrated approach. This includes the consideration of issues related to process qualities, in terms of identifying criteria defining how specific works are carried out and performed, focusing on information flows and the design of reference processes to support the holistic optimization of a construction project.

4.4 Performance-based supplier selection criteria

Focusing on the different stakeholders and their contribution to a successful project, their technical (problem-solving) capability is crucial for providing high quality delivery. Requirements of a more performance-orientated supplier selection target the workforce skills, organisational structures, information flows and exchange within the project team. Factors include employment relationship, staffing schedule, and a proactive and solution-orientated working approach (cf. Wall and Hofstadler, 2016b).

Therefore, environmental management systems (EMS), certifications to ISO 14001 or special in-house policies and guidelines as well as qualification of key project managers can contribute towards a more performance-orientated supplier selection. Considering the composition of teams, the European Court of Justice confirmed in Case C-601/13 Ambisig 03/26/2015 that the academic and professional background of employees and their experience enables an evaluation of teams, especially for the performance of the contract. Hence, previous performance can help to clarify credibility and references projects, in terms of reliability.

Another crucial aspect seems to be the corporate philosophy of a project team, related to the organizational issues of the contractor in terms of their company culture and how projects are handled. This is also linked to performance and interaction with the previous client, considering how they managed to support the project workflow, keeping to the schedule and contributing towards the common project aim. When measuring such issues, the number of submitted claims could be an issue, as well as the evolvement of the cooperation and project development. Performance-based tendering decisions could be conducted using expert interviews with key employees to assess their problem solving capacities as well as their qualification and applicability for project specific requirements. Furthermore, such prequalification information can be obtained from electronic platforms such as ANKÖ or PQ-VOB.

Focusing on the supplier selection process, a committee (experts from different backgrounds, technical as well as representing user and operating perspectives) could provide support from early project stages onwards, defining awarding criteria and providing consistent consideration of these issues and their weighting factors through tendering and awarding stages.

The problem of the supply selection is also based on the fact that not all decisions can be made with measurable parameters that can be indisputably economically justified. This indicates a shift from cooperative to collaborative supplier performance.

A major weakness of SCM is the difficulty of creating a shared and common strategy and vision, achieving and maintaining significant behavioural change among involved stakeholders of the AEC, which in turn leads to a common understanding of project culture. The traditional reliance on price as a major indicator of success as well as fragmented delivery structures and competitive relationships, with the knowledge of the interchangeability of involved suppliers reveals the need for further investigation and research into these relationships and how to implement a continuous information flow towards a collaborative project culture.

Cooperative relationships recognize the potential for both organisations to achieve their aims and maintain a long-term relationship. But they lack the teamwork that is needed between the buying and supplying stakeholders. In collaborative relationships, a holistic view has to be applied for the two organisations to truly realize the benefits of working together to optimize the outcomes for both organizations in terms of developing a high-quality product or service on time and under budget.

5. CONCLUSION AND OUTLOOK

This paper emphasized the importance of sustainable public procurement and its contribution to putting the buildings and construction sector on a below 2°C path in the fight against climate change. There are several policies available, but practical implementation seems to lag behind. It is proposed that supply chain management should be used to deal with the complex situation of supplying and purchasing in the building and construction industry, due to the various suppliers and trades involved.

The aim is to use supply chain management to enable more sustainable decision making in tendering and awarding construction works in order to consider additional criteria rather than simply focussing on the cheapest offer when making the awarding decision. Therefore, the focus is not only on the product related aspects of construction works, but also on process-orientated aspects, thus supporting a more performance-based selection of contractors.

In terms of SCM or SSCM, the existing concepts can be defined as tools for identifying problematic economic, social and environmental issues throughout the supply chain and assessing their potential impact and risks and how to handle their occurrence. Therefore, a spectrum of advanced and innovative SSCM tools and methods are suggested, such as strategic alliancing, pre-qualification assessment and third parties certification of sustainable (environmental) product properties, validation of improvements, etc., in order to target an integrated project delivery.

The implementation of sustainability into the SCM is still limited to the willingness and capability of the client to decide to implement such a process. Thus, the responsibility of involved stakeholders and, subsequently, the practical implementation of sustainable aspects should be increased.

ABSTRACT

Hong Kong is a hyper-dense city with over 7.3 million people living in 1,100 sq. km in which 85% of land is hilly area. Due to the need to build residential developments to accommodate the ever growing population and at the same time, the need to have very concentrated road network systems to support economic growth, residential buildings are unavoidably built next to roads. As a result, traffic noise is undoubtedly the major environmental noise problem affecting residents in Hong Kong. The Government of Hong Kong Special Administrative Region (the Government) is committed to tackle road traffic noise problem through careful planning of new residential developments and also applying latest advancement of road surfacing to reduce noise at source. Alleviating traffic noise impact on new buildings sitting next to busy highways is never an easy task, nevertheless, the Government is forward looking and has been proactively collaborating with research institutes to develop innovative noise mitigation designs such as acoustic windows and acoustic balconies. Both are capable to reduce noise substantially while allowing natural ventilation for residents. On reducing noise at source, low noise road surfacing is a standard road surfacing material for expressway. New forms of road surfacing like polymer modified stone mastic asphalt with different aggregate size and crumb rubber stone mastic asphalt are being explored and put into trial widely on local roads. This paper summarizes the efforts in addressing traffic noise problems affecting residential developments through applying innovative acoustic windows and acoustic balconies; and overlaying low noise road surfacing on local low speed roads. Both means are novel ways that can be applied under suitable situations to achieve a quieter environment for residents in Hong Kong.

Keywords: traffic noise, noise mitigation measures and low noise road surface

1. INTRODUCTION

Hong Kong is one of the most densely populated metropolitan cities and is facing severe and pervasive road traffic noise problems. Due to a host of factors like limited habitable land, the need to provide accommodation for large population and concentrated transport networks to support economic growth, many residential developments are unavoidably built in close proximity to heavily trafficked expressways and roads, e.g. see Figure 1, and as a result, about 960,000 people are exposed to road traffic noise at levels higher than 70 dB(A)L10(1 hour).

There are mounting public concern about the noise environment and its impact on the residents' quality of life. Legislative Council members called for case conferences to look into the situation and pressed for solutions to reverse the situation. In response, the Administration is committed and action plans are in place to minimize the noise exposure. For instance, proactive preventive works are being done in planning of new roads and new residential developments so that future residents would not be affected by excessive road traffic noise. The Government are implementing measures such as retrofitting noise barriers on suitable sections of existing roads to address the existing problems.

For the preventing planning of new residential developments, conventional noise mitigating designs or measures like maximizing the setback from the road; orientating the building block to minimize view angle on the road; single aspect building design with only non-noise sensitive uses facing the road and using noise tolerant building, structure, architectural fin or purposely built barrier to screen off the road are considered for incorporation in the design of development against road traffic noise. However, these conventional noise measures may not be applicable in each and every case due to specific site constraints. Furthermore, these measures can hardly offer adequate noise reduction in the case which noise exceedances are large, say, when the housing block is extremely close to highly trafficked road. Therefore, innovative noise mitigation measures are needed in order to keep the traffic noise at bay. In this respect, the Government has been proactively collaborating with research institutes to

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

develop such mitigation measures in the form of specially designed windows and balconies (acoustic windows and acoustic balconies).

On the other hand, low noise road surfacing (LNRS) delivers promising performance even though noise reduction effect is not large as compared with that from barriers but all residents in the vicinity would be benefitted. As a matter of fact, LNRS has already been adopted for our new high speed (70km/hr or above) roads. The Administration takes further steps to test and to try out different forms of LNRS on local low speed roads.

Figure 1: Trunk roads built right next to residential blocks in the 1980s

2. INNOVATIVE NOISE MITIGATION DESIGNS

Closing of window with suitable pane for better acoustic insulation is a practicable noise mitigation measure in some western countries but not in Hong Kong because of its warm and humid climate, in particular, in summer. It will not only practically deprive the residents of an "open-window" life style but also increase the energy consumption by air-conditioning which is needed for a "closed-window" environment in Hong Kong. Therefore, acoustic insulation is only provided as the "last-resort" for residents to choose closing the window for abatement of traffic noise disturbance.

Therefore, in the context of Hong Kong, it is considered worthwhile to explore innovative designs at façade which can reduce noise transmitted into the housing units while allowing sufficient natural ventilation complying with the relevant statutory requirements. Having conducted studies and mock-up tests, the following special designs of windows or balconies are identified capable of offering sufficient ventilation and very effective in reducing road traffic noise transmitted into housing units.

2.1 Acoustic windows

There are different forms of acoustic windows. One of them is known as acoustic window (baffle type), which basically comprises 2 layers of openable windows separated by an air gap. The opened parts can be staggered on two sides with a vertical gap as shown in Figure 2 or on upper and lower portions with a horizontal gap as shown in Figure 3. For the former, the windows at the outer layer are normally side-hung windows which can be opened by pushing outwards while the window at the inner layer is sliding window. For effective noise reduction, the pane of the sliding window would be slid to the side behind the opened side-hung windows and the side-hung windows on the other side need to be kept close. Under such setting, only small portion of the noise reaching the opened side-hung windows can enter into the housing unit through the gap in-between the overlapping panes at both layers and then the opened part of the sliding window. At the same time, air flow can be maintained through the opened side-hung window, the gap and the opened part of the sliding window as well. The noise reduction mechanism for acoustic window with horizontal gap is basically the same as that for acoustic window with vertical gap.

After carrying out preliminary laboratory tests to demonstrate the noise reduction effectiveness of the acoustic windows with vertical gap, mock up units have been set up at a site to be developed for public housing to evaluate noise reduction and air ventilation performances. The mock up tests also aimed at evaluation of other issues like window cleansing, clothes hanging and maintenance etc with a view to facilitating the detailed design. The results of noise measurement at the mock up units facing the concerned highly trafficked road indicated that the achievable

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

noise reductions could be up to 8 dB(A) and the ventilation performance was also found to be satisfactory. The results of other studies indicate that the noise reduction effectiveness depends on a number of factors such as the gap width, the overlapping length and the sizes of the outer and inner openings etc.

For acoustic window with horizontal gap, the outer layer may simply be an opening on the upper part and the pane of the inner sliding window can be slid up and down. As the screen at lower position at the outer layer is very effective in shielding the traffic noise from street level, comparable noise reduction can be achieved even with a much wider gap between the inner and outer layer, which would probably allow for more ventilation.

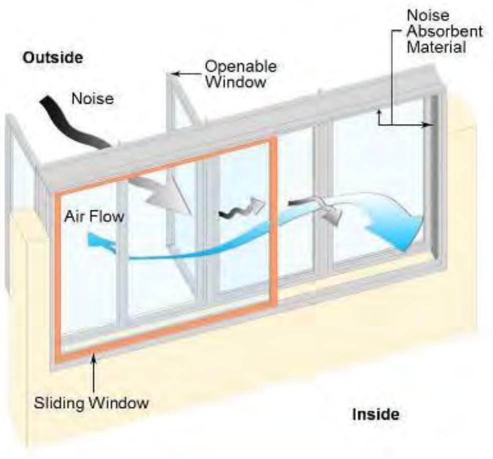

Figure 2: Schematic diagram showing the working mechanism of acoustic window (baffle type)

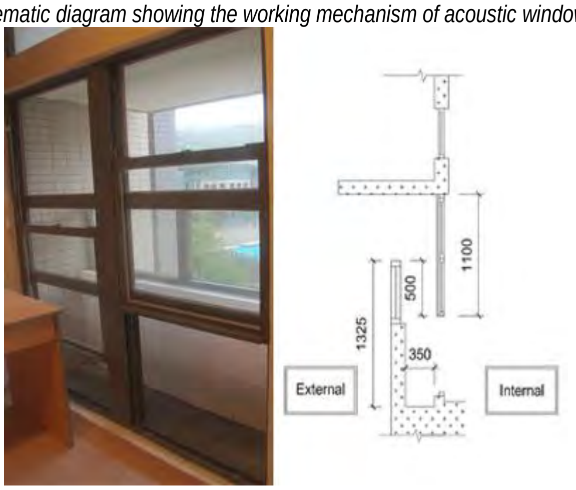

Figure 3: Acoustic window (baffle type) with horizontal gap

Another form of acoustic windows is known as acoustic window (top-hung type), which comprises top-hung windows as upper part close to ceiling and a horizontal panel projecting out from the frame and at the bottom of the windows as shown in Figure 4. The horizontal panel can act as an effective noise screen to reduce traffic noise propagating directly to the opening of the opened top-hung window and, hence, can greatly reduce the noise transmitting into the housing unit. As part of the noise is transmitted into the unit through single or multiple reflections by the pane and the horizontal panel, absorbent may be applied on the side of the pane facing inner and the upward side of the panel to enhance its noise reduction effectiveness. The noise reduction also depends on the height of the window and the extent of the horizontal panel. It is anticipated, with proper design, acoustic window (top-hung type) can achieve a noise reduction of 4-5 dB(A) or even more.

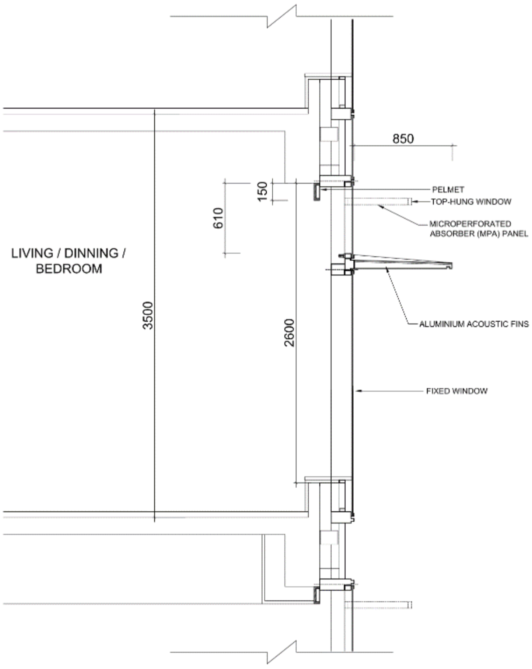

Figure 4: Schematic diagram of acoustic window (top-hung type)

2.2 Acoustic balconies

Balconies have been used in Hong Kong for long time. Features were added enabling noise reduction and hence could be adopted as a measure for mitigating traffic noise impact. The original design of acoustic balcony is just with solid parapets to screen off the noise from entering into the unit through the balcony door and with absorbents applied on the ceiling of the balcony to reduce the noise reflected by the ceiling to the balcony door. It is expected that such acoustic balcony can offer 2-3 dB(A) noise reduction. To enhance the noise reduction effectiveness, further additional features including extending the side parapets to full height side walls, providing a laminated glass panel projecting out from the top of the front parapet and adding sound absorption panels on side walls have been explored into the balcony design. Based on the results of noise measurements at mock up units, these additional features were found capable of offering significant extra noise reduction. Hence, the enhanced acoustic balcony were adopted and implemented in a public housing development in Sham Shui Po, Hong Kong as shown in Figure 5. The noise measurements at some completed housing units on different floors reveal that the noise reduction can be up to 5.5 dB(A).

However, for some extreme difficult cases with large noise exceedance, the above enhanced acoustic balcony is still not able to offer adequate noise reduction. Hence, efforts have been spent to study including other features to enhance the noise reduction further. It was found that, by putting a vertical panel above the front parapet and in front of the balcony door, the noise reduction can be increased significantly and may be above 10 dB(A) on higher floors.

Figure 5: Acoustic balcony in the public housing development in Sham Shui Po

3. LOW NOISE ROAD SURFACE

3.1 Low noise road surface on high speed road

The first trial of polymer modified friction course (PMFC) on a section of expressway was conducted in 1987 in Hong Kong to improve driving safety conditions under heavy raining situation, see Figure 6. Because of porous nature, PMFC brought along noise reduction which was mainly road tyre interaction noise. Measurements were conducted to study its traffic noise reduction performance. It was found that there would be around 5 dB(A) noise reduction in comparing the newly laid PMFC with the neighbouring brushed concrete surface. The maintenance records also indicated that the service life of PMFC on high speed roads was around 5 years .

Figure 6: First PMFC trial on high speed road in Hong Kong

As a result, noise abatement programme was embarked so that 11 kilometres of high speed roads were subsequently resurfaced with PMFC and was completed in 1999, bringing relief to about 16,000 dwellings. PMFC is now standard materials for high speed roads in Hong Kong for the dual effect of noise reduction and reduction of the potential for vehicles to aquaplane .

3.2 PMFC on local low speed roads

To investigate the applicability of PMFC on local low speed roads, some 60 existing road sections with different traffic conditions and road geometries were resurfaced with PMFC. Both noise reduction performance and durability performance were monitored for 5 years. The results showed that just after resurfacing, an average noise reduction was about 2.7 dB(A). From the monitoring data, it is considered that free flow traffic is almost a pre-requisition for PMFC to perform well in durability on local low speed road condition.

3.3 PMSMA6 on local low speed roads

Since not all local low speed roads are suitable for resurfacing with PMFC as locations with frequent stop-and-go etc. will induce repetitive shear forces on the PMFC surface causing development of defects and damage on the porous non-structural PMFC surfaces, following the recommendations of “Review and evaluation of the low-noise road surface programme for low speed-roads in Hong Kong”, thin layer asphalt in the form of polymer modified stone mastic asphalt of 6mm nominal maximum aggregate size (PMSMA6) was trial in different local low speed roads. It is noted that smaller aggregate size could generally achieve better noise reduction ability, stone mastic asphalt of 6mm nominal maximum aggregate size is selected as the base mix. Both noise reduction performance and durability performance are monitored.

3.4 CRSMA6 on local low speed roads

In parallel to trial of PMSMA6 on Hong Kong’s local low speed road condition, feasibility of rubberized asphalt on local low speed roads is also reviewed and explored. Modification based on PMSMA6, rubberized asphalt in the

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

form of crumb rubber modified stone mastic asphalt of 6mm nominal maximum aggregate size (CRSMA6) will be explored in Hong Kong to investigate its field performance under local low speed road conditions.

This idea stemmed from reuse of waste rubber tyre in which on one hand looking for appropriate LNRS for noise reduction and on the other hand providing way out for waste rubber tyres saving space of our very precious and limited landfill areas.

4. CONCLUDING REMARKS

The Administration is committed to keep traffic noise at bay. The innovative noise mitigation designs such as acoustic windows and acoustic balconies are relatively new approaches for reducing traffic noise problems in Hong Kong. Adoption of these designs could offer noise attenuation effect while allowing natural ventilation. Apart from adopting proactive planning approach and also use of noise barriers, the Administration takes big steps forward in exploring use of LNRS particularly on local low speed roads. Different forms of LNRS have been tried and tested out with promising noise reduction results. With the provision of innovative noise mitigation building designs and LNRS, it is optimistic that an acceptable acoustical environment for residents in Hong Kong would no longer be out of reach.

Energy Efficiency for a Sustainable Built Environment in Nigeria

Susanne GEISSLER[a], Ene MACHARM[b]

[a] SERA energy & resources, Austria, susanne.geissler@sustain.at
[b] German International Cooperation (GIZ), Germany, ene.macharm@giz.de

ABSTRACT

Nigeria is a fast growing economy but suffers from serious setbacks due to lack of power supply and the widespread use of ecologically and economically questionable private diesel and petrol generators accounting for over 50% of the active generation capacity. In 2013, the Nigerian Energy Support Programme (NESP) was set up to address and improve this situation. The Programme is implemented by the Deutsche Gesellschaft für Internationale Zusammenarbeit (GIZ) in cooperation with Nigerian partner institutions, and funded by the European Union and the German Government. It aims at improving the conditions for the application of and investments in renewable energy and energy efficiency as well as the promotion of rural electrification. Part of the Programme's activities is on energy efficiency in buildings, to ensure that electricity is saved through concrete measures like contributions to shaping the framework conditions and the implementation of pilot projects as a promotion and awareness creation mechanism.

This conference contribution reports on the approach and on the achievements accomplished so far in the building area. Key to success in developing framework conditions and related procedures is a participatory approach to ensure acceptance and feasibility, the focus on achieving actual energy savings, and the creation of an enabling environment for implementation and roll-out.

Keywords: affordable housing, energy saving, building code

1. INTRODUCTION

1.1 Content of this contribution

This contribution presents the Nigerian Energy Efficiency Support Programme (NESP), and specifically the activities and results achieved so far in the building area. It presents the general objectives of NESP, and continues with the activities in the building sector. Chapter 2 starts with describing the status on the ground, to better understand the setup of the programme presented in chapter 3.

Chapter 4 shows a key result, namely the Nigerian Building Energy Efficiency Guideline (BEEG), and chapter 5 continues with the Nigerian Building Energy Efficiency Code currently under development. The contribution concludes with a short outlook.

1.2 Objectives of the Nigerian Energy Support Programme

The overall objective of the Nigerian Energy Support Programme (NESP) is to improve the framework conditions for the application and investment in renewable energy, energy efficiency, and rural electrification. Specifically, it is the objective to ensure that concrete energy efficiency measures generate energy savings and contribute to reducing the load on the electricity grid. In Nigeria, the residential sector accounts for about 78% of the final energy consumption and consumes around 58% of the total electricity consumption. This situation compounded with the over 17 million units housing deficit in Nigeria certainly explains the urgent need for interventions to improve the conditions in the following areas (GIZ NESP, 2015 and GIZ NESP, 2014):

Policy: As the policy framework was not existing, NESP supported in developing an energy efficiency policy with an energy efficiency action plan as the implementation mechanism. The policy outlines target activities such as developing building energy codes and guidelines.

Standards: Standards on energy efficiency in buildings do not yet exist as the building code in Nigeria only addresses structural strength and fire safety. It is the intention of Nigeria's Government to integrate energy efficiency standards into the already existing building code in order to reduce building energy consumption.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Awareness Creation: Awareness creation could lead to more interest on energy efficiency issues, hence NESP focuses on implementing pilot projects on energy efficiency measures that demonstrate the technical and economic feasibility of energy efficiency, while also implementing public campaigns targeting specific stakeholders to increase knowledge on the benefits of energy efficiency.

Training: Knowledge on energy efficiency in buildings is lacking as many experts are not qualified in the area of energy efficiency concepts and technologies. NESP has developed curricula and handbooks on energy efficiency in building design, energy audit, and energy management. NESP is supporting training institutions with these curricula and handbooks and would train them as trainers in the sector.

2. STATUS ON THE GROUND: OVERVIEW OF THE NIGERIAN BUILDING SECTOR

2.1 Building legislation

The current building code dates from 2006 and does not address energy efficiency and renewable energy use. It is a set of rules to be implemented and enforced by regional governments, currently mainly referring to the structural system, general safety, and fire safety.

While in rural areas legislation is practically non-existent, in urban areas, the building codes and building permit procedures are relevant, except small buildings defined by building area or by building volume. However, building laws are not sufficiently respected, and there is lack of enforcement. People have disregarded the existing code, and often the control that should come from the responsible ministries is very ineffective because of corruption.

The causes of non-compliance with the legal framework are essentially related to:

- The lack of staff for the monitoring of construction sites;
- The lack of sanctions in proven cases of violation of the regulations constituting bad examples which impact on the decision for new constructions;
- The lack of information and communication on the one hand, the lack of good practices in terms of housing on the other hand, also regarding the laws regulating the materials and methods of construction in the built environment;
- The poverty of households;
- The corrupt practices.

The advert effect has been frequent collapse of buildings, water leakages, and abuse of set-back lines. However, there is awareness of this problem, and awareness of the need for improvement regarding compliance and control, and enforcement.

2.2 **Energy utilisation in Nigeria's building sector**

Availability of data for policy making is a prerequisite, and efforts for data gathering must follow a coordinated approach, meaning that data gathering must be institutionalised in responsible agencies. The National Bureau of Statistics mission is to generate, on a continuous and sustainable basis, socio-economic statistics on all facets of development in Nigeria. However, data on building energy consumption is not yet readily available (National Bureau of Statistics, n.d.).

With a population of over 170 million, Nigeria is the most populous country in Africa and the eighth most populous country in the world. According to the United Nations, one in six Africans is Nigerian. The population growth rate is projected to be between 2.5 and 2.7% per annum in the next 20 years. The population of Nigeria is therefore forecast to potentially grow to 310 million by 2035 (GIZ NESP, 2015). The present Government has committed to construct 17,760 houses annually as a short term plan to meet the over 17 million units housing deficit. With the population growth and the increased access to technology it is expected that building energy consumption will continue to increase. This stresses the importance of implementing energy efficiency measures in the building sector and particularly in the residential sector. In the residential sector, tenement, compound, bungalows, and block of flat housing types are the dominant housing options available to households in Nigeria. Also, the majority of rental and ownership households are concentrated in buildings considered old fashioned, while only a small

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

number of ownership households occupy block of flat buildings accompanied with modern facilities and services commonly found in high-income neighbourhoods of Lagos, Abuja, and Port Harcourt.

Most buildings occupied by the higher proportion of households in Nigeria are considered to be over aged and some are in need of renovation and timely maintenance. Governments have low impact on housing provision in Nigeria as the majority of buildings are owned by individuals, family, cooperative groups and societies, as well as multinational real estate companies.

Regarding electricity supply, Nigeria depends on thermal and hydro power plants for its energy production. According to Nigeria Electricity Regulatory Commission (NERC) statistics, 80% of actual generation capacity in 2015 comes from gas based power plants, while the remaining electricity comes from hydro power plants (GIZ NESP, 2015). However, Nigeria's peak energy generation amounts only to a maximum of about 5,000MW with a peak demand forecast of almost 13,000MW and 10,000MW off peak, meaning that the electricity supply of about 60 million Nigerian relies on private diesel and petrol generators (Federal Ministry of Power, n.d. and GIZ NESP, 2014).

Regarding energy consumption, around 85% of Nigeria's consumed energy comes from biofuels and waste. Almost 90% of that energy is consumed for residential usage. Similarly, based on data from the International Energy Agency, residential usage accounts for about 58% of the final electricity consumption in Nigeria. Likewise, it is the residential sector (households) where the increase over the ten-year period is evident (GIZ NESP, 2015).

3. SETTING UP THE ENERGY EFFICIENCY IN BUILDINGS COMPONENT OF NESP

3.1 Basic requirements

Wide application of energy efficiency requires a policy framework and legislation imposing energy efficiency minimum requirements. However, requirements will only be respected when controlled and enforced, and efforts for control and enforcement will be only feasible if there is societal support for the legal obligation. Societal support will emerge from understanding the challenges in the electricity sector and energy efficiency legislation as a means of problem solving. Thus, case studies are important to demonstrate technical and economic feasibility, and trainings are essential to further qualify those active in the construction and real estate business as well as civil servants concerned with checking, control and enforcement. Energy efficiency for a sustainable built environment in Nigeria is achievable by engaging the right stakeholders in all activities to ensure buy-in of energy efficiency concepts.

3.2 Modules of the energy efficiency in buildings component of NESP

The energy efficiency in buildings component in NESP is based on three pillars:

- Stakeholder involvement and awareness creation to generate societal support for the new framework conditions and legal requirements to come.
- The development of standards such as an energy building code regulating energy efficiency in the building sector.
- Implementation of pilot projects to demonstrate feasibility of complying with the new requirements.

An essential element of the first pillar is the Building Energy Efficiency Guideline (BEEG). It provides useful information to professionals in the building sector on key factors to consider when implementing energy efficiency measures in Nigerian buildings. BEEG was launched in June 2016 by the Federal Ministry of Power, Works and Housing with the support of NESP and the EU. More information is provided in chapter 4.

The Building Energy Efficiency Code (BEEC) mentioned above is an essential element of the second pillar and is currently under development. It is developed in cooperation with the Federal Ministry of Power, Works and Housing and Department of Development Control (AMMC) Federal Capital Territory Administration Abuja, as the Federal Code is adopted and implemented on states level. Implementation in Department of Development Control (AMMC) Federal Capital Territory Administration Abuja will be voluntary at first, in order to gain experience and improve procedures prior to imposing legal obligations. More information is provided in chapter 5.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Pilot projects demonstrate feasibility of complying with the new requirements and create material for dissemination to various stakeholder groups. Currently, the following pilot projects are being carried out:

- A Solar Water Heater (SWH) pilot project is being implemented with the aim of demonstrating the technical and economic feasibility of solar water heating technologies. By end of 2016, the SWH systems (68 units and 212 m^2 module area) of thermosiphon flat plate collectors will be installed at a boarding secondary school in Jos (Plateau State) to cater for the bathing needs of 1,000 students. The objective of the pilot project is to increase the use of solar water heaters in boarding schools in Nigeria, and to educate students on solar energy utilisation.
- In 2016, an Energy Audit of the Federal Ministry of Power, Works and Housing building was conducted. Based on the building energy use analysis and the audit results, it was observed that there is much room for improving energy efficiency. Recommendations for energy management in the building include low cost, medium cost and high cost energy efficiency measures. The objective of the pilot project is to increase awareness on energy management and the related benefits in public buildings and to provide a template for carrying out similar energy audits in other public buildings.

4. BEEG: BUILDING ENERGY EFFICIENCY GUIDELINE

The first Nigerian Building Energy Efficiency Guideline (FMPWH-NESP, 2016) includes a general introduction of energy efficiency in buildings at the beginning. Then it divides technically into two parts, namely active and passive elements of energy efficient building, and presents a design guideline how to proceed in building design to achieve an energy efficient building in Nigeria.

The Guideline also includes a description and assessment of building energy simulation and calculation tools as well as whole building design tools and sustainability certification models used globally. The regulatory framework necessary for the implementation of building energy efficiency in Nigeria is presented, and regional hazard to consider when designing buildings in Nigeria is discussed.

The Guideline concluded most importantly with case studies on building typologies, in order to assess and quantify the status quo of calculated energy demand and the impact of specific energy efficiency measures, showing how to improve on future building energy efficiency standards. The building typologies and climate conditions analysed in the case studies have been defined together with Nigerian architects and builders. Because of the lack of data it was not possible to follow a bottom-up approach but it was necessary to apply a model approach based on experts' knowledge. The following building types were analysed: residential buildings (bungalow and apartment) and office buildings (small and large). Two climatic zones have been tested for the building typologies, namely hot and humid climate and hot and dry climate. Although Nigeria has 6 geopolitical zones and 4 climate zones according to Köppen climate classification, the Guideline distinguishes only roughly between the two climates mentioned above. Simplifications were also necessary due to budgetary reasons. In order to define the impact of energy efficiency measures on each building type, a Building As Usual (BAU) scenario was defined for each typology. The BAU represents the usual construction practice in Nigeria and was derived mainly from responses to questionnaires circulated to construction professionals in Nigeria including local knowledge. Three variants on the BAU were modelled with incremental energy efficiency improvements following the concept of energy efficiency hierarchy: to reduce energy demand by passive measures, and to supply remaining energy demand by energy efficient active technologies.

The defined variants for the guideline are:

- Variant 1: Reducing energy demand by simple implementable measures, e.g. improving orientation, optimising window sizes.
- Variant 2: Variant 1 with additional measures, e.g. insulated walls, double glazing.
- Variant 3: Variant 1 and 2 with additional measures such as PV installation to generate electricity.

The simulation tool used for the analysis was DesignBuilder version 3, a whole building dynamic energy simulation tool using the software energy plus for calculating annual energy consumption of building designs. It also has the capacity of analysing both passive and active energy efficiency measures. The main outputs presented in the Guideline are annual energy consumption, annual energy cost, CO_2 emissions reduction, and hours of thermal comfort.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The Guideline promotes the objective of bioclimatic design strategies for Nigeria, in order to minimise heat gains and to promote heat loss by means of building orientation facing mainly north and south with overhangs or external shading. These are the most cost effective measures as they require no or low additional investment cost which is of paramount importance for societal support and wide spread application of energy efficiency in building.

5. BEEC - BUILDING ENERGY EFFICIENCY CODE

The starting point for developing the Nigerian Energy Efficiency Building Code (BEEC) was the analysis of existing energy efficiency building codes implemented in countries on all continents and evaluation studies if available.

Among others, the European Concerted Action on the Energy Performance of Buildings Directive (EPBD) and the EU-funded QUALICHeCK project provided important insight and ideas for discussing the specification for the development of the BEEC with Nigerian Stakeholders (EPBD-CA, 2016 and QUALICHeCK, 2016).

Usually, building energy codes consist of the following elements:

- Scope of the energy building code
- Definition of cost optimum energy performance minimum requirements and calculation methods how to determine them
- Publication of the assessment result (e.g. Building Energy Declaration: DEC, Energy Performance Certificate: EPC, Building Energy Rating: BER)
- Qualification requirements for experts issuing EPCs, BERs or DECs
- Control system, penalties and enforcement

In Nigeria, the challenges for developing a building energy code are manifold:

- There is a lack of knowledge how to plan and construct energy efficient buildings.
- There is a lack of standardised and quality assured materials and products needed for energy efficient buildings.
- The energy building code should avoid increasing investment cost for mass housing, at least in the beginning (urgent need for affordable housing).
- There is a lack of data to determine the status quo of energy efficiency and thus difficulties in determining energy performance minimum requirements.
- Cost optimum levels are nearly impossible to define because of lack of transparency and problems with corruption.
- Input data for energy performance calculations are hardly available or difficult to access.
- Qualification of experts entitled to issue energy performance certificates is an enormous challenge.
- Another huge challenge is the qualification of civil servants entitled with checking whether the building design and the completed building complies with the energy regulation.
- The difficult economic situation of the country is another problematic aspect.

The high importance of affordable housing puts simple but effective no-cost measures to the fore, such as correct building orientation to avoid solar gains and facilitate heat losses, and choosing the correct arrangement of windows (bioclimatic building design), in order to reduce cooling demand.

This creates additional challenges, namely the need to coordinate the approach with urban planning procedures, and the need to agree on the use of calculation tools suitable for taking into account sun exposure of facades depending on orientation and other site-specific features such as natural shadowing.

All these difficulties explain why the code will be voluntary at first, and compliance with the code will be rewarded with incentives. Nevertheless, the code should be developed as a fully functional framework to be implemented on the level of pilot cases, in order to gain experience and create awareness on new necessary building requirements and how to achieve them. Voluntary systems precede mandatory systems to give stakeholders the chance to learn and adapt.

Because of the expected fast increasing electricity consumption and the limited generation capacity lagging far behind demand, energy efficiency requirements clearly refer to the completed building and not only to the building

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

design. It is of paramount importance to increase energy efficiency in reality. It is also evident that the code will only be effective if regularly controlled. In this regard it is planned to entitle civil servants involved in checking building documents and completed buildings and issuing building permits and permits of use to also check whether energy efficiency minimum requirements are met. In Nigeria, the responsible public authority is called Development Control. Collaboration with the Department of Development Control (AMMC) Federal Capital Territory Administration Abuja will be crucial for developing a solution effective in the Nigerian environment. Integrating energy efficiency compliance checks in the daily routine of Development Control will require a substantial training effort.

6. CONCLUSION AND OUTLOOK

Implementation of building energy efficiency codes is essential for improving energy efficiency in the building sector. In 2013, interviews were carried out during the SEEA-WA project in most ECOWAS countries to investigate the status quo regarding energy efficiency building codes and to collect information about the most important barriers for developing and implementing such codes. The results showed that the major problem is not only the lack of legislation but the fact that laws are transferred from abroad, usually from Europe or from America, and are not sufficiently adapted to the needs of the respective country (ECREEE, n.d.).

Thus, BEEC development builds upon the prevailing conditions, and strongly considers local resources and skills available in Nigeria. Energy efficiency for a sustainable built environment is achievable by engaging the right stakeholders to ensure buy-in of energy efficiency concepts. In addition to building related requirements and frameworks conditions to encourage the uptake of energy efficiency measures, monitoring and enforcement procedures must be put in place.

It is important to plan monitoring and control procedures right from the beginning, in order to ensure that verification procedures proving that energy minimum requirements are met can be carried out with justifiable effort. These procedures serve to ensure quality, and if necessary to enforce compliance, in order to create an impact and actually increase energy efficiency.

Because of the enormous housing demand, financing options and the implication of the energy efficiency code to be developed have to be borne in mind. On the one hand, affordable housing for the middle-income class is a key issue for achieving development goals, and specification of minimum energy efficiency requirements has to respect this prerequisite. It must be considered that the projected time horizon for payback from energy efficiency measures is short, due to the rather insecure political environment. On the other hand, energy efficiency minimum requirements must be sufficiently ambitious to qualify buildings compliant with the code for financing with new financing instruments such as climate bonds (Climate Bonds Initiative, n.d.).

Session 4.4: Processes of High-Performance Green Buildings

What Are The Most Effective Drivers of Sustainable Development in The Decision Making Process

Hanne Tine Ring HANSEN[a], Mary-ann KNUDSTRUP[b]

[a] *Søren Jensen, Denmark, hrh@sj.dk*
[b] *Aalborg University, Denmark, mak@create.aau.dk*

ABSTRACT

The identification of the most effective drivers of sustainable development is a focal point for most – if not all – policymakers and companies interested in sustainable development. Whilst the answer to this is of course very contextual this paper presents a practitioner's review of the political and voluntary drivers for sustainable building in Denmark.

The paper identifies the most influential drivers for sustainable development in the Danish Building industry by combining a review of the regulatory political drivers in Denmark with two market surveys for construction clients from 2015 and 2016. The result of these surveys is compared to professional experiences from a number of sustainable Danish building projects completed or initiated in between 2008 and 2016.

It is the conclusion of this paper that whilst the regulatory drivers for energy and health are important when it comes to initiating and sustaining the market demand for sustainable buildings it is actually the economic and social drivers for sustainable building, such as life cycle costs, futureproofing of investments, better quality and Corporate Social Responsibility (CSR), that have the greatest impact on construction clients' decision-making processes. The paper furthermore reflects on how drivers for sustainable development vary depending on the construction client's planning perspective and how the contractor is engaged in the project.

Keywords: policy and regulation, drivers for sustainable development, strategy development

1. INTRODUCTION

Political and voluntary drivers of sustainable development are essential to whether humankind succeeds in its endeavour to create a more sustainable future in which future generations will not have to pay for the previous and current generations' over-consumerism and environmental negligence. If these drivers are too ambitious, people give up on delivering the goals set by the policymakers and if the drivers are too conservative the drivers become obsolete or victim of ridicule. By identifying the most effective drivers of sustainable development the chance of finding the right balance between political and voluntary drivers increases.

The following pages will provide readers with an insight into how regulatory and voluntary drivers are perceived by a Danish professional practitioner from the building industry who draws on experiences from more than forty different decision making processes relating to sustainable building design.

2. POLITICAL DRIVERS FOR SUSTAINABLE BUILDING DESIGN

When it comes to political drivers for sustainable development the UN and the EU have a history of providing effective political drivers for sustainable development. The UN has had a great impact on sustainable development through publications like the Brundtland Report and the fourth assessment report from the IPCC panel whilst the EU has made a significant impact on its member states' energy-efficiency and CO2 reductions in the Building Sector.

From a Danish building practitioner's point of view, the following EU policies have had the largest impact on sustainable development in the Danish building sector until 2016; the 2010 Energy Performance of Buildings Directive and the 2012 Energy Efficiency Directive. The past two years have also demonstrated how the voluntary UN Global Compact and EU directive on Non-Financial Reporting have established an increased awareness about social, as well as, economic and environmental sustainability with construction clients and tenants. This has

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

increased the market demand for sustainable buildings and changed the scope of sustainable building design from energy-efficiency towards a recognition of more holistic sustainable solutions. Last but not least the EU's focus on circular economy, the 7th Framework Programme and the Integrated Product Policy have 1) Provided building designers with incentives to design buildings for low-impact and for disassembly and reuse, 2) Caused the Danish government to change its policies on waste management in general and on construction projects and 3) Provided building product manufacturers with incentives to ensure recycling of resources and the use of renewable energy in their manufacturing processes.

3. VOLUNTARY DRIVERS

Since the mid-1980s when the concept of a 'low-energy building' was introduced in the Danish Building Regulations Danish building designers and construction clients have had voluntary schemes that have ensured improved the energy-efficiency of the Danish building sector. The scope for sustainability was broadened in 2006 when the Nordic Ecolabel (also known as the Swan Label) was introduced for single family homes in a Danish project titled 'Future Single-family Homes'. During the period leading up to the release of the Danish version of the DGNB system in 2012 Denmark saw the first BREEAM International and LEED registered projects and the transformation from low-energy towards a more holistic approach to sustainable building design was complete.

Despite having a nationalised adaptation of the DGNB system available and despite the fact that the LEED system is not the most ambitious certification system in a Danish context some companies still choose to adhere to the LEED system when it comes to sustainable building certification or company policies on sustainable building concepts. Based on experiences with companies like these it is this author's experience that the reasoning behind this choice is strategic and market driven rather than ignorance.

In 2015, the Danish Association of Construction Clients (DACC) conduced a market analysis of how 1) Construction clients, 2) Consultants, 3) Contractors and building product manufacturers perceived sustainability. The survey results are available at DACC's webpage and the results of the survey show that:

- 65% of construction clients regard the term sustainability as a relevant issue in their project organisations
- 62% of the construction clients define their approach to sustainability as a holistic and integrated approach to sustainability and that 53% of the construction clients define their approach to sustainability to include energy-efficiency
- The construction clients identify life cycle costs (LCC) (61%), total value (51%), branding (54%) and future regulatory requirements (32%) as drivers for sustainable development.

In 2016, the Danish Green Building Council followed up with a market analysis in which:

- 75% percent of the construction clients revealed that they expect the demand for sustainable buildings to increase and 25% expect the demand to remain at its current level.
- The construction clients with experiences with sustainable construction were asked to identify which of the following drivers that motivated them to choose sustainable building certification: environmental considerations (65%) lifecycle costs (48%), CSR (44%), Innovation (41%) Future regulations (37%), Fewer construction and design mistakes and a leaner process (27%), Increased sale and leasing opportunity (24%), increased market value (20%), increased demand for sustainable buildings (20%), 3rd party verification (17%).

The answers to these surveys demonstrate that whilst environmental benefits, as well as, current and future regulatory and voluntary drivers are considered important by construction clients' they also place great emphasis on economic drivers as well as tenant requirements which typically focus on social- and economic considerations such as operation costs, indoor climate and health. It is also worth noticing that the market analysis from 2015 did not focus on identifying the drivers of sustainable development but rather the main motivation and that the answers were slightly limited by the pre-defined answers in the survey.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4. THE IMPORTANCE OF MARKET, CULTURE AND ORGANISATION

4.1 The importance of market scope

The market scope of the construction client or tenant is essential when it comes to sustainable development where multinational co-operations or multi-nationally funded or insured co-operations in Denmark tend to choose the American LEED system whilst the nationally focused co-operations and organisations adhere to the Danish version of the DGNB system. The general impression of the development in Denmark is that LEED and DGNB are the main players in the market and other systems like the Swan Label, the Passive House and Active House concepts also appeal to some construction clients. This was confirmed in the DACC market analysis from 2015 where the construction clients have answered that 0% favour BREEAM, 14% favour LEED, 71% favour DGNB and 29% favour another system.

Sustainability consultants thus experience different market-driven approaches to voluntary certification schemes: 1) Nationally focused clients that choose to comply with the Danish version of the DGNB system, 2) Multi-national co-operations that choose to adhere to the LEED system because that simplifies their decision making process and thus their building design paradigm 3) Multi-national co-operations that choose to adhere to the scheme that is the preferred, and often most ambitious scheme, in the country where they planning a new project and 4) Multi-national co-operations or national co-operations that wish to comply with more than one scheme e.g. both the Danish DGNB scheme and the American LEED scheme.

Market scope and uniformity are thus important motivators when it comes to voluntary schemes that promote drivers of sustainable development. This also means that the voluntary drivers of sustainability vary a lot from project to project.

4.2 The importance of culture

When looking at the number of buildings in Denmark that have either undergone certification or that are registered for certification there is an increase in the number of tenders and projects that request sustainable building certification. However, if one only regarded the number of projects registered for certification one might think that neither DGNB nor BREEAM or LEED is very popular in Denmark when in fact most construction clients or tenants request sustainability these days. The difference between the Danish market and international markets with a large percentage of certified buildings can be ascribed to the fact that Danes are still a very trusting people. Because of that they regard certification as a stamp of approval of something that they expect their consultants and contractors to comply with regardless of whether or not they request building certification.

This means that voluntary building certification becomes a motivational driver when the construction client or tenant either 1) Wishes to brand his/her property via third party certification or 2) Wishes to change business as usual and challenge his/her organisation, consultants and contractors to improve their performance towards a more sustainable development. The latter is especially true for clients that take CSR reporting seriously and thus have a need to monitor and report progress. It is also interesting that, after having worked for the same companies more than once and having seen multiple tender material from the same clients, a lot of developers and municipal construction clients start out with the first type of motivation and end up with the latter. This is a testament to the fact that once they gain a better understanding of their approach to sustainability they start to use it as a developmental driver.

4.3 The importance of project organisation

Sustainable development is closely related to change management in the sense that sustainable development is about challenging the status quo and ensuring a change towards a more sustainable development. This means that ownership and communication are essential success parameters that one needs to consider when designing a project organisation for sustainable building project. Experiences with both successful and non-successful processes for decision making on sustainable building projects have verified that this is definitely the case when it comes to sustainable development in the building sector.

If the project organisation does not support a shared ownership or the person responsible for realising the sustainability strategy are placed inappropriately in the project organisation the drivers for sustainable development

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

change during the process at the risk of compromising the original intent behind the selected drivers. This means that the project organisation greatly influences the relevance and appropriateness of the drivers of sustainable development and whether the sustainability strategy for a given project is realised.

When deciding on a project organisation and a type of tender (i.e. turn-key vs. main-contractor vs. multiple individual contractors) one must therefore consider what motivates the different stakeholders at their given role in the project. Sustainable development is possible no matter the selected type of tender but it is important to be aware of motivational factors and how to ensure ownership with all stakeholders and actors involved in the process when designing the tender material.

Table 1 provides an overview of the experienced drivers for construction clients and an overview of the experienced drivers for contractors depending on the type of tender. The tables are based on experiences with more than forty cases of which at least twenty have either undergone BREEAM, LEED or DGNB certification or used the systems as a strategic tool whilst other projects have included a bespoke evaluation system that builds on one or more of these schemes. The table content for each type of project organisation has been generalised which means that the majority of the evaluated projects correspond with the experiences.

Generally, there are two types of construction clients; 1) Short-term perspective clients and 2) Long-term perspective clients. Short-term perspective construction clients are clients that build with the intent to sell (e.g. developers) whilst long-term perspective clients are clients that build and operate their own buildings (e.g. municipal, regional and social housing organisations).

Contractors are engaged in many different ways and at both early and late stages of the planning process. Generally, the earlier the contractor engagement the better the chance of realising holistic sustainability strategies. Four different types of contractor engagement are used in Denmark; 1) Turn-key contraction, 2) Main contraction, 3) Individual contraction and 4) Public and Private Partnership contraction. Of these four the Public and Private Partnership is the only type of contractor engagement that ensures a strong engagement in drivers for sustainable development in a long-term perspective because the contractor takes on the role of the building owner where he needs to ensure the building operation in a long-term perspective.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

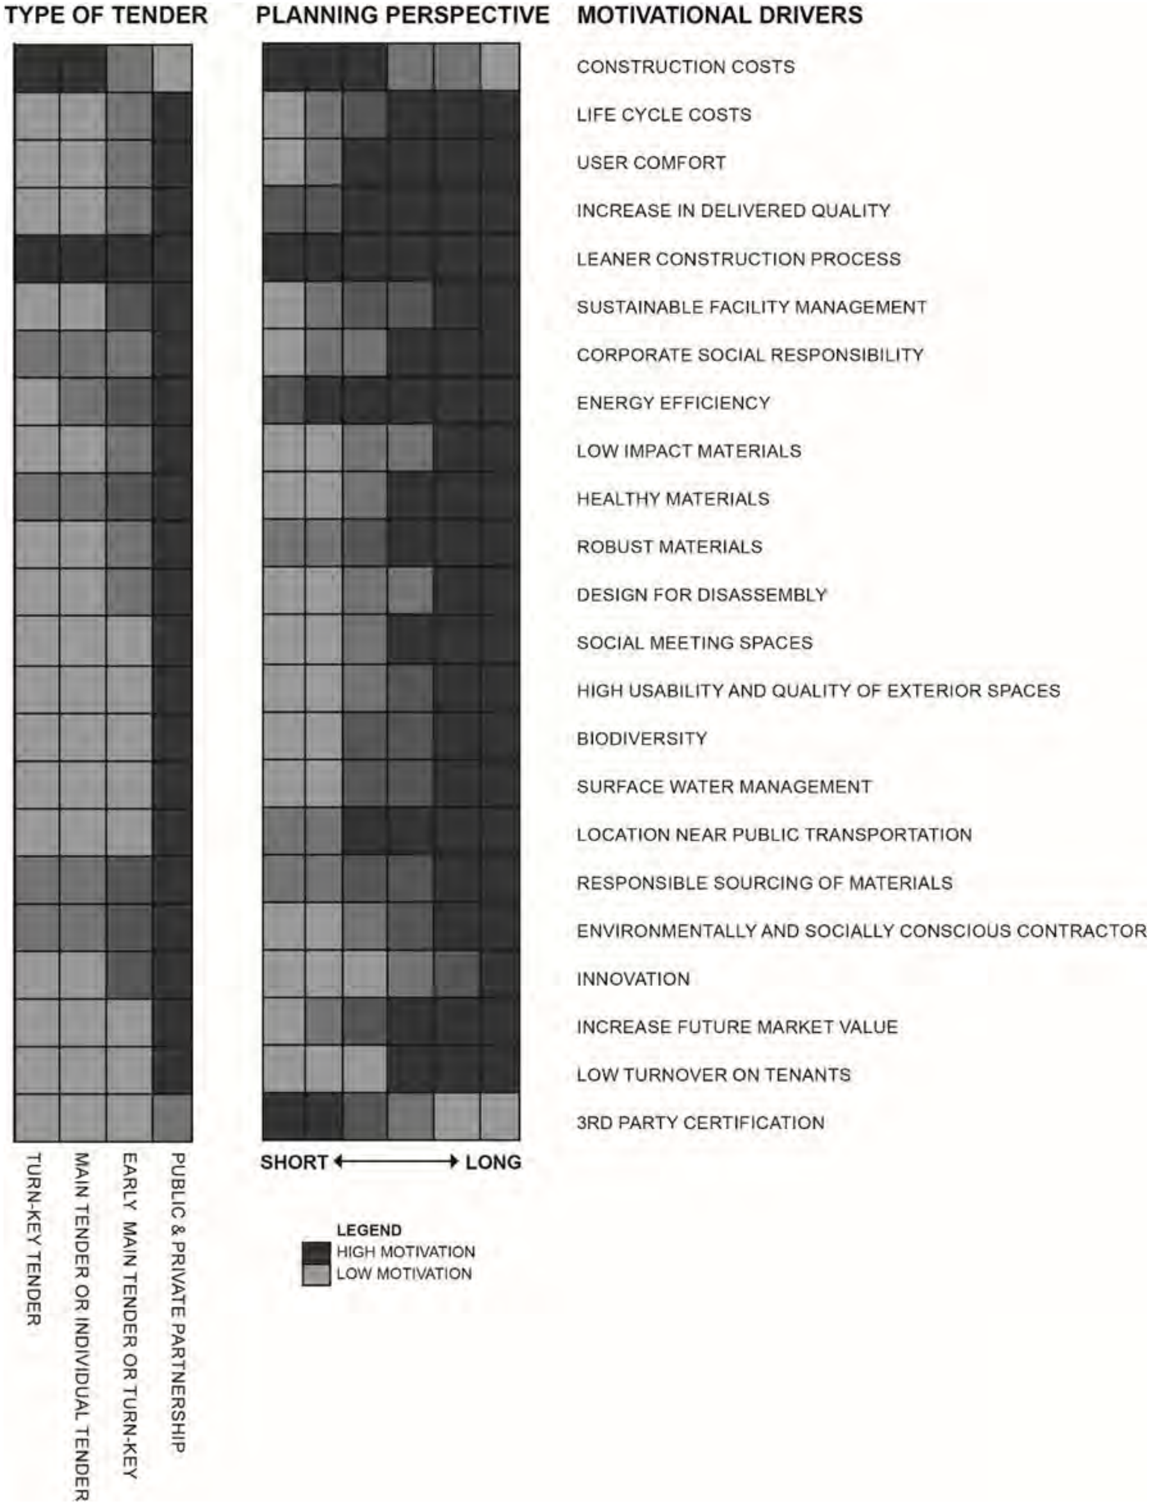

Table 1: The experienced correlation between planning perspective and motivational drivers for sustainability and the experienced correlation between type of tender and contractor's motivational drivers.

5. REFLECTION

This paper compares the practical experiences of a practitioner specialised in sustainable building design with political and voluntary drivers in the Danish building sector.

When creating strategies for sustainable building projects Construction clients and client consultants need to be very careful when designing their project organisation and tender material. Drivers for sustainable development must be identified and prioritised in the initial ideation stage of all projects and an implementation strategy must be developed for the selected project organisation and the type of tender. Contractor motivation must be considered in this process to ensure that the Construction Client's drivers for sustainability also motivates the contractor (e.g. by early engagement of the contractor or financial incentives to perform better).

When it comes to the political drivers for sustainable development a lot of clients are not conscious of EU or UN enforced drivers. They do however still have an impact on the construction client's decision making because they are influential of the Danish building regulations which the market analyses from 2015 and 2016 have verified that construction clients are very much aware of.

When reflecting on which drivers are the effective it is positive to see that the political drivers and the voluntary drivers together ensure a market demand that in turn engage construction clients and tenants to implement voluntary schemes in their projects. In the past decade, the market reached a tipping point where voluntary economic and social drivers of sustainable development became strong and well-known drivers for sustainable building. Energy efficiency of buildings is still a strong driver but that has more or less become a standard requirement in all building projects which motivates construction clients to differentiate themselves more on the social and economic drivers.

Education of construction clients is also relevant due to the importance of early identification and implementation planning of motivational drivers. Today the client consultant, the architect or engineer takes on the role of educator which means that the construction client's knowledge is limited to the expertise of the consultants engaged on the project.

German ÖKOBAUDAT Goes International: An Online Infrastructure for LCA as a Basis for International Structure

Tanja BROCKMANN[a]

[a] BBSR Federal Inst. for Research on Building, Urban Affairs and Spatial Development, Germany, tanja.brockmann@bbr.bund.de

ABSTRACT

LCA at building level is a central instrument for the evaluation of the ecological quality of the building (e.g. global warming potential). In Germany, the federal government provides the online database ÖKOBAUDAT (open source) which supplies the required building materials datasets (Generic data, EPD data) and the calculation tool eLCA for LCA at building level.

ÖKOBAUDAT meets the demands of EN 15804, but also follows an extended ILCD format. As an internet aware data format, it has been designed to explicitly allow publishing and linking of data as resources via the internet. The advantage is that existing software tools with built-in support for the ILCD-format can be easily enabled to support the new EPD datasets. Internationally more and more EPD are produced (According to EN 15804). The possibility to directly online import data with a given harmonized data format which follows ILCD and EN 15804 is a great chance also for international use. Hence, ÖKOBAUDAT and its infrastructure are a good starting point for the establishment of an open international LCA database network. In this paper the quality standards of ÖKOBAUDAT and its infrastructure are described, while the concepts and requirements for realization in an international context will be presented in the paper "International LCA data network – demonstration project for an open international online database structure", (Paper ID 2336).

Keywords: life cycle assessment, database network, sustainable building

1. INTRODUCTION

Sustainability Considerations in the construction sector are nowadays established in an International level, and often, certification schemes are used to evaluate sustainability at building level. Within these, the life cycle assessment (LCA) is a central instrument for the evaluation of the ecological quality of the building: e.g. global warming, ozone depletion, photochemical ozone creation, acidification and eutrophication potential.

In Germany, as part of the Assessment System for Sustainable Building (BNB), the Federal Ministry for the Environment, Nature Conservation, Building and Nuclear Safety (BMUB), provides important infrastructure for choosing suitable building products. There is offered a complete "tool chain". It starts with the basic material data from environmental product declarations (EPD), which are imported in the online database ÖKOBAUDAT, exported from there to the calculation tool "eLCA", and finally are used for the final evaluation of a sustainable building resulting in a bronze, silver, or gold certificate (Figure 1). All provided tools are web-based, cost-free and publicly available; for all of them an English version or other information is given. These tools are administered by the German Federal Institute for Research on Building, Urban Affairs, and Spatial Development (BBSR).

2. ÖKOBAUDAT

The German online database ÖKOBAUDAT is provided by BMUB already since 2009, and it is available for everybody interested in an ecological evaluation of buildings with a consistent database. Main users are planners and architects, who analyze the environmental indicators of the products, services, and processes, as integrated in the database.

The webpage (www.oekobaudat.de) offers a user friendly direct access to the database. Also, basis information, as well as interesting links, is given. Different versions of the ÖKOBAUDAT are archived. This can be relevant for ongoing projects as well as for reproducing former LCA results. Search- and filter- functionalities allow finding relevant datasheets for chosen materials or products directly in the online database. A comprehensive English version of the ÖKOBAUDAT webpage is provided since June 2015.

ÖKOBAUDAT contains generic basic datasets that provide suitable values of the environmental indicators for the building materials, as well as product related datasets that are determined mainly within EPD. Using the generic datasets allows sustainability studies of buildings already in early planning stages when architects or planners do not yet work with product specific but with generic building product information. In a later stage, the generic data in the model is then substituted by specific data representing actual construction products.

ÖKOBAUDAT offers over 1.000 datasets, half of them are generic data. Since 2013, ÖKOBAUDAT comprehensively meets the demands of European Standard EN 15804. The German Institute for Construction and Environment e.V. (IBU), which significantly contributes EPD datasets for the ÖKOBAUDAT, was the first to introduce EN 15804 in its EPD program rules. Other EPD programs followed.

At the moment ÖKOBAUDAT means the online database ÖKOBAUDAT with highly consistent and harmonised data, which can be transferred as a whole "package" to affiliated tools. Via interfaces, direct online transfer, or Excel-sheet ÖKOBAUDAT data are used nationally and internationally by other LCA tools, BIM applications or other. All ÖKOBAUDAT data are quality checked and data suppliers have to confirm, respectively proof conformity with the relevant standards and requirements.

2.1 ÖKOBAUDAT requirements

BBSR has developed "Principles for the acceptance of LCA data in the online database ÖKOBAUDAT" (Published at www.oekobaudat.de in German and English language). Accordingly, the data supplier has to apply for data transfer into ÖKOBAUDAT, where it differentiates between the following data categories:

- Category A: Independently externally verified EPD according to EN 15804
- within EPD program according to ISO 14025
- Category B: Independently externally verified EPD or LCA data with independent external critical review, which comply with EN 15804, but have not been produced within an EPD program according to EN ISO 14025
- Category C: LCA data according to EN 15804 without independent external verification or critical review (Generic datasets).

The category types are important for the required quality procedures, as verification, critical review or audit.

Generic data are surrogate data used if no system specific data are available. The data can either be generated based on data from the industry (but usually not declared as such) or on data from other sources (Literature, expert knowledge etc.). Generic data are usually not developed within an EPD programme. In order to be used in LCA calculations these data follow the same data format, but external verification as for data category A and B is not required. Still, quality assurance for the generic data used for ÖKOBAUDAT, which are based on Gabi database, is given by an audit according to especially developed critical review criteria, e.g. complete and accurate meta-info; use of independent, relevant and qualified references; application of a consistent methodology and modelling principles.

Any other LCA data are currently not accepted for integration in the online database ÖKOBAUDAT.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

As already mentioned, ÖKOBAUDAT is usually addressed as a complete “data package”. Being an important international data provider ÖKOBAUDAT decided to offer additional data, besides to the core ÖKOBAUDAT “data package”. These will be offered in October 2016. Apart from the following, these data offer ÖKOBAUDAT data quality and completely fulfil the “ÖKOBAUDAT-Principles”:

- EPD data in English language

The German Government, in general, requires German language for any public information. For this reason, ÖKOBAUDAT data are offered in German language and EPD data which are offered in English language only, are not integrated in the core ÖKOBAUDAT and will be offered as “additional data” in the first step. Full integration of English EPD datasets is discussed already.

Anyhow, all generic data produced on behalf of BMUB will be provided bi-lingual in German and English language from 2017 on. Also, it is the aim to motivate bi-lingual LCA from German data supplier, as English language is a common agreement for international data network structures.

- EPD data derived with eco-invent as background database

For the calculation of EPD data, generally, different background databases are used. As these may lead to significantly differing results for the considered environmental indicators, usually one background database is prescribed. Within BNB this is the background database Gabi; exceptions are allowed, but equality has to be shown. Also, all benchmarks of BNB refer to Gabi.

BNB decided to use its infrastructure and offer ÖKOBAUDAT as platform for those other data as well, starting with data referring to eco-invent. These data will not be integrated in the core ÖKOBAUDAT.

As a consequence, there will be a core ÖKOBAUDAT, which will be directly used for LCA calculations in eLCA (or other tools), while users will have to decide about the use of the “additional data” in their own responsibility. For eLCA, options for integration of selected “additional data” will be developed.

After application, BBSR (or agent on behalf of BBSR) checks up on the data supplier for fulfilment of requirements, i.e. conformity of program rules, PCR, verification rules with relevant standards. A report will be produced, and sometimes remediation is required. All data transfer procedures are administrated by BMUB/BBSR. Only after approval of a data supplier as such, in a second step, data are transferred ÖKOBAUDAT. All data have to be delivered in the so-called EPD data format (ILCD compatible). At first, data are transferred to an ÖKOBAUDAT-Inbox, where they are quality checked for plausibility and completeness, before finally being released in the actual version of online database ÖKOBAUDAT.

2.2 Technical data transfer

Since ÖKOBAUDAT is presented as online database, the provision of interfaces (API interface) which allow direct online import of LCA data to the database ÖKOBAUDAT is decisive. There are two possible ways:

- Direct EPD data import via interface
- Data transfer via “openLCA”. The openLCA software tool is used to create and export EPD datasets in the EPD data format.

All technical requirements for data transfer and relevant information on interfaces, open source tools and other sources are to be found on the web-page, or ÖKOBAUDAT-Handbook, which supports the user with practical information, or is to be found on the web-page.

The required EPD data format meets EN 15804 but also follows the already established extended International Reference Life Cycle Data System (ILCD) format. Within the EPD format some additional information is given, e.g. administrative information, validity of dataset, safety factors used for generic data. Also, regarding representativeness the dataset sub-type has to be declared, i.e. specific, average, representative, template, or generic dataset. As an internet-aware data format, it has been designed to explicitly allow publishing and linking of data as resources via the Internet. The advantage of this new approach is that existing software tools with built-in support for the ILCD-format can be easily enabled to support the new EPD datasets as well, with only minor changes to their internal information structures. It is to emphasize that ÖKOBAUDAT is running on an open source program software platform (soda4LCA), which allows the development of further modules which use or may add new features to the procedures. Anyhow, with EPD data format data can be exchanged online and transferred to any LCA or other calculation tools, as long as suitable interfaces are provided.

When supplying EPD datasets it is also essential to classify the dataset within the already existing product category structure of ÖKOBAUDAT. File names are always provided by the data supplier. Responsibility on the data file remains with the data supplier at all times. Hence, corrections or required modifications are always carried out by him, and not by BMUB/BBSR.

2.3 Current situation

In Germany, IBU as an important EPD program operator has equipped its own database application with facilities to directly import its data online into ÖKOBAUDAT. As not all relevant institutions are in the position to provide such online databases, the widely-adopted open source LCA modelling tool "openLCA" is offered as part of the LCA infrastructure within BNB. OpenLCA is currently used for data transfer by German EPD program operator ift Rosenheim, and Austrian EPD program operator Bau-EPD, as well as by German Thünen Institute for its averaged LCA data derived from industrial background data for wooden materials (Figure 2).

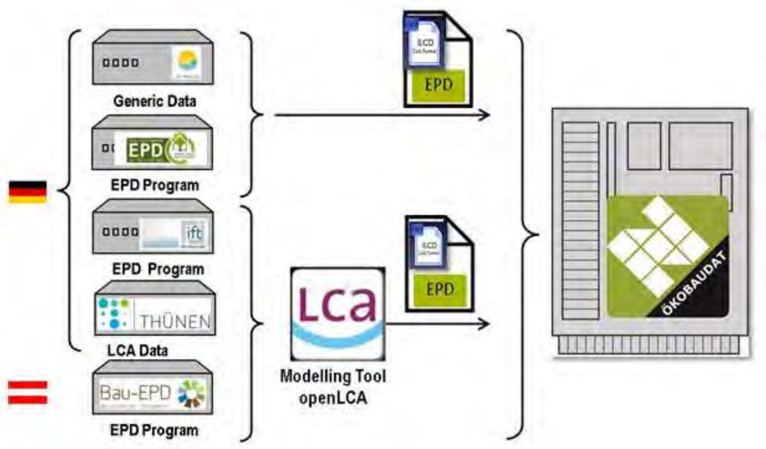

Figure 2: Current situation of data transfer to German ÖKOBAUDAT

ÖKOBAUDAT is an internationally well-accepted database. It is used as such for LCA calculations at building level within different certification schemes, BIM applications. Obviously, with over 1.000 quality checked datasets it is one of the most comprehensive databases with consistent and comparable data, which easily can be transferred to affiliated applications. A wider use of data will be supported in future by providing bi-lingual generic data. Also, the provision of additional data, even if not directly addressed within the BNB tool eLCA for already explained reasons, will be of high importance for many users.

The high data quality of ÖKOBAUDAT is assured by application procedures of data supplier, which comprise a reviewing of conformity of their program rules, PCR documents and verification rules with standards and requirements, as well as by sampling of the finally supplied data. A high consistency and comparability of data is given for several reasons: e.g. application procedures with clear requirements, setting standard for EPD data format, referencing one background database, generic data from one data provider. Also, the co-operation with Germany's most important EPD program operator IBU, who has established important rules and procedures within its program, supports the data quality of ÖKOBAUDAT.

Another important instrument is the "Anwenderkreis ÖKOBAUDAT". In this board BMUB/BBSR, all ÖKOBAUDAT data supplier and other LCA experts develop common agreement on interpretation of EN 15804, data transfer procedures etc. This group significantly supports the data quality of ÖKOBAUDAT by improving harmonization, consistency, and comparability of data, information and processes.

3. GERMAN LCA INFRASTRUCTURE AS A STARTING POINT FOR INTERNATIONAL DATA NETWORK

The current situation is that more and more EPD are produced worldwide following harmonized standards, but no structured data transfer is foreseen. As explained, the possibility to directly transfer data between databases, furthermore export those to LCA tools, with a given harmonised data format which follows the generally accepted European or international standards, is a great chance for the idea of a consistent and harmonised way of using material and product relevant LCA data, or EPD data respectively, for LCA at building level internationally. It is the vision of an open international data network. The main idea is that there exist independent (national) databases which are linked to each other, and due to a common standard allow open search and use of data. Anyhow, each state will have the opportunity to set up own national rules for the use of data in subsequently used LCA tools, or other applications.

BBSR initiated the WG "International open data network for sustainable building" (InData) where stakeholders from 8 European nations started to develop a common understanding for this idea.

The infrastructure and all technical background as described in the article shows that the technical possibilities are already there. Data transfer as practiced for the ÖKOBAUDAT, either directly or indirectly via openLCA could be realized by every interested stakeholder. Furthermore, all tools and programs are open source, which allows for the development of modifications or additional features being open for everybody.

A research project funded by BMUB will set up a show-case for an international system of data transfer (See "International LCA data network – demonstration project for an open international online database structure" paper 2336). As a result, the conceptual framework and the technical applications shall be analyzed, and to some extent realized for demonstration. Apart from the technical possibilities, the definition of common rules and common core information, data quality levels etc. will be crucial, as described in more detail in (Paper 2336).

ÖKOBAUDAT with its acceptance and proofing procedures has set a Standard. Also, in future it will be a "label" for high quality and consistency of LCA data and will only accept data that follow the principles for LCA calculations within BNB. By offering all tools and information as well as datasets themselves in English language ÖKOBAUDAT contributes to a tremendous extent to the open network structure.

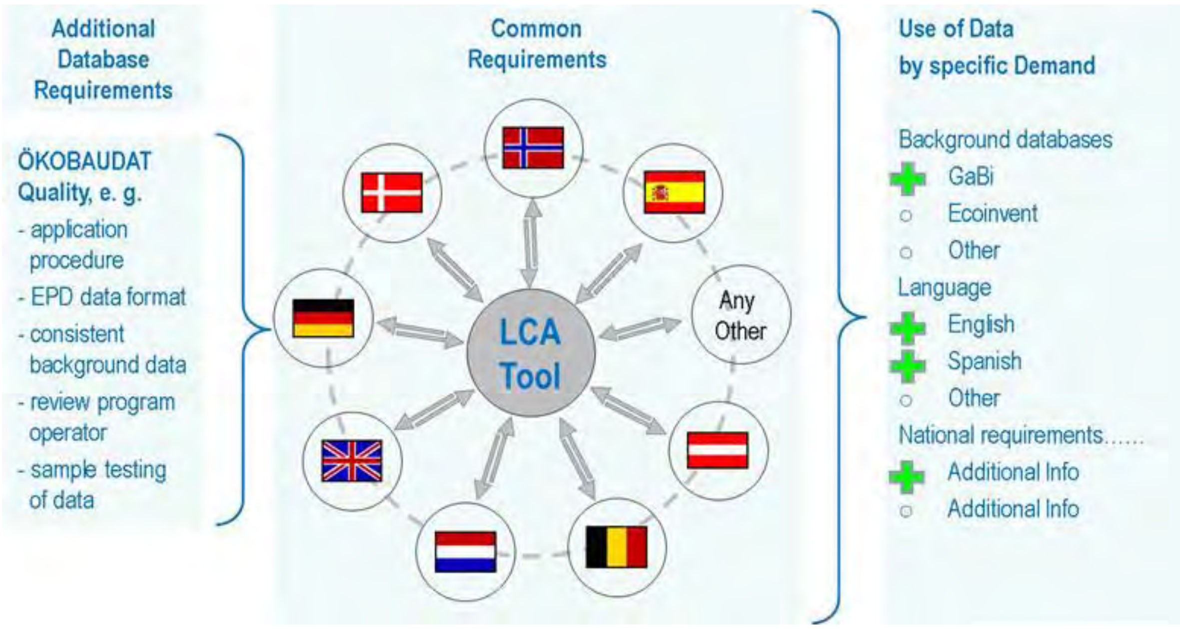

Figure 3: Example for individual use of data within open international data network structure

4. CONCLUSIONS

In Germany, for the use within BNB a complete LCA online infrastructure was developed. EPD data are transferred to the online database ÖKOBAUDAT and exported to eLCA for LCA tools at building level, which leads to final results and certification labels. All information and tools are cost free, publicly available, and open source based. With this, a starting point and the technical basis for the development of an open international data network are given. WG InData and research, as well as bi-lateral cooperation support further developments. Furthermore, it is shown for ÖKOBAUDAT that application procedures, review of program operators, sampling testing, the development of a data format, and also harmonization between national program operators are crucial for a database with high quality level, which offers consistent and comparable data for LCA at building level.

In Germany, the government decided to take the responsibility and bring forward sustainability for federal buildings by establishing the certification scheme BNB. It always was the aim to offer all information and tools with a high transparency with the aim to support the idea of sustainable building in general and to diminish barriers in using it. With establishing the LCA online infrastructure for BNB which may be offer the basis for an open data network, the German government supports European ideas of sustainability. Political programmes and support is very helpful, also for the definition of responsibilities. It is very helpful to run one central national database for EPD data rather than having different databases by several programme operators. Experience in Germany has shown that the centrally bundled provision of data and tools by the government is a highly supportive instrument for a wide application of LCA at building level and the realisation of sustainable buildings.

ABSTRACT

In order to implement sustainability thinking in the construction sector, actors need to have in mind the general principles of sustainability and to rely on guidance for practical implementation. The complexity and multi-dimensional character of sustainability leads to the necessity of a well-structured tool able to accompany the actors in their construction projects, and to recommend relevant questions, actions and decisions at each phase. In 2014 the technical specification ISO/TS 12720 "Sustainability in buildings and civil engineering works - Guidelines for the application of the general principles" was released, based on nine general principles, described in ISO 15392:2008. These principles are: continual improvement, equity, global thinking and local action, holistic approach, involvement of interested parties, long-term consideration, precaution and risk management, responsibility, and transparency. The ISO 15392 standard is very general and difficult to implement in real projects without application guidance. ISO/TS 12720 is able to provide this guidance to actors during the different phases of a construction project, combining different sustainability issues and detailing practical recommendations. Starting from a "vision" of what a sustainable building should be, inspired from a European R&D project, the technical specification (TS) describes a multi-dimensional framework with different view angles. This TS is a powerful tool to facilitate integration and concrete implementation of the sustainability general principles. This paper presents the contents of this TS and its application as a guideline in the elaboration of an ISO standard on visual environment developed by ISO TC 205.The ISO 15392 standard is currently under revision, which presents an opportunity to analyse if new practices like BIM, integrated design, smart-cities, circular economy and resilience, may generate new general principles or bring a new light on existing ones.

Keywords: sustainability principles, ISO standard, design process

1. INTRODUCTION

ISO 15392:2008 is part of a suite of international standards developed by the Technical Committee ISO/TC 59, Buildings and civil engineering works, Subcommittee SC 17 Sustainability in buildings and civil engineering works. In this paper, the background, basics and application of the standard are clarified and possibilities for its further development and refinement are discussed.

1.1 Background

There are currently various developments and trends in relation to sustainable development-oriented design, construction and operation of buildings. This involves approaches that focus on environmental (design for environment, design for deconstruction), economic (design to cost, design to life cycle cost) or social/functional issues (healthy buildings, performance based buildings). However, what has long been lacking is a basis for combining these aspects into an overall concept. At the same time, there is a growing desire among many companies in the construction and real estate sector to contribute to sustainable development. The principles and rules to ensure sustainable development must always, however, be integrated into the responsibilities and duties of the actors involved (here the construction and real estate sector) and adapted to the respective object of assessment (here construction works). To overcome the uncertainty found in the sector regarding the use and interpretation of terms such as "sustainable building", and in particular to distinguish it from the term "green building", a need for clear terminology, principles and concepts arises to support sustainable development in the construction sector.

1.2 Scope and purpose

From the beginning, the aim of ISO 15392 has been to contribute to the creation of a common understanding of sustainability in the construction and real estate sector and to provide a generally recognized basis for this purpose. This basis covers both requirements for sustainability assessment of construction works and principles that should be considered when integrating sustainability aspects into the design and decision-making processes. At the same time, ISO 15392 provides the basis for other standards, including ISO 21929-1, which establishes a core list of sustainability indicators for buildings. The ultimate goal is to ensure the transferability and applicability of the objectives and principles of sustainable development to the construction sector. In future, ISO 15392 needs to be and will be even more oriented to the Brundtland definition of sustainability in order to avoid misunderstandings.

1.3 Linkages between dimensions of sustainability

The description and assessment of the sustainability of products and processes traditionally considers the environmental, social and economic dimensions. This also applies to the assessment of buildings and other construction works. The way the three dimensions relate to each other has long been discussed. ISO 15392 specifies that all three dimensions of sustainability must be considered in a sustainability assessment – simultaneously and in an equal manner. This results in various consequences, even in terms of the establishment of weighting factors in sustainability assessment systems. In the meantime, the subdivision between dimensions or “pillars” causes several problems. Assessment criteria and indicators cannot always be clearly assigned neatly to one of the three dimensions. For any effect taking place in one dimension, side effects and consequences may arise in the other two dimensions. For example, indoor air quality (IAQ) can be considered both an environmental and a social aspect. This topic has been discussed in ISO 21929-1 and is planned to be addressed in the revision of ISO 15392 that is currently underway.

1.4 Areas of concern

ISO 15392 identifies areas of concern and protection goals that are suitable for the development of an understanding of sustainability and identification of criteria. These are shown in Table 1.

Dimension	**Areas of concern**
Economic dimension	Economic resources Asset value (property value)
Environmental dimension	Environment (Natural) Resources
Social dimension	Social infrastructure Cultural heritage Human health and comfort

Table 1: Dimensions of sustainability and related areas of concern

It is planned to refine the concept and terms of the areas of concern and harmonise them within the ISO TC 59/SC 17 suite of standards. Nevertheless, it is worth pointing out that the derivation of assessment criteria and indicators from protected goods and protection goals has proven to be effective.

2. GENERAL PRINCIPLES

ISO 15932 was created as an overarching, generally applicable document addressing sustainable development in the building and civil engineering sector. Specific issues are tackled in various standards elaborated within ISO TC 59/SC 17, all based on the current nine principles listed in 2.1 below.

Public authorities are one of the drivers in promoting the idea of sustainability, especially in the building sector. They act as a role model for private consumers and property investors, creating a demand for relevant, credible, reliable and unambiguous information. It is expected that assessment and certification of the contribution of products, buildings, civil engineering works and related services to sustainable development will be more visible to all actors and will play an even more important role in decision-making in the near future, for example, in public procurement. The standard establishes a common basis for information which the demand side (e.g. public authorities, owners, architects) asks for and enables the supply side (e.g. product manufacturers) to provide it in the right format.

2.1 Current nine general principles

a) Continual improvement

Sustainability is not a value in itself nor can it be seen as an end state that is achieved once the project is completed. Therefore, the concept of sustainability described in the standard measures the contribution of a building or civil engineering works to sustainable development while fulfilling the required functional and technical performance over time. This contribution may vary depending on the construction type or technique used and ideally will be reconsidered during the design process to ensure the performance of the building over time. Continual improvement moreover addresses the scientific basis for assessment, the calculation rules and communication of results as well as monitoring during the use stage by constantly analyzing problems that occurred in the past, deducing measures and metrics as the basis for improvement.

b) Equity

The building and civil engineering sector is one of the most important economic sectors throughout the world, generating tremendous related social impacts (notwithstanding the ecological impacts) and is therefore predestinated to help overcome existing inequalities related to social status, gender, abilities and age. Next to the aspects of creation of jobs, income and reduction of poverty, this principle addresses the satisfaction of basic needs such as affordable housing, healthy shelter and social services provided by the built environment. The diverging interests existing in society need to be considered impartially and in a balanced way, taking into account regional specifics.

c) Global thinking and local action

Sustainable development is a global challenge predominantly pursued by regional or local strategies, which may differ in content depending on the respective context. It is essential that these local strategies contribute to the global aims and that their consequences are considered on a broader scale. Likewise, when strategies are established on a global scale, it is important to consider the impacts and implications on the regional and local level and to take into account the context, such as traditions, needs, capacities and restrictions present at these levels.

d) Holistic approach

The concept of sustainability implies the equal consideration of all three pillars of sustainability (see also 1.3). This is vital to reflect the entire impacts of building and construction works rather than focusing on single criterion based claims, for example, with respect to global warming potential (GWP) or claims that narrow the view to environmental aspects only, such as product environmental footprint (PEF). Moreover, global aims and concerns with respect to sustainable development need to be aligned with needs, requirements and constraints with respect to functionality and efficiency.

e) Involvement of interested parties

Sustainable development generally requires an interested society with responsibly acting individuals. In the construction sector, existing national regulations may require participation of the general public (e.g. in land development plans) or of individuals (e.g. direct neighbours), when planning a building on a specific site. This principle however, seeks to stipulate the direct involvement of all interested parties in all relevant processes. This is applicable to the different interested parties, including manufacturers, designers, construction companies, owners and users all acknowledging their different views, personal concerns, interests and understanding. Direct participation also adds to transparency, when decisions and their justification are discussed in an open manner, easing their acceptance, especially for large-scale projects.

f) Long-term consideration

To benefit from sustainable development concepts, long-term considerations are an important factor during inception and design of a project. It is evident that every decision making process will also take short- and medium-term effects into account. However, the major concern is to maintain the required function of the building or civil engineering works over the predicted service life. The use stage is of paramount importance, although all life cycle

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

stages have to be taken into account to assess the implications of a decision taken on other life cycle stages. The building or civil engineering project becomes part of the built environment, providing the physical and functional environment of a society, forming a cultural identity. The implications reach far beyond the project boundaries. Next to the physical presence of the building or civil engineering work the project effects the environment, the economy and society by forming part of the cultural heritage.

g) Precaution and risk management

Risks may not be prevented but may be avoided by using methods, techniques and products that are proven to be safe and healthy (precautionary principle) rather than adopting them without any risk analysis. However, this principle should not inhibit innovation. Management strategies need to be set up and communicated to identify, analyze and control any potential risk.

h) Responsibility

Decisions or actions taken by individuals or companies during the project will have (next to environmental consequences) legal or financial implications. The legal responsibility and liability is subject to national laws. This principle addresses the moral responsibility for these decisions and actions and implies the facilitation of skills and competencies, both on an individual and the collective level (i.e. companies, authorities, societies).

i) Transparency

This principle comprises two aspects: the transparency related to decision-making processes that may require personal involvement of interested parties and an accessible documentation (system). The second aspect relates to the presentation of information on the contribution of products or building construction works to sustainable development. Basic concerns are credibility, completeness, relevance and an assessment that is easy to understand. Therefore the underlying data need to be traceable and need to be reviewed and verified for certain purposes.

2.2 Revisions under consideration

It is worth noting that the ISO 15392 standard is currently undergoing revision by the working group experts of ISO TC 59/SC 17. Some areas identified for update include more complete terminology that is appropriately aligned to the many

international and national standards that impact or are impacted by this standard and the UN Sustainable Development Goals. As discussed in section 1.4, the Areas of Concern, objectives and the different perspectives of the life cycle will be more definitively related to each of the three pillars of sustainability to promote a common understanding within the building and civil engineering sector. The handling of multiple impacts within multiple impact chains will be elaborated on. The text on the Precautionary Principle will be further expanded to address prevention and avoidance of hazards, risks and waste. The concept of resilience will be elaborated on as an objective of some of the general principles, such as long-term consideration. Contemporary tools and methodologies such as integrated design, smart buildings and infrastructure and building information modelling (BIM) will be identified for achieving one or more of the general principles. Discussions are ongoing to determine if there are any new general principles that should be added. One such concept under consideration is regenerative sustainability, which aims to broaden the scope beyond reducing adverse impacts to actually generating benefits for society and the environment, with a particular focus on the human design element. A primary overall objective of the revisions for the next edition of the ISO 15392 standard is to more clearly demonstrate its value and relevance to the construction sector and the marketplace. It is anticipated that the ISO/TS 12720 application guidance for the general principles will be updated accordingly.

3. GUIDANCE FOR APPLICATION

Two ways to implement the nine general principles described in ISO 15392 are summarized here: the wrong and the best, or the formal way and the real application.

An example of a formal way is to implement the general approach and terms as defined in the ISO 16813 Building environment design — Indoor environment — General principles, developed under ISO TC 205. These general principles for the design of the building indoor environment enable the main participants in the design process to ensure an indoor environment of the quality required for users. They enable the clients and designers to provide the desired quality of indoor environment in a sustainable building according to the fundamentals of the design process with energy conservation and the whole life cycle in mind. The design process aims to ensure that the building design provides the specified quality and performance level of safety, health, comfort, and energy use as well as the sustainability philosophy, ethics, and assumptions taken by the people concerned. Building designers are to define the goals based on the requirements, constraints, and actual conditions to be achieved, integrating the owning and operating costs during the design stage.

A better way, as a realistic tool for designers, is outlined in ISO DIS 16817 Building environment design — Indoor environment — Design process for visual environment with the help of ISO/TS 12720. The purpose of this International Standard is to provide design team members with a design process for the indoor visual environment to achieve required visual comfort, physiological effects of light and energy performance of buildings. The objective of this standard is to provide the design team at each phase of the design process with a way to implement the nine general principles of sustainability in buildings, as described in ISO 15392 and how to integrate these principles in their decision-making processes, as part of a sustainable approach. The scope of this International Standard provides an integrated design process for high-quality indoor visual environment including architectural and engineering aspects of daylighting and artificial lighting for user satisfaction, health, well-being and productivity as well as the energy performance and sustainability of buildings.

The design process is divided into 9 phases: (1) Stage I — Formulation of project definition; (2) Stage II — Schematic design; (3) Stage III — Detail design; (4) Stage IV — Final design; (5) End of design; (6) Development of design criteria; (7) Development of design aids; (8) Cost evaluation; (9) Estimation of primary costs. In each phase we determined which principle could be introduced and which information and concept could be applied, in project information, area of the visual environment design project, detail design and so on. That work was continued by applying ISO/NP 19454 Building environment design — Indoor environment — Daylight opening design process in order to ensure sustainability principles in the visual environment.

All of the sustainability objectives and related issues of concern presented in Table 3 of ISO/TS 12720 were considered and the relevant items related to visual environment were selected, keeping the same structure as the flow chart in ISO16813. The table shows the relationship between design permutations related to daylighting opening design and the optimization of sustainability objectives. The relevance between opening design elements and sustainability objectives and related issues of concern are noted with a “yes”. So a question must be expressed and an appropriate response given.

4. CONCLUSIONS AND OUTLOOK

A uniform understanding of the transfer of sustainable development goals and concepts to the different objects of assessment and practical procedures in the construction and real estate industry is a precondition for taking on the responsibility towards the environment and society. It is necessary to consider the various sustainability aspects in the construction sector not in an isolated way, but rather in an integrated way. Using the described principles, sustainability aspects can be considered in the design and decision-making processes.

It is necessary and useful to exchange experiences, more than ever, on how sustainability aspects are considered in a building's design, construction and operation. Sharing of global experience in the application of these principles in practice will, in turn, increase the relevance and value of the application guidance for the general principles provided in ISO/TS 12720.

Driver and Challenges Facing Leadership in Adopting Sustainability in the **Built Environment: A Developer's Perspective**

ZHANG Xiaoling[a]

[a] *Department of Public Policy, City University of Hong Kong, Hong Kong SAR, xiaoling.zhang@cityu.edu.hk*

ABSTRACT

Sustainable development drives the sustainable built environmental campaign on the global stage, which will continue to be an increasing challenge over the next decades particularly to most developing countries. In order to meet the challenges involved, several major China property developers have initiated a "green building development" campaign. They have established a post of "Director of Sustainability" responsible for overseeing the overall development and implementation of green technologies in their projects. Decisions concerning sustainable building development are often embedded in the typical logic of a property developer's strategy, e.g. from vision, mission and strategy to final objectives. This paper identifies and explores the drivers and challenges confronted by the leadership of real estate enterprises in adopting sustainability, and their strategies and approaches taken to reinforce sustainability in the built environment. By doing so, this highlights the great diversity of drivers and challenges facing entrepreneurs in adopting sustainability and which extends well into the built environment.

Keywords: leadership, sustainable built environment, drivers and challenges

1. INTRODUCTION

For several decades, nations, cities and stakeholders worldwide have begun to promote the construction of "green buildings". Due to different national realities, different countries have different approaches to developing green building. In referring to the environmental performance assessment systems of developed countries, a special organization is usually established by either government or industry associations (Non-government Organizations, or NGOs) by way of the third technical certification to conduct green building reviews and evaluation. For example, the United Kingdom's Building Research Establishment's Environmental Assessment Method (BREEAM) (Larsson, 1998), United States' Leadership in Energy and Environmental Design (LEED) (Crawley and Aho, 1999), Australia's Green Star (Seo et al., 2006), the Japanese Comprehensive Assessment Scheme for Building Environmental Efficiency (CASBEE) (Japan Sustainable Building Consortium, 2006), the GBTool designed by Canada and applied in internationally by over 20 countries (Cole, 1998) and the Hong Kong Building Environmental Assessment Method (HKBEAM) (Davies, 2001). In the USA, green buildings are promoted by NGOs, which aim to use market forces for their development. The U.S. Green Building Council for example, an NGO, established the LEED system, which is designed for market-oriented operation. Before market forces start to play their role in driving green construction projects, however, government intervention is the primary force to encourage building green. In the USA, the federal and state governments have passed legislation concerning the energy consumption of products, mandatory minimum energy standards of equipment, and use government investment projects to demonstrate and encourage state-of-the-art building energy-saving technologies based on building energy efficiency standards. Building environmental rating systems, therefore, provide a way of showing building owners the extent to which a building has been successful in meeting the expected level of performance in terms of the various criteria involved (Buys and Hurbissoon, 2011).

It is necessary to encourage more stakeholders to be involved in initiating green buildings. Real estate developers are considered to be one of the most proactive stakeholders. With the increasing rise in environmental awareness, some pioneers in the real estate industry have gradually entered the realm of eco-friendly design and building practices in building management and taken other green initiatives (Torre, 2013). In China, green buildings are becoming increasingly demanded due to rapid urbanization pressures, low carbon city developments and public, social and private stakeholders' willingness to pay for sustainability. Although the central government in China is committed to delivering sustainable developments, it rarely is delivered in practice once the policy is handed down to a local level. Quite why this situation exists is unknown. Of course, it is possible that it is attributable to the well-known challenges involved in green projects, such as higher initial cost.

In this context, green buildings need committed, forward-thinking leadership to drive through change. Ignoring green building issues is no longer a safe business model, as the current market demands developers to be more innovative than ever before, and it is therefore critical for real estate developers to adjust their core business model to the environmental driven market environment (Torre, 2013).

2. DEFINITION **OF GREEN BUILDING DEVELOPMENT AND ROLES OF "DIRECTOR OF** SUSTAINABILITY

Green building, also known as 'green construction' or 'sustainable building', is a term defined by the Office of the Federal Environmental Executive. This agency defines this term as:

"the practice of (1) increasing the efficiency with which buildings and their sites use energy, water, and materials, and (2) reducing building impacts on human health and the environment, through better siting, design, construction, operation, maintenance, and removal-the complete building life cycle" (Howe, 2010).

It can be traced to many origins over recent decades, being initially called "Arology" in 1960s by Paolo Soleri, an architect combining ecology and architecture (Soleri, 1969). The arrival of the oil crisis in the 1970s, in which the price of oil quadrupled virtually overnight, alerted building providers and operators to the need for greater energy saving and that high energy consumption was unsustainable for development in general. In the 1980s, the excessive focus on energy saving resulted in severe detrimental effects on users' physical and mental health, prompting calls for more attention to be paid to "healthy" buildings. By 1987, the United Nations' World Commission on Environment and Development first defined sustainability as the ability of the present generation of people to meet their needs without compromising the ability of future generations to meet theirs (Yudelson, 2007). This idea was extensively promoted and applied to architecture in the form of "sustainable building".

Since 2000, global warming has increasingly attracted the attention of the international community. The Intergovernmental Panel on Climate Change (IPCC) predicted that greenhouse gas emissions will grow by 25%-90% from 2000 to 2030 (IPCC, 2007), which will have an immeasurable influence on our living environment. Significantly, as is well-known, building construction is one of the major sources of greenhouse gas emissions, with an estimated 36% of greenhouse gases being emitted by building construction related activities (IPCC, 2001; Metz, 2001).

Today, "green building" is based on the theory of sustainability and is part of the concept of promoting sustainability (Chan et al, 2009). It has become a flagship for sustainable development in this century, with a responsibility for balancing long-term economic, environmental and social health. (Ali and Al Nsairat, 2009). According to the USGBC (1998), green buildings incorporate design and construction practices that significantly reduce or eliminate the negative impact of buildings on the environment and occupants in five broad areas of: (1) sustainable site planning; (2) safeguarding water and water efficiency; (3) energy efficiency and renewable energy; (4) conservation of materials and resources; and (5) indoor environmental quality (Council UGB, 1998). Mahsa et al (2011) define a green building as "a structure that is designed, built, renovated, operated, or reused in an ecological and resource-efficient manner". The Building Services Research and Information Association (BSRIA) point out that a green building is conducive to people's health, and its construction and management should be based on the principle of efficient resource utilization and ecological benefits. Generally, green buildings are energy efficient, water conserving, durable and non-toxic, with high-quality spaces and materials with a highly-recycled content (Yunna and Ruhang, 2013). They have both private utility and public utility. Private utility refers to safety, comfort and health as, according to the World Health Organization (WHO), green buildings can provide healthy, comfortable and safe spaces for people's living, working and other activities. In contrast, public utility is recognized as environmental protection through saving energy and water and reducing carbon emissions, which presents a solution to resource and environmental problems.

For the purpose of reducing carbon emissions and alleviating the greenhouse effect, more and more research concerning green building is focused on "low carbon" buildings. As a result, together with energy rating systems such as LEED and Green Star now operating in several countries, green building is gradually being put into practice. China, as a large industrial country and one of the largest energy consumers and carbon emitters in the world, where especially residential buildings are in great demand, has a responsibility to urgently help lead the way (Yunna and Ruhang, 2013).

2.1 The role of the "Director of Sustainability"

The Director of Sustainability is a position that is responsible for achieving one of the corporate goals, e.g., to sustain social responsibility. In general, corporate social responsibility means the organizational consideration of multiple stakeholders and global impact, beyond simply focusing on maximizing the shareholders' wealth (Pienaar, 2010). Many companies associate the expenses involved in social responsibility and green design effort to be in accordance with the idea of integrating economic, environmental and social criteria into strategy and management to create long-term value for shareholders (Smith, 2007). These widespread CSR efforts are driven not only by ideological thinking that firms can be positive forces for social change, but also by the business returns that firms potentially reap from CSR engagement (Du, 2013). Consequentially, corporations now pay more attention to the internal status of "green building". Hence, sustainability is becoming a vital consideration in leadership decision making, and may even lead to the birth of a new "green" position.

As it is important to engage with different stakeholders in developing green buildings, I conducted several interviews with business leaders to elicit their opinions concerning their attitudes to social responsibility or, in other words, the sustainability development views of managers.

According to CEO of Gammon Construction, Ho Corporate Social Responsibility is defined as action to promote and protect the environmental, social and economic interests of future generations, adding that, as part of the commitment to create real value in a changing world, they are determined to hold themselves accountable for the social, environmental and economic impacts of their operations and are committed to developing appropriate policies, business practices and services (Jones Lang LaSalle and LaSalle Investment Management, 2010). Mr Mao Daqing, the CEO of Vanke, one of China's largest developers, believes that corporations will not stay in existence unless they conform to being "green". This is echoed with China Merchants Property Deputy GM, Mr Hu Jianxin's comment that "Real estate is in a process of green innovation that will gradually spread to all levels of the real estate industry chain. Hence, it is becoming a common mission and vision for most Chinese developers to depart from the traditional real estate development approach in favour of developing green buildings (Zhang et al., 2011)Although it is not necessary for a business corporation to found its own energy saving company, it must have a management team to implement requirements from top-down (Jiao, 2012).

In China, some leading real estate developer pioneers, such as China Merchant Properties, Vanke, Modern Land and Landsea real estate, have integrated their own characteristics with a burgeoning green mission since 1999. For example, China Merchants Property (CMP) proposed a "green real estate" concept directly with a guidebook published in 2004 named "The Road towards Green Real Estate". During early 2010, a new mature green operation system first appeared within the CMP management system. Within this system, the CMP headquarters established a Planning Commission Committee and Green Real Estate Research Centre to maintain their green property operation as well as promote new housing products. In each of their local branches, CMP nominates its technology director as a green commissioner to take responsibility for green development. CMP has also established a new position of "Green Technology Director." As the main principal for corporate social responsibility and green real-estate development, the Green Technology Director is responsible for green strategy formulation, implementation, low-carbon green product standardization, technology development (RandD), corporation strategic platform construction and green financial expansion (Zhong, 2011). The directors of sustainability in other real estate enterprises have similar responsibilities. For example, Modern Land has established a chief energy efficiency executive officer to take care of green building and produce a complementary building energy management system that integrates a number of advanced green technologies. Landsea has also instituted a senior technology management position named "Green Chief Architect" who is responsible for reviewing all of development projects in terms of sustainability criteria (see Table 1).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Corporation	Position	Director responsibilities
China Merchants Property	Green Technology Director	(1) Develop, implement and promote corporate green strategies. (2) Standardise product, research and develop specific technologies. (3) Review regional green building projects. (4) Coordinate the relationship between government and corporation financed green subsidies.
Modern Land	Chief Energy Efficiency Executive Officer	(1) Complete the energy saving technology system (2) Provide a comfortable and energy-efficient residential product.
Landsea	Green Chief Architect	(1) Responsible for green building technology counselling (2) Review all green building projects. (3) Continue designing environmental friendly residences.

Table 1: Director of sustainability in three real estate enterprises

3. LEADERSHIP IN PROMOTING GREEN BUILDING DEVELOPMENT: THE STATUS-QUO

3.1 Performance in engaging with green building

Leadership is the capacity for leaders to be engaged with their subordinates and relevant stakeholders, including the interactions among them (Zhang, 2007). The influence of leadership is significant throughout the process of green estate development, particularly the leaders' perceptions of green buildings, green marketing, and green management. Nevertheless, developers perceive the development of green buildings in different ways, which has a direct impact on their marketing strategy, e.g., to prioritise green projects as core products. In a market survey conducted by the China Real Estate in 2011, 36% of the property developers agreed that the green building industry in China is in a 'germination' (initial) or transition stage (from of 'demonstration to rapid development'), while 22% thought it had already passed into the 'demonstration stage.' Distinctive cognition differences have led to particular preferences in green buildings. Proactive business leaders tend to take the initiative in developing green buildings and promoting real estate projects that comply with green guidelines. In this way, entrepreneurial behaviour driven by green leadership can change a property developers' core strategy, technology system, supporting mechanism and development goal to one that is devoted to green real estate.

Furthermore, the leader's perception of the green building development can also influence the formulation and transformation of consumer perception in 'going green' through real estate products and marketing campaigns. Therefore, when developers promote their products in the market, they are also contributing to publicising and popularizing green building development. In fact, there are insufficient intellectual resources available for green building in China. In this context, a proactive leadership of the sustainability mission and vision not only has a significant impact on recruiting the intellectual resources needed for green building, but also in personnel training and establishing a green strategic map, which would eventually lead to a greater core competence to compete in the real estate market. Recently, several real estate enterprises have successfully transformed themselves from the traditional approach to green building development and established their own green real estate research teams. For example, the China Merchants Property Development Company has started a "Green, R and D and Application Centre" with the purpose for achieving the goal of "building green homes and promoting social progress." Landsea has also recruited more than 200 domestic and foreign senior researchers committed to the development of green building technologies.

3.2 Leadership styles for green building

Entrepreneurial leadership can be classified into two types – transformational leadership and transactional leadership - which perform differently in promoting green building development. Specifically, transformational leadership plays a more positive role in delivering green buildings due to consideration of social responsibilities and the interests of secondary stakeholders (Du et al.2013), entrepreneurial spirit. The acceptance of social responsibility is one of the initial moves of housing developers in delivering green real estate. Environmental protection and energy saving are important aspect of company social liability. As a leading property developer, one of the primary goals of the Vanke Group has always been to undertake social responsibilities. Since 2008, the Vanke Group has added "becoming an outstanding green enterprise" to its developing vision. In 2013, its total Green Building Certification Area reached 596.4 million square metres, while the area with "Green 3-stars" reached 172.7 million square metres (Vanke CSR Report, 2013). China Merchants Property Development Co, a developer ranked second only to Vanke, defines its core values as "Humanism, Responsibility, Outstanding and Co-prosperity". Its leaders believe the company can only create more social values by bonding together social responsibility and their own competitive advantage. In order to listen to the voices of all stakeholders, a complete CSR system has been established that provides a stage for the stakeholders to express their opinions concerning green building development.

Another impetus from transformational leadership in green building development is generated by entrepreneurship - the spirit to grab opportunities, confront challenges and take risks even in an uncertain environment. Entrepreneurship also inspires creative and innovative approaches. Corporate innovation is revealed in a spirit of adventure through 'first-mover strategies' (Das et al.1998). As a new venture, green building faces higher costs, more technical difficulty, greater market risk and other developmental problems compared with traditional building. For this reason, many companies tend to stay with traditional building. But entrepreneurial companies choose to seize the opportunity and encourage staff to develop green building in creative ways. In fact, companies that have made a successful green transformation always focus on innovation. For example, 'green gold' is a new concept indicating the high rewards that can be obtained from investing in green building technology, and has already been adopted by major real estate companies such as Vanke, Landsea, and Vantone.

Compared with transformational leadership, transactional leaders are inclined to focus on the pursuit of self-interest rather than the interests of secondary stakeholders (Das et al., 1998). They usually lack a spirit of adventure and innovation. Therefore, transactional leaders are not willing to invest in the green real estate market because of the high risk and high-cost. In China, small and medium-sized real estate enterprises pay less attention to green buildings than to the traditional market, which leads them to behave as transactional leaders. Henda Property Enterprises is a representative case of the transactional style of leadership. As the second largest real estate enterprise in China, the Hengda Real Estate Group has invested less in green building over the years. Its business leaders have placed their emphasis on hard-work and a fighting spirit instead of the change and innovation needed in 'going green'.

At present, there are a total of 112 mature and professional real estate enterprises in China, 27 of which are in a process of green transformation. These enterprises regard green real estate as a corporate strategy. Of the top 10 green real estate enterprises, 6 have written social responsibility and a spirit of innovation into their enterprise vision and business goals. The leadership of these enterprises not only bring their own approach to better development in the green real estate market, but also promote customer awareness and acceptance of green building. In addition, the leadership promotes the development of green building technology and improvement in laws and regulations. For example, the green image imposed on the public promotes the developer's brand and reputation, which can enhance the developer's intangible value and improve overall competitiveness accordingly. In this aspect, the China Merchant Property (CMP) enterprise and one of the top ten developers in the Chinese real estate development industry, provides a good example. According to an interview with one manager in CMP

"A leader does not only lead in performance and capability, but also accepts greater social responsibilities and has a mission to lead the industry to a healthier development .CMP is always committed to external environmental protection so as to secure the long-term value among shareholders and stakeholders. In this way, CMP is on the way towards making a green and social responsible difference of our own future ."

Consistent with its mission, China Merchant Property has been promoting the responsibilities of corporate citizenship and green property brand within the Chinese real estate industry, and has gained the trust and respect of society, which in turn has provided the firm with greater opportunities for further development.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4. DRIVERS OF CHANGE

As the "green building" movement gains momentum, many business leaders of key stakeholders, such as developers, governors, and designers, are anxious to understand the use of green building metrics to make the case for a sustainable future. Through a comprehensive literature review, a list of 16 incentive factors has been compiled as optional factors driving the implementation of green buildings. These factors can be classified into three groups in accordance with the guidelines in the extant literature.

4.1 Financial incentives

Many previous studies agree that financial incentives provide both efficient and effective tools for improving the building energy consumption and environmental protection situation (Jaffe et al., 2002; Dennis, 2006; Qian and Chan, 2007b, 2008b). As green projects can offer reduced operating costs while providing an improved working or living environment such as by natural daylight and better indoor air quality, it is therefore considered by many business sectors that the value of buildings designed by sustainable principles is more than that of conventional buildings – the reduced operating costs being a welcome bonus. In this way, the market demand for green buildings could be met (Baldwin et al, 1998; Clark, 2003). The investment needed during the construction period to develop green buildings is 1%-4% more than that of conventional buildings - substantially lower than is commonly perceived (Kats et al., 2008; Zhang et al., 2011). However, the economic returns due to increased property rents, the energy and water savings, reduced waste and lower operation and maintenance costs during the sales and post-sales period are much higher than the increased construction costs (Kats, 2003; Bradshaw et al., 2005; Johnson, 2005; Braham, 2006; Qiu, 2010). Taylor (2009) and Baek (2008) also include incentive money from utility energy efficiency programs, in terms of structural, mechanical, appliances, lighting, and alternative/renewable energy. In order to acquire the expected financial benefit, it is necessary for owners to understand which incentive programs are available to them, the specific details of each program and the products involved. Income tax credit is another important financial incentive (MTETM, 2007; Hawken et al., 1999). For example, a landfill tax was introduced in 1996 at a cost of £7 per tonne of active waste and £2 per tonne of inactive waste (The Sustainability Construction Task Group, 2002). For the installation of new renewable energy equipment, the tax credit has been increased from 15% to 40% of the expenses; and for high-efficiency insulators, a tax credit of 25% of the investment cost (MTETM, 2007). Green building tax credit is also available to corporate and residential taxpayers who construct a new green building or undertake the green rehabilitation of an existing building (USGBC, 2011). In the case of New York, for example, six different tax credit projects are available, which comprise the whole building credit, base building credit, tenant space credit, fuel cell credit, photovoltaic module credit and green refrigerant credit In addition, many USA municipalities have already offered tax credits and abatements as a means of advancing specific policy agendas to improve green building development.

4.2 Policy incentives of government-related bodies

Recently, government regulations and incentives have led many construction projects to pursue sustainable outcomes (Rahman and Sadeghpour, 2010). For example, the EU Energy Performance of Building Directive requires energy performance certificates for all property bought, sold or rented in the commercial and residential sectors (Strong, 2005). In 2002, Germany passed additional energy saving regulations known as EnEV) which set new minimum and mandatory standards for all new residential and almost all new non-residential buildings (Power and Zulauf, 2011). In France, a subsidy of not more than 20% of the construction costs is granted for the general renovation of private dwellings, and grants as well as subsidies are given for renovations to improve energy performance (Baek, 2008). Many studies have explored the best way for the government to motivate the increased development of green buildings (Varone and Aebischer, 2001; Atsusaka and LeVan, 2003; Qian and Chan, 2007). The Density Bonuses Policy offered by the U.S. government could provide an opportunity for municipalities to tie incentives to specific local public policy priorities. For example a higher percentage increase in Floor Area Ratio (FAR) can be offered to clients after green building certification (Hawkins & Wang, 2013).

The access to relevant policies and preferential loans/loan funds is considered as another effective policy incentive (Power and Zulauf, 2011). It is considered favourable for the public sector to offer low interest loans from a large fund to those seeking to build or renovate to verifiable green building standards. In this way, the concerns over the initial costs of a green building retrofit could be eased to a certain extent. Other forms of government policy incentives exist, such as partially or fully refunded development fees (Circo, 2009). As Nolan (2008) reports, for example, because few municipalities and land use agencies in the USA can afford to relinquish revenues, reduced

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

fees and rebates can only provide meaningful savings to developers if some alternative source replaces the lost revenue involved. One alternative solution, named a "cost-shifting strategy", aims to increase the fees paid by traditional projects by an amount sufficient to offset the costs of the green building program. However, this cost-shifting strategy depends on local circumstances, as expedited review and development bonuses have relatively high value to developers.

"Priority permit processing/reduce the difficulty of the project approval" is another policy incentive (Prum, 2009; Deng, 2012). For example, for developers who adopt specified green building standards several government programs, some aspects of the development permit application are processed more quickly than those submitted by traditional developers (Circo, 2009).

4.3 Corporate-based incentives

Many previous studies agree that corporate-based incentives are both efficient and effective tools to improve the development of green buildings (McMurdy, 1991; Gallarotti, 1996; Warren, 2010). As one of the stakeholders in sustainable development, real estate developers' incentives include: positive benefits for corporate business performance (McMurdy, 1991; Castleman, 1987); strengthening of corporate environmental performance (Carroll et al., 1990); establishment of 'green brands' in the industry (Gallarotti, 1996); green project awards (Tinker and Burt, 2004; AIA, 2006); meeting various shareholder requirement and benefits (Smart, 1992; Ken and Ratnayaka, 1992); philosophy to build green (internally) (Gallarotti, 1996); added value to the property (Warren, 2010); and Marketing/Good Publicity/Awards (Clark, 2003). In many cases, the mere presence of green buildings provides much publicity, which can make it easier for developers to attract new tenants or purchasers – especially where energy savings are involved. In this case, the value of faster sales and higher occupancy rates can substantially improve short run business performance (Clark, 2003).

5. CONCEPTUAL CHALLENGES IN 'GOING GREEN'

Green building development still faces challenges in market penetration (Chan et al, 2009). Business leaders are also faced with challenges and risks before they make the 'go green' decision - failing to meet the required level of certification for example. This risk may be significant where a large number of projects need to meet sustainability standards (Hancock, 2010).

Developers are one of the key participants in green building. From the developer's perspective, there are both ideological and operational challenges to be addressed during the decision-making and delivery processes involved. Ideological challenges include a cognitive bias towards green building development from inside and outside the organization. Internal misunderstanding occurs mainly from the leadership and the corporate culture. As discussed in the previous section, transformational leadership is more willing to adopt green building development than transactional leadership as the former has more sense of social responsibility and is more proactive in embracing challenges and taking risks. Moreover, the attitude of the leadership towards green building development has a profound influence on the choice of development approach for integrating the 'green' concept into the enterprise's personnel management and cultural development. Taking Vanke and Landsea as examples. Landsea values green building development more than Vanke, due to its cultural characteristics since its establishment. Due to its investment in 'green' technology, Landsea has been engaged in a variety of green projects since the early stage of its formation. It provides comfortable, energy-efficient, environmentally friendly residential products with highly cost-effective products in the housing market and it continues to expand its growth in green technology. On the other hand, unlike Landsea, Vanke places less emphasise on green building, giving priority instead to its traditional value of 'high speed of capital recycling' and adherence to the Wal-Mart model of development, which features the production of standardized residential developments around the city outskirts to specifically targeted groups of consumers (Guang, 2009). This external cognitive bias is associated with the public awareness and acceptance of green buildings. Even though the concept of green building has been widely accepted, progress in its adoption is very slow. Newly constructed green buildings are always located in suburbs, such as in a high-tech development zone, which is distant from well-developed public services facilities, such as renowned hospitals and schools. Green buildings are also more expensive in the research and development stages. Consumers may be fond of the advantages of the green building but might not be ready to pay the costs involved.

From the developers' viewpoint, a major issue also concerns the perceived costs involved. From an operational perspective, the challenges confronted by developers include the cost throughout the building life-cycle. The cost

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

of building includes construction costs and operating costs, which specifically refers to the research and development expenses (R&D) incurred with green techniques, manufacturing installation costs, and operating and maintenance costs. R&D for green techniques can lead to a significant cost difference between traditional building and green building (Jerry, 2007, and many others), leading to the general perception that green buildings are too expensive and not worth the extra cost (Kats, 2003). Indeed, Bartlett and Howard's (2000) research indicates that UK quantity surveyors believe that energy efficient and environmentally friendly buildings cost between 5% and 15% more to build from the outset (Bartlett and Howard 2000).

A particular issue concerns the difficulties involved in estimating costs over the lengthy building life-cycle, with uncertainty surrounding future developments and absence of reliable information and associated risks being a major problem (Cole and Sterner, 2000). On one hand, the RandD costs for green technology increase the initial cost of green building. On the other hand, uncertainty of the application of green techniques increases the risks. For example, green building in China must be tested and may fail in the evaluation, which means that if the building does not reach the Evaluation Standard for Green Building (GB/T 50378-2006), then it cannot be classified as a "green building", so that all the effort in the use of green techniques is wasted. The risks can also be defined as opportunity costs. Hence, RandD expenses and opportunity costs both increase the cost of green buildings, and therefore present great challenges for their large-scale adoption. This is reflected in an interview with a developer CEO in talking about the barriers to going green: " It made sense to me to go green. However, there is still a lack of cost analysis and measurement tools in going green due to the initial development stage. For most of the cases, I need to equip myself and the managerial team with 'green' and 'social responsibility ' roles, however, when we get down to the cost analysis and measurement tools, we got stuck there. "

Other perceived challenges to limit the development of green buildings , as shown below (Larsson, 2009):

- lack of simple funding mechanisms to pay for incremental performance;
- difficulty in measuring environmental performance in an objective and reliable way;
- increasing requirements for specialized skills and knowledge in the design and construction process;
- skill deficits in small design firms and contractors;
- lack of suppliers to provide green construction materials and equipment

There are great challenges, therefore, in converting green building intentions into reality. Ultimately, though, it is our responsibility to adhere to sustainable development and it is imperative that green building is implemented, and developing a mechanism for bringing this about is an important mission.

ABSTRACT

Previous studies related to energy efficient retrofit of the existing building stock mostly focused on operational energy reduction either on individual building or on the national and urban level. The evolution of the urban building stock in a resource conservation perspective needs to be further studied. The material and monetary investment and the embodied energy and carbon of building refurbishment need to be examined. However, the life cycle inventory data for reference buildings need to be refined based on thorough case studies. The objective of this study is to obtain the reference flow in the energy efficient retrofit processes of typical residential building, in order to provide accurate data basis for the simulation of the evolution of the residential building stock in a certain urban area. This contribution selects a fragment in the city of Tianjin for a case study. Through field investigation and data collection, we establish the information database for one typical apartment building, which is described in detail with BIM. The LCA results of different retrofit scenarios are analyzed with a BIM-based LCA tool, Tally. The costs are calculated with the quantity data derived from BIM and the prices for Chinese building material and energy. The results will provide reference data for urban fragment simulation in Tianjin and in similar cities in northeast China.

Keywords: residential building, energy efficient retrofit, life-cycle assessment

1. INTRODUCTION

After decades of high-speed development, China's urban construction is getting slow. The planning of the renewal about the building environment has become a major concern in this country's urban development. For many existing buildings, the high energy consumption along with their short life cycles, poor thermal comfortable conditions, and other issues have made their energy efficient retrofit a critical work under the background of urban renewal. In this paper, the Hongshunli community at Hebei district in Tianjin, China is picked as the study case. There are a large number of residential buildings built around the 1980s to 1990s, among which most of them need to be repaired, renewed or demolished as time goes by. In this study, one typical residential building built in the 1980s is selected. The goal is to achieve 65%

and 75% energy saving by proposing an energy efficient retrofit strategy according to the energy conservation design standard of Tianjin. On the basis of this, a complete Revit model of the building is built to conduct the life cycle assessment with Tally, and add-in for Revit. The result contains the material consumption, ecology and costs indexes of the typical building during the life cycle stages of energy saving renovation, operation, and demolition, providing accurate and complete background data for the existing tool named FRASIM established by our group.

2. DEFINITION OF TYPICAL RESIDENTIAL BUILDINGS

2.1 Goal of energy efficient retrofit in Tianjin

There is no energy saving design standard for residential buildings in Tianjin before 1991, only a so-called test data of 1980-1981 Residential general design heating energy consumption level. In order to implement building energy efficiency, Tianjin proposed the four-step energy efficiency standards on the new residential buildings. At present, the goal of energy efficient retrofit of existing residential buildings in Tianjin is to achieve the third step energy-saving (65%), so the study is based on the standard to achieve 65% and 75% energy saving. Table 1 shows the standards for heating energy consumption in Tianjin.

Steps of Energy Saving	1980-1981	the First Step Energy-saving (30%)	the Second Step Energy-saving (50%)	the Third Step Energy-saving (65%)	the Fourth Step Energy-saving (75%)
Heating Energy Consumption (KWh/ m^2a)	147.34	116.76	69.50	55.6	37.04

Table 1: Standards for heating energy consumption in Tianjin

2.2 Basic information about typical residential building

Reference buildings are chosen for the case study urban fragment in Tianjin according to the main features including their year of construction, number of floors, energy saving standards and their structure and material. (Table 2) Five residential buildings in the case study fragment were chosen as representatives of the majority of the housing stock in certain periods. Due to the length limit, this article focuses on one typical building named Sanjieli No.4, which is a 3-story building of brick-concrete structure built in 1980.

Time Period		1976-1991	1992-1999	2000-2004
Main Building Structure		Brick-Concrete Prefabricated Concrete Panel	Brick-Concrete Prefabricated Concrete Panel	Reinforced Concrete
Number of Stories	Low-rise (1 - 3)	●	/	/
	Mid-rise (4 - 6)	●	●	●
	High-rise (> = 7)	○	●	●
Energy Saving Standard		No	First Step (30%)	Second Step (50%)

Note: ● ● ● ● ○
Majority → Few
(Black rectangles are defined as features of typical buildings)

Table 2: Definition of typical residential buildings in the city of Tianjin

Sanjieli No.4 belongs to the reconstruction project of Hongshunli-Huangwei Rd area after the earthquake in 1976. It is designed with no energy saving strategy. The construction time and structural system of Sanjieli represent the general characteristics of residential buildings in Tianjin in the 1980s which are suitable for research as a typical building. Table 3 shows its basic information.

Built Age	Building Structure	Storey Number	Building Area	BIM Model	Building Image
1980	Brick-Concrete	3	1603.5 m^2		

Table 3: Basic information of Sanjieli No.4 building

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. RETROFIT STRATEGY OF TYPICAL RESIDENTIAL BUILDING

According to the related energy efficient retrofit files and cases in Tianjin, the strategy of Tianjin's residential buildings mainly focus on the building envelope, heating, and air conditioning, ventilation system, solar energy system and some other aspects, in which the building envelope and heating system take a large part of it. In this way, this article will mainly focus on the retrofit of these two aspects.

3.1 Building envelope

3.1.1 External wall insulation

A layer of 50mm expanded polystyrene insulation board will be used for the 65% energy saving goal and the 80mm one will be used for the 75% goal.

3.1.2 Roof insulation

The XPS Extruded polystyrene insulation board is used while aiming at 65% energy saving and the thickness is 70mm. Rigid polyurethane board is used at the 75% goal and the thickness is 100mm.

3.1.3 Energy saving of external window

65% energy saving

There are two conditions with the external window retrofit:

- If the windows are already replaced with single-glazed window with aluminum or PVC-steel frame by the residents, an additional layer of single-glazed window with PVC-steel frame will be added to the outside of the existing ones.
- If the windows have not been replaced, the single-glazed window with old steel frame will be replaced with double-glazed windows with the PVC-steel frame.

75% energy saving

If the goal is set to 75% energy saving, all the original windows need to be replaced with triple-glazed window with aluminum frame.

3.2 Heating system

In practice, the retrofit of heating system should be carried out from the indoor system, outdoor pipe network, and heat station. As the research scope of this article focuses on the building itself, only the indoor system is discussed.

The original indoor heating systems of the two typical buildings are separated sub-ring system which has been used for more than 25 years. All the equipment (pipes, radiators, valves, etc.) of the system have reached the usage limit and need to be replaced. The heating system after the retrofit will use a vertical dual-tube system and has an individual metering function.

4. LCA AND LCC ANALYSIS OF TYPICAL BUILDING ENERGY EFFICIENT RETROFIT

For each typical building, the following three possible scenarios are listed:

Scenario 1: Present → 65% energy saving → Demolition

Scenario 2: Present → 75% energy saving → Demolition

Scenario 3: Present → 65% energy saving → 75% energy saving → Demolition

Scenario 1 is to retrofit the typical building to 65% energy saving at one step and keep operating under this condition till its demolition. Scenario 2 is to retrofit the typical building to 75% energy saving at one step and keep operating under this condition till its demolition. Scenario 3 is to retrofit the typical building to 65% energy saving

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

at the first step then another retrofitting may happen later if the structure is still in good form to improve the condition to 75% energy saving and keep operating under the new condition till its demolition.

4.1 Sanjieli No.4

4.1.1 Energy efficient retrofit of Sanjieli

65% energy saving

The U-value of each envelope after 65% energy saving are: External wall U-value=0.442 W/(m²•K), Roof U-value=0.3261 W/(m²•K), External window U-value = 2.4 W/(m²•K). The heating demand after the simulation in IES(VE) software is 54 KWh/m². Table 4 shows the amount and cost of the materials used during 65% energy saving efficient retrofit of Sanjieli.

	Project	the Weight per Square Meter (kg/m²)
Amount	Demolished Material	39.84
	Added Material	83.08
Cost	Project	the Cost per Square Meter (yuan/ m²)
	Recycling Price	10.39
	Input Price	318.41
	Gross (Input- Recycling)	308.02

Table 4: Amount and cost of the materials used of scenario I (Present → 65% energy saving)

Table 5 shows the amount of the greenhouse gas emission and the primary energy consumption of the materials used during 65% energy saving efficient retrofit.

	Global Warming Potential Total (kgCO2eq/ m²)	Non-renewable Energy Demand (MJ/ m²)
Demolished Material for recycling	-4.72	-38.32
Added Material	62.02	642.46
Total	57.31	604.14

Table 5: Amount of the greenhouse gas emission and the primary energy consumption of the materials used during scenario I (Present → 65% energy saving)

75% energy saving

The U-value of each envelope after 75% energy saving are: External wall U-value = 0.3205 W/(m²•K), Roof U-value = 0.1968 W/(m²•K), External window U-value = 1.47 W/(m²•K). The heating demand is 36 KWh/ m². There are two different scenarios under the 75% energy saving situation:

Scenario 2: Present → 75% energy saving

	Project	the Weight per Square Meter (kg/m²)
Amount	Demolished Material	39.84
	Added Material	84.07
Cost	Project	The Cost per Square Meter (yuan/ m²)
	Recycling Price	10.39
	Input Price	394.31
	Gross (Input- Recycling)	383.92

Table 8: Amount and cost of the materials used in scenario 3 (65% → 75% energy saving)

	Global Warming Potential Total (kgCO$_{2eq}$/ m^2)	Non-renewable Energy Demand (MJ/ m^2)
Demolished Material	95.56	-1142.98
Added Material	79.70	738.04
Total	175.25	-404.94

Table 9: Amount of the greenhouse gas emission and the primary energy consumption of the materials used during scenario 3 (65% → 75% energy saving)

4.1.2 General maintenance and retrofit of Sanjieli (Except energy efficient retrofit)

In addition to the initial investment in energy saving retrofit, the repair and replacement of other building components and materials are also happening during the life cycle of the building. Table 10 shows the environmental impacts and amount of the other building components during their repair and replacement.

Building Component	Macro-component	Life	Amount	Global Warming Potential	Non-renewable Energy Demand	Renewable Energy Demand
		year	kg/m²	kg/m²	MJ/m²	MJ/m²
Interior Door & Window	Holistic	40	3.39	5.48	54.38	32.31
Exterior Wall	Interior Mortar	50	33.60	19.84	113.82	2.77
	Interior Painting	10	0.13	0.33	7.36	3.35
	Exterior Mortar	30	33.60	19.84	113.82	2.77
	Exterior Painting	15	0.13	0.33	7.36	3.35
Interior Wall	Interior Mortar	50	99.94	59.28	339.97	3.74
	Interior Painting	10	0.39	0.99	21.98	3.74
Floor	Mortar	50	75.35	44.71	256.43	104.26
	Painting	10	0.29	0.75	16.58	104.47
Ceiling	Mortar	50	30.99	18.41	105.58	125.68
	Painting	10	0.12	0.31	6.83	124.31
Stair	Mortar	50	5.71	3.39	19.42	123.91
	Painting	10	0.02	0.06	1.26	128.19
Total		/	283.66	173.72	1064.79	762.85

Table 10: Environmental impacts and amount of the other building components

For other equipment systems, due to a wide range of materials and difficult to estimate, this article courts their default values by referring to other retrofit cases, shown in Table 11.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Equipment System	Material	Life	Amount	Global Warming Potential	Non-renewable Energy Demand	Renewable Energy Demand
		year	kg/m²	kg/m²	MJ/m²	MJ/m²
Ventilation	Steel Zinked	30	0.77	1.84	22.05	1.07
	Mineral Wool	30	0.13	9.12	106.57	9.48
Water Distribution and Sanitary	Steel	30	0.72	0.59	7.99	0.88
	PIR, PVC	30	0.20	1.01	12.56	1.04
Electricity	Steel Zinked	30	0.19	0.45	5.43	0.26
	Copper Cable	20	0.96	1.63	16.83	1.92
	PVC, PUR	20	0.29	1.47	18.21	1.51
Total		/	3.26	16.11	189.64	16.16

Table 11: Environmental impacts and amount of the other equipment system

4.1.3 The Demolishment phase of Sanjieli

According to the previous analysis, the typical building may be demolished after 65% or 75% energy saving retrofits. Table 12 lists the statistics of the demolition after different energy saving stages.

Energy Saving Goal	Amount of demolished material	Global Warming Potential	Non-renewable Energy Demand	Renewable Energy Demand	Cost
	kg/m²	$kgCO_{2eq}$/ m²	MJ/ m²	MJ/ m²	yuan/ m²
65%	2701.58	69.76	1086.40	41.90	-84.50
75%	2699.99	64.53	1036.24	17.58	-83.81

Table 12: Statistics of the demolition after different energy saving stages

5. DISCUSSION

It can be resulted from the compare of the buildings before and after the retrofit that the heating energy consumption is reduced, following with the deduction of gas consumption which used as the resource of heating. Table 13 shows the comparison of the heating energy consumption, heating price and ecological index before and after the retrofit.

Index	Stage	Sanjieli No.4
Terminal Heating Energy Consumption (KWh/ m².a)	Present Situation	125.3
	65% Energy Saving	54.3
	75% Energy Saving	36.1
Heating Prices (yuan/ m²)	Present Situation	23.8
	65% Energy Saving	14.6
	75% Energy Saving	12.2
Global Warming Potential Total ($kgCO_{2eq}$/ m²)	Present Situation	38.1
	65% Energy Saving	16.5
	75% Energy Saving	11.0
Primary Energy Demand Total (MJ/m²)	Present Situation	634.2
	65% Energy Saving	274.9
	75% Energy Saving	182.7

Table 13: Comparison of the heating energy consumption, heating price, and ecological index

In the previous calculation, the external walls and roofs also contain the general maintenance items. The original residential heating system has been used for more than 30 years which has reached the service life, so the replacement of the indoor heating system is also a maintenance that should not be included in the cost of energy

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

efficient retrofit. The real investments, annual net cash flow and a static payback period of energy efficient retrofit with the consideration of the general maintenance items should be like Table 14.

Sanjieli No.4	Investments (yuan/㎡)	Annual Net Cash Flow (yuan/㎡)	Static Payback Period (year)
Scenario1 (Present→65%)	205.0	16.7	12.3
Scenario 2 (Present→75%)	283.9	19.1	14.9
Scenario 3 (65%→75%)	282.9	2.4	117.9

Note: Calculation method of static payback period: n=I/A
n - static payback period (year)
I - energy saving investments (yuan/ m^2), calculated by the cost of energy efficient retrofit
A - annual net cash flow (yuan/ m^2), calculated by the heat metering price

Table 14

Sanjieli No.4	Primary Energy Consumption of Retrofit	Primary Energy of Heat Saving	Payback Period of Energy Consumption
	(MJ/㎡)	(MJ/㎡)	year
65% (Present→65%)	600.6	359.3	1.7
75% (Present→75%)	679.0	451.4	1.5
75% (65%→75%)	225.9	92.2	2.5

Table 15: The payback period of primary energy consumption

It can be seen from the table 15 that scenario 1 and scenario 2 are basically able to recover their investment over a period of 10 years. At the same time, the payback periods of primary energy consumption of all the scenarios are relatively short and the investment payback periods of scenario 1 and scenario 2 are reasonable. However, the investment payback period of scenario 3 is too long to meet the economic efficiency. Consequently, it is feasible to adopt the energy efficient retrofit in scenario 1 and scenario 2 for the typical buildings in this article. It should be pointed out that the payback period is calculated in the ideal condition. If taking the rebound effect into account, the period should be longer.

For cities in the cold climate zone of China, heating accounts for the major part of the total energy consumption. Therefore, the energy-saving standards mainly set benchmarks for heating energy consumption. The consumption from hot water or other household appliances is not directly relevant to the energy efficient retrofit due to the uncertainties of residents' behaviours. Therefore, this paper focuses on the variations related to the space heating. Hot water and other energy demands are set as default values in energy simulation software (IESVE).

It's important to note that the retrofit strategies will have an unintended effect of making the building hotter in summer. It is partly proved by the results of cooling energy consumption in the rough energy simulation (Table 16). But the increase in cooling energy consumption is negligible in comparison to the decrease of heating energy consumption. To get more accurate results for the change of cooling energy consumption under different retrofit scenarios, further study on the indoor temperatures of different rooms according to their exposures need to be conducted.

Scenarios	Cooling Energy Consumption (KWh/ m^2.a)
Current Situation	5.9
65% energy saving retrofit	6.1
75% energy saving retrofit	6.3

Table 16: Simulation results of cooling energy consumption

6. CONCLUSION

The energy efficient retrofit of the typical residential building reduces its heating energy consumption and improves the living comfort of tenants. In the meantime, the repair and replacement of old components extend the lifespan of the building. The retrofit strategies to reach different levels energy saving standards and the resulting reference flows (primary energy, GWP, costs, etc.) in different life cycle stages (retrofit, repair, replacement, demolition and recycling) are analysed in this study, which could provide reference values for the energy efficient retrofit of existing buildings in cold climate zone of north China. With the analytical results of more typical buildings, the environmental and economic cost benefit of the strategies for urban housing stock update can be estimated.

Session 5.4: Deep Renovations – Policies & Standards

Small, Beautiful, Yet Difficult: Energy Plus Renovation in Small Social Housing Companies

Christian KOCH[a], Anders LUTTEMAN[b]

[a] *Chalmers University of Technology, Sweden, kochch@chalmers.se*

ABSTRACT

Social housing represents a particular challenge of creating sustainable buildings. Large portfolios of post second world war concrete blocks type of building is the epitome of this issue. They are in serious need of renovation to meet future demands of energy consumption and sustainability. This even involves the important aspect of social sustainability. At a time new energy producing renewable technologies represent important contributions to the mitigation of these challenges. This is also the case in Sweden. However, here, beneath the dominant agenda of suburbs to large cities, a series of small social housing company actually operate which have similar issues, yet receive far less attention. The aim of this contribution is to discuss challenges of carrying out energy plus renovation of small social housing companies in Sweden and to present a possible roadmap for meeting the challenges. The theoretical framework draw on conceptualisations of small organisations characteristics, building research on small clients and political science approaches to the role of regulation. The empirical material has been gathered through collaboration with one company and its network among other small housing companies in its area. Research collaboration extends over a year of study. The results show that the limited resources of small social housing companies has to be mitigated through developing a new financial model enabling the rent to stay stable, providing extra manpower in the purchasing process and a network for identifying energy producing and less consuming technologies for the renovation. A roadmap for carrying out renovation is suggested involving all phases of purchasing and operating renovated building blocks. The roadmap suggest moreover systematic involvement of tenants in the process.

Keywords: Social housing, energy renovation, roadmap

1. INTRODUCTION

The Swedish Post War suburban housing construction projects constitute of nearly 1000000 apartments, hence the name “The million program”. All of which came in to place between the years 1965-1974 as a response to the huge demand of housings from a growing population and urbanization. 600 000 apartments of the Million program is in need of renovation and there is a big challenge in both making them energy efficient and to keep the overall cost as low as possible (Lindén, 2015). In the larger cities of Sweden many of these renovations has lead up to an un-proportional rise in rental levels. These higher rents in turn generate gentrification and social exclusion in some areas. The renovation processes in it self is a complex task that requires special knowledge and practical experience from both developers and hired contractors. Houses of “The million program”, and especially the ones in the rural regions of Sweden pose a huge challenge for both owners and tenants. If politicians and owners are to be successful in their aim to renovate all dwellings a new and dramatically different approach needs to be put in place. One of many obstacles that social housing companies have to handle is the tension between different paragraphs in a new legislation from 2011, governing social housing companies. The new law stipulates that a social housing company needs to act as independent subsidiary with standardized market commercial demands on profit and turnover. (Blomé, 2012). Finally and the particular focus of this paper is the many small municipalities and their social housing companies, which is working from a rather different financial and managerial condition compared to the bigger sisters and brothers in the Big City regions of Sweden. This gives raise to this paper main questions:

- What obstacles are commonly addressed by the smaller social housing companies whilst executing a renovation program?
- What kind of actions and steps is feasible to pursue in the renovation process?

And as sub questions to the second main question:

- How to manage, create and distribute knowledge in order to enhance the owners/clients role through out the renovation process and the procurement process?
- What kind of strategy can be considered by a small housing company when handling owners demand, legal and bureaucratic processes in order to create a driving force and willingness for collaboration between all stakeholders?

The paper is structured in the following manner. It commences with providing information on the methodological set up. Then the framework of understanding is given. Then two major section answers to the main questions of the paper. The second section provides a brief presentation of the roadmap suggested to guide small social housing companies in energy plus renovation the paper ends with a conclusion.

2. METHOD

The paper has exploratory character and draws on organisation and management as well as energy renovation literature. Several consequtive literature searches has been made to better underpin and understanding and conceptualisation of the concepts of the clients, energy plus renovation, energy renovation building processes, procurement in building etc. The empirical part has been developed through conversations and observations, in partnership with one small social housing company starting autumn 2015 and during 2016 within the frame of a economic project support from the Swedish Energy Agency. We conducted nine interviews with people who have extensive experience in municipal companies implementing energy renovations or installation of energy producing technologies. Also the researchers have attending meetings between a group of social housing companies that are close to each other geographically and in size. The companies share the same features of being small in size and owned by municipalities in the countryside regions of Västra Götaland. Gathering together this material made it possible for us to condense a few central challenges and suggest a strategy in the shape of a roadmap. It is a limitation that our research has been attached to one social housing company mainly. However at a time that also provided us with valuable knowledge of the challenges of small social housing companies.

3. FRAMEWORK OF UNDERSTANDING

Below are gathered the theoretical elements to respond to the aims of the paper. This includes the understanding of small building clients, facing energy renovation and other challenges and the conceptualisation of the needed building processes. The literature is sparse on small and medium sized building clients, and even more so on small social housing companies. We contend that small building clients in many ways can be compared to other SMEs, also building SME meaning they lack internal resources, they have an informal internal organisation (Hardie 2010, Lu et al 2008, author reference) and energy renovation is not an area were these organisations have extensive competences (Alhourani and Saxena 2009, Granderson et al 2016, Schleich and Gruber 2008). They therefore need to rely on external networking and contracting of competences such as client counsellors. The process of renovation is therefore very much an issue of learning, but also on making choices i.e. it's a political process (author reference). This stand in contrast to many conceptualisation of Building processes, where rational phase model dominate (an example is Sutt 2011). These dominant models also usually assume that the client have endless resources an underestimate the importance of emergent learning and political processes. One central early choice is the procurement form. Normally clients opt for either a design bid build, design build of partnering contracts (Bresnen 2007). Design bid build can be understood as an instrument for handling risk as it provide the client with a clear milestone in the process separating design and production, this mean negotiating time and resources in two steps. On the other hand design build and partnering contract make it possible to utilize the contractors competence early in the design phase, and at a time involves negotiating the building sum early (Sporrong and Kadefors 2014). Our framework for the energy plus renovation thus takes into concern that the client is small. Moreover it is indeed constructed as a phase model, because this provides an attractive order of the argument, yet also knowingly that the actual process will not follow a neat scheme.

4. ADDRESSING THE CHALLENGES

Below we address three challenges: the dialogue with tenants, collaboration with partners and legal issues related to energy use.

4.1 The dialog with tenants

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

A recurring theme during a renovation of social housing is the importance of maintaining a good and healthy relationship with tenants. Historically there are examples of when the The Swedish Tenants Association along with tenants have caused delays and altered the renovation project. This underline why many housing companies have invested considerable resources to engage the tenants and to give them a strong influence on the renovation process. There are examples of renovations where the interaction has become so fruitful that tenants themselves became the main driving force. Giving tenants the opportunity to choose the level of renovation standard is a mean to make the tenants be a part of the renovation process. Some argue that this kind of engagement from the developers is only there as a facade in order to get a smooth and efficient renovation process. Others believe that a strong commitment from tenants themselves improves and streamlines the process and that the dialogue is the alpha and omega of a successful renovation. Regardless, this means that in any case a lot of work when you involve the tenants (Author reference). There are tenant dialogues that have proved to work. On those occasions it has for example been a key person who have had special knowledge and skills to manage the tenant dialogue. If the company does not have such a resource available, a tenant dialogue run the risk of being counter-productive instead. Through a fruitful tenant dialogue it is possible to reach a sort of binding agreement in which both the developer-landlord and the procured contractors together with the tenants' association and tenant agree on the future with regard to costs, quality and choosing materials and renovation standards.

4.2 Collaboration and working together as partners

The choice of procurement process is a challenge. Coordination and collaboration in renovation often proved to be complex. Partnering is one method developed for interaction which tries to streamline the construction and renovation process (Bresnen 2007). The partnering concept is based on the developer and the contractor agree to work together for a common goal and where the risks and benefits are shared equally. Moreover, it is about establishing practices that create and maintain personal relationships in the renovation process. It is also about creating procedures for what to do when a conflict arises or how to measure and control how well the various objectives have been achieved. It may involve two different types of targets. First measurable goals related to the project's impact on the economy, energy efficiency or social betterment of society. Second to set goals about how the stakeholders internally act and behave against each other. This can include goals for responsibility, how much information one should share with each other or targets on how to improve cooperation. Partnering cooperation objectives and procedures relates to all persons who have an active and central role in the planning, design, construction and maintenance. This includes project managers, craftsmen, the developer and the owners and management and other consultants (Kadefors, 2002). The concept of open books provide insight for each participant in the partnership, and improves both trust and frank dialogue. The way to work should be through a current account with the so-called incentives consisting of financial targets attracting contractors and consultants to work more efficiently and more rational in order to be able to receive bonuses or share of profits.

4.3 Legal and financial issues may reduce energy saving

The questions about law versus finances are multiple and complex. At a first glance it could come across like a simple technical vs. mathematical problem. Instead law and subsequent beurocracy is complex and involve many different levels. For example; The construction legislation in Sweden exhibit trade-offs between the requirements on emergency exits, ventilation requirements or any other compelling solutions which in some cases stands in the way of the most energy efficient solution. In such situations it is important to understand and collaborate between administrators and stakeholders within the municipality so that the right technology is selected with respect to legal aspects. It becomes important to understand how the flow of information ought to function between relevant officials and consultants all the way through the blue collars and their practical knowledge. (Author reference 2015). To achieve set goals within a renovation the developer will be faced with various choices and trade offs. It is the final goal and mission set by the developers along with the choosen time horizion that governs the size and type of the investment trade-offs. The following factors should be taken into account:

- Social responsibility of the municipality and the property's tenants (by extension the whole municipality's population) (Lind et al. 2014)
- Laws, regulations and directives that govern the expected standard on the company's properties
- Environmental responsibility (regulated by the owners and the state)
- The discount rate that is controlled by the internal and external market factors

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Depreciation requirements controlled by the timing aspect of choosing the investment horizon(Byman and Jernelius, 2012)
- How to evaluate in monetary terms the improvements coming from investing in soft social values and also how to put this monetary figure into the investment calculations evaluating future profit and success (Johansson, 2012, Lind, 2014)

5. HOW TO HANDLE CHALLENGES – ELEMENTS OF A STRATEGY

5.1 Knowledge in organization to strengthen the role in the procurement and as a developer

Knowledge management in an organization is about how to choose to organize, evaluate and use knowledge in an organization. By pursuing cooperation between the different stakeholders that goes vertically and horizontally throughout the renovation process there will be positive effect on efficiency. The construction process should be organized in such a way that an on-going communication about issues regarding construction, energy, and finance is always present. The creation of knowledge and subsequent solutions must come directly from practice and solved jointly at an early stage in the renovation process (Author reference). In order to reduce costs and increase the efficiency of a project, a client must be able to evaluate quotes which promote various techniques and put them up against each other and simultaneously assess the contractor and the designers' skills to perform the work. The procurer who acquires the ability to combine their own skills of assessing technical aspects in combination with contractor's ability and at the same time is able to deepen and enhance cooperation through out a renovation process will reinforce the developer's role as a strong and robust procurer. Because of the complexity in a larger renovation process a certain amount of strategic thinking is needed (Author reference). It is important as a procurer and developer to define energy demands that are reasonable. There must be specified margins of energy so that entrepreneurs actually will be able to meet the requirements. If the client does not set reasonable standards it could mean that important tender fail to be submitted, or that it provides room for future conflicts that results in higher costs. Clients must understand the principle of give and take to reach their goals. It is also important to create specifications which clearly defines the requirements that must be measured after the renovation is completed. The skills of contractors should be examined. This is done either by triangulation and hearsay. An excessive focus on the lowest price in the tender evaluation is contraproductive towards incentives for cooperation and business opportunities (Bresnen 2007, Kadefors 2002). By understanding and knowing the Public Procurement Act, a developer can in gain advantage (Sporrong and Kadefors, 2014). Ability to cooperate, teamwork, and a good track record are all factors that will beat a lower price. These factors could easily be checked by using the contractors' track-record demonstrating good and successful collaborations. The developer or purchaser must be up to date on the industry's energy requirements and allow to invest in internal and external training. It is only when there is sufficient knowledge that makes it possible to think in new and different ways. Co finance and recruit clients with a long track record of working with these issues within other municipalities. Create contracts that either share risks but also opportunities. It may be better with positive signals about future profit motivation than to threaten with punishment and sanctions. Add incentives of increased profits through further agreements if, and only if, certain requirements are met. Through triangulation ensure such high requirements that contractors who do not measure at an early stage are being disqualified. It is important that this exclusion is done in the right way according to the Public Procurement Act. Some important parameters that are measurable in such exclusion criteria might be: Historical data, the number of complaints that remain after the final inspection, time for completion ofreference projects, delivery of projects on time and number of penalties for delays.

5.2 **Handling owner's pol**itics, legal and bureaucratic processes to create a driving force and enhance collaboration

One of the key factors to a successful renovation project is the driving force that gets the project to move forward. Since many different players are normally involved in a renovation project, it is important that no delays or misunderstandings occurs. The following six areas has been identified as key factors (a-f): (a) Ask for political decisions from owners that are simple and that gives clear information about the size of the renovation budget for energy savings and size of resource allocations. (b) A completed climate plan for the property portfolio at a general level has been shown to increase the likelihood of implementation of energy-saving measures when carrying out renovations. (c) Make sure the issue and topic of energy renovation has been well established among officials and politicians in other parts of the municipality departments. This is particularly important when testing for various permits, building permits, and other resources needed by the officials (Paradis, 2015). (d) There must be clarity in the internal project team about what to do, what the conditions are and that everyone is clear on this. To achieve this, the group should have conducted a feasibility study of the renovation project to conditions, limitations and resources are well known. All employees in the project should have the same basic philosophy and thought. (e) Strategic thinking by project managers and officials who are set to implement parts of the renovation project by identifying and consciously using the established rules and objectives within the municipality and housing company. Such a strategy implies that one should take advantage of the environmental plans, rules and policies that exist to achieve their own projects or team goals (Paradis, 2015). (f) Add resources and time to find / define the persons who are knowledgeable in many different areas needed and who possess the ability to absorb new information. The personell should also have the ability to create alliances and networks and thus have a large contact area within adjacent municipalities. Four important points are (1) Determine together the values that will be the basis for communication within the group in the event of a conflict. (2) Establish procedures within the project that will connect to the projectleader in the event of deficiencies or breach of goals or soft values. (3) Create routines for how to register and manage defects without pointing out or blaming particular persons or contractors. It is important to clarify the difference between practical / physical errors and other values-related issues (4) Create a shared detailed document, describing how the parties should manage, solve and act given objectives, targets, and potential conflicts. Make these routines reciprocal amongst stakeholders in a follow-up communication. Formulate a partnering declaration that express the agreed vision which all participants sign, creating a moral obligation to work towards the common objectives and to do this by some predetermined norms (Nyström, 2007, Kadefors, 2002).

5.3 The road map development

Below follows a short description of the Road Map Development. The road map is suggested as a tool for the social housing developer. Phase 1 encompasses ideas, survey and development of projects. This phase involves working to produce data needed to make a renovation plan. In this phase it is important to find out what purposees the renovation will have. It also include to point out what financial and practical resources exists and in what physical condition the property is in. Phase 2, the planning and tendering phase is about evaluating techniques and requirements in detail. Project together with architects and engineers go through different specifications, requirements and design proposals. The evaluations will be the basis for system documents containing details of design, materials, systems for air and heat, and possibly other energy systems. Phase 3 is the construction and implementation phase. It covers renovation and implementation of energy-producing technologies. The work is driven through the renovation fase based on a detailed planning and control plan. Various energy-producing technologies are being installed. Throughout the practical renovation a variety of checks on contractors, planners and subcontractors are being carried out. Phase 4 is operation and maintenance. This consists of a variety of systems and controls. The work begins with trying to optimize the property and all newley installed energy producing systems. It is through inspections of the property´s systems several years after an energy renovation that faults and errors has been found and the goal is to make the running time as long as possible. In addition, this is a delicate phase in which there is a risk that the skills, knowledge and other important staff can be lost in the transition from the completion of the operational phase (Author reference)

6. CONCLUSION

This paper set out to answer two main questions related to small social housing companies doing energy renovation. First what obstacles would the companies meet whilst executing a renovation program? Second what kind of actions and steps is feasible to pursue in the renovation process, when looking at how to manage, create and distribute knowledge in order to enhance the owners/clients role through out the renovation process and the procurement process? And what kind of strategy can be adopted considering owners demand, legal and bureaucratic processes and collaboration between all stakeholders? The challenges we identify answering the first question is the dialogue with tenants, collaboration with partners and legal issues related to energy use. As solutions to these challenges and answering the two questions we suggest to systematically organise knowledge to strengthen the clients and to form a strategy here presented as a roadmap in four steps. We argue the collaboration with the tenants should be a constructive fruitful process. In cases where the tenants association is strong collaboration can be underpinned for example by agreeing with the tenants' association along with a mediation party that no rent increase may be implemented that can be traced to the renovation. As a response to such an agreement, the tenants association agrees on not put hinders towards the renovation process. We emphasize the need to enhance skills of the clients in relation to negotiations with contractors and consultants.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Energy renovation of the existing building stock is of paramount importance for societies to tackle the climate challenge. Much effort focus on large players, yet most of the building stock is owned by smaller clients that even colloborate with smaller suppliers. We hope with this paper to have contributed to a further focus of small players contribution.

Deep Renovation: Key Action for Active Protection of Modern Heritage. The Case of Architecture for the Service Sector

Claudia CALICE[a], Carola CLEMENTE[b]

[a] *University of Rome, Italy, claudiacalice@gmail.com*
[b] *University of Rome, Italy, carola.clemente@uniroma1.it*

ABSTRACT

This paper is the synthesis of multi-year research activities carried out with the support of Sapienza University in collaboration with some local authorities and private entities on integrated refurbishment planning of tertiary buildings. Despite European Commissions requests (Energy Performance of Buildings Directive and Energy Efficiency Directive) about renovation in the service sector, there are not yet national or european databases and studies, but only some preliminary hypothesis potentials of energy efficiency of the interventions. The very incomplete knowledge of the heritage and its energy consumptions leads to develop only partial studies, without an integrated and multidisciplinary approach. Therefore, there is a lack of retrofit integrated guidelines, especially for the heritage with architectural value but non still included like a consolidated category of historical monuments.

This is the case of directional buildings, in which were involved the best architects and designers in Europe during the post-war reconstruction of the productive and administrative features of European countries. The renovation of a substantial part of this architectural heritage is aimed at protection and promotion, through actions both respectful and effective, in order to answer to even more complex and variable user's needs but the know how is to build yet. This absolutely open and still very unclear question often shows how entities and authorities are underprepared on the best practices to implement in order to protect and enhance architectural heritage.

Keywords: energy saving, heritage, deep building renovation.

1. INTRODUCTION

The integrated refurbishment, and the deep, functional and energy renovation of architecture for the tertiary sector from the last century, is a major commitment for public administrations and private entities that own and manage heritage of importance in terms of size and architectural quality – heritage that in many cases characterizes the diffuse quality of the consolidated city. The organization of tertiary sector building heritage in Italy reflects the country's productive structure, and the dynamics of urban and demographic development in the leading metropolitan areas have evolved. With few differences, this timeline is the same throughout all the building stocks in the traditional and advanced tertiary sector; these buildings are marked by a generally swift functional and technological obsolescence, closely connected to the cycles of operative renewal involving the activities they house. Falling into these categories are various types of buildings that may be catalogued by different levels of complexity in terms of technology and plant, in which energy consumption – generally found to be in decline in residential construction – continues to hold firm, or is seeing a slow and steady rise.

Looking at the buildings of greater architectural importance, the issue of deep renovation brings to bear a number of different competences belonging to various disciplines in technology and plant, as well as those in history and restoration, especially when working in an established historic setting or in a modern setting with strong architectural content. This is the case of the management architecture built during the last century, where the need to reconstruct the productive and administration infrastructure engaged the period's finest designers throughout Europe. The conversion of a considerable portion of architectural heritage to be protected and capitalized on with solutions that both respect pre-existing buildings and are effective in their response to increasingly complex requirement frameworks is an open and still under-examined question; often, even the entities in charge of managing the protection of architectural heritage find themselves unprepared.

2. MATERIALS AND METHODS

2.1 Deep renovation approach in modern non-residential heritage

For decades, the question of intervening in the modern utilitarian heritage has been a characteristic theme of technical design culture almost exclusively of national interest. In the international sphere, the management or transformation of these buildings has often found a quick response in their demolition or reconstruction. This cultural distance – which emerged in the second postwar period from the extremely different situation of architectural heritage for public services among the various European countries more or less stricken by the devastations of war – narrowed, especially by virtue of the modern and reconstruction movement's critical re-evaluation of utilitarian architecture. Although these architectures, to a great degree, have yet to come under categories of monumental landmarking, the recognition of their intrinsic value, or of the value of the urban context they are rooted in, has brought about a new sensitivity in their management. In many cases, no critical design ability for this category of buildings has yet been established, particularly for the reconstruction architectures built between 1945 and the early 1960s. These buildings, when they manage to conserve their morphological integrity, are often highly modified in their interior spaces, in their finishings, and in their decorative apparatus – elements in some cases integral to the design and its architectural quality. These buildings were, with very few exceptions, long considered mere containers of utility, and were experienced, managed, and often mistreated as such.

Part of the responsibility for this *modus operandi* may be laid upon the lack of a culture of "of the 'design for the existing building. The historization of these buildings, conceived as a manifesto of modernization of a country and of its service structures, has made it possible to open up a new line of intervention that, although more aware, has yet to fully mature. Although this kind of highly conservative attitude ends up demeaning the original spirit of the design, on the other hand, in certain contexts, it was deemed indispensable for preserving the architectural image strongly characterized by the technologies originally used.

There are more and more design opportunities appropriately reconciling preservation of the historic urban image, operative refurbishment, and deep renovation; these require a design investment in which functional and technological innovation uphold the architectural image. This is the case with the successful example of refurbishment underway of the Jussieu Campus in Paris, a project that has involved various design groups and the commissioning parties in a complex operation of environmental restoration, recladding, and functional reorganization of the city's main urban campus. These interventions, of importance for the size and quality of the operators involved, present opportunities for experimentation on an issue still far from being systematized. Knowledge of this heritage, organized by building type, intended use, and construction technologies employed, is still very much in flux, and lacks sound, aggregated data.

2.2 The energy efficiency in the modern tertiary sector

The fragmentary nature of the state of the art is due in part to the extreme compartmentalization of the types of ownership, and of the enormous difference of management models between the public tertiary sector and the private one which – in addition to being broken down by the function housed there – is often marked by a clear separation between the building's ownership, management, and end user. The characterization of the heritage is among the reasons why, in spite of strong EU urging, systematized data on the refurbishment of tertiary architecture are still lacking on both the national and European levels, except for forecast estimates of impact on the potential of the sector's energy efficiency efforts in the medium term; at the moment, this appears to be the only potential lever for promoting a systematization of studies on the issue.

The open debate on energy efficiency in the traditional tertiary and high-tech sector has developed since the 1990s, but without conducting an effective strategy for intervention and for the technological and energy conversion of heritage. The difficulty of classifying the common traits of the building stock to be analyzed translates into a low capacity for action, due also to the dearth of effective guidelines in support of design for existing architecture.

The tertiarization of the productive system, and the consequent building transformations inattentive to the rational use of the building resource that have occurred in recent decades, has impoverished the quality of the state of the heritage, and has resulted in steadily growing consumption, from 1990 to the present time, in the tertiary sector – the only sector that, from 1990 to 2012, saw a +105% increase. This is a discouraging rise when compared to the national objective for 2020, which, with the final energy savings achieved in 2011-2013, was only 5.6%

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

accomplished, against 35.2% in the residential sector and 26.6% for industry.Taken together, these factors have brought about the depreciation of certain segments of the existing assets, a factor apparently believed connected with the current economic situation, but actually closely linked to the buildings' state of technological inefficiency. In this heritage of 0.7 million buildings, equal to 3.4 million real estate units for an area covering 0.85 billion square metres, that is being converted at excessively slow and poorly structured rates, the only consumption-reducing dynamics came with the diminished production owing to the continuing economic stagnation in recent years. Since 2013, consumption trends have actually seen a slight reversal in the tertiary sector as well, due in part to the sector's lower productivity, and in part to the effects of the first refurbishments that have been completed, especially on education buildings.

In particular, the national heritage for management facilities, equal to approximately 88.09 million square metres, has an estimated specific consumption of 114 kWh/m^2 - an excessively high figure in line with or outstripping the consumption levels of other sectors of the heritage on which more structured and incisive action has been taken, as in the case of residential and school heritage.

Supported by European funds and by Por-Fesr 2014-2020 operative programmes, incentivize instruments for energy management and renovation have multiplied. These include Legislative Decree n°.102/2014, implementing Directive 2012/27/EU which introduces a programme to improve the energy performance of public bodies' buildings and the obligation for large enterprises to adopt energy diagnosis, in accordance with criteria of quality and reliability, and energy flow monitoring systems. The adoption of monitoring systems makes it possible to establish a highly realistic and precise baseline and breakdown of business energy, with the aim of maximizing the effectiveness of refurbishments. However, these instruments cannot depend on a widespread know-how of comfort to the end users, who still perceive the interventions to be implemented as too complex and ineffective in terms of return on investment.

Regulatory constraint is essential in a technical and decision-making setting that has yet to be sufficiently informed and attentive, both for the public sector tasked with the role of being a model and promoter of best practises in managing its heritage, and for the private sector that labours to find attractiveness in investments outside its own core business – even when these investments bring considerable profits derived from savings on energy bills and from the higher quality of the workplaces.

Beyond the instruments of regulatory guidance on the tertiary sector, the adoption of certain virtuous behaviours like ECMs (Energy Conservation Measures), which spread in the United States starting in the early 2000s, helps raise awareness, among technicians, operators and end users, of the need to govern technological transformations, technical devices, and use behaviours.

Adopting ECMs in the tertiary sector requires guidance strategies based on the creation of extended and diversified databases – currently not available – containing the data needed to characterize buildings and their auditing, and to define "falling rule lists"; these are guidelines, with decreasing likelihood of the investment being effective, that make it possible – also with expeditious auditing activities – to define cost-benefit analyses and unquantifiable impacts, such as the transformation of buildings in an established or modern but highly characterized historical environment. To form this database, it is essential to identify some highly significant pilot cases; studying these buildings is indispensable for the integrated investigation of this portion of heritage.

The management facility type discussed here is specific to Italy: a building block, of medium or high density, often included in the fabric of post-Unification nineteenth-century expansion, almost fully occupying the perimeter of the city block in the fabric it stands on, and in some cases also replicating the proportions of the buildings it has replaced. The fabric of the established historic periphery has grown denser; this periphery is now absorbed by the modern, expanding city where low-density settlement, characterized by the stately villa or the small collective home, is transformed into management, administrative, or commercial architecture, generally occupied by a single activity. This type, highly widespread throughout Italy, is unpopular elsewhere in Europe where, especially in the metropolitan areas, tall buildings prevail, with greater construction densities and greater concentrations of activities different from one another; here, the owner and the end user of the spaces do not coincide, except in the case of public or institutional management architecture.

3. CASE STUDIES IN ROME'S SAPIENZA UNIVERSITY CAMPUS

3.1 The significance of Sapienza University as case study

The research that has been carried out, a portion of whose results are reported, aim precisely at modelling the pilot cases of use for the parametrization of the analyses and of the expected results, and regarded the initial examination of the building heritage of Rome's Sapienza University, from its monumental historic nucleus (1932-35) to the most recent buildings. Aimed at establishing the modes of intervention on prized tertiary heritage designed for education and research, the study made it possible to codify an investigation methodology, integrated from the standpoint of technology, structure, and plant, that might be replicable on other building stocks.

Sapienza University's heritage proved to be a rich sample, given its complexity and technical/constructive quality, with outstanding potential for renovated function and performance (especially in its historic part, where the envelope's construction technologies have been shown to possess relatively good physical/technical and durability performance), and with excellent possibilities for performance implementation by means of minimally invasive interventions. The results on the buildings constructed starting in the 1960s are of a wholly different kind. In these buildings, the performance response, especially of the envelope components and the plant systems, proved to be no longer in line with the use requirements of the housed functions – all the less given the offered performance specifications, which are quite distant from current performance standards in terms of acoustic and visual-attentional comfort, and energy requirements.

3.2 Simulation of deep renovation in two campus buildings

The case of the pharmaceutical chemistry building built from 1962 to 1966 is representative in terms of technology and performance, and was able, through dynamic energy modelling, to identify margins for improvement. The design simulation of synergic interventions on the envelope/plant system (performance improvement of the envelope, a complete reconceiving of the solar shading system, installation of systems to control environmental parameters, multisplit climatization system and the introduction of renewables) brought about a 78% reduction in the energy performance index in terms of kWh/m^3 year (from 68 kWh/m^3 year to 10.5 kWh/m^3 year), and a 40% decline in climate-changing emissions.

Another case study was analyzed within the same university district, with the aim of studying the consumption profile and to identify priorities for action for a building made with bearing walls and restricted by much more stringent requirements for the protection and preservation. The pilot-building is the Mathematics building, one of the most representative for his architectural features, designed by architect Gio Ponti in 1935. The building was altered by the redistribution of classroom, changing his original distribution and character. This pilot project, therefore, has, more than others, complex possibility of renovation, where the technology and energy retrofit must be integrated with conscientious actions, ensuring the functionality and the historical memory of the building.

The envelope is made of bearing walls with no insulation and the windows, in most cases, is the original ones of 1939.The blueprint is design around a big court has the advantage of more natural lighting and good ventilation in the rooms, but also a greater dispersion surface. Bearing walls allow the minimization of thermal bridges, focusing dispersions in the large windows. The average U-value (thermal transmission value) of the external vertical walls was calculated to be about 1.5 W / m^{2}K. The particularity of the building and the potential of the renovation have led to a dual simulation in two different calculating methods: steady state mode and dynamic mode. The first one brings as a result the overall energy requirement of 653 MWh, a carbon footprint of 189 tCO_2/year and an energy performance index of about 50 kWh/m^{3}year. The winter performance, despite the contained presence of thermal bridges, is therefore absolutely insufficient. Using dynamic simulation, however, the research reveals a best summer performance, due to the high thermal inertia of the walls and the floor plan configuration. A smart retrofit strategies for plant system maybe to include this building with all near buildings in an energy district, replacing the generator with radically different technologies, such as cogeneration, which, however, requires an high investment, even for maintenance and management. This action can bring an environmental benefit of 23%.

The high quality design criteria adopted and the high cost of actions on envelope (internal cladding, replacement of windows) lead to have an high payback time (27 years) for an integrated renovation of building-plant system, but still low compared to the reference range of envelope retrofit (about 40 years). This is a consequence of large transparent surfaces, which means an excessive loss in winter and an overheating in summer. Therefore, despite to the high replacing cost, improve window efficiency results in significant savings on heating and air conditioning.

The studies that were done have made it possible to codify an intervention procedure, later tested on groups of buildings deemed exemplary by type, size, and period of construction, with analyses concentrating on post-1945 buildings. The analyses and simulations led to determining the need to perform a deep renovation of the envelope components and of the interior comfort management system, not so much because of the non-optimal conditions of building maintenance, but because of the current requirement frameworks' incompatibility with the design frameworks.

It was found that even when the envelope components still had fair residual performance, the conditions of use of the spaces, and of managing the work for the users' safety, were no longer compatible with the building's original performance. These buildings – originally places of technological, typological, and construction experimentation efforts that were ahead of their time – have not withstood the test of time and of a use that was often ill-advised. The poor use of the envelope components or of some environmental control devices, like mobile shading, differentiated window systems, or natural ventilation devices, has impaired the geometric stability and the seal of the envelope components, negatively impacting the efficiency of the building/plant system. Maintenance interventions implemented without monitoring or technical oversight have further aggravated the general picture of obsolescence of the building's performance system, and has even deprived it of its overall morphological quality.

4. CONCLUSIONS

In the city of Rome, the buildings selected by type, placement, era of construction, and current use, that had characteristics akin to the model described earlier, were analyzed from the historical standpoint, in order to identify the salient traits of architecture and construction to be restored or redeemed; for these buildings, the current use model was reconstructed, along with the events connected with the evolution of the activity contained within them. All the verifications of consistency of the building's active and passive requirements in terms of safety, structural performance, and environmental comfort were made, and its consumption and energy loads were modelled. From this perspective, the building's energy and functional renovation was considered the main driver to trigger an integrated refurbishment of the building, using the parameter of the building/plant system's efficiency as the potential activator of an architectural renovation that would otherwise not be economically affordable.

The results of the research proposed in this paper aim to lead to the construction of a replicable methodology for the preliminary analysis and evaluations useful for deep renovation of tertiary building heritage. During the various steps of the study, numerous selected pilot cases throughout the country were selected, addressed in part to validate theoretical assumptions of research, and in part to check actual strategies of integrated refurbishment, in progress or already concluded, of buildings mainly used for directional, educational and research activities. The modelling work of the "pilot buildings" is still in progress, in order to consolidate the soundness of the sample and validate the results from the first cycle of obtained financing.

ABSTRACT

There is an extensive need for renovation in the existing housing stock and an increased rate of renovation activities is necessary not only to meet international climate and energy targets, but also in order to ensure buildings functions, technical qualities and to provide a good living environment. Thus, the challenges for the housing companies is to meet and balance all the different needs. Research focus on the development of decision support tools and expansion of the renovation discussion from not only a technical issue but also to include a social perspective. But how do housing companies manage renovation activities in a broader perspective and what are the related future challenges in renovation and transformation of building stocks? The aim of this study to investigate how larger housing companies act in renovation projects and to identify perceived challenges in relation to renovation. A questionnaire survey directed to the Swedish housing sector has been carried out including all housing companies with more than 20 employees. Out of 198 companies, 76 companies responded, which corresponds to a response rate of 38 percent. Results show that even if companies have environmental and energy goals or policies, only minor energy efficiency measurements are carried out in renovation projects. Social aspects are increasingly addressed both in policy and renovation. The largest challenges are economy and a limitation of the rent increases in order to ensure that the residents can remain in the apartment or in the housing area after renovation, i.e. to find appropriate rent levels. With a starting point in Swedish conditions, the results are of interest for the transformation process of the European housing stock.

Keywords: housing companies, renovation, questionnaire survey

1. INTRODUCTION

There is an extensive need for renovation in the existing housing stock and an increased rate of renovation activities is encouraged to meet international climate and energy targets (e.g. EU, 2010, EC, 2002), but is also a necessity in order to ensure buildings functions, technical qualities and to provide a good living environment. The challenges for the housing companies is to meet and balance all the different needs. Research focus on development of decision support tools, study of renovation strategies and expansion of the renovation discussion from not only a technical issue but also, for example, a social perspective often applied in specific cases (e.g. Lind et al., 2016, Taillandier et al., 2016, Malmgren and Mjörnell, 2015, Thuvander et al. 2012). But how do housing companies manage renovation activities in a broader perspective and what are the related future challenges in renovation and transformation of building stocks? What are the challenges in relation to different aspects such as technical, environmental, economic, social, and heritage/ architectural values? Most of the empirical research on renovation is based on case studies or interviews which gives in depth-knowledge. Less is known about the general renovation activities in the housing sector. The aim of this paper to investigate how larger housing companies act in renovation projects and to identify perceived challenges in relation to renovation.

2. THE RENOVATION BAROMETER

A questionnaire survey directed to the Swedish housing sector has been carried out in 2015. The survey, called Renovation barometer, covers renovation actions as experienced year 2014 but takes into account a time span ten years back in time.

2.1 Data collection and preparation of questionnaires

The survey includes all housing companies with more than 20 employees owning and managing rental apartments. The questionnaire comprised in total 32 questions (q) within eight sections with addressing the following topics: general information about the companies' portfolio (5q), the companies' renovation activities in general (5q),

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

investigations carried out before a renovation (1q), renovation measures (7q), policy and strategies (5q), follow-up of renovations (1q), need for knowledge and development (5q), and company facts (4q). When relevant, the questions take up technical, environmental, economic, social, heritage/ architectural aspects of renovation. The questions measured the opinion of the respondents by using a Likert scale with a three- to five-point range, a binary scale only allowing yes/ no answers, and questions concerning more general and descriptive information. The questionnaire was pretested on three researches and two housing companies.

Initially, a web-bases questionnaire was sent out to the CEO or property development manager of the company. Because of a very low response rate and difficulties to reach the adequate respondent, also a paper version of the questionnaire was sent out by mail followed up by one reminder. In order to increase the response rate, researchers contacted some of the companies personally. The reasons why some respondents failed to respond were also investigated.

2.2 Data analysis

Data were compiled and stored in a database using the online software SurveyMonkey. The respondents answering the digital version entered data directly into the database. The data from the paper version were entered manually. From there, the data were exported and analysed by using the statistical data program Statistical Package for the Social Sciences (SPSS).

In a survey that aims to assess peoples' attitudes and values there is always a risk that the respondent gives answers that reflect how it ought to be rather than how it is in order to appear good. Possible bias from this should therefore be considered when interpreting the results.

2.3 Responses and respondents

Out of 198 companies, 76 companies responded, which corresponds to a response rate of 38%. Most of the respondents manage municipally owned rental apartments (80%), only a minor share of the respondents manage privately owned rental apartments (13%) or other types of rental tenure (7%).

3. RESULTS

3.1 Upcoming renovation needs and investments

During the last 5 - 10 years, a majority of the housing managers focused on renovation of the stock constructed during the period 1941 to 1960. Not surprisingly, the coming 5 - 10 years the focus will be on the stock constructed 1961 to 1980. The amount of money the companies spent on maintenance and/or renovation was about 19 €/sqm (183 kr/m^2) per year (for 2013, before a national change of accounting system was introduced).

3.2 Technical renovation measures

The most frequent renovation measures the companies usually carry out ('always' or 'often') are adjustments of the heating system (85%) and ventilation system (82%) followed by exchange of pipes and lightings. Measures taken with impact on the climate shell of the building are foremost exchange of the roof covering (59%), exchange of windows (56%), and additional insulation of the attic (53%). Additional insulation of facades is one of the least frequent measures carried out. Only 11 percent of the respondents state that this measure is carried out 'always' or 'often'. Among the measures performed 'seldom' or 'never', we find attic extensions, redistribution of apartments sizes, installation of elevator, and adding of balconies or entrances. Figure 1 shows all renovation measures related to the climate shell, common spaces (laundries, staircases), appliances and installations but also measures that have impact on the distribution of areas such as installation of elevator or addition of attic. Interventions in the apartments are not included.

Factors that usually are prioritized in connection with a renovation are costs in the first place (more than 95 % prioritize 'always' or 'often') followed tightly by energy efficiency measures in the second place (more than 90 %). Less than 50 percent prioritize larger interventions and least prioritized is attractive architecture.

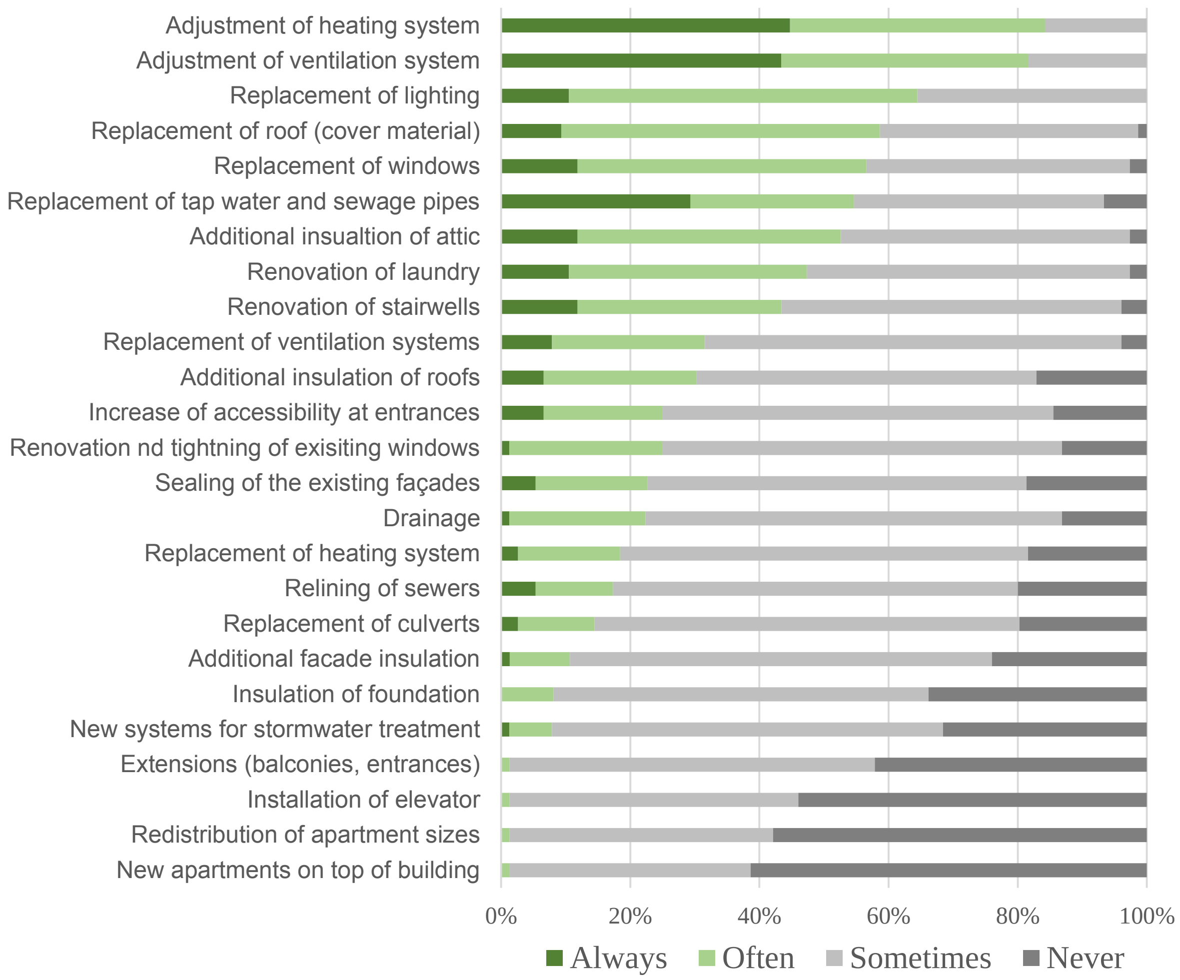

Figure 1: Technical measures that companies usually carry out in renovation. Interventions in the apartments are not included

3.3 Renovation policies and goals

The companies have a broad repertoire regarding different types of policy or goal for renovations (Figure 2). More than 70 percent of the companies have policies or goals for economic aspects, the procurement process, energy use, residents' influence, and choice of materials. Only a small share of the companies, slightly more than 30 percent, have a policy considering heritage values.

When having a look at the difficulties to achieve the goals, economic aspects can be found on the top (Figure 3). More than 60 % of the respondents consider that goals regarding reasonable rent increase and costs in general are difficult to achieve to a 'very high degree' or 'high degree'. Also, to fulfil accessibility goals is a large challenge. Up to 23 % of the companies perceive difficulties to meet the target settings for energy use. Less than 10 % perceive that the selection of materials is a larger problem in terms of meeting targets.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

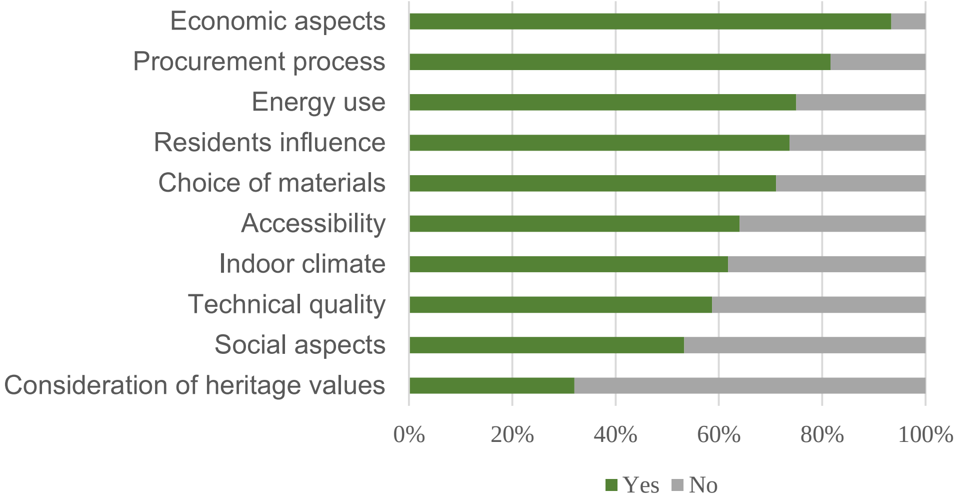

Figure 2: Companies' specific policy or goals for renovation

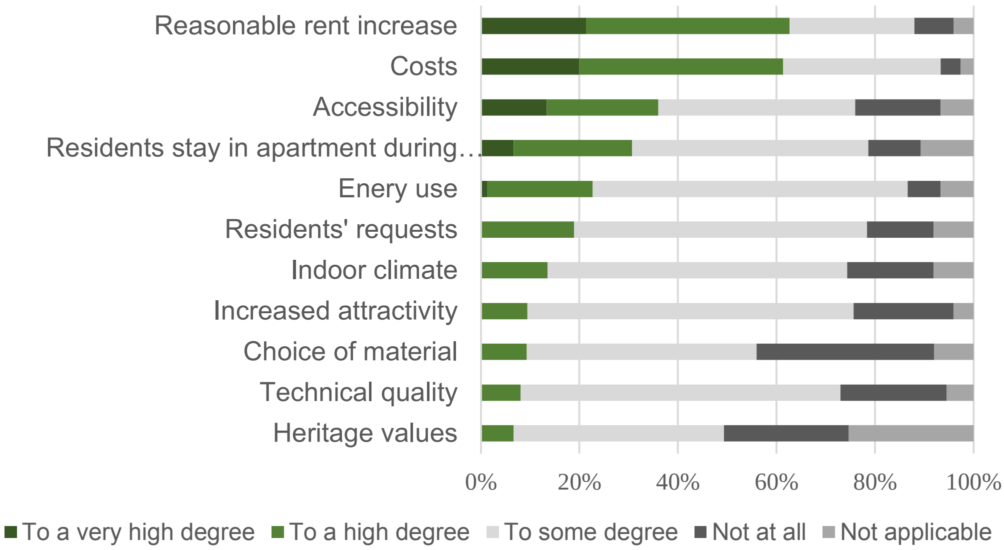

Figure 3: Difficulties to achieve different kind of goals as perceived by the companies

3.4 Need for technical development, knowledge and support

When asking for technical development in the building sector, the respondents state that there is a need for development of renewable energy systems (50%), passive house technology for renovation projects as well as ventilation- and installations systems (both 44%). About one third of the companies see a need for development of measurement and feedback systems to the operation staff, systems that support accessibility and integration of elevators in existing buildings, façade systems, and measurement systems with feedback to the residents. There seem to be good technical solutions for windows, balconies, and roof systems. About 40% of the companies agree on that there is a knowledge need on incentives for behavioral changes and the operation and maintenance of energy efficient buildings. Only 8% see a need for knowledge on heritage aspects and about 23% state that no knowledge is needed on that topic. Regarding different actors need for knowledge or education, the respondents consider the companies' board members having the greatest needs. When it comes to other types of supporting structures such as subsidies, models, contract forms, or decision support tools, almost 37% of the companies agree on a need for subsidies. At the same time, 26% of the companies states that there is no need for subsidies. Subsidies have a top position, both the companies that ask for subsidies and those who do not see a need for subsidies.

3.5 Challenges as perceived by the companies

When the companies were asked to state the three biggest challenges that they face, it was economics, rents, the ability for residents to be able to remain in the apartment after renovation, and profitability over time that was mentioned most (Figure 4a). The statements of the second biggest perceived challenges resulted in a more scattered picture (Figure 4b). Energy, social aspects such as dialogue with the residents, and yet again economy and rents are seen as the main challenges, followed by accessibility issues as well as technical quality.

a b

Figure 4: The biggest challenges as perceived by the companies, a) Biggest challenges and b) Second biggest challenge. Illustrations produced with the online tool WordItOut.

4. FUTURE CHALLENGES FOR RENOVATION

In the coming years, renovation activities will take place in the housing stock from the 1960 - 80s but also continue in the slightly older stock, constructed after the WWII.

4.1 Economy: The predominant challenge in renovations

Economy was found to be the most important factor, but also the most challenging part. Costs have the highest priority in a renovation process as well as the possibility for the residents to stay in the apartment during a renovation, something which is advantageous not only from the residents' perspective but also from an economic perspective. Only less than half of the companies prioritize larger interventions, i.e. packages of renovation measures, which is interesting as companies in other contexts often highlight the importance to co-ordinate different measures to larger packages in order to avoid to disturb the residents too often. When it comes to goal fulfilment, economic aspects are also seen as the most difficult ones, including both reasonable rent increase and renovation costs. Support: subsidies both need for (37%) and no need for (26%). The companies see economy by far as the most dominating future challenges in the renovation debate.

4.2 Energy: One of the largest challenges

Energy use and energy efficiency measures are important questions. Energy efficiency measures have the second highest priority (after costs) in renovations, and more than 70 % of the companies have an energy policy or energy targets. The majority do not perceive difficulties to achieve energy-related goals and almost all companies monitor the energy use after renovation. Regarding energy related measures usually carried out in renovations, mainly minor improvements can be found among the most frequent measures: adjustment of different systems, exchange of lighting, insulation of attic or exchange of windows. These measures are relatively simple to implement. More cost-intensive, non-standard increasing measure, or challenging energy efficiency measures from a technical and/or architectural point of view such as additional insulation of facades is only carried out to a lesser extent despite that there might be large energy saving potentials. The companies also see a need for development around energy issues and would like to see, among others, technical development of renewable energy systems and passive house technology, as well as operation and maintenance of energy efficient buildings. In summary, the companies have good control on energy issues but the energy saving potential is not fully utilized in renovation projects. The companies are aware of that which is expressed in the statement where energy issues are pointed out as one of the biggest challenges.

4.3 Architectural and heritage aspects: Left out in renovations

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Little attention is payed to architectural and heritage aspects and they are not perceived as a challenge by the responding companies. They are either not prioritized or only considered to a little extend. Architectural and heritage aspects are difficult to define and therefore easy to "forget" in the complexity of a renovation process. At the same time, the existing architecture, foremost the facades, has impact on renovation solutions and identity creating effects for the residents and the housing area. Awareness and a more active stance to architecture and heritage values could contribute to better balance of attractive housing and lead to demand and development of well-adapted energy efficient façade solutions. This could be a self-interest of the housing owner. Should it be a challenge? Maybe a challenge also to be addressed more clearly on a national perspective?

5. CONCLUSION

This paper has investigated how larger housing companies in Sweden act in renovation projects and identified challenges. Results show that even if companies have environmental and energy goals or policies, only minor energy efficiency measures are carried out in renovation projects. Social aspects are increasingly addressed both in policy and renovation. The largest challenges are economy and a limitation of the rent increases in order to ensure that the residents can remain in the apartment or housing area after renovation, i.e. to find appropriate rent levels. Economy and costs are dominant challenges in all phases of renovation. The discussion on how to finance renovation projects in order to keep a good technical standard of the buildings, a good indoor climate and housing environment, and at the same time to improve the energy performance of buildings still remains. The fragmented picture whether there is a need for subsidies or not is just one more illustrative example. Architectural and heritage values are not considered as a challenge by the housing managers despite that they have impact on technical solutions, indoor environment and social aspects. The results of the study represent challenges of Swedish housing companies, however, as there are similarities in the composition of the housing stock in other European countries and common goals to fight climate change, deeper knowledge of the Swedish challenges in renovation might contribute to a better understanding of the potentials and barriers for a successful transformation of the European housing stock.

ACKNOWLEGDEMENTS

The research has been financed by the within the framework of the strong research environment SIRen and the Formas-BIC project 244-2010-252.

ABSTRACT

The building sector represents nowadays a key field to achieve the sustainable development goals. In particular, the implementation of energy efficiency measures (EEMs) in existing buildings has been recently acknowledged as very significant to improve their energy performance, as well as to preserve the environment and reduce resource depletion. Building energy renovation projects can also constitute a new source of business for the actors involved in the whole process, including service providers, building owners, and financing companies. Therefore, the adoption of both EEMs and innovative business models (BMs) can foster the achievement of sustainability within the building field. Nonetheless, there is still limited research on how to integrate sustainability analyses into BMs of energy renovation projects for achieving meaningful sustainable BMs (SBMs).

This paper first illustrates state-of-the-art and research gaps in the field of BMs for the energy renovation of existing buildings. Then, it presents the application of an analytic approach aiming to integrate quantitative sustainability analyses into BMs for such projects. The case study examined is a deep energy renovation project of a single-family house, which is part of a Norwegian research project. Some specific performance indicators, such as climate change, energy use, and global cost, are computed for the case study. The findings of this paper can represent the first steps towards a possible operationalization of sustainable business in energy renovation projects, as a blueprint for delivering sustainability.

Keywords: sustainability, building sector, energy renovation, business models

1. INTRODUCTION

Nowadays, buildings are responsible for about 40% of the total energy demand in Europe (Buildings Performance Institute Europe , 2011). Accordingly, the implementation of energy efficiency measures (EEMs) in existing buildings can play a fundamental role in decreasing the environmental impacts of the construction sector. Such measures can also lead to economic and social benefits, e.g., lower energy and maintenance costs, new job opportunities, and higher indoor wellbeing (Xu, et al., 2011; Li, et al., 2013). Moreover, energy renovation projects might represent an important source of business, by involving different actors in addition to building owners, such as service suppliers and financing providers.

In recent years, several academics and practitioners have focused on the definition of business model (BM), but there is still disagreement on what a BM is.

In (Osterwalder, et al., 2005), BM is conceptualized by nine main blocks: 1) Value proposition, 2) Target costumer, 3) Distribution channels, 4) Relationship, 5) Value configuration, 6) Core competency, 7) Partner network, 8) Cost structure, 9) Revenue models. In (Richardson, 2008), the BM concept is organized around the value notion, i.e., the value proposition, the value creation, and the value capture.

Bearing in mind such common definitions of BM (Osterwalder, et al., 2005; Richardson, 2008), it can be stated that the main value proposition in building energy renovation projects is the provision of renovation works, along with a possible reduction of future energy/operating costs.

In this research work, the level of analysis focuses on BMs of energy renovation projects, meaning how such projects propose, create, and capture value, in a triple bottom line perspective and for the whole network of stakeholders.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Presently, the state-of-the-art of business models (BMs) in building projects is still limited (Abuzeinab & Arif, 2014; Pan & Goodier, 2012). An examination of possible BMs for projects of deep energy renovation is shown in (Moschetti & Brattebø, 2016). Here, such BMs are described and categorized with reference to the way of implementing renovation actions and to the drivers for the adoption of these measures.

Although current research focuses on BM changes to matching the shift towards sustainable buildings, further studies are needed. In fact, the innovation of BMs can represent a meaningful approach to boosting the adoption of EEMs in the built environment (de T'Serclaes & Devernois, 2008). In particular, among the research gaps characterizing BMs for building energy renovation, there is a lack of integration of sustainability analyses into the decision and business context. Hence, the issue of defining the best way to make use of quantitative information, deriving from sustainability analytic tools, within qualitative investigations, which are common in BMs (Bocken, et al., 2013). Furthermore, overall analyses on sustainability for energy renovation projects are meaningful for shifting current BMs to sustainable BMs (SBMs). To this aim, environmental, economic, and social criteria should be included in sustainability evaluation, with reference to the triple bottom line approach. Nonetheless, sustainability analyses fragmented and focused on specific sustainability-related aspects represent the current practice (Passer, et al., 2016; Cetiner & Edis, 2014).

This paper aims at contributing to the innovation of the BM concept towards a green shift within the energy renovation context, by means of sustainability performance analyses. To this scope, a case study is analyzed in detail, by quantifying specific sustainability criteria. Moreover, recommendations are provided for a future further development and employment of the proposed approach.

In section 2, the methodological approach followed in this article is presented and the case study is described, together with the analyses performed. In section 3, the obtained results are shown and discussed. In section 4, conclusions are drawn up, with suggestions on possible future research outlook.

2. METHODOLOGY

The research questions addressed in this article are the following:

How can the sustainability level of an energy renovation project be defined? How can quantitative sustainability results be integrated into BMs for such projects?

The analytic approach followed in this paper was already presented, in its embryonic form, in a previous article (Moschetti & Brattebø, 2016). Moreover, such approach was fully developed within another article submitted to a special issue of Journal of Cleaner Production (Dentchev, Nikolay et al., 2016).

Essential stages of the adopted approach include the detailed examination of a case study, the identification of EEM scenarios, and the involvement of the stakeholders in the choice of meaningful sustainability criteria to be assessed in these scenarios. The main aim is to provide a possible way to make use of quantitative sustainability analyses for sustainable business modeling in building energy renovation projects, as a blueprint to delivering future sustainability.

2.1 Case study

The case study analyzed in this paper is a deep energy renovation project of a single-family house, which is part of a Norwegian research project, SEOPP (Systematisk EnergiOPPgradering av småhus fra 1960, 2013-2016). This project was developed between 2013 and 2016, with the objective of defining methods and solutions for the systematic energy renovation of houses built in the period 1960-1990. SEOPP included two demonstration houses, located in Oslo and Bergen. In this research work, the house in Oslo (Figure 1) was chosen for the implementation of part of the proposed analytic approach.

The analyzed house is a three-floor house, including a basement, with a gross internal floor area of 176.7 m^2. The house has a timber frame structure and an average envelope thermal transmittance of 0.24 W/(m^2K), after the implemented EEMs.

The house renovation included: a new internal layout; the addition of further insulation in walls, roof, and basement floor; new triple pane windows; new efficient external doors; the addition of a mechanical ventilation system with heat recovery; and a new wood stove.

Figure 1: A rendering of the single-family house analyzed, as planned after the renovation works

2.2 Business context analysis

The value proposed by the BM of the analyzed case study regarded the deep energy renovation of the house, together with a likely future reduction of energy/operating costs and a general enhancement of the house functionality.

Furthermore, the case study provided the implementation of different measures through several service providers and economic incentives from a governmental enterprise.

The actors involved in this project were several, including a research institute, SINTEF Building and Infrastructure, the Norwegian housing bank, a Norwegian government enterprise, the Norwegian Water Resources and Energy Directorate, an energy consulting company, an architecture firm, and numerous material suppliers.

The network of actors was asked to fill out a questionnaire, inclusive of different questions regarding, e.g., their role in the project, their knowledge about sustainability tools and business models, and their preference about remarkable criteria to evaluate the overall sustainability level of the project.

Based on the highest rated sustainability criteria, the performance indicators computed are: climate change (CC), non-renewable primary energy (NRPE), and global cost.

2.3 Performed sustainability analyses

Adequate analyses were performed to compute the above mentioned performance indicators for the case study.

CC and NRPE were assessed through the life cycle assessment (LCA) methodology, as defined in ISO 14040 (International Organization for Standardization, 2006). Specifically, material impacts were assessed by combining data from Environmental Product Declarations (EPDs) and Ecoinvent 3.0.1 database (Ecoinvent Centre, 2013). The latter was also used for modeling energy carriers and processes and was run in SimaPro 8.1.1 software (Pre Sustainability, 2016). Two impact methods were used to compute the chosen indicators: the cumulative energy demand (CED) method for NRPE and the Recipe method for CC.

The following life cycle phases were considered: pre-use phase, including the materials' production and transport to the construction site; use phase, including electricity and wood for heating, domestic hot water (DHW), lighting, and electric appliances, together with the maintenance activities; end-of-life phase, referring to the waste final handling. The building life span after the renovation works was assumed to be of 50 years.

With respect to the pre-use phase, the total amounts of materials constituting the building envelope and technical building systems, together with main distances from the production places to the construction site, were collected based on the project documentation.

Regarding the use phase, the annual energy demand for heating was estimated by means of a dynamic energy simulation tool, IDA-ICE (EQUA Simulation AB, 2016). Moreover, data on the energy use for indoor lighting, electric appliances, and DHW were derived from the Norwegian standard NS 3031:2014. This standard was also used for the definition of various parameters needed for the energy simulation, such as air leakage, internal gains, and building occupation time. The International Weather for Energy Calculation 2.0 (IWEC2) database by ASHRAE was used as the source for hourly weather data of Oslo. Electric heaters located in all the rooms and an air-to-air heat pump placed in the living room represented the main heating systems. Furthermore, a wood stove was assumed to provide 20% of the energy demand for heating purposes.

The annual values of delivered energy were adapted to the building life span (50 years) and associated to eco-profiles available in Ecoinvent database. Furthermore, some maintenance actions were hypothesized, such as repainting external walls every 8 years; repainting internal walls and ceilings every 15 years, substituting windows and external doors after 30 years; replacing of roof covering every 30 years; replacing electric heaters after 20 years; and substituting heating floor and ventilation system after 25 years.

Regarding the end-of-life phase, information was already available for materials with EPDs, while for the other materials some assumptions were made. Specifically, materials like steel, aluminum, iron, and polyethylene were assumed to be recycled for the 80% of their amounts, while the remainder was assumed to be disposed in a municipal landfill. Wood was assumed to be treated in an incineration plant, while other materials, such as concrete, glass, ceramic, and copper, were supposed to be entirely landfilled.

The global cost was assessed according to EN 15459:2007 (European Committee for Standardization, 2007), through a life cycle costing (LCC) analysis. Specifically, the global cost was evaluated by summing up the investment and annual costs (including running costs and periodic replacement costs) and subtracting the final value of the building components. Both the annual costs and final values were actualized to the calculation year, by means of a real interest rate of 4%.

The investment costs, including the expenses for building materials, plants, and renovation works, were assessed through the available project documents, together with the Norwegian Price Book for the lacking data. The replacement costs were evaluated according to the substitution rate of building components, over the whole life cycle. Instead, the maintenance costs for technical building systems were calculated as a percentage of their initial cost, as in EN 15459:2007. The costs of electricity (0.91 NOK/kWh) and wood (0.65 NOK/kWh) were estimated by means of available statistical prices.

All the costs were considered with the value-added tax (VAT) included.

3. RESULTS AND DISCUSSION

The results for NRPE and CC are shown Table 1, normalized by the gross internal floor area. The use phase for both indicators is dominant among all life stages. This follows the trend in building energy renovation projects, where heating-related impacts lead the whole life cycle. Specifically, the annual delivered energy was 99.7 kWh/m^2, split in: 31.2 kWh/m^2 for heating, 8.2 kWh/m^2 for HVAC auxiliaries, 31.4 kWh/m^2 for DHW, 11.4 kWh/m^2 for lighting, and 17.5 kWh/m^2 for electric appliances.

For the NRPE results, the contribution of the pre-use, use, and end of life phases is within the following ranges: 6%, 94%, and -0.5%.

For the CC results, the pre-use, use, and end of life phases contribute within the following ranges: 10%, 84%, and 6%.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Note that the maintenance actions, inclusive of material production, transport, and cutting waste, are considered within the use phase, where they contribute with 10% for CC and 5% for NRPE.

	Pre-use phase	Use phase	End-of-life phase	Total
Climate change (kg CO_2 eq./m^2)	104.8	894.6	64.3	1063.8
Non-renewable primary energy (MJ/m^2)	1583.7	24010.7	-123.2	25473.7

Table 1: Climate change (kg CO_2 eq./m^2) and non-renewable primary energy (MJ/m^2) in all the building life phases

The results for the global cost are shown in Table 2, where they are normalized by the gross internal floor area. As shown, the investment costs provide the highest contribution to the global cost, around 78%, while replacement, maintenance, and energy costs contribute with 9%, 3%, and 10%, respectively.

It should be mentioned that the investment costs were reduced by the economic support from Enova, a Norwegian energy enterprise, which consisted of around 5% of the expenses for envelope upgrading and balanced ventilation system installation.

Investment costs (NOK/m^2)	Replacement costs (NOK/m^2)	Maintenance costs (NOK/m^2)	Energy costs (NOK/m^2)	Global Cost (NOK/m^2)
14977.0	1798.9	588.5	1892.9	19257.3

Table 2: Main cost categories over the building life phases, actualized to the calculation year

The results of the computed indicators were grouped together and shown in a radar chart, as in Figure 2. A normalized scale factor was defined for each indicator so that they can all be displayed on the same scale, where 0 is the best level and 8 is the worst one.

The objective is to build such graphs for other possible EEM scenarios for the project and to compare them with respect to their overall sustainability level. Indeed, the radar charts should be interpreted considering that the smaller the area of the geometric shape in the chart, the better the sustainability performance of the scenario.

Other EEM scenarios for the analyzed project could include, for instance, renewable energy technologies, such as photovoltaic and solar thermal systems, or business as usual measures.

The analysis of further performance indicators, including social ones, would allow to have a more complete picture of the overall sustainability level of the project.

The radar charts might be used during the design phase to assess the performance of possible EEM scenarios from different sustainability-related points of view. Furthermore, such examinations could be meaningful in the BM perspective to link the value proposition, creation, and capture of the project not only to the economic domain but also to the environmental and social dimensions.

An effective implementation of the proposed analytic approach towards SBMs would involve the formulation of specific constrains, such as: a minimum number of EEM scenarios to evaluate, a minimum number of sustainability criteria and performance indicators to assess, a weight for criteria/indicators, and a minimum overall sustainability level to reach. Therefore, the proposed approach should be included in a more standardized and formal framework, to be actually supportive of sustainable business modelling for energy renovation projects.

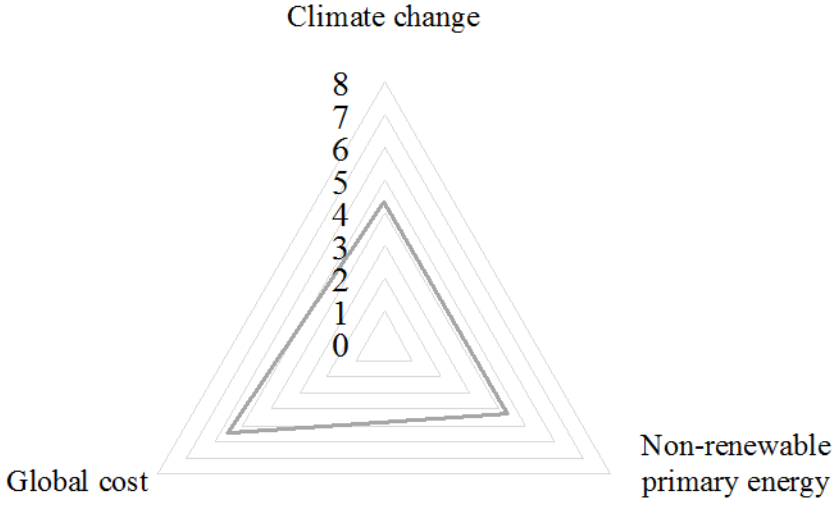

Figure 2: Radar chart including the results of different performance indicators for the case study analyzed

4. CONCLUSION

This research work addresses the lack of innovative approaches for sustainable business modeling in energy efficiency projects within the building field.

In particular, the article presents the early results from the implementation of an analytic approach in a deep energy renovation project, in order to foster BM innovation through quantitative sustainability analyses.

The proposed approach might promote discussion and awareness, among the stakeholder, on how the project could propose, create, and capture value, in a triple bottom line perspective and based on quantitative results. Moreover, such approach might serve for a wider use, e.g., incorporation into building codes for energy renovations or in government incentive programs.

The examination of a case study is meant as a valuable example for other similar projects, with the objective of a systematic integration of sustainability analyses into BMs.

Future research work might be focused on the implementation of the proposed approach in other similar projects, to develop benchmark values for the performance indicators to compute in such projects.

Furthermore, future examinations could cover also other energy efficiency projects in the building field, such as the construction of nearly zero-energy buildings (nZEB).

ABSTRACT

There were 3979 projects, totally 460 million square meters of buildings certificated green building labels by Dec 31 2015, in which only 61 projects and 3.07 million square meters were retrofitted buildings. In China, there are more than 58 billion square meters existing buildings, and the green retrofitting of existing buildings will play a more important role in reducing energy consumption and global greenhouse gas emissions. In this paper, the development of green retrofitting of existing building was summarized. The national standard "assessment standard for green retrofitting of existing building GB/T GB/T51141-2015" was issued on Dec 3 2015, the assessment method and main contents of the standard was introduced.

Keywords: green retrofit, development status, technology application

1. INTRODUTION

The construction and operation of buildings contributed to a large proportion of total energy end-use worldwide. After the reform and opening-up, urban and rural building industry developed rapidly, there have been more than 54 billion square meters existing buildings in China. And most existing buildings built before 1980s had such problems as weak disaster resistance capacity, high energy consumption, and unsatisfactory application function, due to the economic conditions of the time, design standard was relatively low. After 1980s energy saving standard be carried out, the existing buildings energy consumption had improved, but still in high carbon emission or poor environmental performance. It is unreasonable and imposable demolition and rebuild the buildings, retrofitting of existing buildings offers significant opportunities for reducing global energy consumption and greenhouse gas emissions (Zhenjun Ma et al., 2012).

Significant effort towards energy efficiency improvement or sustainable retrofitting in existing buildings had been taken by governments and international organisations at home and abroad. In 2009，US government announced a new $450 million program designed to catalyze a nationwide energy upgrade that experts estimate could save $100 million annually in utility bills for households and businesses(DOE, Buildings Energy Data Book,2010). In 2010, the UK government aimed at reducing carbon emissions by 29% by upgrading the energy efficiency of 7.0 million British homes by 2020 (Department of Energy &Climate Chang, 2010),and the International Energy Agency (IEA) launched a set of Annex projects to promote energy efficiency of existing buildings, such as: Annex 46 – Holistic assessment toolkit on energy efficient retrofit measures for government buildings; Annex 50 – Prefabricated systems for low energy renovation of residential buildings; Annex 55 – Reliability of energy efficient building retrofitting; and Annex 56–Energy and greenhouse gas optimised building renovation(IEA).

How to approach and tackle the existing buildings has great significance on the implementation of such strategies as energy saving, environment protection, establishment of a resource-efficient society and sustainable development, and therefore technical requirements for retrofitting existing buildings are need to be researched. Key phases in a sustainable building retrofit programme, key elements affecting building retrofits and main retrofit technologies were summarized shown as Figure 1.

Most retrofitted technology strategies were related to energy efficiency, Life cycle cost and payback analysis, occupied assessment (Fusion, 2010).

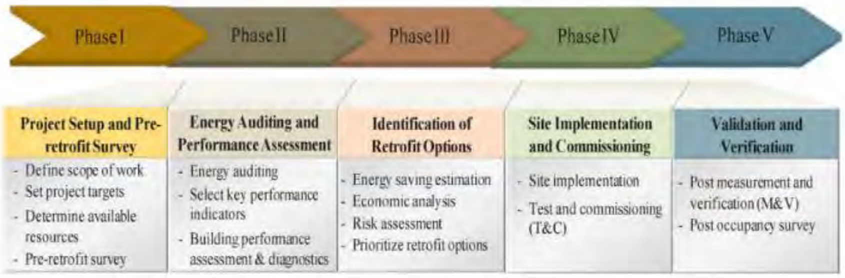

Figure 1: Key phases in a sustainable building retrofit programme (Zhenjun Ma et al.,2012)

In order to push forward scientific research of the project, the Ministry of Science and Technology and Ministry of House and Urban-Rural Development (MOHURD) approved the significant project" research and Demonstration of Key Technology of existing buildings retrofitting, to promote the retrofitting technology develop.

Compared to new buildings construction, there are more limitations for existing buildings in green retrofitting processes. The green retrofit technical application, for instance, must under corresponding evaluation. The investment, technical difficulties, environmental and social benefits factors also must be considered carefully to meet the customer and the stakeholder's demands. Du investigated people's response on building repair and retrofit, and identified the impediments of limited response in a case historical village Shangli located in disaster-prone mountainous area. The result showed that most of the local people were unsatisfied with the limited disaster resistance of their buildings. But their repair and retrofit activities were limited, 3 damaged buildings were not repaired or just partly repaired (Fei Du et al., 2016). The retrofitted work was mainly in Building Energy Efficiency Retrofit (BEER) to improve the buildings energy consumption, little work in green retrofitted buildings, because it need more efforts to reduce the resource consumption, to have a better performance and lower carbon emissions.

Li made a green retrofit survey and analysis of public institution building in Cold Region. Taking Shenyang as the main object of study, surveyed five typical public sector buildings green retrofit situation. Through the survey data analysis, it found that combined with the evaluation index system of green building, the suitable technical measures was the problem of public institutions existing in the retrofit process (Li et al., 2015). So in this paper, the development history was reviewed, and the technology researcher contents and technical measures were summarized. The first national standard "assessment standard for green retrofitting of existing building green retrofitting GB/T GB/T51141-2015" had been was laughed issued on Dec 3 2015, the assessment method and main contents of the standard were introduced. The aim of work is to provide a better understanding of existing building green retrofitting development and practice in China.

2. HISTORY AND POLICY MECHANISM

2.1 Development history

Compared to developed countries, the development process of China existing building green retrofitting had been relatively delayed. And it had experienced four different periods so far, which were the functional and reinforcement reconstruction period, the energy-saving reconstruction period, the comprehensive performance improvement period, and the green retrofitting period. In chronological order, the process was illustrated as below.

Mid of 80s, the 20th century

In this period, with the rapid development of industrialization and urbanization, big industrial enterprise had to move out of city center, many industrial buildings therefore faced function transformation and performance improvement problem. Most buildings needed to be upgraded, repaired, reconstructed or expanded (Bai, 1991). The key research issues were focused in industrial buildings' retrofitted characteristics, technology and policies, cultural and economic benefits. The typical cases during this period included Beijing FANGZHI Textile Building, SHUANG AN Shopping Mall, CHONGWENMEN Hotel, these buildings are still in good condition in the city (Du, et al., 1993, Deng, et al., 1996, Chen. 1995, Shen 1995).

In 1996, the Ministry of Construction (MOC) of the People's Republic of China (PRC) promulgated the "Ministry of construction Building Energy-saving the 9th Five Year Plan and 20-Years Plan ". The 9th Five Year Plan was aimed to improve the urban and rural buildings' thermal environment, people's living environment and to promote

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

energy efficiency. Energy-saving retrofit technologies and at the same time the route map were made up clearly in north of China. Building envelope and heating system retrofit design, construction and economic problems were also discussed during this period (Zhao, et al., 1998, Fang et al., 1998). The discussion and implementation of this issue started from cold north China and gradually expanded to the south regions (Li 1997).

The 10th five year plan (2001~2005)

Individual energy-saving retrofit technology was researched for different type buildings in different climate zones during the 10th Five Years Plan period. In the same period, some key technologies, plans, and standard system research work were carried out step by step. Policy and market mechanism were also established gradually, which promoted many new industries, such as insulation materials product industry, energy-saving equipment and production industry , and new construction materials industry(Tang et al.,2001, Qiu,2003, Wang,2004, Yu et al.,2004, Guo et al.,2004, Wang,2002). A case in Nanjing was studied based on DeST dynamic simulation and energy efficiency retrofit analysis of commercial buildings in the hot summer/ cold winter zone of China (Changhai Peng et al., 2014).

The 11th five year plan (2006~2010)

At the end of 10th Five Year Plan, energy-saving retrofit theory and technology were becoming mature. Several integrated technologies were developed, energy-saving retrofit policies, new energy saving technology and materials standards were also implied and promoted (Li, 2009, Yu, 2007, Jiang, et al., 2008, Zhou, 2006, Chen, 2006). “The comprehensive retrofit technology research and demonstration of existing buildings” was regarded as one of key projects of the 11th Five Year Plan research projects (Yin, 2008).

During the research process of existing buildings’ comprehensive retrofitting, some scholars started to pay attention to environmental burden. Existing building and representative residential building’s status and residential building ecological retrofitting were analyzed and researched in Northeast China old industry areas (Jin et al., 2005). The concept of existing building green retrofit was introduced on ‘The Key Technology Research and Demonstration of Comprehensive Retrofit Project of Existing Buildings Conference’ in Beijing 2009 (Wang, 2012). At present, green retrofit key technology research and demonstration project had been set up as the research theme supported by the National Science and Technology Support 12th Five Year Plan.

The main targets of the project are to study and develop key technologies of structure reinforcement, improvement of soil and foundation, special retrofitting machinery and materials and fire retrofitting machinery and materials and fire safety retrofitting for existing building and to apply for relevant patterns; to develop and revise standards, codes and polices including Technical Code and Improvement of soil and Foundation of existing buildings, Technical specification for repairing water leakage of house, Technical code for maintenance and strengthening of ancient timber buildings. Specification for repairing construction of civil buildings, technical specification for seismic strengthening of steel structures, technical code for indoor environmental improving.

2.2 Policy mechanism

In the perspective of existing buildings green retrofitting development process, its policy mechanism is in correspondence with policy content for different periods. In general, the “Building Energy-saving 9th Five Year Plan and 2010 Plan” established, the overall task, work goals and development strategy of nation’s building energy-saving work. And some implemented policies such as “The Energy Conservation Law of the People's Republic of China”, “The Law of the People's Republic of China on Earthquake in Conformity”, “Civil Building Energy Efficiency Regulations” have provided supervisions in the policy making process of existing building retrofit. Relevant government departments have also published a series of incentives to promote its development, such as “Government Office Building and Large Public Building Energy Efficiency Special Funds Interim Management Measures”, “Heat Metering and Energy-saving Reward Fund Interim Management Measures for Existing Residential Buildings in North District”, “The Instructions on Promoting the Existing Residential Buildings Heat Metering and Energy-saving Work in North District”.

About how to enhance existing buildings energy efficiency retrofit work, Zhang Li and Wang Yonghui had carried out some economic incentives research. Through the study of relevant incentive policies and measures, Wu Yong and Liang Yang suggested to provide subsidizing loan, tax incentives, governmental subsidies and special funds to promote the development of retrofitted buildings. And if the advanced technologies and products were tested in actual project, those manufacturers and enterprises should enjoy tax relief or subsidiary as an encouragement for continuing technical innovation in future (Zhang, et al., 2008, Wu, 2010, Yang, 2010).

In 2012, some important policy were released. 'The Comprehensive Work Plan on Energy Conservation and Emissions Reduction in the 12th Five-Year Plan Period (2011-2015)', 'The Green Building Act Plan', and 'Green Building and Green Ecological District Development Plan in the 12th Five-Year Plan Period (2011-2015)' have partially specified the green building policies and regulations, and specified objective for existing building retrofit as well. It is planned to complete more than 400 million square meters heat metering and energy saving building retrofit in the northern heating area, to complete energy-saving retrofit residential building 50 million square meters in hot summer and cold winter area, and to reconstruct rural dangerous house demonstration projects 400,000 sets. By the end of 2020, it is planned to complete energy-saving retrofit work for most residential building in the northern heating areas.

3. TECHNOLOGY RESEARCH

In 2008, existing building green retrofitting started to grow. In 2011, it substantially stepped into a fast development stage. It was found that different research themes in different period show specific characteristics. Existing buildings function transformation and seismic reinforcement research were the main research themes during the 9th Five-Year Plan Period (1996~2000), during this period researchers paid more attention on the buildings function improvement, to made the old building or dangerous buildings more safe for users and avoided to be destroyed by the hazard.

And the ECR (Energy Conservation Retrofit) and BCPR (Building Comprehensive Performance Retrofit) themes in the 10th Five-Year Plan Period (2001~2005) and the 11th (2006~2010) Five-Year Plan Period respectively were focused on buildings energy efficiency and environmental improving. The GR (Green Retrofit) research was the theme of the 12th Five-Year Plan Period (2011~2015) which was a deep development of BCPR, now it had a system assessment index to the buildings retrofitting process as introduced in the following.

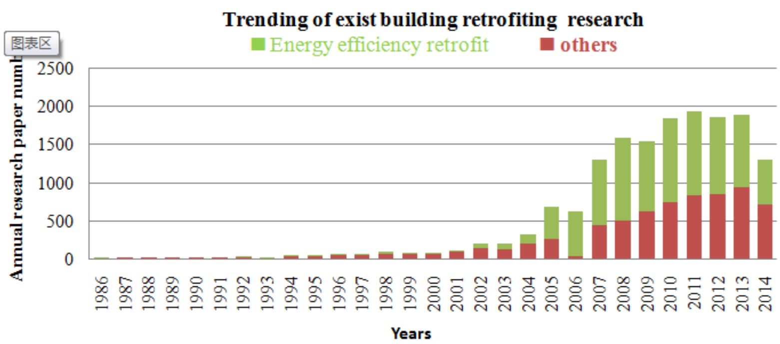

Figure 2: Existing buildings retrofitting research trend

From the Figure 3 we can see that four different themes were put up at the beginning of the Five Years Plan period. Though the research themes were different, the respective research content including the policy mechanism, technology development, standard system construction, project demonstration and application collectively keep a good cohesion relation. BCPR and GR research work and achievement will be introduced in the following article.

Figure 3: The research themes in deferent periods

3.1. BCPR (Building comprehensive performance retrofit)

Through the energy- saving retrofit technology research, it is discovered that there were more comprehensive contents required in existing buildings retrofitting evaluation, besides its safety, applicability, durability and environmental factors. The existing buildings' economic efficiency, technical feasibility and social effect are also need to be weighted. Therefore the comprehensive environment retrofit research, comprises the acoustic environment, light environment, thermal and humidity environment, indoor air quality and other healthy factors were all considered. For example, technical code for sound insulation improvement construction of existing buildings, foundation improvement construction of buildings, strengthening construction of concrete structures, and so on, all of those were needed to be assessed before retrofitting work.

There were ten topics in the 11th Five-Year Plan 'The Comprehensive Retrofit Technology Research and Demonstration of Existing Buildings' research project, which includes standard specification, testing evaluation, reconstruction safety, energy conservation, material and equipment, renewal, demonstration projects, etc.

Integrated retrofitting for existing buildings involves diversified subjects and technologies such as structure design, function upgrading, building materials, renewable energy, history and culture, land resource, natural environment and cultural environment and so on. But all the researched technologies can be classified into 3 types: testing and evaluation technology, the comprehensive performance evaluation and comprehensive retrofitted technology. These research contents had considered every step of the retrofitting demand. For example, the retrofitting need of existing buildings should be tested and evaluated firstly, so the testing and evaluation Technology was studied. Then it was divided into several parts according to the building construction, including the envelope, the equipment and the power system upgrading, the water system, electronic system, and security system fixing, and so on. The retrofitted objects were consisted by residential buildings, office buildings and some public buildings. These buildings were mostly important buildings needed to make the more sustainable, including sustainable utilization of historic buildings and most of them were funded by the government.

Testing and evaluation technology

The testing and evaluation technology is the precondition of existing building retrofitting. Its contents include the safety and durability, disaster resistance and fire prevention diagnostic testing of the façade, foundation and structure of existing buildings. It also established evaluation index of retrofit technology applicability (Wang, et al., 2014).

Comprehensive performance evaluation technology

It is a multi-optimization problem to evaluate the comprehensive performance of existing buildings retrofit. The building's environment performance, functional, healthy, comfort, technical and economic rationality and other factors are all needed to be considered. Such technology considers the architectural space layout, the natural lighting, natural ventilation based on existing building surrounding environment. The fuzzy performance comprehensive evaluation method was then established based on fuzzy and extension theory (Chen long, 2004, Liu et al., 2007, Zhou et al., 2008,Dong et al., 2009, Fei et al., 2012).

Comprehensive retrofit technology

Comprehensive performance improvement technologies include the culture and function promotion, old building reuse, environmental performance retrofit, energy efficiency performance, etc. The energy efficiency factors during retrofit construction, operation and maintenance should all be considered, which constitute an energy efficiency system. Among all the retrofit process, building envelope retrofit is the one of the most important section, which is able to substantially improve the indoor comfort. The specific technologies researched include, thermal energy storage wall, energy efficient balcony structure, ventilation equipment embedded envelope, and so on. Other building equipment retrofit for, like energy station, water pump, ventilator, transmission and distribution system, AC terminal, etc. are also studied as key technologies.

Existing building comprehensive retrofit technology research laid a very solid foundation for existing building green retrofit research.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.2. GR (Green retrofit) technology research

In order to promote the green technology application for existing building green retrofit, the government initiated 'Existing Buildings Green Retrofit Key Technology Research and Demonstration Program' program, supported by the 12th NSTSP. Research contents covered residential buildings, urban communities, large commercial buildings, industrial buildings, office buildings and hospital buildings in different climate zones of China.

The research has already got some achievements, which have been introduced by Wang Jun etc. They also gave a conclusion of the research programme of China's existing building green retrofit and related standards research. Zhou Jianmin reviewed the green retrofit characteristics, indoor environment performance evaluation and test technology. In addition, Meng Chong summarized the existing building retrofit certificated projects(Wang 2014, 2012,Zhou 2013, Meng 2014).

China Academy of Building Research and other institutes were authorized to draft 'National Standard for Green Retrofit of Existing Building Assessment' sponsored by the Ministry of Housing and Urban-Rural Development People Republic of China. The standard consists of 11 chapters: a general provision in the former three chapters, 7 main categories of green assessment index of exist building retrofitting were included in fields of planning and construction, structure and materials, HVAC, water supply and drainage, electrical and lighting, construction and operation management respectively from chapter 4 to 10, and an innovation and improving measures also considered in chapter 11. Now the standard had finished and released by government on December 18, 2015.

7 main categories of green assessment index of exist building retrofitting were paid 100 points (Q1 ~ Q7), and one innovation categories no more than 10 points. they had different weight in design and operation period. And it can be calculated by Equation 1. It was divided into 3 certificated levels, ≥50 ， one star level, ， ≥60 ， two stars level and ≥80 ， three stars level.

$$\Sigma Q = w_1Q_1 + w_2Q_2 + w_3Q_3 + w_4Q_4 + w_5Q_5 + w_6Q_6 + w_7Q_7 + Q_8$$

Equation 1

4. CONCLUSION

The systematic research of energy-saving retrofit work and green retrofit projects has provided good condition and foundation for existing building green retrofit.

The green retrofit of existing buildings produces remarkable economic, social and environmental benefits, and the certified demonstration projects have a good guidance and play an exemplary role in promoting sustainable buildings development. Due to the complex process of green retrofit work, it needs more public attention besides of government promotion. More measures to drive the existing building retrofit market to transform to a more green way should be work out.

With the green buildings development, green retrofit will be play a more important role in sustainable buildings development, and it will be a key research of China's 13th NSTSP. The Standard for Green Retrofit of Existing Building Assessment GB/T51141-2015 would give a support in future, and in the 2030, 3% of existing buildings would be retrofitted.

ABSTRACT

In Japan, energy-saving renovation of existing buildings has become an urgent issue. In the Japanese stock office buildings, the offices that less than 10,000m^2 accounts for 98%.

On March, 2016 Authors designed and completed the renovation for net-ZEB office in the local city Chiba near Tokyo. We introduced various technologies and reduced the energy consumption by approximately 70%. And we created renewable energy to exceed the remaining energy consumption, and it is expected to achieve a plus energy building.

The concept of this renovation project are (1) variety of comfort, (2) super energy saving, (3) work smart, (4) disaster resistance. Without the use of fossil fuels as much as possible, we adopted radiation air conditioning and desiccant air conditioning using geothermal heat and solar heat. And it is characterized by the combination of maximum daylighting and natural ventilation. We were carried out wellness air conditioning control based on the metabolic rate and comfort declaration of workers. We report the effect of the energy reduction by re-design to change work-mode and use of various spaces, and the effect of the energy reduction by façade renovation. This office has achieved a plus energy up to now, and we report the verification result of one year. At last, we consider about the essence of the ZEB renovation from LCC's point of view.

Keywords: net-zero energy building, renovation, wellness control

1. OUTLINE OF THIS RENOVATION OFFICE

In Japan, energy-saving renovation of existing buildings has become an urgent issue. In the Japanese stock office buildings, the offices that less than 10,000m2 accounts for 98%.

This branch office, completed in 2003, has two stories and floor area of 1,318m2. It is located near Chiba City, Chiba Prefecture. Approximately 60 workers are using this office. This office has the plan form of 38.6m × 17m. Existing exterior skins were single skins with vertical fins. The renovation of this actually using office was carried out in half a year from October 2015 while the workers staying in this office. And it’s the office aiming net-ZEB. The generation of solar panel has started from May 2016.

After the renovation, the office layout of the second floor was greatly changed. Previous plan was the layout for few groups that have each desks, meeting tables, filings, and copying machines. After the renovation, the office was divided into Workplace, Communication area, and Filing area. And by renovating the exterior skin to the double skin, the perimeter heat load was greatly reduced.

Figure 1: Exterior of the building after renovation

2. CONCEPTS OF THIS OFFICE ZEB RENOVATION

We have considered the following four concepts in this renovation planning. The first is “Variety of Comfort”, the second is “Super Energy Saving”, the third is “Work Smart”, and the fourth is “Disaster Resistance”.

3. THE CONTENTS OF PLANNING AND TECHNOLOGIES

3.1 Variety of comfort

The first concept “Variety of comfort” consists of items such as:

Instead of keeping the room at constant temperature and humidity, we actively introduce the outside air when good climate and workers feel the natural change. Lowering the ceiling surface temperature slightly improves the comfort by removing heat from person. Also we improve the comfort by lowering humidity. In this way, our proposal is "to achieve variety of comfort, reduce heat load, and reduce energy consumption".

With regard to daylighting, there is only 8.5m distance from window to the centre of the office, and both sides daylighting, and also the office has the top lights on both sides. On the outside of the windows, outside blinds are installed, and automatically adjust the slat angle in accordance with the amount of solar radiation and sun position. Air diffuser is installed on the ceiling for each worker, and workers can adjust the air volume by their smart phone or personal computers. Desiccant outside conditioner supplies the outside air of low humidity to the room. This conditioner is very compact and concealed in the ceiling, and has cooling coil, re-heat coil, and total heat exchanger.

3.2 Super energy saving

The second is “Super energy saving”. In this concept, advanced thermal performance renovation of the exteriors is the first point. We added 100mm heat insulation at roof, also 50mm insulation at exterior wall, and changed "single glass" to "gas-filled Low-E glass". In addition we made outer glass on the outside, and made double skin. In this double skin outside blind automatically moves to cut the solar radiation. The perimeter heat load is reduced to one third, and cooling peak load including the heat of lighting, human and OA machines is reduced 60% from existing office.

Lighting is the LED task and ambient system, and was developed as a product that face is divided into nine parts. Ambient illumination setting is 300Lx at the time of sitting, and 100Lx in the absence, automatically dimming by the thermal human sensors. Task lighting can also adjust the amount of volume and colour individually.

We planned the ceiling radiation system as the air conditioning system. We think important that the ceiling radiation system can use direct geothermal heat. By controlling ceiling surface a little cool temperature, this system removes radiation heat from the person, and gives comfortable feeling to the worker rather than the convection system. We installed the piles to take the heat from the ground on site, and used this direct geothermal heat to the cooling coil of ceiling radiation and desiccant air conditioning. Direct use is carried out all day hours in intermediate season and morning hours in summer etc. When the cooling water temperature rises in summer, the system switches from direct geothermal to cooling heat source. And we also installed the solar heat collection panel on the roof, accumulated hot water to the tank, and used the desiccant re-heat and radiation heating in winter.

Figure 2: Integrating most advanced technologies for ZEB

3.3 Work smart

The third concept “Work Smart” takes the idea to change the environment set point depending on area. At the workplace area, lighting, air conditioning, diffuser etc. are finely adjusted for each worker. At the communications area, workers can select a location, and this area is like an ambient area, and daylighting and natural ventilation are often used. At the filing area, lighting and air-conditioning are operated only when worker enters to see the document for reducing energy consumption. On the other hand, we drastically reduced the number of the printers and copy machines and installed at only one corner in the communications area to minimize the outlet consumption.

Also a trial of wellness air conditioning control system has started. This system combines with the personal health information, such as the metabolic rate and heart rate from the smart watches and smart phones of individual, personal comfort declaration data, position information of the individual, and temperature and humidity data of each zone. It makes the comfortable air-conditioning control such as diffusers air volume or ceiling temperature according to the worker.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.4 Disaster resistance

The fourth “Disaster Resistance” is achieved by performing the three concepts mentioned before. Because of energy consumption minimization, fans, pumps, lighting fixtures, or OA machines can run for a long time. Solar power can be used when there is sunlight. Geothermal heat, solar heat can be used when pumps can move. Natural ventilation can be also used in case of emergency.

Photovoltaics panel is s installed on the roof, and also solar heat collection pane is installed on the roof. Further this office has the re-use lithium-ion battery. If infrastructures are breakdown, this office can run about 6 days in summer, about 3 days in winter, about 7 days in intermediate season.

3.5 Integrated system control

We integrated the above devices, adding indoor and outdoor sensors data, and the control is performed to achieve minimization of energy consumption while keeping the comfort indoor environment. This system is operated by cloud CPU. Operation such as setting point change, real-time monitoring is possible by the parties from outside.

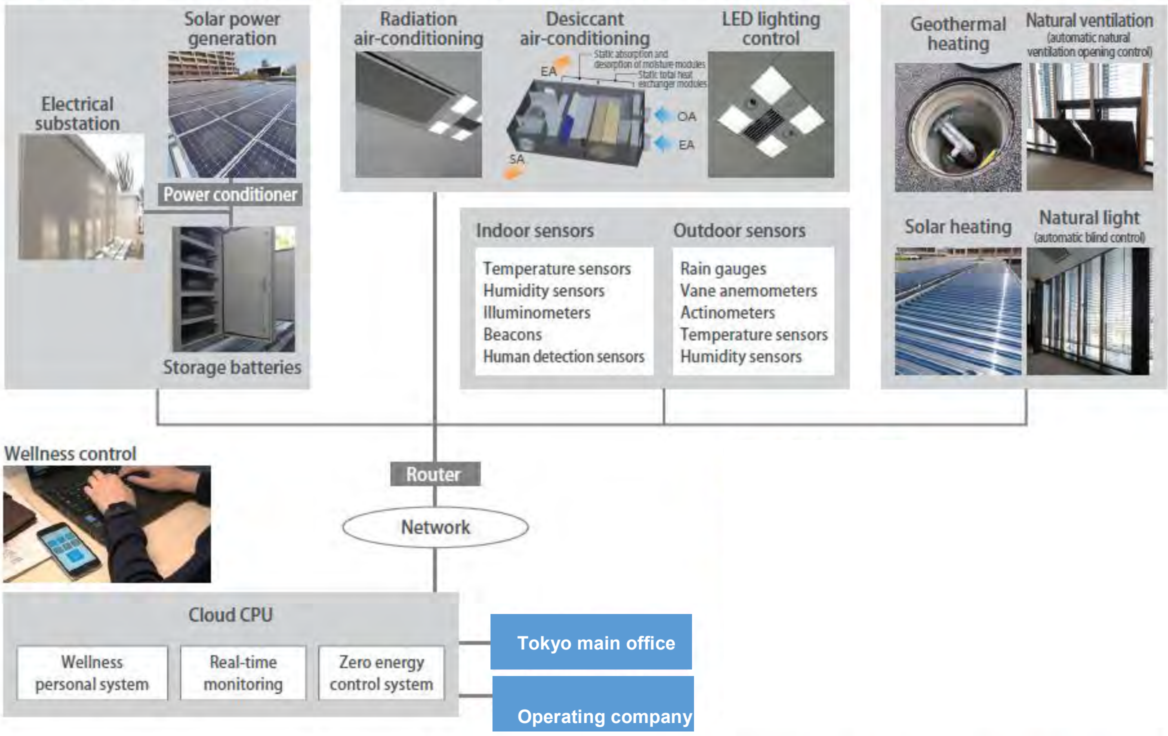

Figure 3: Integrated control system

4. PREDICTION OF ENERGY AND STUDY OF LIFE CYCLE COST

The prediction of energy consumption and energy generation is shown in the Fig-4. We set the reference amount of consumption to the actual consumption of existing office. And we predict that the energy consumption of this renovation office is reduced about 70% by the practice of mentioned four concepts. Further, we predict the remaining 30% is reduced to plus energy by solar power (photovoltaics panel). We note that this energy consumption includes the outlet consumption.

Next, we note the study result of life cycle cost of this building model. In the case of reducing 50% consumption in the renovation, number of years of pay back due to energy cost savings for the investment cost was approximately 15 years. At 100% reduction of the case, it was approximately 20 years.

In the case of reducing 50% consumption in the new construction, number of years of pay back due to energy cost savings for the investment cost was approximately 7 years. At 100% reduction of the case, it was approximately 14 years.

If life cycle of the building is nearly 100 years or there is a risk of energy costs rising, number of years of pay back will be improved. If working hours are reduced by productivity improvement, there is an effect that labour costs will be reduced. And also there is an effect that BCP is improved. In this way, Zero Energy Building can increase the benefits from LCC's point of view.

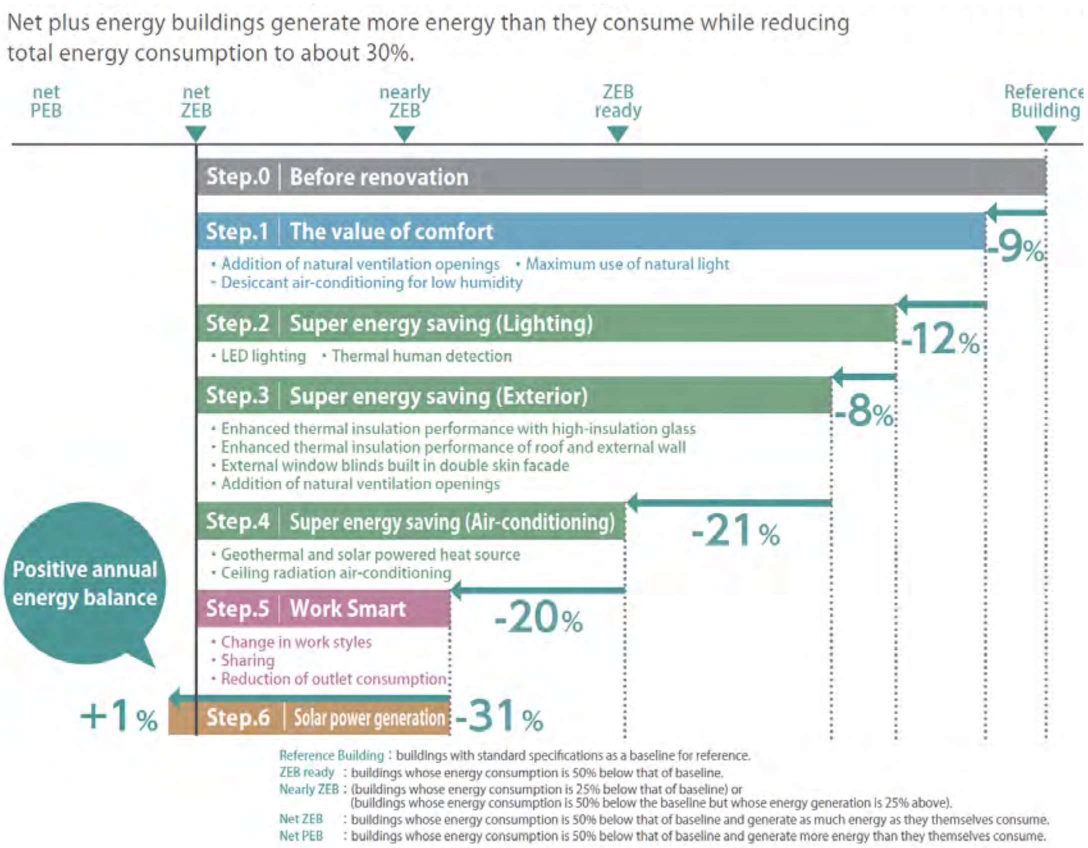

Figure 4: The prediction of energy consumption and energy generation

5. VERIFICATION AND IMPLEMENTATION OF ACTUAL DATA

This building was passed eight months from running. Energy generation has become the result of greater than energy consumption. We will continue the verification and implementation (commissioning) of one year, and report at this WSBE Conference 2017.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

6. FUTURE TASKS

We think there are several future tasks in this building. They are as follows. And we will continue to verify, together with the improvement of how to use.

The operation of direct use of geothermal heat, the operation of direct use of solar heat, setting the indoor temperature, humidity and ceiling surface temperature, commissioning of wellness air conditioning control, matching between wellness control and adaptive model, the expansion of wellness control to the light environment and so on.

Humid Wall: Review on Causes and Solutions

ABSTRACT

Due to having airtight buildings, humid or wet walls have become a common problem in the last decades. Some common consequences of having humid walls is the growth of mold, which has a bad impact on the health and the comfort level of the internal environment. There is evidence that the effect of humidity on health is strong. Furthermore, the moisture content of the wall has a direct impact on its thermal resistance. This is due to the increase of thermal conductivity value of the wall. Briefly, the humid wall problem has a direct consequence on both energy consumption of the heating system and the health of the occupants. Hence, preventing and fixing humid wall problem is a challenge that is worth a closer investigation.

Humid walls can be a result of an external reason; namely external moisture enters the building through the envelope of the building. Alternatively, the moisture that comes from cooking, bathing, washing, and people can constitute an internal cause of humid walls in buildings with poor ventilation system and low insulation level. The current paper studies the causes of humid walls and the possible solutions. Comparisons between different solutions are made.

Keywords: humid wall, drying process, wall treatment, thermal resistance

1. INTRODUCTION

Sustainable design of building concentrate mainly on three area including (Karagiozis, Salonvaara, 2001): 1) energy performance, 2) environmental impact, and 3) inhabitants' safety and health. Exclusively dealing with these critical areas might lead to make the interior environment more isolated from the exterior environment. This results in increasing the indoor relative humidity and, consequently, more ventilation rats are needed. In many cold humid climates, due to having airtight buildings, humid or wet wall became a common and serious problem in the last years (Hens et al., 2007, Vos, Tammes, 1978, Newman et al., 1982b, Newman et al., 1982a). In 1970s, for instance, buildings were constructed and retrofitted to reduce energy consumption. Definitely, these measures made the building more energy efficiency of the buildings improved. However, this approach created problems in respect to stability of the building envelope as moisture accumulation in the building structure (Tariku et al., 2010). In addition, moisture problems are the cause of significant economic costs from both repairs and health of the occupants' perspective (Burke, 2009).

Building envelope, both above and below the grade, plays a role in determining the amount of moisture gain or loss that the building and its mechanical system has to dealt with. Moisture can enter the wall through capillary and small cracks in the concrete rendering and becomes trapped in the construction (Van Belleghem et al., 2015, Barrett, 1998). Buildings in most cases are very tight. This means that in a house with a poor ventilation system, the moisture that is released into the indoor air from cooking, bathing, washing, and people has no other way to escape the house, which might cause condensation on the cooler surfaces. In addition, the moisture can enter the buildings through capillary action. The latter occurs where the water travels through the walls through small pore spaces or small cracks in the concrete and becomes trapped. Some common consequences of having humid wall is mold growing, which has a bad impact on the health and the comfortable level of the internal environment. There is evidence that the relationship between the humid and health is strong since the humid in buildings appears to increase the risk of cough, respiratory illness, wheeze, and asthma (Bornehag et al., 2004).

On the other side, the moisture content of the wall has a direct impact on the thermal resistance of the walls (Tinker et al., 1992). This is due to the increase of thermal conductivity value of the wall. In order to demonstrate the impact of the moisture on the thermal resistance of the wall, many materials have been tested in laboratory with different moisture content. As shown in Figure 1 (Veas, 2006), the moisture content affects the thermal conductivity of the materials and, consequently, the wall thermal resistance. It is worth mentioning that at the design stage the moisture content of wall is usually assumed to be 3% at the inner side of a wall and 5% at the external side (Tinker et al., 1992). Hence, moisture content of building envelope has a significant effect on the heating load of the building. For example, assumed wall thickness is 20 cm of:

- Brick wall: Increasing the moisture content of the walls from 5% to 13% leads to reduce the thermal resistance by 25%
- Concrete wall: Increasing the moisture content of the walls from 3% to 5% leads to reduce the thermal resistance by 20%.

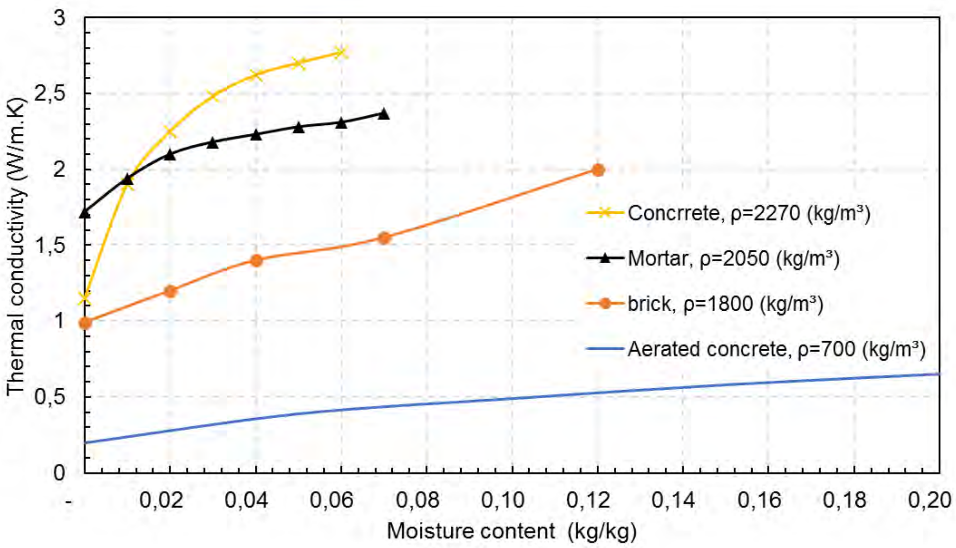

Figure 1: Relation between moisture content and thermal conductivity at temperature equals 20°C

In addition, currently there is general engorgement to refurbish a lot of buildings to match with current thermal performance standards. Yet, humid walls are a barrier to refurbishment as they increase cost of refurbishment. Accordingly, understanding humid walls problem and solutions seem to be of significant benefits for tenants' comfort, building stability, energy performance of the building, and refurbishment of such buildings. Current work, therefore, discusses the sources and the solutions of increasing wall moisture content.

2. SOURCES OF INCREASING WALL MOISTURE CONTENT

To have permeant solution of wet wall, it is very important to know where the moisture comes from. In cold climate, the common cause of humid walls is having the surface temperature lower than the dew point. The latter depends on the dry bulb temperature and the relative humidity. Hence, the internal relative humidity must be kept at a certain level that guarantees the dew point to be kept lower than the surface temperature. This can be achieved either by using dehumidifier and/ or use sufficient amount of ventilation air. In addition, installing insulation on the wall that is exposed to the external cold air can reduce the risk of having wall surface temperature lower than the dew point.

Conversely, in some cases humid wall can be a result of external reason. In such case the external moisture enters the building through the envelope of the buildings.

As depicted in Figure 2, the main moisture sources can be classified into two main categories include (Van Belleghem et al., 2015):

- External source includes precipitation, surface water/ runoff, and groundwater
- Internal source, namely high relative humidity of internal environment.

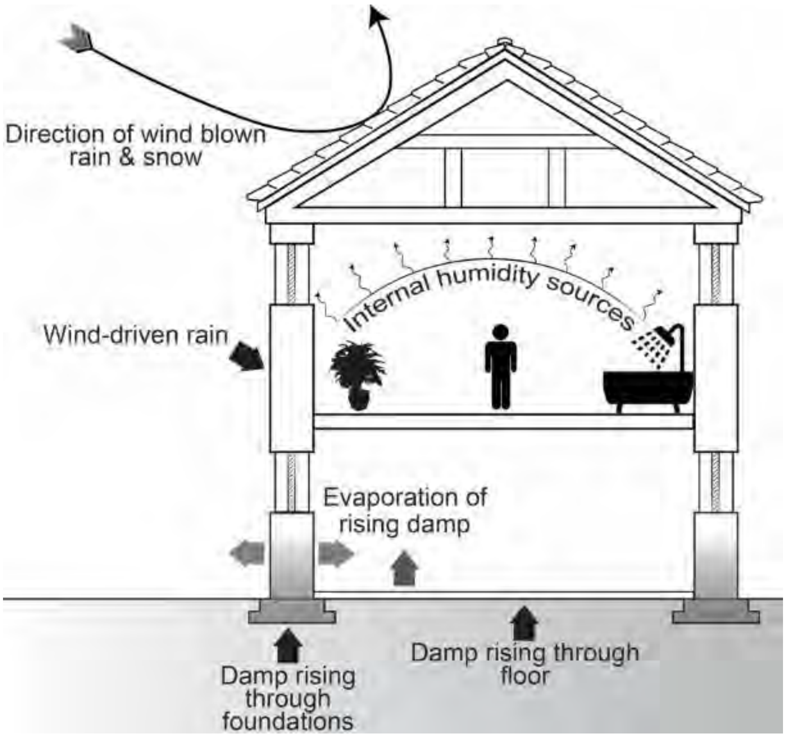

Figure 2: Sources of humid wall problem in the buildings

2.1 Internal source, i.e. the indoor humidity

Moisture released from cooking, bathing, washing, people has no way to escape the house. In the cases where the buildings have poor thermal performance, accumulation of the internal humidity causes condensation on the cooler surfaces. This is a common problem in cold climate buildings where the condensation on the warm side of exterior wall during the wintertime has a high probability for condensation. The temperature of the walls can reach the dew point due to poor insulation or higher thermal bridges (Calbureanu et al., 2010). The relation between the dew point temperatures, dry bulb temperature, and humidity of the air is illustrated in Figure 3. For instance, if the indoor temperature is 20 and the relative humidity is 70%, the condensation will occur on the walls if the temperature of the inner side become lower than 15°C.

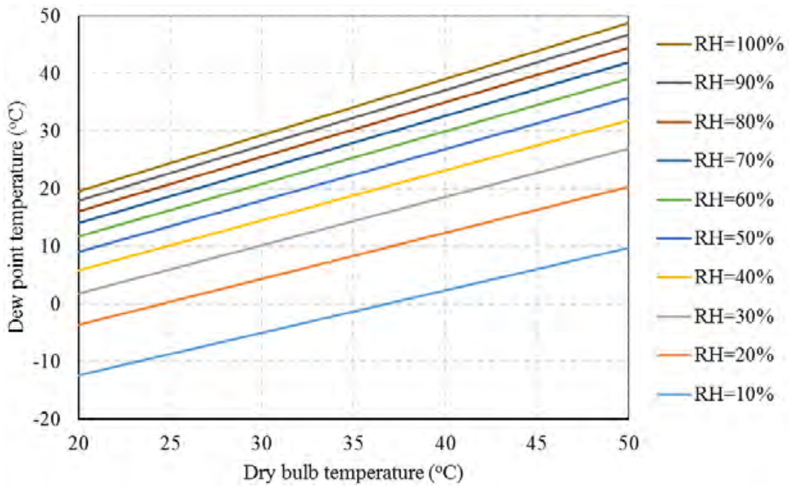

Figure 3: The dew point temperature as a function of relative humidity and dry bulb temperature

2.2 External source, e.g. rainwater

Rainwater, melting snow, or groundwater can saturate the soil around the foundation of the buildings and, consequently, leak in. As well as, the wind driven rain can penetrate the external walls due to the porosity or the cracks that exist in the wall (Van Belleghem et al., 2015, Hens et al., 2007).

2.3 Damp rising

In this case, the moisture is leaking vertically into the building. If the surrounding ground has a high level of the moisture, water will rise by capillary action through the pores and evaporate internally. Consequently, salts crystal is formed on the internal surface of the walls. Hence, even if a solution that prevents ground water to enter the building was applied, the salts on the wall will continue to absorb mustier from the surrounding indoor environment and, consequently, the wall remains wet (Damp proofing, 2016).

3. DIAGNOSE

It is often difficult to detect the cause of wet walls problems in buildings. However, the easiest way to find out the source of the problem is using a large sheet of aluminum foil to be taped to the considered wall and inspect it few days later. Moisture behind the foil indicates moisture is leaking from outside through the walls. While, moisture on the outside surface of the foil means high indoor humidity.

Alternatively, using moisture meter and moisture content of the wall at different depth in the wall. Two cases can be distinguished:

- The moisture content increase with the depth (from inside toward outside): this indicates that the source of humidity is external.
- The moisture content decreases with the depth (from inside toward outside): this indicates that the source of humidity is internal.

4. WALL DRYING OUT METHODS

The speed of drying is largely dependent on (Kidd et al., 2010): 1) drying method, and 2) wall materials. Three methods are commonly used to dry out the wall:

- Heat-based methods: Using heat and ventilation,
- Dehumidifier: Using heat pump to absorb the humidity from the indoor space,
- Chemical-based method: Using chemical agent, such as Sodium hydroxide, to absorb the humidity from the indoor space.

4.1 Heat-based method

In the heat-based method, a lot of heating and air moving system is needed. Hot and drying are with temperature above 40°C must be supplied to the treated space for 2-3 days. By using such method, there is still some doubt as to the possibility of damage to building contents. Therefore, it is important not to over-dry; this wastes energy and time and increases the risk of damage to building components. Therefore, monitoring the drying process is necessary for two main reasons: enables better control of the environment and allows the perfect drying chamber to be maintained more easily. Monitoring is also used to signal the end of the drying process and consequently, save energy and time and saving building components.

Heat-based method can be applied in two different forms:

- Conventional heating method, by supply the hot and dry air to the whole indoor space. The main advantage of this method is that it is easy to install. However, in such method lot of energy and takes longer time when compared to the modified heating method.
- Modified heating method. By installing a plastic sheet close to the treated wall and then supply the drying air (or sucking the air) directly to (from) the space between the wet wall and the plastic sheet, see Figure 4. This method is fast and less energy consumed.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

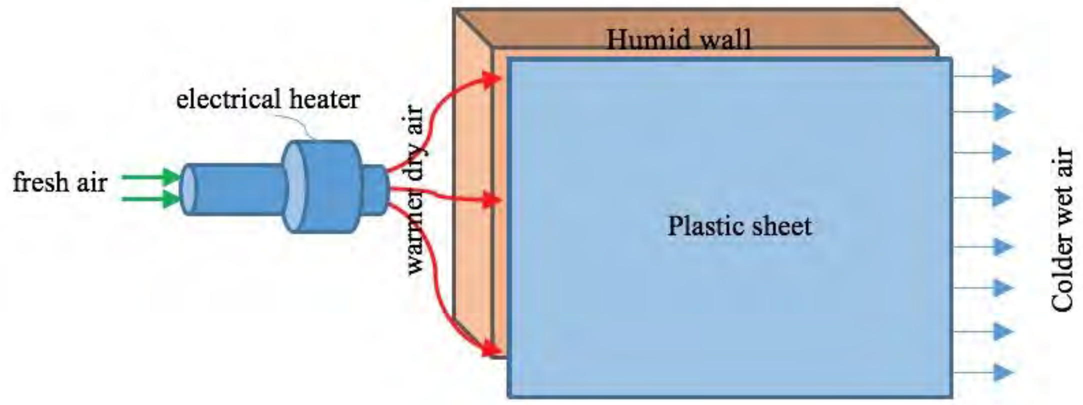

Figure 4: Modified heating method. The drying air pumped in the space between the wall and the plastic sheet

In the case where there is insulation into the wall, tiny holes can be drilled into the wall to be used to inject hot and dry air, see Figure 5

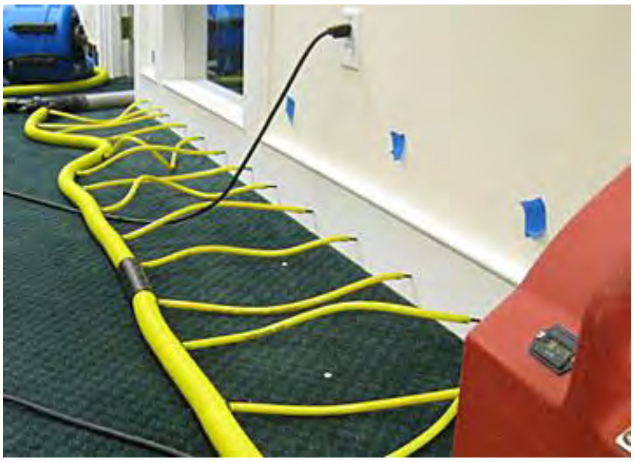

Figure 5: Drying wet wall with presence of insulation

4.2 Dehumidifier

Dehumidifier can be a useful machine to dry out the wall in a closed environment as they rely on creating an unnaturally However, dehumanization process creates a lower vapor pressure condition on the inside of the building than those on the outside so the moisture on the outside of the structure can move into the building. In another word, without a proper building envelope structure, using dehumidifier to dry out the walls engorges moisture moves though the envelope much faster.

The speed of drying is largely dependent on the capacity of the equipment relative to the space to be dried.

- Longer time is need when compared to heat-based method
- Dehumidifier should only be used, if the envelope structure is good. Otherwise, moisture might move through the envelope much faster.

4.3 Chemical base method

In chemical base method, a hygroscopic substance is needed as a drying agent to attract and hold water molecules from the surrounding indoor environment. For this purpose, various draying agents can be used include:

- Sodium hydroxide
- Silica gel
- Calcium chloride.

The drying agent can be placed in the treated space for some days. The drying agent will absorb the humidity from the pace and, consequently, the moisture form the wall will be released into the space. Alternatively, the drying agent can be applied directly to the wet wall by means of installing assistant plastic or wooden plate that is few centimeters far from the treated wall. Then, the drying agent is used to fill the space between the wet wall and the assistant wall. Compared to other methods, chemical-based method does not require energy and drying time is much longer.

5. PREVENT HUMID WALLS PROBLEM OVER AGAIN

In order to prevent the mustier wall problem occurs again, there are some procedures must be taken. The nature of the procedures depends on the source of the humid as flowing:

5.3 Externally source of the humidity

In the case where the humidity source is externally, the wall needs to be treated carefully as follow. Plug holes and cracks in the foundation. Although, holes and cracks in the external envelope let moisture and water leak into the building, patching them perhaps not solve leakage problem. However, plugging the cracks can help to minimize the problem size. Since hydraulic cement can be used under water and swells, such cement works perfectly to seal the hole and lock the plug. It should be noticed that the hole or crack must be enlarge into an inverted "V" with the narrow part of the "V" on the surface of the wall this trick assures that the cement will not be pushed out due to its expansion.

In addition, use waterproofing paint which fills the pores in the concrete or masonry walls seems to be a good method to prevent water from leaking in. to make this method is more effective, the coatings need be applied to bare walls and adding a second coat after the first dries. This guarantees to fill every pinhole and create a continuous waterproofing membrane.

5.4 Internally source of the humidity

If the source of the humid is internally, the wall needs to be insulated carefully. This way will prevent the temperature of the walls to be as low as condensation temperature of the humidity, or what so-called dew point. As mentioned above, dew point depends on the relative humidity and the dry bulb temperature of the air, as shown in Figure 3. The higher relative humidity, the higher dew point will be and, consequently, the possibility of condensing the humidity on the walls will increase. Therefore, ventilation control becomes even more important to removing excess moisture in the air, moisture that is attributed to building materials, people sweating, showering, cooking foods, etc.

It is worth mentioning that the moisture is moving through the envelope structure into the building in summer, while leaving the buildings in the winter. Accordingly, using vapor barriers is a critical issue because it might really create quite significant and problematic conditions depending on where the vapor barrier is placed. In cold climate, where moisture condenses on the inside cold wall during winter months, the vapor barrier must be located on the interior (the warm side of the wall).

6. CONCLUSIONS

Increasing the moisture content of the buildings envelope has significant impact of the energy performance of the building, the on the health and the comfort level of the occupants, and the stability of the building envelope. Current work discusses the sources and the solutions of increasing wall moisture content. In order to get rid of increasing wall moisture content permanently, it is highly recommended to detect the source of the problem. It was shown that there are three main reason to increase moisture content of the buildings envelope:

- Internal reason due to increasing the indoor humidity,
- External reason due to exterior walls exposure to harsh-climate conditions.

A comparison between three drying methods (including heat-based, dehumidifier and chemical-based) was presented. As listed in Table 1, if speed of drying is the overriding consideration then the heat-based with powerful seems to be the proper method. However, there is still some doubt as to the possibility of damage to building contents. On the other side, chemical-based method seems to be the cheapest option, but it requires a long time.

Method	Drying time	Energy requirements
Modified heat-based	short	Low
Conventional heat-based	Relatively short	Relatively low
Dehumidifier	Relatively long	High
Chemical-based	long	No energy

Table 1: Comparison between drying methods

After solving the problem, namely dry out the wall, there are several steps can be taken to prevent humid wall problem such as using thermal insulation on the external wall of low thermal resistance or patching cracks and holes in the walls. The selection of the steps depends on the source of the problem.

Future work will concentrate on a practical case and the implications of different drying methods.

[c] *Research Instiutes of Sweden, Sweden, peter.kovacs@rise.se*

ABSTRACT

The paper presents the test of a multi-value framework for the evaluation of energy producing solar shading on three cases of Swedish retrofitting projects. The evaluation framework was developed in collaboration between academics and industry partners in a transdisciplinary research project and considers: energy production, indoor environment and comfort, visibility and communication, aesthetics, design and process, and maintenance and repair. Results show that the model even though having few criteria gives a general and comprehensive feed-back about the outcomes, challenges and success of the projects. None of the projects scores high in all aspects, instead they exemplify different approaches to energy producing solar shading. All three have shading and low maintenance as important criteria for design. Furthermore, the availability of subsidies to add solar energy production to the shading has been decisive for choosing that solution. Case 1 has had energy production as an important driver and no architect was involved while in Case 3, being a listed building, aesthetics has been crucial. Case 2 shows a way forward with a good collaboration between the actors and a compromise between shading, energy production and aesthetics which respect the original design.

Keywords: building integrated solar energy, shading, retrofit

1. INTRODUCTION

With respect to global warming (Frank, 2005) and heat-islands in larger and denser cities (Santamouris et al., 2001), cooling is set to be a crucial element in building design in order to reach comfort levels. Modern architectural ideals with glass facades have also been identified as the origin of over-heating in buildings (Nässén & Holmberg, 2005). Solving the problem with energy consuming cooling systems goes against goals for increased energy efficiency and the growing importance of sustainability certifications. Solar shading proposes a solution for over-heating while a trade-off between reduced energy demand for cooling and increased need for artificial light has to be dealt with (Nielsen, Svendsen, & Jensen, 2011).

Energy producing solar shading proposes and attractive combined solution offering solar shading at the same time as renewable energy is locally produced. Although costs for solar cells has decreased such solutions are still uncommon sights. Challenges for the multi-functional system include a balance between energy reduction and indoor comfort regarding daylight and glare along with practical issues of maintenance, repair and wind-loads (Roberts & Guariento, 2009), especially for dynamic systems which are the most efficient in terms of balance between shading and daylight (Nielsen et al., 2011). Another crucial barrier for the wider implementation is traced back to the influence of architects and the possibility for a successful aesthetic architectural integration of solar energy in the overall building design (Munari Probst et al., 2013).

This paper presents on-going research on energy producing solar shading in Sweden. The ELSA (Elgenererande solavskärmning) project is carried out in a transdisciplinary setting involving three academic institutions representing architecture, daylight studies and technical expertise in collaborating with the industry representing architect firms, solar energy suppliers, solar shading suppliers, building contractors and lobby organisations for solar energy and shading. A process of gathering feed-back from ten cases of new building and retrofit applying energy producing solar shading was initiated in 2016. This paper focuses on three cases of retrofit which represent an important part of the building stock. The aim for the paper is twofold: 1) To test an analytic multi-value framework developed to evaluate the installation of energy producing solar shading from different value and stakeholder perspectives, and 2) To discuss general experiences from these case studies.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

1.1 Method and material

The choses cases of retrofit represent different types of solutions with respect to shading system and architectural integration. All cases are Swedish non-domestic buildings. In each case a number of key actors are interviewed: construction clients, architects, technical consultants, contractors, installers, operation managers, and end-users. Furthermore, representatives from the local public are interviewed as stakeholders to the visual effects of the systems on the urban environment.

The feed-back study gathers process information from the early design phase to the building in use. Technical information, energy performance and experiences from the system in operation and use are also collected. Opinions on the architectural integration of the system has been identified as one main questions to be addressed as well as the visibility and marketing values. Data collection, still ongoing, is based on structured interviews carried out face-to-face or by telephone. Table 1 shows the actors that has been interviewed so far. Results are to be used as basis for discussing different aspects of energy producing solar shading within the trans-disciplinary research arena.

Case		Actors that has been interviewed
City	*Type of building*	
1. Alvesta	Town Hall	Client (the energy manager); the solar system supplier; 3 users
2. Sollefteå	Hospital	Client (the energy manager); architect; solar system supplier
3. Stockholm	University, entrance hall	Client; architect; maintenance & operation; users/public

Table 1: Interview respondents and type of interview in the three case studies.

2. EVALUATION FRAMEWORK

An evaluation framework was designed based on workshops and discussions in the transdisciplinary research team. The aim is to reflect a manageable number of influential factors that an energy producing solar shading should be evaluated upon and still get a comprehensive idea of its function and value (Table 2). Economy and costs are considered but not explicitly included in the framework instead implicitly evaluated in terms of energy production, user satisfaction, and in branding and marketing. The framework was used to analyse data from the case studied. Three researchers were involved in the analysis and adjustments were made to align different perspectives.

	Grade 0	Grade 1	Grade 2	Grade 3
Energy production	Insignificant production of energy	Covers only a limited part of the building energy needs	Produces energy according to expectations but does not cover building needs	Produces energy according to expectations and covers building needs
Indoor environment	No improvement; significant heat over load and glare problems	Small improvements of over-heating and glare	Improved conditions for over-heating and glare	Large improvements, no over-heating or glare problems
Visibility & communication	No feed-back to users; no communication for the public	Information panel indicating the energy production inside or outside building	Visible information panel and regular feed-back and info online or in newsletter	Visible information panel, web information etc. and knowledge diffusion through partnerships
Aesthetics	Not appreciated among any respondent	A majority (>50%) does not find the plant attractive	A majority (>50%) find the plant attractive	All respondents find the plant to be attractive
Design & process	All parties found project difficult or almost impossible to carry out.	At least 50% found the project more problematic and costly than expected.	At least 50% found the project smooth and efficient.	All parties found the process smooth and efficient.
Maintenance & repair	In need of recurrent maintenance and repair.	Seldom in need of maintenance or repair.	No need for maintenance and only occasional repair.	No need of either maintenance or repair.

Table 2: Evaluation framework.

3. CASE STUDIES

3.1 Case 1: Alvesta Town Hall

An office building from the 1960s had previously been renovated and fitted with a cooling system, but problems with over-heating persisted. In 2015, highly efficient solar cells mounted as on a 'baseball cap' shading were fitted on the eastern and southern facades to limit over-heating and energy use (Figure 1). The municipal agency who owns and manages the building had no previous experience of solar cells. Their energy manager was the initiator and promoter for the system. No architect was involved. National subsidies covering 35% of the total costs of 170.000 € was decisive for choosing solar cells. The system produces 65 MWh/year which covers the electricity need for the building on sunny days and delivers a surplus (~6MW7year) especially in the week-ends which is sold making savings of 25.000 € per year. Although the building now has higher tax rate for being an energy producer the total economic gain is positive.

The client wanted a system free from maintenance. The 'baseball caps' are 2 meters wide and the installation was difficult to attach to the façade. Today the system supplier only does 'caps' that are 1 meter wide. The client thanks the experienced entrepreneur for the success of the installation.

The system has received a lot of attention locally and the solar cells on the roof can be accessed for study visits. The client says that politicians and public servants as happy with the indoor climate and the aesthetics. The solar system supplier is also happy with the results but says that his architect friends does not like the looks. Both the client and the supplier agree that the system is best seen from a distance and that the shading defines the building as a landmark on an urban scale.

Three interviewed users all have different views on the comfort and aesthetics. The system seems to be less efficient on the top floors. Furthermore, the users seem little informed about the function and the value of the system. None of the users are favour of the aesthetics and details are found clumsy. However, they think that the building wasn't that attractive before as it had undergone several renovations. As one user state: "The building is now more blackish and the façade disappears. The building possesses no higher architectural value but it is still the Town Hall and a large visible building." A summary of the evaluation is found in Table 3.

Figure 1: Alvesta Town Hall before and after addition of solar shading.

Value area	Grade	Comment
Energy production	3	Produces energy according to expectations. Surplus energy is sold.
Indoor environment	2	Three users give varying testimony from good to bad.
Visibility & Communication	3	Information panel in the entrance hall. The building receives study visits. The owners engage in knowledge transfer to other municipalities.
Aesthetics	2	3 out of 5 respondents do not find the system attractive or does not have any opinion about the aesthetics.
Design & Process	1	The design process was costly due to extensive calculations for the façade attachments.
Maintenance & repair	3	No need for maintenance or repair so far.

Table 3: Evaluation of case 1, Alvesta Town Hall

3.2 Case 2: Sollefteå Hospital

This hospital building from the 1960s had problems with over-heating and was retrofitted with energy producing solar shading in 2010. The decision to add energy production to the shading was supported by an enthusiastic client and guided by local policy to invest in renewables. The possibilities to get national subsidies was highly supportive for the investment in solar energy.

The architect was satisfied with the collaboration regarding the architectural integration although the other parties were not that interested in the aesthetics. The architect is satisfied with the results which he thinks is not that dominant on the façade. However, he claims that the system "does not add any aesthetic values to the building." A 'cap' like shading as in Case 1 was discussed and dismissed due to aesthetics. The client and the solar supplier are also satisfied with the aesthetics.

Important criteria for the design were shading, cost efficiency and low maintenance. With respect to his experience, the architect calls for more standardised products. In this project the shading lamellas had to be adapted to fit the size of the solar cells (12 cm). The client finds it remarkable that solar cells are not found in the dimensions of the shading as this kind of shading is very common. Due to the different dimension, the assemblage had to be done in two steps first the shading was fitted to the façade then the solar cells. This increased the costs and complication of the project. A summary of the evaluation is found in Table 4.

Figure 2: Sollefteå hospital with the energy producing solar shading.

Value area	Grade	Comment
Energy production	2	Production according to plans but does not cover more than a small part of the building's energy need.
Indoor environment	3	The shading give an improved indoor environment.
Visibility & Communication	3	Information panel at entrance. Information about collaboration on sustainability with the region. Seminars were given at the inauguration. A web-portal provides further information.
Aesthetics	3	All respondents are very satisfied with the aesthetics and the building integration.
Design & Process	2	The solar energy supplier is unhappy about the costly and time consuming installation.
Maintenance & repair	2	No maintenance but some smaller repair. Difficult to find replacement parts as these were specially produced.

Table 4: Evaluation of case 2, Sollefteå sjukhus

3.3 Case 3: Passage at the Royal Institute of Technology

The object is a passage between two building blocks originally built in 1948 and reconstructed as an entrance hall to a lecture hall in 2006 (Figure 3). The passage is designed by Swedish architect Nils Ahrbom and listed. During the reconstruction, the passage which only had high sitting windows were opened up with bay windows and an entrance. The client understood that over-heating would be a problem and searched for a solution. The university and the building manager did not want any exterior shading due to maintenance and risk for fall injuries would somebody climb the system. Instead, a system with glass integrated solar cells were installed in the upper part of the bay windows. The plant was financed to 70% with national subsidies which was crucial for the decision to use this solution. The situation of the passage which is lower than the surrounding buildings limits the insolation of the system and the payback time is consequently very long.

The passage is still over-heated but this is not a problem as it is only a passage. The client considers the installation more of an aesthetic solution for shading than energy producing. All involved actors as well as users and by-passers appreciate the aesthetics. Some users never thought about it as a solar system but when informed they think it goes well together with the profile of the technical University. The system provides shadow on the inside and a pleasant light pattern. The architect had close contact with the City Museum and the son of the late architect during the whole design. A summary of the evaluation is found in Table 5.

Figure 3: Royal Institute of Technology, entrance to lecture halls from inside and outside.

Value area	Grade	Comment
Energy production	1	The plant produces very little energy. There were no high expectations for energy production when installed.
Indoor environment	2	The installation provides some shading and does protect against glare. The passage is warm on sunny days but as it is only a hall way there are no complaints.
Visibility & Communication	1	An information panel besides the entrance door indicate the production of electricity but without reference to the relevance of the production with respect to energy use.
Aesthetics	3	All respondents and the public found the installation very attractive and well integrated in the building.
Design & Process	3	The process worked very well according to all parties.
Maintenance & repair	3	There has been no use for maintenance or repair so far.

Table 5: Evaluation of the Royal Institute of Technology case

4. DISCUSSION

The multi-value framework shows a means to quickly get a comprehensive vision of experiences with energy producing solar shading. Only a few interviews have been made, still and overall picture of the project is achieved. The limited number of evaluation criteria in our model makes it easy to apply and visualise (Figure 4). Return of experience through case studies will always be a trade-off between depths of the study and the number of cases that are possible to include in the study. The weaknesses in our evaluation are the few interviews with end-users and possibly also with representatives from the local public. A full survey among all end-users would need much more resources and the active participation of the project owners. Regarding technical information and experience among professional actors, no more interviews would be needed, and the information should be correct.

On a general discussion on experiences form energy producing solar shading a few statements can be made. Reduction of over-heating has been the main driver for installing the systems. Low maintenance and repair has been important criteria for finding a solution. Only Case 1 put energy production as a top goal. The possibility to receive financial support for solar cells has been crucial in all cases. Aesthetics have to a varying degree been of importance even though discussed in each project.

None of the projects scores high on all aspects of the evaluation framework (Figure 4). Case 1 has been successful for energy production but scores badly in aesthetics. No architect was involved and the energy production has been achieved on behalf on both respect for the building, the urban landscape. The user respondents do not give a unified view of the indoor environment. This could reflect the common view but more interviews could be carried out to get a better picture.

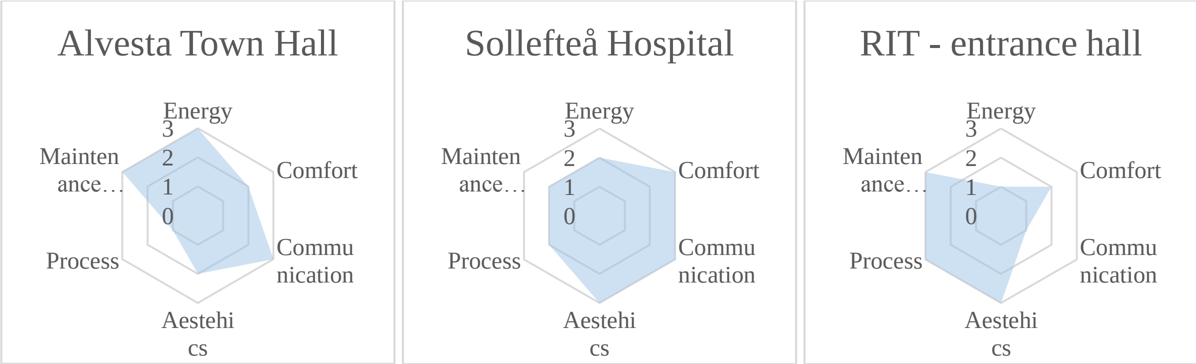

Figure 4: Visualisation of the evaluation of the three cases of retrofit.

Case 3, being a listed object the case has had aesthetics as a primary goal, the client even refers to the system as an "artistic installation". The image value could be discussed in this case as the low efficiency could give a negative impression of this kind of solar systems. Case 2 gives the most balanced outcome. Comfort is reported good and the system works in terms of architectural integration with the existing building. Compared to Case 1, in Case 2 there was an architect involved which has improved the aesthetics while still scoring high on energy production and comfort. With reference to earlier work that point out the architect as an important actor for a market-up take of building integrated solar systems (Kanters, 2011), Case 2, where there was a good collaboration between architect, solar supplier and client, shows a way forward. In Case 1, no architect was part of the project group, but in many projects this would not be permitted. The solar system is definitely a very dominating part of the building and its aesthetics can be discussed. In Case 3, the system is very well integrated and an appreciated part of the building. The energy production is limited but this could be due to the local situation.

None of the cases have had need for maintenance and only Case 2 has been in need of repair. However, especially Case 1 is newly installed and time will show how successful it will be regarding maintenance. Time will also show which of these solutions that will have follow-ups. Case 2 shows the importance of standardisation in order for solar systems to be successfully integrated with other building elements.

5. CONCLUSION

The paper shows that it is a challenge to find a balance between the different criteria which are of importance for achieving an energy producing solar shading system that is efficient in terms of shading and comfort; easy to apply to an existing building and operate and maintain; that produces enough energy to make the investment justifiable; and which can be integrated without compromising the original architecture. None of the studied system would have been installed had in not been for subsidies.

The many and varying aspects for energy producing solar shading calls for an interdisciplinary collaboration, where all aspects need to be discussed and considered. The tested multi-value framework is a means to quickly get a comprehensive vision of experiences which can be a basis for discussions in an inter- and trans-disciplinary team. The value of the results from the return of experience study will be subject for up-coming studies.

ACKNOWLEDGEMENT

We wish to thank all respondents for sharing their experiences and project assistant Frida Bard for help with data collection. The ELSA project is co-financed through the Swedish Energy Agency and the IQ Build Environment joint programme E2B2 with support from the projects' industry partners.

ABSTRACT

The building sector is well known to be responsible for a considerable part of the total European energy consumption. In the endeavor to implement radical reductions, there is an identified potential in addressing the existing building stock through deep renovations. These renovations make up complex, highly interdisciplinary systems. They involve stakeholders across a broad spectrum of disciplines and potentially affect the lives of a large number of occupants. The involved people bring different understandings of value in sustainability into a project and judge the outcome according to this understanding.

As a response to this, a number of sustainable assessment methodologies for the building industry, and specifically for that of retrofitting, have been developed to assist in the decision-making processes and ensure targeted results. However, these methodologies themselves represent a stance on sustainability as they assign weight to different sustainability indicators. As such, the same design may be assessed differently according to the chosen tool. As part of the research project RE-VALUE, this paper presents an evaluation of current practices in a Danish context through a systematic literature review of existing assessment tools. The paper presents the results of a meta-synthesis, which highlights the focus areas of the individual tool as well as patterns and relationships between the tools. Based on the review we discuss a noticeable focus on quantitative, technical values in today's 'assessment practice' and put forward the hypothesis that there is a need to rank qualitative, 'non-technical' values alongside quantitative values in order to deliver significantly improved building performance, which benefits the people who inhabit the built environment. This hypothesis is substantiated through an additional literature review, from which we propose a need to develop a holistic methodology for assessing architectural transformations in deep renovations.

Keywords: sustainable retrofitting, deep building renovation, architectural transformation

1. INTRODUCTION

The building sector is responsible for 40% of the total European energy consumption. In the endeavor to reduce this number, deep renovation of existing buildings has been identified as an important focus area (European Commission, 2014). Such renovation processes make up complex, highly interdisciplinary systems, which involve stakeholders across a broad spectrum of disciplines and potentially affect the everyday lives of a large number of people (Beim & Madsen, 2015). Subsequently, a deep renovation is not 'merely' about optimizing the technical performance of a building, but prescribes a holistic approach, in which measures are considered for their inter-dependence rather than as separate elements in a traditional reductionist line of thought. A number of sustainable assessment methodologies have been developed to assist the decision-making processes and ensure targeted results. Many of these claim to have a holistic approach. However, it is the hypothesis of this paper that the models themselves represent a stance on sustainability as they assign weight to different 'sustainability indicators'. As such, the same design may be assessed differently according to the chosen tool (Tagliabue, 2016). The research project RE-VALUE has been initiated to shed light on available methodologies and the potential to further develop them into a model targeted retrofitting initiatives in Denmark (Kamari et al., 2016). As part of the research project, this paper presents the results of a literature review of existing assessment methodologies. The aim is to compare which sustainability indicators each methodology attach importance to, and to provide a synthesis of the findings, which can improve our understanding of the positioning of each methodology relative to each other.

The transformation towards a more energy-efficient building mass often involves radical changes to the built environment. Depending on the extent of the initiatives, these changes may affect the wellbeing of the people who inhabit the spaces (Acre & Wyckmans, 2015, Beim & Madsen, 2015, Hvejsel et al., 2015). As part of the literature review, the paper examines to what extent each of the included methodologies address the implications of technical interventions on the perceived spatial quality.

The following section provides an overview of the methodological outset for the study. Section 3 includes a mapping of existing assessment methodologies, which forms the basis for a synthesis and discussion in section 4.

2. METHODOLOGY

The evaluation of existing sustainability assessment methodologies is performed as a systematic literature review of 7 selected methodologies. The overall aim of the review in section 3 is to identify to which sustainability indicators each methodology assigns weight. The methodologies have been included in this paper for their relevance to retrofitting in a Danish context. They do not necessarily target retrofitting initiatives, but encompass such projects as part of their scheme. In order to provide a set of 'lenses' through which to map the sustainability indicators in a similar way, the paper leans on the three pillars of sustainability, emanating from the 1987 Brundtland Report: social, environmental and financial sustainability (World Commission on Environment and Development, 1987), adding a fourth parameter addressing process-oriented indicators. The findings of the mapping are communicated through diagrams, which depict the indicators relative to these 'lenses' and a timeline which indicates where in the renovation project the given methodology can be applied. Parallel to this study, the paper 'zooms in' on the social pillar and examines to what extent each methodology addresses the implications of technical interventions on socio-cultural aspects, focusing in particular on the perceived spatial quality. The concept of 'spatial quality' is highly complex in character and has been addressed by several scholars and practitioners through the years. In this paper we focus on the spatial quality in the understanding that architecture is a phenomenon which influences our sense of wellbeing and behavioral patterns (Bek & Oxvig, 1997). It lies beyond the scope of this relatively short paper to unfold the concept of spatial quality. Rather, it is the aim to identify if the included methodologies consider spatial quality indicators. Section 4 presents a meta-synthesis of the individual findings, with the objective to position the assessment methodologies relative to each other and identify potential knowledge gaps, with special attention to spatial quality.

3. MAPPING OF EXISTING ASSESEMENT TOOLS

3.1 DGNB-DK

The DGNB-DK tool is a Danish version of the DGNB tool, developed by Green Building Council Denmark in 2012. The purpose is to secure quantifiable standards, which makes it possible to certify buildings based on a "scoring system". The methodology is not targeted renovations, but has been applied to such projects (DK-GBC, 2016). The model has a relatively even distribution of social, economic, environmental and process-related sustainability indicators. It addresses the concept of spatial quality in the subsection devoted to "social quality", e.g. attention to daylight factor, plan layout and to 'aesthetics' through evaluation of whether the project has been put out to tender in an architectural competition and through attention to building integrated art (Beim & Madsen, 2015) (Figure 1).

Figure 24: Top: indicators relative to process and social, environmental and economic sustainability. bottom: timeline.

3.2 AktivHus (Active house)

AktivHus is a national initiative from 2015, based on the international ActiveHouse principles (AktivhusDanmark, 2015). The methodology is intended as a design strategy and certification tool. The methodology targets new buildings as well as retrofitting projects (ibid, 2016). There is a visible focus on environmental indicators. Social aspects of sustainability are here reduced to attention to indoor climate. The methodology does not consider economic aspects. Beim et al. points out that the methodology does not consider cultural aspects - in this paper adressed under social sustainability - or more process-related aspects of a retrofitting intiative (Beim & Madsen, 2015) (Figure 2).

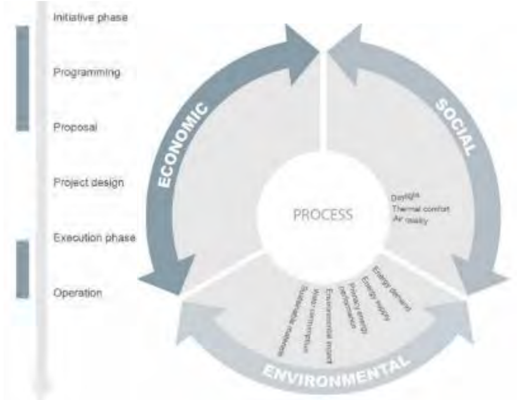

Figure 25: Top: indicators relative to process and social, environmental and economic sustainability. bottom: timeline.

If evaluating the methodology in terms of attention to spatial quality, this is 'only' addressed as a matter of quantifiable indicators related to indoor climate.

3.3 SAVE

SAVE was developed in Denmark in the late 1980's and is now administered by Kulturstyrelsen (The Danish Agency for Culture) (Beim & Madsen, 2015) (Kulturarvsstyrelsen, 2011). From 1992-2007 it served as the basis for development of 90 "Municipality-atlasses" in Denmark. The purpose of the methodology is to assess the level of preservation value in buildings or urban environments. (Kulturarvsstyrelsen, 2011). The methodology has a clear focus on culture-historical aspects. It includes weighting of economic aspects, but only a limited focus on the environmental value (Beim & Madsen, 2015) (Kulturarvsstyrelsen, 2011). The evaluation only focuses on the existing building, and is not considering potential renovation initiatives, including the potential implications on the perceived spatial quality (Figure 3).

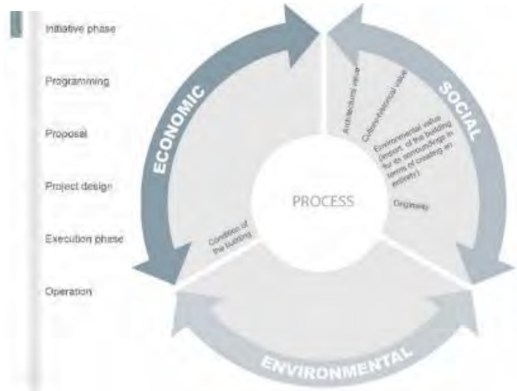

Figure 26: Top: indicators relative to process and social, environmental and economic sustainability. bottom: timeline.

3.4 Evaluering af kvalitet I boligbyggerier (evaluation of quality in housing)

The methodology was developed by the Danish Building Research Institute (SBi) in 2000 for the Ministry of Housing and Urban Affairs. The methodology focuses on residential buildings and aims to provide a holistic tool for evaluating the condition and quality of the building across disciplines, focusing on both qualitative and quantitative indicators (SBi, 2000) and (Beim & Madsen, 2015). Each of the 6 themes are evaluated in relation to

4 different scales in the building and by means of different methodologies, which are described as part of the concept. The methodology has a relatively even distribution of indicators across the three pillars. There is well-articulated attention to the more qualitative aspects related to 'spatial quality', however, focuses on the existing building rather than new initiatives (SBi, 2000) (Figure 4).

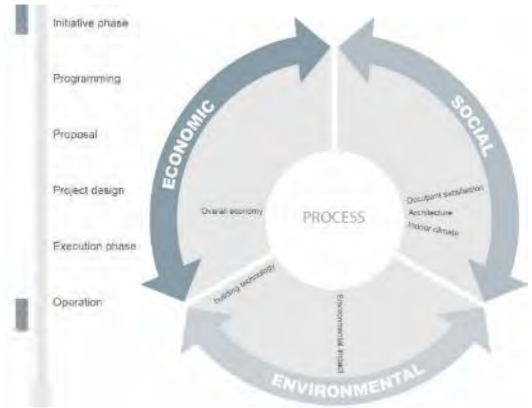

Figure 27: Top: indicators relative to process and social, environmental and economic sustainability. bottom: timeline.

3.5 Totalværdi-modellen (total value model)

The model was developed in 2012 by a partnership of local authorities and consultancy companies (Plan C). The model focuses on process management in the initial stage of an interdisciplinary renovation project, rather than the comparison of specific design solutions. As such, the model does not contain an absolute weighting system. Rather, it provides a digital framework with templates. In the model there is a relatively even focus on each of the three sustainability "pillars", which potentially helps to point out and articulate indicators as a sort of "check list" including both quantitative and qualitative considerations. However, it is up to the stakeholders to set up objectives for assessment of design solutions in later phases. The term "architectural quality" is introduced, but not further elaborated (Schunck et al., 2011). Beim and Madsen point out that the model has a limited focus on cultural aspects, such as building culture and aesthetic qualities (Beim & Madsen, 2015) (Figure 5).

Figure 28: Top: indicators relative to process and social, environmental and economic sustainability. bottom: timeline.

3.6 RENO-EVALUE

RENO-EVALUE is developed by Centre for facility management (CMF) (Jensen & Maslesa, 2015). It provides a tool for clarifying sustainability objectives in a renovation process, comparing alternative project proposals and for evaluating the level of sustainability after completion (Jensen & Maslesa, 2015). The main purpose is to provide a process tool, which can identify each stakeholder's priorities and help establish common criteria for success in the early phases of large-scale renovation projects (Jensen & Maslesa, 2013). The weighting is based on the stakeholders' subjective evaluation. As with the Total Value Model, the model focuses on process-related issues in an interdisciplinary project. The implications on the perceived spatial quality is assessed under the subsection "product" through attention to e.g. indoor climate and comfort. However, the qualitative aspects of "Architecture and aesthetics" are not further elaborated. (Figure 6).

Figure 29: Top: indicators relative to process and social, environmental and economic sustainability. bottom: timeline.

3.7 Arkitektur, energi, renovering (architecture, energy, renovation)
