The concept was developed in 2013 by SBi in collaboration with Henning Larsen Architects. The aim was to create a design guide for architects and engineers, for the early design phase. The guide is based on the understanding that a holistic approach to renovation in terms of energy, daylight and indoor climate should also provide added functional, architectural and/or financial value. The guide is divided into three typologies: single-family houses, multi-storey dwellings and offices, and provides simple tools, suggestions for strategies and cases, which exemplify added value (Marsh et al, 2013). In general, there is an even distribution of indicators. When zooming in on the architectural indicator, the recommendations appear to be less explicit, e.g. the strategy “improved spatiality” (Marsh et al., 2013) and (Hvejsel et al., 2015). (Figure 7).

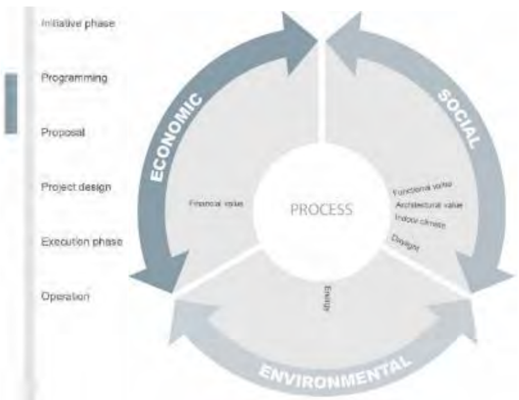

Figure 30: Top: indicators relative to process and social, environmental and economic sustainability. bottom: timeline.

4. FINDINGS AND DISCUSSION

In section 3, we have presented a review of 7 assessment methodologies. This section presents a synthesis and discussion of the findings in the review. The circle diagrams in each subsection of section 3 have served to illustrate that the methodologies address different sustainability indicators. For instance, AktivHus puts emphasis on environmental indicators and indoor climate, whereas the SAVE-methodology emphasizes culture-historical indicators. The RENO-EVALUE methodology has a strong weighting of building process indicators, just to mention a few differences. As such, the diagrams serve to indicate that ‘holism’ is a relative term. Despite the fact that many of the methodologies are characterised as holistic by the developers (e.g. AktivHusDanmark, 2015 and Schunck et al., 2011), not all methodologies address *social, economic* and *environmental* sustainability as well as process-related aspects equally. This supports the initial hypothesis that the models themselves represent a stance on sustainability, which may affect the decision-making process and ultimately the outcome of the renovation project.

In Figure 8 the methodologies are positioned relative to each other. Along the “y-axis” we introduce a scale spanning from discipline specific tools with a delimited focus, e.g. preservation value or energy reduction, to holistic tools in the understanding that they consider *social, economic* and *environmental* and process-related aspects evenly. Along the “x-axis” we introduce a scale spanning from “design guide/process oriented” to ”certification system", which serves to illustrate that the methodologies are targeted different stages of a renovation process. E.g., the TotalValueModel has a strong focus on project management in the initial phases of a renovation process, whereas DGNB serves as an elaborate certification tool, which can be viewed as less operable on the initial phases of a project.

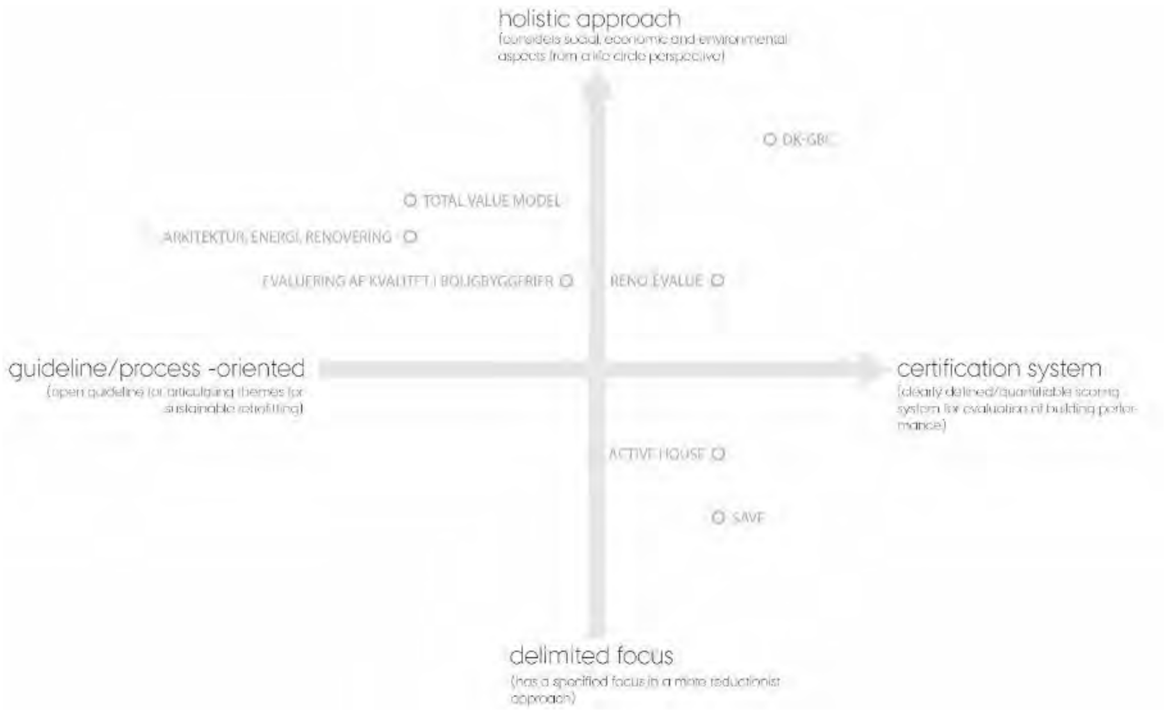

Figure 31: Graphical positioning of the studied methodologies for sustainable retrofitting.

If we 'zoom in' and address the methodologies with specific attention to the socio-cultural sustainability indicators, we see a general challenge in the methodologies when it comes to addressing the spatial consequences of technical initiatives in the early phases of a renovation process. It is well recognized that transformation towards a more energy-efficient building mass involves radical changes to the existing built environment, and thus potentially affects the perceived spatial quality amongst occupants (Acre & Wyckmans, 2015) (Beim & Madsen, 2015) (Hvejsel et al., 2015). A simplified example could be how an added mechanical ventilation system affects the height of a space, thus potentially affecting the perceived spatiality and access of daylight. Or how an added layer of exterior insulation may negatively affect the experienced coherence of a building to its neighbors from a culture-historical point of view. The other way around renovation processes may represent an opportunity to introduce new spatial qualities, e.g. improved access to private outdoor areas, which can help improve the receptiveness towards renovation amongst the residents of a building block. However, the 'soft' character of spatial quality is difficult to quantify, and, it seems, therefore more difficult to 'operationalize' as a part of the assessment methodologies on equal terms with e.g. indoor climate indicators. The methodology 'Evaluation of quality in housing' has a developed system for addressing spatial quality. However, the methodology has not gained currency – perhaps due to the complexity in use (Beim & Madsen, 2015). The methodology "Architecture, Energy, Renovation" on the other hand, is more readily accessible in the early stages of a project, but could be developed further to include more explicit strategies for addressing aspects related to spatial quality.

As such, the findings of this paper indicate a gap in the existing assessment practice. This indication is in line with the main findings of the report "*Værdiskabelse i bygningsrenovering*" (value creation in building renovation) by Centre for Industrialized Architecture in Copenhagen. In the report, Beim and Madsen stress the necessity of qualifying and describing the qualitative values about aesthetic, cultural and social values, in order for them to be addressed on equal terms with quantitative data (Beim & Madsen, 2015). This forms the outset for further studies in the RE-VALUE project, in which the theme will be explored through concrete case studies; firstly in a school renovation project in Copenhagen and secondly in a residential renovation project in Aarhus. The results of these case studies will provide insights into how to address qualitative, spatial aspects of energy renovations as part of a holistic approach to architectural transformation.

ABSTRACT

The transformation of urban building-stocks is fundamental to achieve climate change mitigation targets. As the rate of renewal of the building-stock is low, energy efficiency measures need to be applied when renovation is being done. To evaluate the renovation potential of the existing building stock on an urban level, a local approach is needed to understand challenges and possibilities associated with its transformation. The aim of this study is to investigate the renovation needs and potentials for implementation of energy efficiency measures in relation to owner and type of ownership for the buildings. For this purpose, available databases containing building-specific information have been gathered and processed for the multi-family building stock of the city of Gothenburg, Sweden. These data sources are used to describe the energy performance of the stock and future renovation needs based on type of property ownership while considering the location and context of the buildings using geographic information systems. Building attributes such as year of construction, value year, property owner, geometric data and energy performance certificates are spatially linked and visualized to describe the energy performance of buildings and its relation to renovation need, providing detailed and valuable information to property owners. Buildings from the period 1960 - 1975 are of particular importance as they constitute 42% of the multi-family building stock, have the highest average energy use (146 kWh/m^2/year) and have to a large extent not been renovated. The municipality's housing company own 36 % of the total stock and even more so considering buildings from this period. While there will be a significant challenge in renovating their stock, this also presents an opportunity for large reductions in energy use. By incorporating building-specific information and considering the building in its local setting, a more holistic and realistic view on energy saving potentials can be achieved. The results aim to support owners of larger property portfolios in prioritizing buildings suitable for renovation.

Keywords: multi-building perspective, refurbishment, energy efficiency, GIS

1. INTRODUCTION

Buildings account for about 40 % of the final energy use and 36 % of CO_2-emissions in Europe (BPIE, 2011). At the same time, they provide a possibility for cost-efficient energy efficiency measures (EEM) (IPCC, 2014). The European Energy Performance of Buildings Directive defines efficiency standards for both new and existing buildings targeting these efficiency opportunities (EU, 2010, EC, 2002). The Swedish government has similarly set policy which strives for substantial reductions in energy use by 2020 and 2050 (SOU 2005, Swedish Government, 2009). In order to encourage energy efficiency in buildings, energy performance certificates (EPC) were introduced in Sweden in 2006 as a result of the EU energy efficiency directive (EC, 2002). On a municipality and city level, more ambitious targets on energy savings have voluntarily been adopted. The city of Gothenburg has implemented such targets and aims to reduce energy consumption in residential buildings by 30 % by 2020 compared to 1995 levels (City of Gothenburg, 2009). For developed countries, it is estimated that most of the buildings that will be in use in 2050 have already been built (U.N.E.P sbci, 2009) and the renewal rate of the Swedish residential stock is only 0.6% (Boverket, 2014), which implies a need for EEM in the existing stock if the above-mentioned targets are to be met.

In order to evaluate the renovation potential of the existing building stock on an urban level, a space and context specific approach is needed to understand challenges and possibilities associated with its transformation. By using building-specific information and considering the building in its setting, a better overview can be achieved (Thuvander et al., 2015). In Sweden, there are several data sources available with attribute data on buildings such as EPC, the building and property register as well as cadastral maps. It is important to note that Swedish EPC contain information on measured energy performance and not calculated energy performance. As these datasets contain information on spatial location, it is possible to combine the different data sources for individual buildings using geographic information systems (GIS). Since the property register also contains information about ownership, it is possible to not only aggregate building information to spatial units such as districts or neighbourhoods but also for individual property owners. Furthermore, information regarding the economic extent of past refurbishment activities is known which better enables the analysis of future renovation needs.

The purpose of this paper is to describe the renovation need and related potential for energy savings for the urban housing stock of the city of Gothenburg.

2. MATERIALS AND METHODS

The renovation need is identified for the MFB stock in the city of Gothenburg considering previous renovation activities, energy performance of buildings and ownership. Available databases for the building-stock of the city of Gothenburg are gathered and spatially linked using GIS software ArcGIS (Table 1). The extent of the renovation need until 2025 considering a service-life of 50 years is evaluated both spatially and graphically for different housing owners, managers and types of ownership. A service-life of 50 years is commonly used in renovation studies for Sweden (Mangold et al., 2016).

Data were retrieved from the Swedish Mapping, Cadastral and Land Registration Authority (Lantmäteriet), the National Board of Housing, Building and Planning (Boverket) and the City planning office of Gothenburg. Table 1 shows the building specific databases available for the city of Gothenburg, level of aggregation, the most relevant information they contain, and the identifier for the spatial linkage.

Database/ Data owner	Aggregation level	N	Relevant information	Identifier
The building register	Building	153 000	Building type, construction year, value year and renovation year	Building ID, Property ID, mid-point coordinates
The property register	Property	114 000	Property owner, % owned	Property ID
National EPC database	Building	6 320	Energy use, HVAC systems, energy performance, heated floor area, number of stories, number of apartments	Building ID
Cadastral maps/ City planning office	Building	178 000	2D, 3D (roofs)	Coordinates

Table 1: Building specific databases available for the city of Gothenburg, level of aggregation, and number of posts (N) for the city of Gothenburg, the most relevant information contained, and the identifier for the spatial linkage.

The Swedish Mapping, Cadastral and Land Registration Authority supplied parts of the property register, specifically the provided the building register (50A) and the register of property owners (42P). The building register contains information on building type, year of construction, year of renovation and value year. The value year is calculated based on the year of construction and year of renovation and weighted depending on the economic extent of previous renovation measures. As such it can be used to assess the remaining life-time of a building and to assess the cost of previous renovation activities (Mangold et al., 2016). Table 2 and Equation 1 describes how the Swedish Tax Office requires a renovation to be registered as a change in value year (Swedish Tax Office, 2012).

Renovation cost	Calculation of value year
Less than 20 % of new building cost	No change in value year
20-70 % of new building cost	The value year is set based on Equation 1
More than 70 % of new building cost	The value year is set to the year of renovation

Table 2: Swedish Tax Office's requirements for registration of a renovation as a change in value year (Swedish Tax Office, 2012).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

$$\frac{(Value\ year - Construction\ year)}{Renovation\ year - construction\ year} = \frac{Renovation\ cost}{New\ construction\ cost}$$

Equation 1

The National Board of Housing, Building and Planning supplied all EPC for the city of Gothenburg. The Swedish EPC are unique in that they not only contain valuable information on characteristics of the buildings such as heating, ventilation and cooling system but also measured energy use for space heating (SH), domestic hot-water (DHW), and non-domestic electricity use. However, the Swedish EPC also suffers from some drawbacks. While the energy performance is given separately for SH, DHW and non-domestic electricity use, it is rarely measured separately but rather subdivided by the energy expert issuing the certificate. Similarly, the heated floor area (HFA) is rarely measured but rather derived based on the living area. More information on the Swedish EPC and suggestions on how to overcome issues of deriving the HFA on a stock level have been done by Mangold et al., (2015).

From the City planning office, GIS shape files in 2D were provided for the footprints of the buildings as well as outlines of two different levels of statistical/ administrative areas, base areas and primary areas. The datasets are combined based on the identifiers as follows. The EPC are connected to the property register using the building ID and the register of property owners is connected to the building register using the property ID. Coordinates are used to connect these datasets to each individual footprint in the 2D-map of Gothenburg. As not all EPC contain the correct identifier, 5 901 of the 6 320 EPC are spatially linked to footprints. The HFA from the full set of EPC decreases from 17 500 000 m² to 15 900 000 m² for the information that can be spatially linked to individual buildings.

3. RESULTS

Figure 1 shows the measured energy use (in total for SH, DHW and non-domestic electricity use) for the MFB stock in Gothenburg. It is divided into age-groups, i.e. year of construction, with their associated share of the total HFA. As can be seen, the energy performance is quite even for the stock up until 1980. The sharp decline in energy use in the building-stock occurring during the 1980s can be explained by more stringent demands on U-values being introduced in 1975. Figure 2 shows the distribution of HFA in the MFB stock divided by property owner, property manager or owner type. The municipal housing company (Framtiden AB) owns about a third (36%) of the stock with another third (33%) being private housing cooperatives. The two largest private housing cooperative managers, HSB and Riksbyggen, are presented separately. The last third of the stock is owned by private owners, individuals, foundations and others where the last category includes estates and non-profit organisations.

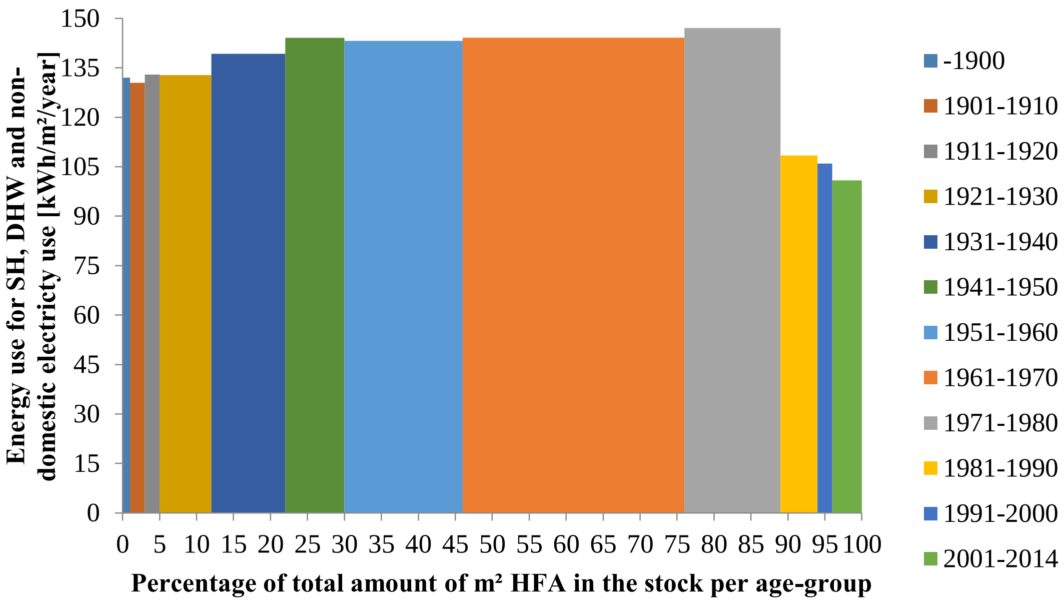

Figure 1: Measured energy use for the MFB stock in Gothenburg by age-groups. HFA, heated floor area.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

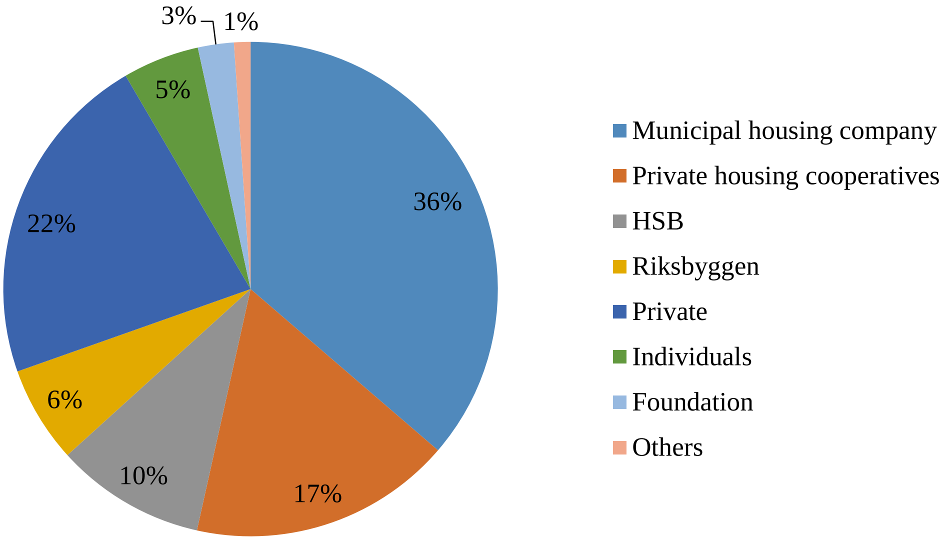

Figure 2: Shows the distribution of HFA in the MFB stock divided by property owner, property manager or owner type.

Figure 3 shows the spatial distribution for primary areas of the sum of m² HFA in need of renovation. On the left, all buildings in the MFB stock are included and on the right, buildings from the period (1960 - 1975), are highlighted. These buildings are of particular importance as they constitute the largest part of the stock (42% of all HFA) and have the highest average energy use (146 kWh/m²/year). Unlike buildings from earlier time-periods, these buildings have to a large extent never gone through a major renovation. The buildings from this period are nearing the end of their service-life and require renovation in the coming decade.

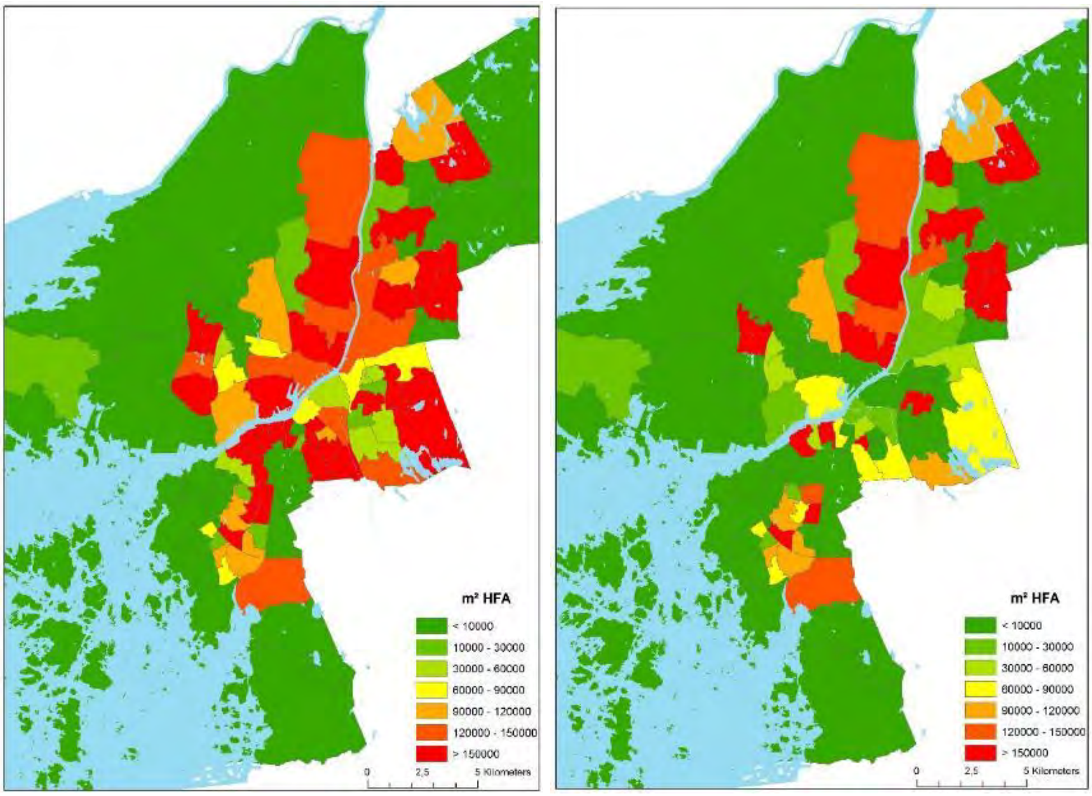

Figure 3: Shows the spatial distribution for primary areas of the sum of m² HFA in need of renovation. On the left, all buildings in the MFB stock are included and on the right, buildings from the period (1960-1975), are highlighted.

Figure 4 shows the share of the stock of the different property owners, managers and owner types that will reach a service-life of 50 years until 2025. It is clear that the renovation need will be substantial as most building owners will need to renovate more than 50 % of their total stock. In total, almost 10 000 000 m^2 of HFA requires renovation using the assumption of a service-life of 50 years. While a service-life of 50 years may be representative for certain building components, it is likely that other components will have a longer life-span. This is also likely to be impacted by the maintenance of the buildings which may vary significantly between different building owners and managers. The highest renovation need can be found in the group of individuals who owns MFB. The municipal housing company, Framtiden AB, have a slightly lower renovation need than private owners on average. The private housing cooperatives managed by HSB and Riksbyggen have a substantially larger renovation need than the average housing cooperative. It should be noted that while the value year changes if the cost of renovation is more than 20 % of the cost of new construction, smaller renovations and regular maintenance which may prolong the service-life of a building significantly is not taken into account.

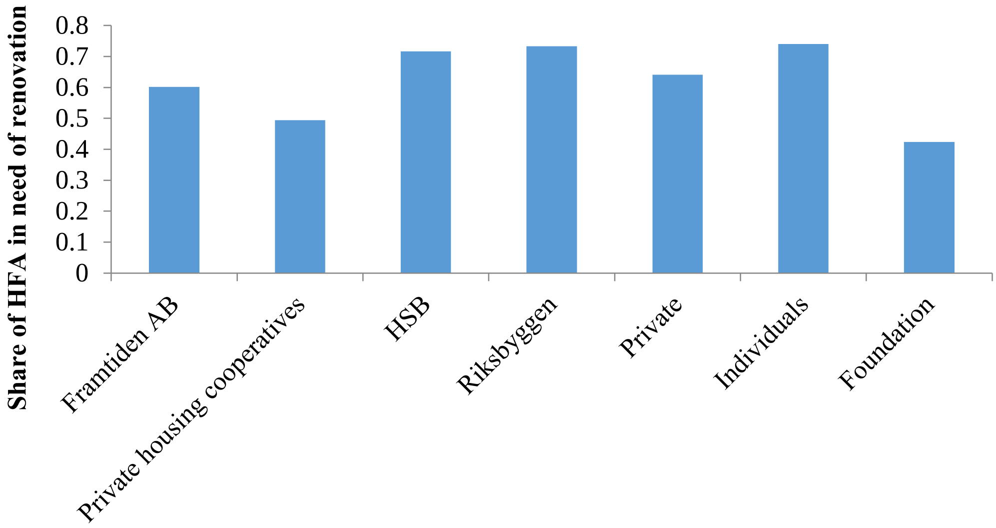

Figure 4: Share of the stock in need of renovation (normalized for total m^2 in stock) of the different property owners, managers and owner types that will reach a service-life of 50 years until 2025.

4. CONCLUSION

This paper has shown that available data sources can be used to describe the characteristics of the stock on a building level while considering the location and context. Building attributes such as year of construction, value year and owner from the Swedish Property register, spatial data provided by the City planning office of Gothenburg as well as EPC from the National Board of Housing, Building and Planning can provide detailed and valuable information to policy makers, urban planners and property owners. In this paper, the extent of refurbishment needs of the MFB stock of the city of Gothenburg has been assessed by ownership type as well as spatially. The extensive need for renovation need during the next ten years also provides an opportunity for achieving considerable reductions in energy demand. This work gives an overview of the existing renovation needs of the MFB in Gothenburg and is a starting point for the development of renovation strategies. Future work on renovation needs should expand the parameters used to describe the composition and state of the stock.

ABSTRACT

Sustainability paradigm foresees a balance of energy production and consumption with no, or minimal, negative impact on environment (within the environmental tolerance limits). It gives an opportunity to a country to employ its potentiality of the social and economic activities. An overview of recent researches about building renovation context demonstrates the lack of an appropriate methodology and decision support framework -by compounding the typical challenges of sustainable retrofitting from theory to implement stages- that takes into account the retrofitting projects throughout more comprehensive insights and perspectives. It calls, therefore, for a deep building renovation approach. The major difference between a deep building renovation project and an ordinary one is commitment to a holistic approach. From one side, it initially should be able to deal with the society including various stakeholders with different priorities and barriers -on the top of the list is behavioral barriers about energy consumption- in order to improve their learning; to the other side, it has to perform multiple optimization through sustainability development perspective in its full sense. The intent is to identify, manage, and evaluate the renovation objectives through different available retrofitting alternatives during the early design stages. In this framework, the paper considers building renovation as a complex messy/wicked problem and later it gives details on how combinations of methods that are parts of SSM (Soft Systems Methodologies) and MCDM (Multi Criteria Decision Making) may support multiple perspectives of such a problem. The aim is to promote a methodology which is initially able to deal with complexity of the detected problem and subsequently to address building renovation process in order to involve the various stakeholders in the design process [and keep them involved in all design stages]. Doing so leads to more effective and sustainable retrofitting actions within different criteria including functionality, feasibility, and accountability.

Keywords: sustainable retrofitting, deep building renovation, holistic methodology

1. INTRODUCTION

Enhancing energy efficiency is not the only goal for renovation of the existing buildings. The main objective has to be creating a high-performance building via application of the holistic and integrated design process, to the project during design stages which makes sure all design goals are met. In modern age and so rising complexity, the extent of this potential can be described and made up in several ways and this can happen with focus on climatic interests, security of supplies, environmental impacts, life-cycle cost, indoor climate, building functionality, spatial quality issues and other relevant arguments (Kamari et al., 2016). To achieve overall sustainability in this regard, these factors must be taken into consideration all together in order to gain "sustained prosperity". But a logical question arises: how can the design team address this complexity among different objectives (?) which itself is methodological issue where the present study as part of a bigger project called RE-VALUE makes effort to deal with. The attempts here is on the development of a holistic methodology to address retrofitting context in order to keep the different stakeholders involved in the process and carrying out a real sustainable retrofitting based on multiple criteria in its totality. Doing so means it deals with the overall objective of the RE-VALUE project (within its macro scale) which is to develop and demonstrate the validity of a generic renovation assessment method within an integrated design schema. For this reason, the present paper primarily (see section 2.1) provides information about the general barriers and challenges in retrofitting context towards formulation of the research problem in section 2.2 that states the main objective of this research project. Later in section 3, it identifies the reasons for the suitability of SSM and MCDM in order to promote a holistic multi-methodology (Mingers et al., 1997) through mixing

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

certain SSM and MCDM that practically able to implement a sustainable retrofitting and overcome existing barriers in actual situation.

2. THE NATURE OF THE PROBLEMS IN SUSTAINABLE RETROFITTING CONTEXT

2.1 Barriers and challenges in retrofitting process

Experience over several decades has demonstrated numerous barriers that hinder the uptake of renovation measures. Having overall view over the sustainable retrofitting context reveals the existence of various barriers based on buildings functions and usage, features, environment and society in the bigger scale (BPIE, 2011). Booth et al. (2013) argue the barriers into the most usual ones as “Pre-bound effect” - which is the divergence between modelled and actual energy consumption for the pre-retrofit -, and “Rebound effect” in which the post-retrofit energy consumption is higher than predicted, due to changes in occupant behaviour following the installation of a measure. For the space reason it seems essential to summarize following discussion; therefore, within a more sustainable and holistic vision, the barriers in this context have been examined and classified in a more precise way by BPIE (2011) throughout “Financial”, “Institutional and Administrative”, “Awareness, advice and skills” and “Separation of expenditure and benefit”. In this regard, the challenges were identified as the main risks which need to be addressed for market uptake within Supply chain, Quality of workmanship, Technical failure, and Disturbance.

2.2 Problem statement and research objective

This section tries to zoom out and seeks for common patterns in order to formulate and simplify above issues into a few main trends so as to deal with the existing complexity through some of their principles and components. In retrofitting context from one side a common reason for many of existing barriers is the necessity of involvement or dealing with its humane society and so lack of learning. In other side there are different criteria or objective which derives into project based on sustainable perspective [as source of Holism] which need to be optimized within a multiple optimization process. Hence it is looked not just as a technical problem but as a socio-technical problem; in this regard we refer word ‘society’ to the community of different stakeholders who are involved in retrofitting process (see Figure 1), and also word ‘technical’ for sustainable aspects of the retrofitting and its various alternatives (see Figure 2). It also has to be noted that the technical part in this model itself has a holistic insight in connection with three pillars of sustainability.

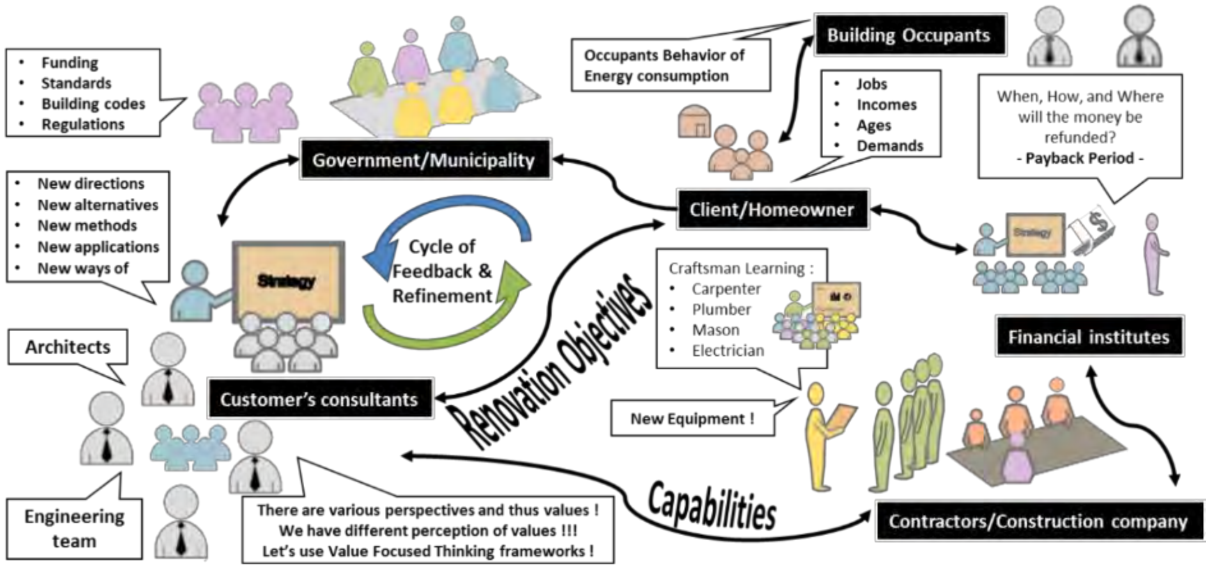

Figure 32: Different stakeholders involved in building renovation context

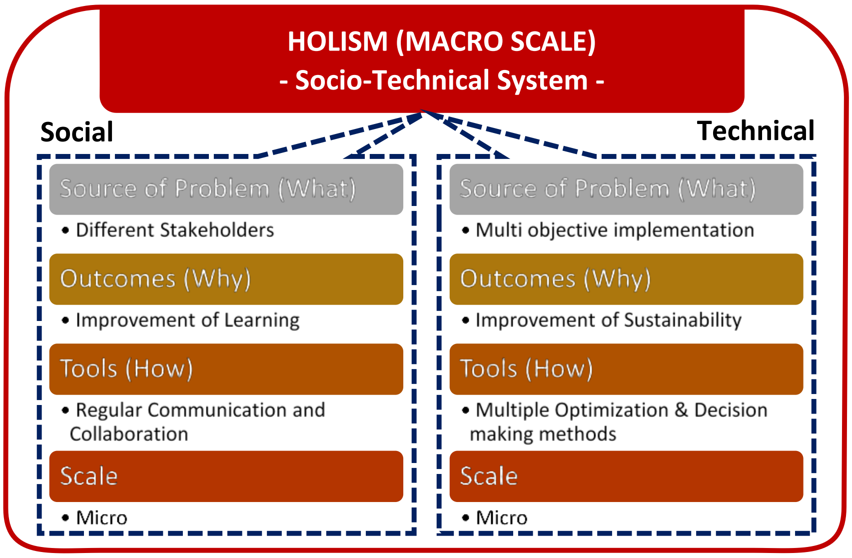

Figure 33: Concept of Holism in retrofitting context

A recent review on existing assessment tools related to building renovation, highlights that 'holism' in relation to building renovation is not an unequivocal quantity. The tools represent a number of different approaches to holism, giving weight to different sustainability indicators (Jensen et al., 2016). The included tools span from process management tools to certification schemes and from a delimited focus to a more evenly weighting of the three sustainability indicators. The major number of the present tools and methodologies are not able to fully address non-technical values alongside quantitative values, especially in relation to social sustainability indicators in aforementioned context.

A retrofitting problem is a complex system because it cannot be fully addressed and evaluated without comprehension of the relationships between its technical objectives and society as well as the influences of its development impact on its environment and world (its neighbors and city in a bigger scale) as whole. Therefore the architects/designer should not only unravel a well technical problem examination, but formulate the problem based on the present circumstances once they begin another. This issue is equivalent from many views to the problems which known as messy/wicked problems. The phrase 'wicked problems' (Churchman, 1967) were originally used in the context of social planning and it used to demonstrate problems that were difficult to overcome, since they address complex social interdependencies. There are at least two attributes of the wicked nature of problems; initially it is difficult to formulate solutions, because of the complexity of a socio-cultural interactions and interdependencies which it happens in; this leads to the inability to foretell long-term effects of decisions since the recognition of the source of the problem is highly complicated. Secondarily the definition of objectives due to various circumstances is provisional, and it entails different features, ideas and interests (Estkowski, 2013). Similarly the characteristics of the concern problems in retrofitting discipline involves many qualitative and quantitative factors and criteria that are provisional case to case. In other words, the alternative solutions for an existing building frequently cannot be applied for others due to the changes in environmental circumstances and various decision makers including customers, designers etc. In this perspective its nature is quite similar the problems discussed above as messy/wicked problems. Therefore the practical needs for improvement in this context is calling for new approaches.

In summary then, the decision regarding retrofitting of existing building is initially a highly complex problem subjected to lack of an appropriate methodology and decision support tool to influence its society and technical part simultaneously. It means the methodology should take retrofitting projects into the consideration, initially in order to address its wicked nature resulting by 'Learning Improvement' among the stakeholders and then 'Multiple Optimization' through identify, manage, and evaluate the building objectives among the different renovation criteria and retrofitting alternatives with a holistic vision (subject to the macro scale - see Figure 2) regarding to functionality, feasibility, accountability, or sustainability in its full sense (Kamari et al., 2016). This explanation informs the next section of the present paper in order to detect the existing methodologies which are able to deal with complexity in retrofitting context and hence gives a short description on the suitability of SSM and MCDM towards proposing a qualified methodology which is structured within mix of methods.

3. DEVELOPING A HOLISTIC METHODOLOGY IN SUSTAINABLE RETROFITTING

3.3 Appropriateness of soft systems methodology (SSM)

SSM was developed by Peter Checkland in 1970s at Department of Systems, University of Lancaster. The SSM approach stems from the 'systems movement', which Checkland (1999) considers as an effort to give holistic approaches in socio-technical problems. It is a method that in a systematic way attempts to establish and framework a debate regarding actions for enhancing the complex and messy situations. Maqsood et al. (2001) describe it as a framework for iterative enquiry and learning about the organization which provides a well-defined action research approach to help address wicked problems. The concept of SSM has been explained more in details by Checkland (2000); he has referenced SSM in an evolutionary path primarily defined as 'seven stages model (1981)' and being developed through 'two main stream approach (1988)' and finally concluded by 'four main activity research method (1990)'. SSM through the last updated approach (four main activity) encourages group learning and is ideal as a group decision-making approach. It is strengthened by the active participants and stakeholders, and encourages joint ownership of the problem solving process. Eventually, SSM is recommended where an organization is seeking to achieve changes in workplace culture and transformation into a learning organization (Rose, 1997). In this perspective using SSM in building renovation context being able to develop an integrated design process which keeps the society involved in all the design stages. It is able to deal with complexity, capture it and communicate it among the key players. Therefore it enables us to address major part of the problem formulated in section 2.2.

3.4 Appropriateness of multiple criteria decision making (MCDM)

MCDM is a sub-discipline of operations research. It has been developed to help decision makers throughout complex decision analysis. The term 'decision analysis' can be explained as a body of knowledge and professional practice for the logical shining of decision problems. Parnell et al. (2013) discuss it as "a philosophy and a social-technical process to create value for decision makers and stakeholders facing difficult decisions involving multiple stakeholders, multiple (possibly conflicting) objectives, complex alternatives, important uncertainties, and significant consequences. Decision analysis is founded on an axiomatic decision theory and uses insights from the study of decision making". In this regard the term MCDM defines as decision analysis involving multiple criteria. The purpose is to support decision-makers facing complex problems based different aims and objectives. According to the reviewed literatures, MCDM is categorized into two main sub-group, Multi-Objective Decision Making (or MODM) and Multi-Attribute Decision Making (or MADM). MODM studies decision problems in which the decision space is continuous. MCDM can be applied in building renovation (Phdungsilp et al., 2004) context through both MODM and MADM and as such being able to equip the design process to primarily deal with existing complexity and different criteria driven from a sustainable perspective.

2.3 Mixing SSM with MCDM

The utilization of different approaches from different methodologies and domains is not a new concept and there are researchers who have put it into the consideration theoretically and also exploited it practically in the past (Jackson, 2003). It is another way of strengthening the Multiple Perspectives view of the complex problems due to the inefficiency of traditional approaches to confront the actual situation. Similarly, the needs for retrofitting context within different situations was considered diverse and complex and thus could not be served by a single methodology; for this reason present section tries to justify use of mixing methods including SSM and MCDM in retrofitting context. It needs to be addressed primarily through their potential benefits and individual lacks in facing a complex problem and secondarily from the dimension/shape of the formulated problem earlier.

The potential of using methodologies such as SSM or MCDM [in addition to preceding sections 3.1 & 3.2] can be considered from their vast application in other complex domain or over developing more complex products; above all, the availability of the various tools and software in making and implementation of decisions in using SSM or MCDM is the other reason that increases their appeals. However, according to the reviewed literatures the most important weakness regarding to SSM is the lack of support given by it during the Selection and Implementation phases and for MCDM it is in problem exploration and structuring stage which relies for the definition of the model only on brainstorming (Jayaratna, 1994). Petkove et al. (1997) underline that it should not be viewed as a rejection of these techniques as a systems science tool. On the contrary, on the basis of Critical Systems Thinking one can find a common foundation for the complementarist use of MCDM techniques with soft systems approaches

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

belonging to the field of problem structuring methods. The authors conclude that there is considerable scope for new and fruitful combined application of MCDM method with different strands of systems thinking and the result enriching both. By use of multiple methods [according to sections 3.1, 3.2, and 3.3], the formulated problem in retrofitting context on one side is fitted to be addressed where we need a regular communication, collaboration and brainstorming among the stakeholders in order to promote learning and participation in a bottom up way by using SSM; and on the other side the criteria can be selected, weighted, and balanced in order to choose the most appropriate retrofitting alternative into a sustainable perspective in using MCDM. As a result of this interventions, the stakeholders can concentrate on building a common appreciation about the most essential issues corresponding to the technical, cultural and political aspects of the problems on hand. Moreover it propel better informed management decision related to the particular situation.

4. The proposed holistic step by step methodology in sustainable retrofitting

The preceding discussions provided indications for developing a methodology including mix of methods. The question then arises how techniques are selected and considered suitable for specific tasks. There are assumption of the various methodologies in order to justify choice of the methods (Mingers et al., 1997; Vo et al., 2001; Jackson, 2003; Petkove et al., 2007) and for the space reason we have to just refer to their works. Comprehensive overview of the methods and approaches belonging SSM and MCDM revealed the suitable methodology and methods which can be exploited in retrofitting context. They were identified through the guidelines provided from cited research works, mapping of the selected methods onto the world of building renovation and inclusion of key players in the problem solving frameworks (see Table 1).

Stage 1	**Finding out about a problem situation, including culturally/politically**	
	Step 1	Problem formulation
	Step 2	Selecting the main design criteria and sub-criteria
	Step 3	Developing measurement scales for the sub-criteria
	Proposed methods: Root definition, Rich picture, CATWOE, PQR (What, How, Why), and Delphi method [03,04,20]	
Stage 2	**Formulating some relevant purposeful activity models**	
	Step 4	Generating alternative solutions
	Proposed methods: Process modeling in SSM [04,15,21]	
Stage 3	**Debating the situation, using the models, seeking from that debate both a) changes which would improve the situation and are regarded as both desirable and (culturally) feasible b) the accommodations between conflicting interests which will enable action to improve to be taken**	
	Step 5	Weighing the main criteria and sub-criteria
	Proposed methods: POT or SAST + Pairwise comparison and/or TOPSIS and/or AHP [12,13,15,19,20]	
Stage 4	**Taking action in the situation to bring about improvement**	
	Step 6	Predicting performance
	Step 7	Aggregating scores
	Step 8	Analyzing results and making decisions
	Proposed methods: AHP and/or TOPSIS [13,20]	

Table 1: Holistic step by step methodology in sustainable retrofitting

The major framework of the above methodology has been developed from “four main activity approach in SSM”; the original methodology can be described as a four main activities process of analysis which uses the concept of a human activity system as a means of getting from “finding out” about a situation to “taking action” and improve the situation (Checkland, 2000). There also eight steps have been outlined that facilitates the avail of the methodology step by step. For each stage the required methods from SSM and MCDM have also been identified; although there is no space in this paper to discuss them one by one but instead the references have been provided to them for further studies.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

5. CONCLUSION

The significant discrepancy in a deep building renovation and an ordinary one is a commitment to holistic approach. Looking at a project holistically for potential energy savings invariably means using an integrated design process. It is then developing a design process which explores the interdependency between different building systems and renovation goals towards achieving sustained prosperity at the end of the day. This paper explored the nature of the problem in retrofitting context as a highly complex and socio-technical system and subsequently investigated and addressed the concept of Holism. It represented a methodology throughout mixing some certain SSM and MCDM in order to support decision-making process. Following the outlined methodology can overcome the problem formulated in earlier section (see section 2.2) based on the nature and mechanism of the methods which are applied in there. It is initially able to deal with the existing complexity and wicked nature of the problem in building renovation domain and subsequently to address the present issues throughout its society (subjects to improve the building occupants' learning) and technical part (subjects to sustainability in it full sense) simultaneously. However the concept of the using mix of methods in retrofitting context stands on the beginning of its path and to utilize the full potential of this concept it needs to be tested in various circumstances and uses of different methods. "Using a multi-methodology reflects the conflicting nature of the criteria guiding decision makers in complex situations and harness their potential to support learning about the problem and more effective decision support", adopted from Petkov et al. (2007).

ABSTRACT

European countries face a large challenge in retrofitting their aging building stock, which they need to embark on, in order to reach European Union (EU) energy and emission reduction targets. Despite significant policy interventions, refurbishment rates remain low and the refurbishments that are carried out often do not meet the energy savings targeted by the EU, for example nearly Zero-Energy Building standards (nZEB). One of the key reasons for the lower than expected energy savings is that current refurbishment approaches tend to focus predominantly on energy efficiency improvements for individual buildings. The integrated energy systems perspective that can be leveraged at a multi-building scale – and is related to possible interactions between building sizes, scales, and the different systems – is not taken into consideration in most refurbishment concepts. The result are suboptimal renovation solutions which do not reach the full energy demand reduction potential of the refurbished building(s).

This paper introduces a methodology for a tool that aims to develop economically and environmentally optimal nZEB refurbishment concepts for multi-building scale refurbishment actions. Increasing the scale of a refurbishment from a single building to a multiple building, or even a building portfolio, will allow to generate economies of scale (both for solution and workforce cost) and facilitate the integration of renewable energy generation. The tool applies the Lifecycle Assessment (LCA) and Lifecycle Cost Assessment (LCC) methods, which makes it possible to optimize refurbishment concepts, both with respect to economic and environmental criteria. Thanks to a multidimensional optimization approach, based on an evolutionary algorithm that can automatically find the Pareto-boarder for a given design space, Pareto-optimal refurbishment concepts are generated. Refurbishment options presented this way can help housing companies prioritize refurbishment needs and actions in their building portfolios, as well as evaluate and select between different refurbishment approaches in line with overarching targets.

Keywords: multi-building perspective, refurbishment, energy efficiency, renewable energy generation, multidimensional optimization, LCA, LCC

1. INTRODUCTION

Buildings account for around 40% of the energy used in European countries. In order to increase the energy efficiency of buildings, decrease energy use and associated greenhouse gas emissions, European countries need to foster the retrofit of their building stock. This is a challenge considering the structure of the European building stock - over 35% of the buildings are more than 50 years old and therefore often do not adhere to current energy standards. The European Union has addressed this issue through the two key directives: the Energy Performance of Buildings Directive [1] and the Energy Efficiency Directive [2]. Through these directives the EU aims to introduce nearly Zero-Energy Building (nZEB) standards across all member states by 2020 and to put in place frameworks, fostering the refurbishment of the existing building stock. However, the current refurbishment rate is still stagnating at around 1% per year (opposed to the targeted 3% annually) and the majority of refurbishment actions performed so far do not meet the high energy demand reduction standard the EU aims for (i.e. nZEB standards).

Numerous decision support tools for building refurbishment exist already to help building owners and designers plan energy efficiency refurbishments. Nielsen et al. [3] and Ferreira et al. [4] give a comprehensive overview of the state of the art. They show that that the majority of the existing tools focus on the technical performance estimation of refurbishment design alternatives generated by engineers. However, tools that support the generation of refurbishment design alternatives in line with concrete quantifiable targets beyond technical requirements (e.g.

economic and environmental targets) are lacking [3]. The goal setting phase is a crucial one, as indicators used by housing companies to evaluate different refurbishment alternatives vary significantly. Some decide based on purely economic-driven return on investment. Others might focus on spending their renovation budget as effectively as possible, taking into account also political and social targets. Consequently, refurbishment concepts that are purely technically driven lead to sub-optimal solutions.

There has been a large body of research in the recent decade on the optimization of building and refurbishment design. A comprehensive overview and review is given by Evins [5]. A lot of these optimization approaches are focused predominantly on technical and not enough on the economic and environmental aspects. This is not ideal, the more so, as even economic aspects housing companies would base their decisions on vary (e.g. only Investment cost vs. life cycle costing) and the calculation frameworks applied differ as well (discount rate, life cycle timespan, etc.). Thus, even optimized refurbishment design approaches that do not take into account the possible variety of indicators within one category will lead to sub-optimal refurbishment concepts.

In addition to this, building refurbishment approaches often do not aim at scale and do not take advantage of all the possible options for nZEB refurbishment design. Especially a joint application of both energy demand reduction and on site-energy generation (e.g. through PV or CHP plants) including the energy management between the two is often not considered. Such concepts increase in viability when going from single building to a multi-building scale, where demand fluctuations are less pronounced and therefore a higher share can be covered through on-site energy generation. Moreover, increasing the scope of the building refurbishment design increases the optimization potential, both in technical and economic terms (e.g. through economies of scale). Increasing the scale can therefore help housing companies get more value for their money, as well as prioritize and plan their refurbishment actions in line with an overarching target.

In this paper we present the methodological approach taken in the DREEAM project, which aims at addressing the issues raised above by developing a tool that can be used to develop strategies for large-scale refurbishment actions. We make use of the ongoing research in building design optimization, life cycle assessment (LCA) and life cycle costing (LCC) for the development of this building refurbishment assessment tool. The suggested methodology extends the design space of refurbishment design to include both the energy demand and supply side and combines this with the application of optimization routine to be used not just to single building refurbishment design but extending it to be used as part of the refurbishment concept development on a multi-building or portfolio scale. The optimization routine can be used for a multidimensional optimization of refurbishment concepts based on stakeholder-tailored environmental and economic indicators.

2. METHODOLOGY

The DREEAM tool is based on a modular structure. The main modules are: the energy module, and indicator assessment module, the optimization module, and different databases that serve as a basis for the performed calculation (see Figure 1). Firstly, the energy module calculates the energetic performance of the buildings through the application of established norm-based calculation methods (see below for details). Secondly, the output serves the indicator assessment module as an input to generate different economic and environmental indicators. Lastly, the indicators then serve the optimization module as a basis to evaluate and optimize the different refurbishment concepts. The tool makes use of a multidimensional evolutionary optimization algorithm, which automatically generates the Pareto-boarder for a given set of indicators. The output of the optimization module is a set of overarching refurbishment concepts for all assessed buildings which make up the Pareto-boarder. Each concept is a combination of refurbishment solutions for each building and each component of these buildings which can be further evaluated by the user and from which most applicable refurbishment options can be selected.

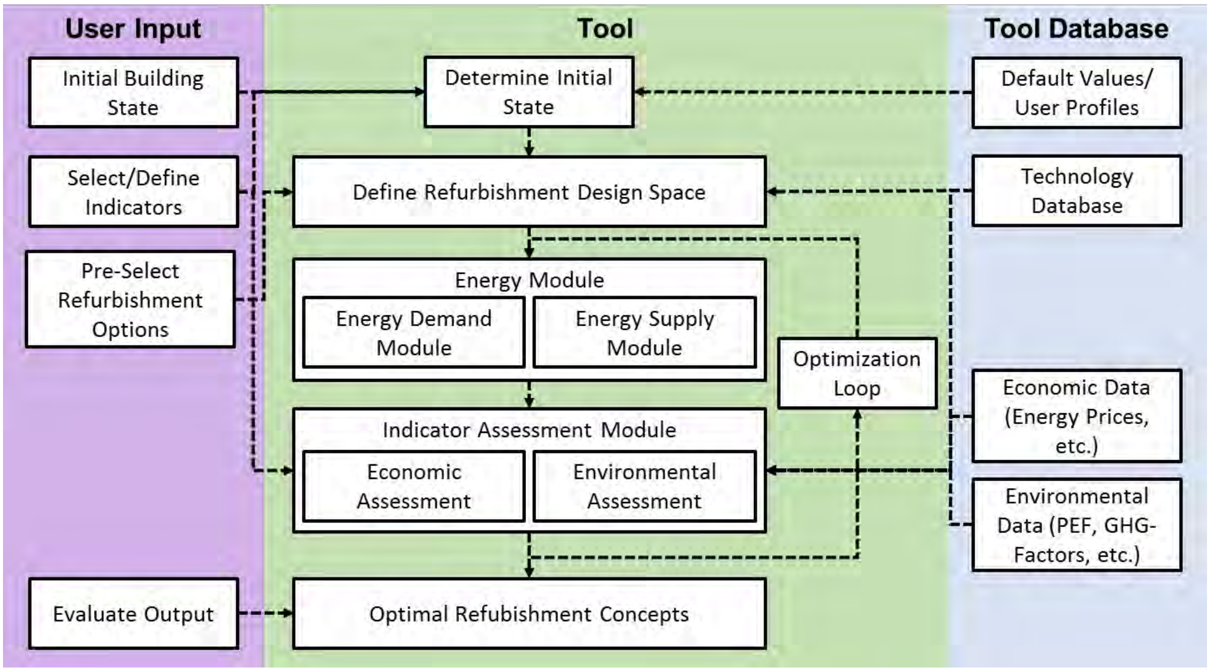

Figure 1: Overview of DREEAM-tool structure

2.1 Energy module

The energy module consists of two main sub-modules, the energy demand module and an energy supply module. The energy demand module calculates the energy demand of the buildings, based on current norms and standards (see Figure 2). The heating and cooling demand is calculated, based on the simple hourly method of the EN 13790 [6]. These standard calculation methods were chosen instead of more detailed dynamic models (e.g. EnergyPlus), due to the fact that the optimization module will have to run many iterations of the model, and the computational demand low for a single iteration should be kept low. The energy demand module is complemented with a module that calculates the on-site energy supply through photovoltaic modules or combined heat and power. Through the combination of these modules, the energy module calculates the energetic performance of the building in its current state or for a potential refurbishment alternative. The output of this module is used by the indicator assessment module to calculate the running costs and environmental impact of the building.

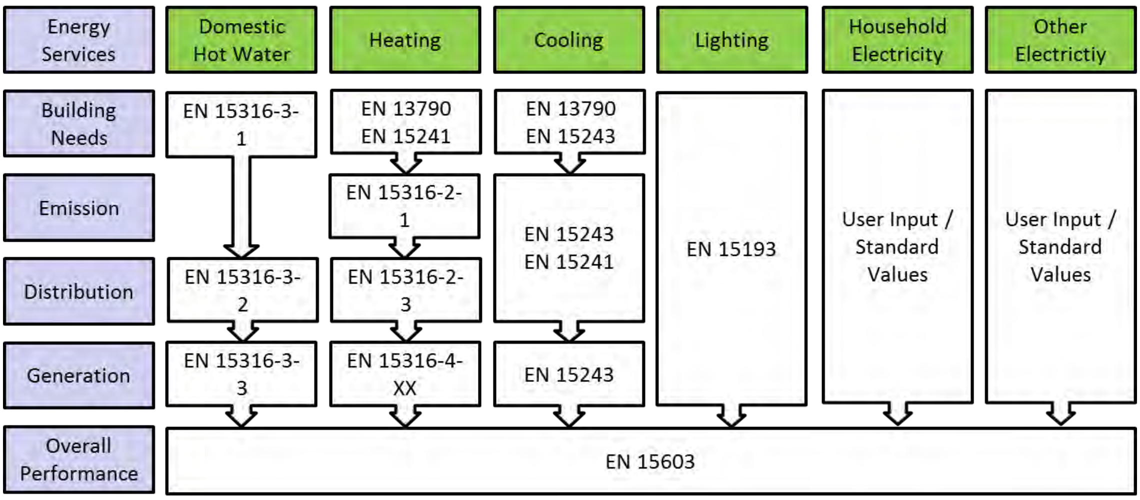

Figure 2: Overview of the building energy demand module and the European standards used for calculation

2.2 Technology database

The technology database is a key part of the tool, in that it constitutes the basis from which the refurbishment concepts can be developed. The database is structured according to the different building components and systems (see Figure 3). For each component the database lists different refurbishment solutions and for each of these solutions it then contains a detailed list of the materials and work needed to install this technology beside the technical performance data. This data is generated using national construction cost catalogues such as [7] for Sweden, [8] for Germany or [9] for Spain and France. The material information is then linked to the data from the database ecoinvent [10], so that the embodied environmental impact of the materials used is also assesses. The cost and environmental data included in the database is then used by the assessment module to assess the refurbishment solutions against economic and environmental indicators.

Building Components

Passive Components	Reference Unit
1. Outer walls against air	m² surface area
2. Outer walls against earth	m² surface area
3. Basement floor	m² surface area
4. Floors against unheated	m² surface area
5. Ceiling against unheated	m² surface area
6. Flat roof	m² surface area
7. Tilted roof	m² surface area

Figure 3: Structure of the component specific technology database listing labour and material cost

2.3 Assessment module

The assessment module generates the indicators that can be used to evaluate different refurbishment options during the optimization routine as well as evaluate the generated output of the optimization module. The assessment module is divided into two submodules, an economic assessment module and an environmental assessment module.

The economic module applies a lifecycle costing (LCC) assessment methodology based on [11], which can calculate the overall life cycle costs as well as other economic indicators such as the Return on Investment (ROI) or the Net-Present Value (NPV). The different cost components are structured according to [11] (see Figure 4). Investment costs are calculated, based on the input out of the technology database which includes labour, material and additional costs. Other costs such as professional fees (planning costs), taxes and profit margins depend on the optimization scenario and can be adapted by the user. The annual costs are calculated based on replacement and running costs. The running costs are based on operational, maintenance and energy costs. The energy costs are calculated based on energy prices included in the tool database and the output of the energy module.

The environmental assessment module applies a simplified lifecycle assessment (LCA) calculating the environmental impact of the current status of the refurbishment approach. Currently only the primary energy demand and the greenhouse gas emission are assessed. Adding further impact categories such as e.g. abiotic depletion potential (ADP) might be considered at a later stage of the tool development. The assessment is carried out by evaluating both the impact of the building use phase through the output of the energy module as well as the embodied impact in the materials. The impact of the use phase is assessed by multiplying the energy consumption with GHG-Emission and primary energy factors of the energy carrier used in the building. The embodied impact is calculated by multiplying the materials used in the refurbishment with factors from the ecoinvent database [10].

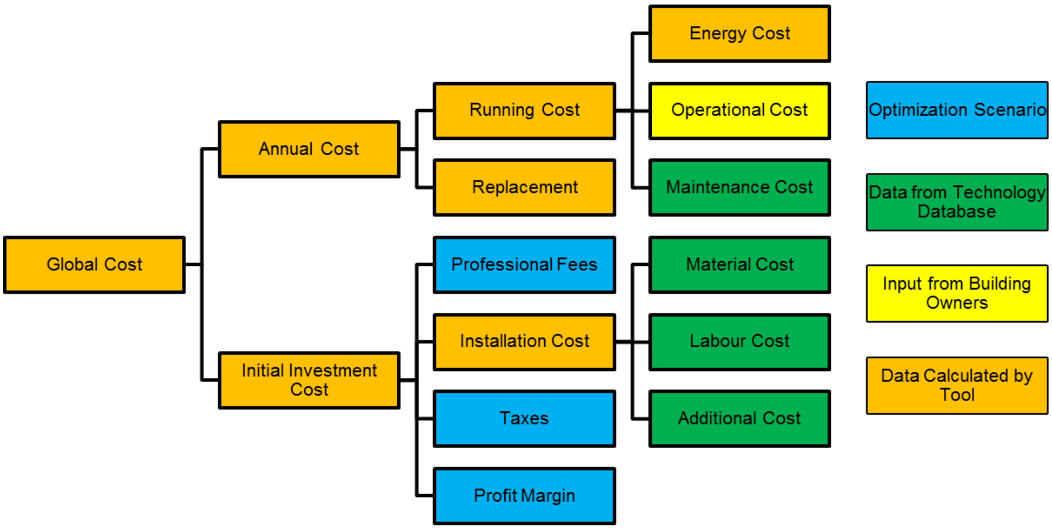

Figure 4: Cost Structure applied in the DREEAM-tool (adapted from [11])

Table 1 shows a list of currently implemented economic and environmental indicators the user can choose from. The tool has also the possibility to add new indicators based on the output of the energy module as well as currently implemented assessment indicators. Especially the combination of both environmental and economic indicators might be of interest to future users (e.g. GHG-Emission savings per Investment Cost). This enables the user to optimize the refurbishment concept beyond best economic solution and evaluate options on how to achieve additional GHG-Emission savings through additional investment. This enables the housing companies to evaluate how much additional investment is needed from subsidies or other funding sources in order to reach a given nZEB standard for their buildings.

Indicators	Calculation
Environmental Indicators	
Final Energy Demand	$E_{final} = \left(\sum_{es\,=\,energy\ service} E_{final,es} \right) - E_{production}$
Final Energy Savings	$E_{final,saving} = \frac{E_{final,SQ} - E_{final,RC}}{E_{final,SQ}}$
Electricity Production	$E_{production} = \sum_{p\,=\,production\ system} E_p$
GHG Emissions	$GHG = \sum_{ec\,=\,energy\ carrier} E_{ec} \cdot GHGF_{ec} + GHG_{embodied}$
Primary Energy	$PE_{tot} = \sum_{ec\,=\,energy\ carrier} E_{ec} \cdot PEF_{ec,tot} + PE_{embodied,tot}$ $PE_{nonrenew} = \sum_{ec\,=\,energy\ carrier} E_{ec} \cdot PEF_{ec,nonrenew} + PE_{embodied,nonrenew}$
GHG Emission Savings	$GHG_{saving} = \frac{GHG_{SQ} - GHG_{RC}}{GHG_{SQ}}$
Primary Energy Savings	$PE_{tot,saving} = \frac{PE_{tot,SQ} - PE_{tot,refurbished}}{PE_{tot,SQ}}$ $PE_{nonrenew,saving} = \frac{PE_{nonrenew,SQ} - PE_{nonrenew,RC}}{PE_{nonrenew,SQ}}$
Economic Indicators	

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Investment Costs	$C_{Investment} = C_{Material} + C_{Labour} + C_{Additional} + C_{Fees} + C_{Taxes} + C_{Margin}$
Running Costs	$C_{Running} = C_{Maintenance} + C_{Operational} + C_{Energy}$
Total Life Cycle Cost	$LCC = C_{Investment} + \sum_{t=1}^{calculation\ period} C_{Running} + C_{Replacement}$
Net Present Value	$NPV = \sum_{t=1}^{calculation\ period} \left(\frac{C_{Earnings} - C_{Running} - C_{Replacement}}{(1+r)^t}\right) - C_{Investment}$
Internal Rate of Return	$NPV = 0 = \sum_{t=1}^{calculation\ period} \left(\frac{C_{Earnings} - C_{Running} - C_{Replacement}}{(1+IRR)^t}\right) - C_{Investment}$
Return On Investment	$ROI = \frac{(C_{Earnings,SQ} - C_{Running,SQ}) - (C_{Earnings,RC} - C_{Running,RC})}{C_{Investment}}$
Cost Savings	$C_{savings} = \frac{C_{Running,SQ} - C_{Running,RC}}{C_{Running,SQ}}$

Table 1: Selection of the main Indicators currently implemented in the Tool from which the user can choose from

2.4 Optimization module

The optimization module makes use of the implementation of the evolutionary optimization algorithm NSGAII (Non-dominated Sorting Genetic Algorithm) [11]. Evolutionary algorithm's such as NSGAII are widely employed in the field of energy efficient building design [5]. The algorithm iteratively generates and evaluates different refurbishment options and thereby searches for the Pareto-boarder based on the indicators selected by the user giving as an output the solutions that make up the Pareto-boarder. A more detailed description of evolutionary optimization algorithms and how they are used in building design is given in [5]. Next to optimization objectives, the user can also define boundary conditions, which constrain the optimization routine for a component (e.g. by defining a maximum insulation thickness that can be applied to a certain component due to space limitations), between components (e.g. choosing different insulation thicknesses for connected components such as neighbouring walls) or on a building level (e.g. by defining a minimum building standard that must be reached). While some of this logic can be included in the tool, a feasibility check and selection process of the output generate by an expert will still be necessary.

3. CONCLUSION

This paper presents the initial methodological framework of the DREEAM tool which is currently being developed into a decision support tool for housing companies. The methodology is based on the integration of building energy demand modelling in combination with LCA and LCC methodologies and an optimization approach. The tool is aimed for supporting the refurbishment process in the early design stage from goal setting to generation and evaluation of aligned design alternatives through the optimization module. By designing the tool for the use on a multi-building or portfolio scale, the tool is aimed for the development of refurbishment concepts that leverages the synergies between buildings and making use of economies of scale. The generated results should therefore help housing companies develop a refurbishment strategy for multiple-buildings or even their whole portfolio.

The next steps will be to advance the development of the tool and an application in three different building sites across Europe (Sweden, Italy and UK). This development will focus on advancing the functionalities presented in this papers, generating a graphical user interface and integrating cost databases of different countries.

ABSTRACT

Regenerative design within the built environment arises from the need to shift from the current fragmented sustainability approaches of 'doing less harm', towards a whole system that actively co-evolves with the living world around us. This idea is starting to become well established in new developments, but this paper will explore how regenerative design can be applied specifically to existing buildings. A 'proactive' retrofit approach is proposed to explore how net-positive, restorative and regenerative concepts can be integrated into building retrofit design process. A regenerative design model is developed to establish a set of regenerative design principles for building retrofits. This model will enable the extraction of key interactions between physical, human and natural systems in the built environment to emphasise how a single building retrofit can positively interact with its surrounding systems. Identifying emerging technologies and building case studies to address these key interactions provides clear and practical guidance for developing a set of regenerative design principles to achieve these 'proactive' retrofit outcomes.

Keywords: design process, building retrofit, regenerative design

1. INTRODUCTION

To move beyond current 'mechanistic' approaches to sustainable design and development, du Plessis and many others suggest that we need a fundamental shift in worldview towards regeneration (du Plessis, 2012). The prevailing fragmented sustainability approaches are grounded in a technological driven mindset which reduces a system to its parts to achieve greater efficiency. The direction of current building retrofits exemplifies this by reducing a building to its components with the aim of greater cost and resource efficiency. While this has an important role within the retrofit process, Figure 1 highlights that without this fundamental transition towards regeneration, it is impossible to go beyond simply slowing the rate of depletion of degradation (Mang & Reed, 2012). Making this transition requires moving away from fear-based approaches with a focus on scarcity of resources, uncertainty and sacrifice, towards a positive model which aligns humanity within a larger community of life (Hes & du Plessis, 2015).

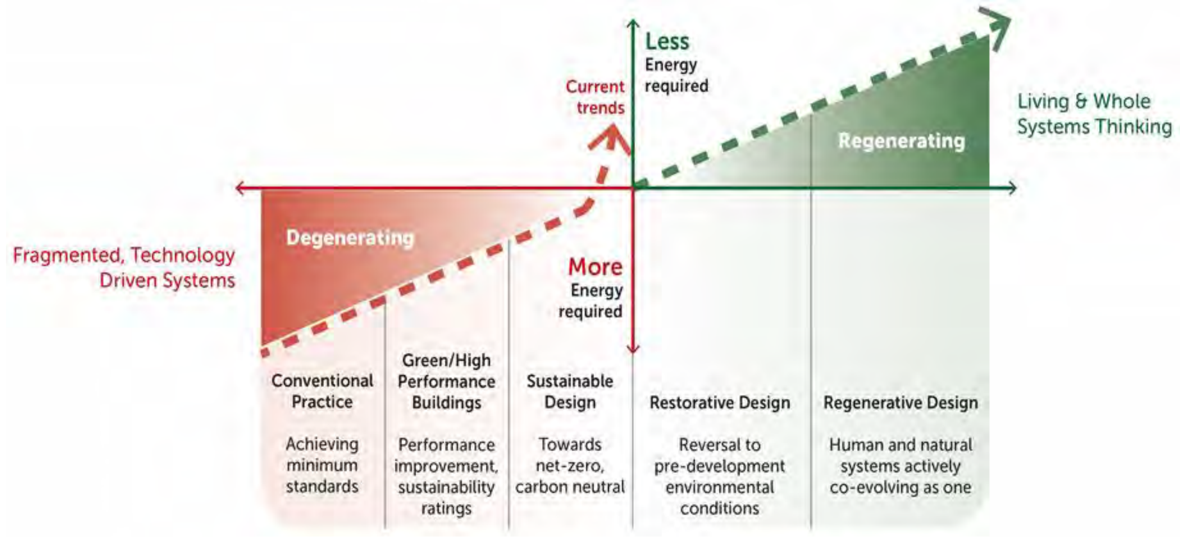

Figure 1: Range of sustainability approaches (Developed from Reed, 2007)

Regenerative design can be roughly defined as the 'reconnection of human aspirations and activities with the evolution of natural systems – essentially co-evolution (Mang & Reed 2012).' Within the context of building retrofits, it is therefore crucial that the role of the building itself be to add value to a system in which it is part (Cole & Fedoruk, 2014). So for a building retrofit to shift towards regeneration, more emphasis needs to be placed on a design process that focuses on the evolution of the whole system and less on the individual building or components. Despite this, Bill Reed suggests that the sustainability approaches presented in Figure 1 are a progression and not exclusive as all practice levels are necessary to achieving this change towards regeneration (Reed, 2007).

Regenerative design concepts are becoming well established in the development of frameworks and tools such as the REGEN tool (Svec et al., 2012), and the LENSES framework (Plaut et al., 2012), alongside existing frameworks such as the Living Building Challenge and One Planet Living. These frameworks provide clear and detailed guidance for achieving regenerative systems and outcomes, but the resulting designs predominantly seem to be new buildings or developments. Whilst this has produced some very promising outcomes, it is critical that building retrofits start to make this shift towards regeneration as the majority of buildings which will exist in developed countries by 2050 are already built (UNEP, 2009).

This paper will explore how regenerative concepts can start to be applied to building retrofits. A 'proactive' retrofitting approach is proposed which seeks to integrate net-positive, restorative and regenerative concepts into the intervention design process. A regenerative design model which explores the interactions between physical, human and natural systems is also proposed as a means of developing a set of regenerative design principles for building retrofits. By extracting the key interactions between these systems, the retrofit focus can now be on the positive interactions a building can have with its surroundings. Emerging technologies and building case studies will be identified to address these key interactions in order to provide clear and practical guidance to achieving 'proactive' retrofit outcomes.

2. REGENERATIVE DESIGN MODEL FOR BUILDING RETROFITS

2.1 Towards 'proactive' retrofitting

Figure 2 highlights the four levels of work in which every living system must continually engage to increase its vitality, viability and capacity for evolution (Mang & Reed, 2012). This 'Levels of Work' framework is applied here to propose a 'reactive' and 'proactive' approach to retrofitting. The below-the-line concepts of operating and maintaining deal only with what is in existence whilst the above-the-line concepts of improving and regenerating explore the creativity and potential in relationship to the larger system (Mang & Reed, 2012). Conventional building retrofits that are focused on efficiency and cost are simply 'reacting' to a negative event or circumstance, and are therefore below-the-line. A 'proactive' building retrofit seeks to integrate net-positive, restorative and regenerative concepts by considering the positive interactions with its surroundings. Despite this, what is crucial to a system's ongoing health and capacity for evolution is its ability to work at all four levels (Hes & du Plessis, 2015). This means that reducing a building's 'negatives' is still crucial to the retrofit process, and in some cases can provide the foundation on which to expand positive interactions with its surrounding systems.

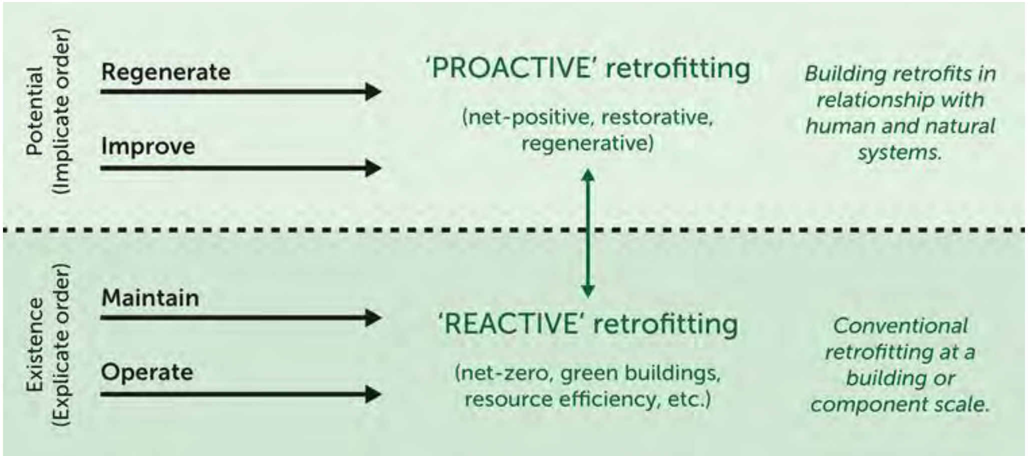

Figure 2: 'Proactive' and 'Reactive' retrofitting (Developed from original by Charles Krone, in Mang & Reed, 2012)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.2 Preliminary regenerative design model

Achieving proactive retrofit outcomes requires not only an understanding of the existing building so as to improve resource efficiency, but a consideration of how this could enhance social connections and strengthen a connection nature. Figure 3 highlights the preliminary regenerative design model developed in this research. This model explores how an energy efficient building retrofit could also improve the health of its occupants and enhance local ecosystems. The cost-benefit is also a crucial aspect of a 'proactive' retrofit, but as it is heavily influenced by contextual factors it will be discussed later in this paper. Identifying and extracting the key interactions between physical, human and natural systems provides a strong foundation on which to develop a set of regenerative design principles by emphasising the positive impact a building retrofit can have on its surroundings.

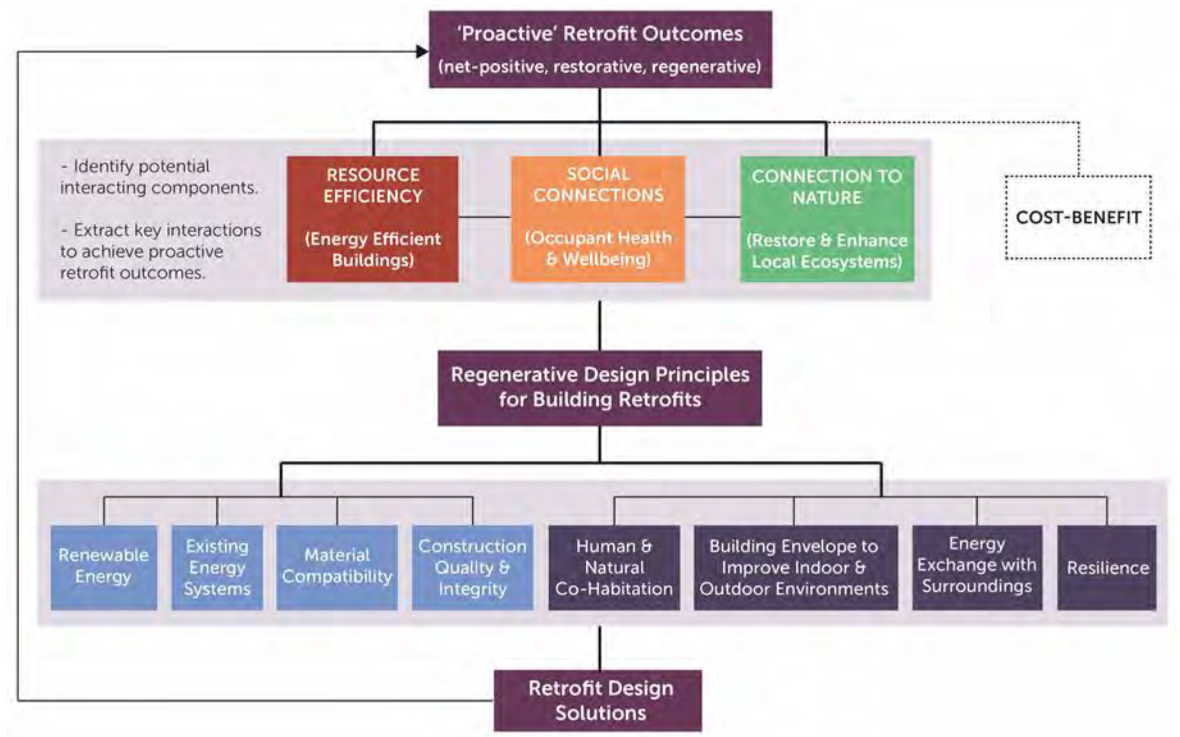

Figure 3: Preliminary regenerative design model for building retrofits

3. DEVELOPMENT OF REGENERATIVE DESIGN PRINCIPLES FOR BUILDING RETROFITS

The development of regenerative design principles for building retrofits is primarily enabled through exploring these key interactions between physical, human and natural systems. Identifying suitable emerging technologies and building case studies exploring these key interactions will ensure these principles are innovative as well as feasible. This first involves identifying and extracting a key interaction between physical, human and natural systems to achieve a 'proactive' retrofit outcome. An interaction between all three of these dimensions will enable a building to not only improve its own performance but also the health of its occupants and its surrounding ecosystems. Relevant examples can then be explored to achieve this key interaction. This involves consideration of how and where these strategies and technologies can be integrated specifically for a building retrofit.

This process will provide the basis to develop a set of regenerative design principles for building retrofits but before they can be applied to a specific building, a deeper understanding of its 'place', and the cost and risk of retrofitting must be considered. An understanding of 'place' as well as the people and technologies already present will highlight the major issues of a specific building. Ultimately this will enable designers to make informed decisions on the appropriate retrofit principles, strategies and technologies to address these contextual-based issues. For the purposes of this paper, one key interaction will be extracted to briefly demonstrate this process highlighted in Figure 4.

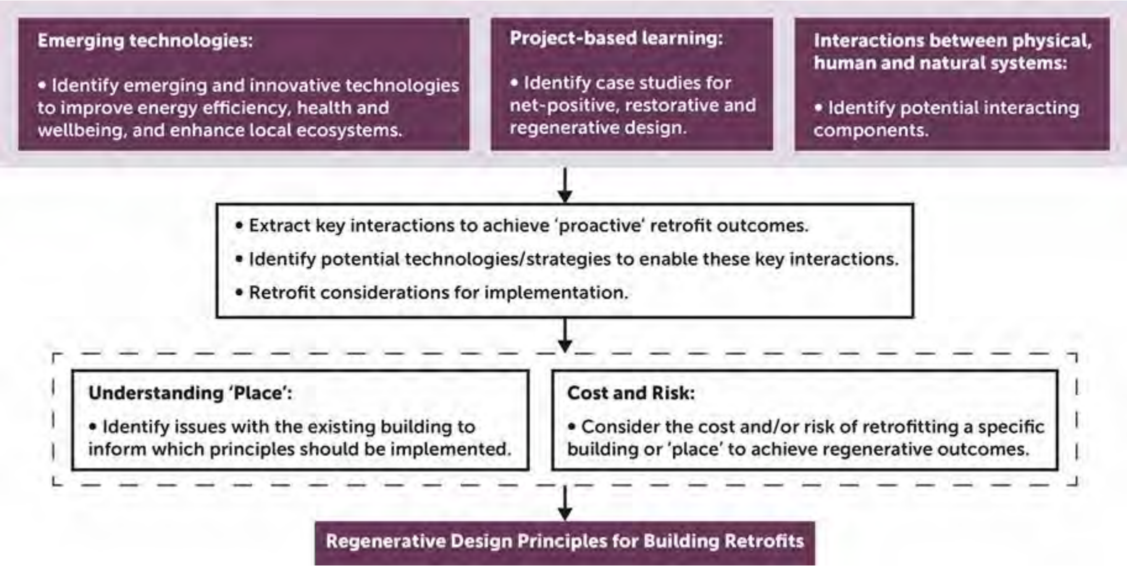

Figure 4: Development of regenerative design principles

3.1 Development of principles through the interactions between physical, human and natural systems

This paper will briefly explore the potential interactions of a building's façade so as to improve energy efficiency and occupant health, and restore local ecosystems. Current façade retrofits are predominantly focused on improving energy efficiency and/or occupant health and wellbeing, with some exploring the connections between the two. Figure 5 highlights that achieving 'proactive' outcomes for a building façade retrofit involves extending this relationship beyond energy efficiency and occupant health to the restoration of local ecosystems. For example, this could involve exploring how a façade retrofit material choice could reduce energy demand, improve thermal comfort and mitigate the surrounding microclimate.

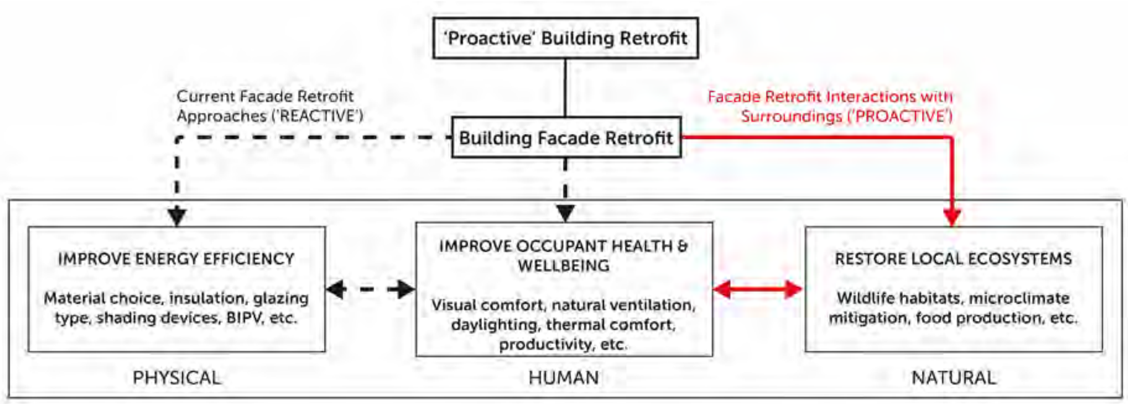

Figure 5: Necessary interactions for a building façade retrofit to achieve 'Proactive' outcomes

By extracting a key interaction which addresses the physical, human and natural systems, the building retrofit focus can expand beyond its site boundaries to positively impact its surroundings. In this way, retrofitting a building's façade can be seen as an opportunity to improve both indoor and outdoor environments. The development of a regenerative design principle entitled 'building envelope to improve indoor environment and restore local ecosystems' therefore has the potential to achieve 'proactive' outcomes for a façade retrofit.

3.2 Examples to inform regenerative design principles

The following examples are briefly introduced here to explore the necessary façade interactions for achieving the principle 'building envelope to improve indoor environment and restore local ecosystems' (Figure 5). In doing so, these examples will provide innovative and feasible solutions for how a façade retrofit can start to improve energy efficiency and occupant health and wellbeing, as well as restore its surrounding environment.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The success of current façade designs, both retrofits and new developments, lies in the ability to link energy efficiency to occupant health, wellbeing and productivity. While this interaction between energy and health may not be 'proactive' in its outcomes, it is still a crucial aspect of retrofitting a building's façade. In some cases this can provide the foundation on which to expand a façade's positive impacts to its surroundings. Deloitte's Amsterdam office, named the 'Edge', is one building which explores these interactions between energy efficiency and occupant wellbeing. The roof and south façade of this building incorporate the largest array of PV panels of any European office building (BREEAM, 2016). This BIPV façade (Figure 6a) assists in powering all smartphones, laptops and electric vehicles connected to this smart building (Marks, 2015), resulting in improved occupant productivity. The Edge also improves the health of occupants upon entry via a fifteen-storey glass atrium (Figure 6b) which provides steady northern daylight and visually connects occupants to the surrounding landscape (BREEAM, 2016). While this building was not a retrofit, the underlying ideas and design intentions behind these façade systems could be adapted into the retrofit process.

(a) (b)

Figure 6: (a) BIPV on the South Façade of the 'Edge' (Source: Ossip van Duivenbode); (b) Fifteen-Storey North-Facing Entrance Atrium (Source: Raimond Wouda).

Although the current approaches to façade retrofits present some promising outcomes for energy and health, the principle 'building envelope to improve indoor environment and restore local ecosystems' requires additional consideration of the external environment. Microclimate mitigation through the use of retro-reflective (RR) materials is one way a façade can start to extend these interactions to restore its surrounding ecosystems. Rossi et al. assessed the angular reflectance of RR films for different angles and concluded that RR materials could be effectively applied as a coating on building envelopes to reduce the circulating energy into the urban canyon (Rossi et al., 2015). Yuan et al. took this one step further to develop a more durable RR material with a glass covering and discovered that RR materials can successfully increase the albedo of urban canyons as well as reduce a building's thermal loads (Yuan et al., 2015). Another way a façade retrofit can restore surrounding ecosystems is through the provision of wildlife habitats. In addition to the already proven benefits of green walls and facades, artificial wildlife habitats integrated into the building envelope have the potential to increase local biodiversity and challenge the traditional rejection of wildlife in an urban context. Lamphier explores this idea by developing a façade system which is specifically designed to attract birds to enhance the dialogue between buildings, occupants and wildlife. This modular cladding system (Fig. 7) offers shading to the building and provides artificial habitats for pigeons while maintaining a high aesthetic quality (Stokes & Chitrakar, 2012).

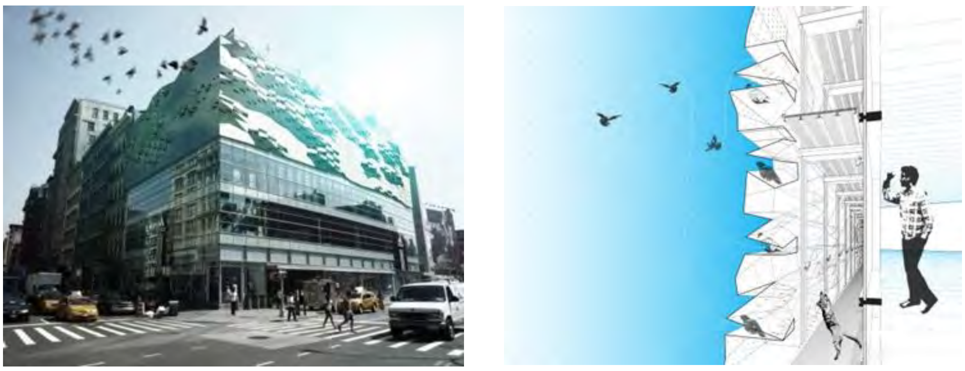

Figure 7: Artificial habitat modular façade system (Source: Trevor Lamphier)

These examples have briefly shown that if we start retrofitting facades towards achieving this design principle, there can be multiple health and performance benefits for physical, human and natural systems within the built environment. More importantly, introducing these examples has emphasised that we already have the means and technology to achieve the necessary interactions for a 'proactive' façade retrofit. What is required to make this transition to regeneration is therefore not a change of techniques but a change of mind (Mang & Reed, 2012).

4. DISCUSSION AND FUTURE WORK

In developing a regenerative design principle for building façade retrofits, this paper has highlighted that we already have the ability to start designing within this regenerative worldview. This idea that a change of mind-set is of more importance than specific techniques, strategies or technologies emphasises that the true benefit of these design principles is in the way they could promote a new or 'proactive' approach to building retrofits. Although the brief examples introduced in this paper have shown specific strategies and technologies which can support this principle, it is the fundamental design intention of a façade positively impacting its surroundings that enables this principle to have a 'proactive' outcome.

This proposed regenerative design model will enable further development of a set of design principles for building retrofits to achieve 'proactive' outcomes. It should be noted that these regenerative design principles will be further developed through a qualitative rather than quantitative approach. Ultimately these principles will provide high-level guidance to designers in order to expand rather than prescribe potential retrofit solutions. Once these regenerative design principles are developed, a process model will be established to guide the application of these principles into practical retrofit solutions. This will involve further consideration of a building's 'place' as well as the people and technologies already present. By doing so, a designer can then make an informed decision about which retrofit principles and strategies are appropriate to address the issues of 'place' and add positive value to the surrounding environment.

Passive Building: Energetic Refurbishment of a Secondary School

Antonio FRATTARI[a], Irene FERRO[b]

[a] *University of Trento, Italy, antonio.frattari@unitn.it*
[b] *University of Trento, Italy, irene.ferro89@gmail.com*

ABSTRACT

The Department of Civil, Environmental and Mechanical Engineering (DICAM) of the University of Trento (UNITN) has developed an analysis procedure finalized to the school buildings energy retrofitting. For this experimental project was identified the high school “Istituto Floriani”, located in Riva del Garda (Italy), as case study to verify the developed methodology.

The procedure consists on the analysis of the energy behaviour of the whole existing building and the consequent design solutions for the retrofit of the building envelope and the building energy systems. The aim of these possible solutions is the improvement of the living comfort and of the energy efficiency too.

The methodology of this procedure was divided in five steps:

- Monitoring of thermal comfort and energy consumption of the building.
- Propose of construction solutions to improve the energy efficiency of the whole building.
- Testing of the predicted solutions through the Passive House Planning Package (PHPP software) to reduce the annual heating demand (< 20 kWh/m^{2}y) and improve the living comfort of the school building.
- Preliminary project of the energy retrofit solutions.
- Executive project.

The preliminary project is ended. It involved, a large number of operators as students and teachers of “Istituto Floriani” coordinated by the DICAM researchers at the different steps of research activity. The DICAM researchers, coordinated by Professor Antonio Frattari, devised the scientific methodology and supervised the whole project especially: the monitoring, the design of the constructive details, the energetic analysis and the final design work aiming to optimize the financial and energy convenience of reclamation. The experts of the “Provincial Agency for Water Resources and Energy (APRIE) of the Autonomous Province of Trento (PAT)” have been involved in the project to define the feasibility of energy retrofit operations and the financing.

Keywords: deep building renovation, energy saving, passive house

1. INTRODUCTION

Old and inefficient buildings have been identified as one of the biggest contributors to energy wastage in the EU. Improving energy efficiency is one of the pillars of the EU’s policy response to addressing the challenges of climate change and the reduction of greenhouse gas emissions.

The good news is that in the past 25 years, significant progress has been made in the development of new building with very low heating demand. Good experience with passive house buildings was one reason for the European Commission to state the Nearly Zero Energy Building (NZEB) as the goal in the second decade of the 21st century. The real challenge now is the existing building stock – mainly built during times where energy seemed to be abundant and cheap and efficient components were not available on the market, these buildings consume between 150 and 250 kWh/(m^{2}a), about a factor 10 more than well – designed NZEBs.

Therefore, existing buildings can be improved during a thorough retrofit process. All the solutions, which have been proven successful in the construction of new NZEB’s can also be applied for retrofits. Through a deep analysis on the Italian building scenario it was defined that a huge amount of residential and non-residential buildings need real renovations, including energy efficient measures. Many schools, built before the '50s and currently used, have a significant effect on energy consumption, but a much more relevant impact on the level of thermal comfort of the occupants.

2. CASE STUDY

However, most of the existing schools have been constructed without any concern for the comfort of the occupants and the adaptation of the buildings to the local climate. The quality of indoor environment has a great influence on the students' learning performance and ability to learn in indoor spaces. It is necessary to improve the quality of these schools. to provide healthy and comfortable study spaces for the students with the use of passive design strategies to minimize the energy loads of the buildings as the school buildings are one of the major energy consumers. This research study is a Secondary school "Istituto Floriani" located in Riva del Garda, in the north of Italy. The methodology developed for the case study was divided into two main phases: the analysis of the existing building conditions and the consecutive renovation project in relation to different constructive and engineering solutions to promote and improve energy efficiency. The entire work plan was drawn up on two years and based on a series of steps that started from the monitoring of thermal and environmental humidity conditions up to the definition of the construction details for the retrofit measures according to criteria of minimum energy consumption.

The case study (Figure 1) is placed in the flat area and enclosed in a mountain landscape all around. The building is oriented at 16 ° from the north, then the main facades are pointed to East and West.

Figure 1: Map showing the school position

The building has four floors above ground and attic space. The structure has a regular distribution through two stairs climbing from the ground floor up to the roof level. The classrooms look out on the entrance garden in the east facade. The windows on the west side illuminate directly the long corridor that extends for the entire length of the body of the building (Figure 2)

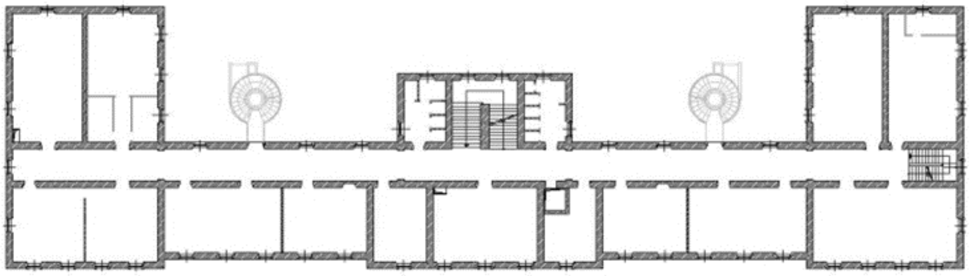

Figure 2: Building floor plan

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. THERMAL COMFORT ANALYSIS

The building taken into account for energy efficiency research project is a secondary school, the age range of occupants is between 13 - 19 years. The comfort analysis according to Fanger's principles has been done on this age range. As level of comfort Temperature (°C) has been assumed T = 20 °C, if the type of school was different (nurseries, kindergarten), had to be reset the conditions of comfort, since the occupants' age range changed.

The condition of thermal comfort, can be defined, from the psychological point of view, as the psychophysical state in which the subject expresses satisfaction with the thermal environment (ASHRAE definition) or, from the sensitive point of view, as the condition in which the subject has no feeling of hot or cold sensation, that is a condition of thermal neutrality (Fanger definition). The parameters on which the comfort feeling depends are numerous: air temperature and radiant surfaces, relative humidity and air velocity, clothing thermal resistance, level of activity of the occupants. The creation of a good living space, from the thermal comfort point of view, is one of the most important objectives to be achieved in building design. As mentioned previously, the thermal comfort is just one of the variables that defines the well-being of occupants, in any home-business-school environment must also take into account other factors such as indoor air quality, light and noise.

3.1 Field measurements

In this study, the indoor air temperatures and relative humidity levels were measured with a data logger in the spring period, from 14th to 24th of April. The measurements took place in four classrooms located on the first and second floor of the school building, facing on the four different facades. The monitoring unit was formed by a multi-measure instrument (Babuc/A) mounted on a tripod at the height of 60 cm on the floor. The proper position has been referred to the requirements of UNI EN ISO 7726 and according to the minimal disturbance for the activity of students and teachers. Different measuring probes were installed on it and a central unit measured environmental values were directly recorded. During the measurement of the thermal parameters in a confined environment, it is important to remember that the human thermal sensation does not depend on the environmental temperature, but on the amount of energy that people's bodies consume in the environment.

3.2 Questionnaire survey

To complete the measurement campaign were distributed to students and teachers the questionnaires drawn from the templates contained in the UNI EN ISO 10551. This questionnaire is a good method to understand directly the level of thermal comfort of the occupants in the environment.

In relation to Fanger’s studies, the analysis of thermal comfort is based on six parameters, four of these were measured through the Babuc and its sensors (microclimatic variables); the others, called individual variables, depend from the activity and the clothes resistance of the occupants were determined by a questionnaire survey carried out in the same days of the measurement campaign. All the students of each classroom had to fill in the questionnaires and also describe thermal sensations and thermal preferences during lesson hours based on the 7-point of Fanger scale.

3.3 Calculation results

A person is characterized by a thermal comfort condition if he/ she does not feel any type of thermal discomfort. The first condition for the comfort is the thermal neutrality, neither too cold nor too hot.

Through the elaboration of questionnaires and the analysis of measurement campaign it was possible to determine the PMV index (Predicted Mean Vote) and the PPD value (Predicted Percentage of Dissatisfied) for each analysed classroom. At the end of the research was defined that in the school classrooms of the “Istituto Floriani” there is a general condition of thermal discomfort and a high percentage of dissatisfied students. The uncomfortable condition is due by “localized discomfort conditions”. Lots of classes are too small for the students that are inside. The internal heat gains are too high and students have to open the windows also in the winter season to decrease the inner temperature. In this way, the students near to windows feel cold sensation and the other students in the opposite position feel too hot. The total PMV defines a situation nearly neutrality but in reality, a lot of people are in uncomfortable condition.

4. MONITORING SCHOOL ENERGY CONSUPTION

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Parallel to the comfort analysis, started the monitoring school energy consumption. The main goals of the energy monitoring activity are:

- To make the students and all school staff aware of school energy consumption;
- To show how is the influence on the consumption in different season and for activity types in the school.

The results of the monitoring increase the knowledge about energy issues and create a basis for the school refurbishment plan and changing the behavior of people so that energy consumption is reduced.

The first step of analysis was to determine the energy sources and define the type and the number of installations and devices attached to these sources. Then itwas possible to access to energy meters and evaluate the yearly consumption total bills from school site staff. In the Table 1 are summarized the energy consumption data, collected in the years 2013 and 2014.

HEATING				ELECTRICITY			
2013		2014		2013		2014	
0,1003 €/kWh $_{heating}$		0,1001 €/kWh $_{electricity}$		0,23 €/kWh $_{heating}$		0,23 €/kWh $_{electricity}$	
kWh/mq	€/mq	kWh/mq	€/mq	kWh/mq	€/mq	kWh/mq	€/mq
112,629	€ 11,30	100,412	€ 10,05	35,617	€ 8,20	33,845	€ 7,78

Table1: Energy consumption for heating and electricity during the years 2013 and 2014.

5. SCHOOL REFURBISHMENT CONCEPT

Now is time to refurbish our old existing buildings and give them other life chances. This is one of the main concepts at the basis of this research. The overall strategy to reuse, refurbish, extend and adapt the existing building proved to be a more economic and sustainable solution than demolition and new build.

5.1 New functional spaces

As mentioned before, “Istituto Floriani” is an old building that in origin was a military barrack. Many years ago, all the inner areas were converted to transform the barrack in a Secondary school that can guest around 800 students. The proposal provides for the functional refurbishment of 4 existing floors and the addition of a wooden elevation to introduce additional space needed for new educational activities.

On the ground floor is provided an entrance hall for public activities, integrated with relational spaces for students, teachers and external visitors. The first, second and third floors are characterized by traditional classrooms utilized by 800 students. The new fourth floor contains an Auditorium (100 seats) and new flexible classrooms; their movable walls can create different spaces in relation to the flexible number of students and provide various training activities based on new teaching criteria.

5.2 Common environmental problems in schools

Before the refurbishment step of entire school, common environmental problems, typical of old buildings, were listed and analysed in detail. They include:

- Overheating and solar glare in summer
- Lack of sufficient daylight, requiring frequent use of artificial lighting
- Inadequate ventilation, resulting in a stuffy environment
- Thermal bridges.

These problems can affect the concentration of students and teachers, and are counter to the principles of inclusive design. The most comfortable classrooms tend to be those that have good daylight and natural ventilation, and include direct views and links to the outside, and windows that minimize direct sunlight penetration and associated heat and glare problems. The orientation of classrooms has a crucial effect on users’ comfort.

6. ENERGY EFFICIENCY STRATEGY FOR REFURBISHMENT

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Very substantial energy savings are possible with refurbishments of existing buildings. The main focus is on the following aspects:

- Thermal protection of building's components: the passive refurbishment is referred to the components which define the continuous thermal envelope as external walls, roof, basement slab and all the transparent elements (doors and windows). A high level of thermal insulation is the essential key for the passive house concept.
- Minimisation of thermal bridges: All the refurbishment strategies which improve the thermal insulation of the building envelope have to take into account the analysis of principal thermal bridges through the use of specific software. This calculation is necessary to choose the best solutions to minimize the thermal bridges problem.
- Improved airtightness: The airtightness of the insulated construction is important for various reasons. The cold air from outside only leads to an increased heating demand and drafts effects. Then the airtightness protects as well from a flow from inside to the outside that is always critical, because warm and humid air condenses on cold areas of building components and can lead to constructional damage.
- Use of excellent quality windows: The U-values of windows (0.8 W/(m²K)) are almost five times as high than those of the opaque building components (0.1...0.15 W/(m²K)). The heat losses through the windows are therefore disproportionately high compared to their relative area. For this reason, the building component 'window' requires such special attention during design and implementation.
- Ventilation with efficient heat recovery: The main aim of a ventilation system, whatever it is and wherever it is installed, is first of all to provide fresh air for the environments, diluting or removing contaminants and so obtaining a good indoor air quality. The attention to indoor air quality in schools is even shown by the development of many guidelines and regulations concerning the appropriate ventilation rates to be used for these spaces.

7. RESULTS

In order to reach a correct energy refurbishment, all the different retrofit steps have to be summarize in a common master plan. It includes information about order and quality of all energy retrofit measures as well as general definitions of the position of the airtightness layer and the thermal insulation layer in each part of the building envelope. The refurbishment plan has been calculated with the Passive House Planning Package (PHPP), a tool for energetic planning of new buildings and retrofits. In the figure below is shown the results table for the refurbishment measures planned for the case study.

Specific building characteristics with reference to the treated floor area — The PHPP has not been filled completely; it is not valid as verification

				Criteria	Alternative criteria	Fullfilled?[2]
	Treated floor area m²	4611,8				
Space heating	Heating demand kWh/(m²a)	7	≤	20	-	yes
	Heating load W/m²	9	≤	-	-	
Space cooling	Cooling & dehum. demand kWh/(m²a)	-	≤	-	-	-
	Cooling load W/m²	-	≤	-	-	
	Frequency of overheating (> 25 °C) %	10	≤	10		yes
	Frequency excessively high humidity (> 12 g/kg) %	2	≤	20		yes
Airtightness	Pressurization test result n_{50} 1/h	1,0	≤	1.0		yes
Non-renewable Primary Energy (PE)	PE demand kWh/(m²a)	38	≤	120		yes
Primary Energy Renewable (PER)	PER demand kWh/(m²a)	22	≤	-	-	-
	Generation of renewable energy kWh/(m²a)	0	≥	-	-	

[2] Empty field: Data missing; '-': No requirement

I confirm that the values given herein have been determined following the PHPP methodology and based on the characteristic values of the building. The PHPP calculations are attached to this verification.

EnerPHit Classic? yes

Task: First name: Surname: Signature:

Issued on: City:

Figure 3: PHPP – EnerPHit verification

EnerPHit protocol is the new certificated standard created by the Passive House Institute (PHI) in Darmstadt for old buildings, differs from other standards for its higher quality of design, components, manufacturing, and construction. Now it is possible to reach high energy standards even with the refurbishment and not only with the construction of new buildings.

8. DISCUSSION

This research started at the beginning of the 2015 and was based on an accurate methodology that guides every single step of this work. Each phase is important and essential for the next. This case study would want to be a pilot project for the deep refurbishment action for a large number of Italian schools. At the base of the intervention there is the purpose to increase the living comfort of indoor environment. Passive house, bioclimatic architecture, Zero Energy Building are different approaches to obtain the indoor comfort and at the same time reduce the annual heating demand. Here we wanted, for the first time in Italy, to follow the criterion of the “Passive house” applying it on a school building. It is a new idea, there are not other examples in similar climate conditions for a comparison and we hope that the Autonomous Province of Trento, our sponsor, will believe in this project and will do the refurbishment following our recommendations.

ABSTRACT

The paper examines the predicaments, prospects, as well as factors affecting High Performance Buildings (HPBs) design in Nigeria's built environment. The study identifies the weak institutional frame work, poor policy implementation, inadequate financing and lack of awareness to socio-economic, technology and sustainable built environment. A questionnaire survey was conducted and directed at the various academic Architects and professional Architects in the Nigeria's construction industry which were selected randomly. A significant and positive correlation was discovered among Architects knowledge of HPBs within the Nigeria built environment and the implementation which necessitate the certain factors. Moreover, the study affirms that a paradigm shift is required to the current socio-political and techno-economic dynamics of the current HPBs in Nigeria's built Environment. This will require the adoption of HPBs pedagogy in recurrent academic literature. This study is concluded by highlighting the future prospects of HPBs development in Nigeria's built environment.

Keywords: built environment, design, factors affecting, high performance building

1. INTRODUCTION

In the prevailing situation, where the global wheel for future socioeconomic growth and sustainable development will require energy efficient building and renewable source of energy (Turkenburg et al., 2000). Africa needs to incline toward sustainable development of the global challenges as well as Nigeria. Nigeria is one of the most resources rich nation in Africa with estimated of 35 billion barrels of crude oil, 180 trillion cubic feet of natural gas, 40 billion metric tons of coal as well as tar sands precious metals, ores which accounts of 90% for GDP annually (Ohimain, 2014).

The construction industry is one of the largest industries that contribute to global warming, traceable to various human activities (Odebiyi et al., 2010). Thus the construction industry features has heavy energy consumption and construction consumes lots of natural resources according to study of Liqun and Yanqun, (2013). Generally, the construction industry in Nigeria is developing rapidly over decades with emphasis on infrastructures due to the uncompromised demand of such facilities. Numerous studies on sustainability and green building had been conducted in Nigeria by some researchers, (Dahiru 2014; Daramola, et al., 2012; Oludaisi 2015; Michael, 2013; Muhammad et al.,2015; Olufunto 2013; Ogunsote, 2011; Waniko, 2013) with the view of assessments, improvement, rating, construction and awareness.

Effort to improve energy efficiency of new building have being reported in many studies of (Chukwu et al., 2014;Diamond et al., 2013; Gidado and Kumo, 2016; Fjola 2016; Gomes 2016; Ogunsanmi and Nduka, 2015) and also Architects Registration Council of Nigeria (ARCON) hold Architectural forum yearly; Architects colloquium (2010;2011; 2012; 2013; 2014 and 2015) on sustainable built environment to extenuate energy consumption in the country (Nigeria) with the perspective of ameliorating occupant productivity and protecting the environment.

A trivial study has provided information on design of high performance buildings (HPBs) without considering the factor that affect such design in Nigerian content. Cho and Haberl, (2006) explained that to build a high performance building it is necessary to consider the whole building design concept during the design phase that integrate all the subsystem of the building to work together.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The study examines the predicaments, prospects, as well as factors affecting High Performance Buildings (HPBs) design in Nigeria. Thus, the study also identify the weak institutional frame work, poor policy implementation, inadequate financing, lack of awareness to socio-economic and socio-technological factors which affect the renaissance of HPBs/ green building designs in Nigeria. Hes, (2007) stipulated that the greatest chance to reduce the environmental impact of a building is to tackle the minimisation of impacts at the design stage, through good guidance with a building brief.

1.1 Research problem

Green building projects design and construction are characterised by the problem of lack of shared perception (Gidado and Kumo, 2016).Thus the key problem facing green building is limited knowledge, experience, and limited technical know-how to apply ecology to construction design (Hankinson and Breytenbach, 2012).In Nigeria, the cardinal predicament of getting HPBs into building industry is the designers hesitation into new innovative technology without the in depth knowledge of design and practice.

1.2 Research aim

The aim of the study is to identify, assess and rank the factors that affect HPBs with the view of improving their design and implementation in Nigeria construction industry.

1.3 Research hypotheses

The hypotheses were formulated for this research include; Chi- square statistical tool was used for testing the hypotheses:

- Null hypothesis (HO); there is no uniform perception on factors affecting HPBs design by Architects in Nigeria's built environment.
- Alternative hypothesis (HA); there is limited knowledge and technical know-how on factors affecting HPBs design by Architects in Nigeria's built environment.

2. LITERATURE REVIEW

2.1 Current green building/ HPBs polices in Nigeria

The actions and policies of national governments can significantly influence the development and diffusion of novel technology such as HPBs and renewable Energy in Nigeria. Emodi, (2016) Highlighted that the national renewable energy and energy efficiency policy outline the global thrust of the policies and measures for the promotion of renewable energy and energy efficiency with the objectives of setting out a frame work for action to address Nigerian's challenges. The current practices must consider Social capital, Economic capital and Natural capital to ensure that building and community create value for all stakeholders (Oliyide, 2015). In addition, these rudiments require government support through the creation of protected vibrant framework. Policy enforcement becomes easy for public adherence when the government is committed to its goals especially by keeping to ethical values (Odebiyi et al., 2010).

Furthermore, the Federal government of Nigeria (FGN) has enacted a number of key energy polices to guide and direct the development and diffusion of renewable energy such can be applicable to HPB. The umbrella policy for energy development in Nigeria is the National Energy Policy enacted in 2003 (National Energy Policy, 2003). In the recent study of David and Olabode (2015), that the policy is aimed at highlighting the dynamic relationship between energy and socio-economic growth and sustainable development in Nigeria.

The study of (Sani and Ahmad, 2011) concluded that strategies towards effective energy code development, implementation and compliance at all levels of government in Nigeria. Thus, the inconsistency in policies implementation couple with the lukewarm attitude of the Federal Government of Nigeria hinders the implementation of building code due to socio-political factors. In the recent study of (Bajere et al., 2016a) highlighted that at the moment, the country does not have a building code setting the minimum design standards for health, safety and welfare of occupant and the government is yet to pass a 2006 Building codes and standards into law.

3. CURRENT PRACTICES AND CHALLENGES OF HPBs IN NIGERIA

3.1 Barriers to HPBs implementation in Nigeria

The development and diffusion of HPBs into Nigeria Energy Economy is a plagued to numerous challenges. As highlighted by (Hekkert et al., 2007), novel technologies such as renewable energy encounter problems competing with conventional technologies.

In Nigeria context, these challenges can be broadly categorized into: socio-political and techno-economic factors. The study of (Bajere et al., 2016b) concluded that the literature revealed the existence of several environmental laws and policies, and the fact that most Nigerian legislations crumble at the implementation stage. This is probably due to inconsistencies in government policies sometimes caused by change in regime and the limited understanding of the process of transferring the laudable provisions into effective tool for managing the environment. This section of the study will examine the crucial barriers and challenges affecting HPBs in Nigeria.

3.2 Socio-political factors

The socio-political factors hampering HPB development and diffusion in Nigeria are largely centred on policy enaction, execution and monitoring. Despite numerous green building polices energy generation, Environmental policy, Building code and power distribution in Nigeria remains dismally low. However, according to Eleri et al., (2012). The poor integration of renewable energy into the Nigerian power mix can be attributed to weak institutional framework, poor policy implementation and lack of awareness. Thus, recent studies of (David and Olabode, 2015) upshot that Nigerian built environment professional are aware of the green building practices applicable to construction projects. There appears to be moderate interest in the practice. The group posit that poor government commitment and unsupportive regulatory framework have stifled development and diffusion of green building.

To curb the socio-political challenges, the Federal Government of Nigeria (FGN) must harmonize green building laws, polices, design, rating, construction guidelines and re-direct national effort towards HPB by focusing on potential sources such local materials, solar and biomass. In addition, the policy implementation must be prioritized and monitored by all ministries, government agencies such as professional bodies charge with green buildings in the Nigeria. The proposed reform required drastic awareness of ministries, government agencies; National Orientation Agencies (NOA) and media in Nigeria can improve awareness and stimulate meaningful significant to underlying on socioeconomic growth and sustainable development in the country.

3.3 Techno-economic factors

The techno-economic factors of HPBs diffusion in Nigeria are centred on the technology and economic aspects of development. Thus, (Jie, 2013)) highlighted that many factor should be taken into consideration in protecting environment and developing the economy, whereby environmental and economic balance should be achieved. The study of (Hekkert et al., 2007) that innovation system theories, the development and diffusion of novel technologies require the participation of stakeholders within the technovation climate. Theses strategic of stakeholder can be broadly categorized into technology producers and technology regulators.

The Technology Producers (TP) comprises technology entrepreneurs, utility companies, power equipment, manufacturers and power distribution companies. The Technology Regulatory (TR) includes; government regulators and supervisor agencies charged with implantation and monitoring energy policies. The role of TPs and TRs is to design, develop and execute innovative technologies and processes for HPBs.

The study of Eleri et al., (2011), concluded that low Renewable Energy Technology development could also be due to lack of local manufacturing capacities, and barriers to financing technologies. Other techno-economic factors hindering HPBs in Nigeria includes; poor state of educational system generally which prevented the development of innovation technologies.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4. RESEARCH METHOD

This research work adopted two sources of data; the secondary and the primary sources of data.

- Secondary sources of data such as journals, conference/seminar/workshop papers, text books, magazines and the internet etc. were used to review literatures in the HPBs field within the Nigeria's context and at large.
- A 5-point Likert scale questionnaire survey (as the primary source of data) was Administered to professional and practicing Architects.

Architects working in the Clients, Consultants, Contractors and the Academic organisation were administered the questionnaires randomly. Mean item score and Chi square-test statistics were used for data analyses.

5. DATA ANALYSIS AND FINDING

5.1 Respondents profile

The questionnaire survey forms were distributed to various Architects practising within Abuja, Bauchi, Enugu, Kaduna, Lagos, and Jos states of Nigeria. A total of 250 questionnaires were distributed and 153 completed questionnaires were received. The Table 1 below summarizes the respondents' profile.

Category Respondents		
Business Category	Respondents	
	Number	%
Developer/Client	19	12
Architects in Academic/Researchers	59	39
Contractor's Architects.	21	14
Consultant's Architects	37	24
Architects in Government Parastatal	17	11
Year of Experiences		
Less than 5 years	6	4
5-10 years	37	24
10-15 years.	53	35
15-20 years.	47	30
More 20 years.	10	7

Table 1: Respondent's profile

The highest participants of the survey were 39% of Architects in academic/ researchers, 24% were consultant's Architects, 14% were Contractor's Architects, 12% were Developer/Client and 11% were Architects in government parastatal. The years of experiences plays a significant role in relation to the respondents; the richer the experiences the vital the information. The respondent with less than 5years of experiences had 4% while that of 7% were those above 20 years' experience, 24% of those with 5 -10years, 30% of those with 15-20 years and 35% of10 -15years of experience. The results indicated that 35% is the highest years of experiences (10-15 years) of the respondents' participation.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

5.2 Factors affecting HPBs design practices

The respondents were asked to provide their perceptions on the factors affecting High Performance Buildings Design and level of impact associated during the process of design practice in Nigeria as showed in the table 1 below.

FACTORS AFFECTING HPBs	Strongly disagree =1	Disagree= 2	Neutral =3	Agre e =4	Strongl y agree= 5	Mean item score	Remarks	Rankin g
Limited knowledge, technical know-how and Understanding by the design professionals	11	9	5	45	83	4.18	Agreed	1st
Lack of design expertise on HPBs	2	15	7	74	55	4.08	Agreed	2nd
Not comfortable with novel technology	15	47	27	56	8	2.97	Neutral	9th
Lack of operational standards for new construction	14	29	7	67	36	3.54	Agreed	6th
Unavailability of local HPBs materials for sustainable design.	3	10	12	93	35	3.96	Agreed	3rd
Lack of adoptable rating tool for Green building.	10	27	37	56	23	3.36	Agreed	7th
Lack of Availability of technology suitable for green Design	9	19	11	87	27	3.68	Agreed	5th
Complicated and unique designs.	4	9	29	81	30	3.81	Agreed	4th
Design operation tends to introduce control risk.	47	65	8	13	20	2.31	Disagreed	11th
High cost of sustainable materials and product.	14	35	67	21	16	2.93	Neutral	9th
Client budget	9	14	5	87	38	3.86	Agreed	4th
Price inflation of construction materials.	17	29	43	57	7	3.05	Neutral	8th
End-User Purchasing/Spending Power.	7	32	20	82	12	3.39	Neutral	7th
Absent of HPBs National building code.	5	29	30	78	11	3.40	Neutral	7th
Political will in government.	9	13	11	47	73	4.06	Agreed	2nd
Tendency of sustaining HPBs practices.	12	47	78	11	5	2.67	Neutral	10th
Absence of statutory law/regulation on HPBs	3	9	37	89	15	3.68	Agreed	5th

Source: Author's field work 2016.

Table 2: Factors affecting HPBs design practices

The affiliated factors affecting HPBs design practices in Nigeria's built Environment are summarized in Table 2 above whereby lack of knowledge and understanding by the design professionals (MS = 4.18) rank first, lack of design expertise on HPBs and political will in government rank second (MS = 4.08) simultaneously, Unavailability of local HPBs materials for sustainable design (MS = 3.96) rank third, Client budget (MS = 3.86) rank fourth, lack of availability of technology suitable for green design and Absence of statutory law/regulation on HPBs (MS = 3.68) rank firth. These results depicted that limited knowledge, technical know-how and understanding by the design professionals, lack of design expertise on HPBs, political will in government where the ultimate impediment for HPBs designs practices. Price inflation of construction materials (MS = 3.05) rank eighth, high cost of sustainable materials and product (MS = 2.93) rank ninth, tendency of sustaining HPBs practices (MS = 2.67) rank tenth, design operation tends to introduce control risk (MS = 2.31) rank eleventh.

5.3 Testing of hypotheses

Chi-square was used for testing of the hypotheses. The values for mean item score were used for data for statistical computation as showed in the table below.

FACTORS AFFECTING HIGH PERFORMANCE BUILDINGS DESIGN.		Level of significance	DF	X^2 Cal	X^2 tab0.05, 64
NUMBERS OF ROWS	17				
		5%	64	1078.51	83.6754
NUMBER OF COLUMNS	5				

Table 3

From the table above, with 64 degrees of freedom (DF) and 5% level of significance, the Chi-square tabulated (X^2tab0.05, 64 = 83.6754) is lower than the Chi-square calculated (X^2cal = 1078.51). Therefore, the Null hypothesis is unaccepted; which put forward that there exist a concrete perception on factors affecting HPBs design by Architects in Nigeria's built environment.

6. CONCLUSION

This is further attested by the Chi-square statistical test which accepts the alternative hypothesis of the research. With the established validated hypothesis that there exist a concrete perception on factors affecting HPBs design by Architects in Nigeria's built environment.

To subdue the existing challenges that were revealed in this research in relation to the Architects perception on factors that affect HPBs design, it will require the adoption of HPBs pedagogy in recurrent academics literature. The perceived factors, such as limited knowledge and technical know-how on HPBs, lack of political will in government and unavailability of local HPBs materials for sustainable design in Nigeria can be initiated into green building movement using local existing materials, resources and training of professionals. With the strategy of incremental adoption and implementation will gradually assist HPBs/green building practices in the future development in Nigeria's built environment. On a global scale, these findings can be utilised as checks for the developed countries that have established benchmarks for HPBs and for upcoming developing nations, these factors may be set as milestones for accomplishments of HPBs.

ABSTRACT

To attain sustainable use of water to meet the challenge of climate change, Hong Kong is transforming itself into a water efficient society. However, success will require actions at various levels. This paper introduces Hong Kong's efforts pitched at individual buildings, driving them to perform better for efficient and sustainable use of water through an array of measures. On the supply side, not only does the Government advocate the use of sustainable water resources such as recycled grey water and harvested rainwater, but private sectors are also encouraged through a green building certification scheme to implement water recycling in new developments. In the meantime, existing buildings are offered with other options on the demand side. Flow controllers are distributed and installed to transform taps and showers into water-saving ones, and water efficiency audits are conducted to guide facilities and trades within buildings to more efficient use of water. Use of water efficient products is being promoted through the voluntary Water Efficiency Labelling Scheme with work in progress on mandating their use in new developments and major renovation. With an aim to enhancing water loss management in inside service, a new voluntary scheme for buildings on leak detection is also being developed. Riding on the advancement in the information and communication technology, the pilot scheme on use of smart water meters can facilitate consumers' self-monitoring of water consumption for conservation and loss reduction. The above measures which touch on the hardware side are coupled with software promotional elements, as it is believed that buildings can only truly make great strides in conservation if their occupants are on the same track. With buildings becoming more water-efficient and occupants more water-conscious, a sustainable use of water can be realised with holistic actions from city, building and individual levels in Hong Kong.

Keywords: high performance building, sustainable use of water, water conservation

1. INTRODUCTION

Providing an adequate water supply for Hong Kong has always been difficult because there are no natural lakes, rivers or substantial underground water sources. As Hong Kong flourished in the past with population and economic growth, impounding reservoirs were constructed and about one-third of the land was designated as water gathering grounds to cope with the increasing water demand. Among the 17 impounding reservoirs of Hong Kong, two reservoirs were innovatively built in the sea, i.e. the Plover Cove and High Island reservoirs. Hong Kong has also implemented an innovative scheme of using seawater for toilet flushing since the 1950s, and has been importing raw water from Dongjiang since 1965. This three-pronged supply structure comprising local yield, imported Dongjiang water and flushing seawater has supported Hong Kong with an uninterrupted and reliable water supply for the past decades, yet demand for water in Hong Kong, like many other cities, is still subjected to the pressure of continual population and economic growth as well as climate change.

To ensure water security and sustainability against the many challenges ahead, a Total Water Management Strategy (TWMS) was promulgated by the Hong Kong Special Administrative Region Government (the Government) in 2008, emphasising the importance of curbing the growth of water demand on one hand and strengthening overall water supply management on the other. Hong Kong has a high density of high-rise buildings. This offers great potentials for efforts pitched at individual building level to contribute towards transforming Hong Kong into a water efficient society.

2. SUSTAINING SUPPLY IN BUILDINGS

In tackling challenges in water resources, measures on both sides of the water balance should be explored. On the supply side, one key initiative under the TWMS is to explore the use of new and sustainable water resources, such as water reclamation (including grey water recycling and rainwater harvesting).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.1. Sustaining supply in buildings

The Government has been taking the lead to promote and implement water reclamation in buildings. Apart from establishing quality and technical standards for grey water recycling and rainwater harvesting, the Government is taking forward plans to include grey water recycling and rainwater harvesting systems for non-potable uses in suitable new public works projects. So far, grey water recycling systems or rainwater harvesting systems have been introduced in over 60 works projects including schools and various government facilities.

A joint circular on green government buildings was issued in April 2015 by the Government's Development Bureau and the Environment Bureau, highlighting the policy on the use of recycled water in government buildings. Under the circular, all new government buildings with the potential of reducing fresh water demand for non-potable applications through rainwater harvesting or grey water recycling are required to have on-site water treatment and recycling facilities installed as far as reasonably practicable. The general principle is that so long as the operating and maintenance costs can be offset by the saving of the production cost for the fresh water saved, installation of such facilities should actively be pursued. Moreover, all new government buildings should aim at maximising the use of reclaimed water from treated sewage effluent, if available, for non-potable applications such as toilet flushing.

Under the policy of the circular, existing government buildings should also aim at maximising the use of reclaimed water, where available, and exploring the use of recycled grey water and harvested rainwater for non-potable applications, whenever there are large-scale relocation or interior renovation works taking place.

2.2. Buildings in the private sector

For private developments, the implementation of water recycling is encouraged through a green building certification scheme, namely the Building Environmental Assessment Method (BEAM) Plus. BEAM Plus sets out best practice criteria on how buildings should be designed, constructed, operated, etc. to reduce their environmental impacts thereby increasing their overall sustainability. For both new buildings and existing buildings, the BEAM Plus assessment confers ratings (Platinum, Gold, Silver and Bronze) according to scores attained.

There is a "Water Use" aspect included in the BEAM Plus with assessment features intended to improve water utilisation and conservation. Apart from encouraging water conservation initiatives such as the use of water efficient devices, credits are granted for utilising sustainable water sources to reduce fresh water consumption. Other than implementing water recycling through harvesting of rainwater and/or recycling of grey water, buildings can also obtain credits for the establishment of an irrigation system which requires limited use of fresh water, or deploying highly efficient irrigation technologies and/or making use of recycled water to reduce fresh water consumption for irrigation.

The Government has been providing support in the reviews for the BEAM Plus Existing Buildings and New Buildings, putting forth more initiatives, hence more credits, in relation to efficient and sustainable water utilisation in the assessment tool.

3. REDUCING DEMAND IN BUILDINGS

On the other side of the water balance, it is also important to manage well and reduce water demand. In fact, water conservation is the cornerstone in the TWMS. After all, a droplet saved is a droplet gained. For existing buildings where implementation of supply initiatives like grey water recycling or rainwater harvesting is often much constrained by space and layout problems of the buildings themselves, options on the demand side is particularly important and useful, as demand management measures can be more easily implemented to facilitate them on the sustainable use of water. Transforming existing devices into water-saving ones

Existing plumbing fixtures installed in buildings are more often than not less water efficient. Retrofitting them with water saving devices is a direct means to reduce water consumption. To this end, the Government has been retrofitting plumbing fixtures with water saving devices in existing government buildings and schools.

Apart from retrofitting the fixtures, an alternative is to transform existing devices into water-saving ones by installation of flow controllers, which restrict the water flow. The Government has rolled out programmes where flow controllers are either distributed or installed to transform taps and showers into water-saving ones.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The "Let's Save 10L Water" Campaign, unveiled in March 2014, encourages the public to implement water saving practices and monitor their own water saving performance by signing a "Water Conservation Declaration". Each participating household is entitled to a pair of complimentary flow controllers for water taps to help conserve water. As of September 2016, complimentary flow controllers have been delivered to nearly 140,000 participating households.

Since August 2014, the Government has also dedicated efforts to install flow controllers to taps and showers at public rental housing estates, government buildings and schools.

3.2. Water Efficiency Labelling Scheme (WELS)

Since 2009, the Government has been implementing a voluntary WELS to cover different plumbing fixtures and water-consuming appliances in phases. By providing consumers with information on nominal flow rates and water efficiency grades, consumers can select water efficient fixtures and appliances by simply reading the WELS labels affixed to the products and their packages. Besides, WELS can promote public awareness on water conservation and efficiency issues, and achieve water savings.

Five types of plumbing fixtures and water-consuming appliances have come under WELS since 2009, namely showers for bathing (in September 2009), water taps (in September 2010), washing machines (in March 2011), urinal equipment (in March 2012) and flow controllers (in August 2014). At the same time, the Government is constantly striving to extend the coverage of the scheme and include more products in WELS.

Positive results of WELS can motivate consumers' use of these products, thereby expanding their market penetration. With increasing market migration to water saving devices, considerable amounts of water can be saved. To step up the gear in water conservation, WELS and the use of water efficient products will be further promoted, with the first move being the implementation of mandatory use of registered WELS products in all new domestic buildings and existing domestic buildings under major renovation together with the toilets in new non-domestic buildings and existing non-domestic buildings under major renovation.

3.3. Water efficiency audits and development of best practice guidelines for trades

With buildings accommodating domestic and non-domestic water users, it is important that demand management measures are formulated and implemented for both sectors. Non-domestic water use accounts for a substantial proportion of the overall fresh water consumption in Hong Kong, and could make significant contributions to water conservation by implementing water efficiency measures.

The Government has conducted water efficiency audits (WEAs) and developed best practice guidelines (BPGs) for water use efficiency for public facilities like public swimming pools, parks and markets, as well as major high water-consuming commercial operations including hotel and catering.

Through the WEAs, information on operation procedures are collected, and typical water use practices and consumption patterns are studied for development of BPGs. In WEAs, water use entities and plumbing arrangement are identified and staff interviewed to obtain information on water use practices and operational data. Monitoring and review of water consumption and flow trend and pattern is also carried out with a view to recommending short, medium and long term measures to improve water use efficiency. Upon completion of the WEA, staff are debriefed of the water consumption status and the recommended improvement measures.

BPGs are developed encompassing improvement or modification to water use hardware, good maintenance practices, as well as education for both staff and clients. The Government also provided support and collaborated with the catering and hotel industry stakeholders by holding a forum in November 2014 to share experiences about implementing best water use practices and water conservation measures. The BPGs for catering and hotel industries will be promulgated in the Water Conservation Week (WCW), a large-scale event to promote water conservation to various sectors in the community to be held in November 2016.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4. MANAGING LOSS IN BUILDINGS

In the course of managing demand, apart from reducing consumption, one must not forget the need to reduce water loss brought by leakages. As property management companies are responsible for the maintenance of the communal service including the underground inside service within a building, the Government sees them as a partner to enhance water loss management at building level.

4.1. Voluntary scheme on leak detection in buildings

The Government is reviewing and formulating a voluntary scheme on leak detection in buildings. The scheme aims to assist property owners and management agents in conducting leak detection for underground inside services to identify areas in advance for necessary maintenance, thus minimising wastage of water arising from leakage and reducing the extent of repair works. Through participating in the scheme, the building management agent could strengthen its capability to achieve value-added performance in meeting the expectation of tenants with respect to the reliability of the inside service whilst earning recognition for being capable of demonstrating consistent compliance with the prescribed criteria under the scheme.

Applications will be assessed based on the methodology, staff qualification, frequency of leak detection works and report submission. Successful applicants will be awarded certificates, as recognition of their efforts to maintain the healthiness of the water supply systems they manage, having fulfilled the criteria concerning leak detection of their inside service and rectification of any irregularity identified.

5. UTILISING SMART TECHNOLOGIES IN BUILDINGS

Monitoring one's water consumption can enhance one's awareness and trigger water conservation and rectification actions. With technological advancement, the application of smart metering for water supply can enable close monitoring of water consumption by consumers themselves and the Government.

5.1. Automatic meter reading system

With automatic meter reading (AMR) system, water consumption data can be read automatically from smart water meters for purposes of billing and also better planning of water supplies. Timely water consumption information can be provided to the consumers through the internet and mobile phone to raise their awareness on water conservation and help stimulate behavioural change. In gist, smart water meters are equipped with units to collect metering data, which will eventually be transmitted to a master station in the Government through 3G/broadband networks.

Benefits of AMR include:

- Improving meter reading efficiency (i.e. Reducing human error);
- Detecting abnormal water consumption (e.g. Leakage of plumbing);
- Allowing better planning and management of water supplies;
- Enhancing services through provision of timely water consumption information via internet and mobile phone; and
- Providing an ideal platform for promotion of water conservation.

5.2. Smartphone application

The Government is conducting a pilot project for smart metering of water supply in selected government quarters and public housing blocks. In addition, a mobile phone application (the App) is being developed to review the feasibility and the effectiveness of using mobile phone for dissemination of timely consumption data to consumers. Apart from consumption data, the App can also provide a benchmark of consumers' water usage and generate alert on detection of suspected leakage of their pipework.

Upon launching of the system, consumers for whom AMR infrastructure has been installed can access their water consumption data and other related information through the App on their smartphone.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The App also has a function for benchmarking the user's water consumption against Hong Kong's overall per capita consumption. Such function can help consumers to gauge how efficient water is being used by them so as to raise their awareness on water conservation.

In addition, based on the consumptions recorded, the system is able to generate alert to the customer's mobile phone on detection of suspected leakage of their pipework (probably due to seepage or dripping tap). Such a function would enable timely action be taken by customers to avoid wastage of water.

6. EDUCATING OCCUPANTS IN BUILDINGS

While many of the implemented measures focus on the hardware, success will not be possible if building occupants are not on the same track. To this end, the Government has taken on a range of key software promotional initiatives to raise the public's awareness and commitment to water conservation.

6.1. Educating the youngsters

Early education has all along been known as an effective means to inculcate the younger generation about adopting good water saving habits that will last for a lifetime. Since 2009, the Government has run a series of well-received school educational programmes, such as school water audits and roadshows to help primary school children establish effective water saving practices and encourage them to promote water conservation to their peers and family members. In furtherance, the Government has rolled out a "Cherish Water Campus" Integrated Education Programme (IEP) in primary schools in the 2015/16 school year, consolidating and combining existing and new school initiatives to keep the concept of sustainable water conservation a key area of study in schools. The IEP integrates theory with practice, with an aim to enhancing students' knowledge about protection of water resources and the global water crisis, and facilitates them to adopt water conservation practices at school and at home, as well as to spread the water-saving message to their peers, families and the community.

6.2. Water Resources Education Centre

In 2012, the Government set up a temporary Water Resources Education Centre (WREC) to enhance the younger generation's knowledge about water conservation. The Government has commenced the design of a permanent WREC at Tin Shui Wai. With an expanded exhibition area, four times that of the temporary WREC, the new WREC will be able to introduce more new initiatives and in-depth materials covering various aspects of water conservation and water resources to cater for a wider spectrum of visitors. The new WREC is expected to be opened in 2018/2019.

7. FUTURE OUTLOOK

Rome was not built in one day, neither was it built by one person. Success on water sustainability in Hong Kong relies on actions at multiple levels, from city to buildings, from community to individuals.

At city level, the Government is pursuing to exploit new water resources that are not susceptible to climate change in addition to the existing three water sources. Hong Kong is now progressing from its current three-pronged water supply structure to a six-pronged structure that comprises local yield, imported Dongjiang water, seawater for flushing, desalinated water, recycled grey water and rainwater harvesting as well as reclaimed water. The six-pronged water supply structure will be the pillars that together support Hong Kong's enhanced water security, reliability and resilience.

At building level, the Government has introduced an array of measures to make buildings more water-efficient. These include the promotion of using sustainable water supply sources, use of water efficient devices, better water loss management and utilising smart technology. The combination of supply and demand measures on both sides of the water balance provides a well-rounded solution for buildings to use water more efficiently and more sustainably.

At the same time, the Government has also adopted a multi-pronged approach which covers software measures targeted to occupants and individuals, for it will be impossible for a building to achieve sustainability if the occupants are not committed to operate them in a sustainable manner. At community and individual levels, efforts have been made to raise water-conscientiousness through promotion and education, with an aim of enhancing awareness of

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

building occupants on water sustainability. By further transforming the awareness into actions, a building can achieve much more on water conservation, water efficiency and water sustainability.

The concerted effort and holistic actions at city, building and individual levels will enable Hong Kong to build high on sustainable use of water for the future generations.

ABSTRACT

Green building (GB) policies have been implemented to promote GB and address climate change. Most of the existing literatures have studied the costs and benefits of developing GB, without considerations of GB policies' impacts. This paper aims to study costs and benefits of implementing GB policy from developers' perspective. It takes the Gross Floor Area (GFA) Concession, which is a popular policy and has been implemented in the US, Singapore and Hong Kong, as an example, to compare its implementation in three regions and analyze how it affects developers' costs and benefits. Findings show that Hong Kong has relatively lower threshold to acquire GFA concession for developers and it is the right time to adjust the GFA concession incentive to reflect the market transformation and further encourage developers to go for higher levels of GB.

Keywords: policy and regulation, costs and benefits, GFA concession

1. INTRODUCTION

Building energy consumption contributes to one-third of greenhouse gas emissions in the world (UNEP, 2009). Besides, building sectors also affect the built environment in other ways, like environmental damage, resource depletion and solid waste generation in the process of building construction and operation. Against this background, green building (GB) as a solution to the environmental problems become popular. However, constructing green building costs more than traditional buildings, which is one of the main barriers to prevent GB development. To promote the GB, various economic incentives have been implemented to reduce or cover developers extra costs, such as GFA concession, tax reduction, and subsidies.

Among all these economic incentives, the GFA Concession Scheme becomes a popular one because it would not affect government income and be subject to government financial situations (Fan, Qian, & Chan, 2015). The GFA Concession Scheme is designed to reward developers extra GFA for their contributions to the public facilities or sustainability and government could save that amount of money in the meanwhile. However, too many GFA concessions would impose additional social costs (Feiock, Tavares, & Lubell, 2008), and few GFA concessions are not enough to motivate developers to construct different levels of green building. Therefore, how to use this instrument to promote GB remains a question. This paper studies the GFA Concession Scheme in the US, Singapore, and Hong Kong and analyzed how the scheme affect developers' costs and benefits and how to adjust it to reflect market transformation of GB.

2. COSTS AND BENEFITS TO CONSTRUCT GREEN BUILDING

The additional costs of green building have been discussed in a lot of articles. For example, Yu and Tu (2011) stated that Green Mark buildings require a range of 1%-3% extra cost compared with non-green mark buildings in Singapore. Their Building and Construction Authority (2015) stated that the cost premiums for GM Platinum, and GoldPlus are S$123/m2 and S$97$/m2 in the residential sector. Kats et al. (2003) claimed 0.66% extra cost for LEED certification, 2.11% for Silver, 1.82% for Gold, and 6.50% for Platinum in the US. Davis Langdon (2007) suggested 3%-5% greater cost for five-star and 6% for six-star in Australia where the Green Star rating system is employed. In Hong Kong, under the Hong Kong Building Environmental Assessment Methods (BEAM), there were 0.8%, 1.3% and 3.2% cost premiums for Silver, Gold and Platinum building respectively (Burnett et al., 2008). However, the HKBEAM has been upgraded to BEAM Plus and experienced two versions for new buildings and three versions for existing buildings. The construction cost of green building has increased with the upgradation of the BEAM Plus. Similar situation also happened in the US. The improvement of the LEED increased the construction costs of green building, which in return influences the updates of the green building incentive.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

In terms of financial benefits to construct green building, Fuerst and McAllister (2008) claimed that green buildings have price premiums, 10% and 31% premiums for GB certified by Energy Star and LEED respectively. Yu and Tu (2011) stated that Green Mark buildings have a price premium that increases with the rating of Green Mark. Miller, Spivey, and Florance (2008) suggested 9.94% price premium for LEED and 5.76% for Energy Star per square foot. However, there are few studies discussing the selling price of GB in Hong Kong. The most relevant one finished by Burnett et al. (2008) studied the financial benefit of GB from the life cycle's perspective, such as reducing sewage charges and energy consumption.

3. Green building incentive schemes

In order to promote green building, customized incentive schemes are acknowledged as one of the most effective approaches for government intervention (Qian & Chan, 2007). Their purpose is to motivate the market and attract the stakeholders' business interests in green building investment through reasonable incentive policies. To fulfill this objective, the incentives should be attractive to business and also be administratively easy for government to implement. The main reasons for instituting incentives for GB promotion are: 1) To correct for external costs; 2) To supply information (when the incentive is tied to a specific action or investment); 3) To reduce investor risk in a new technology; and 4) To accelerate the pace of adoption of efficient technologies.

3.1. The GFA Concession Scheme and developers' costs and benefits

The GFA Concession Scheme is designed to reward developer additional gross floor area for their contributions to the public facilities so that government could save money to invest (Tang & Tang, 1999). It has a long history and been applied to renewable energy of buildings in New Zealand, Japan, France and US (Paetz & Pinto-Delas, 2007), affordable housing incentive scheme in the US, Australia and UK (Fox & Davis, 1975), and green building promotion in the US, Singapore and Hong Kong (Fan, Qian, & Chan, 2015) where different terminologies sharing the same meaning, such as density bonus, GFA concession and GFA bonus, are used. The GFA Concession Scheme addresses the market barriers of higher upfront cost and corrects the misplaced incentives of green building.

3.1.1. US

The Arlington County is the first one to implement the GFA bonus in the US. It started in 1999, and was revised in 2003, 2009, 2012 and 2015 on the basis of the increase in knowledge and market demand for green buildings.

Table 1 illustrates the development history of the GFA bonus incentive scheme in Arlington County. The adjustment of the GFA bonus incentive is based on the market transformation that buildings achieved lower levels of LEED more frequently. Obviously, the assessment criteria and the calculation method of the GFA bonus were becoming more difficult and complicated from 1991 to 2015. The Table 1 indicates that to reflect the market transformation, the adjustment of GFA bonus could start from four aspects: 1) to expand the range of GFA bonus; 2) to reduce the level of GFA bonus; 3) to improve the criteria to acquire GFA bonus by upgrading the green building assessment methods, and adding additional conditions (like energy efficiency): 4) to increase GFA bonus for meeting higher rating of GB or additional conditions, and decrease bonus for lower ratings. From 2009, the incentive for office buildings is separated from and less than that for residential buildings in that office buildings have more market demand. Government incentives were given more to the residential sector. From 2012, the energy efficiency requirement was added in the incentive scheme to further promote sustainability. In 2015, Energy Star certification becomes mandatory to apply for the GFA bonus for the office buildings. Every time to adjust the incentive, developers' costs and benefits were considered. For example, LEED version 4 leads to more construction cost than LEED 2009 and Energy Star certification also costs developers. Therefore, in 2015, the incentive level increases a little to motivate developers to adopt new standards.

3.1.2. Singapore

The Building and Construction Authority (BCA) in Singapore and the Urban Redevelopment Authority (URA) jointly released the Green Mark (GM) GFA Incentive in 2009, which stated that developers and building owners could apply for up to 2% GFA bonus (subject to a cap of 5,000 sqm) in exchange for constructing GM Goldplus building and 1% GFA bonus (subject to a cap of 2,500 sqm) for constructing GM Platinum buildings. During 2009-2013, the total GFA of green buildings increased 34.2 million m2, while before this GFA scheme, the increased total GFA of green buildings only increased 14.2 million m2 within 4 years from 2005 to 2009.

In 2010, BCA announced that under government land sale program, all the new developments on the land sold on or after 5 May 2010 in the Strategic Growth Areas should be designed to meet a higher GM certification (Building and Construction Authority, 2014). In Downtown core, it is required that building should reach GM Goldplus Rating. This policy could help improve building energy efficiency and release heat island effect in city core. Therefore, it is mandatory to construct green building in the Downtown core.

	1999	2003	2009	2012	2015	
Objective	To guide the building design and construction	To include all LEED levels and all the projects	To adjust the bonus to reflect market transformation	To focus on energy efficiency to align with the Community Plan goals, minor bonus adjustment	To encourage developers focusing on the incorporation of energy efficiency into the site plan and on the ongoing energy consumption	
Assessment criteria	• LEED Silver only (commercial office only)	• LEED Certified, Silver, Gold or Platinum	• LEED Certified, Silver, Gold or Platinum	• LEED 2009 Silver, Gold or Platinum • Energy efficiency for commercial office buildings	• LEED version 4 • Energy Star Building certification within four years of occupancy (commercial office building) • Community Priority credits (optional)	
Calculation of GFA concession	• Up to 0.25 FAR (floor area ratio)	• 0.15FAR (Certified) • 0.25FAR (Silver) • 0.35FAR (Gold) • 0.35FAR (Platinum)	**For office buildings** • 0.05FAR (Certified) • 0.15FAR (Silver) • 0.35FAR (Gold) • 0.45FAR (Platinum) **For residential buildings** • 0.10FAR (Certified) • 0.20FAR (Silver) • 0.40FAR (Gold) • 0.50FAR (Platinum)	**For office buildings** • 0.20 FAR (Silver+20% energy efficiency) • 0.35FAR (Gold+20% energy efficiency) • 0.45FAR (Platinum+20% energy efficiency) **For residential buildings** • 0.25 FAR (Silver) • 0.40FAR (Gold) • 0.50FAR (Platinum) **Multifamily residential buildings** • Additional 0.05FAR (LEED +18% energy efficiency	**For office buildings** **Silver** • 0.25 FAR (Energy Star score of 75) • 0.275 FAR (Energy Star score of 75+ one Community Priority credit) • 0.30 FAR (Energy Star score of 75+ Two Community Priority credits) **Gold** • 0.35FAR (Energy Star score of 75) • 0.375 FAR (Energy Star score of 75+ one Community Priority credit) • 0.40FAR (Energy Star score of 75+ two Community Priority credits) **Platinum** • 0.50FAR (Energy Star score of 75) • 0.525FAR (Energy Star score of 75+ one • Community Priority credit) • 0.55FAR (Energy Star score of 75+ two Community Priority credits)	**For residential buildings** **Silver** • 0.25 FAR • 0.275 FAR (one Community Priority credit) • 0.30 FAR (Two Community Priority credits) **Gold** • 0.35FAR • 0.375 FAR (one Community Priority credit) • 0.40FAR (Two Community Priority credits) **Platinum** • 0.50 FAR • 0.525 FAR (one Community Priority credit) • 0.55 FAR (Two Community Priority credits) LEED Gold plus Two Community Priority credits plus Net Zero Energy certification may earn extra density bonus above 0.55 FAR

3.1.3. Hong Kong

Hong Kong has implemented the GFA Concession Scheme since 2011, which grants developers GFA concession if they register the BEAM Plus or reach any level of BEAM Plus, fulfill the Sustainable Building Design Guidelines (SBDGs) and provide the prescribed building features. The floor areas of these building features they designed could be exempted from the calculation of the GFA. The prescribed building features are tailored for the specific built environment in Hong Kong to address the urgent city problems. To some extent, it is mandatory to integrate the features in order to applying for the GFA concession. For Hong Kong government, few construction costs of these building features could improve the built environment. However, for the developers and architects, design the building features and get approval from government takes time and involve approval risks, especially at the beginning of implementing the GFA Concession Scheme. With the practice of participating the scheme, industry is becoming more and more familiar with the SBDGs. The Figure 1 illustrates the statistics of applications for the GFA concession from 2011 to 2014. It is obvious that there are more and more applications and the approval rate is becoming high. This reflects the market transformation that developers could benefit from the participating the GFA Concession Scheme, and the knowledge and market demand for green buildings have increased.

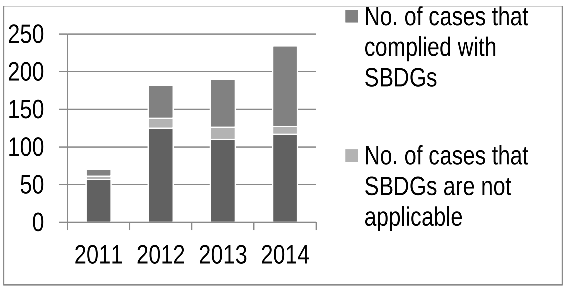

Figure 1: Statistics of applications for the GFA concession Source: Building Department (2014)

3.1.4. Comparison of US, Hong Kong and Singapore

US have longer history of GFA concession incentive to promote green building than Hong Kong and Singapore. It has developed criteria to assess market transformation of green building and detailed methods to adjust the GFA bonus with the market transformation, which has been illustrated in previous section. On the contrast, Hong Kong and Singapore are experiencing the period of trial and error. It takes time to understand how market works and improve the incentive scheme, especially for the construction industry with several years' construction period. Besides, unlike Hong Kong and Singapore, the Arlington County have not considered too much about local built environment. It may be because Hong Kong and Singapore has high development density and land price. The amount of GFA bonus and how to grant it would influence market and built environment more.

Hong Kong and Singapore have integrated GFA concession incentive scheme into the development control system in a different way. In Hong Kong, GFA concession is subject to the floor area of certain building features illustrated in the Building Ordinance. And the BEAM Plus and SBDG are the prerequisites of being granted GFA concession. Only obtaining the BEAM Plus certification and fulfilling the SBDG are not enough to be granted GFA concession. In Singapore, GM Platinum or Goldplus is the only requirement of getting GFA bonus. However, in the new growth strategic areas, it's mandatory to achieve GM Platinum or Goldplus because they are the land sale conditions. This indicates that, when Singapore government made Master Plan, they already made the plan of GB distribution.

There are different methods to calculate GFA concession in Hong Kong and Singapore as showed in the Table 2, which is closely related to the development control. In Singapore, GM GFA is relevant to land value, total GFA regulated in Master Plan and the prescribed green premium. As the prescribed green premium increases with the rating of GM, and further increase the GM GFA bonus that means more salable area, developers are motivated to construct higher ratings of GM. The land value and total permitted GFA are fixed and could be estimated, which reduce the risks to participate the GM GFA Incentive Scheme for developers in Singapore. On the contrast, in Hong Kong, most of the land value is determined by land auction and how many GFA concession developers could acquire is uncertain, bringing more uncertainties to developers. Additionally, not all the exempted floor area could be salable area. It depends on the property market and economic situations. Therefore, under the current systems, developers in Singapore have fewer risks than those in Hong Kong if they participate in the GFA Concession Scheme. In other words, the system in Singapore costs developers less.

On the other hands, the threshold (minimum standard to grant GFA concession) to participate in the GFA Concession Scheme in Hong Kong is lower than that in Singapore (Table 2). Developers only need to register the BEAM Plus that costs them much less than reaching the higher ratings of GB. This little extra cost can help them acquire the GFA concession and make profits from it. That is why after implementing the GFA Concession Scheme, the registered BEAM Plus projects have increased almost one third within one year (Liu & Lau, 2013). Moreover, developers in Hong Kong do not have to provide security deposit like Singapore to guarantee that they would achieve the certain rating of BEAM Plus they committed they apply for the GFA concession. This largely decreases the investment risks for developers. However, with the increase in GB knowledge and market demand, it is the time to adjust the incentives to reflect the market transformation.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

	Hong Kong Gross Floor Area concession (since 2011)	Singapore Green Mark Gross Floor Area incentive scheme (Since 2009)
Objective	To attract developers to construct BEAM Plus building and integrate sustainable building design guideline (SBDG)	To encourage the private sector to develop buildings that attain higher tier Green Mark ratings (i.e. Green Mark Platinum or Green Mark Gold PLUS)
Assessment criteria	• BEAM Plus Registration (Prerequisite) • Sustainable building design guideline (Prerequisite) • Building features illustrated in the Joint Practice Notes (e.g. green features, amenity features.)	• Green Mark Platinum could be awarded 2 % GFA bonus at most (subject to a cap of 5,000 sqm). • Green Mark Gold plus could be awarded 1% GFA bonus at most (subject to a cap of 25,000 sqm)
Calculation of GFA concession	GFA Concession = Exempted GFA + Disregarded GFA + GFA bonus	$\text{GM GFA} = \dfrac{\left[\begin{array}{c}\text{Proposed GFA (sqm)}\\ \text{(subject to MP allowable intensity)}\end{array}\right] \times \left[\begin{array}{c}\text{Prescribed Green}\\ \text{Premium (\$/sqm)}\end{array}\right]}{\text{Land Value (\$/sqm) (determined by proxy using DC rates)}}$
Mandatory / Voluntary basis	• Voluntary to participate in GFA concession incentive scheme; • Mandatory to acquire BEAM Plus certification and fulfill SBDG if developers want all the building features granted GFA concession	• Voluntary for new private development (non-public sector), redevelopments and reconstruction developments to join the scheme; • For the sites where the GM Platinum or Goldplus standards are mandated as part of land sales condition, it's mandatory to reach GM Platinum or Goldplus without GFA bonus. • For the sites where the Goldplus standard is mandated, it's voluntary for developers to attain the higher GM Platinum standard and acquire an incremental GFA incentive (the difference between GFA incentives for GM Platinum and GM Goldplus).
Enforcement	NA	• Security deposit to guarantee that developers achieve the GB grading they committed
Minimum standard to grant GFA concession	• BEAM Plus registration • Provision of prescribed green features • Fulfilling the SBDGs	• GM Gold Plus

Table 2: Comparison of the GFA concession scheme in Hong Kong and Singapore

4. DISCUSSION AND CONCLUSION

This paper discussed how the GFA Concession Scheme affects the costs and benefits of developers. The amount of the GFA concession and calculation method, minimum standard to grant GFA concession, as well as the costs to fulfil different GB assessment system influence developers' costs and benefits. Hong Kong has relatively lower threshold to apply for the GFA concession, compared with Arlington, US and Singapore, mainly because the BEAM Plus requirement to qualify for the GFA concessions is simply to register the projects, which means that buildings do not get certifications and only need to fulfil the prerequisite in each section of the BEAM Plus which costs developers little. After 5 years of implementing the GFA Concession Scheme, there are 66% (860 out of 1312) projects have registered BEAM Plus, and 21% (270 out of 1312) projects have achieved Provisional Bronze or above (Building Department, 2014). It is the right time to adjust the scheme to encourage developers to go for higher levels of GB.

Borrowing the experience from Arlington County, the adjustment of the GFA Concession Scheme could start from three aspects: 1) the prerequisite that register the BEAM Plus should increase to the BEAM Plus Provisional Bronze; 2) grant different levels of BEAM Plus buildings different amount of the GFA concession on the basis of the extra construction costs; 3) give more GFA concessions to the higher levels of GB (like Gold and Platinum).

ABSTRACT

Since the industrial revolution, increasing amount of CO^2 has been released due to the human economic activities. The human society attempt to find a balance in the game of protection and development, which not only protects the unique patterns and traditional way of life, but also allows the residents living here to enjoy the convenience that modern life has brought. To maintain and release the new vitality of the city, and tap the potential value and attraction, and respect the ecological environment, as well as make rational use of the advantages of the geographical environment in order to establish a green and sustainable living environment. Compared to new buildings, conservation projects can reuse the existing constructions' fabric, which can reduce construction debris through the reclamation of carbon embodied in the existing materials. The paper analyzes average embodied carbon intensities and construction costs differences of the major building components between new-build projects and heritage conservations. It aims to establish a carbon cycle model through "calculate-reduce-offset" for the goal of low-carbon city. The authors stress that this framework can enable balanced decision-makings concerning heritage buildings redevelopment in the context of environmental and economic sustainability.

Keywords: embodied carbon, deep building renovation, heritage conservation

1. INTRODUCTION

In the process of modernization, one of the most serious problems the human society facing is global warming, which is believed to be caused by the greenhouse gas, especially, the carbon dioxide. Since the industrial revolution, increasingly amount of CO^2 has been released due to the human economic activities like the combustion of the fossil fuel, the change of the land use method, etc. (IPCC, 2007). The lifestyles of human beings must be to blame. In recent years, with the rapid development of Hong Kong's economy, the problem of the carbon emissions in new building has aroused the society's concern. In refurbished buildings, historic building and urban areas, however, there is still not being paid enough attention.

2. BACKGROUND

Hong Kong, a region represents the economic and cultural prosperity since ancient times, attracts bunch of people to settle down with the benefits of its suitable climate, high quality of living environment and the unique scene of seaside city style. When talks about the rich historical heritage and the extraordinary beautiful urban form in contemporary Hong Kong, it must be owing to the Ming and Qing Dynasties which lasted several centuries. Finally, it formed what we can see today—a characteristic life fulfilled with Hong Kong features.

Currently, the protection mechanism of the heritage is becoming more and more perfect. A great deal of manpower and material resources has been devoted to protect the historical and cultural city by government. In March 2009, the Antiquities Advisory Board announced that the assessment of 1444 historic buildings was completed. Up to 10 September 2013, there have been a total of 942 historic buildings on the key protection list. Well, the162 buildings with Grade 1 status in Hong Kong take up 17.2%%, the 329 buildings with Grade 2 status account for 34.9% and 451 buildings with Grade 3 status account for 47.9%. Compared to new buildings, conservation projects can reuse the existing constructions' fabric, which can reduce construction debris through the reclamation of carbon embodied in the existing materials.

In addition, many experts and organizations set up the concept of low-carbon district or city. It is required for intensive, intelligent, green and low carbon. Therefore, the establishment of a new type of Hong Kong not only has a very broad prospect, but also has a profound and lasting significance.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Such as Tai O, which is regarded as the representative of ancient water towns, is a typical case of urban heritage in Hong Kong. The historical preservation practice of Hong Kong government advocates the exploration pioneer spirit in the world, which always plays a leading role in the whole process of heritage protection. (Yao C.L., 2009) It allows the historical and cultural heritage conservation practice in Hong Kong urban areas to be at the forefront position. In this study, the Hong Kong region as a pilot case, it takes the city representatives of historic districts, respectively. Then it plans to establish a carbon cycle model which is suitable for Hong Kong in order to establish a new-type low-carbon ancient City.

As early as 1987, the "Washington Charter" proposed that "the protection of historic urban areas should become an integral part of the overall effect of social and economic development, and also should be taken into account at all levels of urban planning and management plans." In the process of modernization, the only if the development of ancient city will be integrated into the entire city and its operating mechanism, it's possible to pursue the more efficient and slow-release cultural values by a spirit with more rationality and responsibility in a wider geographical area.

3. METHOD

The methods are as follow:

- Literature review method:

Obtain the information through referring to literature in order to comprehensively and correctly understand the relevant knowledge in the field of low-carbon, and also seek for the calculation method of embodied carbon and carbon emissions, as well as find out the related research factors which are needed to be collected in the survey method.

- Survey method:

Collect the practical condition of related study objects purposefully and systematically through the field visits, then use the conversation, testing and other methods to conduct a deep investigation of heritage buildings or districts so that a lot of data are collected to be used for analysis, comparison and induction.

- Case study:

The calculation methods of embodied carbon and carbon emissions are applied into the research of heritage buildings or districts to determine the value of carbon emissions per unit area in Hong Kong and emission coefficient.

- Comparison method:

Adjust the practical value which is used to build the mechanism and policy of the new-type historical and culture areas through the comparison of the different ancient districts in Hong Kong, even in Pearl River Delta.

4. MODEL

The study attempts to establish a carbon cycle model through "Calculate-Reduce-Offset", and wishes to achieve the goal of low-carbon or even zero-carbon new-type city, in order to make the sense of sustainable development of Hong Kong come true.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

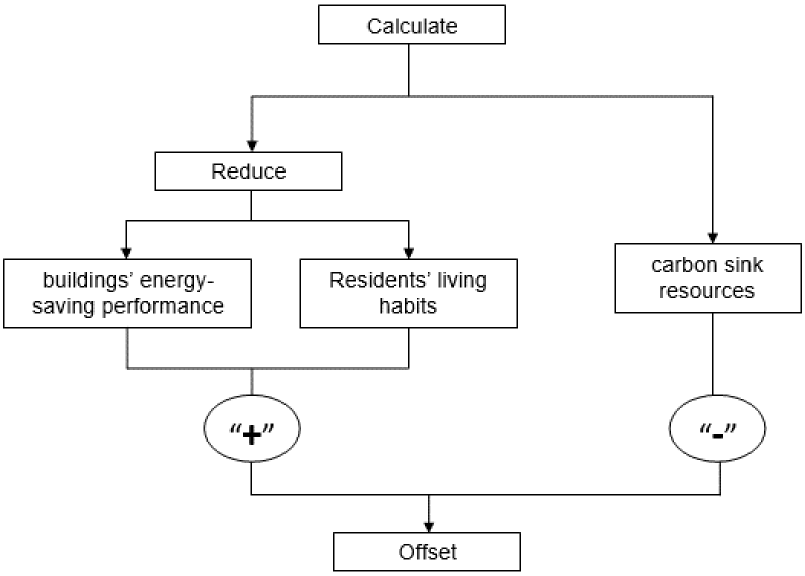

Figure 1: Carbon cycle model

4.1. Step 1: Calculate

Because of the similarity of climate conditions, natural environment, and people's living habits in Hong Kong, the value of carbon emissions per unit area can be calculated through the embodied carbon of the buildings and the carbon emissions of daily life. Thus, we can deduce the amount of carbon emissions that the same type of ancient buildings or district made in Hong Kong.

4.2. Step 2: Reduce

In comparison with the standardized modular system in modern urban constructions, the form of buildings in Hong Kong have in common is that they all have built by seas, so the embodied carbon emissions can be reduced through the optimization of buildings' energy-saving performance.

There is a part of residents still persists the environmentally-unfriendly living habits. By combing and optimizing the living habits of residents in Hong Kong, the ancient districts' carbon emissions of daily life can be reduced.

4.3. Step 3: Offset

As we all known, the majority of historic districts are constructed near seas, and some of them fronting water and with hills on the back. According to this unique natural environment, the carbon sink resources are fully abundant, which plays a very important role in ecosystem services. This study based on the unique geographical environment of historic areas, aims to finding methods for carbon neutrality.

This model aims to establish a carbon cycle model through "calculate-reduce-offset" for the goal of low-carbon historic districts, in order to make the sense of sustainable development of Hong Kong come true. It uses the special environment (water area, wetland, vegetation, etc.) of seaside city, mines the carbon sink resources and makes carbon offsetting strategy. In order to formulate the mechanism and policy framework for the construction of the new-type urbanization.

5. CONCLUSION

With the rapid development of economy and culture in modern society, a lot of modern crisis come into being naturally, such as the large energy consumption, ecological deterioration, disappeared culture and indifferent human feelings. The historic buildings in Hong Kong have a beautiful historic character, and they're regarded as the intangible cultural heritage to be valued and protected. However, the ancient buildings as the carrier of real life rather than the ornamental scenic region are inevitable to be involved in the process of modernization. As a result, the residents' living and tourists' influx as well as a lot of carbon emissions problems come into being naturally.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The study achieves a virtuous circle of "computing-reduction-offset" through the research of carbon cycle model of ancient districts. Such a model conducts a case study on a single village so as to seek the carbon emission coefficient which is suitable to Hong Kong and takes the unit area as a unit, and optimizes the traditional way of life to reduce carbon emissions, and actively uses the geographical environment to conduct the carbon offsets. Then it develops the mechanism to build the new-type low-carbon ancient districts through the experiment of all the historic buildings and districts in Hong Kong.

The study attempts to find a balance in the game of protection and development, which not only protects the unique patterns and traditional way of life of Hong Kong, but also allows the residents living here to enjoy the convenience that modern life has brought. To maintain and release the new vitality of ancient town and village, and tap the potential value and attraction, and respect the ecological environment, as well as make a rational use of the advantages of the geographical environment in order to establish a green and sustainable living environment.

Hong Kong has accumulated a rich experience in the protection of historical and culture buildings and villages, and has always played the important role of leader on a national scale. As the reform forward position of famous historical and culture districts, this study takes Hong Kong as a pilot case, which has a very profound significance and impact.

ABSTRACT

"Water resource is the necessary natural resource for the development of a country's economy. According International Water Association, the total amount of annual precipitation in Taiwan is 2.6 times of the average amount of annual precipitation in all countries in the world. Thus, Taiwan should not suffer from water scarcity. However, Taiwan ranks as the 18th country with physical water scarcity.

Microclimate observation data is acquired from Central Weather Bureau of Taiwan in this research study. Other than analyzing and calculating the information from the database in order to identify the exterior microclimatic factors, the volume of the rainwater collection tanks in Kaohsiung will be calculated for its accuracy in correlation with rainwater overflow and tap water replenishment. Finally, the characteristics of Kaohsiung microclimatic factors collected in this research will be reflected with quantitative data on to the actual design for buildings in Kaohsiung. The main focuses of this research are the following:

- Analyze foundational microclimatic data in Kaohsiung
- The calculation of the volume of the rainwater collection tanks in Kaohsiung
- Provide method to incorporate and reconfigure rainwater collection tanks in accordance with Kaohsiung characteristics.

Keywords: Kaohsiung buildings, water resource, innovative design policy.

1. INTRODUCTION

According to a statistics generated from the United Nations-Water, "household water consumption" makes up 10% of global water withdrawal, indicating that disproportionate water consumption has become a common problem faced by several countries around the world. Taiwan Water Corporation reveals that in the past few years (2004~2015), domestic water consumption is maintained at a level between 257 and 265 liters per capita per day. In terms of industry types, "industrial water consumption" and "commercial water consumption" account for the largest proportion of total water consumption, while "household water consumption" closely followed next, implying that domestic Taiwan Kaohsiung local government must take action to promote guidance policies on water recycling. However, since rainwater collection can be affected by local water production, local water consumption, microclimate change at Kaohsiung Metropolitan District, and architectural volume, while considering about water circulation, considerations in the control parameters such as "overflow" and "shortage" related to water tank's spatial volume must be included, so as to increase benefit in water resource circulation. All this have become the major motivation for this study.

In this study, "Water Resource Sustainability Index" promoted by World Green Building Council is adopted as a solid foundation for analyzing long-term microclimate data of Kaohsiung Metropolitan District generated from Central Weather Bureau. Aside from performing statistical analysis on the big database to grasp outdoor microclimate influencing factors, total input and output volume is estimated for deciding water circulation balances in architectures located at Kaohsiung Metropolitan District. Based on the quantitative data, recommendations that suit local circumstances are proposed in response to rainwater collection analysis and global compliance rate for green buildings constructed in Kaohsiung Metropolitan District.

2. LITERATURE REVIEW

2.1. Specification related to architectural regulation in technicality in Taiwan

"Total daily water demand volume in a building" (Wt) must be calculated based on the standard given in Table 1. In other words, Wt must be calculated based on "daily water demand for individual building category" (Wf) and "floor area not including non-dwelling area" (Af) with spatial area such as parking lot, engine room and warehouse excluded. As to building categories not included in the Table (such as gymnasium and museum), Wt must be calculated based on water demand of the architectural design. However, since there is no prominent relationship between water consumption and floor area when it comes to residential building, Wt must be calculated based on the standard of "4 members per household", "250L of water consumption per person per day" and "total households in a residential building".

Table 1: Assessment and evaluation standards for water consumption in various building categories

Daily tap water substitution volume (Ws) must be decided based on the smaller value of either daily rainwater collection volume (Wr) or daily rainwater use volume (Wd). The main reason behind this principle is that once daily rainwater collection volume (Wr) is greater than daily rainwater use volume (Wd), excessive rainwater resource will be lost without adding any benefit to water conservation.

Since "request volume of rainwater storage tank" (Vs) can affect the usage rate of rain water collection volume, total value of "daily tap water substitution volume" (Ws) multiplied by "rational multiplier of the daily rainwater use volume" (Ns) is applied as the "minimum request volume of rainwater storage tank" (Vsm).

Since rainwater cannot be served as drinking water, tap water substitution rate (Rc) cannot be maintained at a level that surpasses 32% of the substitutable reclaimed water, with the exception of the introduction of high-end water quality processing techniques.

"Daily rainwater collection volume" (Wr) is calculated based on overall rainwater collection system and dynamic analysis on local precipitation frequency. This kind of evaluation will present a relatively negative result in rainwater collection volume and "tap water substitution rate" (Rc) of districts with lower precipitation frequency per day.

EEWH Water Resource Indicator for Domestic Green Building

The Water Resource Indicator is one of the threshold indicators of EEWH-RS; indicator score RS8 must be greater than 1.5 to pass. WI is first calculated by tallying the points for the following water-saving sub-indicators and then converted to indicator score RS8. The calculations and scoring are as follows:

$$WI=a+b+c+d+e+f$$

Equation 1

$$\text{Water Resource Indicator Calculation } RS8=2.50^{*}(WI-2.0)/2.0+1.5 \geq 1.5,\ 0.0 \leq RS8 \geq 8.0$$

Equation 2

Amongst them, RS8 stands for Water Resource Indicator Score; WI stands for water resource indicator (without unit); a stands for Toilet Score (without unit); b stands for Urinal Score (without unit); c stands for Tap for Public Use Score (without unit); e stands for Rainwater Equipment Score (without unit); while f stands for AC Water Conservation Score (without unit).

Residential Design and Encouragement Practices of Kaohsiung Metropolitan District

Article 10: Buildings under five stories with solar power facilities or greening facilities installed at roofs, roof protruding parts, or exposed platforms taking up more than 50% of legal building area can be installed with green power facilities that come with rainwater collection function.

Rainwater collection area generally refers to a part of the building such as roof and the wall. Rainwater storage system, on the other hand, is a part of the building that must be carefully considered for installation; with its volume not only affecting overall systematic benefit but also the building designs itself. In this research, "The Simulation and Evaluation of The Rainwater Utilization on Building Design (2000)" of Architecture and Building Research Institute (Ministry of the Interior) was adopted, with the rainwater utilization calculating software (given in Table 1) directly derived from water recycling calculation of "The Society of Heating, Air Conditioning and Sanitary Engineers of Japan".

2.2. Precipitation data analysis of Kaohsiung metropolitan districts

Based on different landscapes of plain area, hilly area, alpine area, and coastal area in Kaohsiung Metropolitan District, precipitation observatory data for over a decade is applied from Central Weather Bureau as a fundamental data in this research.

Kaohsiung Metropolitan District is located in the subtropical zone with warm temperature and sufficient sunlight throughout the year. Statistics from Central Weather Bureau has revealed that minimum temperature of the district is maintained at a range between 9.6 and 11.5 degree Celsius while maximum temperature of the district is maintained at a range between 36.4 and 36.9 degree Celsius, with average precipitation volume kept at 1,845 mm over the past ten years. Despite the abundant rainfall, precipitation period is generally concentrated in a short timespan that lasts from June to August, with a periodic precipitation volume of 1,199 mm that accounts for 65% of annual precipitation volume (as presented in Table 2). In terms of season, typhoon season usually lasts from May to October while drought season usually lasts from November to April of the next year, indicating a concentrated precipitation volume in the typhoon season. Compared to northern district, a ratio of "precipitation volume during typhoon season" to "precipitation volume during drought season" is merely 6:4, which is not at all beneficial for water utilization.

2.3. **Citizen's water consumptio**n from various building equipment

The term "water consumption per capita per day" can be referred to as "livelihood water consumption per capita per day". According to a calculation result, water consumption per capita per day in 2013 is 284 liters, which is 34 liters more than the international standard value of 250 liters. Due to a combine factors of raising living standard, subtropical climate, warm and humid weather, and higher demand for environmental sanitary and disease control, overall water consumption per capita per day is 250 liters.

Under "Water Consumption per Capita per Day of 250 Liters" proposed by the Ministry of Interior, recycled water can be applied to replace residential water used for toilet, cleaning and other purposes, which takes up 32% of total household water consumption. Tap water substitution rate can be evaluated through the following formula:

PCW = Qu / (Household Water Consumption x 0.32)

Usage / Water Amount	Parts that cannot be replaced by Recycled water 68%				Parts that can be replaced by Recycled water 32%			
	Bathe	Washing Food	Wash up	kitchen usage	Toilet	Cleaning	other	total
Daily average	50	60	20	40	60	10	10	250

Table 2: Water consumption per capita per day of 250 liters

3. CASE CALCULATION

In this research, rainwater utilization calculation software is taken as basic calculation approach, precipitation observation value over the past 10 years is applied as fundamental data, residential buildings in Kaohsiung Metropolitan District is considered as study subjects, and rainwater utilization rate or tap water substitution rate are utilized as referential indicators for rainwater storage tank. Base area: 3478.61 ㎡, basic Information

The above mentioned household water consumption is more difficult to be controlled by the engineering design of rainwater collection system. Under condition where rainwater collection area is kept constant, higher rainwater tank capacity and precipitation usually yield greater rainwater collection and utilization volume, which in turn increases tap water substitution rate. Please be noted that this article is written to discuss two indicators of rainwater storage design – rainwater utilization rate PRU (%) and substitution rate of tap water PCW (%), which are different from the tap water substitution rate Rc stated in the "Technical Regulations for Rainwater Storage Design on Buildings" proposed by Construction and Planning Agency (Ministry of Interior). The tap water substitution rate Rc stated in the regulations can be considered as tap water substitution volume / total building water consumption.

4. CALCULATION RESULTS

4.1. General climate

According to "Technical Regulations for Rainwater Storage Design on Buildings" proposed by Ministry of Interior, recycled water can be applied to replace water used for toilet, cleaning, and other purposes. Since water volume of this kind takes up approximately 32% of total household water consumption, under condition where rainwater can be applied to replace a maximum 32% of total household water consumption, tap water substitution rate can be evaluated through the following formula (Table 3):

Calculate the average rainwater collection volume CRW (m^3) per day per m^2.

(a) Alpine areas: 269 $m^2 \times 8.4mm \times 0.85 \times l0^{-3} = 2.25\ m^3$

(b) Coastal areas: 269 $m^2 \times 2.4mm \times 0.85 \times l0^{-3} = 0.54\ m^3$

(c) Hilly area: 269 $m^2 \times 5.6mm \times 0.85 \times l0^{-3} = 1.28\ m^3$

(d) Plains area: 269 $m^2 \times 4.2mm \times 0.85 \times l0^{-3} = 0.96\ m^3$

Calculate the average water overflow volume (m^3/day).

(a) Alpine areas：2.25 m^3+156 m^3-97 m^3=61.25m^3 (No water overflows)

(b) Coastal areas: 0.54 m^3+156 m^3-97 m^3=59.54 m^3 (No water overflows)

(c) Hilly area：1.28 m^3+156 m^3-97 m^3=60.28 m^3 (No water overflows)

(d) Plains area：0.96 m^3+156 m^3-97 m^3=59.96 m^3 (No water overflows)

Calculate rainwater utilization rate PRU (%) and substitution rate of tap water PCW (%).

(a) Alpine areas：0.38% (Rainwater Utilization Rate)

(b) Coastal areas：1.5% (Rainwater Utilization Rate)

(c) Hilly area：0.6% (Rainwater Utilization Rate)

(d) Plains area：0.8% (Rainwater Utilization Rate)

4.2. Typhoon season

Calculate the average rainwater collection volume CRW (m^3) per day per m^2.

(a) Alpine areas：269 $m^2 \times 1487mm \times 0.85 \times l0^{-3}$=340 m^3

(b) Coastal areas：269 $m^2 \times 601mm \times 0.85 \times l0^{-3}$=137 m^3

(c) Hilly area：269 $m^2 \times 836mm \times 0.85 \times l0^{-3}$=191$m^3$

(d) Plains area：269 $m^2 \times 763mm \times 0.85 \times l0^{-3}$=174$m^3$

Calculate the average water overflow volume (m^3/day).

(a) Alpine areas：340m^3+156 m^3-97 m^3=399m^3(With water overflows 302 m^3)

(b) Coastal areas：137m^3+156 m^3-97 m^3=99 m^3(With water overflows 302 m^3)

(c) Hilly area：191m^3+156 m^3-97 m^3=250m^3 (With water overflows 153 m^3)

(d) Plains area：174m^3+156 m^3-97 m^3=233 m^3 (With water overflows 136 m^3)

Calculate rainwater utilization rate PRU (%) and substitution rate of tap water PCW.

(a) Alpine areas：10%(Rainwater Utilization Rate)

(b). Coastal areas：25%(Rainwater Utilization Rate)

(c) Hilly area：18%(Rainwater Utilization Rate)

(d) Plains area：20%(Rainwater Utilization Rate)

In this study, rain water utilization rate of 30%, 50%, and 70% in “Water Consumption Efficiency” under LEED and rainwater utilization rate of 30%~80% under SBTool are both applied as a grading and evaluation standard. Based on rainwater storage and utilization design in “Building Technical Regulation”, new buildings with total floor areas more than 10,000m2 must have their rainwater storage and utilization system adequately installed.

5. CONCLUSION

The study takes into account the items specified by the LEED Green Building Evaluation of the United States which states the efficiency of rainwater usage as 30%, 50%, 70%, and the evaluation basis of rainwater recycle rate of SBTool of 30% to 80%, and is in accordance with the rainwater storage and recycling policy from “Specification Related to Architectural Regulation in Technicality in Taiwan” which emphasizes that new constructions with the total floor surface area greater than 10,000m^2 is required to install rainwater recycling system. Hence, the study focuses on the data gathered from collective housing as an example and establishes the rainwater recycling rate at 30%, 50%, and 70% to calculate the average mean of the data collected. The result of the rain water recycling rate is calculated as 1m^3 per each of the studied region, and the results of each region's requirement for rainwater storage volume and the replacement rate of tab water are specified in Figures 4.

In other words, in order to satisfy the specification of "Silver Level Rainwater usage rate" of 30% declared by LEED association, the example of the collective housing in the hilly area examined in this study would only need 3m^3 of rain water collection volume; for the "Gold Level of Rainwater usage rate" of 50%, the rainwater collection volume should be 25m^3. In order to obtain the "Platinum Level of Rainwater usage rate" of 70%, the volume should be 35m^3.

Regions in Kaohsiung and Rainwater Usage (%)		Mountainous Region	Coastal Region	Hilly Region	Plains Region	Tab Water Replacement Rate (%)
Suitable Goal for Rainwater Recycling Usage	30%	7.5(m^3)	4.2(m^3)	3(m^3)	15(m^3)	Increase 17.90%
	Annual Saving on Water Bill	2,664 NTD / household	2,892 NTD / household	2,988 NTD / household	1,620 NTD / household	
	50%	12.5(m^3)	7.1(m^3)	5(m^3)	25(m^3)	Increase 31.70%
	Annual Saving on Water Bill	1,896 NTD / household	2,640 NTD / household	2,820 NTD / household	540 NTD / household	
	70%	17.5(m^3)	10(m^3)	7(m^3)	35(m^3)	Increase 43.00%
	Annual Saving on Water Bill	1,356 NTD / household	2,400 NTD / household	2,652 NTD / household	The same amount	

Figure 3: Calculation for the amount of increase needed for the rainwater collection volume in each of the collective housing region in Taiwan

ABSTRACT

Low-cost housing was introduced in South Africa by the newly elected government in 1994 as part of the reconstruction and development programme. Uncontrolled heat transfer in the thermal envelope of these houses result in indoor thermal discomfort. To maintain indoor thermal comfort, occupants spend excessive amount of energy on space heating. Due to total internal reflection, transparent coats can be used to reduce heat propagation through the thermal envelope. This study presents the thermal behavior of a low-cost house with the walls inner surface coated with transparent infrared reflective paint. The thermo-optical properties of the paint were analyzed using Scanning Electron Microscopy/ Energy Dispersive X-ray spectroscopy (SEM/EDX), Fourier Transform Infra-Red (FTIR) and thermal photographic technique. Meteorological indoor and ambient parameters such as; air temperature, relative humidity, solar radiation, wind speed and direction of a low-cost house were monitored. The monitoring period covers both winter and summer seasons before and after coating. The SEM image reveals that the coat is transparent to light. The presence of Al as Al2O3 and other elements were revealed by the EDX spectrum. In the winter season, the indoor heating degree hours were 6674.72 °C h, equivalent to 4.86 kWh/m^2. It was found to drop by 56% with a heating demand of 2.15 kWh/m^2 and 2954.33 heating degree hours, after coating. The paint was able to reduce heat lost through the building walls. It could serve as an immediate and long term remedy to low-cost housing and the emerging energy crisis in South Africa.

Keywords: community empowerment, energy saving, low-cost house

1. INTRODUCTION

Low-Cost Housing (LCH) were first introduced in South Africa by the democratically elected government, in the Reconstruction and Development Program (RDP) in 1994. The program was part of the scheme to reduce the historical inequalities due to the apartheid system of government (Madubansi & Shackleton 2006). As a result of poor craftsmanship and use of inferior building materials, LCH are often characterised by poor thermal performance (Donaldson-Selby et al. 2007; Makaka et al. 2008). Low-cost householders spend significant amount of their income on space heating to achieve indoor thermal comfort. Whereas, household that cannot afford electrical energy, result in the use of coal, paraffin heaters or thick clothing to keep warm (Klunne 2002; Department of Energy 2012).

Thermal insulation can reduce uncontrolled heat transfer through the building envelope. Thereby creating a stable year-round indoor thermal comfort. This paper presents the thermal behavior of a LCH with the wall inner surface coated with transparent infrared reflective paint.

2. METHODOLOGY

2.1 Description of the house

The Low-cost house used in this study is located in Golf Course, Alice under the Nkonkobe Municipality in the Eastern Cape of South Africa. Golf Course is geographically located at 32°S latitude and 26°E longitude at an altitude of 571 m. The local climate is characterized by a summer and mild (no snow) winter conditions, with an average dry bulb temperature of 29°C and 15°C, respectively. An average wind of 2.5 m/s is experienced in Golf Course throughout the year (South Africa Weather Service 2013). Figure 1 shows the location of Golf Course settlement and photo of the LCH used as case study.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 1: Location of golf course settlement
(Source: Google earth map imagery date 10/02/2016 accessed on 12/09/2016) and photo of low-used in the study

With over 200 LCH in the settlement, a LCH with 16°NE orientation and large North facing windows was selected; compliant with the South African National Standards (SANS) 204 building design. Due to lack resources and cooperation of householders, one LCH was used as representative of the entire LCH in the settlement. Giving that more than 97% of the LCH in the settlement share the same design and building materials. The house used, comprises of a bedroom, bathroom, open plan living room and kitchen, with a floor area 41 m^2. The roof is made of galvanized, corrugated iron sheets with no ceiling or any form of roof insulation. The walls are made of M6 (0.39 x 0.19 x 0.14 m) hollow concrete blocks, with no plaster or insulation.

2.2 Characterization techniques

Before the walls inner surface of the house were coated, the coat was subjected to Scanning Electron Microscopy/ Energy Dispersive X-ray spectroscopy (SEM/EDX) and Fourier Transform Infra-Red (FTIR) characterisation. SEM/EDX technique were used to determine the surface morphology and the elemental constituent of the coat that is responsible for its thermal resistance (Goldstein et al. 2012). A drop of the coat sample was spread on a stub. After 24 hours, the cured film was coated with gold palladium (Au–Pd) to increase its conductivity. A JEOL (JSM-6390LV) scanning electron microscope was used to perform the SEM analysis. FTIR technique was used to determine the infra-red transmission of the coat film. The coat sample was painted on a glass slit and allowed to cure for 24 hours. The cured sample was scanned for 5 minutes to produce the infrared spectrum.

2.3 Data acquisition system

The following sensor, equipment were used to monitor the thermal performance parameters of the house. A total of 13 thermocouples were used to measure of the roof, floor, and walls inner and outer surface temperature. HMP50 temperature-humidity probe, hung at a height of 1.80 m was used to measure the indoor air temperature and relative humidity. Figure 2 shows the sensor map of the house and photo of the data acquisition system.

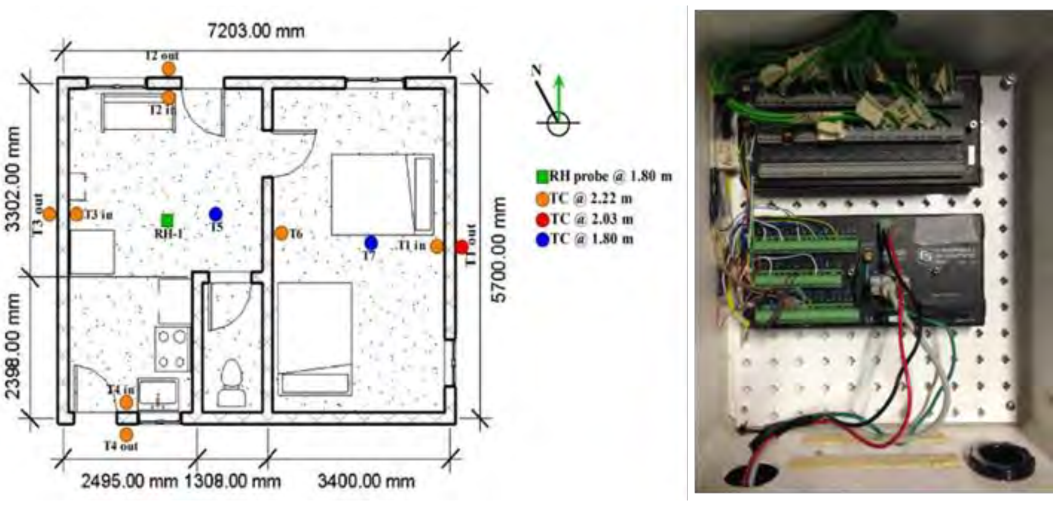

Figure 2: Location of meteorological sensors and data acquisition system

Outdoor weather parameters such as temperature, relative humidity, solar radiation, wind speed and direction were monitored by HMP50 temperature-humidity probes, LI-COR pyranometer and 03001 wind sentry anemometer and vane, respectively. The outdoor metrological sensors were installed on a weather station bracket, mounted 0.44 m above the roof of the house. Indoor and outdoor sensors were then connected to a CR1000 data logger supported by an AM 16/32 relay multiplexer, powered by a 20 V battery charged by a 20 W solar panel.

2.3.1 Thermal performance calculation

Degree-hours method of estimating thermal loads is based on the fact that thermal energy consumption in buildings is directly proportional to the difference between the indoor and outdoor temperatures. In this study, thermal load on the demand side was calculated using degree-hours. Degree-hours is determined by comparing the average indoor air temperature (T_{av}) and a reference based temperature (T_b). Therefore the number of heating (T_h) and cooling (T_c) degree-hours are given as (Kalogirou 2014)

$$DH_h = \sum_m (T_b - T_{av})^+$$

Equation 1

$$DH_c = \sum_m (T_{av} - T_b)^+$$

Equation 2

The +ve sign implies that only positive values are considered. Monthly or seasonal thermal load can be determine by

$$Q_{h,c} = \frac{UA}{\eta_{h,c}} DH_{h,c}$$

Equation 3

Where $Q_{h,c}$, is cooling or heating load (kWh/m^2); $DH_{h,c}$, is the total heating or cooling degree-hours (°C h). $\eta_{h,c}$ is the efficiency of the heating or cooling system and UA is the overall heat loss coefficient (WK-1) of the building.

3. RESULTS AND DISCUSSIONS

3.4. Characterisation analysis

The SEM images were produced in three different magnifications (1600X, 3700X, & 9500X), as shown in Figure 3 (a) – (c). It was revealed in Figure 3a that the coating sample is transparent to visible light and the particles are in different sizes and shapes. Penetrated infrared rays are reflected by these particles, creating a non-linear distribution of the rays. Consequently, reducing the heat transferred to the substrate.

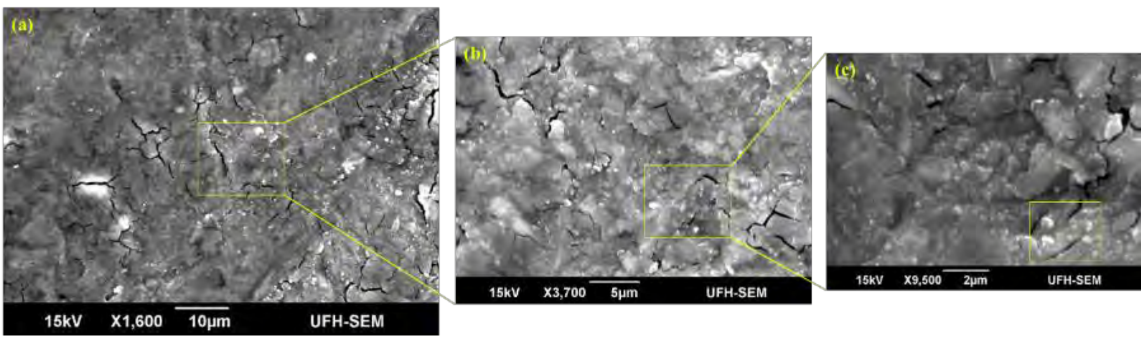

Figure 3: SEM images of coating material at 1600X (a), 3700X (b) and 9500X (c)

The elemental content of the coating sample, measured in weight (%) was determined form the yellow highlighted areas. The EDX scan shows that Al which is present as Al2O3 is the most dominant element. Other elements present in the coating sample and their percentage content were also identified and are summarized in the table below.

Elements	Symbols	wt (%)	Elements	Symbols	wt (%)
Carbon	C	16.45	Chlorine	Cl	3.10
Oxygen	O	31.47	Potassium	K	3.00
Sodium	Na	6.72	Calcium	Ca	0.57
Aluminum	Al	36.41	Titanium	Ti	0.04
Silicon	Si	0.91	Arsenic	As	1.04
Sulfur	S	0.27			

Table 1: Elemental composition of coating material

The FTIR spectrum of the coat sample was measured at a range of 8.0 µm to 20 µm. considering that the human body and building environment radiate maximum heat at 10 µm to 15 µm (Fang et al. 2013; Hass et al. 1997). Thus the human body and building environment is within the range of the measurement. Figure 4 shows the FTIR spectrum of the coating material.

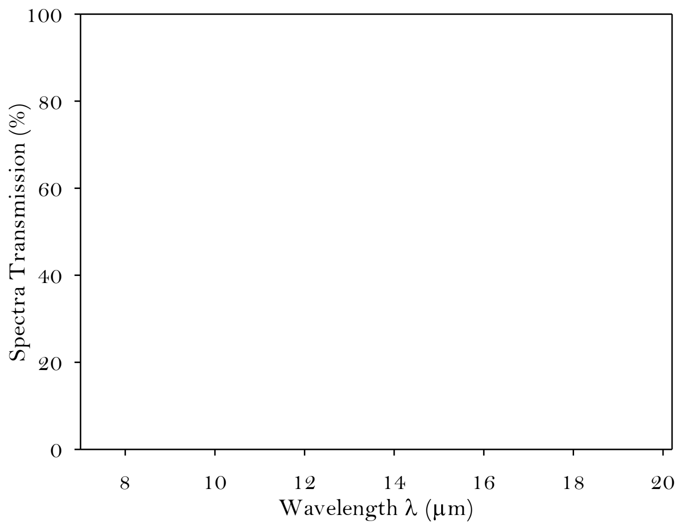

Figure 4: FTIR spectrum of coating material

The dip observed in Figure 4 implies that the coating sample has the ability to reflect infrared radiation in the thermal region. As such, it is capable to reduce heat transfer across the perimeter walls of the house.

3.2 Thermal behavior of studied house

The studied house was occupied by a middle-aged, working class lady with her daughter and toddler. It was noticed that the house is usually unoccupied during the day on weekdays, as the occupants go about their daily activities and only return at night. Also, no mechanical or fossil source of heating or cooling system were used in the house. They often use thick clothes and blankets to keep warm during the winter nights.

3.2.1 Influence of ambient weather conditions

The house was monitored for a period covering all seasons in South Africa, which are autumn, winter, spring and summer. For thermal performance analysis; June to August were considered as winter seasons while September to May represent summer seasons (South Africa Weather Service 2012; Eskom 2016). Figure 5 (a) and (b) show the indoor temperature response to the ambient wind speed and solar radiation in summer and winter seasons, respectively.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

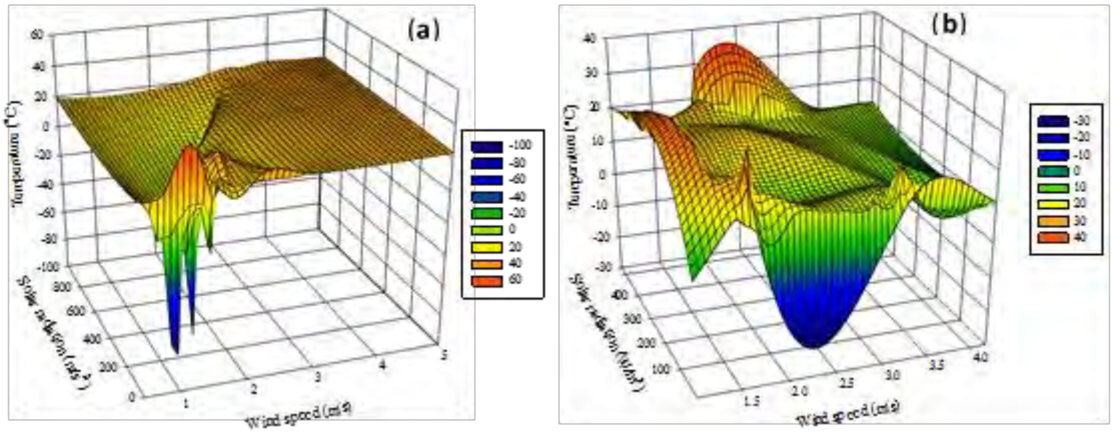

Figure 5: Seasonal indoor temperature response to solar radiation and wind speed

From Figure 5 (a) and (b), it was observed that the ambient solar radiation and wind speed have significant influence on the indoor temperature in both seasons. Increase in solar radiation results in the increase of the indoor temperature. In the summer season, increase in wind speed drifts warm air into the house. Consequently, increasing the indoor temperature; a reverse process was observed in the winter season. This behaviour of the house shows the inability of the thermal envelope to protect the habitable space from the ambient weather conditions. Although, the response to solar radiation indicate a good passive solar design features; that is useful in space heating during the winter season. It could result in overheating in the summer season. It should be noted that the temperature values in Figure 5 (a) and (b) does not depict the exact measured indoor temperature. The extreme values were as a result of the mesh stretching to fit all points.

3.2.2 Influence of thermal envelope

Figure 6(a) and (b) shows the indoor temperature and components of thermal envelope surface temperature on a typical summer and winter day, respectively. On both seasons, the roof and middle-wall temperatures were more dominant. The roof had a maximum surface temperature of 76.70°C in summer and 42.28°C in winter during the day. Whilst, the middle-wall maximum surface temperate in summer and winter season were 62.10°C and 31.90°C, respectively

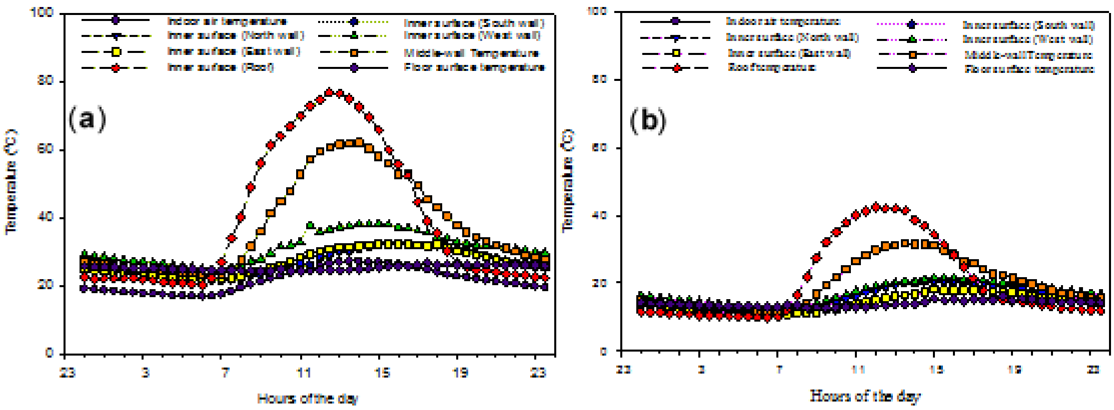

Figure 6: Typical summer daily (a) and winter daily (b) indoor and thermal envelope temperature distribution

However, the indoor temperature with an average summer and winter daily fluctuation of 10.29°C and 7.29°C, respectively was found to closely follow the perimeter walls surface temperatures. The perimeter walls average daily surface temperatures were 11.38°C in summer and 7.75°C in winter season.

3.3 Thermal impact of the coatings

The perimeter walls inner surface of the house were coated in mid-July. The entire process took three days, each day serve as a full curing period for the coats. Before applying the coats, the walls surface were wiped to remove dirt, grease or any contaminations that may lead to flaking or peeling of the coat. All thermocouples mounted on the walls surface were removed and reinstalled after curing. To determine the impact of the coatings, a reference based temperature of 20°C for heating and 24°C for cooling; was assumed (SABS 2011). Figure 7 is used to illustrate the thermal impact of the coated walls surface.

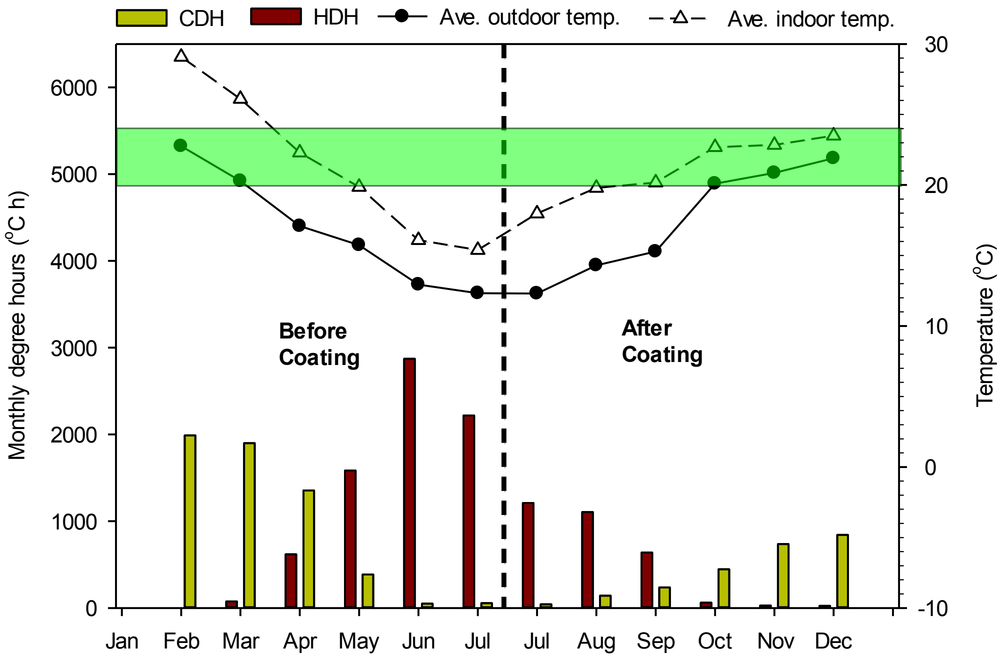

Figure 7: Seasonal thermal performance of the house

The peak thermal load period was observed in the winter season, as seen in Figure 7. During this period, the indoor temperature was completely below the thermal comfort zone. This will require 6674.72°C h of heating degree-hours to maintain the indoor temperature in the comfort zone; corresponding to a thermal load of 4.86 kWh/m². After coating, the thermal load during the peak period was reduced by 56%, resulting in a thermal load of 2.15 kWh/m². Table 2 contains the summary of the annual thermal load of the house before and after coating.

Period	Month and season	HDH	CDH	Load (kWh/m²) heating	Load (kWh/m²) Cooling
before coating	February – April (summer)	696.01	5243.56	0.506301	3.814341
	May – Mid-July (Winter)	6674.72	492.28	4.855415	0.358101
After coating	Mid-July – September (Winter)	2954.33	421.59	2.149078	0.306679
	October – December (Summer)	116.3	2025.57	0.084601	1.473467

Table 2: Annual thermal load

4. CONCLUSION

Energy crisis has been one of the ongoing issues in South Africa. This has seen the country experience a series of load shedding, resulting in the increase in cost of electricity tariffs. Hence, the luxury of excessive energy consumption for space heating is not economically viable to low-cost householders and result in enormous strain on the national grid. The findings of this study show that the coating material has the ability to reduce heat transfer through the perimeter walls of a house; thereby reducing the thermal load in both seasons. Adopting the coating material in newly built or existing low-cost house, will ensure year-round thermal comfort, thus reduce the thermal load.

Dynamic Solar Shading in Sustainable Buildings

Anders HALL[a]

[a] *European Solar Shading Organization / SOMFY, anders.hall@somfy.com*

ABSTRACT

Never before has there been such a focus on designing buildings that work in a responsible and sustainable way. Both for the occupants, the owner and the environment. It is a well-known fact today that buildings account for significant part of the energy consumption in society. Combine this with the issues we face connected to global climate, CO_2 emissions, urbanization and overheating of buildings – and the challenge becomes obvious.

How can we assure that our buildings become energy efficient, sustainable providing a healthy working and living environment?

This Paper does not claim to have "the solution" but aims to describe an important contribution answering to this challenge. How smart and dynamic solar shading is a vital component in both new and existing buildings for health and sustainability.

Yet solar shading alone will not solve the problems. The solution lies in an intelligent combination of different measures, managed via a holistic planning/execution approach supported by local regulation and green rating systems. We will take a closer look at some of the key factors for success based on the knowledge and experience gathered via the international work done by ES-SO (the European Solar Shading organization.)

Keywords: climatic responsive architecture, high-performance building, building energy simulation

1. INTRODUCTION: THE ROAD MAP

We know where we are and have a good view of where we need to go. So we need a Road Map to show the way but, even more importantly, to anticipate eventual obstacles in our way and how to overcome them securing a successful result. Based on this we have identified the following main steps to be addressed and this Paper will mainly focus on the Awareness and Design stages.

Figure 1: The ES-SO road map

1.1 Awareness and knowledge

Today solar shading is typically referred to as a "building accessory" categorized together with furniture, carpets, curtains etc. Choice of products and fabrics has mainly been done based on colours – and not the way it should be - based on energy performance and daylight distribution properties. This need change and solar shading needs to be identified as a "building necessity". But in order to achieve this we must start by addressing Awareness and Knowledge amongst Owners, Architects, Consultants, Builders, Tenants and our own Industry. The University giving a proper education on solar shading to Architects and HVAC engineers is still to be found. Further there is a common misperception that a fixed Solar Heat Gain Coefficient (SHGC), via the coated Glass alone, is the solution. Science and experience show over and over again that the SHGC´s needed are far below what coated Glass alone can provide. Then we need to add the growing demand to provide sufficient daylight for the well-being of people occupying the building. On top of it all – the weather changes constantly. Looking closer on this complex matter makes it clear that solar shading must be both smart and dynamic in order to provide the required benefits.

Early 2017 ES-SO will launch a Training Program to educate our own industry to be able to answer to all new questions relating to our products and solutions that will arise. We plan to have a certification system in place providing a quality mark for those participating and passing the exam. Further we will address the level of knowledge within all different sectors in the building industry. But we also actively work to create a positive and co-operative approach with other industries like Glass, Facade, HVAC and Lighting.

Finally, it is vitally important to create awareness with those involved in the creation of local building regulations and different "green rating systems" in order to reward paying attention to optimized solutions both in terms of technical design and in working models. I would even argue that the ratings should reflect the level of investment as well to avoid just building to achieve the "cheapest points".

It will be in the intelligent combination where we will find the needed solutions for tomorrow. Single smart components will only take us part of the way. To reach success we must allow for working in new conceptual ways and models.

Further to support and substantiate the claims of benefits of smart shading there is a need for Scientific and Practical research studies and documenting Best Practice examples.

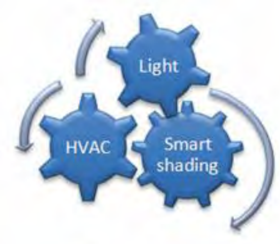

Figure 2: Authors own illustration

1.2 Design and specification

This area is where we see a strong need to address the old "codes of conduct". Personally, I feel this is one of the main sections of the process where we can define the way to success or failure fulfilling the overall energy strategies and CO_2 targets being expressed by governments globally. The challenge is well illustrated by the following:

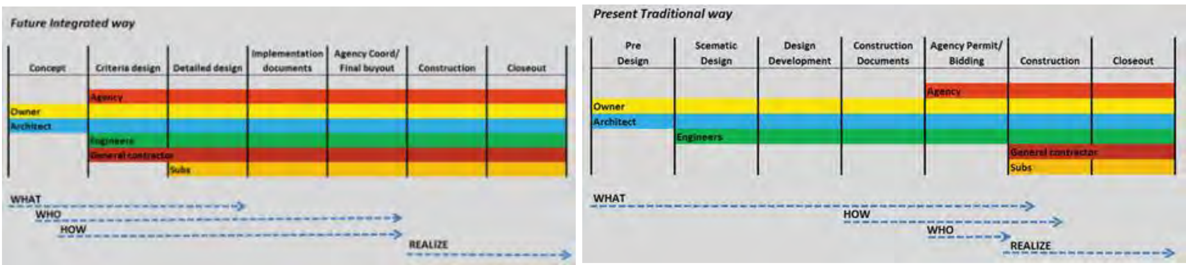

Figure 3: Source - American Institute of Architects, AIA. Authors own layout.

In most projects, at present, the main Contractor (and the Sub contractors) is involved very late in the process. At this point all specifications and detailed planning is already done leaving no room to influence or advice for better solutions in material or products to be used. It also means that the budget frames are already set limiting the room for flexibility. If this change into a more holistic and integrated approach, inviting the Contractor and Sub´s much earlier in the process, it would significantly increase the success factor when the building is brought to life, lead to better quality of integration and decrease the risk for costly mistakes. It would also optimize quality versus budget and allow for a correct way making the ROI and LCA calculations.

Co-operation is working together – not working at the same time!

2. CONTRIBUTION IN CONCRETE TERMS

Let us take a closer look at the focus areas defined for this Paper.

2.1 Awareness: Information and training

As mentioned it all starts with knowledge as it empowers people to dare facing change and to try something new. This is why we have, at ES-SO, been working on several pro-active initiatives in recent time.

- White Paper published 2015. To summarize all potential benefits via use of smart solar shading solutions both in the perspective of energy consumption, CO_2 emissions, indoor climate quality but also in terms of social economic factors
- Technical Guidebook. A free of charge reference guide to calculations and the ISO Standards and EN norms involved
- REHVA Guidebook. A co-production with the European HVAC Organization, REHVA, explaining all aspects of using solar shading as an active part of the HVAC solution in buildings
- Training program. To be ready for implementation early 2017 and a system for "certification of competence"
- Numerous seminars globally at Green Building Councils, Architects, M&E consultants etc

2.2 Awareness: Scientific studies

For the purpose of this Paper we have chosen to share some of results from two different and important studies carried out recently.

2.2.1. **"High performance dynamic shading solutions for energy efficiency and comfort in buildings, 2015"**

In 2015, to support the publication of our White paper, we commissioned a scientific study to Prof Mick Hutchins at Sonnergy Ltd, UK. This study is a combination of a) summarizing results from a selected number of published studies and b) conducting additional simulations based on technologies and material from our industry of today.

This research shows when using external shading (most effective), for Europe, a 40 - 70% cut of energy use for cooling control bringing a 10% reduction of CO_2. These numbers will of course vary depending on the global climatic zone – but we know today that, in general, the saving potential is always significant.

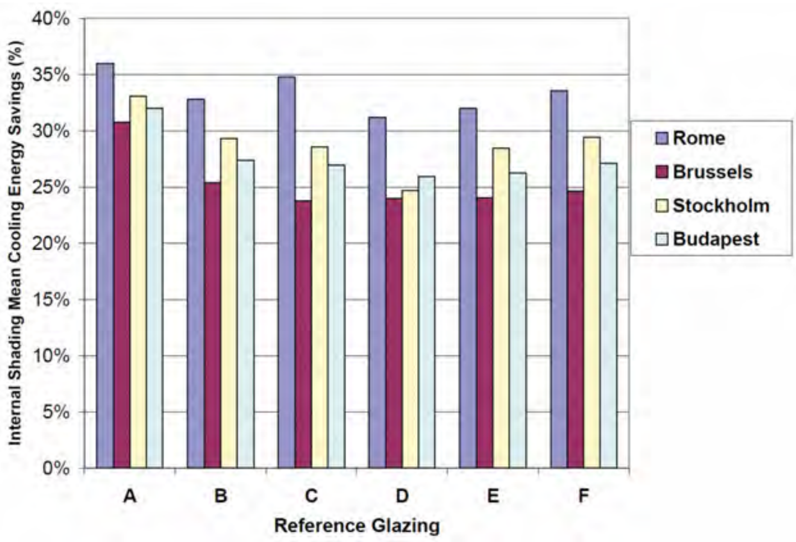

Figure 4: Potential energy savings from use of internal solar shading, ES-SO Study, 2015

This illustration is an example showing the average savings on energy for cooling using automated internal roller shades with various fabrics and combined with EN 14501 and EN 13363-1 reference glazing's.

The savings range between 24 - 36%.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Conclusion from the Study

"Efficient and effective automated control of solar shading is of the highest importance and needed to be seen within the context of the entire building design. Synergies and integration of solar shading with other building technologies is necessary to realise cost-optimal packages of energy saving measures. Highly glazed commercial buildings will not function effectively without intelligent use of automated shading." Prof Mick Hutchins

2.2.2 **"ESTIA: Global lightning performance, 2015"**

This study was commissioned by the Swiss energy authorities to ESTIA SA, Mr Bernard Paule, in order to establish facts from live buildings to be used as input for updating the local building regulations on retrofitting of light installations.

The study also included a live recording on how the manual solar shading (external blinds) was actually used in real life. This is vitally important information as there are various, often wrong, assumptions being made in many leading energy simulations used by HVAC Consultants and Designers globally.

Webcams where mounted to take pictures, every office hour during one year, of the East, South and West facades resulting in approximately 500.000 pictures. Next step was to analyse the manual movements as shown below...

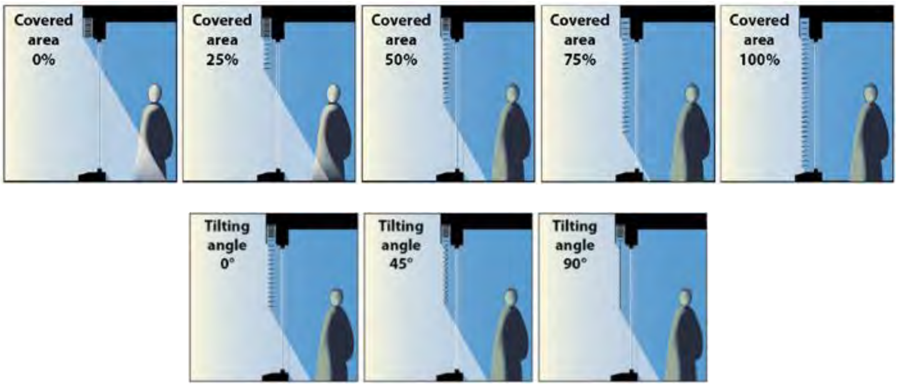

Figure 5: Criteria's for analyze of movements of manual blinds, ESTIA study, 2015

...and then to summarize the result. As shown in the table below the weighted average number of movements per week was 1.74 times only. This proves that manual shading will not be used in accordance with common simulation assumptions resulting in significant loss of potential benefits in regards of daylight provisions. Shading needs to be motorized and automated.

	East façade		South façade		West façade	
Number of blinds observed	27		40		58	
Movements 'up'	990	36.7	1115	27.9	1189	20.5
Movements 'down'	1062	39.3	1226	30.7	1421	24.5
Slat angle change	365	13.5	697	17.4	3505	60.4
Total number of movements	**2417**	**89.5**	**3038**	**76.0**	**6115**	**105.4**
Number of movements per week	48.5	1.72	58.4	1.46	117.6	2.03
Weighted average per week	**1.74**					

Figure 6: Summary of manual movements, ESTIA study, 2015

Conclusion from the Study

"The main conclusion of this study is that the implementation of a CONTINUOUS automation system (hourly adaptation of the blind up or down) allows a gain of several hundred hours of natural light reducing the electricity consumption for artificial lighting up to 35% while preserving the visual comfort and freedom of choice for the users." Bernard Paule

2.3 Design: Simulation software and input data

Normally the facade specification (choice of glass) is set quite early in the design process. Not knowing enough about the potential benefits of the dynamic SHGC, U or LT values smart and dynamic shading can provide leads to specifications based on fixed values and misleading information – with overheating or very low daylight levels as a consequence. So with the ambition to create a positive development and change in "codes of conduct" ES-SO has supported two very important and useful initiatives. It is important to note that both these tools below are made available totally free of charge to anyone with an interest and that the information and data provided can be used globally.

This Paper cannot host a full description of all the functions and possibilities in these tools but the live presentation will give a full insight and allow for any questions to be answered.

2.8 The ESSDA database on performance information

The EU organization Qualicheck, co-funded by the European Commission, has a mission they describes follows:

"The challenges to implement Nearly Zero-Energy Buildings (NZEB) and achieving minimum shares of Renewable Energy are tremendous. There are various indications raising concerns regarding the reliability of Energy Performance Certificate (EPC) declarations and the quality of the works. Achieving a significant improvement requires strong commitment from authorities and other major players."

This means in simple terms that all building material defined must establish an accurate way to present reliable (peer reviewed) performance data to the market and public. In response to this initiative ES-SO has created a web based platform called ESSDA (the ES-SO database). Besides general information about smart shading any global visitor will have full, and free of charge, access to performance data on a wide range of shading fabrics or obtain information that could be used in various other simulation models.

Work is also being done to establish ESSDA as an international reference platform and several simulation software providers are contacted.

This will become an important tool for Consultants and Specifiers enabling them to make sure their specifications are in line with the local compliance regulation.

For free access se References below for the web link.

2.3.2 The ESBO simulation software (early stage building optimization)

As the name suggests it is a tool that can be used for guidance in the early stages of designing a project or making choices of shading for a private residence – before it is too late to change. ESBO was created on the initiative of the SSF (Swedish Solar Shading organization), together with a leading building simulation software developing company in northern Europe, and is today fully endorsed by ES-SO Technical Committee.

In practical terms it is a simplified user interface on top of the equation based calculation model from the master software created for high level professionals.

This free version presents three possible levels of simulations:

Level 1

With just a few choices made you will receive all key values for the Shading/Glass combination selected, both with and without shading for comparison, and the calculation is made in accordance with ISO 15099.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

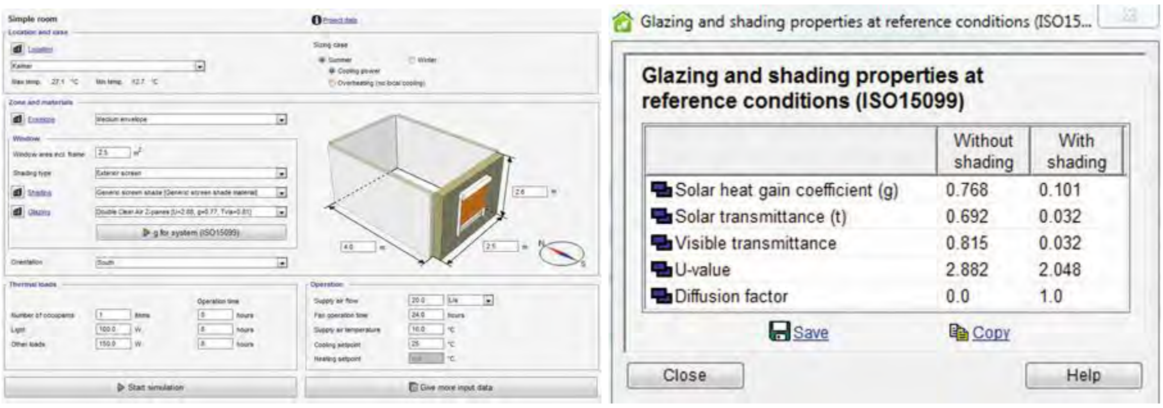

Figure 7: Screen shots from the ESBO simulation software

Level 2

By selecting global location, based on Ashrae climate data, combined with basic settings for the HVAC operation you will be able to run simulations for Cooling or Heating design cases, estimated number of annual overheating hours etc.

Level 3

This level presents a wide variety of input parameters on HVAC, floor heating, chilled beams etc. It also allows for experimenting with different control strategies on the solar shading.

For link to free download see References below.

2.4 Retrofit of existing buildings

In EU, new buildings account for 1-1,5% of the total building stock, which is probably comparative to many developed countries globally. By making only these buildings energy efficient and up to standard means a lot of years needed before we reach even close to NZeB (Nearly Zero Energy Buildings) levels set now for 2030, 2050 etc in many countries. Most buildings have already been built. To refurbish them with dynamic and smart solar shading offers an easy and cost effective alternative compared to many other options at hand like adding facade/roof insulation, changing all glass etc. It can also be applied with a minimum of interference with the present tenants.

2.5 Best practice buildings

Even if many countries still have the levels of compliance set on a quite low and simplified level there are Investors, Consultants and Architects out there that has already obtained a good understanding about the use of smart dynamic shading having the interest and willingness to do more, do better and go that “extra mile”.

We will share two interesting projects. 1 Bligh Street in Sydney, Australia (recently awarded Green Star 6) and the BD building in Gothenburg, Sweden (GBC Gold). Both buildings use highly glazed facades providing daylight, showing very low energy consumption and a working indoor environment with very high quality – much to the credit of the intelligent use of smart and dynamic shading solutions.

Figure 8: BD building, Sweden. Authors own picture.

Through this Paper we hope to have triggered some inspiration to start looking at the concept of smart solar shading as a new and interesting addition to the energy efficient measures needed in our buildings and the comfort, productivity and wellbeing benefits that effective solar shading brings to those who live and work in them.

(All relevant documents and free download of the ESBO software can be provided upon request.)

The Third Success Factor of Renovations with Energy Ambitions

Anke VAN HAL[a]

[a] *Nyenrode Business University, The Netherlands, a.vanhal@nyenrode.nl*
[b] *Delft University of Technology, The Netherlands, a.vanhal@nyenrode.nl*

ABSTRACT

Everyone acknowledges the importance of sufficient financial resources and well-functioning technologies when it comes to renovation processes with energy ambitions. However, Dutch experiences show that these two factors alone do not automatically result in success. More is needed, and this 'more' has to do with less concrete, but in the existing living environment very influential factors such as emotions and wellbeing. This hard to grasp factor is called 'the third success factor of energy friendly renovation processes'.

In the Netherlands, the questions 'What exactly is this third success factor?' and 'How to integrate knowledge about this third success factor in the rational-oriented building industry?' have been put high on the agenda of people who want to achieve the national energy goals related to the built environment. Research that combines knowledge from human sciences with energy efficient renovation experiences, the development of new educational methods, and a search for success stories has been part of joined efforts to find answers to these questions. A national knowledge platform called 'HomeMates' has been established to bundle and share all these findings.

The Dutch experiences are described and discussed in this paper. They are also linked to Canadian experiences, based on the results of a project of Parallel52°, the Dutch Canadian Sustainable Building and Planning network. In this project, Dutch findings and findings in the Toronto area were compared and discussed.

Keywords: renovation, housing, energy, success factor

1. INTRODUCTION

There is a widely supported feeling of urgency regarding climate change. The Paris Climate Conference in 2015 resulted in a worldwide agreement. In the swirl of activities surrounding the negotiations, cities launched initiatives too. By the time of closing, the portal listed commitments from 2250 cities. Evidently cities are taking responsibility.

In the Netherlands, climate change is also a hot topic. The national government has set goals to reduce it, several times already. The latest and most important initiative is the 2013 Energy Agreement for Sustainable Growth (Energieakkoord voor duurzame groei). In this agreement, more than forty organizations, including local governments, have laid the basis for an energy and climate policy. The purpose of the Energy Agreement is to achieve a wholly sustainable energy supply system by 2050.

Many Dutch local governments set climate change-related goals high on their agenda and many activities focus on the built environment. The built environment in the Netherlands is responsible for about 20% of the Dutch CO2-emissions. Privately owned houses create 40% of the emissions produced by the built environment while rented houses create 25%. Housing associations own 70% of the rented houses. Since the Dutch population keeps growing, the energy consumption of the housing stock will continue to rise.

2. DUTCH ENERGY EFFICIENCY POLICIES

The Dutch national Meer-met-Minder (More-with-Less) program was initiated in 2009, with the goal to insulate 300.000 houses a year in a way that improves the energy quality with two Dutch label steps. Unfortunately, a recent evaluation shows that the program does not meet the expectations. Between 2009 and 2012 the number of dwellings that were insulated fluctuated between 200,000 and 250,000, and did not show any signs of an upward trend.

The activities of municipalities are focused mainly on privately owned houses. In this sector, many energy efficiency measures are taken. There is an upward trend in the number of houses that improved the energy quality with one measure (e.g. floor, wall, roof or window insulation, solar cells), so not the preferred combination with other energy efficiency measures (which is necessary to reach the two-label-step).

Housing associations have been active in this field for a long time as well. However, they are not as successful as expected either. The previously mentioned evaluation shows that the current target of the association of housing corporations Aedes, to bring the housing stock of their members up to an average of energy label B, will not be reached if the current pace of the progress holds.

One of the main reasons for the disappointing results is that many residents are not taking the step to a combination of measures. This is caused by the fact that for residents this is a complex decision where many aspects have to be taken into consideration. The behavioral model for energy saving behavior of tenants and homeowners (see Figure 1) show the complexity from the perspective of the government, that has to take all these factors into account. The model clearly shows that there are several motives to decide to, or to decide not to take energy efficient measures (e.g. comfort, money savings, certainty, safety, care for the environment and several emotional motives) and that there are many physical and social issues that affect the decision (e.g. age and energy performance of the dwelling, savings and income of the residents, opinion of neighbors and family). Some practical questions will come up, such as: ‘Will I be living here long enough to benefit from this financially?’ and ‘Are the adjustments to my dwelling easy to implement or not?’ But also more emotional considerations can play a part, such as: ‘Will my neighbors be doing the same?’ and ‘Am I going to spend my money on saving energy or on a new kitchen?’ Some considerations can even be very emotionally charged, like ‘I’d want to, but I’m afraid of the mess and nuisance’ and ‘I don’t want strangers in my house’.

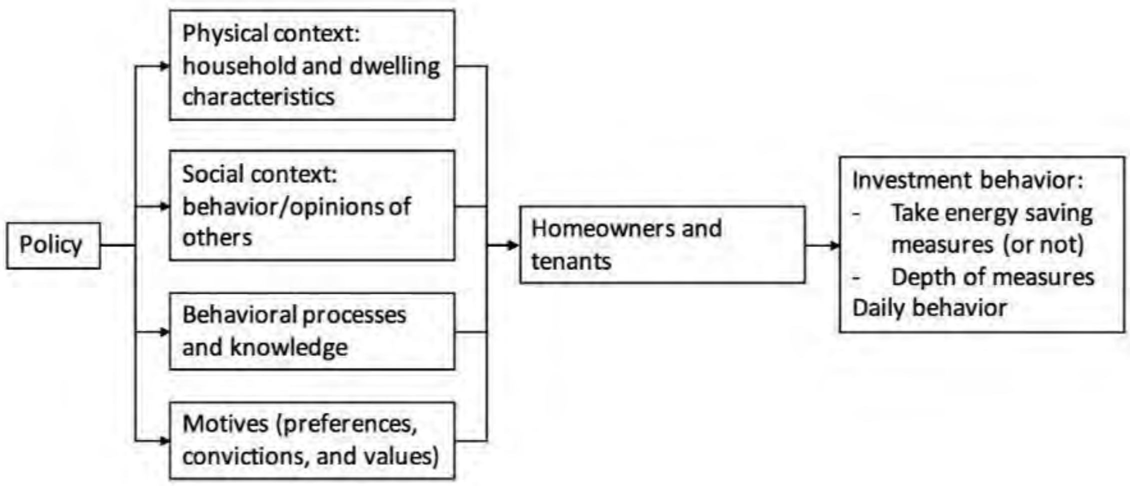

Figure 1: Behavioral model for energy saving behavior of tenants and homeowners

These last two issues introduce another factor that followed from the evaluation: professionals often assume that residents make rational decisions. Despite the fact that most governmental policies are based on the idea of a rational and calculating ‘homo economicus’, also behavioral processes affect the decision (like loss aversion, fear for nuisance, etc.). Decisions are not always rational.

3. A MERGER OF INTERESTS

Professionals should be well prepared to handle these two aspects (complexity and emotionality). To do so, a perspective and a strategy that will be described in this paper is helpful. One of the bases of the perspective and strategy is that energy efficiency (and sustainability overall) is not an important issue for most residents.This means that it is not enough to just bring up good arguments for energy saving measures, more is needed. To compete with other products, taking energy efficiency measures in their homes has to awake some kind of enthusiasm. This idea forms the basis of the ‘Mergers of Interest’-Perspective. This is a way of looking at the issue which assumes that people will start taking sustainable measures sooner when they also contribute to their personal desires. What keeps them up at night? What are their dreams? If professionals would succeed in combining their knowledge of energy efficiency measures with such desires, chances that the previously described problem of residents will choose for a more ambitious improvement of the energy quality of their houses will increase sharply.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

A quote from the book 'Mindfield' serves as a metaphor: "Every time someone – male or female – saw a product that they genuinely found to be attractive, the blood flowed to a small area at the front of the cerebral cortex. The medial prefrontal cortex lit up on the photo like a flame." Like I wrote in 'the Merger of Interests 2.0' : " I realized when reading Frank's words that what has occupied me now for more than twenty-five years, is this: will it ever be possible on a large scale to get people's medial prefrontal cortexes to light up if they see sustainable building materials or measures, or just think about them?"

The Merger-of-Interest Perspective and the resulting Merger-of-Interest Strategy are related to this line of thought. The strategy enhances the chance of sustainable innovations with an integral quality, so with more qualities than just sustainability ones, which makes them more attractive for many more reasons than just energy or environmental ones. The strategy consists of three steps with a fixed sequence:

Step 1: Drawing up an inventory of the interests of people here and now (including all those involved in a project, thus including the offering parties).

Step 2: Defining sustainability measures that promote these interests.

Step 3: Seeking (innovative) funding models that make investments in such measures possible.

The following logic lies at the heart of this sequence: if you offer people something that meets their needs (helps to resolve their problems or helps to embody their ideals), an inner wish is created to have access to it (the medial prefrontal cortex lights up). Then preparedness to be creative in seeking innovative funding models also increases.

An example that illustrates the operation of the Merger of Interests approach will now be outlined: the shoe rack example. When a few years ago a graduate of the Delft University of Technology asked the residents of some portico flats about their feedback after the replacement of their heating system by a more energy efficient alternative, most of them were negative. They complained about the mess, the nuisance of the strangers in their home, the noise of the new system, and that they now had less storage space. However, the feedback of one of the projects was very positive. In that project, they installed the new systems in the hallway, in front of all the front doors. So, in this case, everyone was left with more storage space instead of less, and no strangers had to come inside the homes to maintain the system. Moreover, the system was combined with a shoe rack. This solved the nuisance of the pile of shoes in front of the front door. There was clearly a win-win situation here. After this, the residents generally appeared to have a more positive attitude towards energy saving measures. Without a thorough analysis of what is important to the residents, this solution would have never been achieved.

This example also show the emotional charge that is associated with renovation. The previously mentioned irrational behavior is deeply studied by several scientists and is not as unpredictable as thought at first sight. The title of the inspiring book by Dan Ariely illustrates this very well: *predictably irrational*. However, psychology and behavioral economics are part of a school of science that is often neglected in the education of Dutch housing specialists. Knowledge from human sciences like psychology, behavioral economics, sociology and anthropology, is hardly integrated.

This is a missed opportunity which is clearly illustrated by the example of the payback time:

Virtually every professional who wishes to have a resident opt for energy measures works with a payback period. It concerns a simple sum: the amount of the investment is paid back over a certain period of time, because the costs for energy are lower than they were previously. Nevertheless, residents are often less enthusiastic than the professionals expect them to be. Knowledge from human sciences explains why. For example, the concept known as *loss aversion* is the natural tendency of people to attach greater importance to avoiding loss than to making a profit. Another concept that applies is *delay discounting*, where the value of something decreases instinctively with time, thus with delay. What made perfect sense rationally, becomes emotional and thus the perception changes completely.

Based on the previous, it can be concluded that to enlarge the enthusiasm of residents, professionals should look beyond just the energy efficiency measures. They have to broaden their view and not only focus on the success factors they are mainly educated in: sufficient financial sources and well-functioning technologies. Working towards a merger of interests and using existing knowledge of human sciences are important steps that should be taken.

4. THE THIRD SUCCESS FACTOR

Striving for a merger of interests by broadening the scope and using the knowledge of human sciences is what we call 'the third success factor' (next to sufficient financial sources and well-functioning technologies), which explains the title of this paper. This third success factor can be compared to what often is called 'the X-factor' of a successful singing performance (next to good looks and a great voice): it also concerns a seemingly vague but undeniably influential element of success.

To support professionals by handling the aspects of complexity and emotionality several Dutch professionals, specialized in housing renovations with energy ambitions, joined forces to find an answer to the following question: 'How to integrate knowledge about this third success factor in the rational oriented building industry?' Supported by the Dutch government they established a knowledge platform to integrate this existing knowledge in practice. This knowledge platform is called 'HomeMates': professionals with energy ambitions working together to improve the overall quality of dwellings.

The term 'together' is key to the message that is conveyed by the knowledge platform. It has three different meanings: wanting together (not only the professionals, but also the residents have to want it, that is why their interests have to be determined), bringing together (the interests of the residents have to be combined with the challenge of energy efficiency), and to achieve this, people have to work together.

In 'wanting together' and 'bringing together', the first two steps of the Merger of Interests strategy can be found. The third one, 'working together', relates to the fact that connecting the needs and interests of the residents with energy measures requires intense collaboration between various parties.

To communicate the third success factor as appealing and efficient as possible, various ways of transferring knowledge are conceived through the knowledge platform. Because it is known that good examples are usually being followed, 'success stories' are gathered. For professionals who really want to delve into all success factors of housing renovations with energy ambitions, the Delft University of Technology developed a blended education program in which professionals work together with students of the university. For professionals who only want to take the online classes, an online program is currently being created. This will be in English, so interested people who are not Dutch can follow the course as well.

Since it is known that 'experiencing' increases the chance that knowledge will actually be applied, a half-day reality game has been developed. A lifelike situation is outlined where the professionals try to seduce residents to invest in a combination of energy efficient measures for their dwellings. In the game, professionals place themselves into the position of the different stakeholders. Besides transferring practical knowledge, the goal of this game is to improve cooperation skills.

Additionally, several half-day master classes for specific subjects are being offered, ranging from 'collaborating with residents' to 'the consequences of the third success factor on the organization of companies'. A network of experts with a lot of experience and knowledge in the field is involved with the knowledge platform HomeMates. They developed a master class as well. When a project encounters a specific problem that can possibly be solved by using the knowledge of the third success factor, some of these experts come over for an afternoon to help them. And of course, literary sources are distributed by the knowledge platform. The knowledge about the third success factor is also transferred through blogs, tweets and discussion boards.

5. CONCLUSION

This paper will be concluded with the question if the third success factor of housing renovations with energy ambitions is typical Dutch or not. During the year 2014 this was one of the questions a group of Dutch and Canadian sustainable stakeholders focused on through a series of themed video conferences and a workshop. In this project of Parallel52°, the Dutch Canadian Sustainable Building and Planning network, they shared their experiences, insights, and recommendations, also related with housing renovations with energy ambitions.

From all of the sessions, where more questions were discussed, the outcome was assimilated into "10 Best Things to Know". Two of these 'things' were closely related to the ideas and knowledge behind the 'third success factor': 'Energy cost alone isn't a big enough motivator for change', and 'Climate change talk is a turn off'.

Overall, it became clear that the Dutch and Canadians have a lot in common. They are more alike than they are different. They can inform and inspire each other much more than they do now. For this reason, more knowledge about and experiences with the third success factor of renovations with energy ambitions should be exchanged.

ABSTRACT

In the atypical context of Antarctica, it must be considered the specific environmental conditions of the region in order to make the correct selection of more sustainable and efficient materials. Among them, there are the climatic characteristics, the isolation and the need to preserve the natural environment. The main goal of this research was to evaluate the thermal performance and the energy efficiency of new buildings of the EACF, (Comandante Ferraz Antarctic Station), expected to be finished in 2018, aiming to get and establish parameters for the new Brazilian buildings in Antarctica. To obtain the performance results of the station it was used the software Design Builder, and the study was conducted in two stages: at the first, the definition of the model, the characteristics and the properties of the materials specified in the project; and in the second stage it was determined the methodology for evaluations and the simulations.. The results demonstrated the performance of the building envelope, allowing to evaluate the materials used, pointing out possible improvements. Alternatively it was proposed to replace the galvanized steel coating specified for the envelope, for PVC (Polyvinyl Chloride), material that showed better results regarding the thermal performance and sustainability indicators.

Keywords: antarctica, thermal performance, envelope

1. INTRODUCTION

Performance rating systems, analysis tools and certification schemes serve to contribute to a better performance of buildings; however, there are still difficulties in establishing concrete environmental criteria for buildings, which is due to the broad interpretation of the word sustainability (Smith, 2003). In this context, the concern with sustainability becomes even more important when the place to build in Antarctica where environment, landscape and architectural impact are more critical in comparison to consolidated urban areas (Reis & Alvarez, 2015).

The first Brazilian occupation in the Antarctic occurred in 1984, with eight modules of the EACF (Secirm, 2014). The Station underwent successive reforms over time, and with no formal or environmental concern (Alvarez et al., 2004). In February 2012 a fire destroyed the main body of EACF and in the surroundings were installed the MAE (Antarctic Emergency Modules), which are serving to continue the activities of the station (Mech, 2013). After the event, a public procurement process was initiated for the project of the new permanent buildings through the development of the Terms of Reference, which were aimed at the reconstruction of the Research Station in order to meet the needs of the scientific community and to serve as reference for future buildings in Antarctica (Secirm, 2014).

Considering that the new Brazilian buildings in Antarctica were designed to use innovative techniques it is justified the need for studies on the types of materials proposed especially with regard to thermal performance, aimed at improving comfort conditions. The atypical characteristics of the region suggest systemic studies to gather with less environmental impact and materials that provide energy efficiency, especially about the reduction in fuel consumption for heating. To develop the Terms of Reference that guided the design competition for the Brazilian station, several stations were studied and, among them, the Princess Elisabeth (2007), belonging to Belgium, whose technology envelope is composed of elements in laminated wood and seals composed of a set of nine layers and clad with stainless steel blades.

The Amundsen-Scott Station (2008) belonging to the USA, was built in steel with composite panels by sealing two sheets of OSB - Oriented Strand Board, and the insulation EPS, Expanded Polystyrene (Montarroyos, 2015).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Another reference is the Indian station, Bharati, 2012, built using prefabricated containers wrapped in a sealing structure in sandwich panels with external coating of steel (Montarroyos, 2015).

The old EACF facilities were composed of metal containers made of sealing sandwich, filled with polyurethane. Now, the new facilities will use major structures of high-strength steel (Montarroyos, 2015), to obtain favourable conditions for the improvement of performance and thermal comfort. Considering the technology adopted for the new buildings of EACF, the research aimed to evaluate the thermal performance of a room with high exposure - at the corner of the building - considering as conditioning the material proposed in the project and the possible use of PVC as outer covering of sandwich panels.

2. METHODOLOGY

The research was established from three main stages: characterization of Antarctica and the Comandante Ferraz Antarctic Station; modeling and simulations; and evaluation of thermal performance.

2.1 Characterization of antarctica and the comandante ferraz antartic station

Antarctica has unique environmental characteristics: low temperatures, strong wind gusts, isolation and preservation of the natural environment, which induce a process of human occupation in a sustainable way (Cruz et al., 2007). The Comandante Ferraz Antarctic Station was established in 1984 in the Keller Peninsula of King George Island (Alvarez, 1995). Since its settlement, the EACF passed through several expansion and modification processes, performed with the inherent concerns about the environmental impact and the possible interferences in the local ecosystem, due to poor planning of the previous design (Alvarez et al., 2007).

The new buildings of EACF are being built on the same site of the former, on Keller Peninsula (Figure 1). Its design dates from 2013 and its construction has forecast for completion in the year 2018, according to the Air Defence and Naval (Defesa Aérea e Naval, 2016). The various proposed settings for the station have a total built area of 4,500 m² formed by functional blocks and UIS - Isolated Units (Unidades Isoladas), which in its full configuration will form the basis for the operation of activities and research.

The area of laboratories was designed to meet many requirements, emphasizing the priority of the PROANTAR (Brazilian Antarctic Program) for scientific activities (Brazil, 2012). The project was developed considering the best practices of sustainability and should result in a facility of excellence, the highest quality, to promote its main goal, scientific research (Estudio 41, 2013). The set was designed from containers, which will later be covered by a system composed of insulating material with properties that mitigate the effect of salt spray and low temperatures (Figure 2).

2.2 Modeling and simulations

The climatic conditions of Antarctica were obtained through the weather file EPW, *EnergyPlus Weather* for the year 2002 (Laboratório…, 2015). For the simulations, the conditions of the study area were considered, the windows do not have the any ventilation function and, thus, the model was configured as a closed space. The architectural typology adopted for the simulations was the design of the new EACF buildings of and the room, a laboratory with two external walls (worst situation). The reference values of thermal properties of building components related to the envelope, as well as the characteristics of clothing and activities performed by the laboratory users are shown in Table 1. The clothing and the activity simulate the real indoor working conditions in Antarctica, as well as the type of environment used.

The proposed design for the envelope are sandwich panels consisting of two external surfaces made from galvanized steel coil of 0.75 mm thick, each one coated with PVDF (Polivinilideo Fluoride) paint, internal layer of rigid PUR (Polyurethane) foam, with a distance of 50 cm between the wall of the container and the envelope. The panel is used to cover the outer vertical seal. The floor and has two types, one with 220mm and other with 170mm (Reis & Alvarez, 2015).

It was adopted for the comparative study an exterior coating of PVC, replacing the steel sheet while maintaining the same thermal insulation. PVC is a material consisting of 57 % of chlorine and 43% of ethylene, thermoplastic material and is the second most produced worldwide (Instituto do PVC, 2016).

The simulations were carried out for the Laboratory of Molecular Biology and its environmental conditions (Figure 3). This room is located in the functional block, 5.29 m above the ground (Figure 4). The Laboratory is located at one end of the blocks, having two of its walls exposed to the weather, one facing north and the other facing east. The simulations were carried out for the summer period (21/ Dec to 21/ Mar) and the winter period (21/ Jun to 23/ Sep).

2.3 Thermal performance evaluation

For the evaluation of thermal performance conditions it was used the hourly operating temperatures and comfort temperature defined by ISO - International Standard 7730 (International ... 2005). The criterion to define the comfort temperature was based on the type of activity involved in the laboratory work; clothing of 0.5 clo for summer and 1.0 clo for winter, considering the best category (A), and from this combination resulted a comfort temperature of 23 °C. For environmental thermal performance evaluation indicators proposed by Nico-Rodrigues (2015) were used, which made possible to analyse the hourly changes in operating temperature, for summer and winter.

2.4 Indicators

The indicators used for the systematization of data were the FDT – Frequência de Desconforto Térmico (Frequency of Thermal Discomfort) and GhDT – Graus-horas de Desconforto Térmico (Degrees-hours of thermal discomfort). These results were used as input in the buoyancy diagram.

The FDT quantifies the number of hours of discomfort, in percentage during a certain time interval, and its maximum value refers to the maximum time limit. To set this percentage of the whole time, the the percentage at which the operating temperature is above the maximum comfort temperature is used. In this study, the proposal was to analyze daily periods, of 24 hours, corresponding to a maximum frequency of 100%.

The GhDT is the difference between the hourly operating temperature and the comfort temperature when the operating temperature exceeds the defined value of the comfort temperature established for the month under study. To obtain the maximum reference value it was adopted the highest value of GhDT, considering all the features of the model and climatic conditions. For the analysis of FDT and GhDT indicators was adopted the buoyancy diagram, which considers the assessment of the frequency on two levels: temporary and frequent; and the intensity condition for the degree-hours, light and intense levels (Figure 5).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. RESULTS AND DISCUSSIONS

3.4 Determination of conditions

The results defined the internal hourly air temperature of the Molecular Biology Laboratory aiming to determine the environmental thermal performance with emphasis on thermal comfort using in your envelope galvanized steel and PVC. The results were subjected to statistical treatment to set the maximum amounts of daily GhDT, which is the reference value used for laboratory analysis with the two materials (Table 2).

Seasons	Material	GhDT
Winter	Galvanized Steel	170,20 ºC.h/day
	PVC	170,15 ºC.h/day
Summer	Galvanized Steel	166,4 ºC.h/day
	PVC	300,5 ºC.h/day

Table 2: Maximum reference values for GhDT at each station. Source: Authors

3.5 Simulations

The simulations made possible to assess the environmental thermal performance according to the materials used in the envelope, especially the use of artificial heating as a strategy for thermal comfort. The first series of results showed the internal conditions of the Molecular Biology Laboratory with the use of galvanized steel in the envelope and, afterwards, the results that would be achieved with the PVC replacement.

The values of FDT and GhDT obtained for each day are shown in the buoyancy diagram, characterizing the conditions for thermal comfort (Figure 6). It should be noted that the buoyancy diagram relates the values of FDT with the highest value of GhDT of each season of the year, demonstrating the daily situations, being the best condition that converges to the origin.

The results of performance simulations have shown that the use of galvanized steel in the envelope, partially meets the conditions for thermal comfort determined by the ISO 7730 standard as well as the use of PVC, using a comfort temperature of 23°C. The ISO standard allows some temperature variations, being temperatures of 19 °C be still within the norm, which increases the amount of hours within the comfort limit. And with the use of PVC obtained better performance results compared to the previous situation, especially in the summer season. It was observed that the results of the FDT and GhDT indicated two levels of discomfort for the simulations with the steel - being them levels (A) and (B) - and three levels for the simulations with PVC - which are (A), (B) and (C) - where (A) means days of frequent and slight discomfort; (B) days of frequent and intense discomfort; and (C) days of temporary and mild discomfort.

The results showed both for summer and winter an uncomfortable environment, but the comparative analysis between the two simulated materials showed that a better indoor environment is achieved if the PVC is used in the envelope. Observing the analyzis of materials separately in both seasons, it was found that in the envelopment with galvanized layers, the temperature values remained constantly below the comfort threshold, classifying the discomfort as intense, and a FDT common in winter. In summer the temperatures remained below the limit, but the discomfort is rated as mild to intense, and the FDT remained intense.

In the simulations with layers of PVC, temperature values remained below the comfort limit in winter, with a few days with some hours within the limit, classifying discomfort as frequent, and an often FDT. In summer there was an improvement in the results, almost all days are presenting all hours within the comfort limit, but with a few days still below the threshold, being the discomfort classified as intense or temporary, and FDT ranging from heavy and light.

The adoption of PVC, as an alternative material, would improve the results; however, it is not enough to achieve the optimal results. It is suggested that the wall exposed to the weather also has a spacing of approximately 50 cm, already adopted in the other external wall, serving as attenuator space, which holds a layer with temperature at 10 °C, since this construction proposal has proved effective in other situations analyzed. It is possible to obtain better results using different types of thermal insulation defined according to the physical and thermal properties, greater or lesser thermal inertia. It is noteworthy that the Belgium station , for example, is classified as the most efficient among the studied station due to, between other factors, the adoption of nine insulation layers with properties that potentiated the thermal efficiency of building.

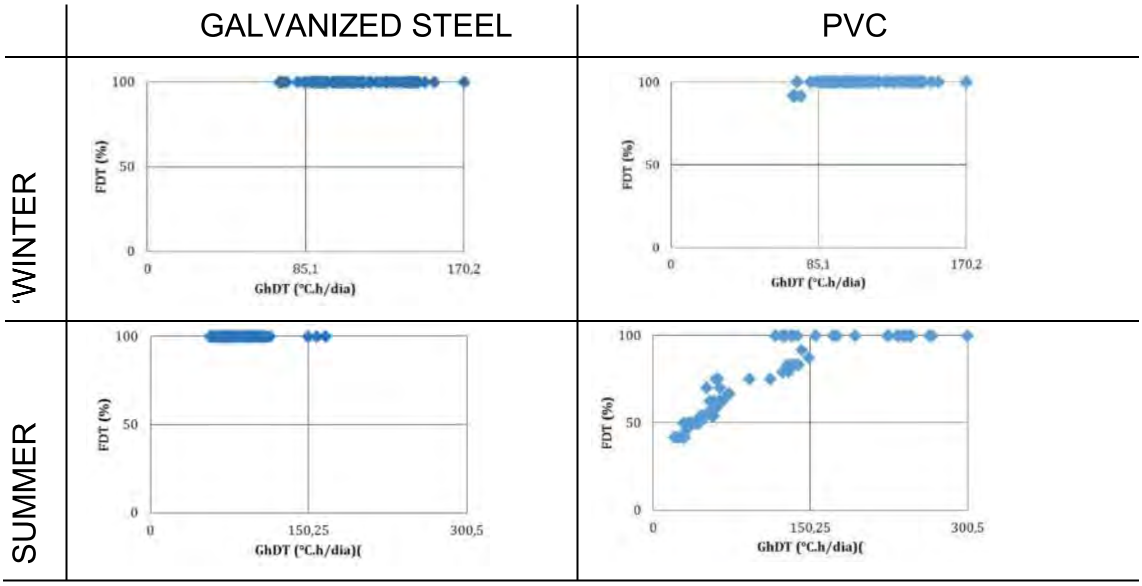

Figure 6: Buoyancy diagrams of the summer and winter seasons. Source: Authors

Another likely factor responsible for improving internal conditions is the incidence of solar radiation and the different behaviour of steel and PVC in the outer layer. In the summer period, the amount of solar radiation is much bigger and keeps the temperature in the space between the panels heated a lot longer. Although the PVC is thinner, its performance is better than the steel plate, as it can be observed in the Spanish station Juan Carlos in which was used a similar material in the form of modular rings of plastic fiber.

4. CONCLUSIONS

From the analysis made with the methodology adopted, it was possible to understand the environmental performance for the buildings in Antarctica, focusing on thermal comfort. The daily fluctuations in the operating temperature guided to solutions aimed at improving the thermal comfort and the indicators allowed the understanding of the internal conditions of the environment.

It is important to know that the building system from containers surrounded by a second outer layer coating on the sandwiches panels is a technique whose maintenance activities may be carried out by the Navy in Rio de Janeiro, which has a lot of experience in such activities in Antarctica. Studies with the use of PVC in the Antarctica environment are still in the initial process, and those results are an incentive for continuity, because it was realized that the model with PVC had an improvement in the results when compared to model that used steel. However, it should be noted that the two construction solutions still require further developments to meet the requirements of the adopted standard.

ABSTRACT

The Decree 1285 of 2015 is the new standard for sustainable construction in Colombia, with technical parameters and design guidelines adopted by Resolution 0549. This normative has increased public and private interest in the subject, in order to develop a sustainable construction industry. However, there is a lack of technical and practical knowledge in architects and builders, and the recent process of training on sustainability guidelines and its relation to the standard are insufficient to shape a critical mass for its application in architectural process. This situation constitutes a commercial opportunity for the promotion of LEED certification in Colombia and their representatives. They having publicity stated in academic events and media, that compliance with a LEED certification is enough to fulfil the guidelines of the Sustainable Construction standard. However, this statement lacks technical support, turning a model of visual, media and distorted sustainability. This paper evaluates the real water and energy consumption of an office building with LEED Gold certification in Medellín and its relation to the sustainable construction standard, with the aim to determine if a building with LEED certification can reach the goals established by the Colombian standard. The results show differences of 172% in energy consumption and 81% in water consumption between the real and the expected consumption. This suggests that there is no guarantee to meet the standard through a payment of a foreign system, but it threatens the expectation of sustainable construction in Colombia.

Keywords: sustainable design education, sustainable construction, LEED certification

1. INTRODUCTION

The Decree 1285 of 2015 is a new standard in Colombia that proposes sustainable construction guidelines for buildings, aimed to improving the quality of life of inhabitants and to promote the implementation of actions with environmental and social responsibility from the construction industry (Ministerio de Vivienda Ciudad y Territorio Republica de Colombia 2015a)

In order to apply the Decree 1285, technical parameters and design guidelines were adopted by Resolution 0549 of July 10th, 2015 (Ministerio de Vivienda Ciudad y Territorio Republica de Colombia 2015b). This resolution is intended to establish minimum percentages of consumption and saving strategies of water and energy in buildings, through the adoption of the Sustainable Construction Guide (Annex 1 of Resolution 0549), with the intention to project an efficient operational life of buildings.

While these situations occur, either a positive application of the rule from the updating and training of professionals or a critical rejection against to implementation of a regulation that can be weakly promoted by the State, it is also expected a model of commercial opportunism, associated with the sale and purchase of LEED certification in Colombia. In other words, the construction sector is in risk of continuing and increasing the practices of pseudo-sustainability as Greenwash, in response to the standard of sustainable construction (González et al. 2012)

According to the previous statement, professional associations assigned to the United States Green Building Council (USGBC), are seeking the implementation of LEED certification system in the country without a critical review of it, from a technical and economic point of view. The process of analysis and marketing of LEED system, developed for seasonal weather conditions, is applied without any consideration of geographical and climatic conditions of the diverse regions of Colombia. In opposite to this condition is necessary to emphasise that

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Resolution 0549, have as a starting point for the energy efficiency and saving water analysis, the incidence of four types of climate differentiated for major regions of the country.

However, after the publication of the Decree 1285 in 2015, academic events and public declarations took place, in which it was stated that 182 projects in Colombia, until July 2015, where LEED certifications were applied, which sums up to a total of 3.7 million m2, "... [They] come surpassing the minimum efficiency established by the guidelines for saving water and energy in buildings..." (Consejo Colombiano de Construcción Sostenible 2015).

Given this situation, it is necessary to establish from an objective point of view, if the application of the LEED system in Colombia is valid and a guarantee to fulfil the requirements of the Decree 1285, with its statutory Resolution 0549. This analysis is, therefore, the overall objective of this article, developed by professionals and researchers in the field of bioclimatic design, energy efficiency and sustainable construction in the Colombian context, with more than 15 years of experience.

2. METHODOLOGY

To perform this research, an office in Colombia, was taken as a study case. This building has a LEED Gold certificate, under the application of the system LEED O + M: Existing Buildings v3 - LEED 2009 (U.S. Green Building Council 2009), which focuses on existing buildings and certifies the operations and maintenance activities, has implemented. The study case is localised in Medellín, Colombia, city with a mild weather according to the Resolution 0549 (Annex 2). The building has a built office area of 50,000 m2, and an average population of 4,000 people.

Based on the consumption data on energy and water obtained from an internal source of the analysed building (Alis Restrepo 2014), correlations between aspects of LEED certification and Decree 1285 were made, with analytical work performed in two stages:

2.1 Analysis of LEED O + M and the respective results of the case study

The scope of the first stage corresponds to the study of the chapters of the LEED certification, with the purpose of identifying the requirements to obtain it. The information is reviewed from the certification guide in the web page of LEED System (U.S. Green Building Council 2009). In this process, the points of energy efficiency and water efficiency are checked to determine the level of sustainability that compliance with these factors represent for the classification.

Finally, public information recorded in the study case "scorecard" is reviewed to determine its particular level of performance in energy and water, connecting their level of certification as a sustainable building. This information is available online in the LEED system, from where it was taken (USGBC 2016).

2.2 Theoretical exercise of application of resolution 0549 on the building

In a second stage, verification of energy and water performance of the study case building were made. Real consumption of energy and water were analysed, regarding energy consumption and water from the guideline of resolution 0549. It was calculated the level of savings required in the study case, according to the percentages of mandatory reduction in water and energy consumption, according to their use and the climate zone where the project is located.

The analysis conditions for the study case correspond to an office building located in mild weather. The baseline type indicated by the resolution 0549 is presented in Table 1. The table shows the values for all the weathers and it is highlighted the mild weather, where the building is located.

Office Building Baseline	Cold	Mild	Warm dry	Warm humid
Energy Consumption (kWh/m^2/year)	81,2	132,3	318,2	221,3
Water Consumption (l/per/day)	45,0	45,0	52,0	45,8

Table 2: Baseline of energy and water consumption for an office building according to resolution 0549. Adapted of Ministerio de Vivienda Ciudad y Territorio (2015b)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Starting from the consumption per m² benchmark, the expected water and energy consumptions were projected, considering the building area and its population. It is important to emphasize that the estimated data will correspond to a building that does not include sustainability criteria. Afterwards, the savings percentages established by the Resolution were applied, considering those percentages that will be required at a national level from 2017. The percentages of water and energy savings are presented in Table 2.

Saving percentages relative to baseline of office buildings (%)	Cold	Mild	Warm dry	Warm humid
Energy	30	30	40	30
Water	30	35	45	20

Table 3: Percentages of savings for office buildings in the second year of implementation of the resolution. Adapted of Ministerio de Vivienda Ciudad y Territorio (2015b)

With the projections of the buildings consumption and the reductions needed according to the parameters of the Resolution, the case should ensure savings of 30% in energy and 35% in water, regarding the benchmark defined for the weather of Medellin. Therefore, it will be expected that a building with energy efficiency and water saving criteria should reach the consumptions calculated. Regarding the objective of this paper, especially a building with LEED certification, as the study case, should have a consumption with the savings calculated, according to the affirmations of the Consejo Colombiano de Construcción Sostenible (2015).

3. RESULTS

3.6 LEED certification O+M and score of study case

According to the checklist of the LEED v4 for Operations & Maintenance: Existing Buildings, there are 110 potential points. Figure 1 shows the range to different certificates depending on the obtained points.

Figure 34: LEED certification rating system. Based of online checklist (USGBC 2014)

The points are classified into 7 categories: Sustainable sites (26 points), water efficiency (14 points), energy & atmosphere (35 points), material & resources (10 points), indoor environmental quality (15 points), innovation (6 points) and regional priority (4 points). Figure 2 shows the seven categories and its respective points.

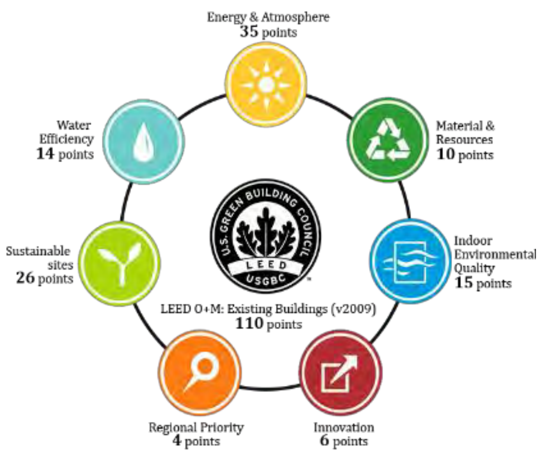

Figure 35: Categories LEED O+M and assigned points. Based of online checklist (USGBC 2014)

With this information, it is possible to deduce that, even if no significant scores are reached in energy and water, whose values added are equivalent to 49 points, it could be obtained from a Certified to a Gold certification level, with the 61 points remaining in the other categories.

The LEED certification process requires the fulfilment of three conditions related to energy and atmosphere: Monitoring the consumption of the building, not using cooling gases with high impact on the greenhouse effects and to be subjected to an assessment of energy performance, executed under Energy Star system's parameters. The report on that last condition will only determine the points to be certified for energy, without conditioning the level of certification for a minimum range of compliance. The water efficiency category only has one prerequisite, a minimum indoor plumbing fixture and fitting efficiency. Is worth noting that the use of efficient fittings, is part of the national normative about hydraulic performance of buildings since 1998.

Figure 3 shows the case study scorecard summary. The study case reached a total of 73 points of 110 possible. Only 33 of those are related to the performance of the project on water and energy use, out of a total amount of 49 achievable points on these topics in the LEED system.

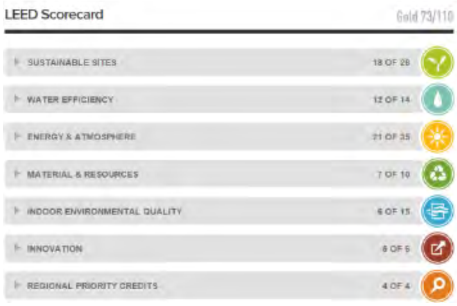

Figure 36: Study case scorecard. Source: USGBC (2016)

The energy and water points obtained by the case study, only represent 45% of the possible certification points. A detailed view of the points in water and energy categories does not find a direct relation to the requirements associated to Resolution 0549 (Figure 4), although energy certification points are developed under a model of analysis Energy Star that may be used in the methodology for the Colombian standard. However, this analysis is developed with a database of buildings in climate, economic and cultural contexts different to the Colombian context.

WATER EFFICIENCY		AWARDED: 12 / 14
WEc1	Water performance measurement	2 / 2
WEc2	Additional indoor plumbing fixture and fitting efficiency	5 / 5
WEc3	Water efficient landscaping	5 / 5
WEc4	Cooling tower water Mgmt	0 / 2
ENERGY & ATMOSPHERE		**AWARDED: 21 / 35**
EAc1	Optimize energy efficiency performance	16 / 18
EAc2.1	Existing building commissioning - investigation and analysis	0 / 2
EAc2.2	Existing building commissioning - implementation	0 / 2
EAc2.3	Existing building commissioning - ongoing commissioning	0 / 2
EAc3.1	Performance measurement - building automation system	1 / 1
EAc3.2	Performance measurement - system-level metering	2 / 2
EAc4	On-site and off-site renewable energy	0 / 6
EAc5	Enhanced refrigerant Mgmt	1 / 1
EAc6	Emissions reduction reporting	1 / 1

Figure 37: Detailed points for water and energy categories. Score obtained by the study case

3.7 The study case expected performance according to resolution 0549 and real consumption of the building

If is considered that a LEED certified building can exceed the minimum ranges of energy and water efficiency established by Resolution, a LEED Gold certification should be near or above to the maximum level range to reach the application of the regulation in its full implementation. In order to determine this aspect, it is necessary to know the real consumption of the building and its relation with the expected performance according to Resolution 0549.

The data of annual energy consumption of the study case over the past six years, are presented in Figure 5. It is important to highlight that since the entry into operation of the building in 2010, it has reduced its energy consumption by 23% by 2015, passing from a consumption of 16,640,867 kWh in 2010 to 12,762,052 kWh in 2015, thanks to the internal management.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

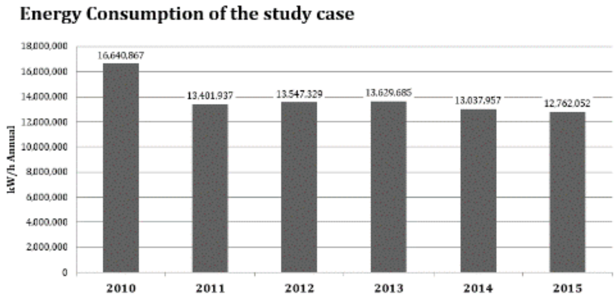

Figure 38: Annual energy consumption of study case 2010 to 2015. Source: Building operator, 2015

The energy consumption includes spaces for a different use from offices, which are responsible for 3% of annual energy consumption of the building, equivalent to 7623 kWh of the 12,762,052 kWh consumed in 2015. Consequently, the analysis will be performed with a value of 12,634,428 kWh annual, corresponding only to the office consumption.

The results of the energy consumption projection and energy consumption goal according to the baseline in the Resolution 0549 are presented in Table 3. The energy consumption projection is calculated based on the built office area of the building, excluding parking lots and areas with different uses, equivalent to 50,000 m^2.

Energy	
Built area Case of Study (m^2)	*50,000*
Baseline (kWh/m^2 annual)	132.3
Average annual energy consumption of study case (kWh)	6,615,000
Mandatory percentage reduction (%)	30%
Annual energy consumption goal of study case (kWh)	4,630,500

Table 4: Energy consumption projection and energy consumption goal. Based in Ministerio de Vivienda Ciudad y Territorio (2015b)

The data in Table 3 show that in the study case, an office building located in a mild weather, with 50,000 m^2, would have a baseline annual consumption of 6,615,000 kWh. Applying the 30% mandatory reduction is determined that the annual energy consumption, should be 4,630,500 kWh. Faced this benchmark, the consumption of the last year of the building, estimated at 12,634,428 kWh, exceeds the baseline in 8,003,928 kWh annual, i.e. 172%.

Regarding water sub-item, Figure 6 shows the values of global consumption the years 2014 and 2015, only data available from the building operator.

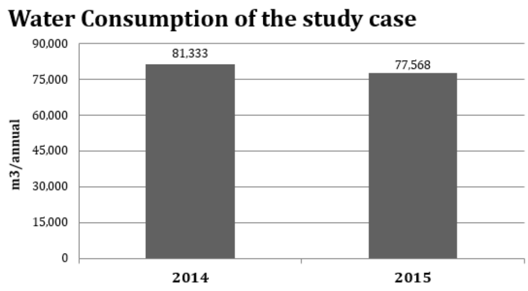

Figure 39: Annual water consumption of study case 2014 and 2015. Source: Building operator, 2015

The results of the water consumption projection and water consumption goal according to the baseline in the Resolution 0549 are presented in Table 4. The water consumption is calculated based on 4000 people, average population in the building.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Water	
Total of people in the building	*4000*
Baseline (l/person/day)	45
Average annual water consumption of study case (m^3)	65,700
Mandatory percentage reduction (%)	35%
Annual water consumption goal of study case (m^3)	42,705

Table 5: Water consumption projection and energy consumption goal. Based in Ministerio de Vivienda Ciudad y Territorio (2015b)

In relation to the baseline of the Resolution, the study case with 4000 people using the building, would have an annual base water consumption of 65,700 m^3 as shows Table 5. Applying the mandatory percentage of reduction corresponding to 35%, a total of 42,705 m^3/ year of water is obtained as consumption goal. Therefore, it is established that the current consumption, corresponding to 77.568 m^3/ year of water in 2015, is 81% above the limit of savings defined by the Resolution.

4. CONCLUSION

The analysis carried out in the study case as a benchmark of a certificated LEED Gold building and its comparison with Resolution 0549, allows to identify the level of complexity that must be anticipated by architects and builders to face the immediate implementation of the new standard for sustainable construction in Colombia, the Decree 1285, from several aspects. The first one refers to a necessary criticism approach, to the analysis process of baseline and savings percentages defined by Resolution 0549.

However, this theoretical exercise was made with an existing building and it is possible that the differences found in this research may be produced because they were not originally designed under efficiency parameters and recommendations of the guide attached to the Resolution, even when it is a sustainable building with a LEED certification. Remains then the possibility that only new buildings, designed under efficiency parameters and according to the Design Guide, have the option of reaching the level of demand required by the Decree. This affirmation should be the subject of an investigation, after this work and in an urgent way, because the imminent entry into effect of the Decree 1285 and its Resolution 0549.

The results of the study case, a building with a LEED Gold certification, facing the efficiency ranges of Resolution 0549, show differences in performance of 172% in energy consumption and 81% in water consumption. This suggests that the guarantee to achieve the requirements of the Resolution, through a payment of a foreign seal, distorted in its own origin, is not only naive but an ethical irresponsibility against the expectation of sustainable construction.

Furthermore, a review of the LEED system allows identifying that according to its operation, the certification can be obtained without significant scores on energy and water items. Although it is necessary to fulfil some prerequisites, the level of energy efficiency and water consumption that these can mean for a building in a context like the Colombian, and its relationship to the new standard of sustainable construction in this country, is still a topic under review.

However, this highlights the need for local responses to achieve a real systemic sustainability, through public policies that are already being implemented in some cities, and the real commitment of the building sector to reach goals beyond a certification or standard compliance. The paper should finish with a conclusion which provides the major points of your paper.

ABSTRACT

China's rapid expansion of urbanisation level has inevitably brought severe pressures on resource conservation and environmental protection in Chinese cities. China has initiated policies, strategies and pilot projects at both national and local level to address these urban challenges. China appears in the frontline of reshaping and redeveloping the urban environments by promoting eco-city projects in recent years. Key performance indicator (KPI) system has been long time used for evaluating the success of urban projects. It has become a pivotal to guide the development of eco-city projects in China. This research paper first elaborates the current practice of using KPI systems as a mean to achieving eco-city development; and will then take a comparison study between various eco-city KPI systems currently being used in China. By identifying the common issues and specific issues from the reviewed KPI systems, this research indicates that there are some convergences amongst different systems. Future eco-city KPI systems may need to consider these common issues, and incorporate the local contexts in tandem.

Keywords: KPI, eco-city, China, urban sustainability

1. INTRODUCTION

A plethora of new city concepts have entered policy and planning discourse all in the wake of understanding that man cannot continue to prosper socially and economically without careful consideration of how it affects the environment. Experts suggest that our activities can no longer be sustained by 1 earth alone, with man's ecology resources and services being used at rate of 1.5 earths and if nothing is done would require more than 2 earths to replenish (Global Footprint Network 2013).

These concepts stem from various literature seeking to identify and achieve sustainability largely based on the triple bottom approach i.e. society, economy and environment, thus concepts such as sustainable cities, eco-cities, green cities, knowledge cities, smart cities, low carbon cities, resilience cities etc. have become titles which policy makers and developers aspire to achieve in pursuit of their own innovative contextual understanding of sustainability (de Jong, 2015). In order to achieve these cities, which represent at some level, a focus on all or particular dimension in sustainability, embedded eco-city wide projects have been embarked on by various nation particularly China. This concept is guided by the use indicators that identify important urban development issues, measure and set standard to be achieved in order to address sustainable development. However, de Jong (2015) identifies the interchangeable use and mix up in terminologies particularly by policy makers, planners and developers. A good example is the Chinese city of Guangzhou which is working with the Singaporean government on an urban development project named the Guangzhou Knowledge city yet the indicators used are noted to be "eco-city indicators"(Crane et al. 2012; de Jong et al. 2013). Another pitfall is the contextual nature which these indicators are noted to be developed by i.e. what might be noted as important in one region may not necessarily be deemed worthy in another e.g. compact design versus dispersed city design (Sharifi, 2013). This would suggest that indicators used to define Eco-cities for instance in Dongstan China may fall short of the mark in Shanghai. Nonetheless, indicators are noted to be the flywheel of this debate and by understanding their divergence and convergence we move closer to developing a set of standardised indicators which may be uniformly adopted in a region or sub region with particular emphasis on eco-cities. This then begs the question what are eco-city indicators, why such interchangeability? And how do we achieve parity?

In pursuit of answering this question, Neighborhood Sustainability Assessment Tools (NSATs) is also reviewed due to their international origins, and will be compared and contrasted with embedded eco-city frameworks within the region of China. As such this papers aims to tackle the question raised by practically identifying common and

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

context specific indicators for eco-city, by establishing there points of convergence and divergence with case study focus of 6 tools, 4 city wide and 2 Neighborhood sustainability based tools within Location in ChinaContent

1.3 The eco – phenomenon

The ideology of an Eco system dates back to the 1970s by members of a voluntary organization Arcology group who strived to redevelop the concept cites living in tandem with nature (Dongtan 2008). Richard Register a co funder of urban ecology as well as the author of eco-city Berkely building cities for healthy future, defined eco-city as a conceptual city focused on the governance and living within the means of the natural environment (Premalatha et al. 2013). With looming environmental crises due to climate change as well, as other related issues such as health and energy poverty. The need for this concept and form of governance has been embraced by a myriad of academics policy makers and developers, with various attempts to interpret this general definition into practical and workable principles city wide construction and implementation (de Jong, 2015).

This venture, however, has not led to a definitive definition of eco-city as no agreeable definition has emerged till date (Premalatha et al. 2013; de Jong, 2015). Joss (2015) addresses the plausible reasons for this event. Firstly, it is suggested that diversity and ideas set in specific locales and governed by traditions as well as competition between various actors has led to the lack of cohesion. Secondly, this lack of coherence is simply an inevitable process towards agreeance, as the current phase could be seen as experimental to be followed by a phase of consolidation leading to more agreeable international norms. However, Joss (2015) also warned that this lack of agreeance by definition may lead to a conceptually vacuous principle i.e. lacking content with a threat of its application being applied for promotional and market fashionable services. Nonetheless, de Jong (2015), who also identifies the terminological fuzziness and confusion, stresses a need for clarification into distinct categories in relation to specific application. This argument invariably endorses the context dependency of eco city and its implementation of its indicators.

Joss (2015), however still argues that irrespective of its contextual proclivities another major reason for lack of definition is that eco cities are inherently future oriented. The reasoning here is that unlike other conceptual cities such as low carbon cities and resilient cities which more definitive in purpose, e.g. reduced pollution, renewable energy use, liveability etc. The form to which eco-city will take is still invisible looking towards the future. This argument is further solidified Richard Registers claims, suggesting that “eco city is an Ecological city, and no such city Exist”

Nonetheless, this should and has not stopped academics and practitioners from striving ever closer towards a unified definition as such Literature provides a myriad of definitions and indicators, qualitative and qualitative in nature which address the eco-city dimensions. For instance Newman and Jennings (2008) link eco cities closely with ecosystem thus creating indicators and principles based on that dimension, Lehman (2010, 2015) relates eco-city to urban development principles with emphasis on infrastructure and environmentally friendly buildings. Suzuki et al innovatively linked eco-city to economic prosperity with the terminology Eco2city, with the basis of its principle being ecologically considerate and economically viable. However de Jong (2015) argues that this leads the concept away from ecology and into a more sustainable arena. This can be seen in older publications by Roseland (1997, 2001) research, which identified 10 attributes pertinent to eco-city. Yet at least 5 out of the 10 refer to socio-economic issues.

- Prioritize land use and create a diverse and compact diverse, green and safe mixed use communities surrounding public transport facilities
- Should focus on transportation systems that would discourage driving and focus on proximity access
- Prioritize the remediation and restoration of damaged urban environment
- Prioritize affordable, safe and economically mixed housing
- Should promote equity and social justice and create improved opportunities for the impoverished
- Prioritize and focus on local, agriculture, community gardening and urban greening
- Promotion of recycling and resources conservation in addition to the reduction hazardous waste and pollution
- Should focus on ecologically derived and sound activities while discouraging those that increase pollution
- Focus on simple and environmentally conscious lifestyle while discouraging excessive consumption of material goods

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Prioritize the promotion of public awareness on the environment and bioregion through education and outreach programs

These descriptions while containing environmental and ecological prerogative have other concepts which promote economic prosperity and social consciousness. Over time the onset of eco-city has acquired a variety of conceptual meanings as shown above, especially as the process of eco-city drives towards policy development and practical implementation, especially in Asia and as such interweaving concepts such as social and economic dimension have become prominent, thus leading to softened environmental focus (de Jong 2013). Moving from the principles of Roseland and Register to the near future of post Brundtland report, the eco-city dimensions are noted to drive from the principles of triple bottom line approach or the 3 pillars of sustainability which is further conditioned by sustainability led dimensions such as urban design, governance and systems (World Commission on Environment and Development 1987). These dimensions are also generally categorized by indicators, specified with details, based on time frames and with a set of targets for the given project (Table 1). An example is the Tangshan Caofeidian International eco-city which has been in construction since 2009 and defines these dimensions with 141 indicators (Joss and Molella, 2013). With a target of 95% energy demand to be met by onsite renewable energy, 60% waste recycling and 20 targets for water preservation and recycling. Furthermore 68 of the indicator apply to city scale 14 on neighbourhoods scale and 25 at site level.

The main points to take away from the eco dimension is the lack or confusion in definition and indicators used to identify what can be termed eco-city however, in the post Brundtland report era, the 3 pillars will be one of the inherent concept used to categorise eco-cities. This process will however start with the understanding of eco-city development in China as the main topic of this paper followed by definition and understanding of underlying principles such as indicators and its utilization in pursuit of eco-city development. This will then provide the tools necessary to may comparison with other similar yet different frameworks such as BREEAM and LEED.

Environmental Sustainability	CO2/GHG	Reducing GHG emissions/energy consumption; promoting renewable energy generation
	Buildings	Reducing energy use; promoting carbon-neutral buildings
	Water	Reducing water consumption; improving water recycling
	Transport	Promoting integrated public transport
	Waste	Reducing waste; increasing waste recycling and waste-to energy generation
Economic sustainability	Biodiversity	Protecting green spaces; promoting biodiversity
	High-skilled, 'green' jobs and employability	Investing in the knowledge economy; attracting 'green' business
	Competitiveness and resilience	Enhancing international competitiveness; promoting community self-reliance
	Smart technology	Promoting 'smart' technological innovation
	Well-being	Improving individual and social well-being
	Housing	Providing affordable housing and mixed usage
	Urban agriculture	Promoting urban agriculture and local food networks
Social sustainability	Liveability	Creating socially inclusive, vibrant communities
	Equity	Fostering equity within and between generations
	Civic engagement	Encouraging participation in public life
	Cultural diversity	Promoting cultural engagement and diversity
Urban design and systems	Compactness	Increasing density of housing, along transport arteries

	Scale	Improving integration across neighbourhood, district, city, and regional levels
	Ecosystems management	Improving information management of urban infrastructure and systems (water, energy, etc.)
Urban governance	Policy coordination	Enhancing multilevel policy coordination
	Public–private partnerships	Promoting partnerships involving public, private, and nongovernmental actors
	Political accountability	Ensuring transparency, openness, and participation; collaborative planning

Table 1: Eco-city dimensions: general dimensions and related targets, based on a sustainability 'triple bottom line' applied to the urban context (Reference: Joss 2015)

1.4 Eco-city development in China

China is undergoing the largest scale of urbanisation in history and at an unprecedented pace. Between 1991 and 2012, China's urban population has increased from 302 to 712 million, or 26.4% to 52.6% in percentage terms (Table 1-2, China Statistical Yearbook 2013). To accommodate the increased population in cities, the built up urban areas have expanded from 12,856 to 45,566 square kilometers over the same period, an increase of 3.5 times greater in about two decades (Table 12-3, China Statistical Yearbook 2013). Also a more radical increase may be expected since urbanization is considered as a major development strategy by the Chinese governments to maintain long-term economic growth. The International Energy Agency (IEA 2012:39) has projected an urbanization rate of 65% by 2035, resulting in an annual increase of 14 million urban populations to reach this predicted ratio.

Cities in general and the built environment in particular, during their life-cycle, have a significant environmental impact both at local and global levels (Graham 2004:12; Girardet 2003:5). The rapid expansion of urbanization level has inevitably brought severe pressures on resource conservation and environmental protection in Chinese cities. The increasing pollution, traffic and energy consumption in the urban areas are becoming alerting matters in China. Only 8, out of 74 major Chinese cities, have satisfied the national air quality standards in 2014 (MEP, 2015). Recognizing these resource and environmental constraints, and moreover, the significance of developing a "resource-conserving and environmental friendly society", China has initiated policies, strategies and pilot projects at both national and local level to address the urban challenges.

Conventionally sustainable city efforts have been focused on individual issues such as urban energy, urban transport, land use, wastes, water and urban health. In recent years there is a growing interest in China to find a new integrated model for urban development as a whole. Effort to create such a new urban development model is manifested in the form of developing eco-cities.

China appears in the frontline of reshaping and redeveloping the urban environments (Joss et al 2011; Zhou et al. 2015; Flynn et al. 2016). Currently there are around 280 Chinese cities that have declared an ambition to develop "eco-city" or "low carbon city" (China Society for Urban Studies 2012, p10). A global survey conducted by the University of Westminster in 2011 recognised 25 eco-city projects in China according to the methodical criteria in that research. This makes china the country with the largest number of eco-city projects, followed by the USA with 17, and the UK and Japan with 16 each (Joss et al. 2011).

China's 12th Five Year Plan for Green Building and Green Eco-city Development, issued by the Ministry of Housing and Urban and Rural Development (MOHURD) in March 2013, requires selection of 100 new urban areas (e.g. new urban districts, industrial park, hi-tech zones), with a minimum size of 1.5 square kilometres, for pilot demonstration of eco-city concept. Till now, throughout the country three batches of city projects, totalling 19, were launched as the national level eco-city pilot projects by. Financial support has been provided to these projects from the Chinese central government. Table 2 gives some basic information about the first batch of national level eco-city pilot projects.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Eco-City projects	Area (km^2)	Projected population (k)	Current status
Sino-Singapore Tianjin Eco-City	30	350	Being constructed and operated
Tangshan Eco-City	150	1000	Being constructed and operated
Wuxi Eco-City	150	1000	Being constructed and operated
Changsha Eco-City	7.6	178	Being constructed and operated
Shenzhen Brightness New District	156	800	Being constructed and operated
Chongqing Eco-City	10	300	Being constructed
Guiyang Eco-City	9.6	170	Being constructed
Kunming Eco-City	160	950	Being constructed and operated

Table 2: The first batch of national level eco-city pilot projects

This research will use 'eco-city' to represent all the efforts that try to create an urban development model which is ecologically sound, economically feasible and socially satisfied. Furthermore, this research is focused on the Key Performance Indicator (KPI) systems of eco-cities. Literature review indicates that there is little research conducted in this area. This paper will take a comparison study between various KPI systems, currently being applied to eco-city development in China, including international rating systems, national standards and local practices. But before this process it is essential to understand the origin of urban indicators and ratings systems in relation to this study.

1.5 Eco-city indicator development

Cities can be defined by population, by administrative jurisdictions, by functions and by territory. As cities have evolved, so has population increased with associated increase in knowledge, improvement in science and technology but so has the carbon foot print. This has ranged from increased demand in energy supply to environmental and ecological damage to the surroundings. These are but a few of the very reasons why a pursuit of sustainable development emerged, with the eco-city being one of the conceptual manifestations of this quest (Lehmann 2015). However, as far as sustainability is concerned various programs and projects of cities exist with self-proclaimed titles of meeting the criteria of what is termed or described as sustainable by the Brundtland report or eco-friendly by developers (Flynn, 2016). It then becomes imperative to reveal the truth behind these claims as well as compare what a city is doing better in the quest to towards sustainable development (Voula, 2005). As such to achieve and repeat eco- cities status it is essential to understand what recipe was used, with the aim of quantifying sustainability progress. In essence understanding the successes and failures in initiatives, better equip future development and in the case of working principle can lead to a repetition of such initiative, keeping into consideration the contextual understandings. As such, indicators, termed as the recipe plays a vital role in achieving this not only for Eco cities but various other frameworks including NSATs initiative and other conceptual cities.

Indicators are generally described to provide information about a known phenomenon (Guy and Kibert, 1998). It is also described by the World Bank as performance measure that combines information to usable forms. In essence they are described as being the summation of complex situations, which provide an indication of the problem at hand (Premalatha et al. 2013). As relates to eco- city, indicators and sub indicators are used to define the problems to be addressed in order to achieve the prescribed ecological, social and economic aims. In essence the indicator can be used to determine the route or direction to be taken to address the problem, usually based on empirical, quantitative and sometimes qualitative evidence and driven by the theme of the project in question (Reed 2006). According to Keirstead (2007) indicators have to 2 critical roles, they reduce the amount of data used to describe the situation and the promoting or facilitating communication between the audiences. A good example is Alberti (1996), where the concept of ecology is used is in pursuit of urban sustainability. This is described as the total natural flow that a city requires in attaining its long term requirements of the populaces. In the development of this

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

definition, Alberti (1996) emphasizes the need of indicators to establish clear linkages between urban pattern and natural resource base with evidence being scientifically founded, implementation being policy relevant and applicability being readily Justifiable for planning.

In summary, As eco-cities are concerned, indicators is a method of simplicity derived from scientific evidence used to inform the audience on key directions to be taken and implemented to achieve ecological and environmental parity in cities with the support of policy sound frameworks and practical usability with in the overall aim of striving towards sustainable urban development (SUD). However, the post Brundtland report era has made SUD unsustainable without the consideration of social and economic dimensions, as such these will be added facet to the description of Eco city indicators. As such indicators used for their contextual aim of achieving any conceptual city goal will be termed Key Performance Indicators (KPI).

2. NEIGHBORHOOD SUSTAINABILITY ASSESSMENT TOOLS (NSATs)

NSATs evolved from environmental building assessment tools. These tools where established 2 decades ago on the environmental motivations highlighted in the Brundtland Report, however they have been initially focused on buildings with tools such as BREEAM New Construction and LEED New construction being developed and with the Evolutionary extension being BREEAM Community and LEED Neighbourhood (Nguyen, 2011). This extension was largely based on the widening scope covered by sustainability which shifted from environmental to social and economic. As such, the inability of buildings assessment to address abstract and community based elements such as connectivity and transport infrastructure and urban form as well as principles like urban heat Island effect (UHIE), led invariably to the development of NSATs (Sharifi, 2014). Similar to the concept of cities these Neighbourhood based tools are governed by indicators, which has been largely identified by experts to be context specific i.e. rooted to locale and location of development but also exhibit universal traits based on global and more uniform environmental and economic issues such as improving employment rate, reducing poverty levels and dampening the effects of climate change. As such Ameen et al. (2015) categorises indicators into common and local urban context with argument that there exist no specific indicators that suits all countries but however, perhaps we can establish a concept which does not suit all locales but developed to suit specific concepts such as Eco or smart indicators.

2.1 Current urban scale KPI systems in China

An urban area physically encompasses multiple buildings and their sites, and the public environment such as roads, open spaces, and landscaping features which exist in between those sites. It also embraces socio-economic features such as social interactions that are generally more intensive at this spatial scale. Currently there are several urban sustainability rating systems being applied at urban scale such as LEED-ND and BREEAM-Communities. As mentioned earlier, they all represent a larger scale of the built environment beyond single building sites and can be applied to any 'organized urban area' that is beyond a single building site. Both LEED and BREEAM have been used in China, for example, 7 projects were certified by LEED-ND in 2012 with a minimum construction area of 200,000 square meters and a maximum of 3.28 million meter square (Green Building Map, 2015).

In China, there are two main eco-city related national standards, which are known as 'National Standards for Eco Garden City' from MOHURD and 'National Eco-District/County Standards' from Ministry of Environmental Protection (MEP). Both of them use KPIs to evaluate environmental performance of urban areas. Currently 11 cities, including Hangzhou, Suzhou and Guilin, have been selected as "National Eco-Garden Pilot Cities" by MOHURD. Moreover, forty-six cities, counties, and districts have been designated by MEP as national "Eco-counties" or "Eco-districts".

At local level, some eco-city projects have launched their own KPI systems to make them more specific to the local contexts. Often these local systems are more ambitious and have higher requirements in comparison with the national standards. For example, all buildings must be certified by a green building rating system required by SSTEC and Wuxi Eco-City; minimum 20% energy consumption must be sourced from renewables in SSTEC and 8% is required in Wuxi Eco-City New City. These indicators and their corresponding benchmarks have not been incorporated in the national standards, which are more focused on urban infrastructure and pollution control.

2.2 Comparison study between urban scale KPI systems

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

This section will conduct a comparison study between the international urban rating systems, eco-city related national standards and local eco-city KPI systems. The purpose is to identify the common issues as well as the individual issues from these KPI systems. This would be helpful for informing future eco-city projects to develop their own KPI systems. These KPI systems reviewed include LEED-ND, BREEAM-Communities, National Eco Garden City Standard, National Eco-County/District Standard, SSTEC, Wuxi Eco-City, Changsha Eco-City and Tangshan Eco-City. The four local initiatives are all recognized as the national eco-city pilot projects by in 2013. The main reason for selecting these KPI systems lies in the fact that they all have been implemented in China's urban sustainability development and represent the efforts from both the central government and the local governments. Some key features of the KPI systems reviewed are presented in Table 3.

System features	LEED-ND	BREEAM Communities	National eco-garden city	National eco-city	Tianjin	Tangshan	Changsha	Wuxi
Developer	USGBC	BRE	MOHURD	MEP	Blue Path	SWECO	CABR	ARUP

Table 3: The key features of the KPI systems reviewed (source: Based on the authors' elaboration)

All these KPI systems reviewed have a similar structure. They all adopt multi-level approach (i.e. categories, indicators and benchmarks) to evaluate the overall urban sustainability performance. All of them have a number of indicators and corresponding benchmarks, which are classified into different assessment categories. It should be noticed that the number of indicators varies greatly between different systems. The Tangshan Eco-City has the greatest number of indicators: 141 indicators being classified into 7 assessment categories. The National Eco-city Standard issued by MEP has the least number of indicators with only 19 categorized into 3 assessment categories. The use of a greater number of indicators may complicate the data collection and assessment process, and in some cases, it may weaken the overall goal (Zhou et al, 2012). However, on the other hand, small number of indicators may not be sufficiently enough for a comprehensive evaluation.

Table 4 presents the assessment categories from the KPI systems reviewed in this study. It is apparent that all of them try to take a comprehensive view on sustainability by addressing environment, society and economy simultaneously. Land use, infrastructure, transport, resource and energy are some common themes in these systems. The comparison of the assessment categories only gives a vague idea on the scopes of different KPI systems. Opinions diverge on what aspects of an assessment category should be examined, i.e. what indicators should be employed to interpret an assessment category. Thus, further analysis is needed to explore individual indicators included in these assessment categories.

	Transportation and Communication	Solid Waste	Green Building
	Building and Building Industry	Transport	
		Green Building	

Table 4: Assessment categories in different KPI systems

It is challenging to put the indicators side by side and conduct comparisons directly between them. Some systems generally have similar assessment categories (e.g., society, resource, transport, ecology, energy), but the number of indicators and their corresponding benchmarks included within each assessment category varies widely across the systems. Different systems also often classify similar indicators and benchmarks under different categories. For example, LEED-ND classifies the indicators used to measure building performance into Green Infrastructure and Buildings, while they are categorized into Resource and Energy in BREEAM-Communities. Alyami and Rezgui (2012) analyze the similarities and differences of 4 different green building rating systems by consolidating the initial categories and indicators into new schemes. Thus, using Alyami and Rezgui (2012) method of classification all the indicators from the 8 KPI systems reviewed in this research are roughly classified into six broad urban sustainability assessment categories to facilitate comparisons. These assessment categories comprise Culture and Economy, Ecology and Livability, Site and Planning, Resource and Environment, Green Building and Infrastructure, and Traffic and Linkage.

Table 5 shows each of the assessment categories encompasses a number of sustainability issues that are synthesized from the eight urban KPI systems currently being used in China. In total there are 44 individual sustainability issues drawn out from maximum of 141 possible indicators. Such a framework allows evaluation of the convergence and divergence of various KPI systems and further identification of both the contextual issues and specific issues. The box will be ticked if an issue is addressed by a KPI system. If an issue is addressed in 6 or above systems it will be singled out as a common issue. On the contrary an issue is seen as specific if it is included in 3 or below systems. Such an effort is useful to understand how the current eco-city KPI systems work and how they inform the development of future eco-city KPI systems. Table 6 indicates the level of convergence of the KPI systems to the proposed framework by examining the number of issues addressed in each of the KPI systems reviewed.

Table 6: Sustainability coverage of the KPI systems reviewed

Table 7 shows the common issues and specific issues identified according to the methodology discussed earlier on. In total 20 issues are regarded as common issues. Among them, eight issues are addressed by all of the systems. These issues are:

- Social security (housing and employment)
- Ecological greening and landscape
- Accessibility to community facilities
- Water resource management
- Waste management
- Natural environmental protection

- Regional energy supply planning
- Building energy consumption

Common Criteria (20)	Specific Criteria (9)

3. DISSCUSSION

From Table 6, we can see BREEAM-Communities and Tangshan Eco-City have the greatest convergence rates with 86.4% and 79.5% respectively. The two national eco-city related standards have the least of 34.1% and 56.8%. The examination of convergence gives an indication of the comprehensiveness of an eco-city KPI system. It seems that the international assessment systems have a broader view on urban sustainability, while the national standards are more limited to environmental and resource issues. The different assessment coverage between them may be due to their intended roles. The international rating systems are used to certify urban sustainability performance which requires greater involvement of social and economic consideration to present a full sustainability assessment. The national standards are set to assess the environmental performance of existing urban contexts, thus they attempt to involve indicators which are easy to collect data from the current statistical sources. This would avoid data inconsistences between cities which are under assessment. So it is not a surprise that they attempt to involve more environmental and resource issues which are well recorded in the current statistical databases. This also may be attributed to the fact that the national standards were published by MOHURD and MEP separately and both have their own definitions on eco or green city. The four local KPI systems are designed to guide the whole development process of a new city project from planning, design to operational management. Thus they need to consider the local contexts as well as include those internationally (e.g. carbon emission) and nationally recognized indicators (e.g. air pollution, water pollution).

The eight issues, addressed in all systems reviewed, reflect the common concerns for eco-city development in China. It is noted that two issues, i.e. Social Security and Accessibility to Community Facilities, are addressing the socio-economic dimensions of sustainability. The rest are mainly related to the environmental and resources dimension. The other 12 common issues are included in 6 or 7 systems. It is not surprising that the main environmental issues, ranging from energy, water, wastes, land-use to site preservation. These issues are seen

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

as common practice in eco-city development. Mixed-use development is fundamental to urban sustainability as it will help to form an inclusive community and provide employment opportunities to local residents. Moreover, it directly affects travel behavior and enhances walkability to local facilities. Such major impacts will lead towards achieving a more healthy and livable urban environments, resulting in promoting quality of life and well-being of the communities. Furthermore, the provision of Green Landscape, Public Space, and Community Facilities plays an important role in urban sustainability. It can encourage people to interact and forge a sense of community, and improve resident satisfaction. These issues are crucial for new urban developments to attract residents. In addition, green landscape can provide local habitat, facilitate the use of rainwater and increase walking. Providing Public Transport Facilities can effectively reduce car dependence which is a key priority of urban sustainability. Green Building Certification has also become a compulsory requirement in eco-city development as building energy consumption is a significant factor determining the energy performance of a city. All the four eco-city projects require buildings to be certified by a green building rating system, such as LEED or China Green Building Evaluation System.

In addition to the common issues, there are nine specific issues that are used by 3 or below systems. However, this does not mean those issues are less important. These issues represent the divergent part of KPI systems currently being used in China. The lack of commonality in the use of these specific issues can be attributed to the following 2 factors, including:

- Purpose: labeling, national standards and local initiatives assessment;
- Local contexts.

Most specific issues are also relevant to some specific building technologies, such as, passive solar design, daylight utilization, building intelligent system and shaded streets. The involvement of such technologies would be depending on the local conditions, e.g. cost and adaptability of technologies.

4. CONCLUSION

KPI systems have played an important role in guiding the current eco-city development in China. This study elaborates the importance of KPI systems in the planning system as a potential mean to achieve sustainable eco-development. The analysis of the current eco-city related KPI systems indicates that they have different assessment focuses and priorities; however, there are still some convergences from the issues commonly addressed by the KPI systems reviewed. Future eco-city KPI systems may need to consider these common issues, and incorporate the local contexts in tandem.

ABSTRACT

The development of “Green and Eco-Urban District” is one of the major tasks in the “national promotion of the construction of ecological civilization (生态文明建设)”, which has also significant impact on the implementation of new urbanization (新型城镇化) in China. Consideration for humanities and humanism, which reflects the qualitative factors besides quantitative ones, is one of the assessment aspects in the Chinese national standard “Evaluation Standard for Green and Eco-Urban District”. This research will first compare the definition of humanities and humanism between China and western countries. Secondly, it will compare the human oriented issues of the four world leading green assessment standards – the US LEED Neighborhood Development, UK BREEAM Community, Japan CASBEE-Cities and German DGNB Urban Districts. Through the above comparisons, this research attempts to establish the assessment method and framework for the humanism aspect (人文章节) of the Evaluation Standard for Green and Eco-Urban District in China.

Keywords: sustainable neighbourhood, humanism, China GBL

1. BACKGROUND

1.2 Definition of humanities and humanism

The character 「人文」which means humanity in China first came up in the Book of Changes (中文名称：《易经》) (Xu, 1992), whose core spirit is the unity of man and nature in Confucian philosophy. While, in the West, humanism means a doctrine, attitude, or way of life centered on human interests or values, in particular it is a philosophy that usually rejects supernaturalism and stresses an individual's dignity and worth and capacity for self-realization through reason (University, 2014). Therefore, it could be found that there are certain differences in meanings of humanity between China and the West.

1.3 Human-oriented content in green and eco-urban district

In 1975, the United Nations set up the United Nations Habitat and Human Settlements Foundation (UNHHSF) and committed itself to the Habitat Agenda with issues as adequate shelter for all, sustainable human settlements, enablement and participation, gender equality, financing shelter and human settlements, and international cooperation and assessing progress (UNHHSF, 1996). We summarized the four principles of the above commitment as sustainability, openness, engagement and equality.

In China, the national urbanization plan for the 2014-2020 period, issued in 2014 (MOHURD, 2014), put forward the human-oriented city construction topic in part three, which contained chapter eighteen including history & culture conservation, cultural and sports facilities and free of charge public facilities.

Through comparative analysis between the United Nations’ Habitat Agenda and National Urbanization Plan (2014~2020), we found out their common principles and different points of focus, shown as Table 1.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Principles	UN Habitat Agenda	Chinese Urbanization Plan (2014~2020)
Public Open Spaces/ Facilities	✓	✓
Public Engagement	✓	×
Equality	✓	×
Sustainability	✓	✓
Green Education	×	✓
History & Culture Conservation	×	✓

Table 1: Comparison of the principles of human-oriented city between China and the United Nations

From Table 1 above, it could be found that the UN Habitat Agenda focuses on the human-oriented urban planning issues and environmental sustainability issues, but lacks due consideration for green education, promotion of green lifestyle and cultural sustainability. In contrast, China pays less attention on human-oriented issues, especially on public engagement and equality. Thus, some form of integration of global and local principles is necessary and may point to a more comprehensive framework on the aspect of humanism. Hence, the integrated framework of the humanism aspect in the Evaluation Standard for Green and Eco-Urban District should include four sub-categories – human-oriented design, green lifestyle, green education, and history and culture conservation.

1.4 Methodology

To establish the detail requirements of the four sub-categories in the aspect of humanism, this research used a comparative study method to compare the human-oriented and social related credits in LEED, BREEAM, CASBEE and DGNB with the aim to extract common and particular requirements in the four standards.

Since presently there are very few standards for defining green and ecological urban districts and the scale for an urban district is different in different countries, the scope for comparison covered three different urban scales, neighbourhood, urban district and city scale. It aimed to identify the human-oriented social issues that are of urban district scale and suitable for adoption in China.

2. LITERATURE REVIEW

2.1 LEED ND, BREEAM communities, CASBEE for cities, DGNB UD

In the 1990s, Americans put forward the concept of smart growth after realizing development problems resulting from loose expansion from urban to suburban. Green districts under the frame work of smart growth becomes the development mode based on a human-oriented concept (Huang, 2008). A community's smart growth means the communities provided well open space, farmland, and expanded the range of transportation, employment, and housing choices. As a guideline for sustainable neighbourhood development, initiated in 2004 (Xin, 2014), LEED ND encompasses not only transportation, ecological environment and economy aspects (Xiaoqian Teng, 2014), but also human-oriented aspects that integrates humanity into the rating system. LEED ND is primarily concerned with site location and land use to the neighbourhood scale, and explores integrated strategies from three parts including smart location and linkage, neighbourhood pattern and design, and green infrastructure and buildings and the human-oriented issues are mainly elaborated in the last two parts. LEED ND-certified developments improve building performance, energy conservation, greenhouse gas emissions reduction, and provide healthier and more productive environment for the occupants.

First launched in 1990, the UK BREEAM was the world's first environmental assessment method for new buildings design (BRE, 2012). The BREEAM Communities that came out in 2009 is an independent, third party assessment and certification standard based on the established BREEAM methodology (Ziping Xu, 2002). The assessment criteria in BREEAM Communities consider human-oriented issues in two aspects, namely governance and social and economic wellbeing. On governance aspect, public consultation and engagement are considered a necessary process in sustainable social development and addresses numbers of related credits that require local community and stakeholders involvement in each development stages in various forms. While economic wellbeing aspect addresses demographic needs and priorities issues to ensure that the development makes provision for housing, services, facilities and amenities on the basis of local demographic trends and priorities and public realm issues to encourage social interaction by creating comfortable and vibrant spaces, by analysis and regulating the multiple uses for different development users, barrier free design and community identity.

Comprehensive Assessment System for Built Environment Efficiency (CASBEE) in Japan, also known as "CASBEE for Cities" (hereinafter referred to as CASBEE-City) was a tool designed specifically for city assessment and was developed in close cooperation with the central government and local governments in Japan to support local governments and other stakeholders to identify environmental, social, and economic characteristics of their cities and in quantifying the effectiveness of city policies (S. Kawakubo, 2014, IKAGA Toshiharu, 2010). Development of the initial version of the tool began in 2008 and it was released in 2011 after extensive discussion among experts in the field (JSBC, 2011, Murakami, 2011). We studied the second, revised version that was released in 2012 for this paper. In CASBEE-City assessment tool, the categories in social aspect included living environment, social services and social vitality, which the assessment is based on quantitative indicators. In living environment category, crime prevention was put forward under the topic of district security and crime prevention was included as a factor to assess of sustainable social development. With the population-aging reality, CASBEE-City conducts quantitative analysis of the population in social services and social vitality aspects. Under social services aspect, it analyses the adequacy of childcare services and adequacy of services for the elderly by indication of the number of childcare and senior care facilities respectively. Besides, evaluate the education and culture quantitatively to show its emphasis on compulsory education as well as the culture communication richness. In social vitality aspect, it addresses regional living population according to the rate of population change due to both births & deaths and migration as people is the basis of a city's development and the key factor of regional sustainability.

The DGNB System was developed in close collaboration with the German Federal Ministry of Transport, Building, and Urban Affairs (BMVBS) and began a pilot phase in 2011 then released in 2012 (Zhu, 2010). In DGNB UD, the credits related on the humanity could be found mainly in two aspects, both sociocultural and functional quality including diversity of social functions, subjective and objective safety and security, comprehensive accessibility and public art setting and process quality (Lu, 2010). Overall, the evaluation is primarily based on qualitative indexes, which the assessment requires corporation approach in certain case that promoting communities' sustainability while in turn increasing the difficulties of communities' development.

2.2 Summary

Although the assessment scale of LEED ND, BREEAM Communities, CASBEE-City and DGNB UD are different, they all address human-oriented and social sustainability issues in different considerations. LEED ND seems more concerned about human's green behaviour. And BREEAM Communities make effort to provide adequate facilities for different needs. While CASBEE-City assessment tool expands the assessment concept of urban development's sustainability and positively responds to social problems and development trends by emphasizing regional security, cultural education and service facilities as well as the relationship between growth trends, childcare and senior care service facilities under Japan's unique aging social structure. DGNB UD in the other hand place emphasis on community accessibility and connectivity.

3. COMPARATIVE STUDY

Latest version of BREEAM-Communities, CASBEE-Cities and DGNB UB were all released in 2012 while LEED ND were updated in 2014. In these 4 rating systems, BREEAM-Communities and LEED ND launched and developed earlier than CASBEE-Cities and DGNB UB. We shall conduct a comparative analysis between the four different rating systems from three aspects, including human- oriented design, green education, and history and culture conservation. The comparative analysis result can be found below in Table 2.

Table 2: Comparison results of the four world-leading standards

3.1. Human - oriented design

3.1.1 Engagement

Except CASBEE Cities, LEED-ND, BREEAM-Communities and DGNB-UD have requirements on public engagement from planning stage to construction stage, especially in BREEAM-Communities. BREEAM has detailed procedures and guidelines for the implementation of public engagement form both top-down and bottom-up approaches. It is suggested that public engagement should be regulated into sustainable and green community development to enhance the awareness of public participation during community's planning and development process.

3.1.2 Public open spaces/ facilities

All the four rating systems place emphasis on provision of the public open spaces and facilities but from different point of view. LEED ND requires the provision of sufficient public open spaces within community, initiating the integration of infrastructure and public spaces as there is great potential for green infrastructure to be made available as neighbourhood facilities like roof garden, children garden, orchard, vegetable garden, street greenery and backyard garden. While BREEAM-Communities emphasizes the multi-functional open spaces from user-demand-side, aiming to create more communication spaces for residents. DGNB UB, on the other hand, focuses on the connectivity and walkability of the open spaces design. Both BREEAM-Communities and DGNB UB regulate for public spaces/ facilities and provide guidance on the accessibility between community and city by enhancing connecting residents to more transportation selections. CASBEE-Cities evaluate quality by the adequacy of cultural services, calculated as number of community centres, together with the number of libraries/ land area of municipality, so as to guide and encourage the provision of public spaces and facilities.

3.1.3 Equality

CASBEE-Cities, BREEAM-Communities and DGNB for UD have social indicators on housing and social mix, education level, and criminal rate. However, the detailed requirements on such indicators are different due to different population configuration in each country. CASBEE focuses more on facility provision for the elderly and children, which reflects the actual situation in Japan. BREEAM-Communities, on the other hand, focuses more on the provision of affordable housing and job opportunities within the communities (Gu, 2013). Whereas DGNB UD has similar requirement on the evaluation of unemployment rate. For LEED ND, it not only requires the provision of affordable housing but also stipulate the different mix of residence types, aiming to encourage better social mix within the communities.

Accessibility for disables is another important indicator for equality. LEED ND and DGNB UD both have credits for barrier-free and universal design. LEED ND gives credits for visitability and universal design to increase the proportion of areas usable by a wider spectrum of inhabitants' mobility, regardless of age or ability. DGNB UD also gives credits on visitability and universal design as being one of the unique features of the system.

3.2. Green lifestyle and education

All four standards have no credits on the promotion of green lifestyle and education. However, behavioural change is given same importance as the technical requirements for environmental sustainability. Thus, the humanity aspect in our country's green building label for urban district (GBL for UD) established requirements for these two indicators, to become an issue of innovation and a special characteristic of this research. It is suggested that credits should be given not ungenerously but should be based on practical results to avoid green education being reduced to just hollow pledge with no accountable achievement on outcome in practice.

3.3. History and culture conservation

For this indicator, only LEED sets requirements for the conservation of historical buildings. Nevertheless, cultural sustainability is a vital part of sustainable development and the humanity aspect in GBL for UD extends the requirements from buildings to the protection of intangible heritage relevant to the country's culture.

4. CONCLUSION AND SUGGESTION

Human-oriented design is the key principle for human-oriented city construction, and is also the core concept for Green and Eco-Urban District development, of which public engagement is an important tool to understand human-oriented planning and design, construction and operation of a Green and Eco-Urban District. It is suggested that criterion should be established to help the Evaluation Standard for Green and Eco-Urban District in China, and guide and ensure the operation of public engagement to safeguard residents' participation. Meanwhile, the standard should also require provision of accessible and inviting public open spaces to improve communities' communication and interaction. In addition, barrier-free-design and senior services facilities should also be considered in the GBL for UD, as well as the free of charge public service facilities to ensure the provision of humanistic care for all different users.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Green education is the important guarantee for Green and Eco-Urban District construction. All four standards, including LEED ND, BREEAM-Communities, CASBEE-Cities and DGNB-Urban Districts have no credits on the promotion of green lifestyle and education, while this aspect was highlighted in GBL for UD. Nevertheless, this part should be scientifically and logically based on practise experience and results covering the whole spectrum of students of different ages to avoid green education being reduced to just hollow pledge with no measurable outcome. Besides, it is suggested in the research to actively promote green life-style starting with changing people's mind-set and behaviour. Districts and communities could compile a green life-style to educate residents how to achieve energy and water saving, waste reduction and travel by public transportation.

History and culture conservation is an integral part of planning and design of Green and Eco-Urban District. For this aspect, BREEAM-Communities, CASBEE-Cities and DGNB-Urban Districts other than LEED set no requirements for the conservation of historical buildings. To revitalize and reuse old historical and cultural buildings is not only a means to save resources but also a good way to preserve our city's historical. In addition, setting urban design guidelines are recommended and helpful to integrate building form and design language, facade treatment and material expression to record the historic evolution of the city, to reflect the regional and climatic characteristics, as well as cultural heritage connotations.

ABSTRACT

Some cities are recognized for their successful application of forms of revitalization of their habitat, while other cities are clogged and choked with traffic and pollution. The inclusion of "sustainable development" in the field of construction is behind new methodologies for achieving a more sustainably built environment. The use of tools to measure the degree of sustainability of cities is the method that receives the most attention in developed countries. However, none of the tools used to date covers all three pillars of sustainability (environmental, social and economic). Previous studies show that the participation of citizens and experts is not taken into consideration. This study (paper) will aim to explain the process of our research for integrating socio-economic aspects in the CASBEE-UD standard (neighbourhood level). First, the study will seek to analyse the existing built environment through a geographic system (GIS) for the identification of spatial indicators. In addition, from the use of social and economic data through the use of statistical analysis, we will select the data that present a true picture of our territory (either an existing district or a new district). The criteria selected in these analyses will be used in a (in an advanced analytic tool) multi-criteria tool to establish the most efficient indicators in order to integrate them into the CASBEE-UD standard.

Keywords: neighbourhood sustainability assessment, sustainability coverage, applicability

1. INTRODUCTION

In recent decades, much has been written about the concept of the need for sustainability in cities. The reason for this is that during the last century, the world has witnessed many social, economic and urban. Everyone knows that the construction sector has a huge impact on the consumption of resources. According to data disclosed by the leading research institutes (World Commission on Environment and Development (WCED), European Commission, 2009), construction industry uses globally about 40% of energy and 40% of natural resources (raw materials and other materials) and produces 25% of waste. Several communities and institutions have developed new methodologies for monitoring the sustainability status of their cities. Some communities (United States, European Community, United Kingdom, Japan, etc.) have launched tools to ensure that the hardware requirements of their cities strive towards sustainability. Three sets of certification have been developed recently: LEED-ND (1998) developed by the Green Building Council in the US, BREEAM Communities (1992) developed by the British organization BRE Global, and CASBEE-UD (2004) developed by IBEC Institute for strengthening the environment and energy conservation in Japan. All these standards are developed at the neighbourhood level. Certification standards mentioned above are the most known and used, but several weaknesses especially the socio-economic aspects. To measure progress towards this desirable state of sustainability, measurable indicators are required to assess urban efforts in the economic, social, environmental. Therefore, the importance of the issue of sustainability in general and in particular on sustainable urban planning in communities, has emerged as one of the key issues that must be taken into account by the authorities and experts. In the same context, at present, there are many areas that have experienced a marked change in their own style and their quality of use. To achieve these objectives, it is necessary to develop clear objectives and effective sustainability criteria. Also, it is necessary to understand and analyse existing certifications, specifically the criteria, which structure and guide the entire evaluation process. The goal is that the knowledge of the certification standards should help in the future development, for a more complete and efficient certification in order to have a tool based on strong sustainability criteria "triple bottom line". The aim of this study is to develop additional indicators to those existing in the certifications of tools to assist planners and citizens to improve the assessment of the built environment (neighbourhoods). Our research is guided by the development of an appropriate methodological approach based on the integration of socio-economic aspects to the CASBEE-UD standard. The article is structured in the following

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

manner: Chapter 1- context; the second chapter is dedicated to the review of the literature; and, the third chapter describes the methodology of our approach; the fourth chapter describes the application of our methodology framework for CASBEE-UD standard; the results and discussion will finish this study.

1.1. Context

In the second half of the twentieth century, the world's urban population has quadrupled from 732 million in 1950 to 2.8 billion in 2000 to over 3.2 billion in 2006 (Redman, 2010; United Nations, 2006). The year 2007 marked a turning point in history when half the world's human population lived in cities (Cities Alliance, 2007). This growth has caused a lot of pressure on a lot of resources and contributed to the depletion of natural and environmental resources. Urban society recognizes that activities that are developed for the production and processing of urban space influence and determine the survival of natural systems. There is now a consensus on the importance and the need for strategies to mitigate these problems and gradually increase the benefits of cities. In addition, the need for corrective actions reinforces the idea of developing new models to replace the current models, to reorient activities and human technology towards sustainability, and to ensure the survival of contemporary urban society. In recent years, there have been various collaborations in the field of construction to environmental objectives and sustainable development. Certification standards are an example of the principle tools that encourage market competitiveness "green." In addition, standards are working to improve the quality of products and services while introducing new criteria and values of productive activities. In the field of construction, the certifications are used in several countries (e.g. USA, European Community, Japan). They are used mainly to guide architects to techniques for the construction of buildings based on rigorous energy efficiency. The standards in the field of urban planning are a recent phenomenon. They have recently developed initiatives which aim to introduce sustainability criteria in the planning process (e.g. the construction of new neighbourhoods or rehabilitation of urban areas). In addition to these tools, which are used for products and value-added services, communities use them as an instrument of local politics. They are also used as means of verification of compliance with regulatory guidelines, or for granting financial credits and investment or to the development of private projects.

1.2. Justification of context

The scale of the neighbourhood is the area where we find all the dimensions to determine the design of a more sustainably built environment. This scale between the scale of the city and the building is very interesting in this context, in operational terms, as it is well suited to the testing of specific practices to increasing urban sustainability. It makes it possible to grasp tangibly urban issues that clearly exceed the size of a single building. The need for coordinated control of urbanization and mobility, the creation of joint dense clusters and the search for a better quality of urban life can be addressed through concrete solutions. It is in this perspective that emerges the concept of "sustainable neighbourhood", namely the realization of urban centres, dense and mixed, whose overall quality meets a thorough vision of sustainability. A number of parameters are however needed to apply the concept of sustainable neighbourhood.

2. THE NORMATIVE EVOLUTION

In the context of urban planning, there is now a broad consensus that sustainability has four main dimensions: environmental, social, economic and institutional. All these dimensions should be taken into account for sustainable development (Valentin and Spangenberg, 2000; Conte and Monno 2012). The evaluation of sustainability is considered the latest generation of impact assessment tools, and can be defined as "a process that directs decision making towards sustainability". Many methodological approaches were used to assess sustainability. All of these approaches use indicators as tools to generate relevant information. From the data, they acquire a wide range of sources. To a large extent, the effectiveness of the sustainability assessment depends on the robustness and rigor of the evaluation methodology. A research framework consisting of indicators and relevant criteria and poorly defined can misinform and mislead policymakers. Despite the relatively short history of the tools, evaluation of neighborhood sustainability (NSA = neighborhood sustainability assessment) has received considerable attention from the scientific community. Most studies have focused on the theoretical and unrealistic aspects. In one of the few studies on this issue, Saynajoki et al. (2012) found that some of the indicators used in the NSA's tools are not relevant. Similar results were obtained in studies that conducted respectively to examine the relevance of LEED-ND for use in England and Germany. This raises concerns that the results of these evaluations can mislead and misinform policymakers. Although there is still some controversy surrounding this issue, different tools have been used to assess the evolution of the neighbourhood in several countries. For example, LEED-ND has been used outside the United States and some countries of the European Community. BREEAM Communities has been used in several countries in the European Community. On the other hand, the CASBEE standard was used, from the beginning, within the country and only by some Japanese cities. After underutilization, this standard has found greater consideration in his country, through its development and its methodology. Now the Japanese government imposed the standard for all major projects. The non-use of CASBEE in other countries is due to its young age and also because the standard to be used needs qualified experts.

2.1 Weaknesses in standards

The information available in the literature demonstrates that the tools need refinement. The most significant weaknesses found in standards and literature are: 1) The extent of sustainability (or sustainability); 2) The inclusion of prerequisites; 3) Adaptation to the locality; 4) The participation of stakeholders and citizens; 5) Placement of the actors in the project phases; 6) The presentation of results; 7) The application of the standard to different contexts.

The purpose of the sustainability assessment is to provide decision makers with a comprehensive and integrated local assessment system in the short and long-term prospects (LEED-ND, 2011 BREEAM Communities, 2009, CASBEE for Urban Development, 2007). Such a system would help them judge what actions should or should not be used in an attempt to create a more sustainable society. For coverage of sustainability, developers can use a better sustainability approach while improving the resilience of neighbourhoods through the provision of communities with strong local economy that are autonomous and have good infrastructure. These criteria are highlighted in a study on the relationship between urbanization and sustainable urbanization led by Oswald & McNeil, 2010; Waheed Khan, and. Veitch, 2009. These criteria are important when addressing affordable housing to inclusive communities, social networks, mixed use, and the local economy. They improve the ability of an area to resist the various social and economic status regardless of their inhabitants. Therefore, the context-specific criteria should be included as well as the weights to be assigned to the values of the relevant specific communities. This could impose an additional economic burden on the developer, but it's the only way we can ensure the viability and reliability of the assessment results. In terms of adaptation to the location, it was stressed that evaluation systems should vary depending on the type of development and also specific questions to the site. Other criticisms are the lack of citizen participation at the time of writing of the project, only because they are written by experts. The importance of the participation of different political and academic actors and the community during the various stages of planning is widely recognized by Khakee (1998). By focusing on the inseparability of planning and evaluation, it suggests that the evaluation should be a discourse between all the actors who are somehow affected by the assessment, and should take the form of negotiations rather than pursuing a solution to a problem. Finally, citizens can participate by providing feedback that planners use for system update. As for the use of such assessments, planners and developers can decide which changes are needed to bring the economic development activities in alignment with the ecological limits and social needs. The evaluation results can be potentially used by different stakeholders, including planners, designers, local authorities, the real estate market and residents. The central objective of most assessment tools is to act as a decision support tool. The final results must provide an adequate and reliable picture of the situation on the ground. They have the potential to guide decisions for planning, guide the evaluation of actions and the degree of progress towards sustainable development and to educate residents. The results should be simple and transparent to avoid greenwashing and unfounded decisions. The results are analysed to assess their ability to meet specified characteristics. BREEAM and LEED-ND Communities have a similar way of presenting the final results. The only difference between the two is that in BREEAM Communities, the projects that fail to acquire threshold points are also labelled. In most cases, certified projects receive a label based on the rankings they have achieved. CASBEE-UD, addressed, to some extent, deficiencies identified by presenting the results of each theme. In addition, there are scales (weak, good, very good, excellent) that can be used to highlight some performances. Although the tools are tailored to the priorities and conditions of their countries, the differences in climate parameters, social, and economic and type of developments are essential to make a customization of standards. However, this may not be possible due to various constraints. In such situations, the adopted standard should be adapted and customized using benchmarks and appropriate weightings to be used as part of the assessment. Due to significant changes in scope, planners should be aware that one size does not fit all. A personalized and customized tool with additional information is required for each development.

3. THE METHODOLOGICAL APPROACH

In this first stage, the opportunity to engage citizens in an urbanization project and the use of certain methods to help communities develop a list of indicators will be discussed. This approach to decision making is primarily a political responsibility. It enables decision makers to explain and justify their choices and objectives to citizens. The methodology is planned in three steps (Figure 1). In the first step, an area will be selected in order to perform a statistical analysis of data.

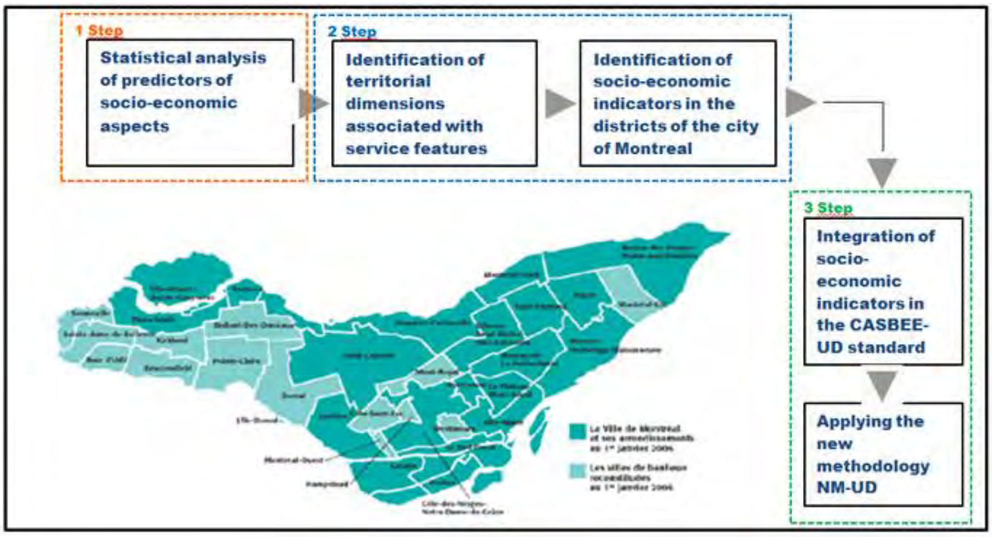

Figure 1: The methodological approach

With the statistical analysis, the independent variables of socio-economic aspects will be selected. In the second step, an analysis of the territory of each district to identify territorial dimensions (average distance of clinics, hospitals, public transportation, etc.) associated with the service functionality will be completed. In the same step, socio-economic and territorial indicators of each selected neighbourhood will be identified. In the third step, socio-economic and territorial indicators will be integrated into the CASBEE-UD standard and the new standard will be applied to the selected territory.

3.1. First step: Search for independent variables

In this stage, the criteria that have been selected are analyzed in four districts of the city of Montreal to measure their degree of sustainability. We initially chose to take the data that were used by the boroughs of Ahuntsic-Cartierville, Plateau Mont Royal, Sud-Ouest and Lachine to test the methodology through a statistical evaluation (see Table 1). The choice of these districts was made to combine the of each district (e.g. economics) in order to create a better sample. For this assessment, a statistical analysis is used for research of independent variables. After testing the results of these four districts, the analysis will be extended to all districts of Montreal for the assessment to be statistically representative. In this first stage, it was found that there are differences between the criteria selected by the standards and those used by the boroughs. To normalize the data, the equation was used to find the value for which our indices are to be divided. This statistical analysis gives the possibility of finding the weighting for each criterion. These statistical analyses will meet the first objective of our research. In this first stage, it was noted that there is an absence of territorial criteria in the characterization of citizen satisfaction. So the next step in an analysis of the territory will be carried out to identify the missing criteria.

Equitable social value and social responsibility	Strengthening cohesion and social equity	Accessibility
		Public spaces
		Density
		Distribution of services
		Inclusion
		Security
	Enhancement of architectural heritage (buildings and materials) and historical (preservation of historical memory)	Structure
		Materials
		Technology
		Protection
		Care and maintenance
		Form
		Architectural fragmentation
		Architectural quality
Economic strategy	Cost reduction	Waste management
		Distribution of functions
		Use - activity
		Contiguity
	Increased cohesion (accessibility and transport) and economic dynamic (jobs and enterprises)	Streets frame
		Public transport
		Ease of movement
		Traffic flow
		Parking
		Link, connection
		Economic diversification
	Multi-functionality of the territory, territorial competitiveness	Location
		Connection
		Partition areas
		Urban frame
		Public areas
		Historical activities

Table 1: Independents variables

3.2. Second step: The location of the essential functions

To meet the second objective, considering the territorial dimension, the proposed approach will be based on the use of geographic information systems (GIS) to study urban form. GIS is composed of different layers of geographic reference information. This will allow the user to combine the desired information and view it on a map. A multi-criteria analysis model will be used to synthesize geographic information to select indicators satisfying citizens' preferences. So the territorial dimensions will be identified to associate with the service capabilities across the GIS software for urban information and geographical shape. This information will include the criteria that are based on territorial characteristics and the location of critical functions for the quality of life of citizens. This approach was made to represent the diversity and distribution of the functions in the territory. Following this approach, the socio-economic and territorial indicators will be identified through a tool for decision support through a multi-criteria analysis method of hierarchical (Analytic Hierarchy Process (AHP)). With this method (AHP) it will be possible to determine the benefit / cost ratio of a project as for the advantages and disadvantages of its implementation that cannot be measured with money. All information is available both quantitatively and qualitatively. With this method, it is possible to treat problems with qualitative data type. This step will meet the second objective.

3.3. Step Three: Integration of indicators and application of the new standard

The third step is structured in two parts. First, the socio-economic indicators identified will be included in the CASBEE-UD standard and this standard will be applied to the selected territory. The application of the new standard (CASBEE-UD new version) validate its power through the comparison between the selected standard and the new standard. The validation will be given either by the presence of socio-economic indicators, either through using hierarchical approach to the decision that will compare the two methods of assessment and see the improvements. For a confrontation with targeted problems, this type of approach leads to innovative solutions, both through the application of certain technological developments by redefining the governance process. This creative dimension is integral to the philosophy of this type of project and often also a success factor for the implementation on the ground of an increased number of sustainability criteria.

4. DISCUSSION

A sustainable neighbourhood should also be considered a closed system and turned in on itself. By its size and quality, it will add value to an urban area far beyond its physical boundaries. In the literature, we realize that certification standards are, however, looking for a common measure. It is important to ensure that all certification steps are measured in the same manner to give a consistent message to the industry. This does not mean adopting a universal certification system. Overall, the various systems have many differences. A rough comparison, carried out by researchers BREEAM, buildings with a score of "Platinum" (the highest) for LEED, reach a score lower in the ranking of BREEAM. In Europe, where the certification standards are more stringent than in the USA. Europe has also adopted the analysis of life cycle assessment (LCA) to a greater degree than in North America. In recent years, Japan, on the other hand, has developed innovative policies with respect to the state of its cities (Tokyo, Osaka). This is one reason why, in this study, the use of CASBEE-UD was chosen as a comparison standard. In its structure CASBEE-UD uses not only concepts linked to the building but also concepts related to the entire site's external environment. However, in this standard, the mainstreaming of social acceptability and identification of relevant indicators are not present. It is believed that the integration of these brings an improvement and a more concrete assistance in the design of a more sustainably built environment. We are of the opinion that this study is not comprehensive, but its structure is possible to highlight the fixed points that could help others seek to improve the structure of existing standards and make them independent of the interests of the furniture market which is oriented more towards labelling rather than take to heart the expectations of citizens.

ABSTRACT

This paper introduces the concept and assessment framework of a sustainability assessment tool for cities around the world, called Comprehensive Assessment System for Built Environment Efficiency (CASBEE)-City (worldwide use version). CASBEE offers systemized tools that can be applied to a variety of spatial scales, such as individual buildings, urban districts, and cities. CASBEE-City (worldwide use version) is specifically designed for city-scale assessment and can be applied to various types of cities globally. The tool enables users to understand target cities comprehensively based on environmental load and quality, comprising environmental, social, and economic quality and activities. A city that achieves high quality measures while imposing a low environmental load is recognized as a more sustainable city within the framework. Assessment items and indicators must be carefully selected to enable assessment of cities in both developing and developed countries. To this end, candidate indicators were selected after reviewing various materials issued by international organizations such as the United Nations and its related organizations (UN-Habitat, UNESCO, World Bank, World Health Organization), the International Organization for Standardization, and the Organisation for Economic Co-operation and Development. Indicators were selected taking several key criteria into account, including data availability, simplicity, reliability, policy relevance, and balance among items. Cities were assessed by aggregating the information from selected indicators. Seventy major cities in the world were assessed using the tool and practicality of the tool has been verified.

Keywords: green rating tool, sustainable cities, comprehensive assessment

1. INTRODUCTION

Twenty fifteen was an important year for reconsidering how we can achieve sustainable development globally. The Sendai Framework for Disaster Risk Reduction 2015–2030 (HFA2) was adopted in March, the Addis Ababa Action Agenda (AAAA) was adopted in July, the Sustainable Development Goals (SDGs), officially referred to as Transforming our world: the 2030 Agenda for Sustainable Development, were adopted in September, the Paris Agreement under the United Nations Framework Convention on Climate Change was adopted in December.

As highlighted in Goal 11 of the SDGs, making cities and human settlements inclusive, safe, resilient, and sustainable is currently a priority. Cities and local and subnational governments (referred to as cities and communities hereafter) are key players in achieving sustainable development by implementing effective local policies, promoting financing, developing high-quality infrastructure, delivering basic services for the citizens, and functioning as a hub of meta-governance or multi-level governance.

To make steady progress toward achieving SDGs, it is vital to assess the effectiveness of implemented policies, and to understand the current conditions in cities and communities by using appropriate indicators and publically collectable data. Consequently, the Committee for the Development of an Environmental Performance Assessment Tool for Cities (2015) has developed a tool that enables all stakeholders to assess cities and communities.

2. STUDY METHODOLOGY

The Comprehensive Assessment System for Built Environment Efficiency (CASBEE)-City (pilot version for worldwide use) tool was developed for assessing cities and communities around the world. CASBEE allows a comprehensive assessment of the target with respect to quality (Q) and environmental load (L). CASBEE

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

calculates the Built Environment Efficiency (BEE) value, defined as Q divided by L as shown in Fig. 1. Cities and communities with high BEE values are more sustainable.

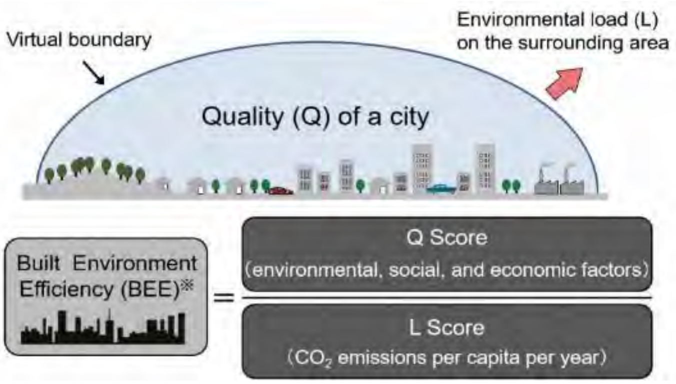

Figure 1: Overall structure of CASBEE-City (pilot version for worldwide use)

The assessment of Q is based on the concept of the triple bottom line, in which the quality of a city or community is comprehensively assessed from environmental, social, and economic perspectives that are the three pillars of sustainability. Assessment of L is based on greenhouse gas (GHG) emissions resulting from daily human activities. Decarbonization requires urgent action, and cities and communities that emit less GHGs are more eco-friendly.

The assessment results for cities and communities are plotted on a two-dimensional graph, called a BEE chart, with the Q score on the vertical axis and the L score on the horizontal axis (left side of Fig. 2). Cities and communities where Q is high and L is low are plotted on the top left of the BEE chart and are more sustainable (right side of Fig. 2). In contrast, cities and communities with low Q and high L are less sustainable under the CASBEE assessment structure.

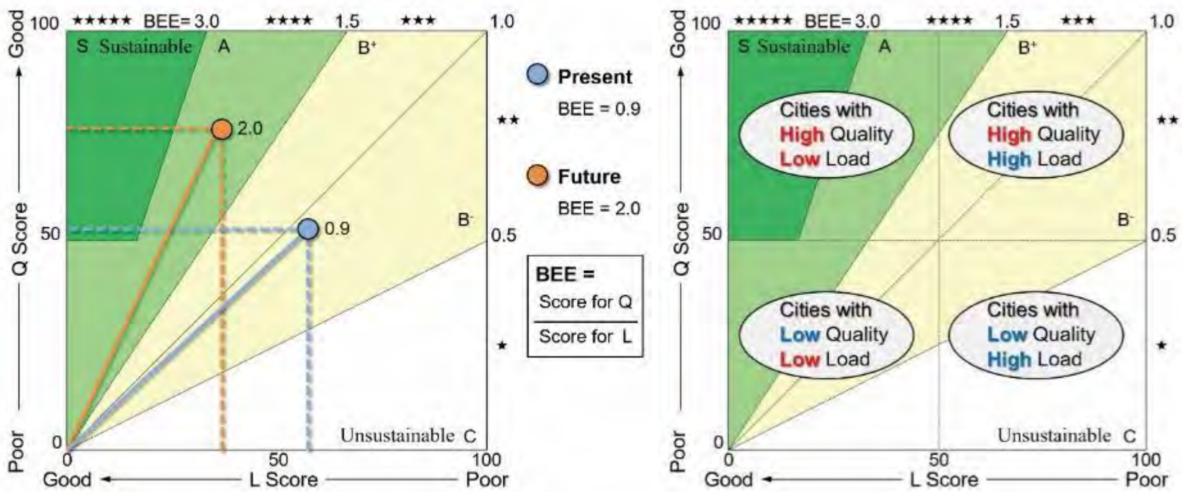

Figure 2: Visualization of assessment results on BEE chart

CASBEE uses a relative assessment system, and a city or community is assessed by each indicator on a scale of 1–5. The CASBEE-City tool was initially developed to assess municipalities in Japan and the worst scoring city or community was assigned as 1 on the scale, 3 indicated an average score, and 5 was the highest score (Murakami et al., 2011; Kawakubo et al., 2011). In this study, the assessment targets are cities and communities all over the world (Fig. 3). These scores are multiplied by a weighting coefficient and the score for Q on the five-point scale is obtained. Finally, 1 is subtracted from the score for Q, and then multiplied by 25 to convert it to 100-point scale (Q Score).

The assessment of L in CASBEE-City is limited to GHG emissions. GHG emissions are converted to their carbon dioxide equivalents and evaluated based on annual GHG emissions per capita (t-CO2 eq/person/year) to ensure a fair assessment regardless of the population size. A L Score on a scale of 0 to 100 is calculated by applying a logistic function where the global emissions average per capita (approximately 5 t-CO2 eq/person/per year) is represented as a median value of 50.

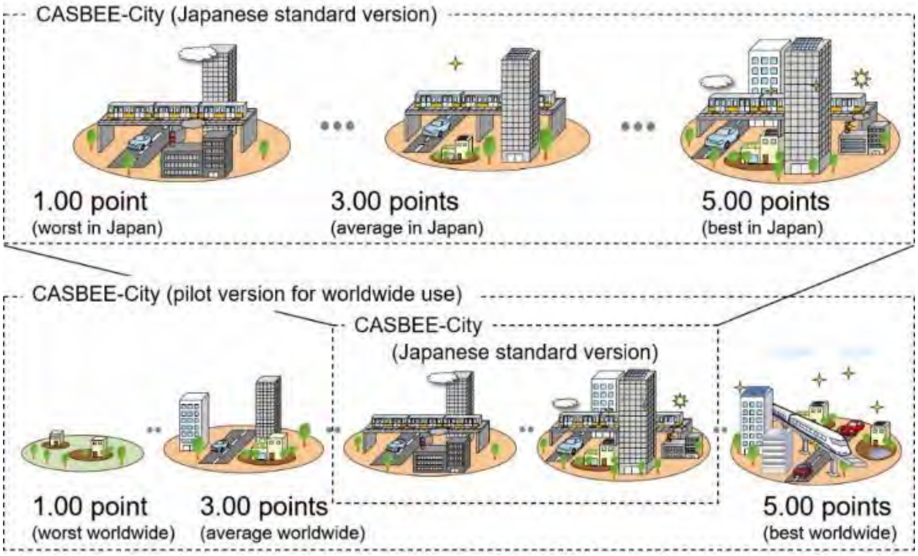

Figure 3: Relative assessment system of CASBEE-City (pilot version for worldwide use)

Assessment indicators that are applicable to cities and communities were selected from the SDGs indicators and ISO 37120 indicators, and some indicators were altered slightly (Fig. 4) (IAEG-SDGs, 2015; ISO, 2014).

Initially, there were more than 300 candidate indicators. The indicators were selected considering the following criteria: 1) data availability, 2) simplicity, 3) reliability, 4) applicability to public policy, and 5) balance among assessment items. The selected indicators are shown in table 1.

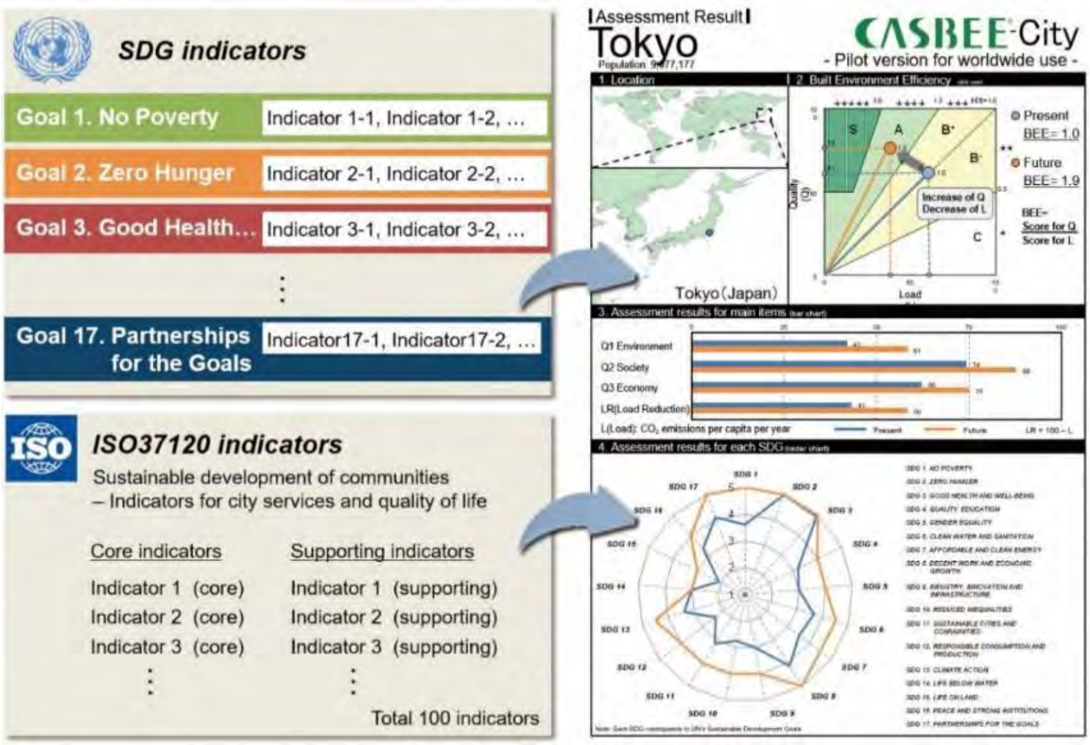

Figure 4: Selection of indicators from SDGs indicators and ISO 37120 indicators

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Q1: Quality (environmental aspect)		
	Q1.1	Percentage of population using safely managed water services
	Q1.2	Percentage of population using safely managed sanitation services
	Q1.3	Annual domestic water consumption per capita
	Q1.4	Percentage of a city's total energy consumption derived from renewable sources
	Q1.5	Mean urban particulate matter air pollution (PM2.5)
	Q1.6	Area of public green space as a proportion of total city space
	Q1.7	Percentage of urban solid waste regularly collected and well managed
	Q1.8	Consumption of ozone-depleting substances per capita
	Q1.9	Percentage of the urban solid waste that is recycled
	Q1.10	Implementation of a transparent and detailed deep decarbonization strategy
	Q1.11	Share of coastal and marine areas that are protected
	Q1.12	Percentage of forest area under sustainable forest management
	Q1.13	Red List Index
Q2: Quality (social aspect)		
	Q2.1	Total fertility rate
	Q2.2	Proportion of population below minimum level of dietary energy consumption
	Q2.3	Prevalence of stunting in children under 5 years of age
	Q2.4	Infant mortality rate
	Q2.5	Death rate associated with HIV/AIDS, death rate associated with all forms of tuberculosis, death rate associated with malaria
	Q2.6	Probability of dying between exact ages of 30 and 70 from cardiovascular disease, cancer, diabetes, or chronic respiratory disease
	Q2.7	Road traffic deaths per 100,000 population
	Q2.8	Average life expectancy
	Q2.9	Number of physicians per 1,000 population
	Q2.10	Preprimary enrollment rate (% of relevant age group)
	Q2.11	Primary completion rate (% of relevant age group)
	Q2.12	Tertiary enrollment rate (% of relevant age group)
	Q2.13	Percentage of women aged 20-24 who were married or in a union before age 18
	Q2.14	Primary enrollment rate of girls (% of relevant age group)
	Q2.15	Women as a percentage of total elected to city-level office
	Q2.16	Annual number of public transport trips per capita
	Q2.17	Number of fire related deaths per 100,000 population
	Q2.18	Violent deaths per 100,000 population
	Q2.19	Percentage of children under age 5 whose birth is registered with a civil authority
	Q2.20	Existence of a national law or constitutional guarantee on the right to information
	Q2.21	Number of homicides per 100,000 population
Q3: Quality (economic aspect)		
	Q3.1	Proportion of population below $1.25 (PPP: purchasing power parity) per day
	Q3.2	Proportion of population living below national poverty line
	Q3.3	Share of the population using reliable electricity
	Q3.4	GNI per capita (PPP: purchasing power parity)
	Q3.5	Youth employment rate (aged 15–24)
	Q3.6	Unemployment rate
	Q3.7	Mobile broadband subscriptions per 100 population
	Q3.8	Number of internet connections per 100 population
	Q3.9	GNI share of richest 10%
	Q3.10	Percentage of urban population living in slums or informal settlements
	Q3.11	Domestic revenues allocated to sustainable development as percent of GNI
	Q3.12	Debt service ratio (debt service expenditure per municipality's own source revenue)
	Q3.13	Share of SDG Indicators that are reported annually
L: Environmental load		
	L	Annual CO_2 emissions per capita

Table 1: Selected assessment indicators for CASBEE-City (pilot version for worldwide use).

Seventy major cities in the world were assessed to check how the tool works, its feasibility, and the accuracy of the assessment results. Cities were chosen from every continent, and included developing and developed

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

countries to determine the progress of SDGs in each region. The tool is theoretically applicable to all cities and communities, including small towns and villages where statistical data exists; however, major cities were chosen as assessment targets because it is easier to collect data for the assessment and to evaluate whether results are reasonable. Figure 5 shows the number and distribution of the assessed cities.

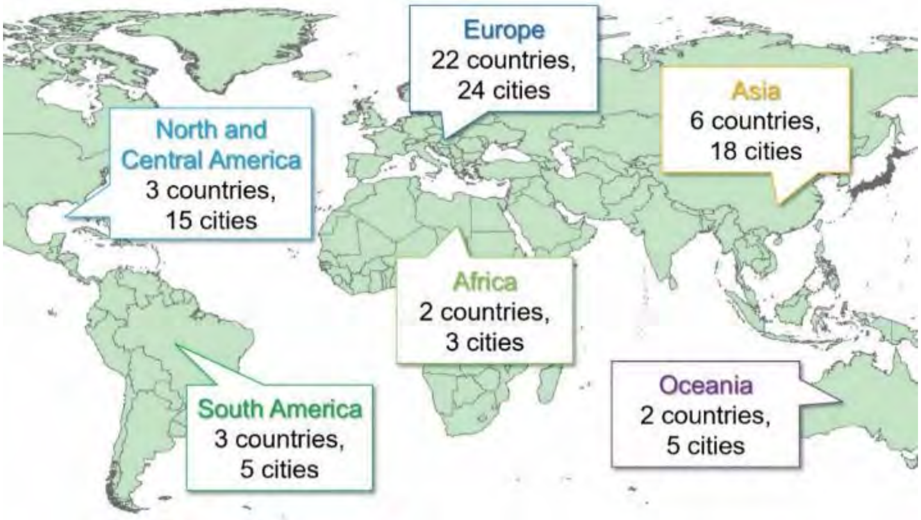

Figure 5: Number and distribution of the cities assessed with the CASBEE tool

3. ASSESSMENT RESULTS

Selected major cities were assessed with CASBEE, and the results are plotted on the BEE chart. Figure 6 shows the assessment results by region, and a single plot represents a city.

Cities in developing regions, such as Southeast Asia and Africa (except some exceptions such as Singapore), tend to have lower Q scores than other cities. In contrast, many cities in developed regions, such as Europe, North America, East Asia, and Oceania, have higher Q scores. However, these results are reversed for L. Many cities in developing regions emit less GHGs than the world average, whereas many cities in developed regions emit more than the world average. Therefore, some cities in developing regions have better BEE (= Q/L) values than cities in developed regions, indicating that more decarbonization is required for cities in developed regions.

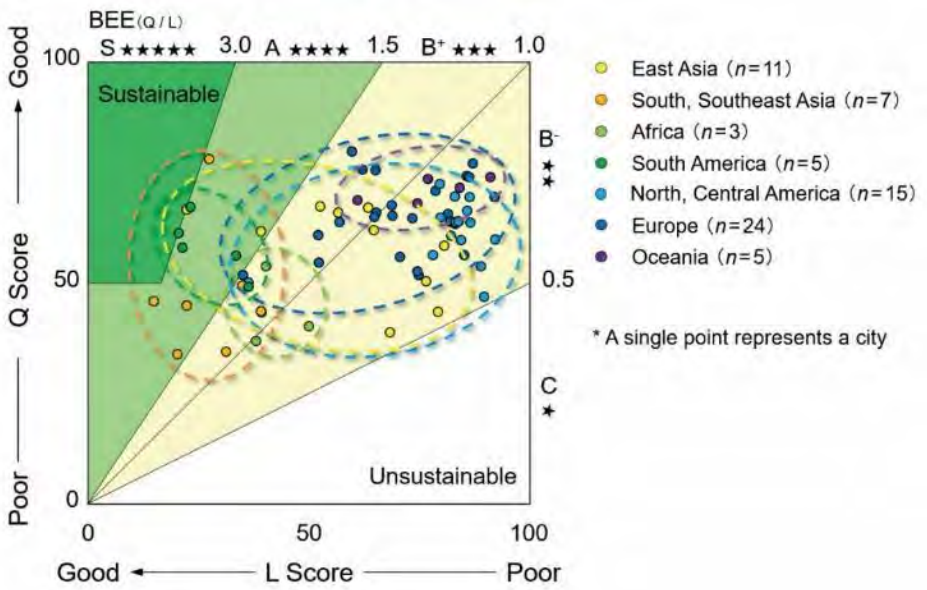

Figure 6: Assessment results for selected cities using the CASBEE tool

Preferred development paths for each city or community group are shown in Fig. 7. Cities and communities in developed regions should drastically reduce L, whereas those in developing regions should increase Q without increasing L. Further international collaboration is required to achieve this goal.

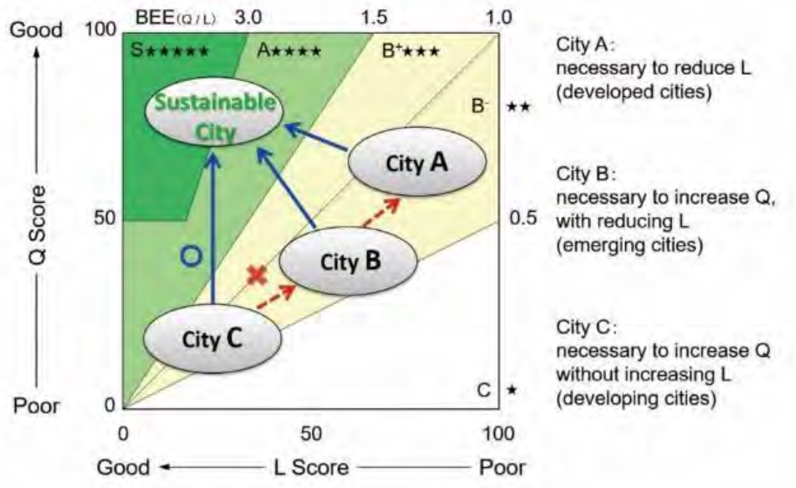

Figure 7: Preferred development paths for each city or community group

4. CONCLUSIONS

The concepts and assessment framework for a sustainability assessment tool for cities around the world, called CASBEE-City (worldwide use version) have developed. The tool consists of approximately 50 indicators that are selected from SDGs and ISO 37120 indicators. The trial assessment of major cities with the tool confirmed that cities in developed regions achieve a high Q score by emitting large amounts of GHGs, whereas cities in developing regions show the opposite trend.

This type of assessment should be performed continuously to monitor progress toward achieving SDGs and other global agendas in cities and communities. It is also important to determine best practices and share the experience of the most sustainable cities and communities to be sustainable in more efficient manner. International collaboration among countries and also at a subnational scale is critical for achieving global agendas.

Although a tool for assessing cities and communities have described to support all stakeholders in understanding the status of their cities and communities, and to help them identify key problems, it is still necessary to improve the assessment structure of the tool. For example, the selection of indicators should be reconsidered because it strongly affects the assessment results. Developing effective, easy-to-use assessment tools is essential for sustainable management of cities and communities, and thus further studies are required in this field.

ABSTRACT

Value Management (VM) is a multi-disciplinary tool developed to ensure that projects are delivered to the best function at the lowest possible overall whole life cycle cost. This implies that VM will not only provide value for money for construction projects but will also enhance projects that are financially, socially and environmentally sustainable. This research therefore, explores the drivers, barriers, benefits and factors affecting application of VM to rail construction projects. Using quantitative approach, data were collected through well structure close-ended questionnaires that were personally distributed and administered on built environment professionals. It was ensured that the respondents have ample experience of construction projects and adequate knowledge of value management concept. Findings from the study revealed that, professionals in rail environment are aware of VM and agreed that its application will not only eliminate unnecessary costs in design, materials and labours but will enhance that projects are conceived and executed in sustainable manner. This is as a result of the fact that VM creates change on purpose rather than letting change happen accidentally. The rate of application of VM to rail construction projects is very low and this is due to reluctance to change as well as lack of guidelines, information, knowledge and experience of the discipline among professionals and other stakeholders in the industry. It is therefore expedient for stakeholders involved in rail construction to pay special attention to the application of VM in their quest to enhance project success and deliver projects that are sustainable in all ramifications.

Keywords: infrastructure development, sustainable neighbourhood, value engineering

1. INTRODUCTION

Value management (VM) is an intensive, interdisciplinary problem solving activity that focuses on improving the value of functions that are required to accomplish the goal, or objective of any product, process, service, or organization (Elayache, 2010). The technique helps in determining the unnecessary costs which can be eliminated to save costs while not jeopardizing the function and quality of the final product. According to Chougule, et al., (2014), the technique was introduced by an engineer named Larry Miles as value analysis in 1947. The term has been used synonymously with value engineering and value analysis. However, Oke and Ogunsemi (2013a) noted that some school of thought believe that value management is a combination of value engineering and analysis. The process is referred to as value analysis at the pre-construction stage and value engineering at construction and evaluation stage. It is not a cost-cutting exercise but the purpose is to improve the value project by eliminating unnecessary costs, which could result in production of product/project at a minimal cost (Oke, et al, 2015).

Value management was initially introduced for manufacturing firms but it has gained wider popularity in the construction industry due to its ability to reduce project cost thus enhancing project value (Bowen, et al., 2010). Oke and Ogunsemi (2011) observed that value management is widely accepted as an important tool in the management of construction projects. While this may be so for construction industries in developed countries, Bowen et al. (2010) noted that the situation is by no means so clear for developing nations like South Africa. This indicate that the technique of value management can aid production and sustenance of sustainable projects. In view of this, this study examined the level of application of value management in rail projects in South Africa and benefits associated with the usage in the quest for continuous delivery of sustainable projects.

2. CONCEPT AND BENEFITS OF VALUE MANAGEMENT

Saving money and, at the same time, providing better value is a concept that is necessary and important in satisfying owners of construction projects and other stakeholders (Bharathi and Paranthaman, 2014). Behncke, et al., (2014) stated that value management is not just focusing on cost reduction, but on the principle of increased value. The principle of value management then becomes necessary in quest for achieving better value of construction projects. An important construction process where effective planning and assurance of value for money are ensured is the design stage. Based on traditional procurement approach, design process begins with the architect's asset, core competencies and desire to create a product that ideally matches the client's priorities (Al-Yousefi, 2007). This indicate that value management should be adopted right from this stage. Rich (2000) noted that the technique assist in terms of achieving the best practice with which to develop an optimal design. More so, in cases where the designer see the need to change the design, the technique allows the changes to be incorporated formally.

Value management has been introduced in the 1950's in the United States and since its introduction, it has been employed in various countries around the world (Chen, et al., 2009). Value Engineering (VE) was developed during World War II as a method to find alternative methods and materials for processes and products that were limited and challenged by rationing. Since its creation, the use of the VE process has extended to the construction industry as a way to maximize the value of a project (Seidel, 2012).

Value management has been considered as an organized approach which can obtain the most optimum value of the unit cost, while assures the quality, safety, reliability, and maintainability of a construction project (Oke, et al., 2015). It is a systematic application of recognized techniques by multidiscipline teams which identify the function of a product or service; establish a worth for that function; generates alternatives through the use of creative thinking; and provides the needed function, reliabilities, at the lowest overall cost or Life Cycle Cost (Simpkins, 2000). Basically, value management is finding alternative ways of eliminating unnecessary cost without having any effect on the quality and functionality of the project. According to Aghimien and Oke (2015), the approach is a strategic thinking process that involves the systematic and objective assessment of project component alternatives. Oke, et al., (2015) explained that value management can be considered as a systematic and innovative multidisciplinary method that examines the functional needs of a product, service and project design as well as facility and system in achieving greater value and optimum cost without affecting the level of performance in the programme and project.

Value management has been internationally recognized as an efficient modern management methods and it has unique benefits of reducing costs while improving product value. Domestic and international practice shows that the application and promotion of value engineering can get great economic benefits (Oke and Ogunsemi, 2011). According to Bowen, et al., (2009), one of the benefits of VM is the provision of good engineering judgement to produce better projects to the clients. It was further revealed that application of VM in any project actually lowers the project cost with a certain percentage which is a benefit to clients. Practitioners apply VM methodology to products and in industries such as the following: corporations and manufacturing, construction, transportation, government, health care and environmental engineering. This is due to the fact that VM methodology easily produces savings of 30 % of the estimated cost for manufacturing a product, constructing a project or providing a service (Chougule, et al., 2014). Chavan (2013) noted that the principle aid correct and cost effective solutions to various construction problems by ensuring functional correctness before deciding on the solution to be implemented.

According to Oke and Ogunsemi (2013b), value management has been practiced for half a century in the construction industry with an intention to bring into existence innovative ideas and solutions for enhancing project value. It concentrates on effectiveness through stating functions, goals, objectives, needs, requirement and desires, then define the quality features that make the product more acceptable (Al-Yousefi, 2007). At the end the value management exercise, it is expected that report and proposal emanating from the process should meet functional requirements at the least possible whole life cost.

3. RESEARCH METHODOLOGY

Due to the nature of this research and information obtained from existing literature in the area of value management and sustainable construction, a descriptive survey design was adopted. This is in line with the assertion of Polit and Hungler (1993) as well as Mouton (2001) that surveys may be used for descriptive, explanatory and exploratory research. More so, the method is useful for obtaining basic characteristics data relating to behaviour, beliefs, abilities, knowledge and opinions of a individual, group of people or situation. Quantitative research technique was preferred in soliciting required information from respondents since needed variables are available in literature. The population include professionals who are directly employed by various organizations specializing in rail projects and consultants working as clients representatives for the projects. Purposive sampling was used in sampling the respondents with a view to involving only individuals with relevant and adequate experience of value management principles and rail construction in the study area.

Close-ended questionnaire was designed for the study due to the advantage of high response rate. The questionnaire was designed in English language as all the respondents were expected to understand the language and could read and answer the questions. In the cover letter, they were given assurance of their anonymity in responding to the questions and that the outcome of the study will solely be used for academic purpose. Instructions and guidelines to completing the instruments as well as the average duration it will require to respond to the questions were also provided. The first part of the instrument was aimed at gaining demographic data relating to level of experience, education etc. of respondents for the purpose of better interpretation of the findings. The other part was structured to obtain information on the application and implementation of value management in rail construction projects.

Due to the require experience of rail projects, the instruments were administered through personal hand delivery and electronic mail on identified respondents. The instruments were retrieved through the same means. 107 questionnaires were distributed but at the end of the collection period, 89 were returned while 82 were correctly and completely completed and found worthy of further analysis. Frequencies and percentage were adopted to analyse questions regarding background information of respondents. 5-point Likert scale was adopted for the main aspect of the instrument and mean item score (MIS) was employed to analyse the data. This is to identify the level of importance of the identified variables in order to rank them accordingly.

4. RESULTS AND DISCUSSION

4.1. Biographical information of respondents

Academic qualification of respondents reveals that 22%, 49% and 29% possess post-graduate degree, bachelor's degree and post matric diploma or certificate respectively. In term of their professional qualification, 24% are construction project managers, 12% are construction managers, 15% are project managers, 17% are engineers, 15% are quantity surveyors, 5% are architects while the remaining 12% are experts in the field of general management, planning, materials procurement, etc. All the respondents have more than 5 years experience in the construction industry and the larger percentage have been in the industry for more than 16 years. All of them are aware of value management principles through seminars, workshops and practical application on construction projects. These findings indicate that information supplied by the respondents are reliable and trustworthy to draw conclusion concerning value management and sustainability of rail projects.

4.2. Benefits of value management for rail projects

Value management is currently utilized in the organisation of about 63% of the respondents, while the reaming 37% are yet to adopt the technique in the development and planning of their projects. More so, 37% have not adopted the technique in any projects, 22% have applied the principle in approximately 1 to 5 projects, about 20% have used the method in approximately 5 to 10 projects, 12% have employed it in approximately 10 to 15 projects while the reaming 10% have applied the principle in more than 15 projects.

Table 1 represents the advantages of the application of VM in the rail environment. The major benefits are concerned with the elimination of unnecessary costs and costly design elements. The study further shows that value management fosters innovation and makes a difference to the way a project is conceived and executed. It could be deduced that all the identified benefits are important judging by the least calculated mean item score of

3.72 (out of the possible 5.00). This supports the findings of Oke and Ogunsemi (2011) that value management mainly focuses on eliminating unnecessary costs and costly design elements, and also do foster innovation within the industry. Wilson (2005) also stated that the right application of the principle improve the quality of project, reduce duration, lower cost and enhance overall function through the provision of alternatives.

Benefits	MIS	Rank
VE has a certain scope in the rail environment in South Africa	4.52	1
Eliminates unnecessary costs and costly design elements.	4.52	1
Fostering innovation.	4.44	3
Certainly makes a difference to the way a project is conceived and executed.	4.42	4
Provides cost effective solutions to the problems faced within the project.	4.40	5
Is with advancement in project management tools.	4.37	6
VE enhances the value of the project.	4.34	7
The project cost reduces to a certain percentage.	4.34	7
Provides good engineering judgement to produce better project.	4.32	9
Better defines the purpose of the project.	4.27	10
Provides alternatives of executing the project.	4.25	11
The function of the project gets improved.	4.22	12
Define project functions, goals, objectives, requirements, design criteria and scope of work.	4.17	13
Reduce complicated projects into basic components by analysing its functions.	4.14	14
Improve project quality.	4.09	15
Lowers life cycle cost of the project.	4.07	16
Develop implementation procedures.	4.07	16
The project period will reduce.	3.72	18

Table 1: Application of VE in rail projects

4.3. Influences to implementing VM in rail projects

This section explores various factors affecting the implementation of VM techniques. It could be observed from table 2 that lack of guidelines and information as well as lack of knowledge and practice of the technique of VM are the most important factors influencing the choice and adoption of the practice for construction projects. These factors are followed by reluctance to change, lack of training opportunities, negative attitude, lack of commitment and conflict of objectives by stakeholders. The least influencing factors are concerned with the impression that it interrupt normal work schedule, notion that it not suitable for low cost projects and believe that it is too expensive to carry out. This support the findings of Oke, et al., (2015) as well as Bowen, et al (2010). The top 5 hindrances of value management were identified to include lack of local guidelines and information, lack of knowledge and practices, reluctance to change, lack of training opportunities and negative attitudes and failure to recognize creativity or innovativeness

Factors	MIS	Rank
Lack of guidelines and information about VE/ VM.	4.27	1
Lack of knowledge and practice in VE/ VM.	4.20	2
Reluctance to change.	4.10	3
Lack of training opportunities in VE/ VM.	4.01	4
Negative attitudes and failure to recognize creativity or innovativeness.	3.99	5
Lack of commitment of leadership/, management.	3.93	6
Lack of trained professionals in VE/ VM.	3.93	6
Lack of good communication, misunderstanding, jealousy, and normal friction between professional team.	3.84	8
Conflict of objectives by different stake holders.	3.79	9
Speculations on the project team members and jumping to conclusions, without properly gathering information.	3.77	10
Lack of involvement of the higher management.	3.65	11
Non conducive environment for team work in a project.	3.53	12
The “problem” not describable in function terms.	3.36	13
Human relations are not respected during the VE study.	3.19	14
Interruption to normal work schedule.	3.02	15
Not suitable for low cost projects.	2.35	16
Too expensive to carry out.	2.06	17

5. CONCLUSION AND RECOMMENDATIONS

This research is intended to give ideas to the organizations working within the rail environment on the application of value management for improvement of value and function of their projects. The study evaluated the level of application of value management in construction projects and despite the level of awareness, knowledge and understanding of value management by construction professionals, it was clear that most project managers do not apply the technique for their projects and in their organizations. Value management has proven to be one of the best tool for enhancing value of construction projects by eliminating unnecessary costs.

The findings revealed a number of factors that affects the application of VM techniques, the most important ones are related to lack of guidelines and information about VM; Lack of knowledge and practice in VM; Reluctance to change; Lack of training opportunities in VM; negative attitudes; and failure to recognize creativity or innovativeness. These are therefore essential factors that should be evaluated by organisations and stakeholders in the rail environment in their quest for adoption of value management for sustainable project. More so, Organisations in the rail environment should be concerned about the training of their employees through VM workshops where the employees will be equipped with knowledge about the technique. Professionals involved in rail construction projects should also be ready to adopt changes and innovation by accepting new ideas and technologies.

Calculation Methodology of GHG Emissions from a Low Carbon Urban Development in an Underdevelopment Country – Case Study from a LEED ND Certified Project in São Paulo City, Brazil

Maria Carolina FUJIHARA[a]

[a] *Green Building Council Brasil, Brazil, mfujihara@gbcbrasil.org.br*
[a] *University of São Paulo, Brazil, mfujihara@gbcbrasil.org.br*

ABSTRACT

Total anthropogenic greenhouse gas (GHG) emissions have continued to increase over 1970 to 2010, even with the implementation of several efforts and reduction policies. Globally, the economic and population growth is directly related to the increase of CO_2 emissions resulting from fossil fuels combustion and industrial processes. Consequently, the direct action in urban areas is essential to the success of global climate change adaptation. Urban areas concentrate today more than half of world's population and much of its constructive aspects and economic activities. All cities activities, and how they manage their impacts on the environment are central parts of the problem. However, to create measures and emissions management policies, and therefore air pollution, soil and water management; it is imperative the creation of measurement mechanisms and qualification of each polluting activity inside an urban development context.

This paper presents the greenhouse gas emissions calculation method for a neighbourhood located in São Paulo city, considered as a low-carbon urban development by having a recognized international environmental certification for its project and construction – the first LEED (Leadership in Energy and Environmental Design) Neighborhood Development in Brazil.

The GHG emissions were calculated for the three main urban activities in this neighborhood - stationary power, ground transportation and household waste - using as a base, reputable internationally calculation methodologies adapted to the scale of the neighborhood.

In order to provide a better view and comparability of emissions scenario accounted for, GHG emissions were adapted and calculated for two other Brazilian cities inventories, São Paulo and Recife, according to measurement scales and compared the final results. The results collected from the urban low-carbon development had showed that it's possible to reduce emissions over time and its applicability is feasible to any other neighborhood/ city in the world, promoting better places to live and less impact on the environment.

Keywords: climate change, sustainable neighborhood, LEED certification

1. INTRODUCTION

The data presented in the Fifth Assessment Report (AR5) of the United Nations Intergovernmental Panel on Climate Change (IPCC, 2014), states that total anthropogenic GHG emissions have continued to increase over 1970 to 2010, even with the implementation of several efforts and reduction policies. In all instances, national, regional and local (cities), increased data were presented over time, mainly, due to fossil fuels combustion and industrial processes.

Globally, the economic and population growth is directly related to the increase of CO_2 emissions resulting from fossil fuels combustion. When demographic data is compared to national GHG emissions, it's possible to observe that seven of the top ten most populated countries are also the top ten biggest GHG emitters in the world, including: China, India, USA, Indonesia, Brazil, Russia and Japan.

Urban areas concentrate today more than half of world's population and much of its constructive aspects and economic activities. All cities activities, and how they manage their impacts on the environment are central parts of the problem, considering each city as a live organism and with differences from each other depending on their growth's profile. To create measures and emissions management policies related to air, soil and water pollution, cities must create measurement mechanisms and qualification of each polluting activity inside of a sustainable urban development context.

Recently, there have been developed many advanced approaches to account GHG emissions from a city context, but none of them related to the neighborhood scale. Its crucial thought, to take a closer to the city's formation and each neighborhood growth's profile separated, to better understand flaws and needs for each individual community and how they are related to the bigger context as the city evolves.

This paper presents the results from the GHG emissions calculation method for a neighborhood located in the city of São Paulo, considered as a low-carbon urban development by receiving the first LEED Neighborhood Certification in Brazil, a recognized environmental certification for its project and construction. Using a local case study as a reference, it was calculated GHG emissions of three main urban activities in the neighborhood - stationary power, ground transportation and household waste - using as a base, reputable internationally calculation methodologies adapted to the scale of the neighborhood.

In order to provide a better view and comparability of emissions scenario accounted for, GHG emissions were adapted from two other Brazilian cities' inventories, São Paulo and Recife, according to measurement scales and compared the final results. This model created is feasible to be applied in any other district or city around the globe, encouraging improvements in urban low-carbon developments and incentives for a more sustainable city's management.

2. COMPACT AND SUSTAINABLE CITIES CONCEPT AND THE CASE STUDY 'PARQUE DA CIDADE'

Cities are key elements to global sustainable development given that the population of the planet becomes increasingly urban, with increasingly larger cities, giving rise to megacities and mega regions. Cities are composed of complex interdependent systems that have influence to support adaptation on climate change through government support backed by cooperative governance between different levels of society. To this point, it is possible to create synergies between maintenance and creation of new urban infrastructure, protection and land use management and support of ecosystem environmental services.

It is common to think that the creation of public spaces is a government's task, being impossible to depend on its provision by the private sector. The criticism lies, contrarily, in the creation of public spaces from private initiative that benefits all involved parties, including the population, the entrepreneur, the environment and the city as a whole. Spaces which are not enclosed, no barriers to entry, no-cost access to the end user, inserted in urban areas (where the cost of land is high), financed by the private sector, and yet, they were not the result of legislation that induced or forced their conception, but the intention of those who undertook the space; are fundamental to the sustainable dynamic conception of a city. In this way, a sustainable neighborhood within a city or a metropolis, induces a necessary change of culture to design larger sustainable interventions.

According to these principles, the choice of a sustainable neighborhood in the city of São Paulo, serving as a case study for the calculation and projection of its GHG emissions in the medium and long term, becomes essential to create sustainable parameters and perspectives in large urban centers, megacities, within under development countries.

The 'Parque da Cidade', multipurpose complex developed by OR - Odebrecht Real Estate Developments, was inspired by the concept of compact cities, which consist of limited space and relatively small, where all the essential activities of a city are concentrated, and which have the premise of sustainability.

The general concept states that Compact Cities are usually assigned by highly dense urban developments, with high socioeconomic diversity and improvement of the public sphere (with appropriate, qualified and planned interventions), establishing ample opportunities for social interactions and exchanges. Promote better sense of public safety by creating a sense of community through proximity, mixed-use practices and sidewalks and spaces for collective use, friendly to pedestrians and located within a small urban grid. It also promotes equitable access to goods, services and facilities available, providing a short commute (home - work - shopping), optimizing the use of existing urban infrastructure and stimulating the reduction of car use. In such a way, the compact cities minimize environmental degradation and provide adequate sustainability for improving the quality of life.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Studies show that four key concepts guide the paradigms of urban form of compact cities and GHG emissions directly related to its activities: Population Density, Mixed-use Activities, Connectivity and Accessibility. All these concepts, in contrast, are directly related to priority transportation that citizens use to move daily.

Glaeser states that it would be better for the planet if the urban population starts to live in dense cities built around the elevator, instead of expanded regions built around vehicles. If urbanization is not directly related to high densities (more people living in less space), GHG emissions tend to increase dramatically, mainly because of two internal factors related to cities: daily commuting in individual transportation and; low demand to create public transportation infrastructure away from condensate centers locations and their related emissions originated from individual transportation. Mixed-use compact core reduces the displacement needs and create sustainable neighborhoods full of vitality.

Apart from being compact, the city must be sustainable and review its cycles of demand and consumption, represented by linear and circular metabolisms cities. According to Girardet cited Rogers (2005), "the solution is in search of a circular 'metabolism' in cities, where consumption is reduced by implementing efficiencies and where the reuse of resources is maximized." The resilience of cities is related to its location and its associated secondary processes, located along its boundaries. According to Tickell cited Rogers (2005), "[...] cities are living organisms that absorb resources and produce waste. The larger and more complex they are, the greater will also be its dependence on surrounding areas, and the greater their vulnerability to changes in their surroundings. "

The current linear processes of extraction, manufacture and disposal must not only be replaced by circular process, including reuse, recycling and polluting processes offsets, but should also be reduced to smaller demands, avoiding losses and minimizing waste generation. Therefore, Sustainable Compact Cities replace the city as the ideal habitat for a society based on community. According to Rogers, it is a type of established urban structure that can be interpreted in any way in response to all cultures.

Following Jacobs line of thought (2011), where she suggests that cities must reinvent and propose new uses and improvements in its already established urban fabric, it can be concluded that in the light of sustainable urban development, grow back into the metropolis and not expand its constructions is another highly important aspect: recycle the territory is more intelligent than replace it. Restructure it productively is possible and desirable in the metropolitan strategic planning. In other words, to regenerate productive existing metropolitan territories must be the same aspect of new economic and technological innovation processes.

3. METHODOLOGY AND TECHNIQUES

Launched in 2012 and still under construction, the 'Parque da Cidade' is a large real estate urbanization project, developed by the private sector Odebrecht Real Estate Developments (OR), with other partner companies, which aims to be an urban landmark for the city of São Paulo and the most sustainable neighborhood in Latin America, after its completion in 2022.

The development consists of a multipurpose complex with over 600.000m² of built area, including: five corporate towers, a tower with commercial offices, a hotel, a mall (shopping center), two residential towers and leisure facilities, living and entertainment spaces as cafes, restaurants and public squares. The project has as main axis a large linear park of 62.000 m² with 22.000 m² of green area, open to the public and provided with services and leisure infrastructure. To ensure that the compact city and circular metabolism concepts will be addressed in this project, the enterprise is seeking various types of environmental certifications, among them the LEED for Neighborhood Development and the Climate Development Program, launched in 2009 in partnership with the C40, the Clinton Climate Initiative and the U.S. Green Building Council, in order to highlight urban projects that seek to achieve positive levels of carbon emissions worldwide.

If on one hand the LEED ND Certification promotes the construction of more sustainable, connected communities and with less pollution; on the other it does not guarantee the emissions quantification of activities occurring inside the city, even though they are activities that promote low carbon emissions. Thereby, cities GHG emissions assessments by GHG inventories' become an essential principle of assessment and early establishment of guidelines and suggestions for the solution of several issues related to public policies and investments.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

However, until recently, there was no global implementation methodology that provided consistent guidelines for conducting GHG emissions inventories' at cities' level. So far, cities have used several methods based on national, local or even their own creation references. Nevertheless, since 2012, due to a joint effort between ICLEI organizations, WRI and C40 (including a global collaboration of various stakeholders), was created a comprehensive new option for the measurement and reporting of greenhouse gases applied to cities called GPC Protocol (Global Protocol for Community-Scale Greenhouse Gas Emissions).

The GPC specifies the principles and rules for the creation of a GHG inventory report for a city; although, it does not specify the calculation methodology to be used to generate emission data. Based on this scenario, the GHG Protocol Brazil tool allows the calculations more quickly and consistently, because it has the data of the activities and secondary values already adapted to the Brazilian reality. Worldwide, it is currently the most commonly used method by companies and governments to conduct GHG inventories and is compatible with the ISO 14064 standard and the quantification methods of the Intergovernmental Panel on Climate Change (IPCC).

3.1. Applying the methodology in the case study

The first step to calculate the GHG emissions of a city or neighborhood is the definition of project's basic items assisted for a GHG inventory, such as the Project Boundary (identification of the geographical area of the city or neighborhood); setting the Period; the Greenhouse Gases that will be calculated and reported; and the Emission Sources (activities inside the project's boundary that emit greenhouse gases).

A unique item of this work consists on the boundary's definition using the scale of a neighborhood and not a city, where it is commonly applied. Another unique item of this work is the time chosen for emissions' evaluation. Traditionally, GHG cities' inventories are carried out after completion of the calendar year, accounting for emissions that have already happened last year. As this neighborhood has not yet been finished, all future emissions will be calculated for the year of its completion: 2022. The emissions were also calculated for the year 2030, not only to create a comparative basis between the projected emissions of past and future years, but also to allow comparison with other cities' inventories.

For this work it was considered the quantification of all greenhouse gases, but only presented the carbon dioxide (CO_2), considered the most relevant and important gas in terms of urban emissions. Still, the sectors and subsectors that have been chosen from the case study to evaluate the sources of emissions were due to its great importance within the context of the neighborhood and the city, as well as its applicability and ease existing data collection for each sector, which are: Stationary Energy, Ground Transportation and Solid Waste.

In general, for almost all sources, cities will need to estimate its emissions by multiplying the 'given activity' generated by an 'emission factor' associated with the activity being measured.

The application of the method in the case study consists on basically to collect existing data of the case study, develop premises of future projections related with the activities that will be evaluated (transport, energy and waste management), based on existing historical data. After the projections are settled, the emissions are calculated for future years, using the emissions' factor for each activity. Then, the indicators with the results are listed and compared with available data from other cities' inventory. The results should be appropriate for comparison within each other, allowing adaptations of other inventories to meet the ranges defined by the case study.

4. CONCLUSION

Total emissions' projection in the 'Parque da Cidade' in 2022 corresponds to 650.900,12 tCO_2e; and in 2030 corresponds to 596.189 tCO_2. There has been a reduction of general emissions over the years, and it can be concluded that this is due to the reduction of incentives regarding the use of individual transportation in the neighborhood, from the sector that emits most CO_2: the Ground Transportation, which for being the most significant, can influence largely the total reduction of emissions in a neighborhood, and a city.

To carry out a comparative model between the selected cities (São Paulo and Recife), it was necessary to calculate the total per capita emissions in each of the examples, taking into account the comparative base scenario of a city with an isolated and measured individually neighborhood.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

	Population	Stationary Energy (tCO_2e/hab)	Household Waste (tCO_2e/hab)	Ground Transportation (tCO_2e/hab)	TOTAL Emissions per hab. (tCO_2/hab)
Parque da Cidade 2022	56.030	0,11	0,037	11,46	11,61
Parque da Cidade 2030	65.000	0,16	0,035	8,97	9,17
São Paulo 2022	12.367.932	0,40	0,038	0,84	1,25
São Paulo 2030	13.171.543	0,49	0,038	1,05	1,58
Recife 2022	1.687.971	0,13	0,042	1,21	1,38
Recife 2030	1.796.222	0,17	0,042	1,74	1,95

Table 1: Final comparison of GHG emissions from the 'Parque da Cidade', the city of São Paulo and the city of Recife

While the 'Parque da Cidade' emits relatively more carbon per capita than the two other cities, basically due to the high emission value of the transport sector, it is the only example presented that reduces their emissions over time to the Waste Sector, Transportation Sector and Total emissions per capita. The high value of per capitas' emissions in the transport sector is due to the fact that the neighborhood has only two residential buildings and ten other commercial buildings, not really promoting mixed-use compact cores.

Regarding the energy consumption of residential and commercial buildings in the case study, the lowest consumption is observed in comparison to other cities, foreseeing to emit 27.5% less energy than the average of São Paulo city in 2022, and up to 32.7% less energy than the average of São Paulo city in 2030. The emissions from the transport sector will be reduced by around 21% over eight years (between 2022 and 2030).

How sustainability occurs only in long term and the policies that promote behavior change and vision within a city must be observed and monitored over time, presently, the studied neighborhood presents an enormous potential for urban and environmental sustainability, mainly promoted by the desired environmental certification criteria. The emissions reduction in long-term still favors the alignment of existing public policies, such as national policies on Climate Change, and international policies as the Conference of the Parties, within a macro economic and urban perspective.

In this scenario it is possible to assess that the key to the reduction of GHG emissions from large urban centers is reducing the use of private cars for commuting, clearly shown to be the greatest emissions inducer. Another major problem arises when countries like China and India begin to develop in the same way that the modern era has developed: depending on the automobile. India currently has the largest road complex in the world, 5.800 kilometers of highways connecting its four largest cities, the Golden Quadrilateral, while launching a very cheap car and accessible to the majority of its population. China invests heavily in huge, generic and aseptic housing estates on the outskirts of their megacities to meet the immigrant population (model failed in the West and widely publicized since the reconstruction of Europe after the war). Obviously, none of the models adequately respond to the needs of a more harmonious planet.

If these super populous countries and others under development countries, including Brazil, continue with the same car cult culture and urban sprawl, investing heavily in public policies that promote their use, our little planet will not be enough to support the high demand for emissions pollutants and greenhouse gases to be released into the atmosphere in the coming years. The biggest concern at this point is to understand how developing countries can align their development policies with its GHG emissions and the role of developed countries in this context.

ABSTRACT

In recent decades, the shortage of natural resources like primary raw materials has increasingly shifted into the focus of public discussion and research. Especially in the resource-intensive construction sector the implementation of a circular economy can strongly contribute to a reduction of primary resource demand. Positive developments can be noticed already, but the desired goal of an effective circular economy is still not being reached. For instance, the usage of recycled raw materials as substitutes for primary resources could be significantly higher.

In order to implement the protection of resources in the construction sector, it is essential to assess resource-saving measures and their impact on conservations as well as stakeholder's motivation to implement them. For this purpose, a Stakeholder-based Assessment Model (SAM) is developed to provide recommendations for political actions and potent measures to foster the circular economy in the construction sector to increase reuse and recycling of construction materials. In SAM, relevant stakeholders are identified and their characteristics and preferences as well as the level of influence on each other are modelled and validated for Germany. Moreover, available resource-conserving measures concerning the construction sector are identified and related measures are grouped together. Thereupon the influence of measures on stakeholders and their willingness to take positive actions in terms of a circular economy have been investigated and modelled. Relevant model data has been gathered by intensive literature review, surveys and expert interviews.

The results show that measures regarding lifecycle oriented planning of buildings as well as the development of stakeholder cooperation are the most effective ones to save resources and to reduce the disposal of construction material. Furthermore, the results demonstrate that a leading role of public authorities is crucial to foster a circular economy.

Keywords: waste management, resource-efficiency measures, stakeholder-based assessment model

1. INTRODUCTION

In recent decades, the shortage of natural resources like primary raw materials has increasingly shifted into the focus of public discussion and research. Especially in the resource-intensive construction sector the implementation of a circular economy can strongly contribute to a reduction of primary resource demand. Positive developments can be noticed already, for example the quality assurance system for recycled construction materials in Germany, but the desired goal of an effective circular economy is still not being reached. For instance, the usage of recycled raw materials as substitutes for primary resources in building construction could be significantly higher.

In order to implement the protection of resources in the construction sector, it is essential to assess resource-saving measures and their impact on conservations as well as stakeholders' motivation to implement them. For this purpose, a Stakeholder-based Assessment Model (SAM) is developed to provide recommendations for political actions and potent measures to foster a circular economy in the construction sector that lead to increased reuse and recycling of construction materials.

2. SCOPE AND RESEARCH APPROACH

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

As resource usage is still quite high in the construction sector, this contribution poses the research question of how relevant stakeholders can be incentivized to reduce their resource consumption or increase the share of recyclables and recycling materials in their current practice? In order to achieve a rethinking on stake-holders' parts and to implement efficient resource usage and resource protection as an integral element of every construction, also certain aspects have to be considered by authorities: Who are the key stakeholders? What is their role in achieving that goal? What are the most effective measures to incentivize the relevant stakeholders? This holistic view on a problem is suggested by the systems approach by Arbnor and Bjerke. Therefore, the developed model has to consider not only the effects of measures on the environment but also on the entire stake-holder network. That means that the effects of internal objectives of stakeholders, their ability to influence resource protection and their influence on each other are also relevant factors in the system.

Therefore, in the following subsections current literature is reviewed regarding their ability to derive political measures and incentives for stakeholders based on analysis and simulation of stakeholder objectives, of economic effects on stakeholders and stakeholder interactions (See section 3). To answer the research question, a model (SAM) is developed in section 4 to evaluate resource-saving or resource protection measures (Political instruments) with regard to the addressed stakeholders and the related stakeholder interactions. For this purpose, several political instruments are evaluated not only by their economic effects but also by their ecological impact. Furthermore, the stakeholders' willingness to act according to the political measure is considered. To compare political measures with each other and to provide decision support for the respective authorities an effectivity value is calculated and recommendations are proposed. Then, the application of SAM in the German construction industry is described in section 5 and model results are shown and analysed. This is followed by a conclusion and an outlook on future re-search.

3. STAKEHOLDER ANALYSIS AND LITERATURE DISCUSSION

The enormous relevance of stakeholder management in the construction industry results from the higher number of stakeholders involved in building projects. Stake-holders follow different objectives and have different motivations. According to Kua, the stakeholders' willingness for pro-environmental behaviour is influenced by willingness conditioning factors such as incentives (given by policy measures or other stakeholders), responsibility and capability influence. The comprehension and consideration of their interests, needs and effects on a project can determine the success of a project. In order to comprehend outcomes of a system, also interdependences and influences within a system are of importance. Stake-holders are highly important as they might have essential information and expertise that are necessary for a project to succeed. Involving those and ensuring their support can help to avoid conflicts and failures. Summing up, stake-holder management helps to understand how applied measures and current situations are perceived und what it means for the project or initiative. There are several definitions for the term stakeholder. According to Mitchell et al., stakeholders are not only a moral, personal or financial interest group of a project or a company because they are affected by project's success or effects, but also those have to spend for instance resources in order to obtain those profits. Moreover, there can be stakeholders without any entitlement to any part of the success and are not affected in any way by its actions but who can still influence other stakeholders. For the purposes of this paper, the focus lies on the definition of Mitchell et. al.

The consideration of stakeholders in a model poses the challenge of quantifying mostly qualitative measures. Some already developed tools might be supportive for quantification and are described in the following. Johnson et al. have concluded that it is not sufficient to understand the needs and positions of stakeholders. Also, the ability and power to enforce their interests hast to be considered. At the same time interest can reflect the strength of their desire to enforce their position in a project. Bourne and Walker suggest a stakeholder circle to visualize stake-holders' power and influence within a project. However, in order to wholly un-derstand stakeholder decisions, it is important to consider their interest. Bourne and Walker go one step further by arguing that in addition the effects of interests have also to be considered. Therefore, they use the stakeholder Vested interest Intensity Index (VilI) to measure power.

$$\boldsymbol{ViII} = \sqrt{\frac{\boldsymbol{v} * \boldsymbol{i}}{\mathbf{25}}}$$

where, v = strength of personal interest in the project of a stakeholder, i = influence of a stakeholder and 25 = 5x5 (Both variables can be valued between 1-5)

Equation 1

Olander combines Bourne and Walker´s idea of the ViII with the power legitimacy urgency model by Mitchell et al. The latter claims that one should differentiate between stakeholders who have influence, independently of the legitimacy of their claims, and those stakeholders, who might have claims, whether justified or not, but who are, at the same time, without any power. Using both models as a basis, Olander suggests, that instead of measuring the power, it is better to measure its effects. He uses the position of stakeholders (Pos) according to McElroy and Mills and also the attributes (A) of the power-legitimacy-urgency-model by Mitchell et al. In addition, Olander applies the vested interest index in order to create a Stakeholder Impact Index (SII), which reflects what effects the stakeholder has on a company.

$$\boldsymbol{SII} = \boldsymbol{ViII} * \boldsymbol{A} * \boldsymbol{Pos}$$

where, A = Attributes and Pos = Position of Stakeholders

Equation 2

These methods provide valuable instruments for the measurement of stakeholder influence and are used in SAM (see section 4.3). At the same time, they pose a difficulty, as in construction there is no central company towards which the relation-ship can be analysed. For that reason, the analysis has to be extended to observe the whole network. It is not relevant in the analysed construction stakeholder net-work how a manager can interact with different stakeholders, but what the mutual interaction of stakeholders means for the set target. Knoeri et al. provides a structural agent analysis by an agent based modelling approach and applies it to the resource use in construction. However, in both approaches the relationship between the stakeholders and mutual influences are hardly considered. Thus, based on current literature the observation of measures' effects on the network is not possible yet. Therefore, in the following a stakeholder-based assessment mod-el (SAM) is developed.

4. DEVELOPMENT OF A STAKEHOLDER-BASED ASSESSMENT MODEL (SAM)

The depicted model consists of two parts. First, the network defines the constants of the model (Section 4.1). On the one hand, those are the success functions which reflect what is important for the different stakeholders. On the other hand, those are the relationships/ interactions between the stakeholders. Second, the effects of measures on the environment are considered. Here, a new way will be introduced to integrate those effects into the stakeholder model by developing the SAM.

4.3 **Definition of stakeholder's characteristics**

Firstly, stakeholders have to be identified and categorized. Stakeholders' needs, interests and motivations have to be understood. In order to do it in a comparative way, an objective function has to be elaborated, which reflects their targets and reflects achievements thereof. Secondly, the relationships between stakeholders have to be made obvious. According to the reviewed literature, their influence on each other and their influence on the group result - resource conservation in this case - was modelled. Thirdly, the possible measures have to be identified as well as their effect on the goal. Lastly, those steps have to be brought together into a corresponding model that enables the joint analysis of all factors.

A stakeholder-network comprises a set of rational stakeholders A= $\{a_1..a_i..a_j..a_n\}$ and a set of possible measures M= $\{m_1...m_k\}$. The first step is to determine how the stakeholders can be defined. As for any economically deciding stakeholder, it is assumed, that his economic success is of a great value for him. Diederichs suggests to use the balanced score card in the construction industry to evaluate target achievements and success. That means that the aspired success is not only defined by financial results, but also through customer orientation, process excellence, customer relationship as well as education and growth. Diederichs also integrates the environmental

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

perspective into this evaluation of success. Finally, that results in the success function of a stakeholder Z_a (Equation 3). The weights of the success function are the basis for the following modelling approach in section 4.2.

$$Z_a = g_{fin_a} * fin_a + g_{cust_a} * cust_a + g_{process_a} * process_a + g_{dev_a} * dev_a + g_{env_a} * env_a$$

where, $\mathbf{fin}$ = financial success of stakeholder a, $\mathbf{cust}$ = customer satisfaction of stakeh. a, $\mathbf{process}$ = success of process design of stakeh. a, $\mathbf{dev}$ = development/ innovation success of stakeh. a, $\mathbf{env}$ = success of environmentally responsible behavior of stakeh. a, $\mathbf{g_{factor}}$= weight of the variables and has to be defined for each stakeh. a (sum of all $\mathbf{g} = \mathbf{1}$)

Equation 3

4.4 Impact of measures on stakeholders

Measures, executed by either process or environmental stakeholders, have an effect of $w_{m,factor_a}$ on the factors of the stakeholder's success based on the values in the balanced score card. To determine the total impact of a measure on the stakeholder's success $(w_{m,a})$ the various effects are weighted using factors weightings.

$$w_{m,a} = \mathrm{g}_{\mathrm{fin}_a} * \mathrm{w}_{m,\mathrm{fin}_a} + \mathrm{g}_{\mathrm{cust}_a} * \mathrm{w}_{\mathrm{m,cust}_a} + \mathrm{g}_{\mathrm{process}_a} * \mathrm{w}_{m,\mathrm{process}_a} + \mathrm{g}_{\mathrm{dev}_a} * \mathrm{w}_{\mathrm{m,dev}_a} + \mathrm{g}_{\mathrm{env}_a} * \mathrm{w}_{\mathrm{m,env}_a}$$

where, $\mathbf{w_{m,a}}$= Impact of measure m on stakeholder a, $\mathbf{w_{m,fin_a}}$= Imp. of meas. m on financial success of stakeh. a, $\mathbf{w_{m,cust_a}}$Imp. of meas. m on customer satisfaction of stakeh. a, $\mathbf{w_{m,process_a}}$ = Imp. of meas. m on process design of stakeh. a, $\mathbf{w_{m,dev_a}}$= Imp. of meas. m on development/ innovation success of stakeh. a, $\mathbf{w_{m,env_a}}$= Imp. of meas. m on environmentally responsible behaviour of stakeh. a.

Equation 4

Moreover, stakeholders can be influenced by measures with different intensities $s_{m,a}$.This value can be compared with the legitimacy value according to Mitchell et al. At the same time, it creates a certain urgency for their position and interest, which can motivate them to act and give more strength to their claims. Stakeholder's readiness to act or accept a measure is preliminary described as $B_{a,m}$. Interactions between the stakeholders are not yet included.

$$\mathbf{B_{a,m}} = \mathbf{w_{m,a}} * \mathbf{s_{m,a}}$$

where, $\mathbf{B_{a,m}}$ = Readiness to act or acceptance of stakeholder a while realizing measure m, $\mathbf{s_{m,a}}$ = intensity-level for the impact of measure m on stakeholder a

Equation 5

4.5 Formulation of SAM

In a network, stakeholders decide dependently or independently from each other. Depending on the effects of measures on their own business, they influence other stakeholders to act in a certain way. This influence of stakeholder $\boldsymbol{a_i}$ on stakeholder $\boldsymbol{a_j}$ in dependence of measure $\boldsymbol{m}$ is quantified by $\boldsymbol{E_{a_i,a_j}(m)}$

$$\boldsymbol{E_{a_i,a_j}(m)} = \mathbf{w_{m,a}} * \mathbf{s_{m,a}} * \mathbf{e}_{a_i,a_j}$$

where, $\mathbf{E_{a_i,a_j}(m)}$ = Influence of stakeholder a_i on stakeholder a_j in dependence of measure m, $\mathbf{e_{a_i,a_j}}$ = General level of influence of stakeholder a_i on stakeholder a_j

Equation 6

The influence of other stakeholders on a stakeholder create an additional readiness to act which is caused for example by neighbourhood effects, voluntary commitments and market adaption, image or competitiveness reasons. Therefore, an additional (Dis)motivation for the stakeholder's readiness to act is considered (Equation 7) based on the average mutual stakeholder influence $E_{a_i,a_j}(m)$ and the general level of influence e_{a_i,a_j} of two stakeholders a_i and a_j.

$$\boldsymbol{Infl_a} = \frac{\frac{1}{n}\sum_{i,j=1}^{n}(E_{a_i,a_j}(m))}{\frac{1}{n}\sum_{i,j=1}^{n}(e_{a_i,a_j})}$$

where, $\mathbf{Infl_a}$ = Additional readiness to act/ acceptance of stakeholder a, n = total number of stakeholders

Equation 7

Since the optimization of success (formulated by their respective objective) is the foremost goal of any stakeholder, it has to be considered, that the success factors affect the readiness to act stronger then the influence $Infl$ does. Accordingly, $B_{a,m}$ is expanded to:

$$\mathbf{B_{a,m}} = \frac{\mathbf{Infl_a} + 2\, \mathrm{w_{m,a}} * \mathrm{s_m}}{3}$$

where, $\mathbf{B_{a,m}}$ = Readiness to act or acceptance of stakeholder a while realizing measure m, $\mathbf{Infl_a}$ = Additional readiness to act/ acceptance of stakeholder a

Equation 8

The magnitude of a possible effect of the measure on conservations of resources is named l_{m_k}. In a general case, when all data is available, l_{m_k} includes economical, ecological and social aspects of sustainability.

The effectivity of a measure is defined as the impact of a measure on the protection of resources. The effectivity of a measure *Eff*(m_k) depends on the influence of each stakeholder on resource conservation and on the strength of stakeholders' readiness to act. Referring to the introduced structure of *VilI* (Equation 1), the effectivity of a measure consists of the effect of a measure on environment (effect of the interest $l_{m_k} * r_{a_i}$), and the readiness to act (Interest B_{a_i,m_k}). By averaging those values, a joint effectivity is calculated by:

$$\mathbf{Eff(m_k)} = \frac{1}{\mathrm{n}}\sum_{\mathrm{i}=1}^{\mathrm{n}} \sqrt[3]{\frac{(\mathbf{l_{m_k}} * \mathbf{r}_{a_i}) * \mathbf{B}_{a_i,m_k}}{250}}$$

where, *Eff*($\boldsymbol{m_k}$) = Effectivity of the measure m_k, $\mathbf{l_{m_k}}$ = Impact of the measure m_k on the conservation of resources, $\boldsymbol{r_{a_i}}$ = Influence of stakeholder a_i on the conservation of resources, $\mathbf{B}_{\boldsymbol{a_i,m_k}}$ = Readiness to act or acceptance of stakeholder a_i while realizing measure m_k

Equation 9

5. APPLICATION OF THE MODEL AND RESULTS

In this section, SAM is applied to the construction industry. Therefore, various current and future resource-saving measures in the construction industry have been analysed and grouped together to sets of measures. In total, 21 sets of measures have been created (see Figure1). Based on surveys and expert interviews with identified stakeholders and detailed literature research, the parameter values for the model were acquired. For this purpose, nine stakeholders of different stakeholder types (builders, department of the environment, architects, constructions engineers and demolition and recycling companies) were interviewed with a survey. The influence of resource saving measures on stakeholders have been evaluated with points in the range of [-2;2]. The influences between different stakeholders have been evaluated with points in range of [1;5]. In general, all sets of measures in the right upper right quadrant of Figure 1 should be preferred as they contribute the most to a conservation of resources and show a high effectivity as well as a high readiness to act. Sets of measures with the highest effectivity are such as set 12 (need to develop cooperation's between the stakeholders), set 18 (necessary improvement of the image of recycling construction materials), set 6 (stronger awareness of resource efficient construction) and set 2 (reducing barriers for resource-efficient behaviour).

The sets of measures 8, 12, 15, and 18 in the upper right quadrant have the highest readiness to act/ acceptance. With set 8 (need of stronger investments for resource efficient research) and set 15 (importance of a high quality in construction to extend the life cycle of buildings).

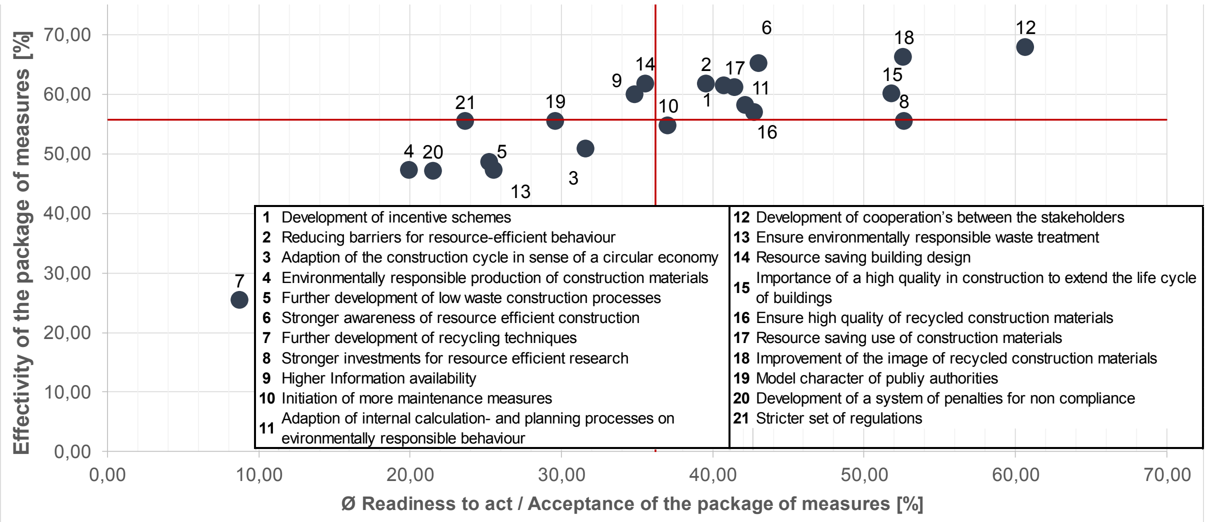

Figure 1: Effectivity Eff($\boldsymbol{m_k}$) of the sets of measures and stakeholder's readiness to act/ acceptance of the measure

Furthermore, based on literature research, survey and interviews it became obvious that the public sector has the highest influence on other stakeholders in the construction sector with respect to their resource-saving decision making. Specifically, it became clear that the public sector must take the leading role, whether in the form of incentives, or the removal of barriers. In particular, the leading role of the public sector in its own resource-saving actions is of central importance, e.g. by explicit preference for RC materials in public construction tenders.

6. SUMMARY AND DISCUSSION

In this contribution, a stakeholder-based assessment model is developed to evaluate the effect of political resource-saving or resource-supporting measures and to provide decision support to public authorities. The model is applied for a stake-holder network in the construction industry in Germany. Main results are that additional cooperation between stakeholders could be beneficial, the image of recycling materials has to be improved and barriers for resource-saving construction (materials) should be reduced. Furthermore, the public sector has a leading role with respect to the usage of recycling materials. To further improve the model results, interviews and surveys will be performed in the construction sector to detail the modelled stakeholders. Furthermore, the ecological effect of a resource-saving set of measures or single measures have to be related to resulting mass flows to better evaluate the impact on the environment. And, the consideration of interdependence of the measures themselves (a measure might be more successful, if another measure has been adopted) and the integration of rebound effects could be promising in future research.

ABSTRACT

This paper's goal is a framework for a comparative depiction of sustainability labels for buildings and other scales. Applying the method of a Comparative Rich-Picture-Diagram (cRPD) allows a multi-scalar and multi-objective analyse of building standards and labels for sustainable construction. This paper presents a two-step part of the method to display the structure of the label, weighting of indicators and translation into a multi-dimensional feature space. It entails the visualisation of the dimensions or pillars of sustainability (society, economy, environment), space (components, integrated systems or building, neighbourhood) and time (phases). The method is exemplified with the Standard Sustainable Construction Switzerland (SNBS) to display and evaluate the functioning of the label. The paper concludes the weighting of indicators show a diverging picture and thus allows to identify hidden drivers and barriers for sustainable construction.

Keywords: *policy and regulation, sustainability labels, sustainable construction*

1. INTRODUCTION

The aim of this paper is to present a theoretical framework for analysis and comparison of sustainability building labels applying the method Comparative Rich-Picture-Diagram (cRPD). Typically these labels, certifications or tools assess the environmental impact and overall sustainability and are sometimes referred to Green Buildings. Due to the complexity of the subject, the authors utilise the term labels to enable a comparison of on the scale of both buildings and neighbourhoods.

The UNEP (2011) states the development of the 20th Century poses a "significant progress of civilisation", which was accompanied by an enormous demand of resources including for the construction sector. The environmental impact of said economic activity has left its marks. The IPCC (2013) showed the impact of anthropogenic CO2-emissions as a main driver of Climate Change. Resource scarcity and Climate Change are accordingly two of the major societal challenges according to both UNEP and IPCC. They identify the construction sector and the increased construction activity as a main driver of the environmental impact. According to UNEP the above progress is accompanied by an unprecedented and ongoing urbanisation. To cope with the development of the increased construction activity results extensive demand of construction materials. The Global Alliance for Buildings and Construction (2016) concludes that "the global building sector consumed (…) over 30% of total final energy consumption", "buildings also accounted for half of the global electricity demand" and "the building sector therefore represents roughly 20% of global-related CO_2 emissions". Considering indirect and direct emissions "buildings and construction represent nearly 40% of energy-related CO_2 emissions.

To tackle the responsibility of the building sector towards the environmental degradation Herazo et al. (2015) and Perez-Lombard et al. (2009) describe the emergence of Green Building labels from 1990's onwards which introduced an assessment of green or environmental performance of buildings Two recognized examples include the Building Research Establishment's Environmental Assessment Method (BREEAM) from the UK and the Leadership in Energy and Environmental Design (LEED) from the U.S.A. Although a second generation of building labels move towards a more holistic approach concluding societal, economic and life-cycle aspects according to Markelj et al. (2013) and Herazo et al. (2015), LEED remains the most popular certification for buildings.

In Switzerland building labels have developed also according to the societal challenges. Similarly, to first generation labels, only covering energy aspects, then including environmental and then second generation aiming for more holistic approaches. The Minergie-Label exemplifies this development. The initial focus was on the criteria of energy efficiency. Later criteria comfort, indoor air quality, material availability and embodied energy were included for the further development into Minergie-Eco. Further consideration of the criteria thermal comfort and energy consumption in the use phase lead to the development of Minergie-P. To conclude the Minergie-A implemented a holistic approach towards assessing and labelling sustainability for buildings. A different example in Switzerland is the 2000-Watt-1t-CO2-society that combines the criteria life-cycle, use and mobility towards a normative goal of sustainability. Aside of assessing buildings it includes a label for districts. Furthermore, the Swiss government responded to the challenges with introducing the Energy-Strategy 2050 to increase energy efficiency and later a Strategy for Sustainable Development. Sustainability and sustainable development is cited in the constitution to seeks a „balanced relationship between nature, its capacity for renewal and supply for human demand", the implementation of said strategies is aimed for at federal and state levels. The Swiss Network Sustainable Construction (NNBS) initiated by the Swiss Federal Office of Energy explicitly builds upon the federal Strategy of Sustainable Development. The strategy identifies construction as a key component for the scale of buildings and sustainable neighbourhood and district development. The three pillars of sustainability, society, environment and economy should find application and certification in sustainable construction through the newly founded "Standard Sustainable Construction Switzerland (SNBS)". This building label integrates the existing Minergie labels in Switzerland, attempting to "close existing gaps and thus connect the three pillars of sustainability through a number of different criteria". Consequently this paper focuses on SNBS to exemplify and visualise the suggested cPRDframework.

1.1 Are building standards and labels expedient?

The societal challenges pose clear demands for sustainable construction and thus exists a need for building standards and label. However, are the so called "eco-label" or "green building label" really "green"? Or put differently, are the building standards and labels expedient for sustainable construction? The efficiency of the building standards and labels is unclear considering the goals of sustainable construction. The federal office for energy (BFE) conducted a study on the success monitoring of the label "Minergie" and showed that "planned values are only in part congruent with energy consumption values in use phase". This leads to the question how building standards and labels function.

1.2 Functioning and structure of building standards and labels

Building standards and labels are typically difficult to understand and complex structured. In literature different studies on building standards and labels focus solely on comparing the qualitative difference regarding the structure and aim. Sutrisna et al. (2007) have applied the "Rich Picture Diagram (RPD)" to model and visualise the complex interactions and procedures between different stakeholders in construction processes. This paper expands their approach to building standards and label that match the complexity of the statement of a problem to construction projects. It should facilitate the application of building standards, the communication thereof and reveal hidden drivers and potential barriers.

In literature only few studies suggest a common framework on the comparison of building standards and labels. This paper builds on the work of Wallhagen et al. (2012) who propose a generic framework with an underlying graphic method to display the hierarchical structure of building standards and labels.

2. APPROACH

2.1 Focus on SNBS

The approach of the proposed framework of a "comparative rich-picture for sustainability label and building standards" is introduced and exemplified in this paper with SNBS. The NNBS promotes the SNBS and establish as building standard. The SNBS states to equally weigh the three pillars of sustainability. The structure of SNBS is the following: The three pillars of sustainability are represented as the three "themes" society, economy and environment. The themes are divided into different categories, which contain each a number of criteria and finally indicators. During writing of this paper SNBS version 1.5 (office) was considered that contains 3 themes, 12 categories, 25 criteria and 76 indicators. On 24 August 2016 the SNBS version 2.0 was introduced that drastically reduced the amount of indicators and thus was also considered as a way to communicate the differences. SNBS 2.0 contains 3 themes, 12 categories, 24 criteria and 45 indicators.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.2 Comparative rich picture diagram

This paper applies the RPD suggested by Sutrisna et al. to display building standards and label similarly to construction projects. The modelling and display of the hierarchical structure of building standards is applied from Wallhagen et al.. A further steps extends the analytical modelling expanded to a multi-dimensional feature-space which should enable to reveal the hidden drivers and potential barriers in building standards and labels. Therefore, it allows a comparative aanylsis of different labels revealing the structure and function. The approach of the adapted comparative Rich-Picture Diagram (cRPD) framework is divided in to several iterative steps: Structural display, weighting, translation into the feature-space.

The structure the themes, categories, criteria and indicators of the SNBS are summarised and displayed. The individual components build on each other and are brought together in the three themes of sustainability.The assessment of the SNSB calculates the weighting of indicators. The SNBS is equally divided into three themes. These are then divided by the amount of categories, criteria and indicators. This reveals the resulting weighting of individual indicators and their percentage on the entire building standard.The last step translates the individual components of the building standard into a three-dimensional feature-space. The three considered dimensions or features are sustainability, space and time. The sustainability feature has three magnitudes society, economy and environment. The magnitudes of the spatial feature has the magnitudes building components, integrated systems or buildings and neighbourhood. The temporal feature has the magnitudes of phases from planning, construction and use.

3. RESULTS

3.1 Weighing of Indicators

The results of the first two steps, structure and weighting of SNBS, show that the three themes society, economy and environment are equally weighted (Figure 1). The 3 themes are equally divided into 4 categories. The 25 criteria however are not equally distributed to the four categories. Furthermore, the 76 indicators are also unequally distributed to the 25 criteria. The initial 100%, which are divided equally at 33% to the three themes result in a range of 0.24% - 8.33% for individual indicators.

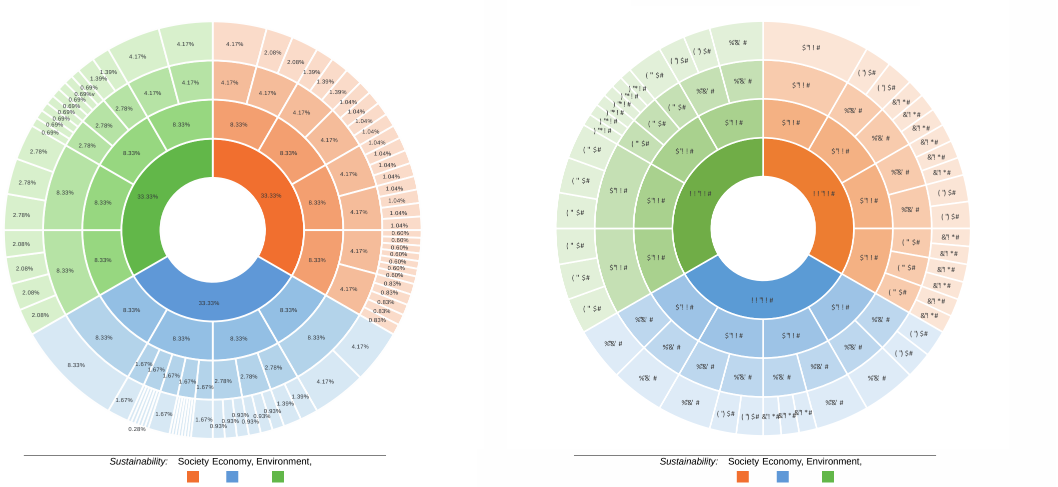

Figure 1: Structure of the label SNBS – Standard Sustainable Construction Switzerland. The innermost circle represents the themes (society = orange, economy = blue, environment = green) respectively the pillars of sustainability, then the categories and outside the indicators. The next circle are the categories, followed by the amount of criteria which are unequally distributed. The outermost circle are the indicators and their weighting in percentage. Left SNBS 1.5 with 76 indicators and right SNBS 2.0 with 45 indicators.

The indicators can be ranked according to their percentage. It displays which indicators have the largest influence on the assessment (Figure 2). The initial distribution on the themes society, economy and environment shift their relevance. The indicators of the theme economy receive the most weight with the largest weighted indicators. The theme economy is then followed by environment. The theme society falls to the third place with the most indicators weighted the smallest.

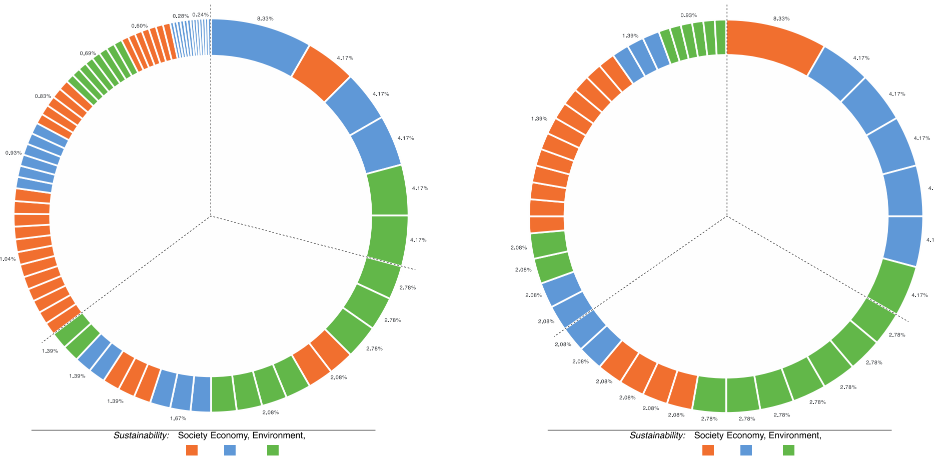

Figure 2: Structure of the label SNBS – Standard Sustainable Construction Switzerland displays the ranked indicators (society = orange, economy = blue, environment = green). Left SNBS 1.5, right SNBS 2.0. The indicators were ranked according to their percentage. The five most important indicators for SNBS 1.5 are the regional economic potential (8.33%), urban and architectural themes, life-cycle costs, total costs, use concept, flora and fauna (each 4.17%). The five most important indicators for SNBS 2.0 are the aims and functional description (8.33%), building materials and building substance, decision making, rent and retail price, demand and available uses (each 4.17%).

3.2 Positioning of indicators in a three-dimensional feature-space

The indicators are translated to their respective dimensions in to a three-dimensional feature-space. The result shows (Figure 3) that the themes society, economy and environment differ and are located in different dimensions or features.

The theme society is the first of the feature sustainability. The largest percentage of indicators of the theme society is located in the feature time during the phase of planning and during the feature space on the scale of the building. We could interpret that the societal focus of the indicators is on the user perspective.

The theme economy is the second magnitude of the feature sustainability. The largest percentage of indicators of the theme economy is located in the feature time during the phase of planning and in the feature space on the scale of the neighbourhood – meaning on a higher level. We could interpret that the economical focus displays the investor perspective.

The theme environment is the third magnitude of the feature sustainability. The largest percentage of indicators of the theme environment is located in the feature time during the phase of use and in the feature space divided between the scale of the neighbourhood and components. We could interpret that the environmental focus displays the embodied energy of construction materials.

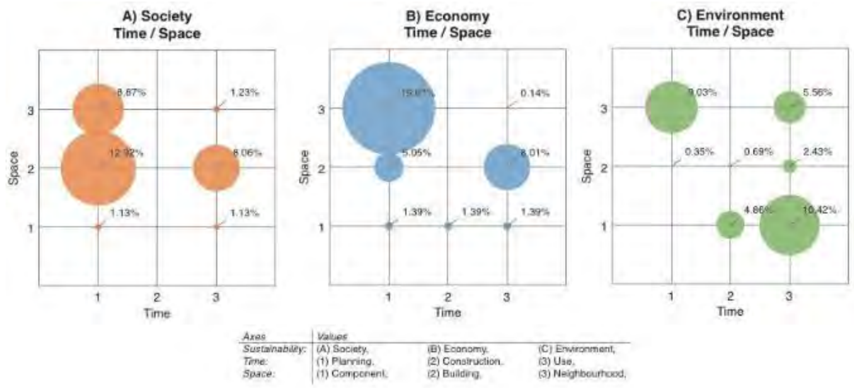

Figure 3: Translation of the indicators into the three-dimensional feature-space. Represented here are the temporal and spatial features regarding the magnitudes of sustainability (society, economy and environment). The size of the circle indicates the amount of indicators at each node.

This displays the focus of individual and potentially conflicting themes of sustainability. Furthermore, it reveals possible gaps and missing indicators. The theme society shows a balance between the planning and use phase.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Accordingly, user and comfort are important indicators. At the same time there is no indicator that covers the construction phase. The theme economy reveals that the focus of a higher level can be attributed to the investor and developer rather than the user of a building. The theme environment shows the opposite where the use phase is the main focus, which means which construction materials are planned and how they are implemented.

4. CONCLUSION

The aim of this paper is to present a cRPD framework that enables better understanding of function and comparison of building sustainability.

This is exemplified by the application of the framework on SNBS to display the label's function and weighting of individual indicators. The results show that the intended equality of the sustainability dimensions in SNBS collide with the unequal weighting of individual indicators. This allows the identification of hidden drivers which for SNBS results in a ranking of the sustainability dimensions according to importance, first economy, second environment and third society. Related to the sustainability dimensions, the feature-space displays drivers also related to temporal and spatial dimensions. For SNBS the societal focus is on the user perspective, the economical perspective is on the investor perspective and the environmental focus displays the embodied energy of construction materials. This clearly indicates diverging and possibly conflicting interests.

The proposed cRPD framework creates the possibility to reveal and discuss openly the potentially conflicting indicators and associated interests. The diverging interests of individual stakeholders from the planning process can be displayed to create a platform for their negotiation. Because the presumptive common goal amongst the stakeholders is sustainable construction. Lastly it would enable to include and consult missing stakeholders and integrate their interests in critical situations. The authors hope for a discussion on sustainable construction and how this is achieved by means of building standards and labels.

ABSTRACT

The sustainability concept of the DGNB system covers the well-known three-pillar model of ecology, economy and social issues, as well as technical quality, process quality and location features.

The system's holistic approach promotes innovation by focusing on overall building performance thus, promotes uncompromising quality, new ideas and innovative concepts. Oder: Certification follows a holistic approach: the DGNB System assesses the entire life cycle of the building. This makes it possible to define sustainability goals right at the start in the planning phase.

Moreover the DGNB offers a tailored approach to suit Chinese green building policies, market requirements or climate conditions.

Several projects in China and other Asian countries have already been awarded with the DGNB Certificate.

In the paper, we are going to present our experience in the development and evaluation of sustainable buildings and districts and will give an outlook on new developments at the DGNB, like the certificate for "buildings in operation" or the guidance of design and quality of projects. Particularly latter emphasizes our focus not only on lowering resource consumption but also on how we feel in our buildings.

Keywords: certification system, life cycle assessment, DGNB

1. THE DGNB SYSTEM – A HOLISTIC APPROACH

Cities worldwide are facing major challenges due to increasing urbanisation. Traffic, smog, and polluted rivers are only some of the visible signs. The distinguishing features of today's future-oriented cities ate that they offer resource and energy efficient construction and operating systems as well as enduring high living standards and distinctive quality of place. Achieving this offer requires proactive, comprehensive, and transparent planning.

1.1. DGNB System in general

Figure 1: The basic DGNB evaluation structure

The DGNB is the German and international knowledge platform for sustainable building and provides the world's most advanced sustainable building certification system. Its aim is the planning and assessment of sustainable buildings and districts. More than 1,200 projects worldwide are pre-certified or certified Further the DGNB is market leader in Germany.

The certification schemes of the German Sustainable Building Council (DGNB) for buildings, districts and industrial locations help consider all aspects of sustainability early in the design phase. Aspects of a district or location's economic, environmental, socio-cultural, and technical qualities are given equal consideration throughout the entire life cycle. The DGNB assessment methodology also addresses the project's process quality and award certificates in silver, gold or platinum, according to the project's overall performance.

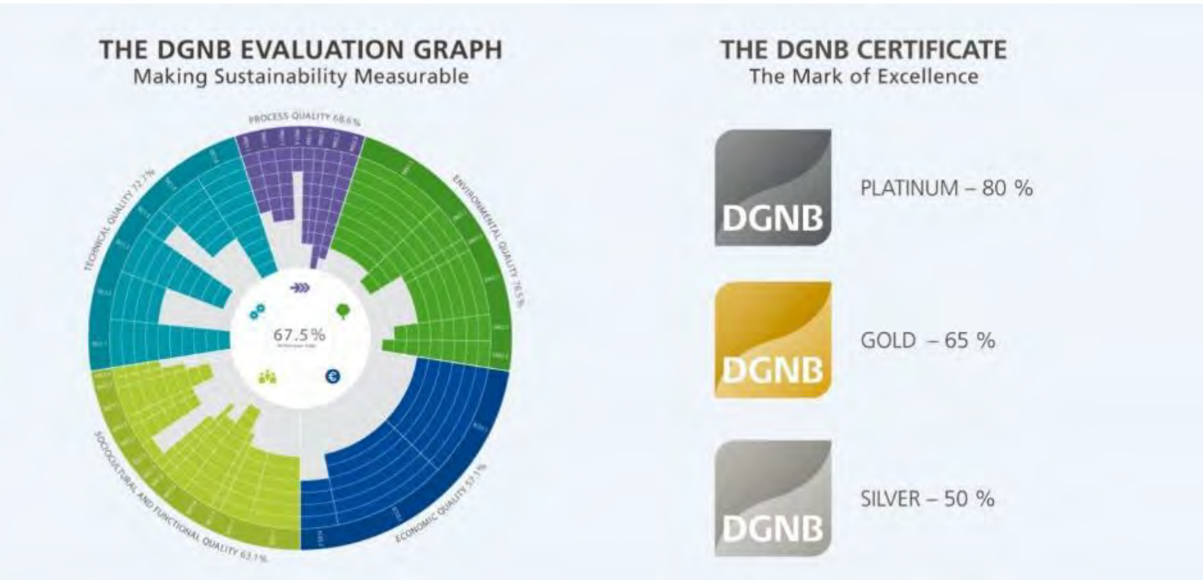

Figure 2: The DGNB evaluation graph and DGNB award's

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

1.2. From China to Brazil – **The DGNB system's global progress**

The DGNB system's unique holistic view of sustainability fundamentally sets it apart from other rating tools. For instance, the DGNB system gauges buildings' and districts' overall performance rather than allocating points for individual measures. This outcome-oriented flexibility promotes innovative and project-tailored solutions.

The certification system enables transparency, quality control, and eliminates planning risk from project conception zo completion. In applying the criteria, the system evaluates all the relevant sustainability factors, and reflects costs and benefits over the district's entire life cycle. Integrating aspects of sustainability, such as resource consumption, mobility, and future user needs in the early design stages results in greater user comfort and higher living standards as well as adding to the district's financial value. This is sustainability "Made in Germany".

1.3. The DGNB system – W**here's the difference?**

In the public perception three of the world's leading systems for certification of buildings as DGNB, LEED and BREEAM are often mentioned in the same breath. Besides the obvious similarities there are some fundamental differences between systems.

Sustainable vs. Green

The term "green building" is very closely linked to the area of energy efficiency, which can be only one aspect of sustainable construction. So the DGNB System is based on the classic understanding of sustainability with the triad of ecology, economy and social. For the purposes of the DGNB a building must always be designed and constructed that it

- Is built and can be operated environmentally friendly and resource-efficient,
- Economically viable, long-term cost-saving and flexible,
- Sets the man in focus by enabling health and comfort.

Life-cycle costs and life cycle assessment

The basic idea behind the DGNB System is the analysis of the entire lifecycle of a project. This begins with the extraction of raw materials and ends with the demolition of the building, and the recycling of components. For the other certification systems available on the market, this is done only to a lesser extent.

Better Projects vs. Individual measures

Whether a measure is useful for a project depends on a variety of factors. In this sense, no individual measures (for example, use of photovoltaic) but targets (for example, 50% less energy demand) are valued at the DGNB system. Here, the result is always evaluated, not the measure itself. The optimum for the individual project is left to the builder itself.

Adaptation of the requirements vs. One system for all

In more than 20 countries worldwide buildings have been been certified with the DGNB system. The special, as compared to LEED is that the DGNB adapts the criteria on the regional circumstances. This includes, for example, the regulatory framework, the specific market conditions and the climatic conditions.
In LEED projects for example you have to use US standards in Europe, which doesn't make so much sense. Thus, it is not adapted to country-specific circumstances.

Measurement of indoor air quality

Because man is in focus, the indoor air quality is a very important point in the DGNB system. Here a real measurement of the pollutant content has been made in the air after completion of the building.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Serial and multiple certification

Furthermore, the DGNB provides a series or multiple certification for buildings that are identical but created at different locations. These include, for example, hypermarkets or manufactured homes. There is the possibility of a simplified, faster and thus cost-effective certification of the individual buildings.

Design quality

As the first certification systems for sustainable buildings worldwide, the DGNB has launched a pilot phase to evaluate the design quality in 2015. Together with the Federal Chamber of Architects and in cooperation with the Association of German Architects BDA an appropriate methodology has been developed. One approach here are recommendations that are given to the project participants in parallel with the pre-certification at an early planning stage of a DGNB Design Committee

1.4. The DGNB systems for districts and industrial locations

The Urban Districts scheme focusses on the spaces between the buildings and the quality of the district's wider location as well as considering overarching concepts for energy, water, and waste, the urban climate, and biodiversity. The aim is to create urban districts which offer their inhabitants high quality of life while making the most efficient use of resources and protecting the environment. Buildings within the urban district are only considered in terms of their basic parameters and need not be certified for an urban district to achieve a DGNB certification.

*Figure 3: Urban district "Carlsberg City District" in Copenhagen (DK),
Pre-certificate in Silver (© Carlsberg Byen p/s, rendering made by Entasis) AND Maidar EcoCity+, near Ulaan Baatar (Mongolia), DGNB Pre-certificate in platinum, © Maidar City LCC*

Business districts combine all aspects of an attractive work and leisure environment. Approaches to improve the quality of place, and the worker's child care and retail amenities are just as relevant as environmental performance and energy technology. Establishing synergies and mutually beneficial relationships between businesses and their urban setting is another important objective in designing sustainable districts. This efficiently reduces costs in the long term. The quality of life is consistently enhanced and joins forces with cost effectiveness and improved productivity to creative decisive added value.

Industrial locations are moving ever closer to the heart of the sustainability debate. DGNB has developed criteria for industry which have been tested in pilot projects for companies such as Volkswagen, Daimler, and Porsche at locations in Germany and abroad. Next to the building's quality and resource requirements, this scheme takes open areas, infrastructure, urban context and planning and production processes into account.

Evaluation Area	No.	Criterion
Environmental Quality 22.5%	1	Life Cycle Assessment – emissions, environmental effects
	2	Biodiversity
	3	City climate
	4	Environmental risks
	5	Water and soil protection
	6	Life Cycle Assessment – resource consumption
	7	Water cycle systems
	8	Land use
Economic Quality 22.5%	9	Life Cycle Costs
	10	Fiscal Effects on the Municipality
	11	Resilience and adaptability
	12	Space efficiency
	13	Stability of value
Socio-cultural and Functional Quality 22.5%	14	Thermal comfort in open space
	15	Open space
	16	Emissions/ immissions
	17	Accessibility
	18	Urban Design
	19	Social and functional mix
	20	Social and economic infrastructure
Technical Quality 22.5%	21	Energy infrastructure
	22	Waste Management
	23	Smart Infrastructure
	24	Mobility infrastructure I
	25	Mobility infrastructure II
Process Quality 10%	26	Integral planning
	27	Participation
	28	Project management
	29	Governance
	30	Monitoring

Table 1: Criteria overview of the DGNB Districts system, Version 2016

1.5. The DGNB system for buildings in use – Slim, practically oriented, economically

The new DGNB system "buildings in operation" complements existing DGNB certificates to the assessment of existing buildings with the focus on operational aspects. The usage profile is an easy to handle tool to evaluate and improve the sustainability of the building involving operators and users over only 9 criteria of the sustainability of buildings is evaluated in operation. Applicable for any type of building.

1.6. The DGNB award for design quality

To complement the existing certification system the DGNB takes also the design quality of a Building into account. This should be judged in addition to technical and often quantitative requirements for sustainable building now also the first time the qualitative aspects. There is a two-stage approach, responding to the following target groups:

- Projects at an early stage, which are registered for the DGNB pre-certificate or certificate.
- Projects after completion, which have already received a DGNB Certificate or are shortly before the test.

1.7. The use of the DGNB system in Asia

The unique feature of the DGNB system is its flexible structure, which allows it to adapt to country specific conditions. This is fundamental since a city in Asia, for example, is in many aspects – such as climatic, cultural, and legal frameworks – not comparable to a city in Europe.

The advantages of the DGNB system are now acknowledged by relevant bodies in the construction and real estate sectors. Particularly in Asia, the interest for the DGNB Certification system increased in recent years, and up to date several buildings have been certified or have started the certification process. Also, there are many requests for certification of urban districts and industrial locations. One of these projects is the Sino-German Ecopark in Qingdao (CN) for instance.

To increase awareness about sustainable construction and the DGNB System in China, the DGNB regularly offers training events on related topics. I addition, the DGNB is continuously expanding its network to governmental and non- governmental organisations in Asia, such as Deutsche Gesellschaft für Internationale Zusammenarbeit (GIZ). It also takes part on relevant events such as the "BAU Congress China" and the "China Green Building Conference".

Figure 5: The German Entreprise Centre, Qingdao, DGNB Pre-certificate, Source: Sino-German Ecopark Real Estate AND BASF R&D Center Shanghai, DGNB Certificate, Source: BASF

The most advanced sustainable building certification system – made in Germany, applied in China:

- Internationally recognised quality standard for excellence
- Tailored to suit Chinese green building policies, market requirements and climate conditions
- More than 1,200 certified projects worldwide
- 200 Chinese experts trained as DGNB Consultants
- Holistic approach facilitates focusing on overall building performance

2. DGNB ACADEMY – KNOWLEDGE ON SUSTAINABLE CONSTRUCTION

The key to sustainable building goes beyond the projects that are submitted for certification. Trained experts are needed who understand where changes are required in order to ensure that sustainability is more deeply embedded during planning and construction.

With this goal in mind, the DGNB offers a targeted training concept for Chinese experts that enables them to qualify as a DGNB Consultant. Over the course of three days, the participants are taught everything there is to know about the application of the certification system. The training is aimed at all actors involved in the construction process, from the planning and construction to the operation of sustainable buildings or districts. In the design and planning processes, the DGNB Consultant is responsible for the implementation of the DGNB's requirements and priorities.

The training aims at enabling the participants to apply appropriate strategies to effectively address the impacts and interdependencies between social, economic and ecological sustainability criteria in the planning and construction phases. At the same time they learn to use the DGNB System as a planning tool. As early as in the design phase, they will be able to identify optimization potential that can improve the performance and quality of the project.

ABSTRACT

Kaohsiung City's urban landscape is adorned by its majestic mountain, streaming river, wavy ocean, and abundant sunshine. To further complement the city's vibrant atmosphere, the Kaohsiung City Government initiated a project to adjust its industrial structure to promote Kaohsiung as a green eco-city. The goal of the project is to provide a greener, safer, and most importantly, a more sustainable environment for Kaohsiung's citizens so as to create a truly happy and prosperous living environment.

To reach these goals, the Kaohsiung City Government took action with a series of policies to increase solar energy production. Firstly, it established an operating network by forming an inter-departmental task force to promote photovoltaic (PV) systems in the public and private sectors. It also linked professional organizations with local communities, and set up a dedicated hotline for consultation and inquiries. Secondly, it strengthened its photovoltaic infrastructure through formal statutes and regulations. This includes the announcement of a series of official solar photovoltaic policies, the promulgation of a floor area ratio incentive, and the enforcement of mandatory policies to increase photovoltaic implementation. Thirdly, it designated target sites to serve as examples of the project. This includes installing photovoltaic systems on public rooftops, building photovoltaic demonstration zones, transforming illegal structures into solar power providers, and assisting the fishing and agricultural sectors in building photovoltaic systems.

In total, Kaohsiung's 557 cases in 2015 oversaw an instalment capacity increase of 28,491 kW (or 28.491 MW), generated 37 million kWh of power annually, decreased carbon emissions by 23.3 thousand tons, and created a PV industry with a net worth of NTD 2,841.1 million. This study looks at the evidence of achievements the city has made promoting scientifically meaningful architectural aesthetics in its innovative green buildings and energy technology, as well as the success it has seen pushing the policies through a bottom-up structure. In conclusion, it can be said that, using a model based on a project developed by our institute, the Kaohsiung City Government has successfully made the renewable energy become an integral part of Kaohsiung's lifestyle, creating a threefold win for the government, the institute, and the people of Kaohsiung.

Keywords: solar photovoltaic, policy, suit locally, the city of green daylight, low carbon

1. INTRODUCTION

Despite having transformed itself from a wholly industrial city into a thriving metropolis, Kaohsiung City was still marked by its over-concentrated population, lack of green spaces, and excess of artificial heat sources. Kaohsiung is also much hotter compared to its neighbourhood areas, and its temperatures may well continue to rise while its humidity simultaneously lowers as Kaohsiung's population, commercial activities, and density in land use all continue to grow, leading the city to become what is commonly known as the urban heat island. As a result, increasing the city's green spaces has become a priority in its efforts to lower the rising temperatures.

Over the years, Kaohsiung City has gone through extensive measures to become its own city. Not only has it upgraded its hardware and software to create a healthy, sustainable, ecological, and cultural environment, it has also established itself as a diverse and sophisticated municipality, and rolled out innovative policies such as the Green Building Self-Governance Ordinance and the Regulations Governing the Establishment of Rooftop Solar Photovoltaic Systems so as to achieve its five core values of "ecology, economy, liveability, creativity, and

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

internationality." Its strategies, which have been widely recognized, also include inserting an aesthetic sense of technology into the city's photovoltaic systems, promoting innovative green buildings and renewable energy technology, and using a bottom-up incentive to encourage owners of illegal structures to spontaneously come forward. Evidence of the city's efforts can be identified throughout the city as the government continues to build a greener, healthier, and more sustainable city.

2. OBJECTIVES

Working in coordination with Kaohsiung's climate, the Kaohsiung City Government set the goal to generate 150 MW worth of solar photovoltaic power within four years. It set up an interdepartmental task force to collectively promote the photovoltaic systems within the following five categories: general constructions, public buildings, schools, factories, and fishing and agricultural facilities.

The Kaohsiung City Government set the four-year goal as a mean to fulfil its global responsibilities against greenhouse effect as well as to take care of its citizens in the long run by implementing its core values of bringing "ecology, economy, liveability, creativity, safety, and internationality" into their daily lives.

3. POLICIES AND STRATEGIES

With global warming on the rise, the Kaohsiung City Government was ahead of its time when it initiated its photovoltaic project prior to the promulgation of Taiwan's Renewable Energy Development Act. While the city's geological climate rendered it a suitable candidate for solar energy, the reality on the ground was that current building regulations, the conditions of existing structures, and the price of setting up photovoltaic panels had made it hard to promote solar power on a city-wide scale. Having identified these obstacles, the government saw a need to relax existing laws while aggressively pushing, promoting, and subsidizing photovoltaic constructions. It also listed the photovoltaic project among its priority policies for better effect. Therefore, the Kaohsiung municipal government proposed the four year plan and the specific ten action plan. (Table 1)

	Transforming illegal structures into solar power providers
	Building photovoltaic systems in the fishing and agricultural sectors

Table 1: Kaohsiung government put forward the specific ten action plan

3.1 Creating an operating network

Appointing an interdepartmental task force

The interdepartmental photovoltaic project task force was established with Kaohsiung deputy mayor as convener, deputy director general of the Secretariat as deputy convener, and the Public Works Bureau as chief managerial office. The task force is in charge of supervising the promotion of the photovoltaic project within the five categories of general constructions, public buildings, schools, factories, and fishing and agricultural facilities. The major and assisting offices in charge of the categories (as shown in Figure 1) work together to fulfil the city's innovative vision.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

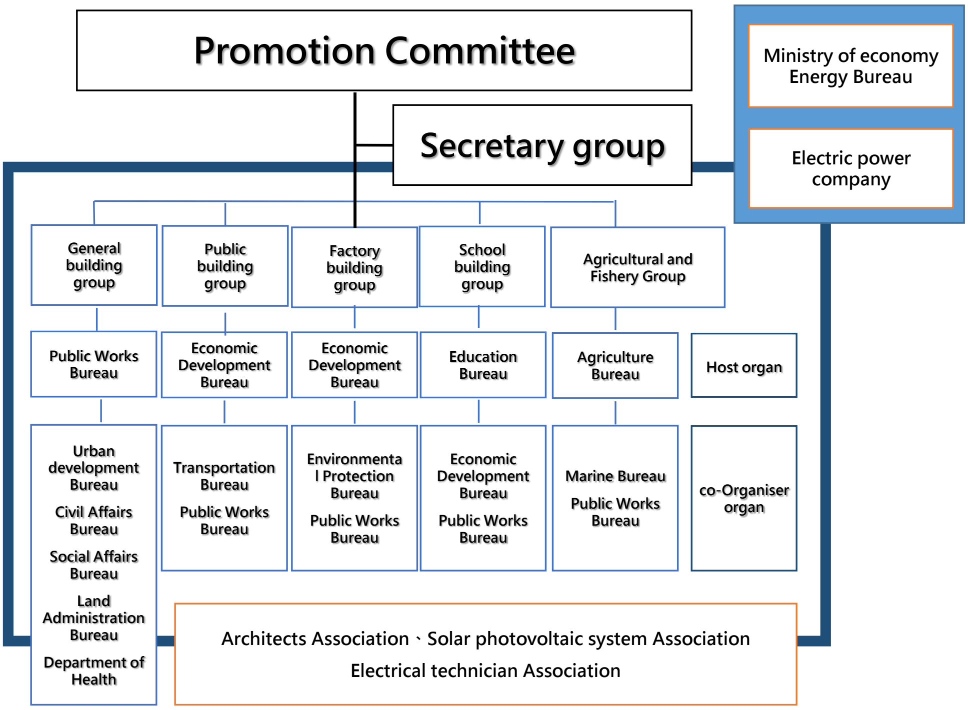

Figure 1: Plans to promote the organization chart

Giving local communities professional assistance

To promote widespread installation of photovoltaic systems across the city, the Kaohsiung City Government sought the assistance of professional associations (Figure 2). This includes the Kaohsiung Architects Association, the Kaohsiung Professional Civil Engineers Association, the Real Estate Development Association of Kaohsiung, the R.O.C. Solar Photovoltaic System Trades Association, the Taiwan Professional Electrical Engineers Association, the Taiwan Photovoltaic Industry Association, the Taiwan Electrical Contractors Association, and the Taiwan Solar Thermal Energy Association. In addition to signing official MOUs with the associations and hosting public briefing sessions to provide more information for the public, the government set up a platform to help pair citizens interested in installing photovoltaic systems with suitable vendors.

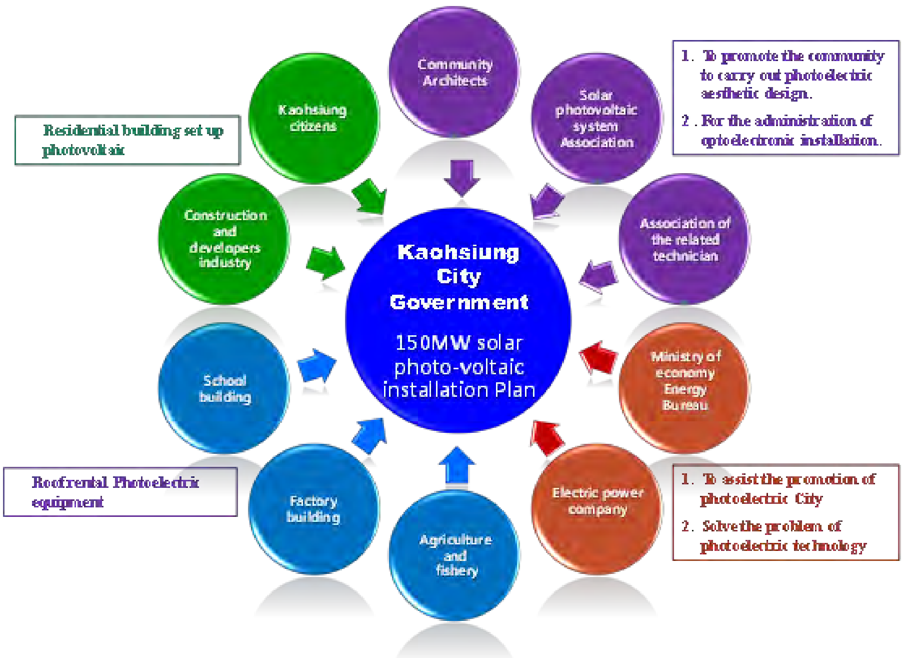

Figure 2: Combination of professional groups and community participation in the operation of the photovoltaic project.

Setting up a dedicated hotline

A dedicated service hotline was set up so as to increase the efficiency and efficacy of installation requests. The service hotline not only takes inquiries and applications, but it is also in charge of collecting statistics and data.

3.2 Utilizing policy as promotional tools

Formulating statutes and regulations

The Kaohsiung City Government has since 2012 formulated four architectural laws governing the instalment of photovoltaic systems. The laws were created so as to promote the generation and utilization of the renewable solar energy.

In 2014, the laws were incorporated into a comprehensive project consisting of six laws, a platform pairing individuals with professional instalment vendors, and a subsidization program. Through the formulation, execution, as well as review and revision of these statutes and regulations, Kaohsiung's solar photovoltaic systems, intelligent energy management operations, and green building standards have been significantly improved. As the scale of income from promoting green buildings grows, the city is able to continue expanding solar power instalments and energy-saving buildings.

Providing floor-to-area ratio incentives

Another important promotional policy is the floor-to-area ratio (FAR) incentive. Areas with lower FARs will be granted a 30 percent FAR incentive with the instalment of photovoltaic systems. This allows areas consisting mostly of low-rise buildings become so-called "sunshine communities." Meanwhile, residential areas with an FAR of 180 percent must install a rainwater storage capacity that is at least 0.132 times the measurement of the area, build a green roof, or install photovoltaic panels that generate more than 2 kW power per building.

Making photovoltaic systems mandatory

The Kaohsiung City Government was able to make photovoltaic instalments mandatory in urban areas, open spaces, and the Kaohsiung LOHAS Housing Project by providing construction businesses with incentives during the initial reviewing stages in urban design projects and the licensing review of construction permits.

3.3 Designating exemplary demonstration sites

Installing photovoltaic systems on public rooftops

As action always speaks louder than words, the Kaohsiung City Government took the lead to install solar photovoltaic systems on the roofs of government buildings and public schools using a rental program. In having vendors set up the solar panels, the government is estimated to have saved around NTD 500-700 million in installation and maintenance fees. In addition to giving the city solar energy, the model also creates economic value for the local solar power industry, and at the same time serves as an example of the project's benefits, attracting public attention and recognition. In doing what's best for the environment, Kaohsiung increases its use of renewable energy, helps the solar photovoltaic related industries grow, and ultimately strengthens the city's economic structure and overall competitiveness.

Building photovoltaic demonstration zones

The Kaohsiung City Government has chosen the area surrounding the Pier-2 harbour, the Jhongdou redevelopment zone, and the area of the 2014 Kaohsiung gas explosions as the city's photovoltaic demonstration zones. The goal is to gradually have the installation of photovoltaic systems expand around the zones and ultimately link up to form a photovoltaic power city.

Transforming illegal structures into solar power providers

Kaohsiung City prides itself in its counselling rather than punishing attitude when it comes to illegal structures. It encourages owners of illegal structures to convert their illegal rooftop dwellings into photoelectric facilities (Figure 5). It also provides loans and subsidies as incentives to increase interest as well as lower installation thresholds.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The new structures, on the one hand, help solve the two most common problems seen in illegal rooftop dwellings, i.e. leaking and overheating, and on the other hand, can be legally built with an additional sunroom compartment. While the city is significantly beautified, the power generated can be sold to the Taipower Company for additional income. As a result, the original hot and stuffy city has the opportunity to be transformed into a pleasant and a steady provider of renewable energy.

Building photovoltaic systems in the fishing and agricultural sectors

Kaohsiung encourages its farmers' associations, traditional wholesales markets, animal protection units, agricultural facilities, and 95 livestock and poultry farms to install solar photovoltaic systems. It is also working with the various agricultural and fishery associations in encouraging the conversion of idle building rooftops into solar panel units.

4. RESULTS

Due to the nature of its development, Kaohsiung City's heavy-industry based economy has come with the price of serious air and environmental pollution. According to statistics, Kaohsiung's annual carbon emissions of 97 million tons make up 25 percent of the nation's total. What's more, each citizen's personal carbon emission is 2.67 times the nation's average. Nonetheless, the city's 2015 statistics show that the 557 photovoltaic application cases successfully created an instalment capacity of 28,491 kW (or 28.491 MW), generated 37 million kWh of power annually, decreased carbon emissions by 2.33 million tons, and created a PV industry with a value output of NTD 2,841.1 million.

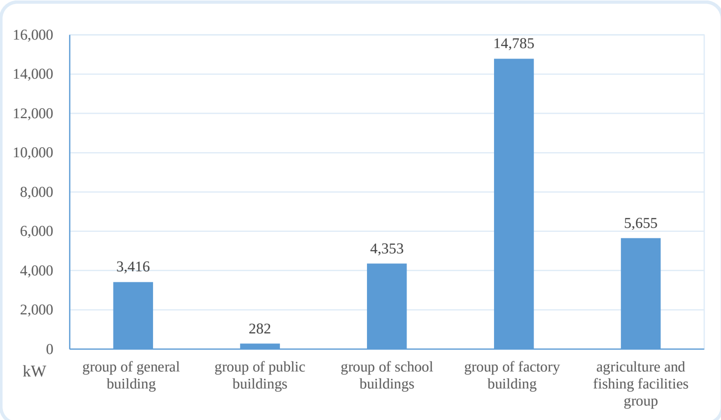

Figure 3: Various groups have been set up photovoltaic capacity

As indicated in Figure 5, factories have the largest photovoltaic power output at 14,785 kWp; fishing and agricultural facilities come in second at 5,655 kWp. It can be said that these traditionally high carbon emission industries are now fulfilling their social responsibilities in reducing greenhouse effect.

Shown in Figure 4, Kaohsiung City, the implementation of the solar photovoltaic policy has a number of specific implementation of the case, According to the situation of different groups, The presentation of the optoelectronic aesthetics of different buildings, Not only create a new state of the city state, Kaohsiung is also the specific contribution to the global energy conservation and carbon reduction.

5. STAGE CONCLUSION

With the combined use of six laws, one subsidy plan, and one pairing platform, Kaohsiung City's solar photovoltaic project has been deemed a success. According to statistics, the city is estimated to see photovoltaic output of at least 30MW annually. The new regulations have also helped increase the overall number of green buildings in Kaohsiung. Kaohsiung's creative and diverse efforts to create a greener city have set an example of what could be achieved. It's achievements between 2000-2016 (as of May) are as follow:

- The total of 3,027 applications has a joint capacity of 152,615 kW (152.615 MW), generates 180,741 kWh annually, has reduced carbon emissions by 15,366 tons, and has created a NTD 15.26615 billion output value for the photovoltaic industry.
- With the talk of an international carbon tax of NTD 1,940 (EUR 50) per ton of emission likely to become a reality, Kaohsiung City's estimated 30 MW annual photovoltaic output may help lower carbon emissions by 24,276 tons per year. This would amount to saving NTD 47.1 million annually, and a cumulated NTD 924 million in 20 years.
- The cost saved from having to dismantle illegal rooftop structures, including paying personnel fees, dispatching vehicles, and processing construction waste, is estimated at NTD 135 million per year, which adds up to NTD 27 billion in 20 years.
- As the metal roofs of illegal rooftop structures are converted into solar panels, sunshine is absorbed and transformed into electricity, resulting in a drop in the city's scorching temperatures.
- The photovoltaic project's annual value output of NTD 20 billion helps increase employment opportunities.

ABSTRACT

Prefabricated modular construction is one of building solutions that has positive effects on construction time and waste management. In general, thermal performance of the building envelope is an important parameter which dictates the operational energy consumption. There are some prefabricated modular buildings available in Australia. However, their thermal performance benchmarks have not been well documented in the literature. Innovative panel systems have been proposed to improve the cost competitiveness and to achieve better performance. It is essential to know the current performance so that newer panels can be proven to be better. This paper investigates the thermal performance of four prefabricated modular buildings currently available in the Australian market. The buildings were selected to represent single-family houses with different floor areas. A building energy performance simulation tool was used to predict the cooling and heating loads of each building. The findings based on the simulations are presented in this paper.

Keywords: modular buildings, thermal performance, heating and cooling, energy simulation

1. INTRODUCTION

Due to the increasing trend of energy usage and greenhouse gas (GHG) emissions, various sectors throughout the world give priority to reducing GHG emissions and increasing energy efficiency. Building sector accounts for almost one third of world's total energy consumption while it is the source for intense GHG emissions as well. For instance in Europe, Buildings account for 40% of the energy consumption and 36% of the CO2 emissions. Energy consumption of the buildings in the US was about 40% of total energy consumption in 2012. Furthermore, in 2015 around 20% of total energy consumption of Australia was associated with residential and commercial buildings.

Modular buildings are the outcome of off-site manufacturing technology in which up to 70% of the construction is carried out in factory. They are factory constructed three dimensional units and transported to the building site. Prefabricated modular construction offers benefits in terms of construction time, cost and waste management. These benefits lead to reductions in materials and energy use and waste during onsite construction. Further benefits are improvement in environmental performance and building overall quality due to standardisation of methods and components.

Previous researches show that up to 70% of buildings' energy consumption is associated with the operational phase. The reduction of energy usage by applying engineered materials and appropriate designs are well documented in the literature. Several studies have been carried out focusing on the environmental performance of residential buildings considering different stages of building life ranging from whole life cycle environmental assessment to merely construction or operation. They have emphasised on various effective factors such as building design, physical properties, passive strategies and occupants. A few researches have been carried out focusing on life cycle costs of prefabricated and modular buildings using life cycle assessment (LCA) method. However, the thermal performance of the prefabricated modular residential buildings is not well documented in the literature. It is necessary to investigate the current baseline performance of these buildings in order to prepare a guideline to improve the new buildings to be constructed in future.

This study investigates the thermal performance of four prefabricated modular buildings as a part of baseline performance evaluation of modular construction in Melbourne, Australia. The materials and systems investigated in this paper are applied in Australian modular construction industry. EnergyPlus was used to simulate the building and estimate the building cooling and heating loads. The main focus of this study is on the building size and

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

envelops design. The results of energy performance simulations for four sample buildings are presented in this paper.

2. THERMAL PERFORMANCE EVALUATION

2.1 Sample buildings

Four floor plans (Wattle, Banksia, Territory and Outback) which are available in the Australian market were investigated. These sample buildings exemplify the typical residential plans constructed by modular construction method. The detailed building data were obtained from the website of a modular construction company in Australia. All selected modular buildings are single story residential buildings. The location considered was Melbourne, Australia. Figure 1 shows the floor plans of the selected buildings. The smallest building is Wattle constructed with only one module (12192 x 3000x 3100 mm at 17 t) and the largest building is Outback constructed of four modules. Banksia and Territory are constructed by using two and three modules respectively.

2.2 Simulation method

The 3D models of the buildings were generated using "OpenStudio" plugins in Sketchup environment. Afterwards all required features of the building were defined in OpenStudio. In this paper the main focus of simulations is to investigate thermal performances for different building sizes. In this respect, other factors that affect the energy consumption of buildings such as location, orientation, annual climate and environmental conditions are considered fixed for simulations. No internal heat loads related to occupancy and equipment were considered. The materials used in building construction, their thicknesses and properties are presented in Table 1.

Figure 1: Floor plans of the four sample buildings

EnergyPlus website provides weather data for different locations based on various data resources. The provided data relevant to the site for Victoria, Australia are based on RMY data source which is Australia representative meteorological year climate files developed by "Australia Greenhouse Office". In order to acquire representative long term data, the weather file was generated by using "Meteonorm". Meteonorm is a Swiss made software providing worldwide weather data in various export formats. Data source used by this software is "world meteorological organization" (WMO) which is providing accurate scientific weather information.

For all buildings 'Ideal Air Load' option was selected in EnergyPlus. The schedules for heating and cooling were defined according to local seasons. According to Lhendup et al the heating season is from 1 May to 31 October; whist the cooling season is from 1 December to 28 February. During the remaining months the heating and cooling systems are not active. The thermostat set points for heating were 21°C during the day (6 am – 10 pm) and 18°C during the night (10 pm – 6 am). The thermostat set point was assigned as 24°C for the cooling season. Table 2 shows the main features of the buildings defined in OpenStudio.

3. RESULTS AND DISCUSSION

3.1 Effect of building size

Building size can affect the total energy consumption and energy consumption per unit floor area. While the total cooling and heating loads tend to increase by growth of building size, the loads per floor area is expected to decrease. Table 3 shows the total floor area and floor area of conditioned spaces for four sample buildings. The conditioned spaces are living room, bedrooms and study rooms for which 'Ideal Air Load' option has been set in EnergyPlus. The unconditioned spaces include the bathrooms and storages. Table 3 shows that the ratio of conditioned spaces has been decreased as the total floor area increases. While 92% of the spaces in the Wattle building are conditioned, this percentage decreases to 85% in the Outback.

Building	Area (m^2)				Window to wall ratio (%)				
	Floor	Conditioned	Walls	Window	North	East	South	West	Overall
Wattle	40.2	36.9	85.21	11.75	3.74	27.88	3.64	78.38	14
Banksia	68.4	61.8	104.12	6.91	9.26	5.04	5.61	5.04	7
Territory	109.7	94.4	116.56	12.34	7.03	14.69	3.33	21.01	10
Outback	135.7	114.8	148.20	18.34	30.55	4.84	11.33	5.15	12

Table 3: Areas and window to wall ratios of the buildings investigated

3.2 Effects of wall to window ratio and conditioned area

The components and configurations of building envelope highly affect the energy consumption of the buildings. The location and size of the windows, the construction of exterior walls and roof, window and wall areas and the window-wall ratio are some of the envelope parameters that highly affect the amounts of heat gain in summer and heat loss in winter. An increase in window area especially on north façade can increase the cooling load during summer. Table 3 shows the window and wall areas as well as window to wall ratios on the exterior walls facing different directions for all simulated buildings.

Banksia has smaller window area than Wattle which causes a dramatic fall in window to wall ratio of Banksia (see Table 3). Wattle has large windows and a big glass door on the east and west façade respectively. Regarding the fact that Wattle is the smallest building and therefore wall area is lower than other three buildings the high value of window to wall ratio can be justified.

3.3 Cooling and heating loads

The simulations of four sample buildings were carried out in order to evaluate the thermal performance. According to the results, the cooling load is considerably lower than heating load for all buildings. This is due to the climate conditions of Melbourne in which the heating season is longer and more heating load is required to fulfil indoor thermal comfort. The annual cooling load is maximum among all simulated buildings for Wattle being equal to 0.43 GJ. This can be explained due to higher window to wall ratio and larger total surface area to volume ratio which can result in higher load per unit floor area. The annual cooling load per unit area for Bankisa, Territory and Outback are relatively close (0.18, 0.17, and 0.19 GJ respectively). The cooling load for Banksia is slightly higher than the one that of Territory. This can be explained by the fact that the window to wall ratio on north façade is higher for Banksia which caused more heat gain during the summer. The heating load increases with a rise in total building area. Since window area has less influence on heating load compared to cooling load, the heating load increased consistently from Wattle to Outback The values of annual heating loads are 13.08, 21.06, 26.09 and 33.25 GJ for Wattle, Banksia, Territory and Outback respectively. The maximum and minimum cooling loads occur during January and December respectively. The heating load is maximum in July and minimum in October.

Figures 2a and 2b show the values per unit floor area for heating and cooling loads respectively. The heating energy per floor area decreases with the rise in the floor area. However, it increases slightly from "Territory" to "Outback". This pattern verifies the fact that rather than floor area other factors such as building envelope design parameters can influence the energy consumption of the buildings. For instance, the addition of shading devices can significantly reduce the cooling load since it limits the amount of solar heat gain received from glazed areas. Similarly the glazing type and properties of glazing affect the heat transfer between indoor and outdoor environments and the heating and cooling loads accordingly [25]. Building orientation is another factor that affects the building energy consumption since the amount of solar heat gain can vary by changing the orientation. Other

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

factors such as occupation and compartmentalisation can affect the building loads. However, the occupancy was not considered in this paper. Also compartmentalisation is expected to have small impact on the loads of the sample buildings investigated in this paper. Cooling load per unit floor area decreases consistently with increasing floor area (Figure 2b). To justify the change in heating load per unit floor area the trend of increase in floor area as well as window to wall ratio should be considered.

The sharp change in the cooling load between Wattle and Banksia can be explained by considering the high amount of total cooling load for Wattle. Since the total cooling load of other three buildings were of close values, the consistent reduction of the cooling load per floor area from Banksia to Outback is reasonable.

Figure 3 shows the annual electricity consumption per floor area for the sample buildings. These values have been calculate according to peak demand of each building and by selecting appropriate equipment with adequate capacity from Australian energy star rated equipment list. Table 4 provides the capacities, cooling and heating coefficient of performances (COPs) of the heat pumps selected. It is apparent from Figure 3 that the electricity consumption per floor area decreased consistently from Wattle to Territory, but increased from Territory to Outback. The increase in the electricity consumption for Outback is due to the lower COPs of the heat pump available and selected to meet the higher peak loads (see Table 4).

Building	Heat pump model	Heating (kW)	Heating COP	Cooling (kW)	Cooling COP
Wattle	Daikin FFQ25C2 / RXS25K3	3.2	4.00	2.5	4.46
Banksia	Daikin FTXM50P / RXM50P	6.0	4.23	5.0	4.24
Territory	Daikin FTXM60P / RXM60P	7.0	4.07	6.0	3.87
Outback	Daikin FTXS71L / RXS71L	8.0	3.67	7.1	3.41

4. CONCLUSION

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

In this paper energy performance simulations of four prefabricated modular houses have been carried out using EnergyPlus interface with OpenStudio. The buildings have been selected from a supplier available on the market. The number of selected sample buildings was limited to four which are representatives of single family residential houses with different floor areas. A larger number of sample buildings that could provide better opportunity for more expanded results and discussion is to be considered in future works. Except building envelope parameters and floor area all other effective factors have been remained constant throughout the simulations. The heating and cooling seasons for Melbourne have been defined according to literature and applied in the simulations.

The results reveal that heating and cooling load of the buildings highly depend on both floor area and window to wall ratio. While the energy required for heating showed increase in buildings with larger floor area, the cooling load followed a different pattern that indicated the impact of envelope parameters. Results showed that for Melbourne climate the heating load is significantly larger than cooling load. The monthly results show that the highest heating load occurs in July for all buildings. The highest cooling energy is consumed during January for all buildings. The heating and cooling energy per floor area show a decreasing trend with increase of floor area. Results also indicate that window to wall ratio has higher impact on cooling load compared to heating load.

Energy Saving Potential of Thermal Broken Fenestration System in Hot Climate Counties

Simon WONG[a]

[a] *Technoform Bautec Hong Kong Ltd., Hong Kong SAR, simon.wong@technoform.hk*

ABSTRACT

The unprecedented volatility in energy prices of the last few years and rising global warming problems, has led the topic of "Energy Conservation" to become the most important and relevant topic worldwide. Building, Industrial and Transportation are the three major sectors contributing to the energy consumption globally. Building energy accounts for more than one third of the global consumption and thus, many countries take top priority in increasing the building energy efficiency.

Hong Kong is located in southern China with typical maritime subtropical climate. The long summer begins from April till October with hot and humid weather conditions, with occasional tropical typhoons. Temperatures in the afternoon are usually hottest, especially in July and August with an average temperature higher than 31°C, while it could be as high as 33°C in the New Territories. In addition, Hong Kong as a metropolitan city, with a high density of high-rise buildings, is affected by the heat island effect.

With greater awareness in building energy efficiency and green building codes, there is a rise in demand for high-performance window systems. However, the common fenestration systems used in Hong Kong combines high-performance glazing with non-thermal insulated frames. Such design combination results in a significantly lower overall thermal performance of a window system.

In this paper, we investigate how the thermal transmittance of frames (U_f value) has a direct influence on solar heat gain of fenestration system with a experimental and simulation analysis to understand the importance of using high performance fenestration system with low U_f value in tropical and sub-tropical countries such as Hong Kong.

Keywords: U value, solar heat gain coefficient SHGC: overall thermal transfer value OTTV

1. INTRODUCTION

1.1. Background

With the rapid economic development and increasing quality of living, Hong Kong's construction industry has developed rapidly and a comfortable living environment is essential to meeting the people's increasing demand for better living conditions.

Hong Kong is located in the South China region and is connected with mainland China in the northern part of the island, while the south faces in the direction of the South China Sea. Summer are hot and humid with temperature between 27 ~ 33°C with typical subtropical monsoons; winter are cool and dry, but rarely falls below 5°C. Hong Kong is a cosmopolitan city with the world's third highest population density. Crowded commercial and residential high-rise buildings form Hong Kong's urban landscape. This is a reason for the urban heat island effect.

In cities like Hong Kong, with a long period of high temperature. Building energy consumption accounts for more than 90% of the total energy consumption. Improvements should be made on the thermal performance of building envelope, thereby reducing the building air conditioning load, achieving better building energy efficiency.

At present, the OTTV is the only mandatory criteria to evaluate the thermal performance of building envelope; this evaluation includes the thermal transmission through the opaque walls and roofs, and the solar radiation through the window glass.

In the sub-tropical and tropical climatic regions, building envelope is constantly exposed to solar irradiation all year round. The traditional method of improving the thermal performance of fenestration is by adding a shading system to prevent sunlight from passing through the glazing, thereby reducing the solar heat gain through the fenestration.

However, building designer tends to neglect the solar heat gain effects through the overall fenestration system in the building envelope.

In this paper, we will find out how the solar heat gain coefficient SHGC is directly influenced by the Uf value of the fenestration system's opaque frames and how the thermal performance of building envelope can be effectively improved by the thermal broken aluminium fenestration system.

1.2. Concept of OTTV and development

The OTTV (Overall Thermal Transfer Value) concept was introduced by the US in the 70's. It was widely used to measure the thermal performance of building in Asia Pacific countries, and Hong Kong is one of them. According the "Code of Practice for Overall Thermal Transfer Value in Building 1995", the OTTV calculation equation is

$$OTTV = (Aw \times U \times \alpha \times TDeqDw) + (Afw \times SC \times ESM \times SF)/ Aow$$

Equation 1

The formula considers the heat gain through the opaque wall and roof, as well as the solar radiation through the glazing. However, it ignores the conductivity and solar heat gain effects from the fenestration system's frame.

Singapore is another Asia country which has implemented the OTTV concept and the country later modified it as ETTV (envelope thermal transfer value, the calculation equation is:

$$ETTV = 12\,(1- WWR)Uw+3.4(WWR)U+ 211(WWR)(CF)SC$$

Equation 2

The formula considers three key criteria, the heat gain through the opaque wall, heat gain through the windows and solar radiation through the glazing. Basic concept is similar to OTTV's but the TDeq (annual equivalent temperature difference) and SF (annual equivalent solar factor) are simulated by actual climate condition.

The weather conditions and humidity levels between Singapore and Hong Kong are similar. Therefore, the experimental results for thermal broken fenestration system could give significance reference to Hong Kong.

2. ALUMINIUM PROFILES HEAT GAIN

2.1 Solar heat gain coefficient

With reference to the ETTV equation, we assume a room with a window wall ratio of 1 (window only, without opaque wall), and CF=1 (based on south-east facing vertical window), the ETTV equation can be expressed as:

$$ETTV=3.4U+211SC$$

Equation 3

From the above equation (3), it can be illustrated that the thermal transmittance of the window (U value) has a less significant influence to the ETTV than compared to the shading coefficient SC value. Based on this concept, it is understandable why building designers are more concerned with the SC value of the fenestration in hot climate areas. With this design concept, energy-saving windows and doors designs with low U-values are not often considered as an important design parameter.

In fact, there is a big misconception of designs taking into consideration only the SC values. The SHGC solar heat gain coefficient, also known as solar radiation admitted through a window, is the fraction of the solar radiation heat passing through the window. The SHGC includes two parts; solar radiation heat entering directly through the glass and the heat gain through the window frame component which absorbs and re-radiate inwards.

At present, both Hong Kong and Singapore both assumes that the U value and SC value of a window system is equal to the U value and SC value of the center-of-glazing. However, consideration of the solar heat gain through the window frames should be accounted for in evaluating the energy performance of the building. This can be done by converting the equation's SC value to SHGC value by dividing the SC value by a factor of 0.87.

2.2 Frames sample test

The following is a test conducted by Solar Energy Research Institute of Singapore (SERIS) to analyse the solar radiation absorption by the window frames and re-radiation inwards as a heat gain. Figure 1 is the actual test site, with its façade facing west and it is not shaded by trees or other structures. The room is air-conditioned during typical office hours. 10 aluminium profile samples with different colour and performance (with thermal break or without thermal break) were placed into the window opening as shown in Figure 2 and Table 1. All test samples are monitored by the many sensors located in the test facility, recording in 2 seconds intervals, and the data are then stored in the computer.

Figure 1: Test site

Figure 2: Aluminium profile samples

1	No thermal break, light color	AL_LC	2	No thermal break, dark color	AL_DC
3	With low performance thermal break, light color	TBL_LC	4	With low performance thermal break, dark color	TBL_DC
5	With moderate performance thermal break, light color	TBM_LC	6	With moderate performance thermal break, dark color	TBM_DC
7	With high performance thermal break, light color	TBH_LC	8	With high performance thermal break, dark color	TBH_DC
9	No thermal break, light color		10	No thermal break, dark color	

Table 1: Aluminium profile samples for testing

Figure 3 shows on a representative day during 14:00-18:00 hours, with solar radiation intensity being highest in the day. Outdoor air temperature was up to 38°C, while the indoor temperature maintained stable at 22-23°C by air-conditioning. Figure 4 shows the heat flux through the black aluminium non-thermally broken sample is the highest, with more than 400W/m², much higher than the light coloured high-performance thermal break aluminium samples which recorded a low heat flux of 60W/m².

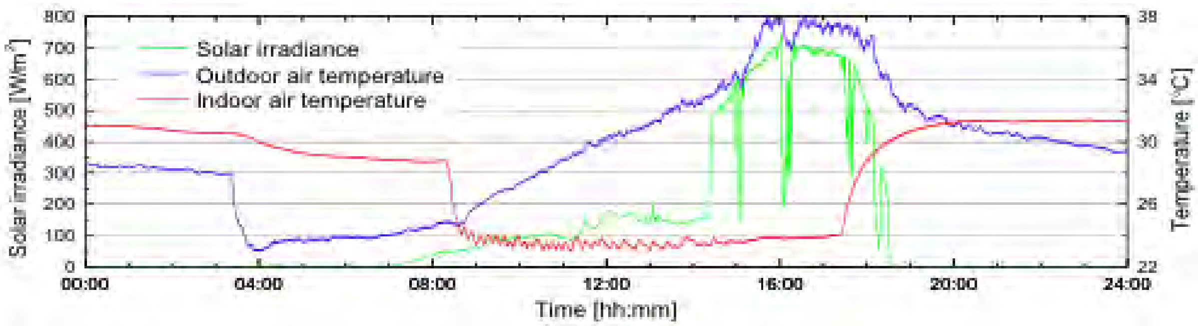

Figure 3: Solar irradiance and indoor/ outdoor air temperature

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

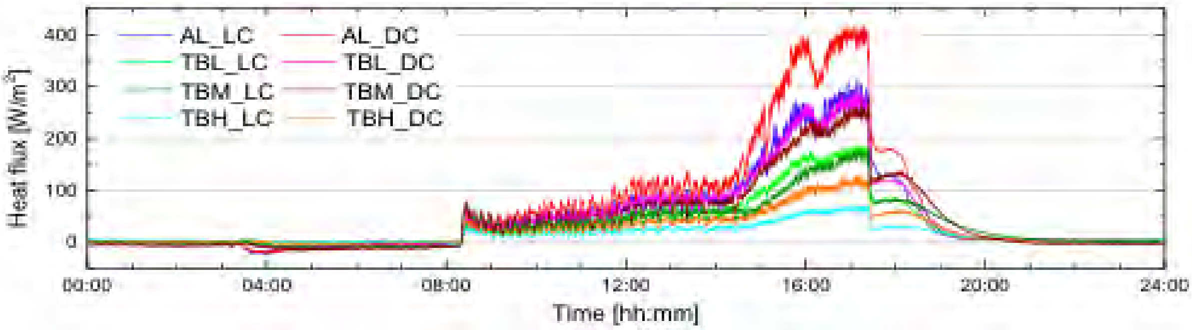

Figure 4: Heat flux through frame samples

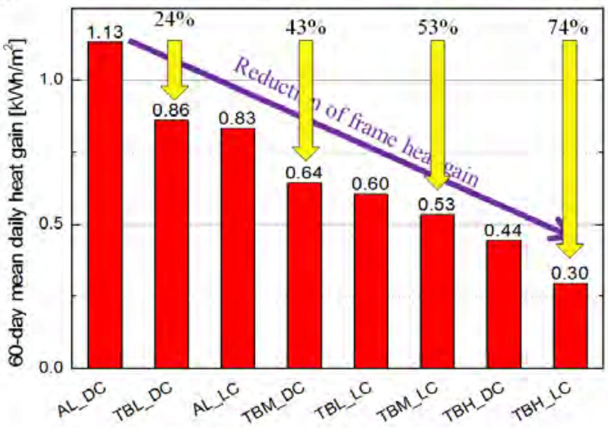

Figure 5: 60-day mean daily heat gain [kWh/m²]

By comparing the average daily heat of the non-thermal broken aluminium profiles in black colour with other thermally broken profiles, we could find that by using light-colour high-performance thermal broken profile the heat gain could reduce by 74%, relating to 0.83kWh/m².

This experiment proves that the solar radiation could be re-radiated to the interior through the absorption by the aluminium profiles. It is also affected by the surface colour and the thermal transmittance value of the profiles. The darker the surface colour, more solar radiation is being absorbed. The higher the thermal transmittance value of the profile, more heat flux per unit are, therefore more heat is transferred from the outside to the inside.

2.3 The relationship between U value and SHGC

In general, like Singapore, the SHGC only considers the centre-of-glazing and is then used to calculate the ETTV. But with reference to ISO 15099, NFRC200 or JGJ/T 151-2008, the solar heat gain coefficient of the frame is:

$$g_f=\alpha_f \cdot \frac{U_f}{\frac{A_{surf}}{Af} \cdot h_{out}}$$

Equation 4

And the SHGC of the whole curtain wall is:

$$g_{cw}=\frac{\sum g_g A_g+g_p A_p+g_f A_f}{A}$$

Equation 5

The above equation shows that the SHGC of the curtain wall is obtained by the area weighted average method of the solar heat gain from the frame, glass and the opaque panel.

After the conversion between shading coefficient SC and SHGC value, it can be substituted into the ETTV formula to calculate the thermal performance of the building envelope. The above formula shows that the U value and the shading coefficient were directly correlated, in the calculation process, the solar heat gain of the window frame is very important.

3. HIGH PERFORMANCE THERMAL BROKEN WINDOWS

3.1 Simulation analysis

By using the simulation software THERM, calculation of the U value of non-thermal broken aluminium profiles, thermal broken aluminium profiles and Passive Window profiles was done. We further substituted it into equation (4) to obtain the SHGC results as below:

	Non- Thermal Broken Aluminium Profile	Thermally Broken Aluminium Profile	Passive Window Profile
Uf value (W/m²K)	6.96	2.02	1.13
SHGC	0.18	0.05	0.03

Table 2: SHGC of different aluminium profiles

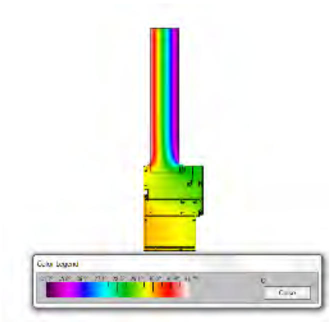

Figure 6: Non-thermal broken

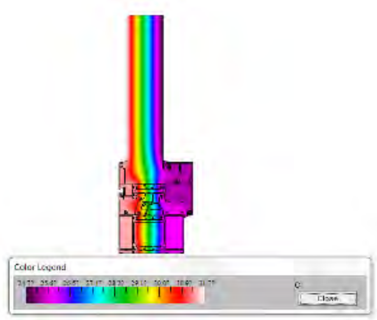

Figure 7: Thermal broken

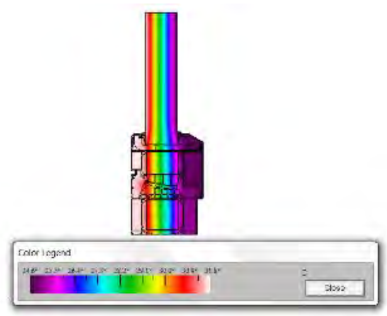

Figure 8: Passive window

The Uf value of non-thermal broken profile is 6.96 W/m²K and the SHGC is 0.18, while the Uf value of thermal broken profile is 2.02 W/m²K, the SHGC is 0.05, the Uf value is reduced by 71% and the SHGC is reduced by 72%. Similarly, the use of Passive windows, compared with the non-thermal broken profiles, Uf values and SHGC can be large reduced by 84% and 83% respectively.

3.2 Thermal performance of different windows

Below we evaluate the possible reduction of heat gain by high performance thermal broken windows. We assumed that other parameters of the windows are fixed, with a the glass to frame ratio is 75%, and with a single open sash.

	Non-thermal Broken Window	Thermal Broken Window	Passive Window
Project Area of the Frame Af	0.5m²		
Project Area of the Glass Ag	1.5m²		
Project Area of whole Window Aw	2.0m²		
Perimeter of glass vision area, lg	4.5m		
Glass Frame ratio	75%		
Solar absorptance of the outside the Frame Surface α_f	0.7		
Outdoor surface heat transfer coefficient h_{ex}	22W/(m²K)		
Frame Outside Area (m²) Frame Projected Area (m²) Asurf/Af	1.2		
U value of Glass	1.6W/(m²K)		
SHGC value of the glass	0.35		

Linear Thermal Transmittance ψ_g	0.05 W/(mK)	0.11 W/(mK)	0.11 W/(mK)
U Value of the Frame	6.96 W/(m²K)	2.02 W/(m²K)	1.13 W/(m²K)
SHGC Value of the Frame	0.18	0.05	0.03
U Value of the Window Uw	3.05 W/(m²K)	1.95 W/(m²K)	1.73 W/(m²K)
SHGC Value of the Window	0.31	0.28	0.27
ETTV (WWR=1， CF=1)	85.6 W/m²	74.5 W/m²	71.4 W/m²

Table 3: Parameter table of different windows

By the using the same SHGC glass, the results illustrated the following:

1. The SHGC value of window could show reductions of 9.7% and 12.9% by using thermally broken profile and Passive window profile respectively;

2. The ETTV of window could show reductions of 13.0% and 16.6% by using thermally broken profile and Passive window profile respectively.

The above results show that the window frame U value is closely related to the overall thermal performance of a window system. The use of thermal broken aluminium window can reduce the overall envelope heat gain more than 10%. With rational choice of window frame, reasonable configuration, the high performance thermal broken window can achieve the desired energy saving effect for the building.

4. CONCLUSION

The comparison shows that the U value of the window frame is an important factor in influencing the shading coefficient and the solar heat gain of the building envelope.

Today building energy consumption is the major part of Hong Kong total energy consumption and is increasing annually. However, awareness of building energy efficiency is low, while the concept of energy conservation is relatively weak. The primary task of reducing energy consumption can be achieved by increasing the energy efficiency of buildings; and we can start by improving the building envelope thermal performance.

Window frames, although only a small part of doors and windows, contributes significantly to the overall thermal performance of a window. High performance thermally broken window systems can effectively reduce the heat gain through the fenestration and thus reduce the energy consumption of the entire envelope to achieve the desired energy saving effect.

Potentials of Energy Efficiency and Generation Strategies for High-rise Office Buildings in Hong Kong

YU Cong[a], PAN Wei[b]

[a] The University of Hong Kong, Hong Kong SAR, yucong@connect.hku.hk
[b] The University of Hong Kong, Hong Kong SAR, wpan@hku.hk

ABSTRACT

Office buildings are a major building type responsible for a large proportion of the total electricity consumption in Hong Kong where most office buildings are high-rise due to the scarce developable land resources. There are more limitations to the selection of energy saving strategies for high-rise office buildings compared with low or medium ones, as high-rises are associated with more complex design on the fabric, envelope and service systems. It is therefore vital to explore measures for reducing energy consumption of high-rise office buildings.

This paper aims to examine the potential of energy efficiency and generation strategies for high-rise office buildings in Hong Kong, and to develop scenario-based design strategies. A reference building model was first established using a typical real-life high-rise office building in Hong Kong. Using the reference building, the energy consumption was estimated with the aid of the energy simulation tools DesignBuilder and EnergyPlus. The potential of various energy saving and generation strategies was then investigated using the reference building and the tools. The strategies included chiller system selection, daylighting control, cooling setpoint temperature, PV system, and wind system. The results show that adopting water-cooled HVAC type and daylighting control system can reduce approximately 10% and 11% of the total energy consumption, respectively. The cooling setpoint was found to lead to an energy use saving by 4%. The use of PV systems was found to offset 4% of the total building energy use. The wind turbine however was found to have little effect on energy efficiency. The strategies together can help achieve up to 30% of building energy use reduction, yielding an optimised scenario. The findings inform future high-rise energy use parametric research and are useful to engineers for designing energy-efficient office buildings. Future research should also explore building fabric measures in order to maximise energy reduction potential.

Keywords: energy use, energy modelling, high-rise office building

1. INTRODUCTION

Buildings are proved to be the biggest single contributor to total energy consumption in many countries, accounting for as much as half of their primary energy resources (Pan and Garmston 2012). Commercial buildings account for a substantial proportion of energy consumption in Hong Kong. According to the Hong Kong Energy End-use Data published by EMSD (2015), electricity consumption in the commercial sector rose by 19.5% from 84921 Terajoule in 2003 to 101480 Terajoule in 2013. Due to the scarce developable land resources in Hong Kong, the majority of buildings in the city are high-rise; approximately one in five are office buildings, which offer a considerable energy saving potential (Rating & Valuation Department 2000). To realize such potential, it is vital to examine the existing building's energy performance and make comparison with the estimated energy performance of buildings with energy saving strategies. There has been increasing pressure on architects and engineers to design more energy-efficient buildings and building services systems (Yu and Chow 2007, Lam, Wan et al. 2008, Pan 2014). However, there is a limited understanding of the selection of energy-saving measures for high-rise office buildings that require more complex designs for both building fabric and building services compared with low or medium-rise counterparts (Pan, Qin et al. 2016).

It is generally accepted that computer energy analysis techniques are valuable design tools for the design and analysis of buildings and building services installations, particularly for large office buildings. DesignBuilder and EnergyPlus are two typical examples of widely used computer simulation tools for estimating buildings' energy consumption. This paper aims to examine the potential of energy efficiency and generation strategies for high-rise office buildings in Hong Kong, and to develop scenario-based design strategies. For this research, a typical real-life high-rise office building in Hong Kong was selected to be the reference building for investigating measures that affect energy consumption. Five energy strategies, namely, chiller system selection, daylighting control, cooling setpoint temperature, PV system and wind system, were analysed utilizing the tools DesignBuilder and EnergyPlus.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Integrating the results, the paper presents an optimised scenario with maximised energy use reduction from employing these energy efficient measures and draws conclusions.

2. THE REFERENCE BUILDING

Hong Kong Monthly Digest of Statistics (2016) conducted a survey of investigating the existing commercial buildings. It contains the existing buildings basic information in Hong Kong, for instance, building construction, address, number of storeys, building cost, usable floor area and gross floor area. The most prevailing storeys in Hong Kong were found to be between 20 storeys to 40 storeys through the Hong Kong Monthly Digest. Lam (2000) considered that the main type of high-rise office buildings in Hong Kong is with either square or rectangular configurations. Therefore, a 26-storey office building (Figure 1) with square configurations located in Kowloon was selected as the reference building to represent the typical office buildings in Hong Kong for investigating the potentials of energy efficiency and generation strategies. Due to the limited access to the actual metered energy use data, a top-down approach was adopted to establish the reference energy model by using the end-use energy distributions reported by EMSD (2015). As there is a set of standard energy modelling inputs for office buildings in Hong Kong, the use of this top-down approach was considered practical and effective.

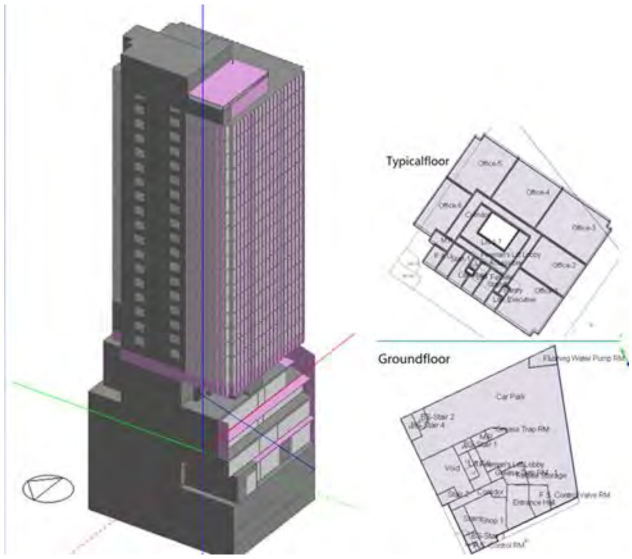

Figure 1: The private office case building and composition of different floors

This building has a total of 26 storeys that the podium layer (1 - 5F) is used for food and beverage and the tower part (6F - 26F) is designated used for offices. The office is designed as core tube type that it has a core area to place lift and lobbies and equipment room surrounded with open office area. This building has the overall area above ground 24698.74m^2; underground 4603.43m^2. The geometric model was built by the architectural drawings and design specifications. The data inputs of the energy model of the prototype were based on the drawings and relevant information provided by the design team, supplemented by the optimisation design and the overall building performance comparison as set in the Performance-based Building Energy Code (PB-BEC 2007). The weather file used in the energy simulation is provided by Energy Plus weather database (CHN_Hong.Kong.SAR.450070_CityUHK.epw). The office is assumed to be opened from 9 am to 6 pm from Mondays to Fridays and from 9 am to 12 am on Saturdays. Occupancy and operation schedules from PB-BEC are used in this study. The lighting of parking is assumed to be on operation all day. The minimum shading coefficient is 0.25. Lighting luminance is 300 Lux for office building according to the Standard for Lighting Design of Buildings (GB50034 2004). The design temperature in summer is assumed as 24°C.

Cooling is provided by a set of centrifugal chillers and no heating is provided. Air Handling Unit (AHU) is adaptable in the spacious space because it provides both fresh air and returned air. All the food areas at 1 - 3F are served by AHU system with variable speed control. However, due to the limited height in the office room, the FCU (Fan Coil Unit) system has smaller size than AHU system. Thus, all the office areas at 6 - 26F are served by FCU system with dedicated outdoor air system. A split-type AC system is provided for the control room since the control room does not have the same schedule compared with other areas. The VRF (Variable Refrigerator Flow) system is used by management office in 1F and lift machine room in 18/ 19F. Table 1 displays the input parameters of the reference building.

Item	Details
Building Type	High-rise office building
Location	Kowloon, Hong Kong, China
Building Height	112.75m (26 above ground, 3 basements)
U value (W/m^2K)	Opaque Wall 3.3, Below grade walls 1.99, Window 1.57, Opaque Roof 0.39
Curtain wall type	Low-E Glass with SC=0.25, VLT=42
Fresh air rate	Office, lobby, corridor, retail area 10 l/s/person, parking & mechanical room 6 ACH, restroom 15 ACH, kitchen 50 ACH
Equipment power density	Office 25 W/m^2, retail-sales area 15 W/m^2, restaurant 20 W/person
Occupancy density (m^2/persons)	Office 8, lobby 10, restaurant 5, corridor 50
Lighting power density (W/m^2)	Lobby 14, office 17, parking 2, corridor 5, restroom 10

Table 1: Input parameters of the reference building

3. ENERGY USE IN THE REFERENCE BUILDING

The reference building was established through an iterative process and energy simulation and verification drawing on EMSD released end-use energy data and engagement with professionals. The EUI was estimated to be 282.4 kWh/m^2, and covered in order of significance, cooling electricity (41.9%), fans (23.6%), appliances (17.5%), interior lighting (16.5%), and then pumps (0.4%) (Figure 2).

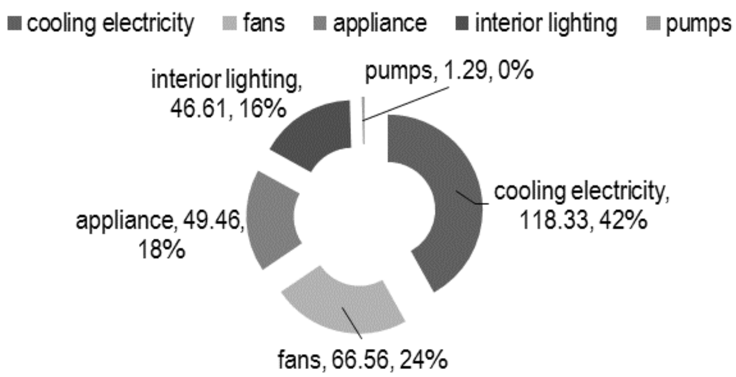

Figure 2: Energy use of the reference building (kWh/m^2)

The whole energy use is in agreement with that reported in previous studies, e.g. 259.2 kWh/m^2 by (Yu and Chow 2007). The total HVAC system consumes 66% of the overall energy use, which reveals substantial energy saving potential. Energy use of appliances is mainly caused by the use of office equipment, such as computers, printers and so on, and also depends on human behaviours with uncertainties to a great extent. The appliances are therefore not considered in the analysis in this paper. Although the proportion of interior lighting is not high (16%), it still has the conservation space by adopting the energy efficiency measures.

4. ANALYSES OF ENERGY EFFICIENT STRATEGIES

Previous studies indicated that the following strategies showed remarkable energy saving potential. Those are chiller system selection, daylighting control, cooling setpoint temperature, PV system and wind system. Ellis and Mathews (2002) estimated that energy savings could be maximum around 70% through the use of better design technologies to coordinate the building demand with its HVAC system capacity. The Hong Kong government, with the support of EMSD, encourages the owners of non-domestic premises to use water-cooled chiller system (EMSD 2015). Yu and Chow (2007) modelled daylighting for offices using Trance 600 and found that applying daylighting strategy will save as much as 41% of the lighting energy use and 16% of the overall building energy use. In the year 2006, the Hong Kong Environmental Protecting Department (EPD 2006) suggested a recommended temperature (25.5°C) of the indoor cooling setpoint temperature to reduce the energy use. There is a belief that

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

operating at the high end of this range or above it will reduce the total energy use in the office buildings by making the cooling system more efficient. Fong and Lee (2015) indicated that the high-rise office buildings in Hong Kong had the energy saving potentials by adopting PV system. However, based on site survey, the existing office buildings in Hong Kong are normally air-cooled with low temperature and do not utilize daylighting control or energy generation strategies. It is significant to analyze whether these strategies are still applicable in Hong Kong. Therefore, the energy efficiency and generation strategies investigated in this paper are: (1) Chiller plant system optimisation, (2) Indoor air setpoint temperature, (3) Daylighting control, (4) Photovoltaic system, and (5) Wind power generation. The design parameters of these five strategies are listed in Table 2. Table 3 displays the energy saving comparison of five energy saving measures. By adopting these energy efficient strategies, the performance of energy use for the high-rise office building ranged to different extents as detail explained below.

Energy saving strategies	Original	Optimisation
Chiller type optimisation	Air-cooled with COP 3	Water cooled with COP 5
Indoor air setpoint temperature	24°C	26°C
Daylighting control system	No	Yes
PV panels & BIPV	No	Roof (15% efficiency) and facades (4.5% efficiency)
Wind turbine	No	Roof

Table 2: Design parameters of five strategies

	Water-cooled chiller	Indoor air setpoint temperature	Daylighting control	Original	PV system	Wind turbine
HVAC system (kWh/m²)	157.43 (-15.44%)	171.20 (-8.04%)	177.57 (-4.62%)	186.18 (0%)		
- Cooling	71.45	105.35	110.37	118.33		
- Fans	66.56	64.63	65.91	66.56		
- Pumps	11.46	1.23	1.29	1.29		
- Heat Rejection	7.96	0.00	0.00	0.00		
Interior Lighting (kWh/m²)	46.43 (0%)	46.61 (0%)	25.03 (-46.30%)	46.61 (0%)		
Interior Equipment (kWh/m²)	49.34	49.46	49.46	49.46		
Electricity generation (kWh/m²)	0	0	0	0	-11.64	-1.72
Total End Uses (kWh/m²)	253.34 (-10.29%)	270.41 (-4.25%)	252.06 (-10.74%)	282.40 (0%)	270.76 (-4.1%)	280.68 (-0.35%)

Table 3: Comparison of energy saving measures

Ciller plant system optimisation (Compared with water-cooled chiller)

Most existing commercial buildings in Hong Kong adopt air-cooled chiller system with a typical COP of 3, which is adopted for the reference building. The government, with the support of EMSD, encourage the owners of non-domestic premises to use water-cooled chiller system by joining Scheme for Wider Use of Fresh Water in Cooling Towers in Air Conditioning Systems for their fresh water cooling towers installations (EMSD 2015). Water-cooled chiller systems are therefore adopted with the COP of 5, which are analysed in comparison with the air-cooled system.

The scenario adopting water-cooled chiller system consumes much lower energy (282.4 kWh/m²) than the reference building adopting air-cooled chiller system (253 kWh/m²). This is mainly because of the significantly reduced (by 65.6%) cooling energy of the water-cooled chiller (71.45 kWh/m²) from that of the air-cooled chiller (118.33 kWh/m²).

Indoor air setpoint temperature (24°C to 26°C)

Theoretically, the higher indoor air setpoint temperature will lead to the lower cooling demand, and thus it will save energy. However, the consideration of the conflict between human comfort degree and energy saving is significant as well. By comprehensive consideration, the recommended cooling setpoint is set as 26°C. The cooling setpoint was found to lead to an energy use saving by 4%.

Daylighting control in office area

Daylight control is an energy management technique that reduces overhead lighting use by utilizing the ambient (natural & artificial) light present in a space and dimming or switching off lighting when sufficient ambient light is present or when space is unoccupied. It is quite useful in the open office area with plenty of windows. Daylighting control is proved to be a good strategy to decrease the overall building's energy consumption by around 11%.

Photovoltaic system

The electricity generation of PV system would be closely related to the availability of solar irradiation of a place. In this paper, the building-integrated photovoltaics (BIPV) on facades and PV panels on the roof are investigated. BIPV and PV panels for the reference building are assumed with the efficiency rate of 4.5% and 15% respectively. Seventy-two solar cells in each m-si PV module. The size of the solar cells is 125 mm × 125 mm. Table 4 displays the detail input parameters for PV system at standard testing conditions. The annual cumulative global solar radiations on the vertical walls facing different directions are investigated. The result indicates that the PV system can generate 11.64 kWh/m^2 electricity annually, which can afford approximately 4% of the overall energy use.

System	BIPV system (facade)	PV system (roof)
Solar cell type	a-si	m-si
Rated power at the maximum power point (P_{mp})	105 W	180 W
Rated voltage at the maximum power point (V_{mp})	30.2 V	35 V
Rated current at the maximum power point (I_{mp})	3.48 A	5.14 A
Open-circuit voltage (V_{oc})	38.8 V	43.5 V
Short-circuit current (I_{sc})	4.3 A	5.53 A
Size of module	1.4 m ×1.1 m×7 mm	1.580 m × 0.808 m× 50 mm
Temperature coefficients of I_{sc}	0.00559 A/K	0.002765 A/K
Temperature coefficients of V_{oc}	-0.13968 V/K	-0.1479 V/K
Photovoltaic efficiency	6.8 %	14 %

Table 4: The operational data of a-si and m-si PV modules at standard testing conditions (STC) (AM1.5, 1000 W/m^2, 298 K)

Wind power generation

Wind velocity at the height of wind turbine rotor center can be calculated by V = VTMY(Z/ZTMY)1/7. Where, VTMY is the wind velocity at the data collection site, here wind velocity in the TMY weather data used, m/s; Z and ZTMY are the wind turbine rotor center height and data collection site height, respectively. The annual average wind speed: 7.3 m/s (113 m) 7.4 m/s (124 m). Detail information is showed in Table 5. The result shows that the wind turbine has little effect on the energy use.

Manufacturer	Windspot
Model	Windspot 3.5kW
Rated power	3.5 kW
Reference annual energy output	18 MWh
Cut-in wind speed	3 m/s
Rated wind speed	12 m/s
Cut-out wind speed	20 m/s
Rotor diameter	4.05 m
Hub height	12 m

Table 5: Details of the small horizontal axis wind turbine (HAWT)

5. CONCLUSION

The reference high-rise office building was established through an iterative process and energy simulation and verification drawing on EMSD released end-use energy data and engagement with professionals. The EUI of the building was estimated to be 282.4kWh/m^2, and covered in order of significance, cooling electricity (41.9%), fans (23.6%), appliances (17.5%), interior lighting (16.5%), and pumps (0.4%).

Five energy strategies, namely, change of chiller type, daylighting control, increase of cooling setpoint temperature, PV systems and wind turbine, were then investigated. By adopting these strategies individually, the EUI was found to range from 252 to 282.4kWh/m^2/year. More specifically, the adoption of water-cooled HVAC type and daylighting control system can reduce approximately 10% and 11% of the total energy consumption, respectively. The cooling setpoint was found to lead to an energy use saving by 4%. The use of PV systems was found to offset 4% of the total building energy use. The wind turbine, however, was found to have little effect on energy efficiency. Thus, should the four measures (i.e. excluding wind turbine) be adopted, the building's energy use reduction could sum up to 30%, yielding an optimized scenario. Nevertheless, further energy use reduction can be enabled through addressing passive energy saving factors such as building design and fabric (e.g. envelope, infiltration), which should be explored in future research.

The findings contribute to a better understanding of the energy saving measures influencing energy use in high-rise office buildings and should inform energy-efficient building design in urban contexts. These findings have significant implications for future high-rise energy use parametric research and practices of engineers and architects in both building initial design and retrofit stages.

ABSTRACT

This paper discusses the energy impact of corridor design for school buildings in the cold climate of China. Local school buildings were classified into three types in terms of the corridor design patterns. Architectural related parameters of corridors which could have a potential impact on the energy consumption were summarized and discussed, including: form and orientation, temperature control, opaque envelope components, glazing, ventilation and infiltration. The annual heating, cooling, lighting and total energy consumption were compared. Results showed that form and orientation have the most significant influence on building energy consumption while opaque envelope insulation of corridors shows the least effect on energy demand. By combining the most beneficial strategies at each step, this study resulted in a better performing corridor design that increases the energy-saving by around 6% for the double-sided corridor building type and 17% for the one-sided enclosed corridor type of school building respectively.

Keywords: school building, corridor design, energy saving

1. INTRODUCTION

School buildings account for a considerable proportion of public buildings. Research has shown that school campuses are among the major energy consumers and energy conservation enforcement of school campuses would reduce Car-bon Dioxide emissions up to 25% (Zhou et al., 2013). There is a large body of research on the relationship between school building design and energy or environmental performance. The focuses have been put on the classroom due to the large proportion of school surface they occupy in school buildings (Perez et al., 2009). However, little attention has been paid to the common area in school buildings such as the corridor space. Their energy consumption also accounts for a certain proportion of the school energy consumption (Pitts and Saleh, 2007). Besides, such common areas play an important role in the ability for students to rest and communicate. A comfortable common area can have a potential impact on students' study results (Kwong et al., 2009).

The performance of transitional space in schools did not get a lot of attention from researchers. Though some researchers have investigated specific energy saving measures for transitional spaces like temperature control (Pitts and Saleh, 2007), but other parameters like the geometry or the glazing design of corridors are seldom considered. Furthermore, the relative importance of these strategies on the energy consumption is much less studied. Thus, the effect of school transitional space such as corridors on building energy consumption needs to be studied.

2. METHODOLOGY

The main objective of this study is to find energy-saving solutions for the corridor design of school buildings in the cold climate of China. First, local school buildings were characterized to establish specific school corridor models. Secondly, the design parameters of the corridor space that can have a potential influence on the performance were classified and then tested by category using Designbuilder software (Designbuilder, 2014). Then a sensitivity analysis was done to compare the relative importance of the different strategies. Last, integrated design solutions were defined by combining the strategies that provided the highest energy benefits for the building in each step. These combined strategies were also tested to examine the energy saving potential of corridor design.

School building model

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The corridor typologies to be studied were identified based on literature and on the investigation of local school designs in the cold climate of China (Zhang and Li, 2000). In total, three corridor designs were identified (Figure 1): Double-sided corridor (Type A), in which classrooms are on both sides of a corridor, one-sided enclosed corridor (Type B), in which classrooms are positioned on one side of an enclosed corridor, one-sided open corridor (Type C), in which classrooms are positioned on one side of an open corridor.

Double-sided corridor school building (Type A)	One-sided enclosed corridor school building (Type B)	One-sided open corridor school building (Type C)

Figure 1: Classification of three types of school buildings according to corridor design in the cold climate of China

To simulate the three corridor designs in Designbuilder, a rectangular volume was selected as the basic shape since the rectangular shape accounts for a large proportion of school buildings in China. The size and numbers of various rooms were kept identical for each type as shown in figures in Table 1. The U values of external walls, internal walls and roofs were set as 0.35, 1.05 and 0.49 W/m^2K separately. Moreover, the zones were assumed to be occupied between 8:00-12:00 & 14:00-17:00 (Monday–Friday). Typical Chinese school holidays including vacations in the hot summer and cold winter accounting for 95 days in a year were considered. In addition, the minimum required illuminance level of classrooms is 300 lux and the corridor and staircase require at least 100 lux (Code for design of school, 2011).

Corridor space characteristics

Corridor design parameters were classified into five categories: form and orientation, temperature control, opaque envelope components, glazing, ventilation and infiltration. A summary of the corridor design variables are presented in Table 1 and introduced as below.

	Double-sided corridor (Type A)	One-sided enclosed corridor (Type B)	One-sided open corridor (Type C)
Configuration.

[b] Best practice building from Designbuilder (Designbuilder, 2014).

Table 6: Three school building models and investigated corridor design parameters

The four principal orientations: 0° (south), 90° (west), 180° (north), and 270° (east) were considered. The orientation variations were obtained by rotating the whole building clockwise. The width of corridor were set as 1.5m, 2.4m and 3m, which represent the mean value of three periods (before 1980, 1980s, 1990s to now) of school design in China (Wang, 2007). In accordance with the code for school design (Code for design of school, 2011) the standard temperature range of corridors in schools is 16°C-26°C. Two of these ranges for internal temperature in the enclosed corridor spaces were also simulated with following values: 14°C-28°C and 12°C-30°C. This strategy is inapplicable for the open-sided corridor building type. For Types A and B, the U values of external corridor walls were changed to 0.30 and 0.25 W/m²K, and the U values of roof insulation changed to 0.35 and 0.15 W/m²K. The double glazing was set as the base case of the experiment, and then replaced by single glazing, triple glass and low-e double glazing. Table 2 shows the different characteristics of each glazing type. For Type A and B, the variations were applied to the exterior corridor walls, and for Type C changes were applied to the external walls of the classrooms adjacent to corridor. The range of exterior window to wall ratio was 20% to 40% according to local standards (Code for design of school, 2011). Lastly, different mechanical ventilation rates combined with various basic infiltration rates for enclosed corridors were also simulated for Types A and B.

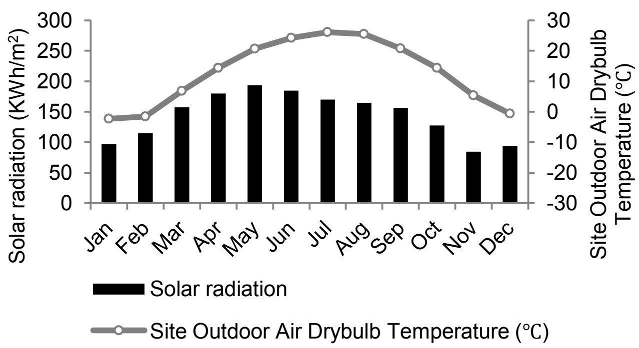

Figure 2: Yearly solar radiation and outdoor air temperature of Tianjin

Glazing description	Solar transmittance	U-value (W/m² K)
Type A. [Sgl: Clr 6 mm]	0.82	5.78

Table 7: Characteristics of the different glazing types

Climate data

This study employed the climate data of Tianjin (39.13N, 117.20E) in China, known as a cold climate city based on the climatic classification of Köppen–Geiger. The solar radiation and outdoor dry air temperature are presented in Figure 2.

3. RESULTS AND DISCUSSION

3.1. Effect of each corridor design parameter

Figure 3 shows the influence of form and orientation on the energy demand of school buildings. As expected, Type C consumes the least energy in most cases with no extra air conditioned corridor space, while Type B has the highest energy demand in all cases. Moreover, buildings with 0°(south) and 180°(north) rotation angle show less energy use than other orientations. This is explained by the significant variation in cooling energy demand. For heating and lighting, there are only small variations. Considering corridor depth, the energy demand increases steadily as the corridor width increases except for Type C where the effect is marginal. In addition, it can be observed that for the two enclosed corridor types (Type A and B), the energy variation can primarily be attributed to the increased energy demand of the corridor itself (Figure 4).

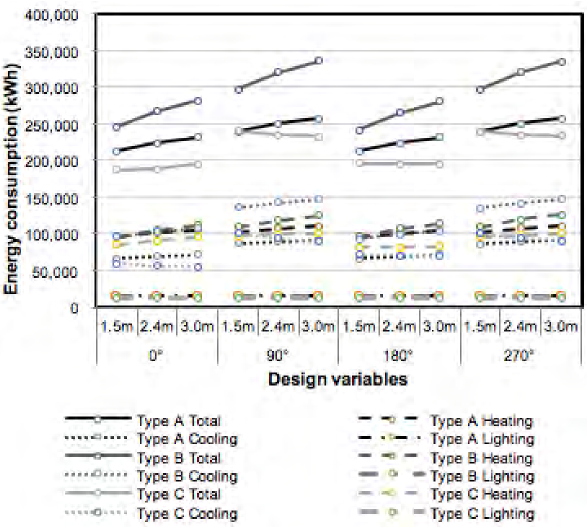

Figure 3: Annual energy consumption for different forms and orientations

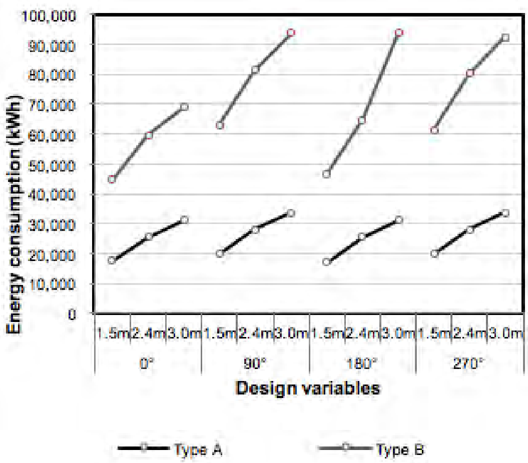

Figure 4: Annual energy demand of corridor space for different forms and orientations

Figure 5 shows that building energy demand decreases with the increase of the allowed temperature range in the corridor; however the trend is much more apparent for Type B but becomes less obvious for Type A. It can be explained by the fact that the corridors in Type A have less interfaces connected to the outside and it therefore becomes easier to maintain the indoor temperature. Figure 6 shows that annual energy savings of corridor space can reach 29,000 kWh for Type B but only 11,000kWh for Type A.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

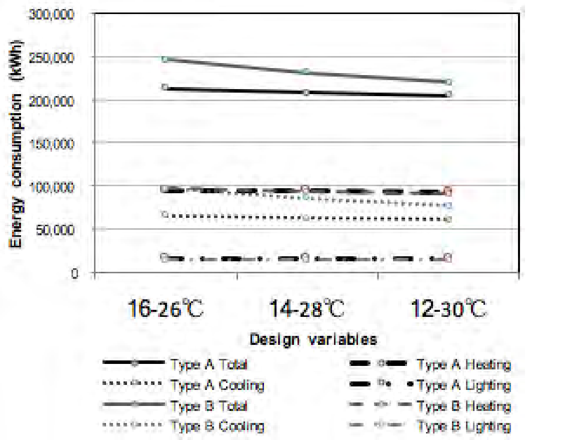

Figure 5: Annual energy consumption for different temperature control

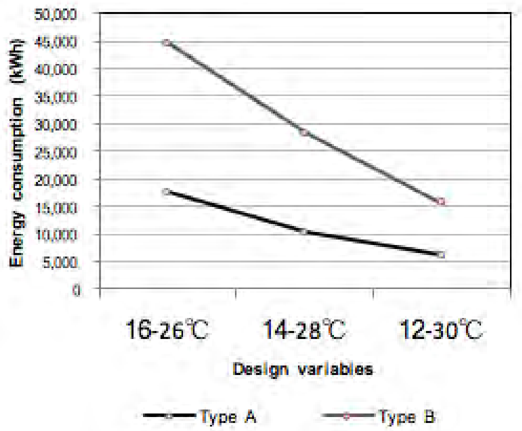

Figure 6: Annual energy demand of corridor space for different temperature control

For opaque envelope component design (Figure 7 and Figure 8), the change in building energy demand is only marginal and does not appear to be affected by varying the U values for corridor walls and roofs. This result suggests that simply increasing corridor wall and roof insulations regardless of other parameter designs may not lead to expected energy savings in the cold climate of China.

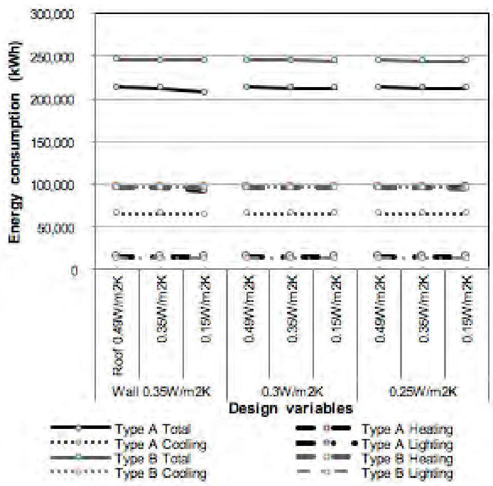

Figure 7: Annual energy consumption for different opaque envelope designs

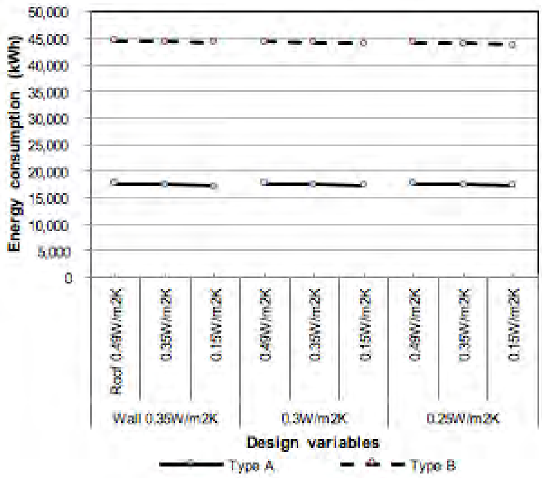

Figure 8: Annual energy demand of corridor space for different opaque envelope designs

Figure 9 shows the effect of various glazing ratios and types on the energy demand. Low-e double glazing performs slightly better than the other three glazing materials for Type B. But it has almost no effect for Type A and C. Moreover, for Type B and C, heating energy demand increases when the WWR decreases while cooling energy demand steadily decreases with the decrease of WWR. This leads to a marginal decrease of the total energy demand of Type B and a slow energy increase for Type C when the WWR decreases. Furthermore, Figure 10 shows that the energy savings with the decrease of the window to wall ratio is more obvious in low performance glazed rooms (double and single glazing) but becomes less significant in high performance glazed rooms (triple and low-e glazing). In addition, for Type A the energy variation in all aspects is negligible due to much less window area of the corridor space.

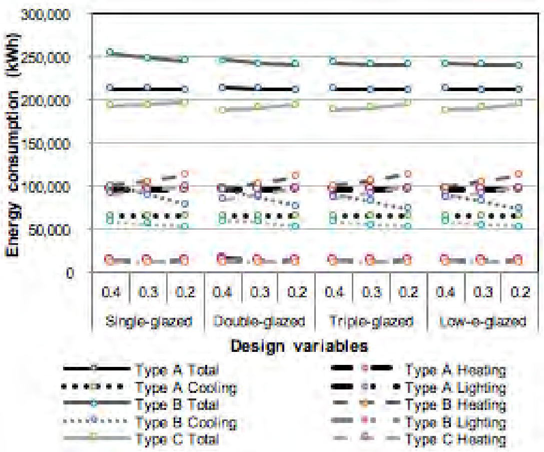

Figure 9: Annual energy consumption for different glazing

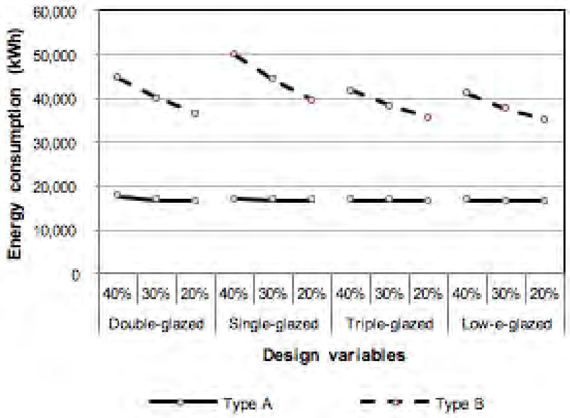

Figure 10: Annual energy demand of corridor space for different glazing

Figure 11 and Figure 12 show that both the total building energy demand and the corridor energy demand increase steadily as the ventilation and infiltration values increase. The reason is that the heating energy growth rate is larger than the decrease rate of cooling energy demand. In winter, a higher air exchange rate allows more cold air into the building, thus leading to the increase of heating energy demand. In contrast, in summer, a higher air exchange can dissipate indoor heat more quickly to the outside resulting in a lower energy demand.

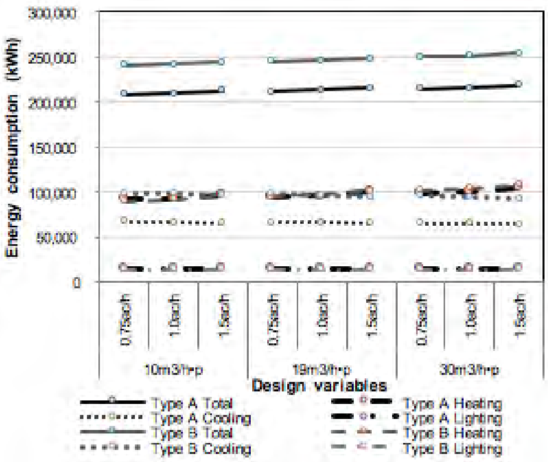

Figure 11: Annual energy consumption for different ventilation and infiltration

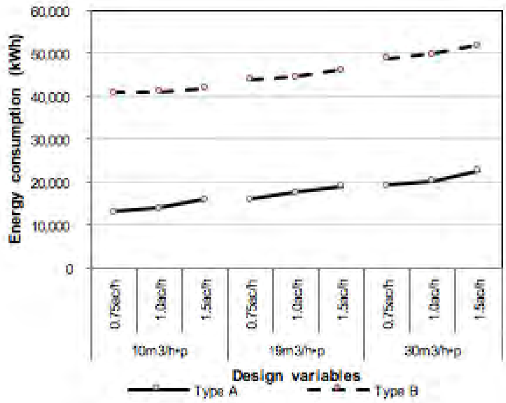

Figure 12: Annual energy demand of corridor space for different ventilation and infiltration

A sensitivity analysis was set up in order to understand the influence of each corridor design variable series. The total building energy consumptions for five design series were summarized and displayed using a boxplot shown in Figure 13. Form and orientation of corridors has the highest effect on total energy consumption for all building types especially for Type B, of which the energy variation can be 93,000kWh. This indicates that inappropriate design of form and orientation may result in very high energy consumption. Contrary, opaque envelope design results in a minimal energy change. Both glazing ratio and the corridor material have a relatively larger influence on the total energy demand of building types B and C while the effect on Type A is marginal. In addition, temperature control in corridors is more influential for Type B whereas the ventilation and infiltration strategy has a similar modest effect on building types A and B.

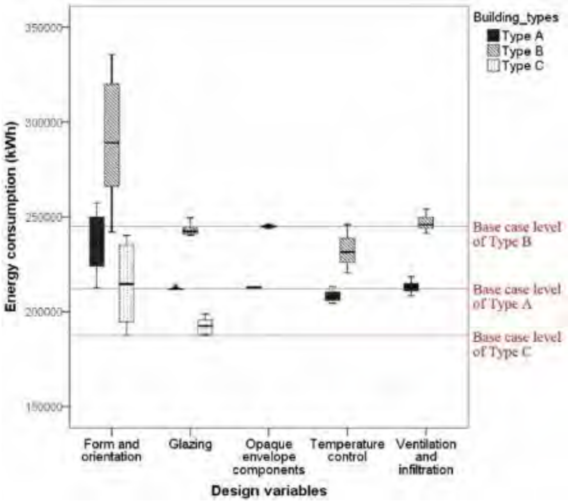

Figure 13: The relative importance of corridor design variables

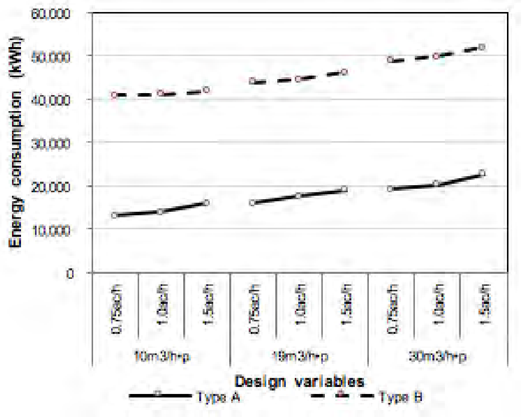

Figure 14: Comparative energy analyses of the optimized design and the basecase design

3.2. Integration of corridor design strategies

According to the results obtained from the previous analyses, an integrated design solution was defined. The final combination of the design of the corridor was selected based on the strategies that provided the highest energy benefits for the building in each step. Comparing the results of the optimized design to the base case shows that the strategies are quite effective. The combination of energy-saving measures reduces the total energy consumption by 6% for Type A and 17% for Type B (Figure 14). It is noteworthy that for Type C the base case has the best energy performance parameters thus there is no energy variation for the optimized design.

4. CONCLUSION

In this study, the effect of corridor design parameters on building energy demand was assessed for three types of school buildings in cold climates. Considered design strategies are: form and orientation, temperature control, opaque envelope components, glazing, ventilation and infiltration. The main findings of this study are as follows:

- Generally, Type C consumes the least energy annually while Type B has the highest energy demand.
- Form and orientation of corridors can significantly affect the total building energy consumption. Buildings with 0°and 180°rotation angle perform better than other orientations. Narrow corridors have the best performance for Type A and B while the effect is only marginal for Type C.
- Considering glazing, we found that corridors equipped with a 20% WWR of low-e double glazing results in the highest energy-savings for both Type A and B. For Type C a double glazing with a 40% WWR has the lowest energy demand. Moreover, the influence of glazing on the building energy consumption is larger for Type B and C whereas the effect on Type A is marginal.
- The design with the widest temperature range and the lowest ventilation and infiltration rates can achieve the minimal building energy consumption. However, temperature control brings more energy benefits for Type B than A while ventilation and infiltration strategy has a similar, modest, effect on both types.
- The design of the opaque envelope component for corridors has little effect on the energy demand.
- Finally, the integration of the corridor design solutions offers a saving in total energy by around 6% and 17% for Type A and B respectively. For Type C, the base case has the best energy performance.

This study indicates that corridor parameters should be carefully addressed when designing school buildings. Proper design of form and orientation combined with other elements, such as glazing, temperature control, ventilation and infiltration will noticeably reduce building energy demand. Further research will try to clarify other corridor design parameters like shading which could also have potential effect on the energy consumption.

ABSTRACT

Construction materials are a crucial part of our built environment, but whilst the energy use of buildings is often discussed, rarely is their material consumption. Furthermore, with increasing populations and urbanisation, demand for these materials continues to increase, and in turn, so will the embodied environmental impacts created from the extraction, processing, transport and maintenance of these materials. Shorter building lifetimes are also becoming more prevalent, in part due to densification in urban areas. This creates both wasted materials and embodied impacts. A suggested greenhouse gas mitigation strategy is therefore to extend the lifetime of materials/components, e.g. through reuse, in order to displace the need for new materials and their associated impacts.

However, this calls for a new way of thinking about the built environment, it becomes a system of stocks and flows, where the output flows should be redirected into inputs. However, this requires a much greater understanding of this system, which is in essence the material metabolism of the built environment. To date, research in this area has largely focused on single buildings, and techniques such as design for deconstruction and reuse that seek to improve the availability of reused materials, this could be thought of as a circular economic approach. However, for a true assessment of circular economic potential, a single building is not sufficient, as it provides a limited feedstock for future buildings. To capture the full extent of flow interactions, a wider system should be investigated – that of a neighbourhood/city - enabling better identification of the interdependencies that exist and potential synergies to be made between these flows, across multiple scales. This paper presents the background literature and an initial scoping exercise of such an assessment, focusing on a neighbourhood in Sheffield, England.

Keywords: circular economy, material metabolism, embodied energy

1. INTRODUCTION

With the Paris agreement at COP21 there was a global consensus to act on climate change, and to mitigate greenhouse gas emissions. All countries in the agreement must regularly report on their emissions, and define their 'Nationally Determined Contribution' (NDC), with the aim that temperature rises will be kept well below a 2 degree rise (United Nations, 2006). As countries ratify the agreement and propose their NDC targets they will need to be implementing mitigation strategies that maximise all opportunities. Cities account for 75% of global greenhouse gas emissions, so will likely be the focus of these strategies (UNEP, 2016). Transport emissions and those from energy use in buildings are two commonly targeted areas. However, emissions associated with the materials that construct cities are rarely considered, these emissions are termed embodied and include all those emissions attributed to material extraction, processing, transport, manufacturing, maintenance and end of life. The carbon dioxide associated with the production of the steel and cement that goes into the built environment contributes at least 3.2 $GTCO_2$/year (estimated from Allwood et al. 2012). Thus, to maximise potential reductions, material choices and construction strategies should be a part of all countries' greenhouse gas mitigation strategies. Hand in hand with this, is a need to preserve natural resources, which the built environment has a huge draw on. If materials in the built environment are thought about as a system then there are three key components, the inputs, the stock (those materials in-use) and the outputs, which are frequently thought of as demolition waste. This system could be termed the material metabolism of the built environment and could be studied at many different scales, from neighbourhood, to city, to country. If the environmental impacts of material metabolisms are to be reduced, then a good understanding of the volume and types of materials is required throughout the system. This would also open up the opportunity to understand the potential for redirection of material flows, turning outputs into inputs.

This approach has most recently been termed a circular economic approach, as championed by the Ellen MacArthur Foundation (2015), where the emphasis is on maintaining the asset value of resources. Keeping materials in circulation for as long as possible should reduce the requirement for new materials and thus their associated embodied impacts. This approach has been successfully deployed where product sharing/leasing is beneficial, such as tool sharing (Ellen MacArthur Foundation, Unknown date), products which have a relatively short life span have also been identified as a priority and studied, where examples include mobile phones. (Ellen MacArthur, 2012). However, the longer life spans in the built environment do present some challenges, particularly around traceability and evolving standards. There is also currently little understanding of the material stock in sufficient detail to understand circular economic potential.

This paper presents a summary of existing research on the application of the circular economy in the built environment, as well as an overview of analysis techniques that could be applied and adapted to understand circular economic potential at a neighbourhood scale. A pilot case study is then summarised to demonstrate the potential of the approach.

2. STATE OF THE ART

There are two key areas of existing research that contribute to this idea of understanding and optimising the material metabolism of the built environment: (1) research that explores circular economic approaches in construction – these ideas could be applied to optimise the system; and (2) material flow analysis of the built environment as these methods can be applied to quantify system inputs, outputs and stock. The following two sub-sections provide a summary of some of the key literature in these areas.

2.1 The circular economy in construction

The circular economy encapsulates a series of different ideas that focus on moving away from linear waste streams to closed loop, circular systems, effectively prioritising the higher levels of the traditional waste hierarchy, such as reuse. A key distinction of the circular economy as outlined by the Ellen MacArthur Foundation (2015) is the emphasis on maintaining asset value and explicit separation between biological and technical material streams. The introduction of a 'share' resources/products to the system is also new when compared to the traditional waste hierarchy, and could be applied to the sharing or co-occupancy of space in a built environment context or potentially leasing of a product or service. The technical side of the Ellen MacArthur Foundation diagram (2015) has the following strategies in order of priority: share, maintain/prolong, reuse/redistribute, refurbish/remanufacture and recycle. These strategies aim to keep resources in circulation at a high a value as possible.

Introduction of a circular economic approach into construction can be seen at a building level, as identified in the case studies explored by Cheshire (2016). Magdani (2016) also outlines a building level approach taken at BAM Construct UK, discussing their first circular project, Brummen Town Hall in the Netherlands. This project was particularly suited to this approach as the client wanted a building that would last 20 years, but occupancy was uncertain after this time frame. This meant that the project was designed for deconstruction and material reuse, so that elements could be easily separated at tend of life, elements such as structural timber could be returned under a contract to the suppliers, retaining value (Magdani, 2016).

A broader country wide approach to introducing the circular economy in construction is suggested by Esa et al. (2016), who explore strategies to manage construction and demolition waste in Malaysia from a circular economic approach. A review of existing research on the reduction of construction and demolition waste is conducted, using this as a basis for the development of a theoretical framework to introduce a circular economy that works across scales (Esa et al., 2016).

However, whilst a circular economic approach could be introduced to simply prioritise and manage construction and demolition waste, for the opportunities to be most clearly recognised it would be useful to have a clear understanding of existing stocks of materials and to estimate the circular economic potential of these. Thus, when a decision is taken whether or not to demolish, the circular economic value would be known, which could in turn influence the demolition strategy, so for example, if a high reuse potential was identified, the building might be systematically deconstructed to facilitate maximum material/element salvage with minimal damage. Literature to date has not explored circular economic potential of neighbourhoods or cities. However, the academic fields of

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

urban metabolism and material flow analysis are applied in order to understand material metabolisms, although this is often at high level. The next section presents an overview of research in this area.

2.2 Material flow analysis in the built environment

This section summarises some of the key studies that have conducted material flow analyses of the built environment in order to improve understanding of material metabolism. The global growth in demand for materials, from 1900-2005, was estimated by Krausmann et al. (2009). They show that the pace of use of materials has increased, and predict that due to the relationship between the demand for materials and economic development there will be a sharp rise in material demand from developing countries as they grow their economies. Tanikinawa et al. (2015), Ortlepp et al. (2015) Brattebo et al (2009), Wang et al. (2015), Huang et al. (2013) and Fernandez (2007) take a country level approach to assess the material metabolism (or elements of it). Whereas, Wiedenhofer et al. (2015) take a regional approach, Rosado et al. (2016) focus on the material metabolism of cities, and Marcellus-Zamora et al. (2016) take a more neighbourhood approach, exploring a 3km^2 area of Philadelphia. There are however methodological similarities across these. Tanikinawa et al. (2015) provide a comprehensive analysis of the different material flow analysis methods that have been used to assess material stocks, categorising these into bottom-up accounting, top-down accounting, demand-driven modelling and remote sensing approaches. Their definitions can be summarised as follows: bottom-up accounting is a snap-shot inventory of objects within a defined area; top-down accounting uses time series, statistical data to follow material inputs, stocks and outputs within a system; demand driven modelling explores the demand for materials for certain end uses over time, using indicators such as population to model future demand; finally, remote sensing pinpoints areas of human activity and associated stocks using satellite based data, making it particularly useful for areas with insufficient statistical data.

A bottom up approach is taken by Tanikinawa (2015) to estimate the historical material stocks in the built environment of Japan, mapping the masses of materials across the country, and highlighting the build-up in stock of construction materials such as cement and aggregate. Ortlepp et al. (2015) calculate material composition indicators, extrapolating these with a bottom up approach that estimates floor areas for non-domestic buildings in Germany, in order to estimate total material stocks in non-domestic buildings in Germany. Ortlepp do highlight 'that greater knowledge is required of the quantity and quality of materials within the built environment in order to calculate output flows accurately and thus to support resource recovery', this is indeed is key if the circular economic potential of material stocks is to be assessed. Brattebo et al. (2009) take a more top down approach, supplemented with demand modelling to explore the energy and material metabolism of the building stock in Norway, focusing on residential stock and road bridge stocks, mapping historical use and scenario modelling future options. The use phase was shown as the dominate area when life cycle energy is estimated for these residential stocks. Associated masses of concrete and wood stocks and flows are also estimated, although as this is total mass, without use type there is insufficient detail to estimate circular economic potential.

There are a series of studies that investigate the material metabolism of China, with Wang et al. (2015) estimating the iron and steel stocks throughout China's economy, including the construction sector. They combine bottom-up sampling with top down mass balancing, concluding that reinforced concrete construction was the major driver for stock growth, but only a fraction of these stocks are currently recovered at end of life. This is particularly troublesome when the circular economy is considered as the value of materials is not being maintained when buildings reach the end of their life. In reality, with current design approaches, the best circular economic outcome for reinforcement steel would be to separate from concrete contamination and recycle the scrap in electric arc furnaces. Huang et al. (2013) take a broader approach, combining top down and demand modelling to estimate the material demand of construction in China, suggesting that the demand for iron ore and limestone will begin to decrease after 2030. They also suggest that increasing building lifetimes and recycling demolition material would reduce the demand for new material. This starts to come in line with a circular economic approach, although the data resolution is insufficient for a full assessment that incorporates reuse potential. An earlier study by Fernandez (2007) also estimated the material demand of new construction in China, assessing the material intensity of three major building types and scaling to estimate demand. The circular economy is also explicitly addressed in this work, suggesting two key areas to target (1) building design and (2) urban planning. Fernandez (2007) stresses the need to analyse the metabolism of cities, and suggests that 'material and energy flows are tracked, recorded, and used to develop future targets', it is also suggested that this type of analysis should be used to inform city planning.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Wiedenhofer et al. (2015) model the material metabolism of residential buildings and transport networks in the EU25, using a dynamic bottom-up modelling strategy. They suggest that for non-metallic minerals, maintenance-related inputs are significant, varying between 34% and 58% of domestic material consumption. They also highlight the significance of recycling, suggesting that if all recycled materials are used for stock maintenance they could account for 75% of this input demand.

Rosado et al. (2016) take a city wide, top-down approach to the material metabolism, analysing historical use in three metropolitan areas in Sweden. They highlight the problem that 80% of resources consumed are non-renewable, thus requiring a circular economic approach to this material to maintain value. The role of recycling to reduce the demand for import of materials and to retain non-renewable resources is also emphasised. However, they state 'there is an imbalance between the types of materials consumed and stocked, which limits the proportion of the consumption that could potentially be recovered by recycling' (Rosado et al., 2016).

Existing material flow analysis studies have predominately focused on the recycling potential of stocks when considering end of life scenarios. This is appropriate as the majority of studies estimate masses of different materials, so recycling potential can be estimated, whereas the preferred circular economic strategies, which maintain higher value of material require a more detailed understanding of the material metabolism. To ascertain opportunities to prolong building life, or reuse elements a much more detailed understanding is required of individual buildings, for example what is the construction technique, how are elements joined together, what is the age of the building and how does this influence the former details. Creating this understanding will require multiple datasets and combined material flow analysis approaches. The next section gives an overview of a pilot study conducted in order to explore and test the validity of this approach.

3. CASE STUDY ASSESSMENT

A bottom up approach was taken to conduct a material flow analysis on Walkley, a neighbourhood of Sheffield in the UK, with an emphasis on using existing, freely available data. Two main datasets where utilised: Light detection and ranging (LiDAR) and digimap, and Geographic Information System (GIS) software was used to handle and manipulate the data. LiDAR uses a pulsed laser to measure variable distances, the dataset used from the UK Environment Agency was collected from the air, and provides terrain mapping, which is typically used for flooding analysis (Environmental Agency, 2016). By subtracting the Digital Terrain Model from the Digital Surface Model, a dataset can be created which shows all objects above ground level, including buildings and vegetation. When this data set is combined with digimap, which gives geospatial data from ordnance survey, building massing can be derived. It was found from spot surveys that LiDAR provides better height data than digimap, so combining these two datasets gives a more accurate building stock massing. An example output showing a highlighted street, which was studied in detail, is shown in Figure 1.

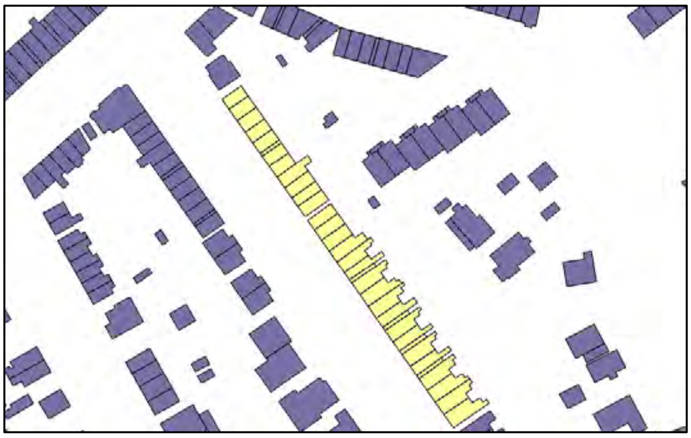

Figure 40: Example mapping output, with the street selected for detailed assessment shown in yellow.

Walkley, the case study neighbourhood, consists of largely low-rise residential buildings, the age profile of the housing in this area is shown in Figure 2. This shows that the housing stock in the area is relatively old, with 75% of the housing constructed pre-1925, 3% 1925-1955, and 22% post 1955. The street under assessment consists of brick construction. The GIS model was used to estimate the total volume of bricks in this street (see Durkin & Densley Tingley, 2016 for details of this calculation and the associated assumptions). The number of bricks in this street was estimated at 475,000. Norby et al. (2009) assess criteria for brick reusability, which is largely dependent on mortar type, Table 1 summarised their findings. If the age profile of the area is assumed to be reflective of this street, an estimated 364,800 bricks could be salvaged for reuse. Considering the value of this future resource, the price of a new brick in the UK is approximately 75p, so this asset of bricks can be valued at £273,600, and when using current embodied carbon factors, equates to an expended embodied carbon of 200,640 $kgCO_2$.

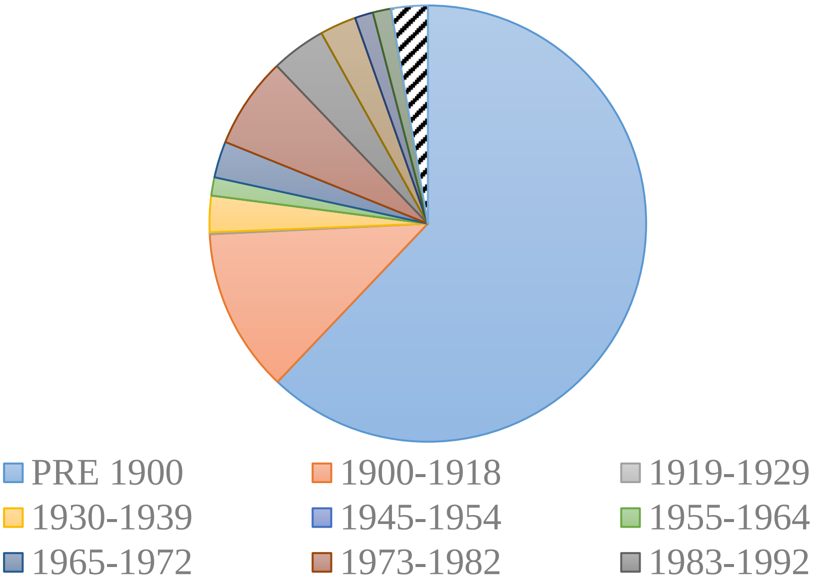

Figure 41: Housing Stock Age Profile, data taken from Consumer Data Research Centre (2016)

Age	Mortar types in Europe	% Brick Reusability
Pre-1925	Likely to be lime mortar	100%
1925-1955	Could be lime, cement, or a mixture	60%
Post-1955	Likely to be cement	0%

Table 1: Mortar Types in Europe and Brick Reusability Assumptions

4. CONCLUSIONS

This paper has summarised some of the key literature on the use of the circular economy in the construction sector, and has reviewed a range of material flow analysis techniques to ascertain the state of the art in these areas and explore their current limitations. A pilot case study on a street in Walkley, Sheffield is then conducted to test a bottom-up, remote sensing method that seeks to gather information at a high resolution. This pilot case study demonstrates the potential of this approach to develop a detailed understanding of the material metabolism of a neighbourhood, and estimate its circular economic potential. Further work will seek to develop this approach, reducing the number of assumptions required, expanding to time series data and estimating the uncertainty in results. The potential for automation of material recognition will also be explored. Furthermore, additional datasets, for example planning information will be sought, testing their use and integration into GIS to provide further detailed information on the building stocks. The current approach focuses on the façade materials, but if this is combined with material intensity estimates, such as those used by Ortlepp (2015), a greater understanding of the whole material metabolism could be developed. Although defining material use type e.g. steel reinforcement, steel I-Beam will be required so the range of circular economic potential can be assessed. By advancing techniques to develop a detailed understanding of the material metabolism of cities more strategic decisions can be made about a neighbourhood's building stock, enabling the value of resources to be maintained at the highest level possible, and environmental impacts from new resource use reduced. This paper is the first step in a piece of work to generate a detailed understanding of these material metabolisms and thus shape more strategic use of existing and new buildings.

ABSTRACT

Using industrial outputs (coproducts) of multiple product (multifunctional) processes as mineral admixtures in cement making became a consolidated practice, driven by CO_2 reduction oriented strategies adopted over the past decades. Brazilian cement makers now revise their strategic planning for the years to come. Life cycle assessment (LCA) allows consideration of manifold environmental impact categories to provide a broad evaluation of both material and process loads. Multifunctional processes modelling remains, however, as a challenging task within LCA practice. The most common approach used for such modelling credits the avoided burdens related to the substituted product to the multifunctional process that generated the recycled coproduct. Still, the 'avoided burden' approach fails to fairly distribute recycling effects across the partnering industries that enable it. This paper assesses the 'net avoided loads' by using four mineral admixtures to replace clinker in cement production: blast furnace slag, fly ash, calcined clay and limestone. LCA platform and impact method used were, respectively, SimaPro 7.3 and CML 2001 (baseline). For coproduct mineral admixtures (blast furnace slag and fly ash), we fully modelled the recycling effects and assigned the corresponding avoided and generated loads to each player in the joint industrial system, following the 'avoided problem' approach. From the admixtures studied, calcined clay clearly performed worst in all impact categories predicted by CML, whilst ggbfs and fly ash behaved similarly and avoided the largest net loads in all categories. For blended cements, low clinker replacement ratio cements had environmental results very close to the reference. Despite its medium clinker replacement ratio, CP-IV-32 (28%-calcined clay) results were clearly biased by that admixture's poor performance. The cements with the highest clinker replacement ratio performed best: 66%-slag CP III-32, followed by 50%-fly ash CP IV-32. The 'avoided problem approach' allowed a complete and coherent modelling of recycling implementation within cement manufacturing. Information on 'net' impact avoidance enlightens and can scientifically ground cement industry's strategic agenda for sustainable practices.

Keywords: life cycle assessment, multifunctional processes, cement mineral admixtures

1. INTRODUCTION

Brazilian cement production increased from 39.4 Mt in 2001 to 72.0 Mt in 2014 [1]. This manufacturing magnitude, however, is followed by environmental impact significance. Cement making is responsible for 5% of total global anthropogenic emissions [2], and is one of the great contributors to natural resources depletion.

To decrease its impact potentials, Brazilian cement industry has long profited from collaboration with different industrial sectors, to replace carbon intensive clinker with varied mineral admixtures. Table 1 describes the normalized types of Portland cement available in the country, along with respective clinker replacement ratios.

Type	Acronym	Content (% in mass)				National standard
		Clinker	ggbfs[a]	Pozzolana	limestone	
Portland Cement	CP I	100	0			[3]
	CP I-S	99-95	1-5			
Portland-Composite cement	CP II-E	94-56	6-34	0	0-10	[4]
	CP II-Z	94-76	0	6-14	0-10	
	CP II-F	94-90	0	0	6-10	
Portland-Blast furnace slag cement	CP III	65-25	35-70	0	0-5	[5]

Life cycle assessment (LCA) stands out as a robust method to account for a material's environmental performance, however, some methodological issues hinder its thorough application. The choice of impact distribution methods in multifunctional processes gives rise to extensive debates, which directly affect strategic decision making by companies that use coproducts as alternative input material.

National studies aiming to document Portland cement's environmental loads typically disregard coproduct impacts, considering bfs or fly ash as mere residues. Such practice therefore disregards international LCA trends, especially a EU directive [7], which shifted some types of waste to coproduct status, which would then bear corresponding environmental loads.

Saade, Silva and Gomes (2015) [8] assessed how different impact distribution methods affect bfs attractiveness to the cement industry, and considered the avoided burden approach as the most coherent method to model recycling processes, though it needed adaptation to the recycler's perspective. Further research then proposed an 'avoided problem' approach to adjust distribution of recycling effects into the industry partners enabling it [9].

This paper applies such 'avoided problem' approach in LCA to calculate the 'net' avoided loads that arise from using calcined clay, limestone and two coproducts (blast furnace slag and fly ash) as clinker replacements in blended cement production.

2. METHODOLOGICAL APPROACH

Given our focus on modelling multifunctional (steelmaking and coal-based electricity generation) or monofunctional (calcined clay and limestone making) processes, we performed cradle-to-gate LCAs and excluded use and end-of-life stages.

Firstly, actual avoided burdens were calculated using the 'avoided problem approach' [9], following Equation 1.

$$I_{net} = I_{subst} - [I_{proc} + I_{other} - I_{EOL}]$$

Equation 1

Where I_{net} is the 'net' avoided burden; I_{subst} is the impact avoided by replacing a giving product with a coproduct; I_{proc} is the coproduct processing impact, I_{EOL} is the coproduct's end-of-life impact, if not productively used; and I_{other} are all other loads that may arise to enable coproduct recycling, e.g. transportation loads.

In the case of monofunctional process outputs, such as calcined clay and limestone, I_{proc} represents the manufacturing loads, and I_{EOL} equals zero.

Secondly, the avoided/added burden related to solving coproduct end of life or material supply problems is respectively assigned to the multifunctional and recycling partners, following the 'avoided problem approach' illustrated in Figure 1.

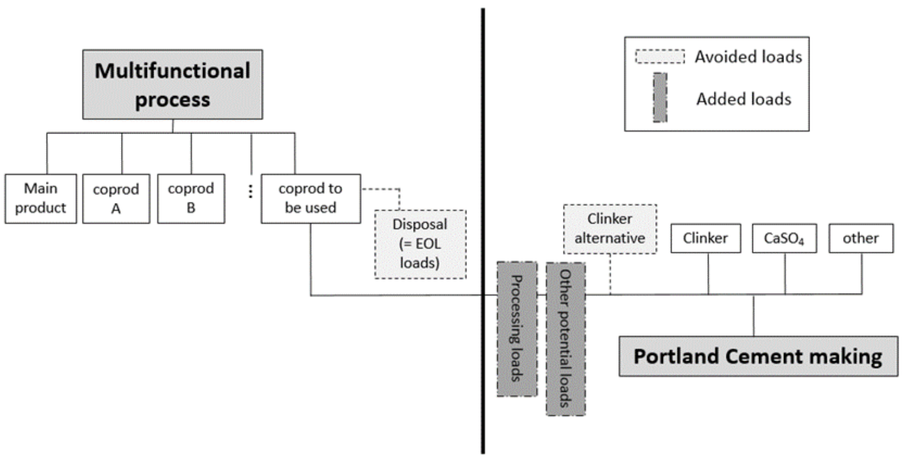

Figure 1: Impact distribution according to the avoided problem approach (adapted from [9])

Blended cement production cycle modeling used foreground data collected from national reports [10]. Due to the lack of national information, fly ash and blast furnace slag processing were modeled after [11], whilst end of life data came from adapted Ecoinvent v 2.2 data, by switching the default energy grid to the Brazilian correspondent. Limestone foreground data was also adapted from Ecoinvent v 2.2 in the same way. Calcined clay foreground data was obtained from a local cement making company. As it only produced CP IV-32 with 28% of clinker replaced, that was the only cement with calcined clay modeled. All background data came from the Ecoinvent v 2.2 processes, adapted with Brazilian energy mixes.

Table 2 summarizes technical properties, cement composition, LCA inputs and tools used in the assessments. Impact assessment results covered natural resources depletion, human health and ecosystem quality, divided in the ten impact categories calculated by CML 2001 (baseline).

	CP I-S-32	CP II-E-32	CP II-Z-32	CP II-F-32	CP III-32	CP IV-32	CP IV-32
% clinker replaced	5%	30%	10%	10%	66%	50%	28%
Functional unit	Step 1: 1 ton of blended cement*						
Reference flow	50kg $CaSO_4$	50kg $CaSO_4$	50kg $CaSO_4$	50 kg $CaSO_4$	50 kg $CaSO_4$	50kg $CaSO_4$	40kg CaSO4
	900kg clinker	650kg clinker	850kg clinker	850kg clinker	290 kg clinker	450kg clinker	680kg clinker
	50kg ggbfs/fly ash/limestone	300kg ggbfs	100kg fly ash	100kg limestone	660kg ggbfs	500kg fly ash	280kg calcined clay
Impact evaluation method	CML 2001 (baseline)						
LCA platform	SimaPro 7.3						

* Step 2: the functional unit was the 'equivalent binding capacity of 1 ton of clinker', and the reference flow was the corresponding mass of each admixture analysed

Table 2: Technical properties, compositions and tools used in cement LCAs

In the first analysis step, the functional unit only considered the replacement of clinker with the same mass of admixtures, disregarding their binding capacity. In the second step, the equivalent binding capacity [12] of the clinker replacement materials was factored in (Equation 2).

$$BE = cem + k.SCM$$

Equation 2

Where BE stands for binding equivalent value, cem stands for remaining clinker dosage, k is the admixture's coefficient and SCM is the admixture dosage.

K-values for ggbfs and fly ash are 0.9 and 0.6, respectively [11]. Thienel and Beuntner (2012) [13] determined a range of calcined clay's k-values between 0.6 and 1.0.

Some researchers try to calculate limestone's contribution to cement mechanical strength development [14]. Addition of limestone itself does not form calcium silicate hydrates (C-S-H), but rather increases particle dispersion and triggers nucleation, which accelerates C-S-H formation. Due to its reduced binding capacity, limestone was excluded from this analysis phase.

3. RESULTS PRESENTATION AND DISCUSSION

3.1. Clinker replacement net loads

The net environmental loads resulting from replacing clinker with the same mass of the different admixtures studied were calculated according to Equation 1. Calcined clay clearly performed worst in all impact categories predicted by CML, whilst ggbfs, fly ash and limestone achieved similar avoided loads (Table 3).

Impact category	Unit	ggbfs	fly ash	calcined clay	limestone
Abiotic depletion	kg Sb eq	1.42	1.49	-0.26	1.56
Acidification	kg SO_2 eq	1.03	1.31	0.84	1.25
Eutrophication	kg PO_4--- eq	0.24	0.25	0.18	0.23
Global warming	kg CO_2 eq	866.45	885.19	858.20	887.89
Ozone layer depletion	kg CFC-11 eq	1.45E-05	1.54E-05	-2.00E-05	1.53E-05
Human toxicity	kg 1,4-DB eq	47.27	51.82	21.16	46.81
Freshwater ecotox.	kg 1,4-DB eq	14.22	15.77	10.29	14.60
Marine ecotox.	kg 1,4-DB eq	37933.71	40967.65	15376.48	39558.91
Terrestrial ecotox.	kg 1,4-DB eq	1.10	1.22	1.03	1.18
Photochemical oxidation	kg C_2H_4 eq	0.03	0.05	0.02	0.05

Table 3: Net avoided loads associated to replacing 1 ton of clinker with 1 ton of different mineral admixtures

When binding capacity was taken into account (Table 4), clinker replacement with calcined clay again performed worst, particularly in terms of abiotic and ozone layer depletion categories. Top calcined clay k-value limit equals clinker's equivalent binding capacity, but at an environmental cost that makes its replacement counterproductive. When working at the lowest calcined clay k-value, binding capacity rivals that of fly ash, but also at a negative environmental performance.

Impact category	Unit	ggbfs (k=0.9 [11])	fly ash (k=0.6 [11])	calcined clay (k=0.6 [14])	calcined clay (k=1.0 [14])
Abiotic depletion	kg Sb eq	1.40	1.39	-1.53	-0.26
Acidification	kg SO_2 eq	1.00	1.31	0.53	0.84
Eutrophication	kg PO_4--- eq	0.24	0.25	0.13	0.18
Global warming	kg CO_2 eq	862.49	873.62	828.52	858.20
Ozone layer depletion	kg CFC-11 eq	1.42E-05	1.42E-05	-4.48E-05	-2.00E-05
Human toxicity	kg 1,4-DB eq	46.71	51.44	0.13	21.16
Freshwater ecotox.	kg 1,4-DB eq	14.05	15.74	6.53	10.29
Marine ecotox.	kg 1,4-DB eq	37489.52	40294.90	-2638.01	15376.48
Terrestrial ecotox.	kg 1,4-DB eq	1.08	1.21	0.90	1.03
Photochemical oxidation	kg C_2H_4 eq	0.03	0.05	0.004	0.02

Table 4: Net avoided loads due to replacement of 1 ton of clinker with mass of ggbfs (1.11 ton), fly ash (1.67 ton) or calcined clay (1.0-1.67 ton) with equivalent binding capacity

Fly ash and ggbfs use as clinker replacement avoided the largest net loads in all categories. Due to its higher binding capacity, less ggbfs is needed than fly ash to deliver the same 'service' as clinker. This advantage is, however, nearly neutralized by processing impacts, which are higher for ggbfs than for fly ash and explains their similar performances.

3.2. Net loads distribution: Portland cement impacts

Results in Tables 3 and 4 indicate fly ash and ggbfs as similar, best performing alternatives from all admixtures studied. Nevertheless, overall environmental performance is also influenced by clinker replacement ratio in blended cements. Figure 2 displays the impact profiles of the analysed blended cements, calculated using the 'avoided problem approach' (Equation 1 and Figure 1) and normalized in relation to CP I-S-32 with limestone.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

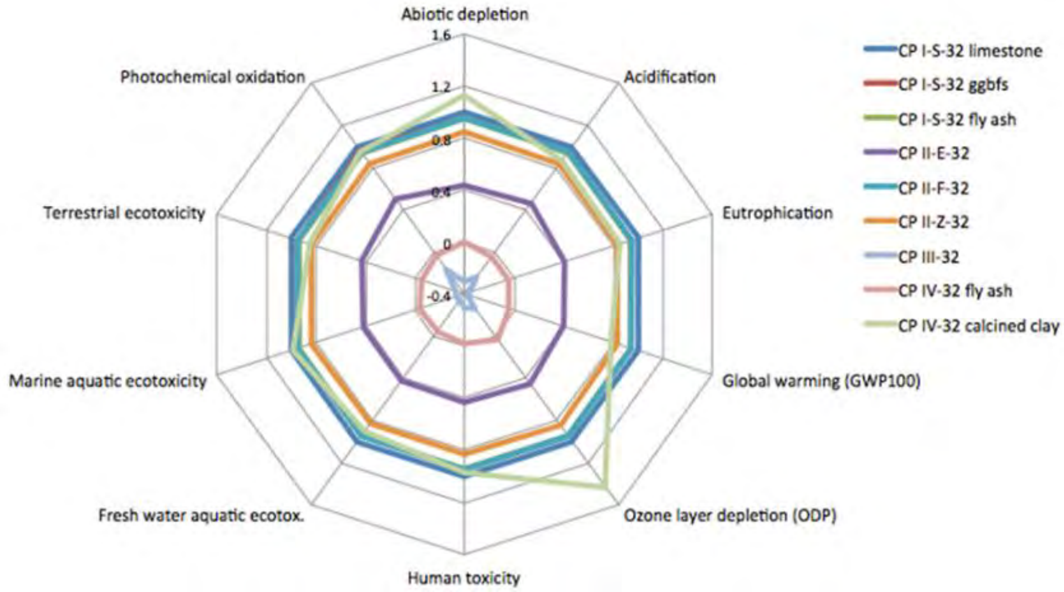

Figure 2: Portland cements impact profiles, normalized in relation to CP I-S-32 with limestone

Analyzed cements can be grouped into: low (up to 10%), medium (around 30%) and high (over 50%) clinker replacement ratios. CP-II-F-32 (10%-limestone) and CP-II-Z-32 (10%-fly ash) had discouraging environmental results, very similar to the reference CPI-S-32 (5%-limestone). Despite its medium clinker replacement ratio, performance of CP-IV-32 (28%-calcined clay) was clearly biased by that admixture's poor performance - particularly regarding ozone layer and abiotic depletion potentials - which shifted its final performance towards those of low clinker-replacement ratio cements. Intermediate performance was achieved by 30%-slag CP II-E-32, whilst the cements with the highest clinker replacement ratio performed best: 66%-slag CP III-32, followed by 50%-fly ash CP IV-32.

Although not considering EOL loads in impact distribution (those are credited to the multifunctional processes, according to Figure 1), use of the 'avoided problem approach' allows a coherent view of actual impacts associated to recycling implementation within cement manufacturing. Information on 'net' impact avoidance enlightens and can scientifically ground cement industry's strategic agenda for sustainable practices.

4. FINAL CONSIDERATIONS

The Brazilian Cement Roadmap, launched in 2014 by the Cement Sustainability Initiative (CSI) and the International Energy Agency (IEA), identified a need for immediately prospecting alternatives to supply clinker substitutes. Use of LCA to model such practices is paramount, but challenged by the multifunctional nature of processes generating potential alternatives.

Current recycling modeling approaches are incomplete and fail to distribute recycling effects into the industry partners enabling it. The 'avoided problem approach' helps to prevent those issues and offers a consistent and complete GHG emissions modeling backdrop to adequately inform the cement industry's decision making.

The 'net avoided burden' indicator carries valuable information for all industries involved, and can be used as reference metric to assist alternatives ranking, independently from the impact distribution method chosen.

Specifically to the cement industry, the proposed calculation procedure and results shown in this paper can assist in screening potential admixtures before advancing on technical feasibility investigation, as well guide environmental feasibility assessment of typical procedures for obtaining and using mineral admixtures.

Steelmaking speed is not keeping up with Brazilian cement industry's growth, so the industry not only uses other coproducts, but started to import bfs. Although not contemplated here, transportation-related impacts would enter Equation 1 as 'other loads' (l_{othe}), and can significantly alter the impact profiles of admixtures and cements alike. This topic is currently addressed in complementary studies.

ABSTRACT

The effective application of the generally recognised concept of embodied environmental impacts depends on a common and clear understanding of definitions and scope of analysis. This is especially important in the construction sector because of the range in focus from product level to the whole building level, and the varied nature of different life cycle phases. This paper addresses these considerations from a systems perspective, but particularly focused on embodied energy and embodied global warming potential (GWP) indicators, to inform their assessment methods, and the interpretation of results. Existing knowledge gaps are identified and a consistent and expansive set of recommendations to assist the calculation of embodied impacts datasets, and the interpretation and application of these data in the practical design process of buildings is presented.

Keywords: embodied energy, embodied GWP, embodied carbon

1. INTRODUCTION

A systems view of global resource depletion and environmental impact implies that a design approach to buildings focused on their operation stage alone may lead to a sub-optimal solution, resulting in great loss of significant opportunities to conserve our resources and reduce the potential adverse effects on the environment. For example, it may be possible to design an energy efficient building solution focused only on the operation stage but associated with an increased embodied energy consumption and greenhouse gas emissions (GHG) due to the selection and use of building products and technology systems that are themselves highly energy- and emissions-intensive to produce. The building design process should take into account, among other aspects, the environmental "areas of protection", as intended in life cycle analysis (de Haes et al, 1999), during the full life cycle of the "final product". In building and construction, the ultimate or final product should be the whole building, which in itself is an assembly of different construction products and materials. The indicators selected in this paper that consider the areas of "natural resources" and "natural environment" protection are embodied energy and embodied global warming potential (GWP), sometimes also called embodied GHG emissions or partial carbon footprint.

In the existing life cycle oriented standards dealing with the sustainability assessment of buildings within ISO/TC 59/SC 17 (ISO 21931-1:2010 and ISO 21929-1:2011) and CEN TC 350 (EN 15643-2:2011 and EN 15978:2011), the quantification of embodied energy is performed as part of the assessment of the indicators measuring the use of non-renewable and renewable primary energy resources or measuring the abiotic resource depletion potential (ADP) of fossil fuels (included only in CEN TC 350 standards for expressing the concern over the scarcity of fossil energy resources) for the lifecycle stages other than the operation. Likewise, the quantified embodied GHG emissions are represented by the environmental impact indicator GWP. For this purpose, this paper refers to embodied GWP as part of the life cycle GWP. However, the standards do not provide a complete picture and a detailed understanding of the various perspectives and practices, as well as their overlaps. This leaves room for a range of interpretations and misunderstandings that could lead to mis-applications or sub-optimal decisions. Many stakeholders who are now considering these aspects much more frequently in their decision-making (like designers, construction product manufacturers, procurers and others) need consistent and technically-sound information about important aspects of embodied energy and embodied GWP (Balouktsi et al., 2016).

Towards this goal, this paper clarifies the definitions of, and the scope or boundary of analysis for, embodied energy and embodied GHG emissions/ embodied GWP, and addresses the following specific questions: How the calorific value of feedstocks is treated? Should both the energy-related and material (non-energy)-related use

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

(feedstock) of fuels be accounted for as part of the embodied energy? What is embodied GHG emissions and what is its relationship with “embodied global GWP”, “embodied carbon” or the widely used term “carbon footprint”? How the biogenic carbon stored in wooden and other biogenic products is treated? What is the difference between the “virtual” embodied energy and carbon, and the “real” embodied energy and carbon in a product or building? What are the possible interpretations emerging from the different approaches? Is there any difference about the embodied energy when designing a building and the embodied energy of an existing building? The analysis presented herein draws partially on the contributions of the authors to the discussions within the International Energy Agency (IEA) EBC Annex 57 “Evaluation of Embodied Energy and CO2eq. for Building Construction”.

2. LIFE CYCLE RELATED SYSTEM BOUNDARIES

Following the current international and European standards, a building’s life cycle consists of four main stages (Figure 1): product stage, construction process stage, use stage, and end-of life stage. In EN 15978:2011, there is also an additional and separate information module (module D: benefits and loads beyond the system boundary). Each stage is further divided into several modules. In stages A and C, the included modules describe a logical sequence of building-creation and end-of life processes (activities usually occurring in a linear way), while in stage B the processes occur usually in parallel (use, operational energy use, operational water use, etc.) or cyclically/ regularly during the building use (e.g. use - maintenance - use). This results in a diversity of interactions. For example, module B4 – replacement includes the production, transportation and installation (replacement process) of the replaced components (A1-5 for replaced components) and the end-of life stage of the removed component (C1-4 for the removed component). Furthermore, a selective deconstruction (C1) is a prerequisite for exploiting the recycling potential of recyclable construction products and materials (environmental benefits reported in module D).

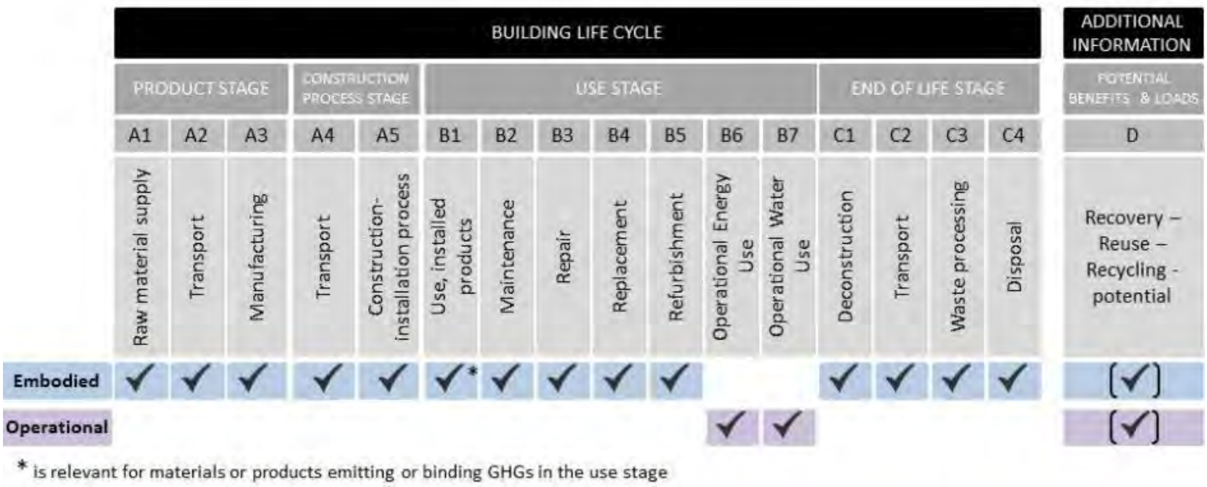

Figure 1: Embodied and operational impacts (Energy & GHG) in life cycle of buildings based on the modular approach of EN 15978:2011 Standard. Module D must always be reported separately.

The exact presentation of the included life cycle phases is a prerequisite for transparency and comparability, e.g. see Ref. (Lützkendorf et al, 2015).

3. PERSPECTIVES AND INTERPRETATIONS OF EMBODIED ENERGY

3.1 Types of primary energy resources

The scope of the indicator(s) used for quantifying embodied energy consumption is strongly influenced by the purpose of each respective study and the information that is available. In any case embodied energy should always be expressed in primary energy terms, thus calculated at the natural resource level. At the same time, it should always be clearly specified which energy resources are quantified and considered in the indicator(s). For this purpose, a clear differentiation between the various types and uses of primary energy resources is needed. For example, different levels of disaggregation of total embodied energy into its individual parts are illustrated in Figure 2. The first level is the total (aggregated) embodied energy without any differentiation between renewables and non-renewables. At the second level, a distinction should be made among the following types of energy:

- Use of renewable energy resources (biomass, solar energy, geothermal energy, wind power and others)
- Consumption / depletion of non-renewable energy resources (fossil and nuclear energy resources (Frischknecht et al., 2015)).

At the third level – which is the one the authors suggest – a further distinction should be made (and this applies to energy resources that can serve diverse purposes) between:

- Energy resource consumption as a result of energy-related use of energy resources
- Energy resource consumption as a result of non-energy related (usually called feedstock) use of energy resources. These can be either renewable (e.g. biomass as feedstock) or non-renewable (fossil resources as feedstock).

Within the group of biomass, it is also useful to distinguish between wood-based biomass and other types of biomass because of the effects of carbon sequestration associated with this specific type of biomass.

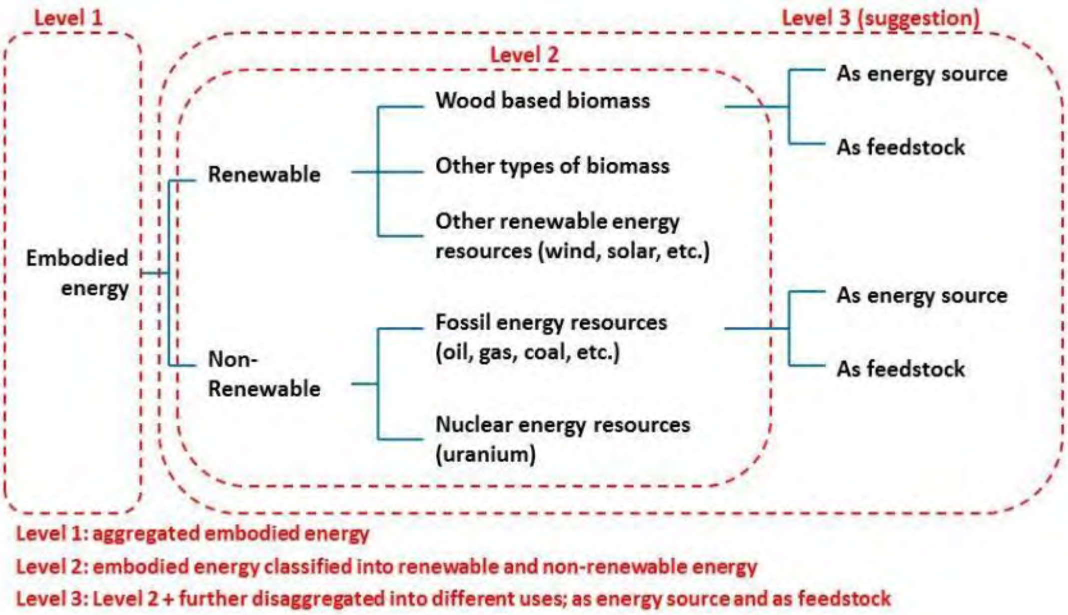

Figure 2: Aggregation levels in embodied energy indicator based on the types and uses of resources

3.2 Non-renewable energy resources: focus on fossil fuels

Often, fossil energy resources can serve two different purposes; their consumption can be both energy-related and non-energy-related (feedstock energy). In the first case, the primary energy resources are consumed as a fuel (e.g. fossil energy resources are combusted and as a consequence CO_2 is released into the atmosphere). This type of energy is not a physical part of the product, but is associated with it; therefore, it is embodied in a "virtual" sense as a way of allocating the energy consumed along the supply chain of a product or building to the specific product or building (Type I in Figure 3). On the other hand, feedstock energy is the primary energy (resources) which is not consumed as a fuel, but used as a raw material (this applies to specific products embodying fossil materials without using them as a fuel, e.g. petrochemicals may be used as feedstock to make plastics and rubber). This energy (calorific value) is not released but retained (contained in the product) throughout the product lifecycle, and therefore, is available for use as fuel energy outside the system boundary. Thus, there is the potential to be partially released and recovered at the end of life stage, usually through incineration. This type of energy is a physical part of the product, and thus, is embodied in a "real" sense (Type II in Figure 3). Processes that use fossil fuel resources as a fuel have very different impacts from those that use them as a feedstock to produce another product. To reflect these differences, and to get an accurate idea of the different impacts, the calorific value of a feedstock should be included in an embodied energy indicator as a separate stream of information. This is in line with CEN TC 350 standards, which include two different indicators (among others) to describe these two cases of resource use:

- Use of non-renewable primary energy excluding energy resource used as raw material

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Use of non-renewable primary energy resources used as raw material

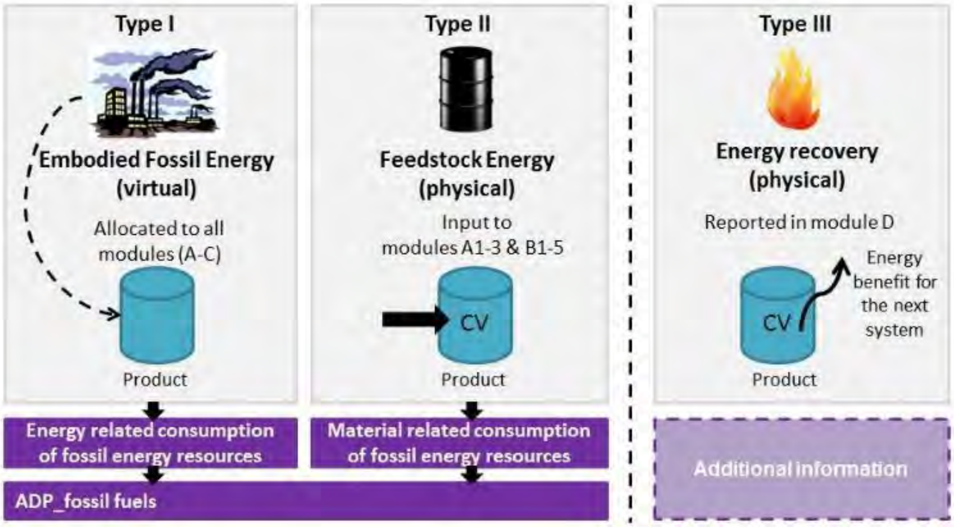

Figure 3: Classification of embodied energy (Fossil) into different types distinguishing between the energy embodied in a "Virtual" sense and in a physical sense (Calorific Value - CV) in a product.

Feedstock energy, considering that it represents a permanent loss of fossil energy resources, is also part of the environmental impact related indicator "abiotic resource depletion potential for fossil fuels (ADP_fossil)" within the same group of standards. In addition, since any feedstock energy from a building product may result in an energy benefit through its recovery, this must be identified and reported separately in Module D as additional information (Type III in Figure 3). However, care must be taken to ensure that there is no double-counting here.

3.3 Renewable energy resources: focus on wood-based biomass

Similar to the fossil energy resources also biomass can be used both as a fuel and as a feedstock. Again, CEN TC 350 standards include two specific indicators, among others, for describing these two different perspectives:

- Use of renewable primary energy excluding energy resource used as raw material
- Use of renewable primary energy resources used as raw material

However, in many studies the calorific value of timber is excluded from calculations when used as a feedstock, since it does not represent a permanent loss of resources. It is only identified and reported in Module D, as a potential energy benefit for its future use as a fuel. Here, it is suggested that a description of the material use of renewable primary energy resources is provided separately in Module A.

4. PERSPECTIVES AND INTERPRETATIONS OF EMBODIED GWP

4.1 Types and sources of GHG emissions

In literature, the term "carbon" contained in the concepts of "embodied carbon", "grey carbon", "carbon footprint" and other related concepts is often used as a catch-all term and can mean:

- carbon dioxide (CO_2) alone;
- the six main (groups of) gases identified in the Kyoto Protocol (CO_2, CH_4, N_2O, HFCs, PFCs and SF_6); or
- the numerous GHGs specified by the 5th IPCC report (2013).

GHG emissions are generally reported, using the GWPs of the individual GHG gases expressed in units of kg carbon dioxide equivalent (kg CO_2e), taking into account the different impact of GHGs on global warming. In some cases, the fluorocarbon gases (F-gases) regulated under the Montreal Protocol may be also included in the embodied GWP, besides the ones specified in IPCC report. Here, it is recommended to quantify the embodied GWP by including in the CO_2e all GHGs specified by the 5th IPCC report and to include the F-gases only where

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

relevant. However, to clearly understand what may be included in an embodied GWP, the determination of the emission types included in the calculation of CO_2e is not sufficient; the different sources of embodied GHG emissions related to construction products and buildings have also to be identified.

The majority of them arise directly from the energy-related use of fossil energy resources (fuel-related) – thus, they are directly linked to the "virtual" embodied energy (most significant). But these do not give the whole picture. There are also the non-fuel related CO_2 emissions occurring from the manufacturing processes (process emissions) as a result of specific chemical effects (e.g. CO_2 is emitted as a chemical reaction in cement manufacture). Both of these types of emissions are related to processes allocated to the product; therefore they represent a GWP in a "virtual" sense not a physical one (Type I, Figure 4). Another special type of emission is the carbon contained in the body of a product. Carbon that is stored in a material, previously absorbed from the atmosphere, is usually described as "sequestered" or "stored". Biomass based materials like wood absorb the carbon during growth and lock it away safely in the wood product as installed in the building until the building is demolished (or the product is replaced) and the biomass incinerated. Thus, here the carbon is a physical part of the product, and thus, is embodied in a "real" sense (Type IIa in Figure 4). It is a highly debatable issue how to treat biogenic carbon stored in wood-based products. In case the biomass used can be assumed to originate from sustainable forest sources, biogenic carbon emissions can be regarded as zero based on the idea of biogenic carbon neutrality. In this sense, carbon storage in wood products is balanced during natural decay or incineration of the products. However, it can also be included in the assessment result as additional environmental information.

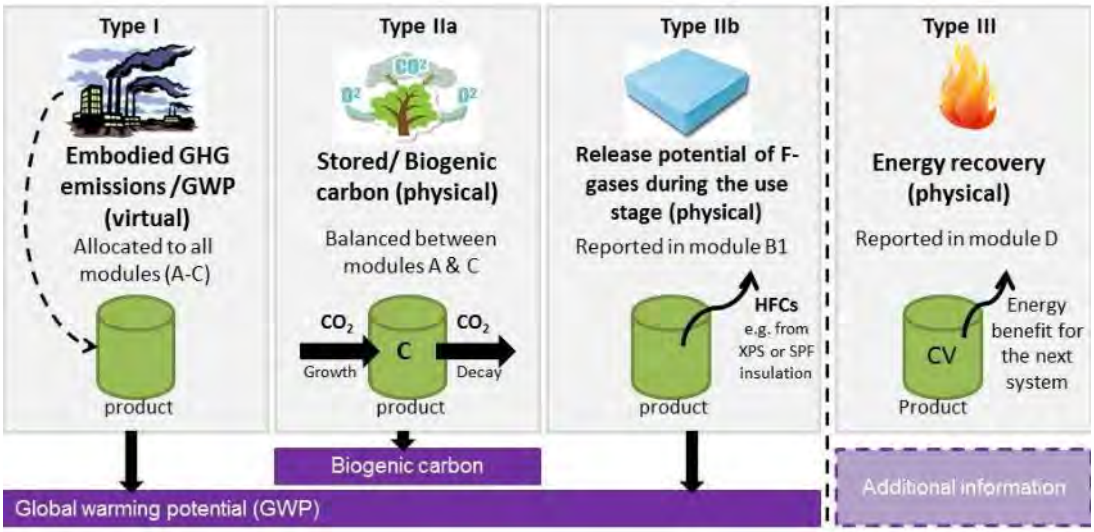

Figure 4: Classification of embodied GHG emissions/GWP into different types distinguishing between the emissions embodied in a "virtual" sense and in a physical sense (carbon and HFCs) in a product.

Finally, there is the potential for some materials and products to emit F-gases during their use in the building's operation. F-gases, which contain HCs, HFC, HCFC etc., can be used in the insulation material (e.g., as blowing agent) and cooling systems (as a refrigerant) in buildings. These gases are released to atmosphere from the insulation material and leaks from cooling system over the building life. However, they do not come from fossil fuel burning, rather than used as feedstock in insulation material and are released into the air in the use stage of building. Similarly, coolant leaks over the use of building and end of life phase of building. These have, sometimes in specific areas of the world, a significant influence (Type IIb in Figure 4). So far, there is no clear guidance on which stages these emissions should be included (embodied or operational). The way these gasses are considered differs depending on the stakeholder group.

As described above, the authors recommend to clearly describe and identify the items included in Table 1 when quantifying embodied energy and embodied GHG emissions. Further, it would be ideal to report separately the "virtual" embodied impacts and the physical embodied impacts.

Aspects/ Indicators	Virtual (allocation of processes)	Physical (real)
Embodied Energy	Use of fossil energy resources as energy source	Use of fossil energy resources as feedstock (energy recovery potential)
	Use of nuclear energy resources as energy source	
	Use of wood-based biomass as energy source	Use of wood-based biomass as feedstock (energy recovery potential)
	Use of other renewable energy resources as energy source	
Embodied GWP	Fuel-related GHG emissions	F-gases released during the use stage
	Process GHG emissions	
		Biogenic carbon stored in wooden materials

Table 1: Summary of "Virtual" and "Physical" part of embodied impacts (Energy & GHG Emissions)

5. DISCUSSION

In the design stage of buildings, the indicator embodied energy can be used for the description, assessment and targeted influencing of the use of primary non-renewable and renewable energy resources for the lifecycle stages other than the operation. The prevailing design objective is, among others, the conservation of resources by limiting the consumption of fossil energy resources and the optimization of the life cycle primary energy consumption. ("design for environment") The use of resources is interpreted as an "environmental load". Another approach to conserving resources is to influence the durability, and easy dismantling and recycling of the building already in the design stage. It is possible to specify the existing potential, provided the use of appropriate procedures and a future possible demand, in terms of material recycling and energy recovery. This potential may, inter alia, be expressed as recoverable or saved energy for the next system. Assuming scenarios for deconstruction, such information can be described in module D as additional information, besides the information related to the life cycle of buildings. Embodied energy in this case will thus become a "potential" for reuse. The embodied energy in existing buildings can be interpreted as "potential" that can be tapped by demolition and recycling (urban mining). So it is an "ecological value" that is preserved through building maintenance and modernization or unlocked through demolition and recycling.

6. CONCLUSIONS

Different terms and definitions are currently used to describe embodied energy and embodied GHG emissions. To alleviate the confusion surrounding these topics, consistent and technically-sound information about important aspects of these embodied impacts are required. Specifically, the paper has focused on providing clarifications about the boundary or scope of analysis, and the different types and uses of primary energy resources that can be considered in an embodied energy indicator on the one hand, and the different types and sources of GHG emissions considered in an embodied GWP on the other hand. We also made the distinction between "virtual" embodied impacts as a result of an allocation of energy consumed and GHG emissions occurring along the supply chain of a product or building to the specific product or building and the impacts embodied in a "real" sense constituting a physical part of the product.

ABSTRACT

The embodied energy of a building is expected to be a significant component of life cycle energy for naturally ventilated or partially air-conditioned buildings in developing nations. This necessitates a detailed understanding of various aspects of embodied energy. The non-renewable energy embodied in a building in the form of construction materials and site processes has been well explored in the literature. However, the energy expended by the human workforce during building construction has not been explored in developing nations like India. While the construction industry is heavily mechanized in developed countries, substantial amount of construction work is done manually using human workforce in developing countries. This study presents a method to estimate the human embodied energy associated with masonry work and determines the relative proportion of non-renewable embodied energy due to transportation and equipment use with the human embodied energy. Volume of masonry work completed per month and the number of masons and helpers associated with masonry work were gathered for 16 months. The total volume of masonry work completed during 16 months is 4441 cu.m. The non-renewable embodied energy required for materials manufacturing, transportation of materials to site and the equipment use for lifting blocks to the required floor was determined. Further, the human embodied energy used for masonry work was assessed. The energy used for transporting materials to site is 67 MJ/ cu.m. The energy used for lifting equipment is 0.92 MJ/ cu.m. The human energy used is found to be 29 MJ/ cu.m. It is found that the human energy is close to 1/3 of the total energy used for on-site construction processes.

Keywords: *embodied energy, human energy, masonry work*

1. INTRODUCTION

The construction industry consists of building of new structures, repair, maintenance or renovation of buildings and infrastructure projects (Behm, 2008). It involves the use of resources namely materials, machineries, manpower and money. The Indian construction industry is one of the fasted growing economies and ranks second in providing employment next to the agricultural sector (Swarup, 2007). The construction industry in India is witnessing a rapid growth and there is a tremendous movement towards sustainable development.

The major phases of a building life cycle are production (mining of raw materials, transportation, manufacturing of building materials and transportation to suppliers and contractors), on-site construction (transportation to the site and installation of building components), use (heating, cooling, lighting and ventilation), maintenance/repair and end-of-life (demolition, transportation, land filling, recycling and reuse). The typical distribution of energy in the building life cycle is as follows: initial embodied energy - 10 to 20%; operating energy – 80 to 90% and the demolition energy - <1% (Ramesh et al. 2010; Kofoworola and Gheewala 2009, Keoleian et al. 2000).

Studies have been carried out to find the embodied energy of buildings in India (Reddy et al. 2003, Ramesh et al. 2012, Varun et al. 2012, Devi and Palaniappan 2014). However, these studies do not provide the energy expended by the human workforce during on-construction. Held et al. (2013) estimated the embodied energy including human energy related to water treatment and supply. Dixit et al. (2015) included human energy while calculating embodied energy of construction materials. The embodied energy associated with human workforce during building construction has not been investigated adequately for construction projects. This article presents a case study on human energy associated with masonry work using a construction project in India.

2. CASE STUDY

The data was collected for 16 months from a residential building construction project. The building consists of 5 blocks. Each block has a material hoist which is used for lifting of materials. The total volume of masonry work is 4441 cu.m. Table 1 presents the quantity of work done and the number of workers deployed.

Months	Masonry work (cu.m)	Number of Masons	Number of Male helpers	Number of Female helpers
1	70.68	89	135	119
2	221.9	252	384	327

Figure 42: Masonry work quantity and construction workers

3. METHODOLOGY

This study calculates the energy required for manufacturing, transportation, lifting of materials and the laying of masonry work. The quantitative data were collected from the site. The total work volume is 4441 cu.m (75% block work and 25% cement mortar by volume). The thickness of masonry work is 230 mm. Cement concrete block is used for masonry work. The mix proportion of cement mortar is 1:4. The thickness of cement mortar used for binding the cement concrete blocks is 6 mm. The quantity of cement mortar presented in this study excludes the cement mortar use for plastering on the exterior and the interior sides of the wall. The embodied energy of cement, sand and cement concrete blocks are based on the Indian data (Reddy et al. 2003, Shukla et al. 2009 and Development Alternatives, 1995). For material transportation, this study assumes suitable vehicle mileage vehicle and the transportation distance to calculate the diesel fuel usage and transportation energy. The energy required for on-site construction processes has two important components. The first one is the equipment energy which is normally used for lifting materials and the second is the human energy which is used for placing of block work and mixing of cement mortar. Each worker is assumed to work for 8 hours per day. For calculating the energy used for material hoist, the energy data were collected from the site. The percentage of lift cycles for each material lifted per month is quantified for material hoist. In addition, the contractor also maintains the electricity meter data and operating hours of each material hoist used for lifting block, cement, sand, debris and other miscellaneous items. During the study, it is assumed that material hoists lifted the same amount of weight in each lift cycle, thereby electricity consumed is considered the same irrespective of the load lifted. The total lift cycles for each material lifted, operating hours and electricity use are documented on a daily basis. The study found that the energy used by material hoists for lifting the block work and cement mortar are 0.05 kWh/cu.m and 0.15 kWh/cu.m respectively. All material hoists are run using electricity.

The human energy is calculated based on the framework shown in Figure 1 and this study used the methodology provided by Held et al. (2013). The age of the workers is derived based on work sampling done at the site. Most of the workers are of 18-30 years (including the mason and the helper) with an average weight 62.5 kg for male worker and 57.5 kg for female worker.

Based on the equation provided by Food and Agriculture Organization (FAO) 2001, Basal Metabolic Rate (BMR) is derived for each category. A Physical Activity Ratio (PAR) is the energy spent for a specific activity per unit of time, expressed as a multiple of BMR. The FAO report (Food and Agriculture Organization, 2001) compiled results

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

from a number of studies of PARs of various activities. The embodied human energy is calculated using the Eq. (1) (Held, 2010; Held et al. 2013).

Embodied human energy (MJ) =

(PAR-1) x (BMR (MJ/hr)) x (Number of work hours per day) x (Number of days work performed) x (Workers per activity) x (Number of activities)

Equation 1

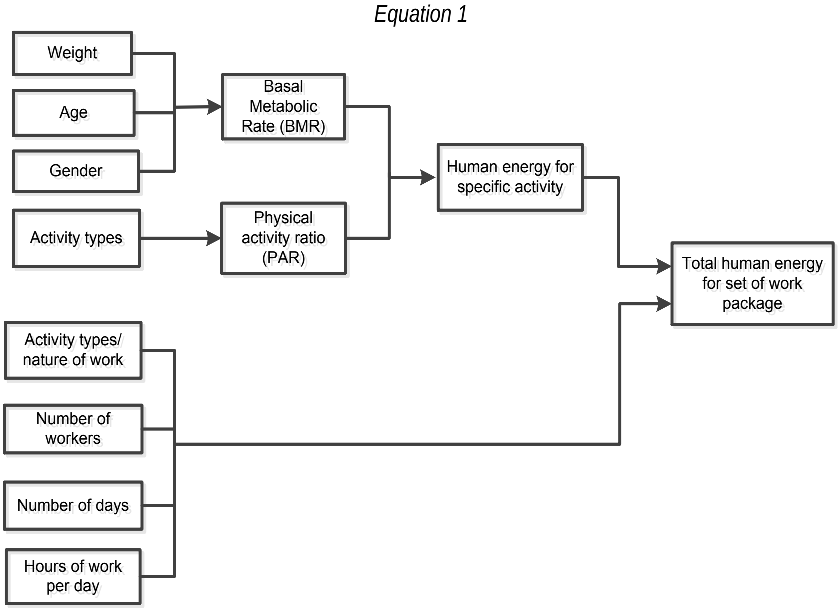

Figure 1: Framework for calculating human energy (adapted from held et al. 2013)

4. RESULTS

The embodied energy of construction materials is calculated based on the Indian data. Table 2 presents the embodied energy for manufacturing materials. It is found that the material flow per unit volume of masonry work is 1.815 tons/cu.m. The embodied energy of materials is found to be 1.408 GJ/cu.m.

Material	Weight		EE (MJ/kg)	Energy	
	kg	(%)		MJ	(%)
Block	5494500	68	0.475	2609887	42
Cement	486351	6	6.85	3331507	53
Sand	2081584	26	0.15	312238	5
Total	8062435				
Total primary energy (MJ)				6253632	

Table 2: Energy for manufacturing of materials

Table 3 presents the energy used for transportation of materials. It is observed that the energy used for material transportation is 67.09 MJ/cu.m. The energy used for on-site construction processes is classified into two components - lifting of materials using material hoist and laying of masonry work using human workforce. Table 4 presents the energy used by material hoist for lifting materials. It is found that the energy used for lifting is 0.92 MJ/cu.m.

The human energy used for laying is calculated using Eq.1. Table 5 presents the calculation of BMR. Table 6 presents the PAR for some construction activities. Table 7 presents the human energy used for laying masonry work. The human energy used for laying is found to be 29 MJ/cu.m. Figure 2 shows the relative proportion of energy used for lifting and laying of block work. On an average, 3% of the energy is used for lifting the materials and 97% of the human energy is used for laying. Figure 3 shows the energy use for lifting and laying of block work

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

on a monthly basis. The lifting energy is in the range of 2.6% to 3.3%. The human energy spent by male helpers is highest followed by male masons and woman helpers on a monthly basis. It is mainly due to the higher number of male masons deployed per month. However, the human energy measured per unit quantity of the work per person indicates that the male mason energy is the highest (8.7 MJ/cu.m) followed by male helper (6.6 MJ/cu.m) and female helper (5.4 MJ/cu.m). Figure 4 presents the relative proportion of transportation, lifting and laying. It is observed that the transportation energy, lifting of material energy and human energy for laying are 70%, 1% and 29% of the total on-site construction energy. Similar studies have been carried out for quantification of human and embodied energy (Held et al 20). It is found that the human energy account for 1 to 25% of the total embodied energy for different activities involved in the water improvement processes.

Material	Weight (kg)	Capacity of trucks	Unit	One way distance (km)	No. of trips	Fuel use (diesel in litres)
Block	5494500	10	cu.m.	20	306	3497
Cement	486351	200	bags	100	49	2800
Sand	2081584	10	cu.m	10	130	743
					Total fuel (litres)	7040
					Total primary energy (MJ)	297961

Table 7: Human energy used for laying masonry work

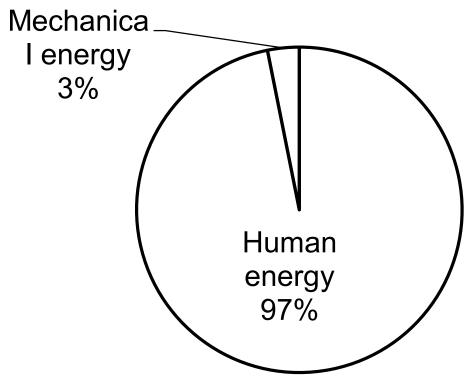

Figure 2: Relative proportion of energy use for lifting and laying of masonry work

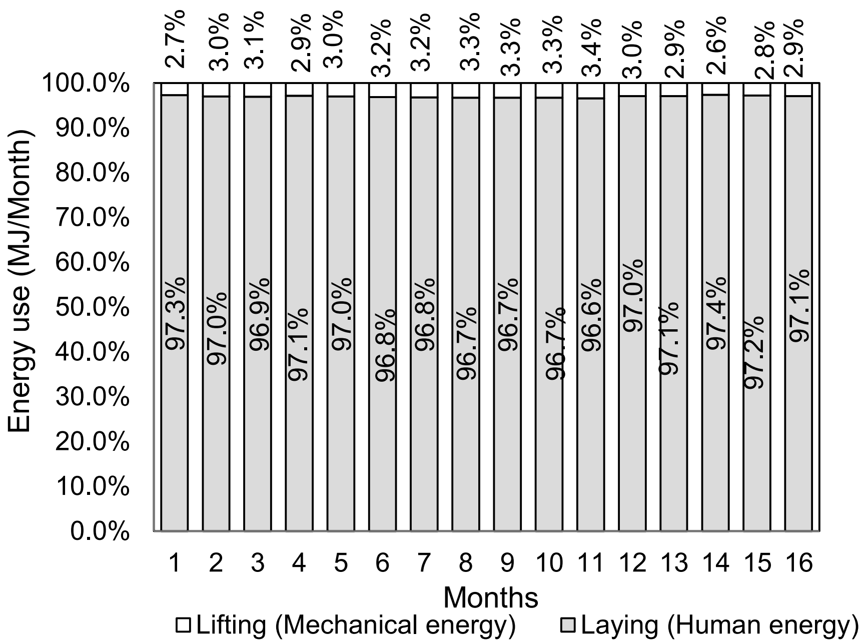

Figure 3: Relative distribution of energy use for lifting and laying masonry work

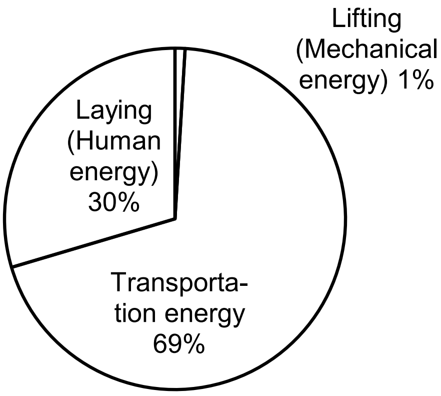

Figure 4: Relative proportion of energy use for transportation, lifting and laying

5. CONCLUSIONS

This study determined the human energy used for masonry work and compared it with the total non-renewable energy used during on-site construction for transportation of materials to site and lifting of materials at site. It is observed that the transportation energy, lifting/material handling related energy and human energy represents 70%, 1% and 29% of the total energy used during on-site construction respectively.

It is concluded that the human energy is close to 1/3 of the total energy used during on-site construction for masonry work. The limitation of this study is that the human energy calculation is based upon the published literature from other countries which may be different with respect to workforce in India. However, this study provides an insight on the significance of human energy in Indian construction projects where substantial amount of human workforce is employed. This work can be further extended for other construction activities.

ABSTRACT

Buildings account for nearly 45% of the worldwide energy consumption and carbon emissions, and play a vital role in formulating sustainable strategies. Many regions and countries have set targets to achieve low or zero energy in their building energy policies. However, despite the policy drive, the uptake of low energy building (LEB) has been low in practice. Previous research on LEB was largely technical solutions oriented. Some examined the impacts of low energy design solutions on the economic effectiveness and energy efficiency of the building over the building's lifespan, but there is still a lack of exploration of the embedded relationship between the cost and energy performance of buildings.

The aim of this paper is to explore the relationship between the costs and energy consumption of buildings from the life cycle perspective. A combination of a critical literature review and case studies of 5 residential buildings selected from UK and Australia was employed for the research. The results of the review suggest that there is second order polynomial regression relationship between the costs and energy consumption of buildings over their lifespans. The optimizations of the cost and energy efficiency of buildings are found to be not mutually exclusive goals, which need to be considered in a synergistic way in order to allow low energy designs and construction practices to be achieved cost-effectively. The findings should inform designers in their decision-making on building design and material selection to make LEB more cost attractive. The identified life cycle cost-energy relationship contributes a novel life cycle perspective to future systemic research into building energy and economics.

Keywords: low energy building, cost-energy relationship, life cycle assessment

1. INTRODUCTION

Buildings take up nearly 45% of the worldwide energy consumption and carbon emissions (Butler, 2008). With the population growth, building services enhancement, comfort level increase and the rise in time spent inside buildings, building energy consumption will experience a predictable growth in the coming future (Pérez-Lombard et al., 2008). It is therefore very important to improve the energy efficiency of buildings in order to alleviate the building energy demand but provide the same or even higher level of the indoor comfort for inhabitants. Low energy building (LEB) has been drawing more and more attention as a result of its superiority on addressing the shortage of energy supply from the building sector through a comprehensive energy systems design.

A number of religions and countries have set regulatory targets to achieve low or zero energy in new buildings within the next decades as part of their building energy policy, like EU and US (Recast, 2010; Sissine, 2011). Despite the policy drive of LEB, the diffusion of LEB in the building market is however slow (Pan, 2014; Pan and Ning, 2015). The prohibitively high costs of low energy design solutions added to buildings are identified as the main barrier (Pellegrini-Masini et al., 2010). A challenging task for architects and other building professionals today is to design and promote LEB in a cost effective and environmentally responsive way (Hui, 2001). Previous research on LEB was largely technical solutions oriented. Some examined the impacts of low energy design solutions on the economic efficiency and energy use of the general building over the building's lifespan, but scant research provided an insight into the embedded relationship between the cost and energy consumption of buildings. In addressing this gap in knowledge, the aim of this paper is to explore the relationship between the cost and energy consumption of buildings from the building's cradle-to-grave life cycle. Following this introduction, the paper investigates the cost effectiveness and energy efficiency LEBs in a systems manner in order to give a more comprehensive view on different technologies applied to the building. Based on the critical review, case studies of 5 residential buildings selected from UK and Australia is employed to examine the life cycle cost-energy relationship of buildings. The paper then compares and reflects on the results in relation to the findings of previous research, and finally draws conclusions.

2. COST EFFECTIVENESS AND ENERGY EFFICIENCY OF LEBS

In general, energy efficient measures are more indispensable compared with renewable energy and other technologies considering the restrictions come from the cost effectiveness and energy efficiency of the potential technologies as well as building surface area in real ZEB cases (Fong and Lee, 2012). In addition to these common considerations, many regions and countries have their own building energy standards and design guidelines based on the region's typical building designs, local climates, and construction practices (e.g. Zero Carbon Homes and Nearly Zero Energy Buildings in the UK (Regulations, U. B., & Directives, E. U. (2014), ASHRAE Energy-Related standards and guidelines in the US (Holness, 2008) and the Design Standard for Energy Efficiency of Public Buildings in China (Bureau, 2005)).

Author	Country	Building Type	Technologies	Energy Efficiency	Cost Effectiveness
Kneifel (2010)	US	Commercial building	Thermal insulation, low-emissivity windows, window overhangs, and daylighting controls	Conventional energy efficiency technologies can decrease energy use by 20–30% on average and up to over 40% for some building types and locations.	58% buildings have an adjusted internal rate of return above 3.0% with one year study period. Over 56% for all study periods have an AIRR greater than 10%.
Zhu et al. (2009)	US	Residential house	High performance windows, compact fluorescent lights, highly-insulated roofs, air conditioners with water-cooled condensers. PV tiles, thermal mass walls, integrated collector storage	A radiant barrier and a water-cooled air conditioner are major contributors to energy savings; insulated floor slab and thermal mass walls are ineffective. Photovoltaic roof tiles produce enough green power to cover the use, and solar water heater can reach peak efficiency of 80%.	PV tiles show a good financial return when rebates are considered. The Integrated Collector Storage (ICS) unit has a high efficiency but with a little higher thermal price. Thermal mass walls are too costly to have wide market appeal.
Marszal and Heiselberg (2011)	Denmark	Multi-storey residential building	PV and air/solar source heat pump; PV and ground-source heat pump; PV and district heating grid.	The most energy efficient solution is the one in which the PV installation is combined with PV/T and a solar heat pump.	The investment in energy efficiency is more cost-effective than investment in renewable technologies.
Moorea (2014)	Australia	Residential house	6 star building envelope, 8 star building envelop, photovoltaics (PV), a solar hot water (SHW) system).	A single detached 6 star BAU house was calculated to generate 8.3 t/yr of CO2-e for the operational phase of the house.	The ZEH scenario achieves pay-back in around 12 years for a high energy price or 14 years for a low energy price.
Morrissey and Horne (2011)	Australia	Residential building	Glasswool insulation ceiling, glasswool insulation wall, polystyrene insulation extruded, shading, windows and weatherstrip	'Six stars' scenario brings 24% energy efficiency improvement; 45% for 'Seven stars' scenario; 65%' for Eight stars' scenario.	For low energy price modeling, the 'seven stars' scenario produces optimal NPVs over 5 and 10 years time horizons,39.23$AUS/SqM CFA at 5 years and 48.95$AUS/SqM CFA at 10 Years; for high energy price scenario, 'eight stars' is the optimal across both 25 years and 40 years time-horizons (72.76$AUS/SqM CFA at 25 years and 99.96$AUS/SqM CFA at 40 years).

Table 1: A summary of cost effectiveness and energy efficiency of some recent studies of LEB

3. THE COST-ENERGY RELATIONSHIP OF BUILDINGS

Previous research has realized the importance of identifying the relationship between the cost and energy consumption of buildings. Gustavsson et al. (2010) penetratingly pointed out those connections, trade-offs and synergies between the cost and energy consumption of a building in different phases of the life cycle must be identified in order to ensure that any further energy efficiency improvement of the buildings could be achieved in a cost effective way. Langston and Langston (2008) investigated the relationship between the life cycle energy and capital investment of 30 recently completed residential and commercial buildings, and observed a positive correlation between the predicted life cycle energy and capital cost investment. The same correlation is also found between the embodied energy and cost investment of individual building components as well as of the entire buildings by Jiao et al (2012). Three commercial buildings in China and New Zealand were compared and the results show a stronger correlation of the individual building components compared with that of the entire buildings.

The research was carried out through the examination of the empirical studies of life cycle assessment of buildings. In total 5 buildings with 51 cases from UK and Australia were collected from previous relevant research. Table 2 gives a comprehensive overview of the main characteristics of the cases presented in literature. Where a source is reported to have more than one case, it means that either different design scenarios or research designs, i.e., energy price and studied lifespan, of the same buildings were presented in the source itself. Cases differ for country, climate, type of building, building parameters, type of construction method, assumptions on indoor climate design and occupant behaviour, and source of data (whether measured or calculated). For this reason, it would be inappropriate to directly compare the cases against each other. Rather, the overall variation of the life cycle cost-energy relationship within each individual case has been examined, and then these different variations have been compared amongst the various cases. Cases also differ in the anticipated assumptions for the values of key parameters that are applied in the cost and energy calculations, like discount rate, inflation and studied lifespan, and also floor area. Cost data (life cycle cost and NPV) and energy data were normalized per unit of area (dollar/m^2) and per unit of area and time (kWh/m^2 year) in order to neutralize these differences.

Source	Country	Case numbers	Type of buildings	Area (m^2)	Lifespan (years)	Energy price	Data	Building designs
Cuellar-Franca and Azapagic (2014)	UK	1	Detached house	130	50	NA	T+G	Strip footing, foundations, brick external walls and pitched roofs with, concrete tiles
		2	Semi-detached house	90				
		3	Terraced house	60				
Moorea (2014)	Australia	4-6	Detached house	249.6	60	High	T	Photovoltaic panel, building envelope
		7-9			40			
		10-12			20

Note: NA, not applied; G, graph; T, table and/ or text.

Table 2: General information of the selected cases

The relationship between the costs and energy consumption of the studied 51 cases are statistically very significant (Figure 1, 2 and 3). Although linear regression describes the data reasonably well, second order polynomial regressions accounted for more of the variance. In all cases, curvilinear patterns provide the best fit with the data. The r^2 values for the second order polynomial regressions are all equal to 1, which indicates the second order polynomial regressions perfectly fit the data. The limited data size should be taken into consideration for the high r^2 values.

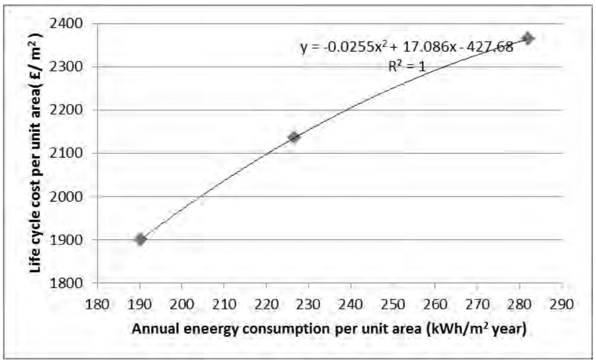

Figure 1: The relationship between the life cycle cost and energy consumption of Cases 1-3

The buildings in Case 1 to 3 are detached house, semi-detached house, and terraced house respectively with the difference in the floor area. The total life cycle cost per square meter increases gradually as the annual energy consumption per square meter grows (Figure 1). In a world, the most energy saving house may have the lowest life cycle cost. This result conforms to the general costs and energy consumption patterns of buildings. The assumptions made in this examined research are also quite reasonable. Owing to relative small proportion that construction cost takes in the overall life cycle cost of buildings, the construction and end-of-life costs are assumed to be similar for the detached house, semi-detached house and terraced house, albeit they are varies in building area. In addition, another assumption is that the household size for all three types of houses is the same, and thereby the energy used for water heating, cooking and appliances is the same. Therefore, it is not surprising that the larger floor area (e.g. detached house), which has a lower energy use per unit area, will have a lower life cycle cost per unit area than a smaller one (e.g. terraced).

In Cases 4-27, three different design scenarios with three different levels of annual energy consumption, i.e., 33.49, 48.08 and 60.9 kWh/m^2 in respective are applied in a detached house (Figure 2). Each group of data represents three different levels of annual energy consumption and associated NPV under different examined lifespans and energy prices. The figure shows that the NPV per unit area rapidly rise with the energy consumption per unit area goes up.

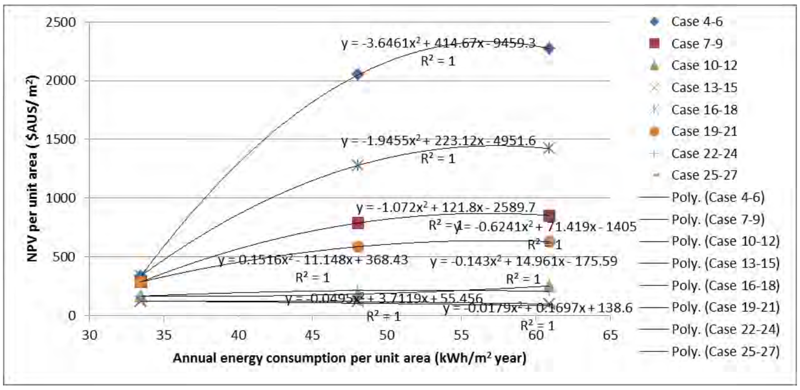

Figure 2: The relationship between NPV and energy consumption of Cases 4-27

In Cases 28-51, three different design scenarios with three different levels of annual energy consumption, i.e., 64,100 and 138kWh/m^2 in respective are applied in a detached house (Figure 3). Each group of data represents three different levels of annual energy consumption and associated NPV under different examined lifespans and energy prices. The figure shows that the NPV per unit area decreases slowly as the energy consumption per unit area increases.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

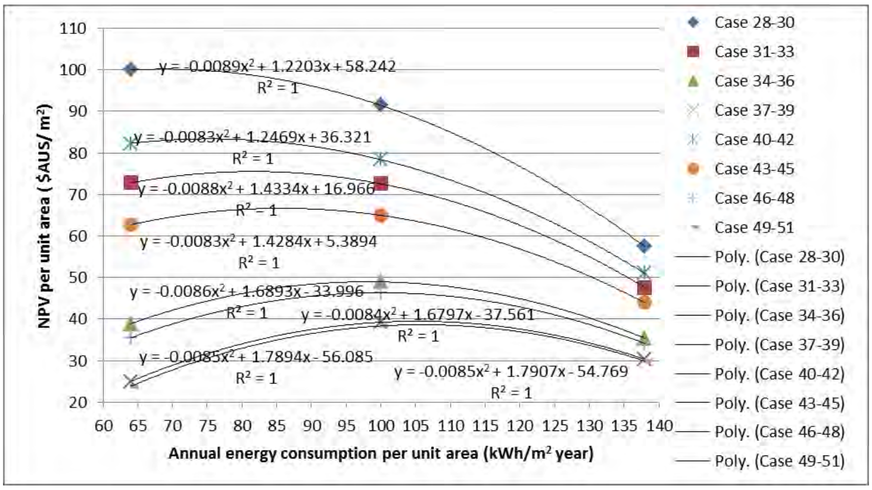

Figure 3: The relationship between NPV and energy consumption of Cases 28-51

Compared Cases 4-27 with Cases 28-51, the key similarity concluded from Figure 2 and 3 is that both energy-efficient and renewable technologies are found to have positive influences on the building's energy consumption and overall cost performance over the study periods. Furthermore, longer study lifespan and high energy price would bring a higher NPV compared with shorter study lifespan and low energy price. However, the major difference comes from the variation direction of the two groups of lines. In Cases 4-27, a positive relationship is found between NPV and annual energy consumption, while a negative relationship is found in Cases 28-51. Such difference may be attributed to the economic efficiency of examined low energy designs applied on buildings. Cases 4-27, both energy-efficient measures and renewable technologies (e.g. photovoltaic panel) are studied in the life cycle cost and energy performance evaluation of zero (net) energy house, while Cases 28 to 51 examined the impacts of energy-efficient measures only on the cost performance and energy consumption of the building. The economic efficiency of photovoltaic panel is relatively lower over economic-efficient technologies. The cost of installing photovoltaic panel is quite high in order to achieve a low level of energy consumption and therefore leads to a low NPV value. However, the high NPV will be abstained to achieve the same energy consumption level through the application of mere energy-efficient technologies.

4. DISCUSSION

The results of this study support the finding of previous research that a correlation is embedded between the costs and energy consumption of buildings over the building's lifespan. Also, this paper contributes to elaborating such relationship by deriving three improvements. Firstly, the results identify the second order polynomial regression relationship exists between the costs and energy consumption of buildings over their lifespans. Secondly, the results suggest the economic efficiencies of the applied low energy design solutions crucially determine such relationship is positive or negative. Finally, the results highlight the importance of the longer study lifespan in improving the significance of such relationship. Langston and Lauge-Kristensen (2013) emphasized that cost should also be accounted over a longer time span when conducting the life cycle costing of an asset since any shorter lifespan that is applied cannot ensure sufficient time for the energy efficient building to maximize its economic efficiency.

5. CONCLUSIONS

This paper has examined the embedded life cycle cost-energy relationship of buildings. The research was carried out through a combination of a critical literature review and case studies of 5 building selected from UK and Australia. The paper concludes that there is second order polynomial regression relationship exists between the costs and energy consumption of buildings over their lifespans. This paper suggests that the optimizations of the costs and energy efficiency of buildings are not mutually exclusive goals, which need to be considered in a synergistic way in order to allow low energy designs and construction practices to be achieved in a cost-effective way. The identified relationship between the costs and energy consumption of buildings can be exploited to enable better design solutions to be identified. The low and zero energy designs usually apply to exist the low-rise buildings from a variety of demonstration projects (Fong and Lee, 2012), especially in residential buildings. Nevertheless, it has been proven that a certain amount of potential for energy saving can be achieved on office buildings in Hong Kong (Lee and Yik, 2002). The embedded life cycle cost-energy relationship of high-rise buildings in Hong Kong should be investigated in future research to identify the most economical and environmental-friendly design solutions.

Session 5.5: SBE Assessments – Green Building Policies

From Research to a National Standard: SBTool and Protocollo ITACA

Andrea MORO[a]

[a] iiSBE Italia R&D, Italy, andrea.moro@iisbeitalia.org

ABSTRACT

In the context of the European research project (Environmentally Compatible Job), the Italian national team was established in 2000 to participate in the Green Building Challenge process (GBC). The GBC was launched some years before to create an international generic framework useful to develop locally contextualized building assessment tools. At that time the name of the framework was “GBTool”, now known as “SBTool”. A first contextualized version of GBTool to Italy was presented on the occasion of the Sustainable Building 2002 conference in Oslo. The same year the annual meeting of the IFC (International Framework Committee), the managing structure of GBC, was hosted in Torino (Italy). On that occasion a seminar was organized to show the state of art at word level about sustainability assessment systems. On that occasion, ITACA (Federal Association of the Italian Regions) decided to adopt GBTool to develop a new public assessment system: Protocollo ITACA. The need of the Italian region was to improve the impact of incentive based policies for sustainable buildings. The integration of an assessment tool in such policies was considered a good strategy. From 2002 to 2003 the first version of Protocollo ITACA was developed. In January 2004 the conference of the Presidents of the Italian Regions officially adopted it. With the support of iiSBE Italia, progressively 15 Italian regions adopted Protocollo ITACA and started to implement it in policies, building codes, urban plans, public tenders, etc. Actually more than 2000 buildings have been assessed in the context of public initiatives. The next step has been in 2015 the recognition of Protocollo ITACA by the Italian National Standardization body UNI as national standard (UNI PdR13:2015) and the set-up of a certification system under national accreditation (Accredia RT33). This made the assessment system fully suitable for market uses.

Keywords: policy and regulation, green rating tool, green procurement

1. THE PROJECT ECJ AND THE GREEN BUILDING CHALLENGE

In the late 90’s, one of the first European projects dealing with the topic of green building, ECJ – Environmentally Compatible Jobs, was exploring the possible drivers to move the Italian building practice towards a better energy-environmental performance. The idea at the base of the project was to create new job opportunities for professionals, workers and construction companies through the widespread of green building principles in the building sector.

Among the possible drivers one was considered of the maximum importance: the availability of a national building rating system. In Italy at that time, environmental building assessment systems weren’t known at all. Only the energy certification was widespread because mandatory. In general, sustainable building was a new them for the Italian building sector.

The ECJ project considered the development of an Italian rating system a prior driver for two reasons. The first, a building assessment systems gives to green buildings the possibility to emerge in the real estate market. A label is the objective proof of a superior quality. Consequently, the availability of a national rating system was expected to stimulate the investments in green building because potentially more profitable. The second, a building assessment systems allows public authorities to raise the impact of their sustainable building policies. A rating system can be used to fix in a measurable, reliable and verifiable way the performance targets of a policy, program, regulation. The assessment systems can be linked to incentive based policies, building codes, urban plans, public tenders, etc.

The first task accomplished in ECJ was a state of art study about the existing building assessment systems. BREEAM was already consolidated and LEED was emerging. But at that time, both systems were considered not contextualizable to Italy. The “contextualization” was considered a fundamental principle for a new national assessment system. Contextualization means the use of local technical standards and the capability to reflect the

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

national priorities with regards to environmental, social and economic issues. Following this approach, the GBTool was chosen as reference framework.

1.1. The Italian national team in GBC

In 2000 the Italian National Team in the Green Building Challenge (GBC) international process was set up with the participation of many relevant national organizations such as the Italian National Research Council, ENEA, Politecnico of Torino, Politecnico of Milan, Environment Park.

The Green Building Challenge was a world level initiative, initially coordinated by NRC Canada and later by iiSBE (international initiative for a Sustainable Built Environment), for the development of a transnational generic assessment framework (GBTool). Through the contextualization of GBTool it is possible to develop local tools. The contextualization process of GBTool consists in the selection of the criteria of interest, the assignment of a weight to criteria, categories and issues and the definition for each criterion of a performance scale based on regional benchmarks (minimum acceptable performance). In this way all countries involved in GBC had the possibility to share the same harmonized methodological approach, criteria and indicators with the possibility to develop a full contextualized local tool.

In the period from 2000 to 2002 the Italian National Team developed the first version of GBTool for Italy that was tested on residential buildings, offices and a shopping centre. The Italian Team participated to the IFC's activities (International Framework Committee) formed by all the national coordinators. The role of the IFC was to improve and update the Generic Framework. The role of national teams to contextualise it.

In 2002 the results of the first GBTool test in Italy were presented in occasion of the Sustainable Building conference organized in Maastricht. The first relevant use of the Italian version of GBTool was in the Guidelines for the Sustainability of the Olympic Villages on the occasion of the XX Olympic Winter Games hosted in Torino (Italy). The Guideline was intended to drive the design and construction activities of the media and athletes' villages and addressed to residential buildings. Always in 2002 the annual meeting of the IFC was hosted in Torino. On that occasion the first conference on green building rating systems in Italy was organized. In that period 25 national Team were active in GBC and the conference illustrated the results achieved by all of them in their countries. Among the participants there was a key organization: ITACA

2. FROM GBTOOL TO PROTOCOLLO ITACA

ITACA is a no profit association whose members are the Italian regions. By the Title 5 of the Italian Constitution, energy and environment fall into the competence of regions. In 2001 ITACA activated a working group to define harmonized regional policies for the promotion of green building in Italy. The main objectives of ITACA was to develop a public rating system to support regional policies targeted to green building. After the GBC conference in Torino, above mentioned, ITACA asked the GBC Italian Team to collaborate. For ITACA, GBTool was the perfect tool to develop the new public assessment system with a regional approach. Italy is composed by 20 regions with very different climate conditions and building practices. The intention of ITACA was to develop a national version of the new assessment tool and then to leave the regions to further contextualize it modifying weight and benchmarks to better reflect the local conditions.

In 2003 the new tool based on GBTool was ready and it was named Protocollo ITACA. On January 2004 Protocollo ITACA was officially adopted by the Conference of the Presidents of the Italian Regions. Since that moment, Protocollo ITACA is the official public assessment tool of the Italian regions. Starting from 2004, the Italian regions began to adopt Protocollo ITACA and to use it in public policies. The first one was Regione Piemonte that included the assessment tool in a very important urban retrofit program (Neighbourhood Contracts II) giving incentives based on the level of score produced by the application of Protocollo ITACA. Other regions (Tuscany, Marche, Puglia, Liguria, etc.) followed.

Considering the increasing use of the Protocollo ITACA and the need expressed by the Regions to be supported in its implementation in new policies, iiSBE Board of Directors decided to establish a national chapter in 2005: iiSBE Italia. The national chapter acts on behalf of iiSBE and manages the use and implementation of GBTool in the Italian context. An agreement between iiSBE Italia and ITACA is then signed. iiSBE Italia is recognized as the

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

technical control body of the Protocollo ITACA assessment system. Since that moment iiSBE Italia is supporting ITACA in the developments and update of Protocollo ITACA.

A major update was done in 2007. Beside the full version of the assessment systems (70 criteria) it was produced a light version (15 criteria). The idea was to facilitate the use of Protocollo ITACA by professionals, considering that the wide majority of them was not used at all to building rating systems. A "compact" version was intended to be more easily "acquired" in a first phase by professionals and organizations in the building sector. This strategy showed to be very effective helping a wider use of Protocollo ITACA.

In 2009 and 2011 new versions of the national system was issued following the new Italian energy regulations. A key principle in the development of Protocollo ITACA is its total alignment with the national and regional energy certification standards and with the Italian technical standards (UNI). This alignment allows to reduce the effort, in terms of cost and time, necessary to apply Protocollo ITACA. The energy calculations done for the mandatory national certification are the same one requested in Protocollo ITACA.

3. FROM PROTOCOLLO ITACA TO A NATIONAL STANDARD

In 2011 about 2000 buildings were already assessed in Italy with the 15 different regional versions of Protocollo ITACA. In that period, the private sector started to ask ITACA to implement a national certification system fitting also the market needs. Up to that moment the use of Protocollo ITACA was limited to public policies. Almost the 99% of the 1500 buildings were certified because a public incentive or regulation. The Protocollo ITACA systems was not organized to act as certification system for the real estate market. In 2011 in many regions it wasn't possible to receive a voluntary Protocollo ITACA certification if not in the context of a policy or program.

The private sector was asking an assessment system operational and accessible in the whole country based on a unique standard. What was appreciated by the private construction companies of Protocollo ITACA is its affordability, operability and limited cost maintaining in the same time the technical and scientific value of the assessment. All element favourable for a mass diffusion of building certification.

To answer this need, the strategy of ITACA and iiSBE Italia has been developed in two directions. The first move has been to transform the national version of Protocollo ITACA in a national standard (UNI). The second to define a certification process under national accreditation.

3.1 The new national standard: UNI PdR13

In 2012, an agreement was signed between ITACA and UNI (Italian National Standardization Body) and a working group activated with the support of iiSBE Italia. In less than one year, the 2011 version of Protocollo ITACA was updated in the UNI PdR 13 standard, named "Environmental sustainability of construction works - Operational tools for sustainability assessment".

The PdR 13 is articulated in three sections. The PdR 13.0 concerns the "General framework and methodological principles". The methodology described is the SBTool. This origin of Protocollo ITACA and PdR 13 is declared in the first part of the standard. The other two sections (PdR 13.1 and PdR 13.2) contains the description of criteria, indicators and assessment methods for the residential buildings (PdR 13.1) and non-residential buildings (PdR 13.2). UNI is the only organization allowed to distribute the PdR13. The document is downloadable form the UNI website for free because it is a public assessment tool. With this move two objectives were reached. The first was to make available in the whole country a national assessment tool as UNI standard. The second to strength the value of Protocollo ITACA. Today it isn't anymore only the public assessment system of the Italian regions but instead it is the official technical assessment tool for Italy.

3.2 The implementation of the national certification process

Always in 2012 a second agreement was signed between ITACA and Accredia. Accredia is the national Italian accreditation body. It is the national organization that accredits certification bodies to can carry out inspections and audit activities with regards to UNI standards. ITACA and Accredia, with the support of iiSBE Italia, defined the Technical Regulation 33 (RT33) for the accreditation of organizations with respect to UNI PdR 13 – Protocollo ITACA. To be accredited a certification body must comply with the RT 33 requirements. One of them is the availability of an accredited assessor. This one is a professional, usually an architect or engineer, that took a training course and passed an examination. The accreditation of assessors is done by ITACA. Training courses and exams are organized and managed by iiSBE Italia.

3.3 The implementation of the national certification process

To manage the whole national system ITACA created a new no profit organization, the Comitato Protocollo ITACA. Comitato Protocollo ITACA is the organization that manages the national registry of certifications and that issues the certificate on the base of the audits done by the accredited certification bodies.

iiSBE Italia collaborate with Comitato Protocollo ITACA performing the second level audit, controlling the work done by the certification bodies. To obtain a Protocollo ITACA certificate the owner of the building can choose any accredited organization consulting the national registry that is a web based portal. He's free to choose its preferred certification body. The PdR13 is a fully certification system following the ISO requirements in this field.

The establishment of the PdR13 not only made available a fully operational national certification system to the private sector. It is also encouraging the adoption and use of Protocollo ITACA by public administrations, such as municipalities or agencies. One of the main problems in the use of a rating system in local policies is the control of the assessment. For instance, if an incentive, financial of other nature (i.e. increase of volume), depends on the score achieved by the building, the public administration should be able to check the assessment report provided by the owner or the professional. This aspect created in the past many problems. With the RT33 and the new national certification process a public administration just has to ask a certificate issued by the national registry.

This approaches combines the public and private needs in one open and transparent systems that is expected will encourage the mass diffusion of sustainability certification in Italy.

ABSTRACT

With the introduction of the Guideline for Sustainable Building the Federal Government has enforced an important component of its sustainability strategy in the public sector. In the first step the Federal Building Authorities are obliged by edict to evaluate their buildings, using the Assessment System for Sustainable Buildings (BNB). BNB has become the most important tool to implement high quality standards. The actual task is, to establish good conditions for a broad implementation of the BNB into practical work of the public sector in total. The leading question is, how the Network for Sustainable Federal Building can be used as a quality assurance tool within the implementation of the BNB in the public sector.

The Office on Sustainable Building within the Federal Institute for Research on Building, Urban Affairs and Spatial Development (BBSR) has the task of advising the Federal Ministry for the Environment, Nature Conservation, Building and Nuclear Safety (BMUB) concerning Sustainable building and supporting and coordinating the Network for Sustainable Federal Building. The BBSR also develops and coordinates research projects in the frame of the "Research Initiative Future Building" in order of the BMUB. This includes activities related to the development of instruments and tools for the application of the Assessment System BNB and the scientific evaluation of results from the implementation.

The Network for Sustainable Federal Building brings together around 380 BNB sustainability coordinators from federal and state administrations, thereby creating an internal information and communication platform. One key element of the network is the annual convention for all those who apply the BNB. It gives the chance to regularly exchange experiences on implementing the BNB in the relevant building authorities.

The paper will show first results from the implementation in practice. Further information is carried out with the Information Portal Sustainable Building "http://www.nachhaltigesbauen.de/".

Keywords: policy and regulation, green rating tool, public sector

1. INTRODUCTION

With the introduction of the Guideline for Sustainable Building in 2001 the Federal Government has enforced an important component of its sustainability strategy in the public sector. It was made obligatory for the Federal Building Authorities and operates as a practical aid in the planning phase, the construction, the utilisation including the structural maintenance and the modernisation.

In March 2011, a reworked version of the Guideline for Sustainable Building was introduced by the German Federal Building Ministry. Thus the Federal Building Authorities were obliged by edict to evaluate Office and Administration Buildings, using the Assessment System for Sustainable Building (BNB). Using the Assessment System is voluntary for other building authorities, such as Federal States, municipalities or the private sector.

The Office on Sustainable Building within the Federal Institute for Research on Building, Urban Affairs and Spatial Development (BBSR) has the task of advising the Federal Ministry for the Environment, Nature Conservation, Building and Nuclear Safety (BMUB) concerning Sustainable building and supporting and coordinating the Network for Sustainable Federal Building. The BBSR also develops and coordinates research projects in the frame of the "Research Initiative Future Building" in order of the BMUB. This also includes activities related to the development of instruments and tools for the application of the Assessment System BNB and the scientific evaluation of results from the implementation into practice.

2. EVALUATION OF SUSTAINABILITY IN THE PUBLIC SECTOR IN GERMANY

2.1 The round table for sustainable building

According to the national Sustainability Strategy in Germany the Round Table for Sustainable Building was established in 2001, as an advice board for the Federal Building Ministry, and has since then supervised the development of sustainable building on a federal level. The Round Table is constituted of numerous representatives from the building industry, the building materials industry, the Chamber of Architects, the Chamber of Engineers, federal, state and municipal building authorities as well as scientific institutions.

The continuous involvement of the Round Table ensures the further development of sustainable building, with a high level of acceptance within the German building sector. The different working groups of the Round Table make a key contribution to the systematic and content-based development of a uniform national assessment system in Germany, which also forms the basis of the Assessment System for Sustainable Building (BNB). Furthermore, the federal states and municipalities will receive information and advice, to strengthen the implementation at the same level.

2.2 The guideline for sustainable building

As a result of concrete specifications by the Federal Ministry for the Environment, Nature Conservation, Building and Nuclear Safety (BMUB), the Guideline for Sustainable Building [BMUB, 2014] and the introduced Assessment System for Sustainable Building (BNB) [BMUB, 2016a] have become the most important tools with which to implement high quality standards in federal construction. With the introduction of the Guideline for Sustainable Building the Federal Government has enforced an important component of its sustainability strategy in the public sector.

The Guideline for Sustainable Building explains the generally valid principles and methods for sustainable planning, building, operation and use of buildings and properties. It thus addresses both, the planning, design and construction as well as the use and operating phase of existing buildings. However, this Guideline also serves as a tool when it comes to considering aspects of sustainability during the entire life cycle of buildings and properties. Therefor the Guideline is broken down into the following parts:

- Part A - Principles of sustainable building
- Part B - Sustainable building projects
- Part C - Recommendations for the sustainable use and operation of buildings
- Part D - Refurbishment of buildings

The documents needed to implement the Guideline for Sustainable Building are included in Annexes and can be downloaded via the "Information Portal Sustainable Building (www.nachhaltigesbauen.de). These documents include, for instance, the criteria profiles, input data or minimum fulfilment levels for the BNB Assessment System. This concept enables the ongoing updating of the information, tools and other documents which supplement this Guideline and thereby ensures that these documents are as up to date as possible.

3. NEW QUALITY STANDARD FOR FEDERAL BUILDINGS

3.1. The assessment system for sustainable building

Various research projects, financed under the Research Initiative "Future Building" of the Federal Ministry for the Environment, Nature Conservation, Building and Nuclear Safety (BMUB) provided the basis for a research- and planning-based sustainable construction evaluation system for office and administrative buildings, being advanced as "Assessment System for Sustainable Building - BNB".

The System follows an integrated approach of evaluation taking the life cycle of a building into account and carrying out quantification according to transparent and comprehensible rules. For the actual observations of the life cycle, the first 50 years of a building are worked into the calculations. The Evaluation is based in five main groups of criteria of sustainable building: ecological quality, economic quality, sociocultural and functional quality, technical quality and process quality.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The main goal sought in the ecological dimension is primarily the protection of resources by optimally using construction materials and products, minimizing use of space and of media (e.g. heat, electricity and water).

All requisite energy and material flows from the gain through the refinement and transport to the installation or disassembly alongside the global and local effects on the environment made by the energy use of the construction materials or the buildings are considered. Generally, this reduces environmental pollution at a local and global level. Different methods of analysis, e.g. risk analysis, analysis of the material flow, the material analysis and the ecological balance, are to be applied to objectively assess the environmental compatibility of construction products and of the whole building concept.

The costs which go above and beyond the mere costs of purchase and assembly – especially the life cycle costs are considered in the economical dimensions of sustainability. This places the focus on life cycle costs relevant to the building, the economic viability and the value stability. As practice has shown, the life cycle costs can by far exceed the costs of construction. By analysing the life cycle costs, considerable opportunities for saving money during planning can be identified. As Life-Cycle-Costs (LCC), the costs of construction, the construction use costs and the demolition costs are additionally considered.

In addition to the question of functionality, the question of aesthetic design, the health aspects and comfort are relevant points in considering the social and cultural dimensions of sustainability. Winter and summer heat insulation contributes to comfort just as much as the noise protection or a deliberately chosen type of construction material (e.g. the use of emission free products). Construction designs, choice of material, building construction and technology are to be interpreted to that effect and to be optimised, if needed. At the same time the construction design is to be made flexible enough that it can be easily adapted to the changing parameters e.g. change of use/ user.

Alongside the ecological, economical and sociocultural aspects, the functional and technical properties (technical quality), the planning and implementation (process quality) and the local characteristics are decisive for the description and value of a building. This has extended the three columns of sustainability to five quantifiable qualities of sustainability – informatively supplemented by the local characteristics. The various aspects of sustainability interact directly with each other, so that the goal becomes a holistic and simultaneous assessment of every aspect.

The BNB is organized into three different levels. The actual definition of the qualities takes place on the criteria level. These are described in detail in 45 criteria profiles on the basis of a total of around 150 indicators. The criteria profiles are grouped thematically in 11 criteria groups and 6 main criteria groups, thus making it possible to identify special qualities on each level. An overall score is calculated, based on the evaluation results and a specific weighting. The location profile, which is influenced by the planning activities only in a limited degree, is mentioned separately. The modular structure of the system enables a differentiated presentation of the results; particular attention can thus be drawn to exceptional qualities in one or more subordinate areas of the assessed building. Depending on the overall performance, the building can be awarded with a bronze, silver or gold certificate.

The Federal Ministry for the Environment, Nature Conservation, Building and Nuclear Safety (BMUB) therefore provides free available quantitative data for life cycle analysis, which ensure that sustainability criteria can be included in planning and construction processes and comprehensively documented. BNB enables a transparent and objective evaluation of the sustainability of public buildings.

3.2. Development of instruments and tools

Different fundamental tools are available to support the application of the Assessment System BNB in the federal building authority. These tools are designed within the frame of various research projects of the “Research Initiative Future Building” to enable and ensure the integration of sustainability aspects into planning, design and execution and their documentation. These include tools like:

- eBNB - Electronic assessment system for sustainable building
- WECOBIS - Ecological building material information system
- eLCA - Electronic life cycle assessment tool
- ÖKOBAUDAT - Online building material database

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

During the planning and construction phase a wide range of relevant data from various sources would be generated by the project participants. It is necessary to integrate selected data into the Assessment System BNB to get an auditable data base for the assessment and the documentation of the sustainability. The Electronic Assessment System for Sustainable Building (eBNB) [BMUB, 2016b] enables the project-related collecting, recording and controlling of all parameters necessary to effectively implement the requirements of sustainable Building. The data can be used during the planning and building process for controlling, after finishing the building for quality assessment and during the using phase to evaluate its success.

The development of the eBNB was commissioned as a project within the frame of the Research Initiative Future Building of the BMUB. The target was to develop a computer-assisted assessment and documentation tool, ensuring planning and building support through the Assessment System BNB by providing a project management system that was oriented towards sustainability. In addition to this eBNB should also allow the scientific evaluation of building measures and the generation of parameters for future projects. It is applied during all life-cycle phases of a building and also serves to maintain and continuous develop the assessment methods of the BNB. Initial results already indicate the project's comprehensive success.

WECOBIS [BMUB, 2016c] is a web based building material information system providing basic knowledge about healthy and ecofriendly construction. This web portal was developed by the Federal Institute for Research on Building, Urban Affairs and Spatial Development (BBSR) and the Bavarian Chamber of Architects, the contents are edited by an international group of specialized editors. WECOBIS categorizes environmental and health aspects of building materials according to the life cycle phases. With the focus on the Assessment System BNB, WECOBIS offers especially prepared knowledge on building materials for certain BNB criteria profiles.

Building activities are characterized by enormous energy and material flows. The effects of a building on resource consumption can be described based on the eco-balance methodology. The Electronic Life Cycle Assessment Tool eLCA [BBSR, 2016] has been developed under guidance of the BBSR to support users calculating the impacts on the global and the local environment. In conjunction with the online database ÖKOBAUDAT, eLCA offers a quantitative assessment across the entire planning process. The application of eLCA by different users in a longer test phase, among others in the building authority as well as universities, attest, that this instrument is well suited to implement the expected goals.

ÖKOBAUDAT [BMUB, 2016d] makes available quality-checked product-related data sets from the construction sector for all relevant building materials on the basis of their life-cycle phases. These generic data from the Environmental Product Declaration (EPD), compliant to the European DIN EN 15804, can be directly exported to the eLCA tool. In this form, the eco-balance enables a significantly higher quality of decision-making during the planning process.

4. IMPLEMENTATION OF THE SUSTAINABILITY ASSESSMENT

4.1. Federal building authorities

In the first step the Federal Building Authorities are obliged by edict to evaluate their buildings, using the Assessment System for Sustainable Buildings (BNB). For instance for newly erected office, administration, educational and laboratory buildings with investment costs of €2 million and above, the appropriate BNB requirements must be applied so that the building quality fulfils the "Silver Standard". This Standard is going far beyond today's usual standards in terms of energy efficiency, environmental effects and user comfort, among others. The Federal Government plays a model role, especially with gold standard certified buildings. Ambitious new construction projects such as the Federal Environment Agency in Berlin-Marienfelde and the Federal Ministry of Education and Research (BMBF) in Berlin have already been awarded the highest "Gold Standard" BNB certification.

The BMBF is the first federal civil building project that was realised by Public Private Partnership (PPP) and also the first building of that kind and size that received a certificate of BNB in gold. The project distinguishes itself by very high qualities and degrees of fulfilment in all main criteria groups of the assessment system BNB (81 % - 99 %). This outstanding pilot project is now the best federal building according to proven sustainability requirements. The six-storey building of the Federal Ministry of Education and Research (BMBF) was designed for about 1.000

office workplaces and is integrated in the existing development at the Berlin "Spreebogen" vis-a-vis the government district as a recognizable city block.

The energy concept for BMBF combines measures of optimizing the building physics according to the construction and technical systems which are in some places conventional and in other places very innovative. The project could be realized in a high economic efficiency with a high energy quality and a high level of comfort for the user. In order to ensure the flexibility and adaptability of the building for possible changing user demands in the future, the building enables different types of efficient office structures. The requirements according to the user demand for a high level of comfort are met by numerous aspects. An interdisciplinary planning team ensured that the requirements of sustainable building were adhered to using an integral planning and a holistic approach during the whole planning and building process. The procurement and the supply of materials were controlled with an extraordinary effort and the extent and quality of the building and material documentation is exemplary. The degree of fulfilment of the requirements of BNB according to process quality is 99 %.

Beside the BMBF numerous other current federal building projects consider the requirements of the BNB, like for example: the new office building for about 30 employees of the Federal Environment Agency in Berlin is designed as the first federal "zero energy building" and received the certificate of BNB in gold in 2015.

The renovation and reconstruction of the listed Federal Constitutional Court in Karlsruhe received the first certificate in silver according to BNB Complete Refurbishment Module, with a view to balancing the existing building structure.

4.2. Network for sustainable federal building

Within the Network for Sustainable Federal Building, the BBSR currently brings together around 380 BNB sustainability coordinators from federal and state administrations, as well as the Institute for Federal Real Estate (BImA), thereby creating an internal information and communication platform. The Information Portal for Sustainable Building serves as a forum for discussing and sharing experience gathered in practically applying the BNB, thus promoting further development of sustainable building. The experience gathered while applying the BNB system variants in practice is reflected in the FAQs published in the portal.

One key element of the network is the annual convention for all those who apply the BNB, which is organized by the Department of Sustainable Building. It gives sustainability coordinators the chance to regularly exchange experiences on implementing the guideline and the BNB in the relevant building authorities. The two-day event provides a mixture of plenary lectures, discussion groups and workshops on specific themes, such as contractual design, the introduction of new instruments including electronic Life Cycle Assessment (eLCA) and the concrete study of the building authorities' practical experiences.

The Network for Sustainable Federal Building is becoming increasingly important with respect to allocating tasks of compliance testing to federal building authorities. The tasks concerning advice and certification for federal building measures, which were assumed by the BBSR until the end of 2014, will be successively taken over during 2015 by the Federal Office for Building and Regional Planning (BBR) and by the offices responsible for technical supervision in the individual states on their own authority.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

On this basis, compliance testing for the overhauled and extended Federal Constitutional Court in Karlsruhe was carried out during its award process by the Baden-Württemberg Control Centre for the Sustainable Building of Federal Buildings. The Control Centre was also assigned with compliance testing of federal building authority measures for the BNB use profile “Research and Laboratory Buildings”, to ensure a uniform standard of assessment on a federal level. In coordination with the BBSR, it has already been able to successfully complete compliance testing for four laboratory buildings. The Federal Office for Building and Regional Planning continues to carry out compliance testing for building measures that are implemented on its own account, including for this system variant.

5. CONCLUSION

Sustainable procurement is a fundamental principle of the Federal Government in Germany and the German Assessment System Sustainable Building (BNB) addresses important climate-relevant effects. The Guideline for Sustainable Building was implemented into the practical work of the Federal Building Authorities. All federal projects are a part of the sustainability strategy of the federal government and they demonstrate that higher qualities according to the holistic approach of sustainability can be implemented in daily praxis. The experiences can be used for new recommendations or future requirements for sustainability projects in the public sector. The BNB has been successfully applied for federal buildings.

The intensive specialist exchange between the newly created compliance testing offices and the Office of Sustainable Building achieves quality assurance with respect to the uniform interpretation and application of the BNB and thereby makes a decisive contribution towards implementing sustainable building within federal building authorities. The actual task is, to establish good conditions for a broad implementation of the Assessment System BNB into the practical work of the public sector in total. Now other clients, such as the federal states and the local authorities are invited to make use of the BNB-System. Now the challenge is to introduce the BNB Assessment System in the municipal sector and residential construction.

Further result would be considered by the presentation. More information is carried out in the internet with the Information Portal Sustainable Building “http://www.nachhaltigesbauen.de/” of the BMUB.

ABSTRACT

The assessment of building materials and products in the US has been rapidly evolving since the onset of the contemporary American green building movement in the early 1990s. Presently three green building organizations, the US Green Building Council (USGBC), the Green Building Initiative (GBI), and the International Living Futures Institute (ILFI), offer competing visions of criteria for sustainable products, among them how to determine the safety of products from a chemical perspective. In assessing the safety of building materials and products in their green building assessment processes, the USGBC Leadership in Energy and Environmental Design (LEED) and the ILFI Living Building Challenge (LBC) rely on hazard-based assessment (HBA) which entails designating specific materials that are not suitable, from a toxicity perspective, for use in a green building. A competing vision, promulgated by the GBI in the forthcoming version of the Green Globes building assessment system, is risk-based assessment (RBA) which contends that simply banning products because they contain certain chemicals is inadequate and unscientific because the dose and the exposure scenario are not considered. Recent changes to the ANSI/GB01 standard underpinning the GBI's Green Globes certification system offer an alternative, risk-based approach for assessing materials toxicity.

Hazard-based tools include Cradle to Cradle, DECLARE, and GreenScreen. Some hazard-based tools provide a list of banned materials while others provide a more detailed analysis with various levels of action required depending on the ingredients of the product. Risk-based product assessment tools follow the procedures outlined in NSF/GCI/ANSI 355: Greener Chemicals and Processes Information Standard which provides the rules for this process.

This paper will present trends in building materials/products toxicity assessment and provide an analysis of these approaches regarding their impacts on the stakeholders in the US design and construction industry.

Keywords: hazard-based assessment, risk-based assessment, materials toxicity

1. INTRODUCTION

The sustainability assessment of commercial and institutional buildings in the US dates from 1998 when LEED v1, the pilot version, was completed and issued for testing. Since that time LEED has evolved through several editions: LEED v2 (2000), LEED v2.1 (2002), LEED v2.2 (2005), LEED v3 (2009), and LEED v4 (2013). The early versions of LEED prior to LEED v4 did not address materials toxicity per se but did include consideration of volatile organic compound emissions from interior finishes such as carpeting, paints, ceiling tiles, and other building interior products in the context of indoor air quality. This was also true of the approach used in the first two versions of Green Globes which also addressed VOC emissions from various classes of materials that could affect indoor air quality.

Post-2010 evolutions of LEED and other US green building assessment systems have significantly altered the evaluation of materials and products by including life cycle assessment(LCA), Environmental Product Declarations (EPDs), ingredient reporting, and toxicity evaluations as issues for project teams to consider. This paper will discuss the most recently emerging issue of building materials assessment, materials toxicity assessment, and the two major approaches being used for this purpose risk-based assessment (RBA) and hazard-based assessment (HBA). Building materials toxicity has emerged as an important issue in the green building community and LEED v4, for example, offers three options for addressing so-called chemicals of concern. One of these options is transparency with the desired outcome being that the disclosure process will motivate manufacturers to more carefully scrutinize their product ingredients and begin a process of eliminating chemicals with documented significant impacts on humans and ecosystems. More recently, ANSI/GB01-2017 (draft), Standard for Green Building Assessment under development by the Green Building Initiative (GBI) that will eventually become an updated version of Green Globes applies a risk-based approach that takes into account the dose and exposure scenario to assess the statistical probability of harm.

2. RISK ASSESSMENT VERSUS HAZARD ASSESSMENT

At present there are two fundamental approaches competing for inclusion in building product toxicity evaluation process: risk-based assessment (RBA) and hazard-based assessment (HBA). HBA relies on so-called red lists of chemicals generated by promulgating organizations that are considered to be problematical for humans or other organisms. According to the International Program for the Good Management of Chemicals (IOMC), hazard is "… the inherent property of an agent or situation capable of having adverse impacts on something, hence the substance, agent, source of energy, or situation having that property." Hazards are based on the toxicity of a chemical, its ability to produce harm and adversely affect living organisms. Chemicals that have such an adverse effect are also referred to as poisons. In the green building context, the impacts of interest are those that affect humans and other living organisms throughout the life cycle of the product or material. In contrast, risk is the "… probability of adverse effects caused under specified circumstances by an agent in an organism, a population, or ecosystem". The relationship between risk and hazard is straightforward and is credited to Paracelsus in 1538:

$$\text{Risk} = f\,(\text{Hazard} \times \text{Exposure})$$

Equation 1

Risk is a function of both the hazard and the exposure or dose of the chemical based on exposure scenarios. The risk to workers manufacturing a product, to construction workers installing the product in a building, to occupants of the building during the building's use phase, and to demolition workers during the end of life removal phase are likely all different. The science of toxicology, which controls all regulatory decisions regarding chemicals and toxic organisms in food and other products to which humans are exposed, is based on risk. Although common foods often contain small quantities of hazardous substances such as arsenic, nickel, and formaldehyde, government agencies tasked with protecting the general public have determined that if the concentrations of these chemical are below a specified thresholds, then for the likely exposure scenarios the risks are acceptably low. Gasoline and diesel fuels, well-known hazardous chemicals that are toxic and flammable, are used in automobiles and other vehicles because they are engineered to make the risks from chemical exposure, fire, and explosions within an acceptable range.

2.1 HBA for building materials

HBA is predicated on identifying chemicals that can threaten the human and ecosystem health. Chemicals that could be used in green building products and materials and are considered hazards are published as "red lists" generated by green building organizations such as the ILFI use in conjunction with the LBC building assessment system. Perkins + Will, a well-known design firm has developed and publishes a Precautionary List, a variety of a red list for use in its projects (See Table 1). As described by Perkins + Will, "… the Precautionary List includes substances commonly found in the built environment that have been classified by regulatory entities as being harmful to the health of humans and/or the environment." HBA tools such as Green Screen have been developed to provide comprehensive assessment. Referenced in LEED v4, Green Screen reviews 650 internationally recognized lists and sub-lists of high hazard chemicals for its clients for the purpose of highlighting potential problems with their products.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Alkyphenols+	Hexavalent Chromium (VI)
Arsenic*	Hydroflurocarbons (HCFCs)
Asbestos+	Lead
Bisphenol (BPA)	Mercury
Bromochlorodifluoromethane*	Organostannic Compounds
Cadmium	Pentachlorophenol*
Chlorinated Polyethylene (CPE)	Perfluorocarbons (PFCs)
Chlorinated Polyvinyl Chloride (CPVC)	Phthalates
Chlorobenzene+	Polystyrene*
Chlorofluorocarbons (CFCs)	Polyurethane foam*
Chloroprene (2-chloro-1, 3-butadiene)	Polyvinyl Chloride (PVC)
Chlorosulfinated Polystyrene (CSPE)	Short Chain Chlorinated Paraffin+
Copper (for exterior material)*	Urea-Formaldehyde
Creosote	Volatile Organic Compounds (VOCs)
Halogenated Flame Retardants	

Table 1: Chemicals listed in the LBC Red List and the Perkins + Will Precautionary List.

Note: Chemicals that are only on the LBC Red List are designated with a (+) and those that are solely on the Perkins+ Will Precautionary List are followed by a (*). All other chemicals are on both lists.

There is currently no such thing as a standardized red list and there are significant differences in the chemicals listed in the versions published by the ILFI, Perkins+Will, and others. Clearly it is open for question as to why arsenic and asbestos are not on both lists.

Hazard-based assessment does not take into account exposure scenarios and thus there is no associated probability of impacts. Various hazard tools or certifying organizations have different reporting thresholds for determining if a hazardous chemical must be reported. Most require de minimis reporting of chemicals present in a product at a concentration of 1000 ppm (0.1%) or greater, the standard used by the US Environmental Protection Agency. However, some organizations have a requirement to report the presence of all chemicals down to a concentration of 100 ppm (0.01%).

2.2 RBA

The framework and requirements for RBA are described in NSF/GCI/ANSI Standard 355: Greener Chemicals and Processes Information (2011). This standard identifies chemical ecologic, health, and safety characteristics of concern, plus process manufacturing factors for assessing sustainability impacts (i.e., mass efficiency, water usage, energy consumption, bio-based content, and process safety). Risk based assessment requires that the exposure scenario be considered to determine if for a given hazard, a hazardous effect is produced. The route of exposure (oral, dermal, or inhalation) and the amount, duration, and frequency of exposure are all major determinants of toxic manifestation. Product formulation is also important because the other produce constituents such as solvents, binders, surfactants, and viscosity agents greatly affect the exposure and absorption of a hazardous constituent. Additionally, the toxic effects are also a function of the concentration of a hazardous constituent in the product, the total volume used, and the rate of exposure. To be able to fully characterize the hazard of a specific chemical ingredient, the type of effect, the exposure conditions, and circumstances of exposure must be known. The combination of exposure and the spectrum of hazards are expressed as a dose-response relationship. Care must be taken when extrapolating data from, for example, animal tests, where high concentration of chemicals may be used to determine the likely impact on humans for much smaller doses. A number of chemicals on red lists are likely the result of the difficulty in connecting high dose animal test results to human impacts. When the situation has been thoroughly described and the dose-response relationship can be applied, a risk characterization can be performed. This can be carried out using the process described in the national consensus standard, NSF/GCI/ANSI Standard 355. This standard identifies the chemical, ecologic, health, and safety characteristics of concern. It also identifies process manufacturing factors for assessing sustainability impacts such as mass efficiency water usage, energy consumption, bio-based content, and process safety. In the implementation of this process, web-based tools, such as GreenSuite, incorporate algorithms that utilize the ecological, health, and safety hazard characteristics defined in NSF/GCI/ANSI Standard 355 and normalized data to screen and prioritize chemical inventories, determine product risks, or assess comparative product risks for procurement, utilizing objective criteria and standardized hazard characteristic data.

3. MATERIALS HAZARD AND RISK-BASED ASSESSMENT SYSTEMS AND PROGRAMS IN THE U.S.

The following paragraphs describe the most commonly used HBA and RBA systems in the U.S. The HBA systems referred to in LEED v4 include Cradle to Cradle, the Safer Choice Label, the Health Product Declaration (HPD), DECLARE, and GreenScreen. The LBC relies on the DECLARE system, a HBA developed by the LBC promulgating organization, the ILFI. The new version of Green Globes relies on RBA as defined in NSF/GCI/ANSI Standard 355 and implemented in tools such as GreenSuite. REACH is a European system designed as a RBA but the REACH Restricted List is sometimes used to support HBA.

3.1. Registration, Evaluation, Authorization and Restriction of Chemicals (REACH)

REACH is a regulation developed in 2007 by the European Chemicals Agency (ECHA) to improve the human and environmental protection against risks posed by chemicals ranging from industrial processes to day-to-day use. According to the ECHA, "In principle, REACH applies to all chemical substances; not only those used in industrial processes but also in our day-to-day lives, for example in cleaning products, paints as well as in articles such as clothes, furniture and electrical appliances. Therefore, the regulation has an impact on most companies across the EU. REACH places the burden of proof on companies. To comply with the regulation, companies must identify and manage the risks linked to the substances they manufacture and market in the EU. They have to demonstrate to ECHA how the substance can be safely used, and they must communicate the risk management measures to the users." REACH has four processes to regulate a substance, which include registration, evaluation, authorization, and restriction. Registration is required for all substances manufactured or imported in quantities of over one ton per year, unless no risk is associated with the chemical. The information required for registration varies according to the available information on that chemical, the tonnage to be manufactured/imported, the use, and exposure. In the evaluation phase, manufacturers must electronically submit a Technical Dossier and a Chemical Safety Report (CSR) through the International Uniform Chemical Information Database (IUCLID), a software application used to store and exchange data on chemical's information. The chemical assessment or CSR ensures that the risks from the chemical life-cycle are under control. If risks are not under control and no more iterations are possible to control the negative effects, the chemical use will be restricted and will be included on the REACH restricted list. The REACH regulation is referred to in the LEED v4 rating system under the Material Ingredient Optimization criteria. Although designed for RBA purposes, in the context of LEED v4, the REACH Restricted List functions as a very large red list.

3.2. Cradle to Cradle

The Cradle to Cradle (C2C) product certification system suggests that products should be designed based on the nature's model and eco-efficiency, encouraging the upcycling vision of converting products and materials into biological or technical nutrients at the end of their useful life without compromising the human and environmental health. Therefore, the C2C is a health-based assessment focused mainly on the waste generation of products and the hazard assessment of ingredients. C2C is one of the HBA tools reference in the LEED v4 Materials and Resources category/ The C2C certification is a multi-attribute evaluation on five categories: material health, material reutilization, renewable energy and carbon management, water stewardship, and social fairness. Requirements are completed in chronological order for each category, so the level of accomplishment on each category determines the category achievement rating, which could be Basic, Bronze, Silver, Gold, and Platinum. The product final certification is based on the lowest achievement level from all five categories. The Material Health category has 11 requirements that range from a simple verification on banned chemicals until a hazard-risk assessment of the product. The very first step for the material assessment is a comparison of the product's chemicals with the two C2C banned lists, a group of chemicals forbidden to be intentionally used over 1000ppm because of their adverse effects on the environmental (Biological Nutrients list) or human health (Technical Nutrients list). The allowable threshold may vary for some chemicals in the Technical Nutrient list if management plans are able to minimize the exposure effects. Manufacturers are required to characterize all homogeneous and generic materials in their products, creating a "Bill of Materials".

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.3. US EPA: Safer Choice Label

The Safer Choice Label is the most recent update of the program known as "Design for the Environment"(DfE) developed by the U.S. Environmental Protection Agency (EPA) in 1992 to recognize products with reduced impacts for human health and the environment. The program was first developed to help consumers make decisions during purchases. Nowadays, the Safer Choice label is mandated by many jurisdictions and is referred to in the LEED v4 requirements for existing buildings and is preferred for Federal Agencies by virtue of Executive Order 13693 (2015).

Manufacturers are required to disclosure all chemicals intentionally added to the product, including those from third-party suppliers, regardless of the percentage on the product. A third-party profiler, normally NSF International or ToxServices, is responsible for developing the hazard profile, and identifies and evaluates the available toxicological and environmental fate data. The report is reviewed by the EPA and evaluated against the EPA's Safer Choice General Standard and the specific requirements according to the ingredient functional-class.

The Safer Choice program uses a Safer Chemical Ingredients List (SCIL) designed to help manufacturers find alternative chemical that satisfies the Safer Choice criteria. The list contains around 750 chemical ingredients divided according to the chemical functional class and labeled with colors according to the level of concern of each chemical. The complete assessment will provide thresholds levels and information about the chemical safer use that can be included on the SCIL.

3.4. Health Product Declaration (HPD)

The Health Product Declaration (HPD) is a customer-led collaboration that aims at improving building industry performance by increasing transparency, openness, and innovation in the product supply chain of the building industry. HPD is an open standard that lists the product contents and health hazards associated with the products. Hazard identification in HPD is based on HPD priority hazard lists, the GreenScreen list translator and, if available, full GreenScreen assessment (HPD Standard Version 2). HPD does not provide any information regarding the risk associated with handling and/or using materials and products. Also the HPD does not provide any information regarding the environmental impact of a products life cycle or the health impacts of substances used/created during the manufacturing of products. The HPD standard focuses on materials and substances. For materials, HPD is concerned with the percentage of the materials in the final products (variation range of material, ranges in similar products, alternate and undisclosed percentage) and the inventory threshold (100 ppm, 1000 ppm) required level for Safety Data Sheets (SDS) as described by the Globally Harmonized Systems of Classification and Labeling of Chemicals (GHS), OSHA MSDS thresholds and/or other types of protocols. HPD can be used as material certification in both LEED v4 and LBC.

3.5. DECLARE

DECLARE is a building material ingredients disclosure system that aims to increase transparency and open communications in the building industry. Manufacturers can enter DECLARE and reveal all ingredients of their products to the public. Designers can also use the DECLARE database to choose non-hazardous substitute materials. DECLARE requires reporting of all intentionally added ingredients by manufacturers plus residuals up to 100 ppm, the name of the chemicals, CAS number, and the percentage range and weight of all ingredients. It is worth noting that there is no need to report natural occurring, unintentionally added ingredients and process chemicals. Manufacturers should evaluate their products to see whether there are any materials on the DECLARE red list (determined Red List Compliance). However, there are some exceptions for some specific red-list materials.

DECLARE has a large red-list database. Although the DECLARE red list database was launched in 2006, it is constantly updated to be in compliance with LBC version 3, the EPA Action Plan Published List, the REACH Substances of Very High Concern (SVHC) List and the Cradle to Cradle Banned List. DECLARE is mainly used in LBC, however, it is recently officially recognized by USGBC as a way of earning points in LEED v4.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.6. GreenScreen

GreenScreen for Safer Chemicals is a hazard-based assessment method developed by Clean Production Action. GreenScreen is an open source assessment with publicly available criteria for categorizing chemicals based on their hazards. There are two type of analysis in GreenScreen assessment including the GreenScreen List Translator and the GreenScreen full life cycle assessment. A GreenScreen full life cycle assessment evaluates chemical hazards, identifies concerns, and considers safer alternatives. GreenScreen provides a third party verification HPD for green facade products. The List Translator does not include the hazards associated with manufacturing and degradation of the product. The List Translator is an online tool to check 650 internationally recognized lists and sub-lists of high hazard chemicals. The List Translator categorizes chemicals based on their hazard level. There are two types of lists for categorizing chemicals: authoritative lists and screening lists. The full GreenScreen assessment is categories into five benchmarks, and provides all the data based on 18 hazard endpoints. The evaluation includes the chemical hazard after its breakdown in the environment. The GreenScreen benchmark is built based on 12 Principles of Green Chemistry and the US EPA's Design for the Environment (DfE) alternatives assessment method. DfE aims to produce information about safer commercial products and has proposed hundreds of alternative chemicals and technologies to ensure safer products. GreenScreen is a hazard-based assessment and as such there is no consideration of dose and exposure scenarios.

3.7. GreenSuite

GreenSuite is a risk assessment tool supported by hazard data from Relational Chemical and Product Database (R-CPD) for 30,000 chemicals and categorized in modules with 44 ecological, health and safety (EH&S) endpoint criteria as defined in NSF/GCI/ANSI 355: Greener Chemical and Processes Information standard. It is one of the tools that meet the requirements of the Green Globes section that addresses risk assessment The R-CPD database is claimed to be the largest available database that continuously collects data and has been in existence since 1985. GreenSuite has an integrated Environmental Health and Safety (EH&S) system that utilizes a web-based technology to customize via the data for specific industries. The GreenSuite system benefits from an advanced internet technology known as the Sustainability Oriented Architecture (SOA4), which allows users to design, modify, organize, and integrate database applications over the Internet. GreenSuite includes the issues from pre-manufacturing and Material Safety Data Sheet (MSDS), to emissions monitoring and waste disposal.

The GreenSuite analysis includes several modules. The first four modules provide analytical data for any product in any industry. The fifth module develops factors for the sustainability assessment of the manufacturing process including water usage, energy consumption, waste generation, and others. The sixth module requires detailed and confidential process information from suppliers to assist supply chain risk assessments. The final two modules comprise the exposure scenario risk assessment for chemicals and products.

4. SUMMARY AND CONCLUSION

In the U.S., building assessment systems such as LEED, Green Globes, and the LBC began to incorporate consideration of product and materials safety from a toxicity standpoint into the materials category for each system. In the assessment systems developed prior to 2010, hazard or risk assessment of materials was not considered and thus consideration of materials toxicity in building assessment is a relatively new addition to the portfolio of issues addressed by these systems. The initial strategy was the HBA approach, simply generating red lists of chemicals to be used as a basis for banning products and materials. In the case of the LBC, as an example, the appearance of any chemical on their red list was cause for either eliminating the product or being denied certification. More recently RBA, which takes the dose and exposure scenario into account and applies the science of toxicology to the analysis, is gaining traction and is in the process of being incorporated into the next version of Green Globes. Tools such as GreenSuite provide a user friendly, web-based approach for determining the risks of the chemicals in a product as a function of the actual use of the product. These tools afford a high degree of flexibility and allow analysis of not only the use phase scenario but also the manufacturing, installation, and demolition phases as well.

ABSTRACT

Assessment tools are widely used in Europe and worldwide, addressing building and urban scale. These various tools don't allow the comparison of the performance of the built environment and lead to a confuse situation, for construction stakeholders, buildings owners and building users. The Common European Sustainable Built Environment Assessment (CESBA) initiative promotes the use of assessment tools, contextualized to the regional/ local context and harmonized through common principles and key performance indicators in order to ensure the comparison of performance. To go further than the building scale, CESBA uses these principles in the European project CESBA Alps to develop a new and innovative approach: assessing the built environment at territorial scale.

Keywords: assessment, contextualization, harmonization, empowerment, Europe

1. INTRODUCTION

European Union's 28 nations with different legal, cultural, climate and technical background have to work together to meet the Paris Agreement on climate change from 2015. The building sector and built environment has an important role to play. They have become a cornerstone of the EU climate protection program and have a crucial role to play in the achievement of the long term 80-95% greenhouse gas emission reduction objective. In this perspective, the EU released a series of political and legislative initiatives in order to reduce the environmental impact of buildings by improving their overall resource efficiency and, as a consequence, enhancing the competitiveness of construction businesses and the quality of life of European citizen.

As pointed out by the European Commission in its recent Communications "Resource efficiency opportunities in the building sector" (COM (2014) 445 final) and "Strategy for the sustainable competitiveness of the construction sector and its enterprises" (COM/ 2012/ 0433 final) one of the main issues in the building sector remains the lack of comparable and accessible data and assessment methodologies.

Therefore, a harmonization of building assessment systems is needed in order to make the quality of the built environment comparable and enable policy makers to better steer the development of the sector. Furthermore, it will also enhance knowledge diffusion among companies and thus improve the control of the quality of buildings and eliminate export burdens for SMEs.

The European Commission also underlined in its „Communication on Resource efficiency opportunities in the building sector" (COM (2014) 445 final): „There is a risk that the indicators they [Member States] eventually develop will differ, leading to an unnecessarily complex business environment." In order to tackle this issue and ensure the effectiveness of certification labels, CESBA proposes to create a common and integrated approach promoting a harmonization of assessments throughout Europe.

While assessment rating tools at building scale are already well established, while many experiences have been carried out at small urban scale/ district scale, very little experiences were developed to set up and implement assessment and rating tools for territories (see Figure 1).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

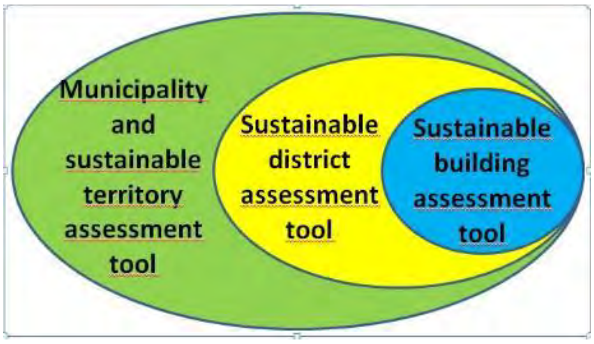

Figure 1: Assessing various scale

In order to be able to compare buildings, neighbourhoods, villages, cities, territories and to share experiences between public and private stakeholders in Europe, CESBA promotes a harmonized and integrated approach, which is flexible enough to consider regional needs and circumstances, and to provide an open source framework with minimum requirements to ensure the quality of certification processes. This applies on a global perspective on all continents as well.

2. COMMON EUROPEAN SUSTAINABLE BUILT ENVIRONMENT ASSESSMENT (CESBA) GOALS

CESBA stands for Common European Sustainable Built environment Assessment and is a common bottom-up initiative towards promoting a harmonization of assessments of the sustainable built environment throughout Europe based on nine principles.

2.1 CESBA history

During the project ENERBUILD, funded by the Alpine Space programme, partners found too many sustainable building assessment systems on their territories, and felt that users and stakeholders were disoriented. This profusion of system was the starting point of an international conference held in Lyon in February 2011: "From Europe to territories: what possible convergence? ": the question of convergence was on the table.

To share this vision and to disseminate these results, to start the work with the EU commission, the first CESBA conference in Brussels was organized on 10th October 2012, and the website launched. After the launch of the idea several institution were interested to know more about the initiative. Partner began to present CESBA on various occasions all over Europe, even on the World Sustainable Building conference in Spain 2014.

CESBA developed its own method – the CESBA Sprint Method – to bring people with different technical, cultural and native language together and prepare common results. The 2nd CESBA-Conference was held as the first CESBA Sprint Workshop Hochhäderich/ Austria in 2013. During these 3 days over 100 experts in various fields defined core elements of the CESBA approach.

2015 the CESBA Association was officially launched.

2.2 CESBA principles

CESBA is based on nine principles. These principles are used to develop assessment tools for any scale addressed by the tool: building, neighbourhood, territory.

2.2.1 The user first

CESBA focuses on the people who use buildings. On average people spend 90% of their life inside buildings. The aim is to design, build and operate the buildings in order to meet the users' requirements and needs, providing an improved comfort, and an ecological and economical construction and operation.

The users are the main actors in a building. The awareness for their rights and responsibilities builds the base for win-win situations. Obtaining the users' participation and support is crucial to achieve the highest quality of use and energy-efficient building operation.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The monitoring of building performance indicators guarantees a sufficient check of the building's function ability and comfort provided to users. The indicators used to communicate performance to the end users have to be target-oriented and easily understandable.

The revolutionary approach of CESBA is the change of the perspective. By putting the user at the centre of the initiative, the purpose becomes to design, construct, operate and maintain buildings to meet their functional requirements and comfort.

2.2.2 Sustainability

Sustainability regards economic, environmental and social aspects. The term built environment refers to the human-made surroundings that provide the setting for human activity, ranging in scale from buildings and parks or green space to neighborhoods and cities that can often include their supporting infrastructure, such as water supply, or energy networks. The built environment is a material, spatial and cultural product of human labor that combines physical elements and energy in forms for living, working and playing. It has been defined as the human-made space in which people live, work, and recreate on a day-to-day basis.

2.2.3 Regional contextualization

Building assessment systems must be contextualized to the region where they are applied, in order to reflect the local specific priorities, cultures, habits, and construction practices. This means using local units of measure, adopting national/ regional standards and regulations, giving due consideration to the local climate, and accounting for availability of natural resources and cultural aspects of design. At local level it is fundamental to set the relative importance of environmental, social, economic, legal and political issues. Each criterion included in the assessment tool should be assigned a relative weight and a reference benchmark (minimum acceptable performance level) adequate to the local conditions. The value of rating results diminishes when systems are used in contexts outside of their origin.

2.2.4 Comparability

The performance results shall be comparable thanks to points/ targets. Further national tools shall be translated into one language. Further the inputs in the assessment shall be defined and not the outputs.

2.2.5 Mass orientation

Building rating systems can play a key role in moving the built environment towards a better sustainability. To reach this objective they have to be widely adopted by the different stakeholders of the building sector: architects, designers, public organizations, construction companies, investors, etc. Only a "mass oriented" approach allows reaching this objective. "Mass oriented" means that the objective of the certification is to reach 100% of constructions.

2.2.6 Simple to use

A "mass oriented" building assessment system has to find a right balance between the simplicity to use and the scientific/ technical value. The assessment must be precise, not simplified, clear, affordable and visible. A system requiring complicated calculations or the availability of data that are not easy to find would request too much time and effort (costs) to be widely used. Simplicity helps the dissemination of assessment systems among the stakeholders. Effective training courses can be implemented to improve the skills of professionals in building assessment.

2.2.7 Open source

Using an open source approach allows CESBA to be appropriate to its context by paying special consideration to the environmental, ethical, cultural, social, political, and economic aspects of the community it is intended for. Consequently, this approach allows for regional adaptations in the guidance system. In addition, the open source approach allows CESBA to be a low-cost alternative to more expensive and proprietary alternatives of sustainable building assessments. The open source way provides a bottom-up initiative for the standardization and

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

harmonization of sustainable building assessments. The knowledge and results generated by CESBA can be used to support incentive systems, regulations and laws on a regional, national and European level.

2.2.8 Transparency

The public should have access to the performance results especially for public buildings. Privacy rules have to be considered. The visualization of the results must be understandable. Guidance for further understanding shall be delivered. For the assessment a guideline is laid out before the assessment. All indicators have to be checked step by step along the guideline. An external certification body does the final check. The simplicity and transparency procedures (guideline, external independent control) guarantee the best possible quality of the assessment.

2.2.9 Co-creation

CESBA is developed by several people and organisations from various European regions, with experts providing input on their field by contributing as Wiki editors. The knowledgebase and further areas of content development are discussed and agreed during common and open CESBA Sprint Workshops. All necessary support software, databases and tools will be jointly developed.

3. GENERIC FRAMEWORK AND KEY PERFORMANCE INDICATORS

Based on the comparison of existing assessment tools and regional success stories like KGA (Vorarlberg/ Austria) CESBA develops its own generic framework. This framework is a benchmark to harmonize existing and upcoming assessments schemes in Europe.

The first steps toward the needed harmonization of the systems are:

- To define common principles regarding built environment sustainability certification;
- To define a core of common criteria and indicators that would allow a comparison between the performances of buildings, neighborhood, village, cities, territories certified with different labels.

In this sense an interregional generic framework like CESBA generic framework can play a key role. The CESBA generic framework for buildings has been developed during the project ENERBUILD as a synthesis of the most important building assessment criteria in the Alpine region. The CESBA generic framework need further interaction with other European institutions that have similar objectives in the way to define a consensus based set of core criteria applicable and significant for all Europe.

The CESBA cycle conveys the concept of CESBA that is defined by harmonized indicators; tools and services usable during the whole life cycle and an ongoing dialogue with society (see Figure 2).

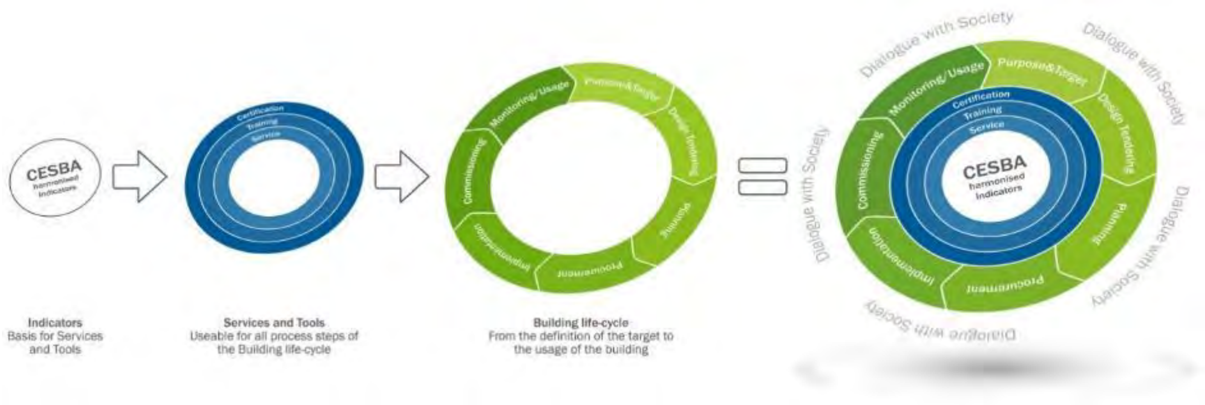

Figure 2: The CESBA cycle

The building scale is addressed by the Enerbuild outputs and will be reinforced in the frame of the EU macro-regional strategy for the Alpine region; the district scale will be addressed with the CESBA Med project in the European macro-region Mediterranean.

In addition to these approaches at building and district level, the project CESBA Alps funded by the Alpine Space program, develops an innovative approach, addressing the territorial sacle, following exactly the principles of CESBA:

- Development of regional tools by regional actors to assess built environment at territorial level (contextualization, co-construction, simple to use)
- Definition of a transnational common set of indicators, to be included in all regional tools (harmonization)
- Test and validation in territories
- Guideline for the use of assessment tools in public policies.

First results will be available in 2017.

4. POLICY RECOMMENDATIONS

More than a common European approach to assess the environmental performance of the built environment, CESBA also wants to promote a new culture in Europe – one that will be more likely to take into account the overall impact of construction on the European environment. In this perspective, the CESBA partners propose several concrete recommendations

4.1 Promotion of a common open source approach towards sustainable built environment

- Adoption of affordable and operable key performance indicators at EU level
- Necessity to coordinate diverging/ different national approaches
- Develop comparable assessments
- Share best practices
- Use online tools (social media, platforms) for networking and creating synergies
- Avoid a complex business environment
- Integration of regional and local specificities

4.2 Promotion of the use of assessment in public initiatives for the built assessment

- The EU Ecolabel for buildings currently under development could benefit from the CESBA methodology and key performance indicators
- Introduce mandatory EU Green Public Procurement criteria based on the agreed EU Framework of common indicators
- EU funding for public building projects must become conditional upon applying Green Public Procurement criteria
- And also in incentives based policy, building codes, urban plans

4.3 Consider the build environment in its local and regional context

Reach political and management support at regional and local levels

- Achieve regional sustainable built environment strategies and action plans
- Monitor local needs and specificities
- Favour local practices and resources in the sector
- Using EU Regional Funds to develop a long term sustainable built environment framework
- Creation and stimulation of sustainable building clusters

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

5. EMPOWERMENT THROUGH COOPERATIVE PROJECTS

The European Union is a mix of cultures and economies that will reach its full potential through mutual understanding and close cooperation. As the top-down approach is limited due to the lack of knowledge on regional circumstances and its difficulty to reach citizens, local craftsmen, local administrations etc. Therefore a bottom-up approach is needed.

A bottom-up approach supports cultural diversity, regional responsibilities, and regional economic cycles, further it is in line with the subsidiarity principle of the European Union. Therefore since 2011 over 30 public and private European organizations from 13 nations from all over Europe have been involved to establish the non-profit bottom-up movement CESBA.

CESBA empowers people, organizations, and regions and offers a productive perspective. The movement works on 4 dimensions: communication, Sprint Method, organization, common projects.

- Communication: All relevant information regarding CESBA is available on the CESBA wiki. Everybody can gain the regular CESBA newsletter. To be accessible the process offers specific regional points of contact, technical interfaces, a online knowledge platform, capacity building and public meetings.
- CESBA Sprint Method: on equal bases people with different technical, cultural background and native language work together to define, elaborate issues for the CESBA movement.
- Organization: CESBA is organized as a non-profit association the membership in the CESBA movement is for free.
- Common projects: Working in common projects across borders helps to explain, test and develop approaches to realize the intended and accepted goals. To overcome the barriers the partners work in common transnational EU-projects.

6. CONCLUSION

The CESBA approach offers a European approach of harmonization of a wide variety of built environment assessment schemes while integrating the building, neighbourhood, city, and territory level.

CESBA's intrinsic force is the empowerment of local and regional initiatives to work together for a common good which yields profit for every participating partner by using European research funds. Therefore CESBA is closely linked to application in the public and semi-public sector on local and regional level.

CESBA offers a global perspective as well. Therefore it invites other bottom-up initiatives for common efforts. Nevertheless CESBA is not finished. CESBA is an ongoing process of integration of new research results, political programs, and continuous lobbying for its 9 principles.

LEED CS in Brazil: Discussing the Validity of the Method for the Improvement of Environmental Quality on Buildings

Monica Santos SALGADO[a]

[a] Federal University of Rio de Janeiro, Brazil, monicassalgado@ufrj.br

ABSTRACT

The construction industry has a negative impact on the environment, due the exploitation of raw materials, transportation of materials and the construction process itself. In Brazil, discussions around the alternatives towards a more sustainable construction have led to the adoption of some foreign systems for the environmental evaluation of buildings – particularly the North American LEED certification. On August 2016, registers indicated 354 certified buildings in the country. Despite the dissemination, LEED's validity to orient the production of sustainable buildings should be discussed. This research has the intent to analyse the contribution of LEED rating system for the improvement of environmental performance in Brazilians' buildings. The research method includes, at first, the assessment of certification map, in order to identify LEED type most widely adopted – which revealed the preference for LEED CS (for Core and Schell). Second, the analyses of the scoreboard for each LEED CS certified building. Results indicate that some relevant environmental targets had been often ignored by certain LEED CS certified buildings. So, it is necessary to review the exaggerated importance given to environmental rating systems, and to enlighten some new possibilities that will lead civil construction industry to the next level towards sustainable development.

Keywords: design process, green rating tool, high-performance building

1. INTRODUCTION

During United Nations Conference in Stockholm on 1972 the main goal has been the establishment of strategies for sustainable development. In what refers to civil construction industry, only in 1999 the CIB (International Council for Research and Innovation in Building Industry) prepared a specific document, entitled "Agenda 21 for sustainable construction", and, three years later, "Agenda 21 for sustainable construction in developing countries". Those documents reveal three aspects to be considered due the accomplishment of environmental targets: the definition of environmental performance levels for buildings; the necessity of changes in design and construction management, and the importance of the investment in actions for the implementation of a new culture on civil construction sector.

The environmental certification has arisen as a consequence of this effort towards the improvement of environmental performance of buildings. In this sense, since 1990's architects and engineers have the opportunity to evaluate the environmental performance of buildings through different rating systems. Among the methods, the English BREEAM (UK), the French HQE®, and North American LEED™ should be highlighted. Further analysis confirms that the evolution of rating systems in different countries is largely based on those initial rating systems.

The first Brazilian Building to obtain an environmental certification was a bank, which received a LEED certification on 2007. However, after almost twenty years, it is necessary to continue questioning at what level those methods are truly contributing for sustainable construction. In the words of Cole:

"The prevailing mechanistic, anthropocentric worldview has been some 500 years in the mankind and is now ingrained all aspects of western society and culture. It has (…) dictated the reductive approaches used to understand and evaluate building environmental performance. Almost all current building environmental assessment system, for example, are based on the simple addition of points attained by meeting a series of discrete performance requirements."

This research has the purpose to discuss LEED rating system contribution to the improvement of environmental performance of buildings in Brazil. The research method includes, at first, the assessment of certification map, in order to identify LEED type most widely adopted and, second, the analyses of the scoreboard for each LEED CS certified building. Although the results cannot be considered conclusive, this contribution can give a glimpse of what should be done in search of a more sustainable construction.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2. LEED CERTIFICATION IN BRAZIL: CASE STUDY

Although since 2003 there is a specific Brazilian method to certify buildings with high energy efficiency – PROCEL Edifica – only on 2014 Brazilian Central Government has established that PROCEL labeling should be compulsory for public buildings (Normative Instruction n ° 2 – Ministry of Planning, Development and Management). For the private market, there is no regulatory requirement in what concerns environmental performance of buildings.

At the same time, LEED™ and HQE methods have made their way to Brazil. The French methodology has been adapted, resulting in the AQUA Brazilian certification. On August 2016, BREEAM has not certified any building, AQUA process has certified 253 buildings, against 354 LEED certifications. Thus, it is correct to say that LEED certification is the most popular in Brazil Real Estate market.

Until LEED version 3, the types of assessments were: LEED-NC – for new construction and major renovations; LEED-OM – for existing buildings; LEED-CI – for commercial interiors; LEED-CS – for Core and Shell; LEED for schools; LEED for retail; LEED for healthcare; LEED for homes; and LEED-ND – for neighborhood development. Version 4 has changed that classification. The environmental analyses consider seven dimensions: Sustainable Sites, Water Efficiency, Energy and Atmosphere, Materials and Resources, Indoor Environmental Quality, Innovation in Design or Innovation in Operations and Regional Priority Credits.

Some difficulties pointed by Udall and Schendler about LEED method, are: the high cost of certification, the “Point mongering” (what happens when the design team becomes obsessively focused on getting credits, regardless of whether they add environmental value); the complexity of Energy Modeling; and the fact that the certification process takes a long time.

Table 1 presents certification numbers of all LEED Buildings in Brazil until August 2016.

	PLATINUM	GOLD	SILVER	CERTIFIED	TOTAL
LEED CI	6	21	8	8	43
LEED CS	5	71	45	28	149
LEED OM	0	9	10	5	24
LEED Home	0	0	1	0	1
LEED School	0	1	1	0	2
LEED NC	3	41	45	30	119
LEED Retail	1	2	3	10	16
TOTAL	15	145	113	81	354

Table 1: LEED certifications granted in Brazil until August 2016
Source: Green Building Council Brazil, 2016

LEED CS (for Core and Schell) is the most widely adopted certification. One possible reason is the similarity with PROCEL label requirements, particularly in what concerns to energy consumption.

The interest in LEED certification is concentrated on the southeast region (82% of certified buildings), as highlighted in Table 2.

	NORTH	NORTHEAST	MIDWEST	SOUTHEAST	SOUTH	TOTAL
PLATINUM	0	0	0	3	2	5
GOLD	0	1	5	55	10	71
SILVER	0	1	1	37	6	45
CERTIFIED	0	1	0	27	0	28
TOTAL	0	3	6	122	18	149

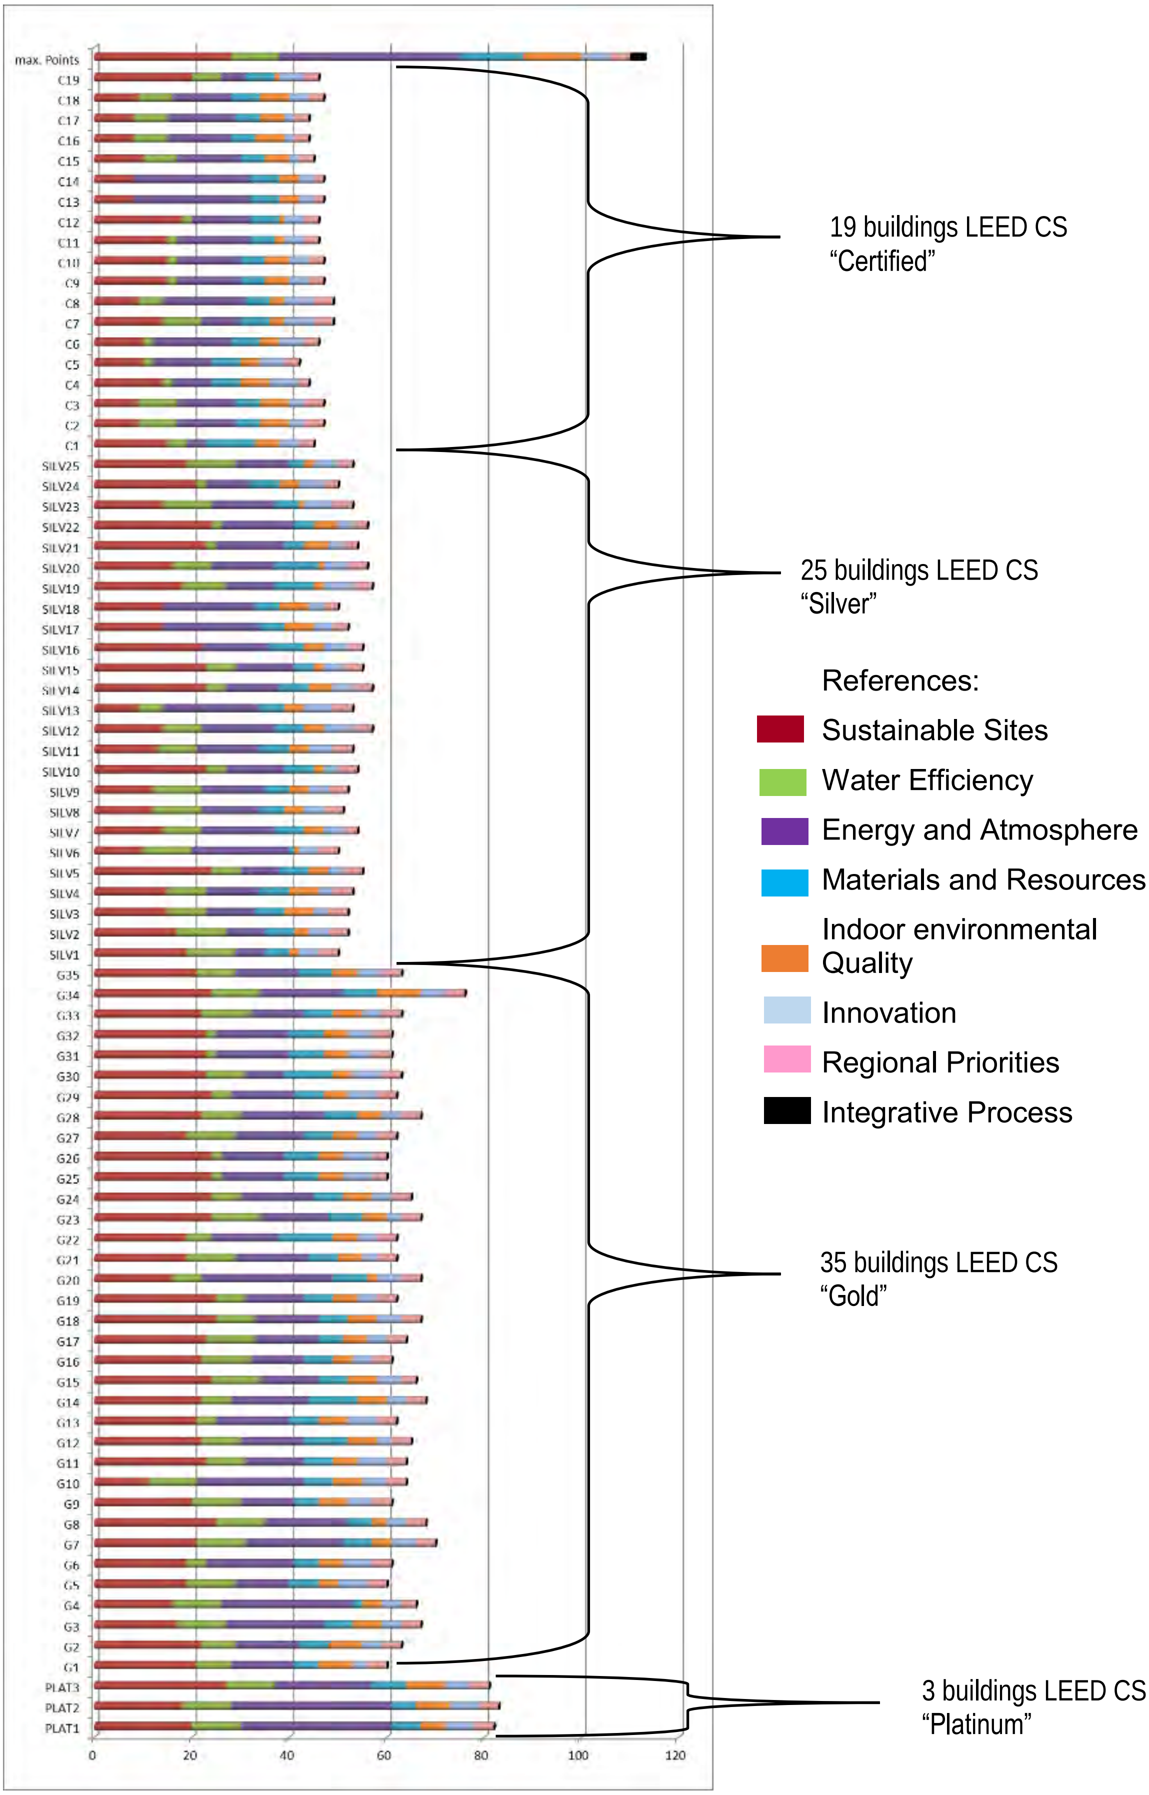
Table 2: Certified LEED CS buildings in Brazil (until August 2016)
Source: Green Building Council Brazil, 2016

According to Green Building Council, 55% of LEED CS certified buildings in Brazil has adopted the version 3, 16% adopted version 2 , 28% has confidential data (impossible to know which version has been adopted) and version

4 has certified only three buildings until August 2016. So, this research analyzed the 82 scoreboard of buildings that has been certified on LEED CS version 3 (the most popular).

In order to deepen the research on those 82 buildings Graphic 1 presents how each environmental dimension has been accomplished. It is possible to notice that even in different classifications (platinum, gold, etc), some environmental dimensions were frequently being neglected.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk



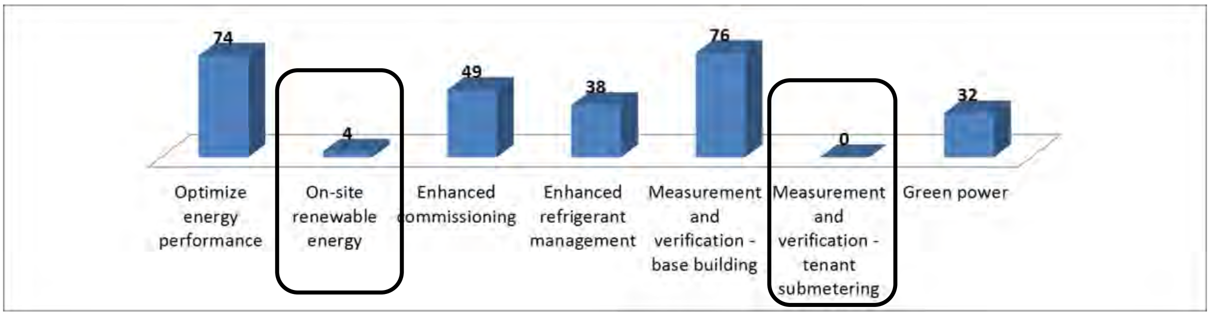
Graphic 1: 82 LEED CS certified buildings in Brazil (until August, 2016) - percentage achieved in each Dimension

3. DATA ANALYSIS – LEED CS IN BRAZIL

Data analyses allow identify the environmental requirements that seem to be more difficult to be achieved (requirements that rarely has been achieved by LEED CS certified buildings). Four dimensions call our attention: "Materials and Resource", "Energy and Atmosphere ", and "Indoor Environmental Quality".

In relation to “Materials and Resources” two goals had not been achieved by most LEED CS certified buildings: Building reuse (related to the recycle or reuse of existing walls, floors and roof); and Materials reuse (related to the recycle or reuse of preexisting materials). However, those requisites can normally be achieved in refurbishment projects.

In relation to “Energy and Atmosphere”, two goals had not been achieved by most LEED CS certified buildings, as presented on Graphic 2:



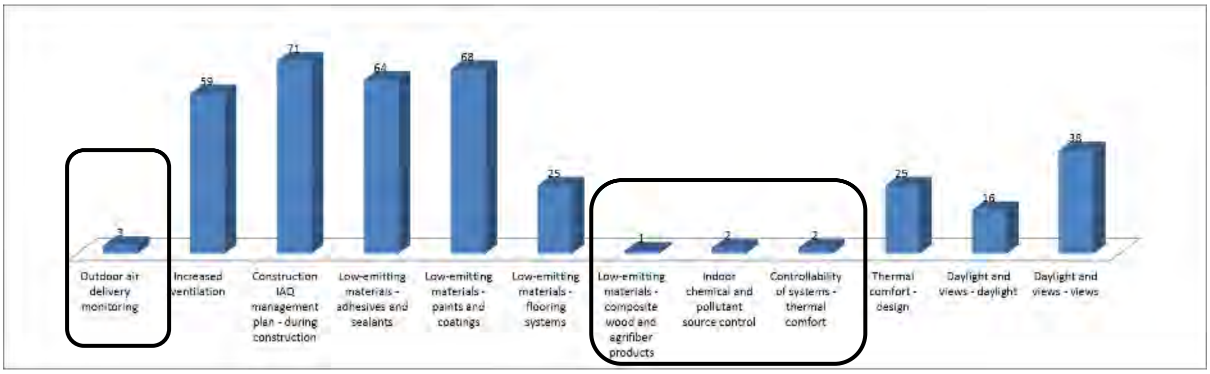
Graphic 2: Energy and atmosphere dimension – number of certified enterprises among 82 LEED CS certified buildings in Brazil (2016) that meet the requirement (total or partially)

Among the 82 Brazilians’ buildings certified as LEED CS (2009 vrs3), only 4 meets the requirement related to “On site renewable energy”, and none has ponctuated on “Measurement and Verification – tenant submetering”. The intent of those requisites are described below:

- On-site renewable energy: To encourage and recognize increasing levels of on-site renewable energy self-supply to reduce environmental and economic impacts associated with fossil fuel energy use;
- Measurement and Verification - Tenant Sub metering: To provide for ongoing accountability of building electricity consumption performance over time.

In relation to “Indoor Environmental Quality Dimension”, four goals had not been achieved by most LEED CS certified buildings, as presented on Graphic 3:

- Outdoor Air Delivery Monitoring: To provide capacity for ventilation system monitoring to help promote occupant comfort and well-being;
- Low-Emitting Materials - Composite Wood and Agrifiber Products: To reduce the quantity of indoor air contaminants that are odorous, irritating and/ or harmful to the comfort and well-being of installers and occupants;
- Indoor Chemical and Pollutant Source Control: To minimize building occupant exposure to potentially hazardous particulates and chemical pollutants;
- Controllability of Systems - Thermal Comfort: To provide a high level of thermal comfort system control by individual occupants or groups in multi-occupant spaces (e.g., classrooms or conference areas) and promote their productivity, comfort and well-being



Graphic 3: Indoor environmental quality dimension – number of certified enterprises among 82 LEED CS certified buildings in Brazil (2016) that meet the requirement (total or partially)

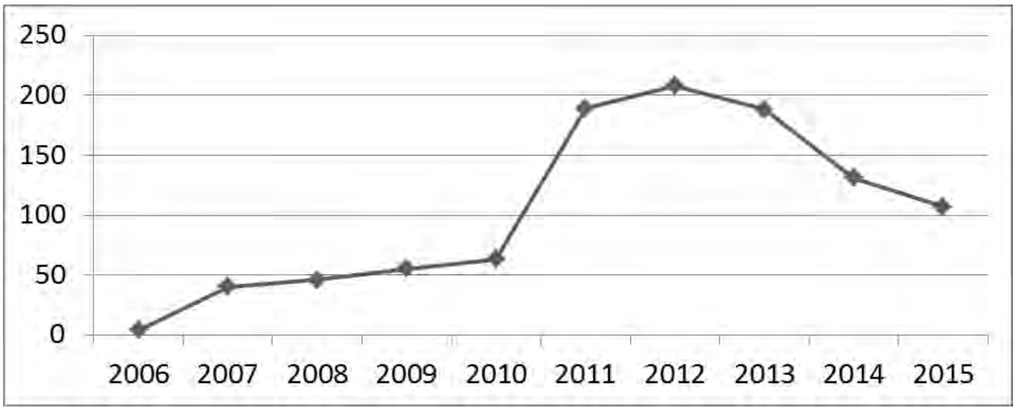
It has also been noticed that some certified buildings presents minimum punctuation on "Water Management Dimension". None of certified buildings (not even the Platinum certified) had punctuated on "Innovation Dimension", which considers the design solutions with exceptional performance (above the requirements set by the LEED Green Building Rating System).

4. FINAL CONSIDERATIONS

Offer the entrepreneur the easiest way to obtain a green certification (as presented by some environmental rating systems) is revealed as pernicious, because it leads to the search of the fastest way to obtain the green seal, in opposite to the search for high environmental quality solutions for buildings.

In what refers to LEED CS method, it was observed that some environmental requirements are rarely achieved. To understand why it has happened, it would be necessary to know the details of each design and construction process of certified building. Maybe the building had already obtained the required score to be certified and, in this case, the entrepreneur felt little motivated to continue investing in the improvement of environmental performance. This seems to be the most vicious problem on environmental rating systems: professionals do not pursue design solutions for sustainability, but only the solutions that can bring the necessary punctuation to obtain a green certificate.

The analysis also indicates that, in Brazil, there are few certified buildings. Initiatives are grouped on one region (Southeast) – mostly commercial or corporative facilities – which can signalize the intention of entrepreneurs to add green value to their firms through the green label of their headquarters. It is worth mentioning that the number of new LEED registers in Brazil is dropping significantly, as presented on graphic 4, which indicates a reduction of interest in LEED certification that should be analysed in future research.



Graphic 4: LEED registers in Brazil: from 2006 to 2015
Source: Green Building Council Brasil, 2016

However, the discussion around sustainable construction is changing, and there are some new concepts emerging, particularly: integrative design and regenerative development. According to Boecker et al the concept of integrative design is different from integrated design because the latter term implies something that is past and completed, while the word "integrative" suggests an evolving process and implies that we're never really done. Integrative design intends to guarantee the participation of a multidisciplinary team of architects and engineers discussing environmental targets since the beginning of architecture design (conceptual phase) and over all the design process. This modus operant offers new possibilities, through continuous exchange of ideas about the ideal solution for the project.

The second concept, related to regenerative design, will gain momentum over the next decade as a necessary approach to green building strategies, as mentioned by Cole. The author emphasizes that the transition from green buildings practices to those more firmly framed by regenerative development, will parallel the shift from a mechanistic to an ecological worldview.

Finally it is worth mentioning the importance of environmental rating systems as the first step towards sustainable construction. The new version of LEED system (Version 4) seems to presents advances in comparison to the last one. However, the age of environmental rating systems is reaching its end, and it's time to look forward.

5. ACKNOWLEDGMENT

The author thanks National Council for Research and Development – CNPq – for the financial support of this research.

ABSTRACT

The green building rating systems (GBRSs) are leading to great influences on the ways stakeholders approach design, construction, and operation management of buildings. A plethora of existing studies are on the effects of GBRSs on environment performance or property value. However, there is a dearth of studies relating to its effects on construction waste minimization (CWM), which is one of the important indicators of going green. This study aims to empirically investigate the effects of GBRSs on CWM by making use of a large set of data resulted from the construction waste management practices in Hong Kong and the Hong Kong Building Environmental Assessment Method (HK-BEAM). By analyzing the big data, it is found that the intervention of HK-BEAM resulted in 36.36% waste reduction by weight for demolition works. However, it barely affects the CWM when the whole construction process is considered. The policy implications based on the findings serve as valuable references for policy-makers to improve the CWM-related items in HK-BEAM in order to achieve lower-waste construction in Hong Kong. As big data for enhancing public policy-making is still at initial stage, it is recommended to effectively use historical structured databases scattered in public sectors to create insights for policy-making.

Keywords: waste management, HK-BEAM, construction waste minimization

1. INTRODUCTION

The green building (GB) movement is rapidly sweeping the world as the construction industry responds to contemporary challenges such as natural resource depletion, pollution, curtailing greenhouse gas emissions, and human-induced global warming (Peuportier, 2001; Saiz et al., 2006; Wu et al., 2005; Junnila, 2004; Ortiz et al., 2009; Shen et al., 2016). GBRSs in many countries have been established and widely recognized for sustainability assessment, including the Leadership in Energy and Environmental Design (LEED) in US and Building Research Establishment Environmental Assessment Methodology (BREEAM) in UK. Although these systems differ in terminologies, structures, evaluation methods, weighting, and documentation requirements, they all share common themes of energy efficiency, water conservation, site selection, building materials, and indoor environmental quality (Cole, 2003; Wu and Low, 2010; Zuo and Zhao, 2013). There is a plethora of studies relating to the effects of GBRSs on sustainability performances, such as enrichment of biodiversity and protection of the ecosystem (Bianchini and Hewage, 2012), reduction of greenhouse gas emissions (Jones, 2015), improved health conditions for residents and greater social productivity (Singh et al., 2010), and enhancement of aesthetic appeal and comfort for occupants (Zhang and Altan, 2011).

Construction industry alone generates a large proportion of the total solid waste landfilled globally (European Commission, 2013; HKEPD, 2015; MoE, 2014), the disposal of which brings considerable pollutants to air (Sam-Cwan et al., 2001), water (Mor et al., 2006; Al Sabahi et al., 2009), and soil (Garcıa-Gil et al., 2000), and pressure on valuable landfill space (Lu and Tam, 2013). With large amounts of construction activities being conducted, construction waste, also called construction and demolition (C&D) waste reasonably attracts the attentions of stakeholders of environmental protection, such as policy-makers and researchers. Therefore, construction waste minimization (CWM) plays an important role for construction industry to pursue sustainability, thus accounts for certain proportions in GBRSs ranging from 8% to 12% for sustainability assessments (Wu et al., 2016). Existing studies were conducted to investigate the scopes in GBRSs such as LEED, BREEAM and HK-BEAM, and found CWM is one of them (Tam et al., 2004; Cha et al., 2009). However, there are few studies that reversely examine whether these GBRSs indeed have significant impacts on CWM with the use of empirical data. But without the necessary evidence, CWM-related points may be surrendered to other green scopes such as energy efficiency or water conservation.

This study aims to comprehensively understand the effects of GBRSs on CWM in the context of Hong Kong, where both are well developed but not juxtaposed to enable a holistic picture to form. To achieve this aim, a big data approach is adopted by analyzing the full-population historical data recently given rise from waste management practices and HK-BEAM assessments. In order to provide an understanding of the inherent link between CWM and GBRSs, this study first reviews the building-related construction waste and GB movements, with the problems at hands identified in Section 2. The next section (i.e. Section 3) provides the methodology of conducting the comparative study. Then, Section 4 provides the readers with the data analysis and results, followed by Section 5, where the research findings are discussed. At last, conclusions of this study are drawn in Section 6.

2. METHODOLOGY

This research adopts big data analytics to investigate the effects of GBRSs on CWM. The methodology is divided into two steps described as follows.

2.1 Hypothesis on the effects of GBRSs on CWM

All other things being equal, achieving or attempting to achieve GBRSs certification contributes positively to waste minimization, i.e. leads to a lower level of waste generation.

2.2 Testing the hypothesis using big data analytics

This research comes at an opportune time with a big dataset having become available only recently, which reveals a full picture. This study secured all the data from 1 Jan 2011 to 30 June 2016: 7,045,539 disposal records generated from all the 26,566 construction works in Hong Kong, which opened billing accounts from 2005 to 2 September 2015 before work commencement. The databases for the construction works and records are displayed on Figure 1. All the data were well structured in various databases, based on which the dependent variable (waste generation rate) WGR can be computed. This study has also sourced the data of all the 808 buildings (as of 20 June 2016) that have been certified or registered for certification by BEAM Plus mapped as shown in Figure 2 (HKGBC, 2016). The information of the 808 buildings is extracted and shown in Figure 1.

Figure 1: Screenshots of the structures of the big data

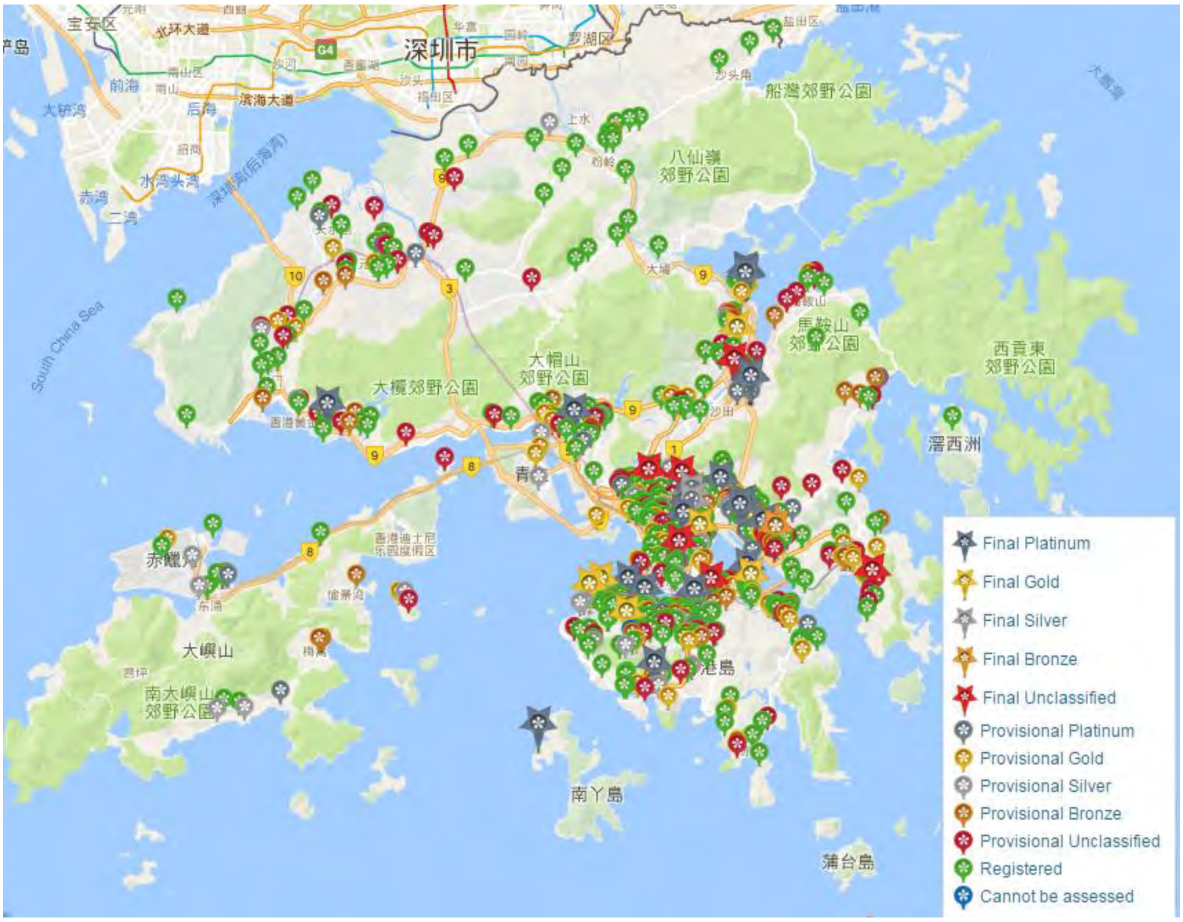

Figure 2: A screenshot of BEAM Plus Directory Map (HKGBC, 2016)

The databases demonstrated in Figure 1 provide the calculation of WGRs with full availability. The links between these databases are further illustrated in Section 4. A random group of WGRs in the pattern, WGRi=WGi/CSi, tends to be a positively skewed distribution (Lu et al., 2015; Lu et al., 2016). WG is the waste generation amount, while CS is contract sum in the equation. Hence, this study compares the medians between the two groups of WGRs, which are expressed in the same pattern with that in Lu et al. (2015) and Lu et al. (2016). Mood's median, as a non-parametric test, adopted to test the equality of medians from or more populations (Conover, 1971). If the p-value of Mood's median test is small, the two populations have a significant distinction in terms of their medians. Altogether, a big data approach with the use of the sets of secondary data portraying a full, objective picture of all the buildings, rated and unrated, including their profiles and their waste generation, is employed to investigate the effect of GBRSs on CWM in this study.

3. DATA ANALYSIS

3.1. Computation of WGRs of BEAM-driven and ordinary construction works

A newly developed construction project in most cases consists of three main stages in order of demolition, foundation and building. As a construction project in Hong Kong is completed by one contractor throughout all these stages or several contractors in charge of separated ones, there might be one or several billing account opened for a project and recorded in "Database for 26,556 C&D projects" in Figure 1. According to the data availability, this study not only investigates the whole process of the construction projects, but also the individual stages. For each work, the amount by weight of every lorry of construction waste are extracted from 'Database for 7,046,395 waste disposal records' according to the account No.. With the use of contract sum, the WGRs of the BEAM-driven demolition, foundation, building, and whole-process works are calculated using Equation 1. For a construction work i, which sent j lorries of construction waste to the disposal facilities, the WGR for project i can be expressed as:

$$WGR_i=(WG_{i1}+WG_{i2}+WG_{i3}+\ldots\ldots+WG_{ij})/CS_i$$

Equation 1

For the comparison between BEAM-driven and ordinary works, the same steps are performed to calculate the WGRs of these types of construction works recorded in 'Database for 26,556 construction and demolition projects' excluding BEAM-driven works. Totally, the results consist of eight groups of WGRs. However, outliers exist among the obtained WGRs. In case of the manually recording mistakes and some extreme, the outliers are excluded to ensure the high veracity of each group of WGRs, specifically led by full coverage of waste generation amount, and record validation of contract sum for every construction work. After outliers excluded with a confidence level of 95%, the profiles of the eight groups of WGRs are displayed in Table 1.

Construction type	BEAM-driven	Ordinary
Demolition	158	205
Foundation	238	276
Building	61	200
Whole process	26	120

Table 1: Profiles of the construction works

3.2. Comparing the WGRs between BEAM-driven and ordinary construction works

As discussed in Lu et al. (2015) and Lu et al. (2016), the median of a random group of WGRs, positively-skewed distributed, is representative for the WGR value (i.e. waste management performance) of the largest amount of individual construction works. As WGR is the key performance indicator for C&D waste management (Lu et al., 2015), this study selects WGR to indicate the performance of each group of projects. This study evaluates the CWM by comparing the WGRs between BEAM-driven and ordinary construction works. With other variables controlled, if BEAM-driven projects has lower WGR than ordinary ones, the effect of HK-BEAM on CWM can be regarded positive.

All the groups tend to accord to the positively skewed distribution, the median WGR is tested representative for the waste management performance of each type of BEAM-driven and ordinary construction works. The medians are calculated, and the results are listed in Table 2. In this context, the difference between the BEAM-driven and ordinary medians for each construction type can be regarded as the CWM, which is calculated and listed in Table 2. The significance of the difference (i.e. CWM) is statistically examined using Mood's median test approach. The p-values of the tests fill the third column, the interpretations of which (i.e. significances) are in the fifth. When p-value is less than 0.05, the difference between the medians can be regarded significant. The fourth and fifth columns in Table 2 show that only the demolition works are significantly affected by HK-BEAM in terms of the CWM (CWM=220.22 ton/mHKD, and CWM significance=Yes), while other construction types (i.e. foundation, building, and whole process) remain unaffected. Demolition waste actually takes a small proportion of the waste finally sent to facilities as analysed using the full data in Hong Kong, while foundation takes the largest proportion among the three stages.

Construction type	BEAM-driven (ton/mHKD)	Ordinary (ton/mHKD)	*p*-value	CWM (ton/mHKD)	CWM significance
Demolition	385.43	605.65	0.005	220.22	Yes
Foundation	170.65	127.541	0.066	-43.11	No
Building	13.25	22.99	0.288	9.74	No
Whole process	36.98	40.08	0.296	3.1	No

Table 2: Mood's median test results: BEAM-driven and ordinary construction works compared

4. DISCUSSIONS

The most valuable finding of this study is the HK-BEAM, as an example of GBRSs, stimulates the CWM only at the demolition stage, yet barely has influences on a whole construction project. Table 3 shows the weighting of the items aiming for the 3Rs (reuse, recycle and reduce) of waste management in HK-BEAM. At demolition stage, the total amount of materials is large, which implicates the great potential of the reuse of the existing building structures and other elements thus enables practitioners with more operability to satisfy the 1st item of Material Aspect (MA1). Another reason for the success of demolition waste reduction might due to the great potential of reusing the demolition materials in landscaping and planting, which additionally reduces the difficulty of meeting the 7th item of Site Aspect (SA7). Other than MA1 and SA7, MA4 and MA10 are items both for demolition waste reduction. The total weighting of the four items accounts for 4.05% of overall attainable credits, while that aiming for waste reduction at foundation and building stage is only 2.18%. In addition, it is obviously more operative to recycle and reuse demolition waste, which is generated in large amounts in a short period. However, for foundation and building, it is more difficult and costlier to operate the waste reduction. The waste materials from the two stages are more fragmentary than those from a demolished building, which includes reusable structures. Therefore, practitioners attempt to achieve HK-BEAM through demolition waste reduction, thus the CWM at demolition stage is successfully stimulated by HK-BEAM. Considering the severe environmental impacts given rise from construction waste, it is suggested the total weighting of CWM in HK-BEAM be improved by adding attainable credits or bonus on the easiest measurable but most waste-minimizing items, such as the adoptions of prefabrication technology, deconstruction, and sustainable forest products.

Items		Attainable credits	Attainable bonus	Attainable overall grade
Site Aspects (SA)				
SA7	Landscaping and Planters (using previous materials)	1		1.14%
Material Aspects (MA)				
MA P1	Timber Used for Temporary Works	Required		
MA P3	Construction/ Demolition Waste Management Plan	Required		
MA P4	Waste Recycle Facilities	Required		
MA1	Building reuse	2	1	1.09%
MA2	Modular and Standardised design	1		0.36%
MA3	Prefabrication	2		0.73%
MA4	Adaptability and Deconstruction	3		1.09%
MA 6	Sustainable Forest Products	1		0.36%
MA10	Demolition Waste Reduction	2		0.73%
MA11	Construction Waste Reduction	2		0.73%

Table 3: Weighting of the items aiming for CWM in BEAM Plus (HKGBC, 2012)

This study also found HK-BEAM fails to complete the CWM tasks at both foundation and building stages, where a dramatically higher amount of construction waste, particularly generated at foundation stage, has been delivered to the waste disposal facilities. The average amount is 22,808 tons for foundation, 5,294 tons for building, and 2,683 tons for demolition. Lu et al. (2015) found the inert waste generally comprises 99% of the total waste generated at foundation stage. This indicates the great potential of conducting 3Rs of waste generated when a project is at foundation stage. In order to stimulate the waste reduction, the government is strongly suggested to target on the waste minimization at foundation stage. The attainable credits and bonus for MA11 should be gradually turned up until BEAM-driven projects send significantly smaller amounts of waste arising from foundation and demolition to the disposal facilities. In particular, foundation, which serves as the most wasteful stage with largest amounts of inert waste generation, should be attached with more importance supported by encouragement policies. For example, HK-BEAM makers can isolate foundation waste minimization as another item set with more attainable credits and bonus for foundation stage than building and demolition.

5. CONCLUSIONS

This study analyzed the effect of HK-BEAM on minimizing C&D waste by looking into the demolition, foundation, and building stages, and the whole construction process. The analysis takes advantages of the recently available databases generated from practices of the waste management and green building promotion implemented by public sectors in Hong Kong. The results show the intervention of HK-BEAM can lead to 36.36% waste reduction at demolition stage for the reason that the demolition waste reduction items are attributed with more credits, and enabled with more operability to achieve compared with the other CWM-related items. However, little significant CWM is achieved at foundation and building stages owing to the insufficient proportion of attainable credits and bonus allocated to them. Policy implications are considered that public sectors should increase the CWM-related proportion in HK-BEAM, in particular, focus on the foundation stage, which is the most wasteful evidenced by big data of C&D waste management.

ABSTRACT

Unlike it is in the developed world, green buildings (GBs) have been a relatively new concept in emerging markets. In Vietnam for example, local green building rating systems, such as LOTUS was first released in 2010 by Vietnam Green Building Council (VGBC); and Excellence in Design for Greater Efficiencies (EDGE) was introduced in 2015 by the World Bank's International Finance Corporation (IFC). As a result, the number of certified GBs in Vietnam is still limited. Given this slow development in GBs, uncertified regular buildings are still dominant in Vietnam, contributing to substantial energy use and pollution. To reduce emissions and improve energy efficiency, it is thus essential to embed sustainable design and construction practices in uncertified regular buildings. As the first step towards this journey, this study investigated the effect of participants' characteristics on the implementation of sustainable practices in regular building projects. In particular, a questionnaire survey was conducted to understand how participants' GB-related knowledge and project roles affect the extent to which various sustainable practices were implemented in building projects in Vietnam. Statistical analysis showed that the degree of application of the sustainable practices was positively correlated with participants' GB-related knowledge. Hierarchical moderated regression analysis further showed that participants' roles (e.g., owners and designers) moderated the relationships between their GB-related knowledge and the application of sustainable practices. Specifically, this relationship was most significant for owner representatives, followed by designers and constructors. These findings imply that practitioners, especially those working for owners and designers, should be equipped with adequate GB knowledge to advance sustainable building practices in fast-growing emerging economies.

Keywords: green rating tool, green building, emerging markets

1. INTRODUCTION

Construction and operation of buildings have substantially impacts on a country's economy, society and environment. They are however also one of the major contributors to greenhouse gas emissions and other environmental pollutants in both industrialized and developing countries (Kientzel and Kok, 2011). As such, sustainable construction practices have attracted significant interest in developed countries and more so in some developing countries (Hassan et al., 2016). Indeed, a recent report revealed that emerging economies have experienced a strong green building (GB) growth, expecting to grow two to six times over current levels in the next three years (Dodge Data & Analytics, 2016).

Vietnam is an emerging market where its economic growth is among the fastest in the world since the early 1990s (World Bank, 2016). Unlike it is in the developed world, however, GBs is still a relatively new concept in Vietnam. For example, a local GB rating system (i.e., LOTUS) was first released in 2010 by Vietnam Green Building Council (VGBC); and Excellence in Design for Greater Efficiencies (EDGE) was introduced in 2015 by the World Bank's International Finance Corporation (IFC). As a result, as of 2015, there were only about 70 certified or registered GBs in Vietnam under different GB rating systems, including LOTUS, the U.S. Leadership in Energy and Environmental Design (LEED), EDGE, and Singaporean Green Mark (Millet, 2016). This means that despite of the promising GB growth, newly constructed and existing uncertified conventional buildings (refer to hereafter as "regular buildings") are still dominant in Vietnam and other emerging economies. To reduce pollution and energy use associated with regular buildings, it is thus essential to explore the opportunities to embed sustainable practices into their design and construction. As noted by Bartlett and Howard (2000), a good understanding of GBs benefited both business and the environment. As the first step towards this journey, this study empirically

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

investigated the effect of participants' characteristics, namely their GB-related knowledge and project roles, on the implementation sustainable practices in regular building projects in Vietnam.

2. RELATED WORK AND HYPOTHESIS

Previous studies have identified several practitioner-related enablers for the adoption of sustainable practices in buildings design and construction. The designers' and senior management's supports, project managers' competence and project team members' GB-related experience and knowledge were critical factors for successful GB project deliveries in Singapore (Ofori and Kien, 2004; Li et al., 2014). Similarly, in Turkey, project owners' sustainability commitment, top management's support, and the collaboration among project parties were found to be critical (Aktas and Ozorhon, 2015). Constructors' early involvement, and architects' early inclusion of green strategies in their designs are also important enablers (Swarup et al., 2011). A recent study further showed that clients and market conditions play a critical role in catalyzing the diffusion of GB guidelines in countries such as India, Indonesia, and Turkey (Mollaoglu et al., 2016).

On the other side of the same coin, some studies identified project participants' misperceptions about GB (e.g., high cost and technical complexity and challenges) and lack of relevant knowledge as key barriers toward the deliveries of GBs, especially in emerging markets. For example, Zhang et al. (2010) found that GB implementation in China are hindered by the perceived high cost, technical difficulty during construction, and lack of knowledge and awareness of green technologies. Lack of interest and communication amongst team members and low interests from clients and market were some challenges facing Singapore (Hwang and Tan, 2012). Lack of knowledge was identified as an major barrier for sustainable and energy efficient buildings in countries including Venezuela (Pietrosemoli and Monroy, 2013), Korea (Kang et al., 2013), Malaysia (Shari and Soebarto, 2014), and Kuwait (AlSanad, 2015).The literature review indicated that much research has been done with regard to the potential effect of various participants' characteristics (e.g., levels of supports, interest and commitment) on the sustainable practices in the building sector in emerging economies. Among the various practitioner-related factors discussed above, project participants' GB-related knowledge has been consistently identified by many researchers as critical. This criticality stems from the fact that, in spite of the governmental efforts, the decision to implement sustainable practices majorly depended on project parties, including owners, designers, and contractors (Hassan et al., 2016). Thus, their GB-related knowledge can significantly shape the practices and outcome of GB projects. Indeed, Abidin (2010) found that the effort towards adopting sustainable practices in Malaysia depended largely on individual project participants' awareness and knowledge about GBs. Similar conclusions were also found in Kuwait (AlSanad, 2015). In Brazil, Teixeira et al. (2016) indicated that green training was positively associated with the implementation of green supply chain practices.

Even though prior studies have suggested the potential effect of different project participants' GB-related knowledge on the adoption of sustainable practices, there is still a lack of empirical evidence to support this relationship; and investigate how it may be moderated by participants' roles (e.g., project owner, project manager and team members). In addition, most of the prior studies focused mainly on GBs. Given that regular "non-green" buildings will remain dominant in emerging markets in the near future, it is equally important to embed sustainable practices in such buildings. Taking altogether, this study aims at filling these gaps by quantitatively investigating the interactive effect of participants' GB-related knowledge and roles on the adoption of sustainable practices in regular building projects in Vietnam. In particular, this research aims to quantitatively test the following hypotheses:

- Hypothesis 1 (H1): Participants' GB-related knowledge (GBKn) is positively related to the application of sustainable practices in a regular building project.
- Hypothesis 2 (H2): Participants' roles (i.e., owners, designers, constructors) moderate the relationships between their GB-related knowledge and the application of sustainable practices in a regular building project.

3. RESEARCH METHOD AND MEASURES

A questionnaire survey was conducted to test the proposed hypotheses. The unit of analysis is "a building project." Thus, survey respondents were asked to choose one building project that they were most recently involved and to: (1) rate the degree of application of various sustainable practices in their selected projects; (2) report their demographic information such as their positions, years of experience, and knowledge of GB rating systems. The questionnaire (in either online or paper-based format) was sent (either by emails or hand-delivery) to a total of 850

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

potential respondents who work in the construction industry in Vietnam. A total of 240 responses (i.e., 225 hard copies and 15 online forms) were received, resulting in an overall response rate of 28%. Among these, 36 surveys were eliminated due to incomplete responses in the questionnaires or the respondents have less than 3 years of experience. At the end, a total of 204 valid responses remain for further data analyses.

Sustainable practices in a country will be influenced by the local GB certification systems. Thus in this study, sustainability in a building project was measured by a total of 39 sustainable practices derived from the GB criteria listed in LOTUS, a widely recognized local GB rating system in Vietnam. These include 6 items in energy (E), 5 in adaptation and mitigation (A), 4 in water (W), 4 in materials (M), 4 in ecology (Eco), 4 in waste and pollution (WP), 4 in health and comfort (H), 4 in community (CY), and 4 in management (Man). Specifically, survey participants were presented with these 39 sustainable practices and were instructed to rate "the degree that each practice was implemented in their selected project" on a 5-point scale (1: "not at all"; 2 = "small degree"; 3 = "moderate degree"; 4 = "high degree"; 5 = "very high degree").

4. RESULTS

4.1. Characteristics of respondents

Table 1 summarizes the project profile and respondents' characteristics. Out of the projects selected by respondents, 169 (82.8%) were regular buildings (non-certified) while 35 (17.2%) were certified GBs. Respondents' roles in their selected projects included owner representatives (25%), designers (36.8%), constructors (36.8%), and others (1.5%). In terms of professional experience, respondents had 3-5 years (47.5%), 6-10 years (34.3%), 11 - 15 years (10.3%), and 16 years or more (7.8%). This distribution somewhat reflected the young Vietnamese labor workforce and population. More than three quarters (77%) of the respondents had no prior experience with GB projects while about a quarter (23%) of them was involved in at least one GB project. Regarding knowledge of at least one GB rating system, 34.8%, 19.1%, and 46.1% of them reported that they were "not familiar," "somewhat familiar," and "familiar," respectively.

Description	Frequency	Percent
Surveyed projects:		
Regular building (non-certified)	169	82.8
Certified green building (LOTUS, LEED, etc.)	35	17.2
Role in the surveyed project:		
Owner representatives (owner and PM consultants)	51	25.0
Designers (architects, engineering designers)	75	36.8
Constructors (contractors, construction managers)	75	36.8
Others	3	1.5
Years of professional experience:		
3-5 years	97	47.5
6-10 years	70	34.3
11-15 years	21	10.3
16 years or more	16	7.8
Prior experience in certified green building project(s):		
No	157	77.0
Yes	47	23.0
Knowledge of at least one green building rating system:		
Not familiar	71	34.8
Somewhat familiar	39	19.1
Familiar	94	46.1

Table 1: Characteristics of respondents

4.2. Applications of sustainable building practices

Table 2 summarizes the overall degree of application of sustainable practice categories in regular and certified GB projects. On average, all sustainable practices demonstrate a much higher level of adoption in certified GBs as compared with regular buildings. The overall degrees of application (AllGB) were 2.73 and 3.46 for regular and GB projects, respectively. Sustainable practices in categories such as waste and pollution, materials, health and comfort, and management tended to be applied to a much higher extent in certified GBs than regular buildings.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

As expected, sustainable practices were more common among certified GBs. This means that there is still a long way to go with embedding sustainable practices in regular buildings. As such, an investigation into how the participants' roles and GB-knowledge may affect the adoption of sustainable practices in regular buildings is essential. Such an understanding may inform the development of strategies to better equip project owners, designers, and constructors with the necessary knowledge to voluntarily adopt sustainable practices in future regular building projects.

Sustainable building practice	Regular building		Certified GB	
	Mean	SD	Mean	SD
Energy (E)	2.86	0.61	3.40	0.70
Water (W)	2.51	0.79	3.12	0.83
Materials (M)	2.42	0.75	3.30	0.73
Ecology (Eco)	2.59	0.74	3.24	0.71
Waste and Pollution (WP)	2.44	0.71	3.44	0.82
Health and Comfort (H)	2.90	0.75	3.70	0.71
Adaptation and Mitigation (A)	3.00	0.70	3.65	0.61
Community (CY)	2.89	0.72	3.57	0.56
Management (Man)	2.83	0.72	3.63	0.66
Overall (AllGB)	2.73	0.56	3.46	0.52

Table 2: Degree of application of sustainable design practices

4.3. Effect of knowledge in sustainable design of regular buildings

As per research objectives, only the effect of participants' GB-related knowledge and roles on sustainable practice among regular building projects was examined. Thus this analysis only included the 169 surveys that focused on regular buildings. Among these, 3 surveys were further removed due to that respondents reported "others" in their project roles (Table 1). Consequently, a total of 166 responses remained, whose respondents' roles falling into owner representatives, designers, and constructors.

Analysis of variance (ANOVA) was conducted to test H1 (Table 3). For all roles, the degrees of application of the sustainable practices were statistically significantly different in all categories across GB knowledge groups. H1 was thus supported. Table 3 also displays these tests for separate participant roles (i.e., owner representatives, designers, and constructors). One can observe a variation across different roles in terms of whether the effect is significant or not. This implies a possible moderating effect of participants' roles on the relationships between their GB-related knowledge and the application of sustainable practices, as stated in H2.

Category	All roles	Owner representatives	Designers	Constructors
Energy	√	√+		
Water	√	√+		
Materials	√+	√+	√-	√-
Ecology	√+	√+		
Waste and pollution	√+	√+		√
Health and comfort	√+	√+	√-	
Adaptation and mitigation	√+	√+	√-	√
Community	√-	√+		
Management	√+	√+		√
Overall	√+	√+		√-

Significance level of 0.1 (√-); 0.05(√); and 0.01 (√+)

Table 3: Results of ANOVA for testing hypothesis 1

Hierarchical multiple regression analysis was thus conducted to test H2. In particular, this analysis assessed the incremental explanatory power of variables in each block (Cohen et al., 2003). In the first step (Model 1), two variables, namely GB related knowledge (GBKn) and participants' roles (Role), were included. In the second step (Model 2), the multiplicative interaction terms were computed between GBKn and the moderator variable (Role) and entered to the regression equation. In order to reduce multi-collinearity, all study variables were mean-centered (Aiken and West, 1991). Table 4 summarizes the hierarchical multiple regression analysis for the overall sustainable building practices (AllGB). Model 1 showed that participants' role and GB-related knowledge accounted

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

for a significant amount of variance in the application of the overall sustainable building practices ($F(2, 163) = 12.384$, $p < .001$). Model 2 with the interaction between Role and GBKn accounted for significantly more variance than just Role and GBKn by themselves ($F(3, 162) = 12.500$, $p < .001$). R square change = .056, $F(1, 162) = 11.183$, $p = .001$ indicated that there is potentially significant moderation between Role and GBKn on the application of the sustainable practices. Similar findings were also found for individual sustainability categories except "management" category. H2 was thus generally supported.

Study variable	Statistics	Model 1	Model 2
GB-related knowledge (GBKn)	Beta	.349*	.964*
Role in the most recent project (Role)	Beta	.114	.633*
Two-way interaction (Role x GBKn)	Beta		-.825*
	R^2	.132*	.188*
	ΔR^2	.132*	.056*
	F	12.384*	12.500*

⁺Standardized coefficient; *p < .001

Table 4: Results of the hierarchical moderated regression

This interaction effect is further assessed by using PROCESS (i.e. an SPSS add-on) developed by Hayes (2013). As an example, Figure 1 illustrates the interaction plot for the energy category. The interaction plots for other sustainable categories (i.e., water, materials, ecology, etc.) show similar patterns. These interaction plots suggested an enhancing effect that as GB-related knowledge of participants increased: (1) the degree of application of the sustainable practices also increased; and (2) the degree of increase in the adoption of sustainable practices is the most significant for owner representatives, followed by designers and constructors. Additionally, participants work as owner representatives that were familiar with GBs had the highest degree of application of the sustainable ideas in their most recent projects.

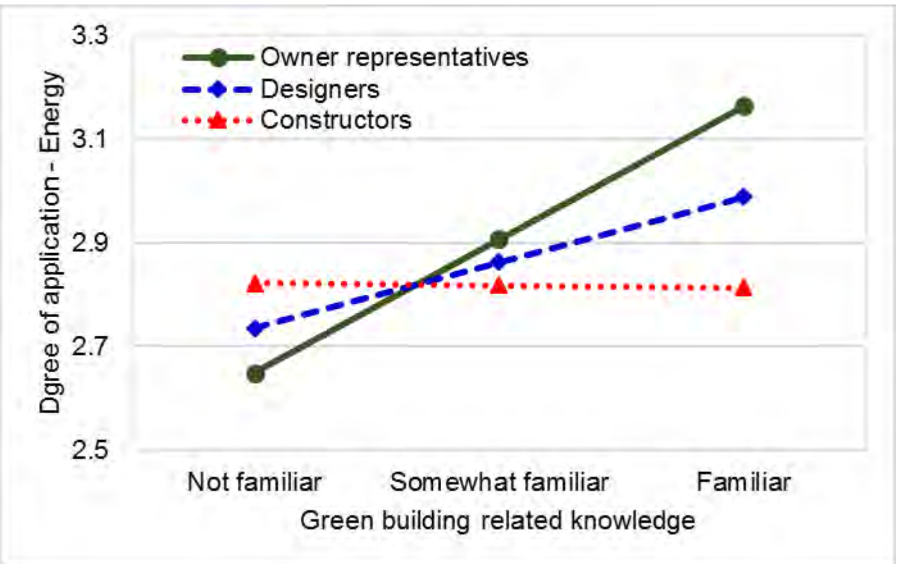

Figure 1: Interaction between practitioners' roles and GB knowledge in sustainable design

5. DISCUSSION AND CONCLUSIONS

Given the dominance of regular buildings in emerging economies, embedding sustainable practices to the design and construction of such buildings is imperative to reduce their negative environmental impacts. This is however a challenging task due to the common lack of knowledge of sustainability in such countries. To overcome this, this study empirically investigated the relationship between participants' knowledge and the adoption of sustainable practices; and the moderating effect of their project roles in Vietnam. As expected, the degree of application of the sustainable practices in certified GBs was found to be much higher than that in regular buildings. For regular building projects, the results confirmed a positive relationship between the participants' GB-related knowledge and the level of sustainable practices. Specifically, the adoption of sustainable practices in regular buildings increases as participants' GB-related knowledge increases. The research findings further suggested that this positive effect is the strongest for project owner representatives. In other words, if project owners (and/or their representatives) have good levels of GB-related knowledge, they are more likely to make the strategic decisions that can facilitate sustainable practices in the whole project life. These findings highlight the importance to provide appropriate training to project participants to advance sustainable practices in fast-growing emerging economies like Vietnam. In cases where resources for GB training are limited, the priority should be given to the training programs targeting at project owners (and/or their representatives).

Although prior studies have investigated issues related to GB project deliveries, few provided an empirical evidence on the contribution of project participants' knowledge and roles to the sustainable practices in regular buildings in emerging economies. As such, this study offers important theoretical contribution and opens the door to more future research on the interface between human factors and sustainable practices. The findings may also inform the development of practical strategies to develop the supporting human capital. Despite of the focus on the Vietnamese building industry, the research methods and implications can be applied to other countries, especially emerging markets.

[c] Building and Construction Authority, Singapore, may_siu@bca.gov.sg

ABSTRACT

Singapore's Inter-Ministerial Committee on Sustainable Development had set a target for Singapore to green 80% of its buildings by 2030. To meet this target, the Building and Construction Authority's (BCA) Green Mark Scheme was launched in 2005 as a lever to set parameters and establish indicators to guide the design, construction and operation of green buildings within tropical climates. In pace with technological advancements and tapping upon best practices from the industry and worldwide, the BCA Green Mark scheme has undergone regular enhancements since then to continually push for higher sustainability standards in buildings - which must further evolve and incorporate new innovative and integrated solutions to be future ready amidst the challenging scenarios of the next decade. This paper details the fundamental revamp of the Green Mark scheme for new developments to its fifth incarnation - Green Mark 2015/ 2016. A milestone criteria that has been streamlined and aligned with globally recognised key sustainability outcomes, Green Mark 2015/ 2016 aims to transform the next wave of green building design through greater emphasis on climatically contextual design, total building energy performance, life cycle approach towards resource use and the liveability of the indoor environment. The criteria was developed in extensive partnership with more than 130 industry stakeholders and academic bodies. This collaborative 'co-creation' approach facilitates a practical dimension to the scheme and empowers industry professionals to take ownership in pushing the frontiers for greener buildings.

Keywords: high-performance building, design process, green rating tool

1. GREEN BUILDING TREND IN THE NEXT DECADE

1.1 Green buildings are becoming the norm

With rapid urbanisation, buildings are being built at an unprecedented rate. Worldwide studies in green buildings have instilled greater awareness and willingness in global sectors to appreciate the rising urgency and benefits in environmental sustainability. In addition to the primary drive towards reduce emissions, pollution and environmental degradation, there is also an increase in consumer demand for green buildings as they simultaneously offer a healthier environment. With the advent of disruptive technology, such as smart technology, the way we design and operate buildings will progressively evolve in positive ways. The building industry is opening their arms to the increasing pool of shareable knowledge and analysed data, lower costs of advancing technology, and rising stature of green branding. There is a widespread call to arms in the form of conferences, discussions and engagements for the sector to be informed, and also to be heard. These essential factors are propelling the demand of green buildings in years to come.

2. GREEN BUILDING TREND IN SINGAPORE

2.1 Singapore green building journey

Over the last decade, the Green Mark (GM) scheme has been instrumental in stimulating the growth of green buildings (GB) in Singapore. It has been an effective tool in setting parameters and establishing indicators to guide the design, construction and operation of buildings towards increased energy efficiency and enhanced environmental performance. With the Green Mark and the GB masterplans, the number of GB has increased from 17 in 2005 to more than 2800 today. This translates to more than 84 million m2 of green GFA, equivalent to over 31% of the total building stock in Singapore. This is on track to achieve the target of greening 80% of Singapore's buildings by 2030. Our efforts in greening the built environment have also gained traction on the international stage, with 305 GM project applications across 14 countries overseas.

The GM scheme has also been extended to include (i) premises within buildings, to help enable tenants implement sustainable practices and minimise operation cost, and (ii) developments beyond buildings, to recognise

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

sustainable practises at broader levels such as urban planning in district developments. To date, 17 GM schemes have been formulated.

With these achievements, Singapore was ranked second in corporate strategy consultant Solidiance's The Top 10 Global Cities for Green Buildings 2016 white paper, just behind Paris but ahead of London.

BCA GREEN MARK SCHEMES FOR NEW BUILDINGS

- BCA Green Mark for Non-Residential Buildings
- BCA Green Mark for Residential Buildings
- BCA Green Mark for Landed Houses

BCA GREEN MARK SCHEMES FOR EXISTING BUILDINGS

- BCA Green Mark for Non-Residential Buildings
- BCA Green Mark for Residential Buildings
- BCA Green Mark for Existing Schools
- BCA Green Mark for Healthcare Facilities

BCA GREEN MARK SCHEMES FOR BEYOND BUILDINGS

- BCA-NParks Green Mark for Existing Parks
- BCA-NParks Green Mark for New Parks
- BCA Green Mark for Infrastructure
- BCA Green Mark for Districts
- BCA-LTA Green Mark for Rapid Transit System

BCA GREEN MARK SCHEMES FOR WITHIN BUILDINGS

- BCA Green Mark for Office Interiors
- BCA Green Mark for Restaurants
- BCA-IDA Green Mark for Data Centre
- BCA Green Mark for Supermarkets
- BCA Green Mark for Retail

Figure 1: 17 Green Mark scheme

2.2 GM buildings are performing better than non-GM buildings in Singapore

In the BCA Building Energy Benchmarking Report 2016 , it was shown that the average Energy Utilisation Index (EUI) of GM commercial buildings was lower than the average EUI of similar non-GM commercial buildings (see Figure 2)

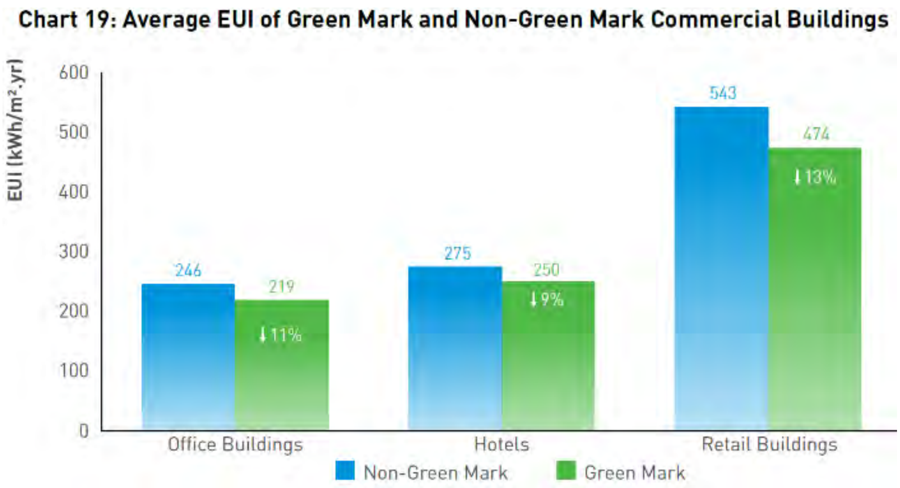

Figure 2: Average EUI of Green Mark & Non-Green Mark buildings

2.3 Some green building strategies have become prevalent

In addition, from a detailed statistical analysis of all projects certified under the previous GM versions, the following GB practices have been found to be prevalent through voluntary best practices:

- Majority of projects adopted the following GB strategies:
  - Water-efficiency: water efficient fittings, water saving strategies for cooling tower and linking water meter to building management system
  - Environmental protection: greenery in projects averaging more than twice its site area, usage of green cement and provision of green building user-guides
  - Indoor environmental quality: Usage of low volatile organic compound (VOC) paints
- Solar photovoltaic installed in Green Mark projects accounted for half of Singapore's grid-connected installed capacity.

2.4 Continuous enhancement of GM to keep pace with technology development and best practices

Since the launch of the first version of the GM scheme, it has undergone continued enhancements to keep pace with technology development in alignment with best practices from the industry here and in advanced countries (see Figure 2). The latest iteration, GM for Non-Residential Building (NRB) 2015 was implemented in 2016. GM for Residential Building 2016 and GM for Existing Buildings 2017 will be implemented over the next few years.

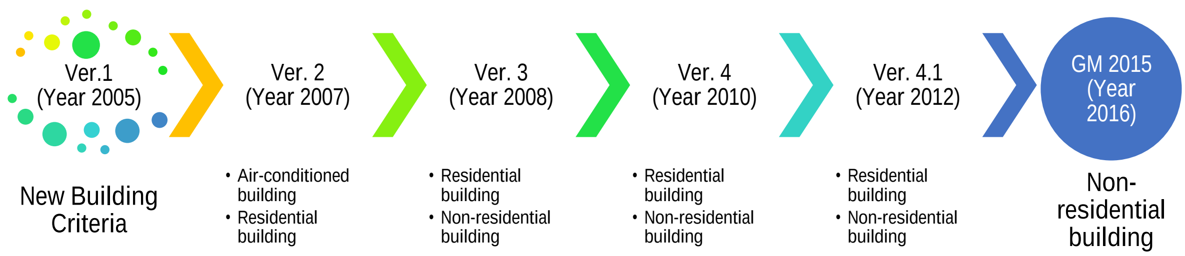

Figure 3: Evolution of Green Mark scheme

3. THE INTEGRATED APPROACH – THE NEW BCA GREEN MARK SCHEME

There is an increasing need for Green Building rating tools to be 'integrative' in multiple aspects, including not just their criteria, but also the development and implementation stage of the rating tools. Working closely with industry experts in the evaluation will provide a relevant depth in the rating tool and an engaging outreach over the industry. Additionally, it is necessary to unify the technical aspects with stakeholder's engagement to allow a lifecycle approach in energy management at various levels. Tying in passive design with active response systems, alongside the integration of time as a factor throughout the building's phase, ensures continuity and consistency

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

in the building's performance. This overarching sense of integration is crucial in creating buy-in from the industry, value-added solutions, well-rounded projects and a more complete sustainable building, and the new Green Mark schemes were developed with this approach.

During the conceptualization of the new GM schemes, BCA took this opportunity to take stock of our achievements, identify our goals over the next 5-10 years, and streamline our assessment processes. The aim was to create a new set of criteria that will set the direction for the next chapter of Green Mark and our industry.

4. UTILIZING A HOLISTIC ASSESSMENT APPROACH TO WEAVE SIGNIFICANT ELEMENTS TOGETHER

4.1 The new Green Mark - Co-developed and co-owned by the industry

Through a process of creative-collaboration, 'specialist technical taskforces' were set up to map directions, review standards and map practical pathways for the new GM criteria development in the new version, complementing the increasingly robust regulations and building codes. 14 industry taskforces, co-chaired by industry experts, were formed, tapping on the knowledge of 134 industry members. This process facilitated a practical dimension to the scheme but also empowered ownership and drive among industry professionals in striving for better performance.

4.2 The BCA Green Mark - Recalibrated for better comprehensiveness

To make GM more comprehensive and well-rounded in addressing various sustainable parameters, the structure and credit system of GM was re-calibrated (see Table 3) and analysed alongside various international rating tools (see Figure 7).

Section	Total Credits
Climatic Responsive Design	30
Building Energy Performance	30
Resource Stewardship	30
Smart & Healthy Building	30
Advanced Green Efforts	20 (Bonus credits)
Total	120+20

Table 1: Green Mark credits distribution for GM non-residential building: 2015

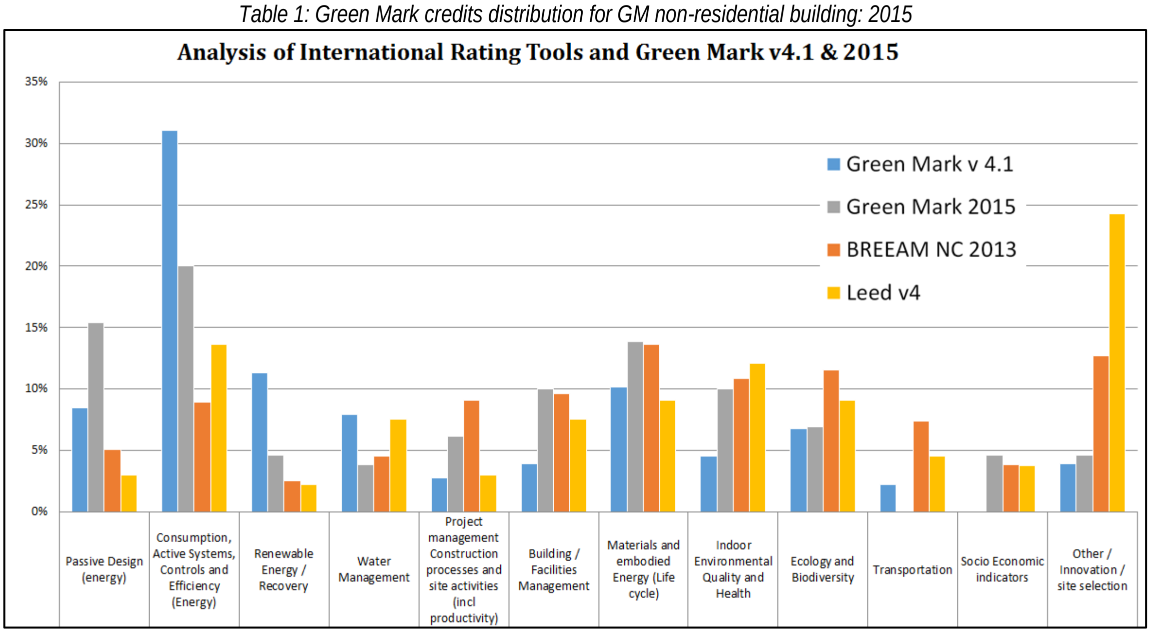

Figure 7: Analysis of various green building rating tools

4.3 The BCA Green Mark section 1 - Climatic responsive design

This section recognises the fundamental design and leadership required to develop a sustainable building for the tropics. The criteria provide a scoring framework that rewards the design approach and decisions at the brief formulation through to the detailed design stages of a project.

- Leadership – Effective leadership and collaborative teamwork to influence and drive improvements to the overall environmental credentials of projects, throughout the various project stages.
- Urban Harmony – Consideration of the building's human centricity and whether it is in sync with its surrounding context with respect to its immediate locale.
- Tropicality – Shaping building passive design in consideration of the climatic context to enhance effective thermal comfort for its occupants.

4.4 The BCA Green Mark section 2 - Building energy performance

This section's focus is on the energy effectiveness of the building. This delves into the energy efficient systems, total building energy consumption and the adoption of renewable energy.

- Energy Efficiency – Optimising the efficiency of high consumption mechanical and electrical systems.
- Energy Effectiveness – Holistic consideration of the effectiveness of energy systems' performance usage and consumption.
- Renewable Energy – Driving the creation of opportunities for generation and utilisation of renewable energy.

4.5 The BCA Green Mark section 3 - Resource stewardship

This section acknowledges the project team's effort to reduce the environmental impact of a building through sustainable construction approaches, the adoption of sustainable building systems and products by functional groupings and sustainable strategies in water and waste management.

- Water – Encouraging responsible use of water in buildings through water efficient monitoring and potable water replacement strategies.
- Materials – Reducing the carbon footprint emerging from construction activities by promoting sustainable material and practices via a life cycle approach.
- Waste – Responsible management of the building construction and operational waste.

4.6 The BCA Green Mark section 4 - Smart and healthy buildings

The quality of our built environment (indoors and outdoors) is critical for enhanced liveability among Singapore's community and end-users. On the other hand, engaging users 'smartly' can spur the necessary behavioural practices for more effective energy consumption. This section will be enhanced to look deeper into smart control strategies and indoor environmental quality management.

- Indoor Air Quality – Ensuring good air quality within functional spaces.
- Spatial Quality – Ensuring quality spaces that are acoustically and visually comfortable, inclusive and connect occupants to the natural environment.
- Smart Building Operations – Optimising equipment and related processes for energy reduction and comfort requirements through the use of automation and data and behavioural science.

4.7 The BCA Green Mark section 5 - Advanced green efforts

Finally, this section acknowledges additional efforts done by project team.

- Enhanced Performance – Greater recognition for projects that exceed the performance benchmarks stated in the criteria.
- Demonstrating Cost Effective Design – Recognising projects that demonstrate high levels of environmental performance without much increased cost.
- Complementary Certifications – Recognising the use of rating tools that rate environmental sustainability beyond the built environment.
- Social Benefits – Rewards projects that contributes to social sustainability.

5. FURTHER ENGAGEMENT WITH THE INDUSTRY STAKEHOLDERS

5.1. Pilot phase of GM non-residential building: 2015

Following extensive industry consultation and its development, GM Non-Residential Building: 2015 was launched for piloting at IGBC 2016. During the 1-year pilot phase, BCA has worked closely with industry stakeholders to pilot test the Green Mark criteria with actual projects. The first project has since completed the Green Mark board presentation and was on track to attain Green Mark Platinum under the pilot scheme. The project team found the criteria well aligned with their own sustainability goals. Besides doing the piloting, briefings to various industry associations and government agencies as well as consultation with the Green Mark Advisory Committee helped to finalise the criteria. GM RB: 2016 is currently undergoing its piloting phase.

6. CONCLUSION

The success of the new GM will mainly be attributed to the approach it has taken. It weaves together the different sustainable elements and presents a more refined and comprehensive slew of measures to address the evolution of green buildings as we strive to work towards the strategic goal of advancing Singapore's continued leadership in the region. Its integrative approach in its development, criteria and implementation has been well received by the building industry and will aid future projects to be more sustainable. These collective efforts will accelerate Singapore towards meeting the national target of greening 80% buildings by 2030 and underpin our vision of being a global leader in 'green' buildings with special expertise in the tropics and sub-tropics spearheading our journey towards a future-ready built environment.

Certification of Sustainability – Case Study Analysis of New German Standard

Merten WELSCH[a]

[a] *Federal Institute for Research on Building, Urban Affairs and Spatial Development (BBSR), Germany, merten.welsch@bbr.bund.de*

ABSTRACT

New sustainability requirements for federal buildings were defined by the Federal Building Ministry in the last years. As a result the Assessment System for Sustainable Building (BNB) was established as one of the most important instruments for the implementation of higher quality requirements for federal buildings.

Since 2015 the first results of complete certification processes according to BNB are available. As one of the first federal buildings the new Ministry of Education and Research (BMBF) in Berlin was certified with the BNB Gold Certificate and is now an outstanding example for sustainable building in Germany. This pilot project is the best federal building according to proven sustainability requirements. Special and innovative features of the building include for example a reduced energy demand (optimized heat insulation, PV modules integrated in the façade, gas-powered fuel cell), optimized selection of materials, optimized flexibility and optimized accessibility. Beside these building aspects there were also implemented exemplary quality assurance systems during the whole planning and construction phase.

Beside the BMBF numerous other current federal building projects consider the requirements of the BNB. All these projects are a part of the sustainable strategy of the federal government and they demonstrate that higher standards according to the holistic approach of sustainability can be achieved in day-to-day-business. The experiences can be used for new recommendations or future requirements for sustainability projects in the public sector.

The BNB and additional planning tools are published via the Sustainable Building Information Portal of the Federal Building Ministry (www.nachhaltigesbauen.de). Some selected contents are available in English.

Keywords: *certification of sustainable buildings, life-cycle assessment, best practice*

1. INTRODUCTION

Building in Germany is being geared towards sustainability. The German criteria checklist for the comprehensive assessment of sustainability aspects of buildings was developed by Federal Building Ministry and German Sustainability Council DGNB and is now used by the public sector and in a similar way by the private development sector.

The Assessment System for Sustainable Building (BNB) focuses on the entire life cycle of the built environment, covering all aspects from planning and construction to building operation with a view to optimizing overall quality.

As part of the German government, its sustainability strategy is assuming an exemplary role in implementing sustainability objectives in construction. Specific requirements for federal building projects are set out in the Sustainable Building Guidelines and the associated Assessment System BNB. The overall requirement is to attain the "Silver Standard" according to BNB for those federal buildings for which a BNB variant is available. As a result the BNB was established as one of the most important instruments for the implementation of higher quality requirements for federal buildings.

Since January 2015 the first results of complete certification processes are available. As one of the first federal buildings the new Ministry of Education and Research in Berlin and the new Federal Environment Agency in Berlin were certified with the BNB Gold Certificate.

2. IMPLEMENTING SUSTAINABLE REQUIREMENTS FOR FEDERAL BUILDINGS

2.1 Principles of sustainable building

In general, the classical understanding of sustainability is based on three dimensions: ecology, economy and socioculture, which are to be considered over a long period of time. The goal is to observe and to evaluate the entire useful life of a building – colloquial referred to as the life time of a building. For the actual observations of the life cycle, the first 50 years of a building are worked into the calculations.

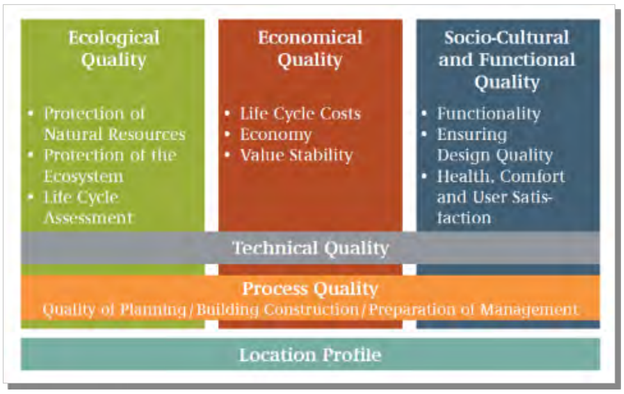

Figure 1: Qualities of sustainable building

Nachhaltiges Bauen

Figure 2: Logo of BNB in Gold

The main goal sought in the ecological dimension is primarily the protection of resources by optimally using construction materials and products, minimising use of space and of media (e.g. heat, electricity and water).

All requisite energy and material flows from the gain through the refinement and transport to the installation or disassembly alongside the global and local effects on the environment made by the energy use of the construction materials or the buildings are considered. Generally, this reduces environmental pollution at a local and global level. Different methods of analysis, e.g. risk analysis, analysis of the material flow, the material analysis and the ecological balance, are to be applied to objectively assess the environmental compatibility of construction products and of the whole building concept.

The costs which go above and beyond the mere costs of purchase and assembly – especially the life cycle costs are considered in the economical dimension of sustainability. This places the focus on life cycle costs relevant to the building, the economic viability and the value stability. As practice has shown, the life cycle costs can by far exceed the costs of construction. By analysing the life cycle costs, considerable opportunities for saving money during planning can be identified. As Life-Cycle-Costs (LCC), the costs of construction, the construction use costs and the demolition costs are additionally considered.

In addition to the question of functionality, the question of aesthetic design, the health aspects and comfort are relevant points in considering the social and cultural dimensions of sustainability. Winter and summer heat insulation contribute to comfort just as much as the noise protection or a deliberately chosen type of construction material (e.g. the use of emission free products). Construction designs, choice of material, building construction

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

and technology are to be interpreted to that effect and to be optimised, if needed. At the same time the construction design is to be made flexible enough that it can be easily adapted to the changing parameters e.g. change of use/user.

Alongside the ecological, economical and sociocultural aspects, the functional and technical properties (technical quality), the planning and implementation (process quality) and the, in part, local characteristics are decisive for the description and value of a building. This has extended the three columns of sustainability to five quantifiable qualities of sustainability – informatively supplemented by the local characteristics. The various aspects of sustainability interact directly with each other, so that the goal becomes a holistic and simultaneous assessment of every aspect.

2.2 How to use the "BNB"

The planning-based Assessment System for Sustainable Building (BNB) is distinguished for its comprehensive consideration of the entire life cycle of buildings. The assessment of building qualities is accomplished in accordance with transparent rules and objective, essentially quantitative methods.

No individual measures are evaluated in the results-oriented system, but rather their documentable effect on the overall concept of the building. Its application takes place throughout the planning stages, which means that it contributes not only to the optimization of the building but also and at the same time to quality assurance.

The BNB is organized into three different levels. The actual definition of the qualities takes place on the criteria level. These are described in detail in 45 criteria profiles on the basis of a total of around 150 indicators. The criteria profiles are grouped thematically in 11 criteria groups and 6 main criteria groups, thus making it possible to identify special qualities on each level.

On the basis of the degree of fulfilment, a score is assigned to the quality levels – Gold, Silver or Bronze. The results are presented in greater detail on a certificate with the Logo of BNB, representing the respective quality level. Additional information regarding the building is contained therein.

Figure 3: BNB gold certificate for BMBF

The modular structure of the system enables a differentiated presentation of the results; particular attention can thus be drawn to exceptional qualities in one or more subordinate areas of the assessed building. The BNB and additional planning tools are published via the Sustainable Building Information Portal of the Federal Building Ministry (www.nachhaltigesbauen.de). Some selected contents are available in English.

3. CERTIFICATION OF THE FEDERAL MINISTRY OF EDUCATION AND RESEARCH IN BERLIN

3.1 General information on the project

The new Federal Ministry of Education and Research (BMBF) in Berlin is the first federal civil building project that was realised by Public Private Partnership (PPP) and also the first building of that kind and size that received a certificate of BNB in gold. The project distinguishes itself by very high qualities and degrees of fulfilment in all main criteria groups of the assessment system BNB (81% - 99%).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

This outstanding pilot project is now the best federal building according to proven sustainability requirements. The six-storey building of the BMBF was designed for 1,000 office workplaces and is integrated in the existing development at the Berlin "Spreebogen" vis-a-vis the government district as a recognizable city block.

The building is composed of two U-shaped office wings which are connected by a central block. The greened and noise-protected interior courtyards are opened to the railway line and thus enable a visual connection to the northern urban space.

Figure 4: Federal ministry of education and research in Berlin (BMBF)

Figure 5: Interior courtyard

On the ground floor there are the entrance area with a visitors center, a canteen, a library, childcare facilities, five greened interior courtyards and the two-storied foyer that leads to the conference center at the first floor. The offices on the upper floors are mainly designed as single-user workplaces and are supplemented with spacious open communication areas in the centered corridors.

The building is structured in several utilization units. Beside the 350 office workplaces for the employees working in Berlin, other 650 office workplaces, which are rented for third parties, were realized in a second utilization unit. The building features an excellent overall quality that is recognizable by the gold certificate with a degree of fulfilment of 86.2 % and it features a number of over-average – and in parts outstanding – specific qualities according to sustainable building as shown subsequently.

Users	Federal Ministry of Education and Research and others
Owner	Institute for Federal Real Estate (BImA)
Building Category	Administration Building
Type of Project	Public Private Partnership (PPP)
Total Building Costs	115 million Euro
Architect	C. Pelzeter; Heinle, Wischer und Partner, Berlin
Building Company and Contractor	BAM Deutschland AG
Completion	August 2014
Gross Floor Area	58.000 m²
Workplaces	1.000
BNB Certificate	Gold (86.2%)

Table 1 Characteristics of BMBF

3.2 Specific qualities according to sustainability

3.2.1 Ecological and energetical quality

The energy concept for BMBF combines measures of optimizing the building physics according to the construction and technical systems which are in some places conventional and in other places very innovative. As a result the energy demand of only 36.1 kWh / (m²a) deceeds the strict requirements in Germany for this project by 71.6 %. Special and innovative features of the building for reducing the energy demand are for example:

- optimized heat insulation (heat transfer coefficient walls: 0.19 W/(m²K); heat transfer coefficient windows 0.84 W/(m² K))
- photovoltaic modules on the flat roof and integrated in the façade that produce about 100,000 kWh electric energy per year
- thermal activated ceilings instead of radiators in the offices
- ventilation system with heat recovery in every office, in conference rooms sensitive to CO_2 concentration
- LED lighting sensitive to movement and daylight in all offices
- external jalousie with light-diffusing slads in upper third and internal sun-blind with translucency in upper third for maximizing daylight even in a closed state
- combined heat and power (CHP) with block-type thermal power station (BTTP) and gas-powered fuel cell for generating electricity, heat and cooling instead of district heat (this system minimizes the primary energy demand and the CO_2 emission)
- the different system components are cross-linked with the building management system (BMS) by an intelligent interconnection (smart grid)

Figure 6: PV Modules in the Façade

Producer	Fuel Cell Energy Solutions GmbH
Electrolyte	carbonated
Operating Temperature	600–650 °C
Fuel Gas	natural gas
Output Power	250 kW electric, 160 kW thermic
Efficiency	47 % electric, 79 % total
Savings Compared to Seperated Generation	about 30 %

Table 2 Characteristics of Fuel Cell System in BMBF

3.2.2 Economical quality

The project could be realized in a high economic efficiency with a high energetic quality and a high level of comfort for the user. In order to ensure the flexibility and adaptability of the building for possible changing user demands in the future, the building enables different types of efficient office structures.

Figure 9: Communication area

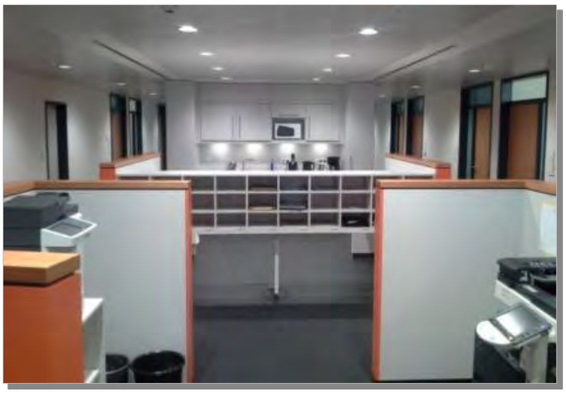

Figure 10: Office facilities, mailboxes and tea kitchen in open areas

3.2.3 Socio-cultural and functional quality

The requirements according to the user demand for a high level of comfort are met by numerous aspects, as for example:

- According to indoor air quality and avoidance of harmful substances the highest quality levels of BNB were met by choosing low-emission building products.
- The accessibility of the foyer and of the office areas is over and above the normal standard (building, interior courtyards and floors are accessible without steps; well-spaced corridors and office rooms for wheelchair users; tactile guidance strips; speech modules in elevators; information in Braille or raised letters; barrier-free toilets on every floor).
- A competition for art in architecture was realized with more than 300 submitted designs of which 4 were chosen, as for example a virtual sculpture of air, light and water vapour with a connotation to a rainbow at the banister in the foyer.
- 282 bicycle stands are available for the employees.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- A high level of noise protection was realized.

Figure 11: Tactile guidance strips

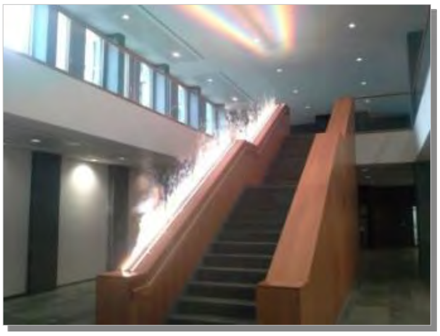

Figure 12: Virtual sculpture (artists B. Burchhardt, A. Lippke, M. Stammen)

After the first months in use the Federal Minister of Education and Research Johanna Wanka said "We feel very comfortable in these sustainable premises."

3.2.4 Process quality

Beside the BMBF numerous other current federal building projects consider the requirements of the BNB, like for example:

- The new office building for 32 employees of the Federal Environment Agency in Berlin is designed as the first federal "zero energy building" and received the certificate of BNB in gold in 2015 (more information: www.umweltbundesamt.de/).
- The renovation and reconstruction of the listed Federal Constitutional Court in Karlsruhe received the first certificate in silver according to BNB for complete refurbishment (more information: www.bnb-nachhaltigesbauen.de/).
- The aim for the new extension building for 100 employees of the Federal Environment Agency in Dessau is a "zero energy building" and a certificate of BNB in gold (more information: www.umweltbundesamt.de/).

All these projects are a part of the sustainable strategy of the federal government and the experiences can be used for new recommendations or future requirements for sustainability projects in the public sector.

ABSTRACT

A new methodology is proposed to asses integral performance of building with respect to energy and materials requirement over the building life cycle. Because the method builds on existing methods for Energy Performance and Materials Performance of Buildings, as defined by Dutch National Building Code, it provides an easily applicable method that allows optimized building design with respect to environmental impacts. Two case studies, one for building renovation and one for new Near Zero Energy Building show the advantages of integral assessment. Extending this approach for building assessment to other countries seems a logical step as it gives designers a better insight in total building performance.

Keywords: *green rating tool, design process, policy and regulation*

1. INTRODUCTION

The introduction of an energy performance requirement in the building regulations in Europe has resulted in major improvements in the energy efficiency of new buildings. Governed by the framework of the Energy Performance of Buildings Directive (EPBD Recast) each EU member state has formulated a methodology for energy performance evaluation for different building types. These calculation methods and performance standards, have been implemented in the national building regulations in each country. This legislation has been very successful in reducing the energy demand of buildings and in stimulating technological development for energy-efficient energy systems, building insulation and renewable energy. As a result the energy demand of new buildings has been reduced by a factor 10-100 since the 1970's. Moreover, from the year 2020 onwards all new buildings in the EU will have to conform to a "near-zero energy" (NZE) standard.

Now that NZE becomes the new standard, the role of building materials and embodied energy or related CO2-emission is becoming more and more important. It is recognized that a focus on energy efficiency only, entails a clear risk of having buildings not necessarily performing very well with respect to other environmental criteria.

However, a broader assessment of the environmental impact of buildings, including materials, is not done regularly yet. Already for a long time there exists within the building community a great demand for methods to support the selection of environmentally benign materials for buildings. Formerly, lists of "preferred materials" or "materials to be avoided" were used. Although such lists are easy to use, the draw-back is that they do not allow for performance-based building design and optimization of the design with respect to materials choice.

In the research community Life Cycle Assessment (LCA) is a broadly accepted methodology to assess the environmental impacts of products . This LCA method has been applied to buildings as well (see, for example, ref. However, among architects, technical consultants and construction companies the use of Life Cycle Assessment for building design and building maintenance is no common practice yet, mainly due to the relative complexity of LCA tools.

In order to fill this gap a process was started 20 years ago in the Netherlands to develop an LCA-based calculation method which was specifically focused on buildings and relatively easy to use. Moreover, this calculation method was meant to become part of the National Building Code, just like the energy performance method. Next to a calculation method, a national LCA database for building materials was set up, providing the necessary data for the assessments. As a result the so-called "material performance assessment of buildings" became obligatory for new buildings in 2014. Important is that the new method is restricted to only the materials used in the construction and maintenance of the building. This restriction was applied because the operational energy consumption of buildings is already governed by the existing Energy Performance standard.

So effectively there are now in the Netherlands two different performance indicators: one for the energy consumption during building use and one for the environmental impacts from materials. This raises the problem, that for designers it is difficult to determine the optimal solutions with respect to energy systems and the selection of materials with an impact on energy efficiency. For example the installation of solar panels or the addition of extra insulation to a building will result in a negative effect on the material performance due to additional materials, while on the other hand they improve the energy performance of the building. As the two indicators have an entirely different way of "impact assessment" and of normalization they cannot be compared or balanced against each other.

From a scientific point of view it would be quite logical to consider all environmental impacts from the building life cycle in one assessment system, and not divide it in two separate, incomparable assessments. On the other hand the building sector is very much accustomed to the use of energy performance methods and standards and a change towards an entirely new methodology would be problematic. In order to tackle this problem, we have developed a new framework to integrate the existing assessment methods for energy and materials performance , in such a way that their respective results are aggregated into a single indicator. In this method the LCA impacts of operational energy consumption are calculated and combined with the LCA results of the building materials, into a single impact score: I = E +M.

Below we will first outline the setup of the two existing assessment methods and describe how they were combined into a single, aggregated indicator. Then we will discuss some practical examples assessed with the new methodology and draw some conclusions.

2. EXISTING METHODS FOR ASSESSMENT OF BUILDING PERFORMANCE

2.1 Energy performance of buildings (EPG)

The method for calculation of the energy performance of buildings has been set up differently in each European country. In the Netherlands the method called "Energie Prestatie van Gebouwen" (EPG) is based on a quite detailed energy balance for the building, together with a typical meteorological year and a standardized building use . Local energy conversion systems (e.g.PV systems) are modelled with either standardized or customized conversion efficiencies.

As result from these model calculations the yearly energy consumption is determined in terms of the quantities of final energy carriers entering the building (i.e. electricity, natural gas, heat from district heating, biomass). The final energy consumption values are converted into equivalent primary energy requirements and normalized to a standardized primary consumption for the considered building type, thus resulting in a dimensionless Energy Performance Coefficient (EPC).

According to the present building standards a new residential building must have an EPC of 0.4, which corresponds to a primary energy demand of 60 kWh/m2 for a typical row house.

2.2 Material performance of buildings (MPG)

The evaluation method called "MilieuPrestatie van Gebouwen"(MPG) is a relatively new, standardized method to assess the environmental impacts of the materials used during the life cycle of a building. This life cycle includes resource winning and production of building materials as well as the construction, maintenance and decommissioning of the building. Also energy requirements during construction and decommissioning are included. The assessment is based on LCA methodology and all data about the building materials are derived from a national database of environmental impact data (Nationale Milieu Database, NMD) which has producer-specific and more generic data for building materials and products. This database is managed by an independent organization which also safeguards the quality of LCA data submitted by producers.

Note that energy requirements for production of materials ("embodied energy"), as well as GHG emissions from material production ("embodied CO2") are all included in the MPG evaluation. So all effects caused by building construction, maintenance and demolishment, except for operational energy consumption, are in principle covered

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

by this method. Within the MPG method, standard values are predefined, for example with respect to the expected service life of buildings: 75 years for residential buildings and 50 years for non-residential buildings. More importantly the MPG definition document prescribes the impact assessment method that needs to be used. It was decided to perform the impact assessment in the first step on the basis of the CML method for Life Cycle Impact Assessment which discerns 10 impact categories. Because the assessment method has to be useful for building designers, a second step is applied in which all impacts are aggregated into one single impact score, with weighting factors based on the so-called "shadow price" for each impact category. The shadow price (in €) was set equal to the virtual cost to avoid or prevent the damage of an environmental impact. No normalization is performed.

With this method the environmental impact is expressed into one final score, using the functional unit prescribed by the MPG, as "€ per m2 per year".

3. NEW METHOD: INTEGRAL PERFORMANCE OF BUILDINGS

It is not always convenient to have two different assessment systems and performance indicators when actually it is the environmental life cycle performance of the building that one would like to consider. For an integral performance indicator we therefore take the life cycle methodology as starting point. The material performance indicator (MPG) is already evaluated according LCA methodology, so we need to assess the impacts of operational energy consumption (i.e. energy consumption during the utilization of the building) with the same impact assessment method. The amounts of energy consumed may then be derived from the energy performance calculation (EPG).

This sounds fairly simple, but it should be done very carefully in order to avoid double counting or not accounting some material or energy flows. For that we have to take a close look at the system boundaries defined in the two respective assessment methods.

We discern 5 different boundaries which are relevant for our considerations:

- the building boundary, where also energy flows entering the building are being measured (energy metering);
- the project boundary (i.e. a group of buildings with collective energy services);
- the system boundary for Energy Performance of Buildings calculation (EPG);
- the system boundary for energy distribution within the Netherlands;
- the system boundary for assessment of Material Performance of Buildings (MPG).

Whereas the Material Performance evaluation considers in principle a global system boundary, in line with general LCA methodology, the method for Energy performance considers a national or even subnational system boundary. Winning and distribution of natural gas, biomass and waste is not accounted explicitly in the EPG method, and production of electricity is only accounted with a standard conversion factor for primary energy and for CO_2 emission. Also notice that environmental impacts from the energy distribution system are outside the scope of both the EPG and the MPG methods.

For all energy conversion processes it should be considered carefully whether or not their material and energy flows are accounted in one of the methods. For example if we look at the conversion of natural gas in a gas boiler within the building we can notice that the inflow of gas into the building is well accounted for by the EPG method because it carefully models the efficiency of the heating system. But the emissions from the combustion process to the atmosphere (i.e. CO_2, NO_x) and to the water (acids) are not accounted for anywhere.

So, in order to obtain a complete assessment of environmental impacts, on the basis of EPG and MPG, we consider for each energy flow entering the building:

- Are all upstream impacts from the energy winning, conversion and distribution activities taken into account?
- Are all emissions and material inflows for the energy conversion processes within the building taken into account?

In practical terms this means that for each final energy carrier that may be consumed during utilization of the building we have to establish an impact factor (or a set of impact factors) which allows us to assess all

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

environmental impacts of the energy consumption using this carrier. For energy carrier inflow into the building (Ei) we have defined the corresponding environmental impact EPGi* as:

$$EPG_i^* = IF_i \times E_i,$$

Equation 1

where

E_i = final energy consumption for energy carrier "i" (in MJ), as derived from EPG

IF_i = environmental impact factor for energy carrier "i" (impact unit per MJ)

E_i^* = environmental impact for energy carrier "i" (in impact units)

We determined impact factors for a number of major energy carriers, all for the context of the Dutch energy supply system [see ref. [16] for details].

If we add up the EPG*-results over all relevant energy carriers flowing into the building (e.g. gas and electricity) a total environmental impact score for the operational energy consumption of the building EPG* is obtained:

$$EPG^* = \sum_i \ EPGi^*,$$

Equation 2

Finally the integral environmental impact of the building is defined as:

$$IPG = MPG + EPG^*$$

Equation 3

The IPG score gives the desired score assessing the environmental impacts for operational energy consumption and the impacts related to materials use. As mentioned, impacts of embodied energy for materials are included in the MPG score.

Now for LCA practitioners and scientists in general the described method might sound as a cumbersome way to obtain results that can also be found by way of a standard LCA approach. The important difference, however, is that in our approach we make use of the results that are obtained from standardized calculation methods that are implemented in the Dutch Building Code and which are therefore familiar to the building community. In other words, without setting existing methods aside, we are able to derive integral impact scores for the building performance by applying just a few simple additional calculations. Moreover, the extra calculation step can easily be included in existing software tools for energy and material performance evaluation, like GPR Building and in that case requires almost no extra efforts from building designers.

In the next section we will explain what new insights can be gained from this new assessment tool for a case study on the construction of new houses. Elsewhere we have also discussed a case study for building renovation.

4. CASE STUDY: NEW NET ZERO ENERGY BUILDINGS (NZEB)

The IPG methodology should also be very useful for optimized design of new buildings especially as these have to meet the Net Zero Energy Building (NZEB) standard.

As a reference we start with a row house, which is built to comply with the draft NZEB standard. This house has a usable floor area of 124 m2, R-values for the building envelope of 6-7 (m2.K/W), triple glass windows (U=1.1 W/m2.K) and a high-efficiency gas boiler for heating and DHW supply. In order to make it NZEB it is also equipped with about 20 m2 of PV panels (3 kWp) and a Solar Hot Water system (2.5 m2).

First the effects of increased insulation thicknesses in the façade and roof was investigated. A feeling among designers may be that increasing insulation is not good for the environment because of the higher environmental load of the required materials. From our analysis we can observe that the contribution from the insulation material is never more than 3,5% of the total building's impact, even if we would go to an unrealistically high R-value of 20 m^2.K/W (see also ref.[16]).

But what is also clear is that the energetic effects of insulation beyond R=5, are very small. Partly this is due to type of house (row house) with only 98 m2 of exterior surface area. For a free-standing house the energy saving effects would have been larger. So there is no immediate reason to save on insulation thickness, because of concerns about the materials impact. The optimal thickness can be determined for each building type and climate, by using an analysis as shown above.

More significant effects can be seen in the next set of calculations were we look at solar energy installations. In Figure 1 we depict our NZEB house in 3 variants: 1) without solar energy installations, 2) with only photovoltaic panels (20 m^2, 3kW_p) and 3) a solar hot water installation of 2,5 m^2 and a slightly smaller PV panel area (17,5 m^2, where part of the PV panel area is replaced by solar hot water collectors. Figure 1 is a bit complicated because the PV panels generate more electricity than is used by the building (excluding domestic appliances!), which results in a negative impact from the PV generation. For this reason we show in a separate bar in Figure 1 the IPG-value, which is the sum of all impacts: IPG = MPG-building + MPG-solar + EPG*-gas + EPG*-electricity.

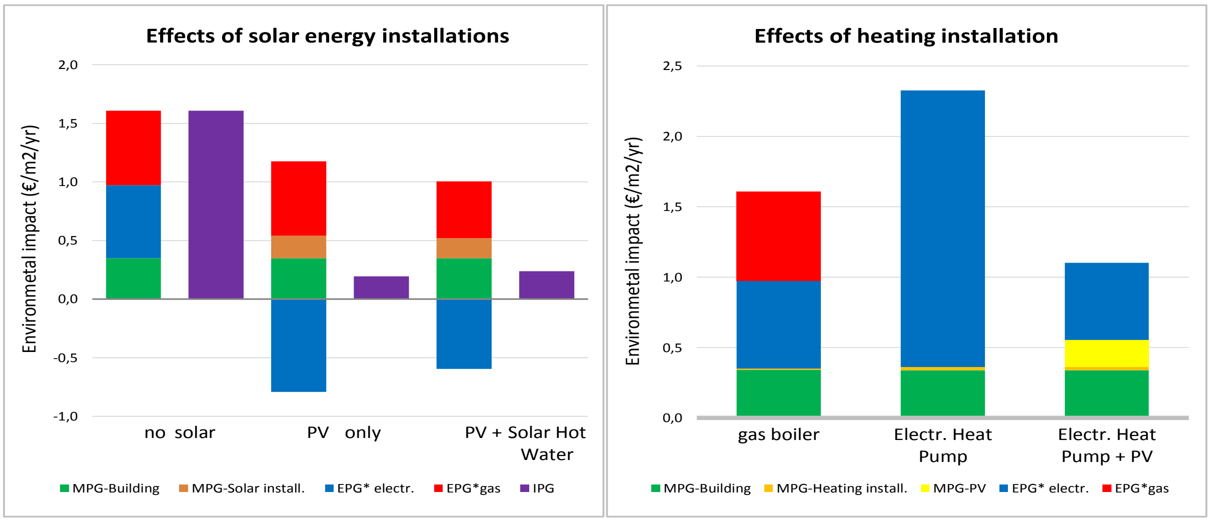

Figure 43 and 2: Effects on total environmental impact of building in relation to choice of solar energy installations and choice of the heating installation

Although the MPG-value from the PV installation is quite significant, about 50% increase in total MPG, the overall effect of the PV is very positive: the IPG-value is reduced from 1,61 to 0,19 €/m^2/yr. The replacement of 2,5 m^2 of PV panels by a solar hot water collector results in a slightly worse overall impact (0.24 €/m^2/yr). In this case the choice for a solar hot water system gives no improvement in environmental terms.

Figure 2 shows the effects of choosing a different type of heating installation, either a gas boiler or an electrical heat pump (ground water as source). Because the heat pump uses a substantial amount of electricity (from the grid) this has a significant negative effect. However if we add a PV installation (20 m^2) the total impact is about 30% better than with only a gas boiler (and no PV). Nonetheless, the situation with gas boiler and PV (Figure 1) if found to be most environmentally friendly choice for this building. To make the all-electric variant of this building the most environmentally friendly we need to install an additional area of PV panels.

One conclusion is that the choice of installation for heating or for renewable energy generation has more effect on the total environmental impact than the level of insulation, beyond a certain adequate insulation level.

5. DISCUSSION

It is clear that many assumptions affect the precise outcome of our calculations. Therefore the reader should be quite careful to extend the results beyond the scope and background data of our study. On the other hand the more general conclusions with regard to energy-related versus material-related impacts of façade and roof insulation should be fairly robust. Also our conclusion about the large effects of the choice of energy conversion equipment for heating and the effectiveness of PV systems should be reasonably robust as long as the background energy supply system is not entirely different from the Dutch system (for instance 100% hydro-electricity).

6. CONCLUSIONS

A methodology has been developed that makes it possible for building designers in The Netherlands to make an integral assessment of the environmental impacts of a new building or for building renovation projects. The new aspect is that our method is built on two existing building assessment methods that are already in use in the building community and which are part of the Dutch National Building Code. Because it builds on existing methods it is very easy for the building designer to determine the integrated environmental impact indicator for his plans, without necessity to learn complicated LCA tools.

In a number of typical examples we have shown the added value of the integrated assessment when designing a new construction at NZEB level. All-in-all the impact from materials choice and material amounts increases if we go towards near zero energy levels. For photovoltaic panels the material-related impact is fairly high (in comparison with other building components) but overall PV systems show a very large beneficial effect on the life cycle performance of the building.

Our general conclusion is that the proposed methodology to determine integrated environmental impacts provides valuable new insights for building designers. The new methodology and the related tools, will assist designers in making the right choices for specific buildings in specific circumstances. In our opinion it would be fruitful to develop and apply comparable methodologies in other countries. Our approach has the advantage that it provides a relatively easy assessment system for building designers without the need to learn new LCA tools which are not specific for buildings.

In view of the EU policy objectives to reduce the broader environmental impacts of buildings it would be advisable to develop further convenient methods and tools for life cycle impact assessment *at the building level*, such as described in this paper. Moreover, such tools should be easily applicable, so that they will be used in practice by building designers that wish to optimize their design with respect to integral environmental quality.

ABSTRACT

Assessment systems are recognized to be a powerful tool to promote the movement of building sector towards a better sustainability. Actually only in Europe more than 60 building rating systems are in use at local, regional and national level. This fact should be considered positive, but a critical issue emerged: ratings (scores) and labels are not comparable. The assessment systems are different in methods, physical and time boundaries, issues taken into consideration, number of criteria, scoring systems, etc. This lack of conformity created confusion among the building sector stakeholders. A harmonization process is clearly needed at transnational level in the way to create a common approach to building assessment that would enforce the effectiveness of certification labels. To achieve this objective, the CESBA (Common European Sustainable Built Environment Assessment) initiative has been launched with the involvement of numerous public and private European organizations from 15 countries. Since 2011, the principle proposed by CESBA for the harmonization of building assessment systems is to establish a transnational core set of KPIs (Key Performance Indicators) based on common metrics, a common denominator, that each system should adopt to guarantee the comparability of assessment results concerning the most important issues. Besides the usual label/ certificate produced by each assessment system, it will be possible to have a Passport that will show the value of the common KPIs. The Passport isn't a new assessment systems and it doesn't produce a rating. The rating will always be given by local systems on the base of regional priorities and context. The objective of the Passport is to allow the transnational comparison in absolute terms of the performance reached by each building to measure the progress toward common objectives (i.e. Global Warming). The CESBA approach has been proposed by the EC in the Communication 445 of 2014.

Keywords: green rating tool, policy and regulation, green ethics

1. THE ISSUE: IT IS NOT POSSIBLE TO COMPARE SUSTAINABILITY LABELS

Only in Europe, more than 60 building rating systems are actually in use at national, regional and local level. This number is increasing because assessment systems and relative labels are recognized to be a powerful tool to promote the movement of building sector towards a better sustainability. Assessment systems are more and more adopted by public authorities to empower the impact of their policies. Private companies use them to promote green buildings in the real estate market. If from one side the diffusion of all these numerous assessment systems is positive on the other hand this is creating confusion among the private and public stakeholders, citizen included.

The reason for this confusion is due to the fact that all the assessment systems produce results and labels that are not comparable. The assessment systems are different in methods, physical and time boundaries, issues taken into consideration, number of criteria, scoring systems, etc. This lack of conformity brings to labels not comparable and usually the differences are not understood. Building sector's stakeholders perceive the assessment systems on the same plane, while they address specific targets: public buildings, lighthouse buildings, passive or active energy buildings, etc. The problem is critical for the lack of a complete and clear communication about the different labels, that often are promoted trough marketing campaigns that don't clarify the specificities of each system.

1.1. **Why the assessments' results are not comparable?**

The lack of comparability is due to several aspects. Starting from the physical boundaries, the building assessment systems evaluate different physical objects. Some take into consideration only the building. Others the building and its outdoor area. Some other take also into consideration the quality of the location. For instance, evaluating the proximity to services or public transportation. Time boundaries, that concern the life cycle phases of the building, are also different. Many assessment systems take into consideration only the design and the as built phases. Other include the pre-design phase that deals with process aspects (i.e. adoption of an integrated design methodology). Few take in account the construction phase evaluating for instance the impact of the construction site on the surrounding area. Very few consider the in use phase and the end of life of the buildings. Different physical and/ or time boundaries make not comparable the performance scores achieved by buildings. But there are other important elements that have to be considered. For instance, the assessment themes. Very few assessment systems include all the dimension of sustainability, limiting the evaluation to the environmental and/ or social aspects. The economic aspects are not included. The number of criteria can strongly vary: from 10 to more than 200. This is due to the different methodological approach between the performance based systems (few criteria) and the prescriptive ones (high number of criteria). The assessment of a performance is usually more complicated than evaluating the respect of a specific prescription. But also in the case of performance based criteria, the calculation is usually based on different standards and regulations with the consequence of not comparable indicators' values. Finally, the methodologies differ. The characterization, normalization and aggregation of indicators' values could be based on very different methodological principles. A harmonization process is clearly needed at transnational level in the way to create a common approach to building assessment that would enforce the effectiveness of certification labels.

2. A STRATEGY FOR HARMONIZATION

The solution for the harmonization of building assessment systems can't be their convergence in a unique common system. For two reasons. The first is to respect the "contextualization" principle. Building practices, environmental, social and economic priorities are different in each region and assessment system must reflect them. Sustainability issues don't have the same importance in all regional contexts. For instance, "water consumption" is an issue very important in South Europe. In North Europe it isn't relevant. Consequently, the efforts to reduce the water consumptions of a building should be more awarded in a South European context. In the same time benchmarks (minimum acceptable performances) depend on the building local practice. It is not meaningful to fix a minimum performance value or a best practice at transnational level. For instance, if in a country the use materials from renewable sources is a common practice, this practice can't be the minimum performance requirement in other countries where the use of renewable material is unusual.

In general, assessment systems should provide evaluations and scores that indicate how much a building is better with regards to the regional building practice. Contextualization means also the use of the local standards, regulations and units of measure. If this aspect is respected, the assessment systems will be more accessible to all. The contextualization principle is the main issue concerning for the diffusion of the "international" assessment systems that are not sufficiently flexible to be fully adapted to local contexts. The second reason for the impracticability of a unique assessment system isn't technical. As already pointed out, actually dozens of assessment systems are already available. All these systems are owned and managed by different public or private organizations. It would be impossible to have all of them converging in a unique common certification system.

A possible winning strategy for assessment harmonization is the definition of a transnational core of common indicators (Key Performance Indicators - KPIs) that are relevant in all contexts and regions. To allow the transnational comparability, the KPIs should be calculated using a common metric. A core set of transnational indicators shouldn't provide a rating because, as already mentioned, performance scores are based on local priorities. KPIs have to be expressed only in absolute terms (i.e. kWh/m^3, $Kg\ CO_2/m^2$). In this way it is possible to compare the performance of buildings located in different regions assessed through different assessment systems. The adoption of a transnational core set of KPIs by the existing and future assessment systems would guarantee a minimum common base to compare the results concerning the key sustainability issues. The existing systems to be harmonized would just have to integrate the transnational core of KPIs that will act as a common "harmonising" denominator. There is not the necessity to significantly modify assessment methods and tools.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. INTERNATIONAL INITIATIVES FOR THE HARMONIZATION OF BUILDING ASSESSMENT SYSTEMS

The possible definition of a core set of transnational KPIs for the harmonization of assessment systems has been explored by several research projects and activities promoted by different international organizations.

In the past period, the Sustainable Building Alliance carried out a study to define a framework of common metrics to assess the environmental performance of buildings based on the European standards developed by the CEN TC 350.

The idea of a common document to compare the performances of buildings assessed with different systems has been proposed by the European project Superbuildings. The project developed the idea of a “building signature”. It consists of a radar profile which summarize the value of 12 quantitative indicators (environmental, social and economic) with the intent to compare them with a regional average. The 12 indicators of the building signature are: energy, water, natural resources, waste, GWP, thermal discomfort, amenities, social comfort, human toxicity, operation, flexibility, eco-toxicity.

In 2011 it was launched the CESBA initiative by a network of European projects in the field of the territorial cooperation (Interreg), involving numerous public and private European organizations from 15 countries. CESBA is a collective European bottom-up initiative that provides knowledge on harmonised built environment assessment. CESBA stands for “Common European Sustainable Built Assessment” and its principle for the harmonization of building assessment systems is to establish a transnational core set of KPIs (Key Performance Indicators) based on common metrics that form the transnational CESBA Passport. The CESBA Passport isn’t a new assessment systems and it doesn’t produce a rating. The objective of the Passport is to allow the transnational comparison in absolute terms (i.e. Kg Co_2/sqm year) of the performance reached by each building to measure the progress toward common objectives (i.e. Global Warming).

The harmonization principle based on the establishment of a common set of indicators has been adopted and proposed by the European Commission that in 2014 issued the Communication 445 “Communication from the Commission to the European Parliament, the Council, the European Economic and Social Committee and the Committee of the Regions on resource efficiency opportunities in the building sector”. In this document it is stated that “the fact that there is no established comparability between the different schemes also adds to the uncertainty and complexity for businesses”. The solution indicated by the European Commission is that “a common framework of core indicators, focusing on the most essential aspects of environmental impacts should nonetheless be established. This will allow comparability and provide consumers and policy makers with easier access to reliable and consistent information”.

Many positive benefit are identified in the COMM 445 (2014) for the establishment of a common core set of indicators:

- Allow easier communication of information to professional and non-experts;
- Provide reliable and comparable data to be used in decision-making covering the entire life-cycle of buildings;
- Enable the setting of clear objectives and targets, including system boundaries, for building performance, complementing already existing European legislation on buildings;
- Increase awareness of the benefits of sustainable buildings among actors engaged in providing buildings, as well as private and public clients, including users of buildings;
- Facilitate the effective transfer of good practices from one country to another;
- Reduce the cost to assess effectively and communicate the environmental performance of buildings;
- Provide public authorities with access to core indicators and to a critical mass of relevant data on which to base their policy initiatives, including Green Public Procurement;
- Widen the market for sustainable buildings to more countries than current trends indicate and to other buildings sectors such as non-residential buildings and, eventually, to the residential market.

4. THE CESBA PASSPORT PRINCIPLE

The harmonization approach of CESBA is in line with the European Commission intents expressed in the COMM (2014) 445. The particularity of CESBA, with regards to other harmonization initiatives at transnational level, is to address specifically the public assessment systems. With "public" CESBA intends the systems that are owned and managed by a public authority (country, region, city, agency, etc.) and used primarily to improve the effectiveness of policies on sustainable building. Actually many incentive based policies are using building assessment and rating systems because they allow to define objective and verifiable performance targets. Public assessment systems address both public buildings (social houses, schools, hospitals, etc.) and private (residential buildings, tertiary buildings, shopping centres). They are used in building codes, urban plans, public tenders. What has to drive the harmonization of public assessment systems is to keep their affordability and operability. Public assessment systems are intended for a "mass certification" approach with the objective to reach the 100% of buildings. CESBA defined 9 key principles for the harmonized public assessment systems. They are:

- The User first!: CESBA focuses on the people who use buildings. The aim is to design, build and operate the buildings in order to meet the users' requirements and needs, providing an improved comfort, and an ecological and economical construction and operation;
- Sustainability: The assessment covers all aspects of sustainability: environmental, economic and social ones;
- Regional contextualization: Building assessment systems must be contextualized with the region where they are applied, in order to reflect the local specific priorities, cultures, habits and construction practices. This means using local units of measure, adopting national/ regional standards and regulations, giving due consideration to the local climate, and accounting for availability of natural resources and cultural aspects of design.
- Comparability: The performance results shall be comparable in absolute terms thanks to the adoption of the core set of criteria;
- Mass oriented: Building rating systems can play a key role in moving the built environment towards a better sustainability. To reach this objective they have to be widely adopted by the different stakeholders of the building sector: architects, designers, public organisations, construction companies, investors, etc. Mass oriented means that the objective of the certification is to reach 100% of constructions;
- Simple to use: A mass-oriented building assessment system has to find a right balance between the simplicity to use and the scientific/ technical value. The assessment must be precise, not simplified, clear and visible. A system requiring complicated calculations or the availability of data that are not easy to find would request too much time and effort (costs) to be widely used. Simplicity helps the dissemination of assessment systems among the stakeholders;
- Open source: Using an open source approach allows CESBA to be appropriate as to its context by paying special consideration to the environmental, ethical, cultural, social, political and economic aspects of the community it is intended for. Consequently, this approach allows for regional adaptations in the guidance system;
- Co-creation: CESBA harmonization is developed by several people and organisations from various European regions, with experts providing input by contributing as Wiki editors. The knowledge base and further areas of content development are discussed and agreed during common and open CESBA sprint workshops;
- Transparency: The public should have access to the performance results especially for public buildings, while keeping in mind privacy rules. The visualisation of the results must be clear and offer guidance for further understanding.

CESBA proposes a core set of 11 common indicators: non-renewable primary energy, primary renewable energy use, CO_2 emissions, indoor air quality, thermal comfort, building life cycle cost, reused/ recycled materials, water consumption, solid waste, user involvement, monitoring/ optimization of operation. This core set of indicators has been produced with a co-creative approach through a workshop with more of 100 participants from 11 countries (CESBA Sprint Workshop, Voralberg, September 2013). The bottom – up approach is a characteristic of the CESBA initiatives. Individuals with different backgrounds (engineers, architects, policy makers, SME, etc.) meet and find a shared common position.

The KPIs metrics are actually under test in the context of ongoing European projects (CESBA Alps – Interreg Alpine Space, CESBA MED – Interreg Mediterranean). A first group of 6 assessment systems used by public authorities are collaborating for the implementation of the CESBA Building Passport. In particular the Italian national system Protocollo ITACA, the French BDM, the Austrian KGA, the Czech SBTool CZ, the Portuguese SBTool PT and the Spanish VERDE. The CESBA Building Passport will be operative by 2018. The CESBA Passport system will be manged by the no profit CESBA Network Association, located in Voralberg (Austria).

ABSTRACT

The growing awareness for sustainable construction increases the demand for low environmental impact products among others. This poses new challenges to construction product manufacturers (CPM) not only in terms of developing such products, but also in terms of providing detailed and reliable product information to designers and procurers, as well as manufacturers of more complex products, including information on the use of resources and resulting effects on the global environment, the service life, as well as their behavior when it comes to maintenance, deconstruction and recycling.

Often, meeting the information demands from designers and procurers means to provide information on: the energy consumption and greenhouse gas emissions related to the production process of the product including both upstream and corporate processes; the energy consumption for the installation and dismantling processes; the service life and maintenance possibilities/needs, and take-back and recycling possibilities. The collection and publication of such information becomes a competitive factor for enterprises and enhances their overall image. Additionally, the optimization of the manufacturing processes and the commitment to sustainability becomes an area of interest for CPMs. The saving or substitution of primary energy sources and primary raw materials lead to benefits such as reduced costs and positive sustainability reports.

However, small and medium-sized manufacturing enterprises (SMEs) often shy away from the effort associated with these tasks. They are not always familiar with scientific principles and normative requirements. It is necessary to support them with knowledge and resources and advise them on the compilation of product information. This paper addresses essential results of IEA EBC Annex57 and specific recommendations, accompanied by supporting information. Additionally, within the paper recommendations are given to improve their production and procurement processes as well as related environmental product information, seeking to improve their overall market competitiveness.

Keywords: small and medium-sized enterprise, environmental product declaration, supply chain

1. INTRODUCTION

Nowadays, the growing adoption and implementation of sustainable practices in the construction sector increases the demand for environmentally responsible and healthy construction products on the market. Building clients/developers and procurers are increasingly integrating specific requirements for sustainability already in the client's brief, and later on in the tender documentation, as an addition to the requirements for technical, functional or design quality of construction works. This places a certain responsibility on the designers, build contractors and vendors to choose construction products that comply with these requirements. In this regard, products making a significant contribution to the conservation of resources and the reduction of adverse effects on the environment are preferred by building stakeholders wanting to make a statement that they are not concerned solely about how the product performs in their building, but also about its environmental impacts.

Within the framework of a sustainability assessment a Life Cycle Assessment(LCA) of the building is increasingly required. LCA data on construction products provide the basis for this, and thus a need for such information is evident. Considering also the European Construction Products Regulation (CPR) that includes the sustainable use

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

of natural resources, particularly in relation to recyclability, durability and environmental compatibility as a basic requirement for construction products, further consequences for construction products and the declaration of their performance are already on the way.

This poses new challenges to construction product manufacturers (CPMs) not only in terms of developing such products, but also in terms of providing objective, unbiased and transparent environmental information on their products to other stakeholders along the supply chain. Meeting these information demands often means to cover every stage of a product – from how it is manufactured, to its installation and use in the building, to what happens to the product when its end-of-life is reached. Manufacturers who collect and publish such information demonstrate their own commitment to reporting and continuous improvement, providing a basis for communication with other stakeholders – this leads to an increased credibility, differentiates the enterprise from the competition and enhances its overall image.

There are already existing standards, such as ISO 21930 and EN 15804 providing rules for the generation and presentation of construction product-related environmental data in a harmonized way. These can be used for the purposes of assessing embodied energy and global warming potential as part of the total environmental related information (i.e. embodied impacts) of a construction product. The derived information on construction product can then be used as a source of information for the overall assessment which can only be performed on the building level (EN 15978), taking into account the functional and technical performance respectively.

However, due to their lack of resources and limited access to information, small and medium-sized manufacturing enterprises (SMEs) often shy away from the effort associated with these tasks. It is necessary to support them with knowledge and resources to overcome the lack of know-how and advise them on the compilation of product information. This paper addresses essential results of the international project IEA EBC Annex57 and specific recommendations, accompanied by supporting information, specifically to be used by SMEs of construction product manufacturers. Additionally, within the paper recommendations are given to improve their production and procurement processes as well as related environmental product information, seeking to improve their overall market competitiveness.

2. THE PLACE OF SMEs IN THE SUPPLY CHAIN

SMEs have particular characteristics that can present challenges due to the presence of fewer technical and financial resources for gathering data across different parts of the business operations and the overall adoption of a strategy for the measurement and monitoring of the embodied impacts of their products. Construction product manufacturers, in their attempt to showing good ethics along with taking responsibility for environment and society, can unlock their potential of influencing the embodied energy and global warming potential of their products through, for example:

- The choice of specific primary raw materials, energy sources and technologies for the manufacturing process.
- Advancing the technical characteristics of their products in terms of durability, maintainability and serviceability, as well as ease of dismantling, reuse and recyclability.
- Expanding their operations on the product lifecycle through the provision of life cycle support services (e.g. maintenance contracts) and take back programs at the end of the product's service/ useful life.
- Technically advising and supporting clients and architects on how to better install and use their products (Maintenance instructions)

Therefore, the provision of "better" products in combination with the publication and active handover of credible environmental product information supplementing the information on the technical characteristics of the product, and the transition to life cycle support services, can improve the competitive position of SMEs.

The group of construction product manufacturers is diverse – from single parts/material manufacturers (dealing with the mining and materials manufacturing) to "end-use" product manufacturers. In this regard, operations and structures can vary significantly between manufacturing SMEs. In order for an enterprise to assess the embodied impacts across its operations, it must initially identify the boundaries it will work within and the processes over which it has an influence over.

The manufacturers' main responsibility is to describe their own/ corporate processes (e.g. fuel and material use, as well as pollution, due to the manufacturing equipment and processes) as clearly, completely, and accurately as possible. Over these processes the manufacturer has a direct influence, thus, calculating the on-site impacts of product manufacturing, the so-called gate to gate impacts (A3 in Figure 1), can be the starting point in the quantification and assessment of the product's embodied impacts. This information can enable the identification of key "hot spots" of embodied impacts in the production process and the potential for product or energy source substitution. Every activity carried out before the manufacturing process in the supply chain belongs to the upstream processes. Although a manufacturing enterprise has no means of direct influence over these processes, it can still place pressure backward in the supply chain by asking lower-impact materials and/ or energy sources inputs to make the product (A1-2 in Figure 1), as well as related credentials for every supplier it cooperates, through its procurement processes.

After looking on site and upstream, it is time for the manufacturer to look downstream (A4-C4 in Figure 1), at the processes occurring once the product leaves the factory. Downstream life cycle stages include the transport and construction process, the use stage and end-of-life management. Manufacturers have no direct influence over the life cycle of their products after their delivery. What they can do is to provide information on what are the impacts of their products under specific conditions of use (based on different scenarios). For example, this includes information on the energy consumption for the installation and dismantling processes, information on the service life and maintenance possibilities/ needs and information on take-back and recycling possibilities. The consideration of the downstream processes depends greatly on the type of the product – for instance, in cases the product is used as an input to another product and is not a ready-to-install product in the building (e.g. cement), describing the post-gate life cycle stages does not make sense.

In case the enterprise has an established a take-back system itself, it might also have a direct influence over the recycling processes. A manufacturing company, by taking increasing responsibility for the end-of-life management of its products and designing them in such a way to be reused or recycled inside the facilities, reduces the need for new materials in production and creates a tight "inner circle" allowing the use of less material, labour, energy, and capital. In this way, a contribution to the shift toward a circular economy can be made.

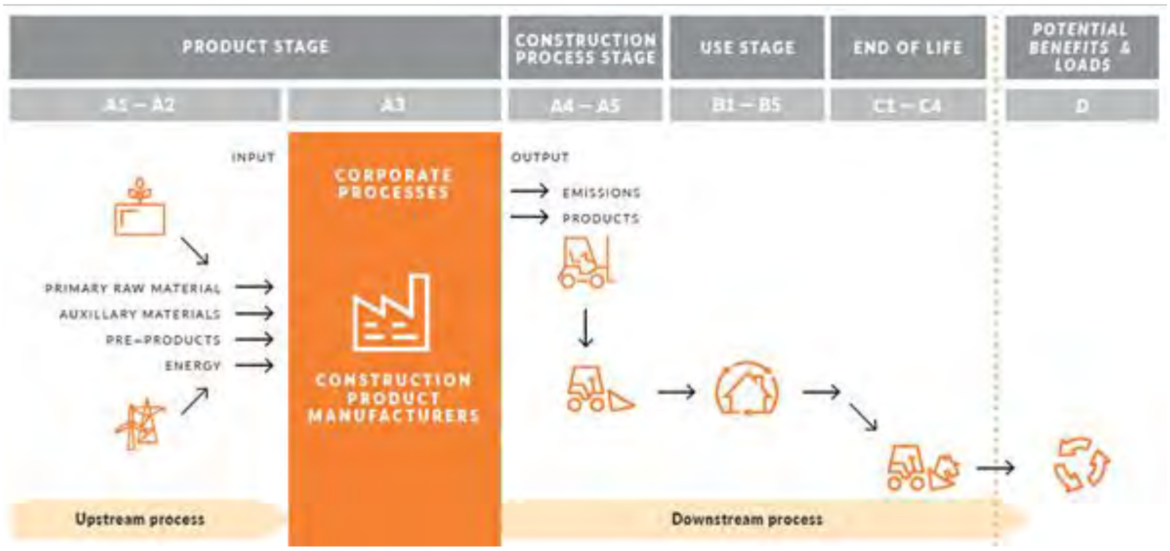

Figure 1: Data collection and provision in the supply chain of a construction product. the description of the product-related life cycle information (A1-C4 & D) is based on EN 15804

3. APPLICATION POSSIBILITIES

To create more benefits for CPMs as well as stakeholder over the life cycle of a building, primary goals must be set and assigned to each life cycle phase. Methods and steps of action regarding embodied impacts must be chosen accordingly. An example for better understanding of this specific course of action: In the life cycle phases A1 – A3, with the main target of reduction of embodied impacts, multi criteria decision making (MCDM) – e.g. pictured as "A" in Figure 2 - can support decision making regarding raw material or transport options, integrated process optimization in manufacturing, etc. Further steps of action for each life cycle phase are illustrated Figure 2.

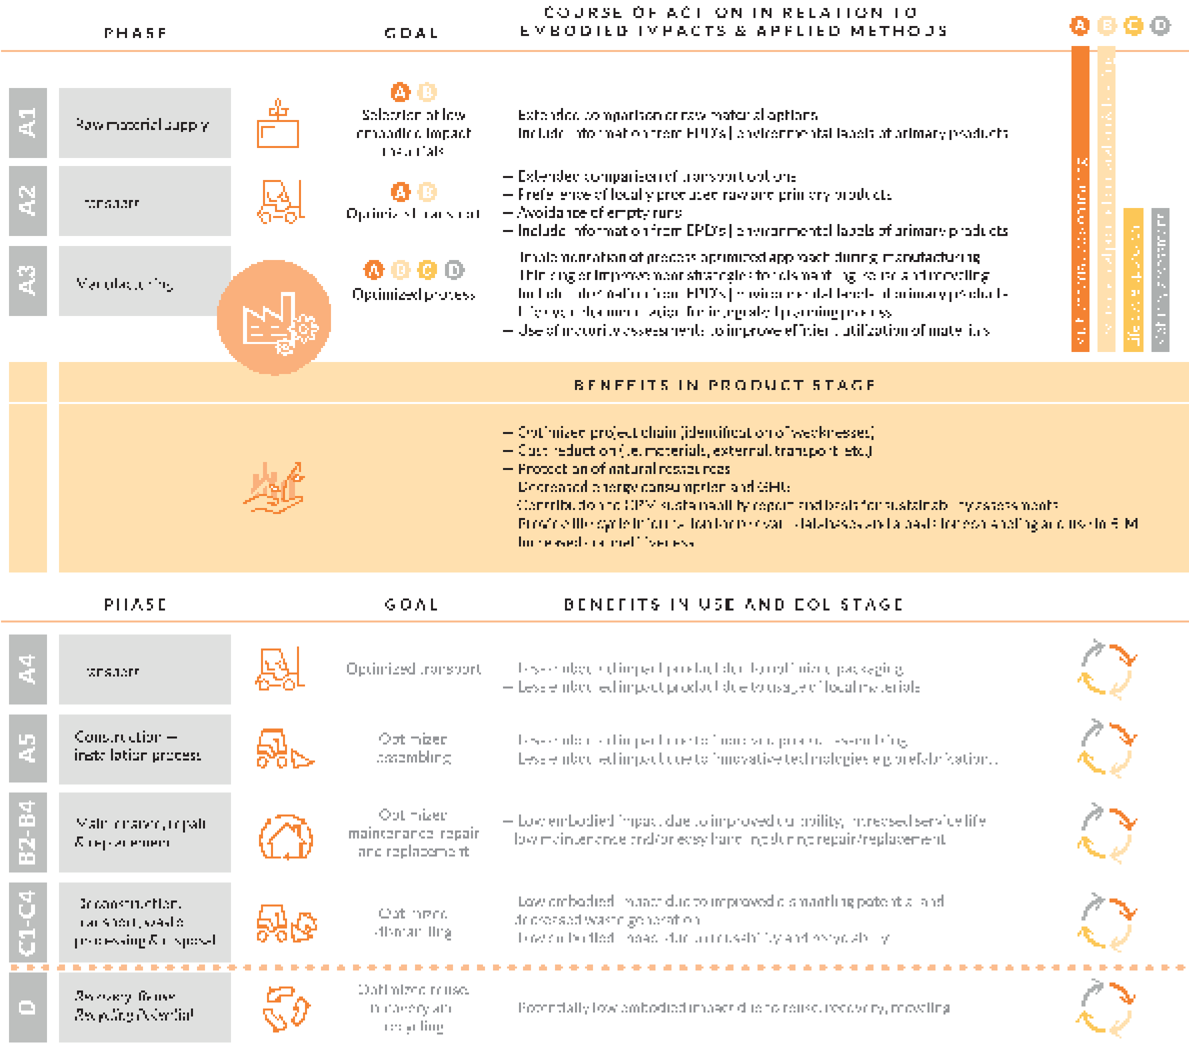

Figure 2: Course of action and benefits in relation to embodied impacts

Optimisation of the processes within the enterprise: Can be especially beneficial in case competing with other enterprises. Conducting a life cycle assessment of its product can help a manufacturing enterprise to identify problematic areas of, and therefore potential improvement strategies for, the production processes and opportunities for product-related optimization for a transition towards a highly competitive product. In this sense, better choices regarding raw materials, energy supply sources and technology sources can be made based on an embodied energy analysis.

Contribution to lower costs through energy conservation and substitution: As the use of fewer energy resources and the generation of less environmental pollution result, for the most part, in an improved financial performance. The enterprise pays less for inputs, as well as for waste and pollution management.

In-house comparison of location/ sites: Is especially important for enterprises operating in more than one location. Comparing the different manufacturing technologies used in the different locations and identifying which locations are associated with the higher embodied impacts make it easier to identify hotspots.

Benchmarking for the energy intensity of production (industry comparison): Is important to identify and recognize less energy intensive production processes and the emerging low impact products. Manufacturers should actively engage in reducing their product's carbon-equivalent footprint and work with industry associations to develop EPDs for their product category. In addition, it is recommended to engage with these associations to provide transparent LCA data that can be used as an example and benchmark for their products. Once benchmarks have been established, a link to these benchmarks can be made.

Contribution to the enterprise's sustainability reporting: By indicating reductions in energy consumption and environmental impacts of the manufacturing or corporate processes. Sustainability reporting can therefore be improved and influences further the image and value of the enterprise. Furthermore, product responsibility can be better demonstrated when offering take-back-guarantees and publishing appropriate product-related information.

Compilation of information for Business-to-Business (B2B) or for Business-to-Consumer (B2C) communication: At present, purchasers expect from the product provider to include information on the impacts their products have on the environment and health, including embodied impacts — related information. Only with this given information they are able to calculate the cumulative embodied impacts over the whole life cycle. Additionally, end customers are increasingly interested in access to information on environmental information to make a better purchase decision directly at the hardware store.

Applications for Ecolabels and EPD's: Are useful tools both for communicating product information and marketing purposes. EPDs are also useful in terms of providing leverage during negotiations with primary product suppliers in the course of a process and product optimisation. Some label awarding organisations for environmental labels require the presence of information on embodied impacts in addition to other environment and health related information. The results of an embodied impacts assessment can be an input to the EPDs.

Provision of data for databases: In a simple and understandable way to make it easier for clients and users to compare different products and their specifications. Overall, it is important for manufacturers to effectively communicate embodied impact information associated with the production, installation, use and disposal or recycling of construction products to the interested stakeholders (e.g. clients, designers, purchasers, etc.) along the building supply chain. The resulting data provided by the construction product manufacturer can be made available for example in databases for design professionals and consultants and/or LCA specialists.

The application of the previously described measures additionally contributes to "green" supply chain management. Improvements may occur in term of product, information, cost or service. In this case, the latter is associated with benefits in maintenance and deconstruction services or information offered regarding these processes.

4. RECOMMENDATIONS

Data collection is one of the key challenges (and sometimes a barrier) to completing an assessment of embodied energy and global warming potential, especially when data is needed down the supply chain. Data used for product assessments can be divided into two main categories:

- Internally collected data (data generated/ collected within the enterprise); usually physical data directly attributable to the specific product, and
- Third party data (obtained either directly from the suppliers'/ service providers or indirectly from other third party sources) including energy and emission coefficients to be used in calculations to determine embodied energy or GHG emissions per functional unit

However, how to improve the collection processes of external/third party data? SMEs are in a position to determine the amount of energy as well as the type and quantity of primary and auxiliary products used for their own processes. They are also in a position to estimate the cost of internal transport as well as the transport modes and distances for the delivery of primary and auxiliary products. This information must be combined with primary energy and emission coefficients acquired from external sources. This includes information about processes, over which the manufacturers have no direct influence.

There are different types of data sources, from where such coefficients can be sourced. The most important source of information is the material/ product suppliers and service providers themselves. What they usually offer is either the results of specific LCAs or product/ process-specific environmental product declarations (EPD's). Care must be taken to ensure that this information includes all the related upstream processes and are based on a uniform system. It is recommended for SMEs to contractually regulate the nature and extent of the supply of information from all the material suppliers and energy service providers. There are cases, however, in which suppliers'/ service providers do not have specific LCAs/ EPD's for their products/ services but instead they offer the average data of their industry association (sector or generic EPD) as an alternative solution. It is recommended, if such average data are sourced, to be listed separately. In case primary energy and emission coefficients cannot be directly obtained from the suppliers or service providers, these should be sourced from good quality databases. If existent, national LCA databases should be preferred, since they are usually freely accessible and subject to a quality control.

Besides collecting the appropriate data for performing an embodied impacts assessment, it is also important to effectively communicate the results to other stakeholders. Promoting high levels of transparency and interpretation can increase confidence in results. This can help an SME to enhance profits and reputation, and therefore ensure a good return on investment on the assessment itself. For example, for increasing credibility, a manufacturer may choose to comply with certain standards (e.g. EN 15804) and thus comply with certain reporting requirements and communication templates. EPD's are one possibility (Type III declarations). Within the EPD context in its current form, the manufacturer is requested to describe one or two typical scenarios for each downstream information module (A4-C4 & D, Figure 1). However, to respond to a possible future development of EPDs and to support in a better way the designers and other stakeholders, the provision of different "case-based information packages" for each information module will be a necessity. This will allow the users of the information (e.g. designers) to select which information package is more relevant to their building case/ scenario.

5. CONCLUSION AND OUTLOOK

Nowadays, construction product manufacturers are being increasingly asked to provide information on the environmental and health-related impacts of their products in a transparent and accountable way. This enables consumers to make informed decisions about the products they purchase. This demand has been driven both by an increased presence of green or sustainable public procurement in many countries and the growing reliance of building sustainability assessment and certification systems on comprehensive and detailed information on the construction products installed into the building. Considering also that within the framework of a sustainability assessment it is increasingly required to perform a full LCA for the building under investigation, and that LCA data on construction products provide the basis for this, a need for such information is evident.

For manufacturers who already work their way into these complex issues, the engagement with issues related to embodied impacts is a perfect start. However, due to their lack of resources and limited access to information, small and medium-sized manufacturing enterprises (SMEs) often shy away from the effort associated with these tasks. Therefore, it is necessary to help them overcome the lack of know-how and advise them on the compilation of product information. The paper has provided specific recommendations in this direction, specifically to be used by SMEs of construction product manufacturers seeking to improve the confidence in their dissemination results and their market competitiveness.

The authors recommend that information on the environmental performance of construction products should always be combined with technical information on how to better install and use them (instructions for installation, maintenance, reinstallation, etc.) as an additional support/service to the clients. At the same time, it becomes important for construction product manufacturers to think about expanding their operations on the product lifecycle through the adoption of take back strategies at the end of the product's service/useful life as a way to contribute to the shift towards circular economy. Therefore, the provision of "better" products in terms of their environmental performance, in combination with the publication and active handover of credible environmental product information supplemented with "enhanced" technical information on the installation and maintenance of the product, as well as the transition to life cycle support services, can significantly improve the competitive position of SMEs.

ABSTRACT

The discussion about the difficulties related to the integration of environmental sustainability requirements in Brazilian public buildings, leads to the analysis of the limits imposed by the laws related to the bidding process. In 1993 Brazil legislation established the 37th article of Brazilian Federal Constitution by means of the signature of federal law number 8666 enforcing general rules on administrative contracts for design projects (design, projects, constructions and engineering services). All institutions of public administration must obey this regulation. In 2010, the law received an amendment obliging all contracts to observe sustainability requirements. In 2014 the certification by PROCEL Edifica, Brazilian energy efficiency method for buildings, became compulsory by means of Normative Instruction number 2 from Management, Planning and Public Budget Brazilian Ministry (MPOG/Brazil). In this sense, some difficulties have been observed, particularly in how to choose which sustainability rating system should be adopted to complement PROCEL Edifica. SBTool (Sustainable Building Tool) assessment (proposed by iiSBE - International Initiative for a Sustainable Built Environment) is freely available and, for this reason, could be easily integrated on government biddings. Thus, this research deals with the analysis of the potential in adopting SBTool tool in Brazil's public biddings in order to lead development assessment of projects with high environmental quality. Results indicate some challenges that must be dealt with, in order to customize SBTool method to Brazilian urban needs and environmental characteristics all over the country.

Keywords: sustainable public buildings, sustainable rating system, green procurement

1. INTRODUCTION

On 4th August 1987, The United Nation's Report of the World Commission on Environment and Development (WCED), has published an important document known as Our Common Future, bringing the concept of sustainable development, and the necessity to ensure that the needs of the present should not compromise future generations (UN, 1987). Eleven years later, in 1998, The Kyoto Protocol treaty was signed in Kyoto, Japan, committing State Parties to reduce greenhouse gas emissions. It entered into force only on 16th February 2005.

The path to sustainability has not been regular nor straightforward, it forms a complex net. In order to reflect reality, the sustainability assessment must consider the whole building life cycle (pre-use phase, use phase and post-use phase). Kibert states that products, systems, techniques and services needed to create buildings in harmony and synergy with nature are rare. It is important to note that Kibert is a researcher from the United States, country that has access to better data bases for US than the ones that exist for Brazil, where still the needed construction materials database to implement the use of Life-Cycle Assessment methodologies do not exist. In this sense, Kibert wrote:

"Buildings are often assembled from components manufactured by a variety of manufacturers that have paid little attention to the environmental impacts of their activities."

This reality is true for many other countries and is the great challenge for implementing LCA, an important sustainability item. Even now the sustainability concept has not already been completely understood by all stakeholders in building construction sector. The simple use of sustainable materials or systems is not a guarantee of effective good results during the use phase. But it is undeniable the role of building environmental rating systems as a guide.

It is generally accepted the current era of rating tools commenced on 1990, with BREEAM (UK) rating tool, followed by the French System HQE in 1996 and the US LEEDTM in 2000. Further analysis confirms that the evolution of rating systems into different countries is largely based on those initial methods. Although the discussion about

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

sustainable construction has started around 30 years ago, only in 2010 Brazilian government determined sustainability to be compulsory. Launched in 2003, the PROCEL Edifica Certification has been attracting the attention to energy efficiency issues applied to buildings, but has reached timid results. Although being compulsory for public buildings since September 2014 by means of Normative Instruction number 2 from Management, Planning and Public Budget Brazilian Ministry [6], public administrators have to face many difficulties because the country still lacks regulations to allow punishment in case both determinations (law 8666/1993 and IN 2/2014) are not complied.

This paper intends to bring the debate to public project management for the production of sustainable buildings. By force of law these contracts require technical evaluation of design, with the use of clear and objective criteria, with no interference of subjectivity or biased assessment. This goes beyond the quality of the design and yet includes environmental sustainability assessment.

Thus, this research presents the results of an initial analysis considering the potential of SBTool (Sustainable Building Tool) in public biddings in order to guarantee the assessment of sustainable buildings design. Developed in an international collaborative process, SBTool is a generic framework for rating sustainable performance of existing buildings and building designs. It may also be thought of as a toolkit that assists local organizations to develop local SBTool rating systems.

The results indicate the complexity of sustainability in construction, which needs the participation of architects, engineers, owners, users, suppliers and all stakeholders involved on civil construction industry.

2. SUSTAINABILITY IN PUBLIC BIDDING

In 1993, Brazil implemented into practice the 37th article of Brazilian Federal Constitution by means of the signature of Federal Law N° 8666, enforcing general rules on administrative contracts for design projects (construction and engineering services). It seeks the best proposal for the Public Administration, usually by choosing the lowest price but also can be by lowest price together with best technique. All government levels must obey this regulation in a very complex procedure. In 2010 this law received an amendment obliging all contracts to observe national sustainable aspects referred to building construction.

From the implementation of this law a complex series of laws that regulates public biddings was put into force. The newest law [9] has focus on bidding procedures and contracts awarded by public enterprises and joint stock companies, designed to ensure the selection of the most advantageous offer, including regards to the life cycle of the building. Bids and contracts ruled by this law, among others, must respect the following:

- Adequate final disposal for solid waste generated by the contracted works;
- Mitigation of environmental damage through constraining measures and environmental compensation (to be defined in the licensing procedure);
- Use of products, equipment and services that are proven to reduce the consumption of energy and natural resources;
- Assessment of neighbourhood impacts, according to the town planning legislation;
- Protection of cultural, historical, archaeological and immaterial heritage, demonstrating an evolution process towards sustainability.

The laws require the exclusive use of objective criteria, previously determined by the public announcement (called “Edital”). These same criteria will lead the contract management itself.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. ENSURING SUSTAINABILITY OF BUILDINGS WITH SBTOOL

SBTool is freely available to the public and, for this reason, can be easily adapted and integrated in public procurement bidding processes.

The SBTool is provided by iiSBE and has a generic structure which needs to be adapted to local conditions, calibrating parameters with proper definition of weights and benchmarks. It is worth emphasizing that this generic tool does not certificate, since the local iiSBE Chapters may determine whether there will be a certification system, or not. According to Larsson, the tool consists of two assessment modules that are connected to the building's life cycle. The first module refers to the building pre-design phase and the second to the building evaluation. The first brings local data and the second module contains building data as the project phases, construction and operation (use). Each module is divided into two Excel files, respectively named files “A” and “B” which work linked to one another.

The file “A” refers to an appropriate generic structure for a particular country or region set by the head of the regional organization in order to reflect important local issues. In this file the weight of parameters and benchmarks for the type of occupation are established and also information such as latitude, longitude, annual rainfall volume, population estimates, among others.

The “A” file is also configured for its particular type of occupation. It may have mixed uses, but limited to a maximum of three types, creating “A” files, e.g. for residential, commercial buildings, different urban areas etc.

In turn, the “B” file contains specific information for a particular project filled in by the project designer or by a professional qualified by iiSBE. However, before being released to the designers, the local representative must check whether the “A” and “B” files are linked and leave visible only the relevant information in order to prevent possible confusion during filling the “B” file. There can be several “B” files derived from a single “A” file, since they have the same type of occupation, and “B” file settings are automatically determined by the adjustment made in “A” file.

SBTool provides a list of criteria, divided in the four phases of the life cycle and 8 categories aiming to cover the three dimensions that define sustainability – environmental, social, and economic aspects. The number of criteria of each category varies according to the type of scope to be used: maximum scope, medium or low. The maximum covers all sustainability issues proposed by the tool, the minimum corresponds only to the essential evaluation criteria, while the medium is a balance between the previous two. Thus, a building can be evaluated in only 3 or 107 criteria, depending on the type of scope and phase of the life cycle. iiSBE recommends for starters the use of the minimum scope to reduce complexity of evaluations.

Projects are evaluated according to the four phases of the building lifecycle - pre-design, design, construction and operation - and the weighting system is adjusted according to the local characteristics.

4. CHALLENGES AND OPPORTUNITIES IN THE USE OF SBTOOL

SBTool is a flexible tool and adaptable to the particularities of different locations in different territories, which is one of the great advantages towards commercial certifications. But SBTool itself does not certificate but by partnership certifications can be granted as done in countries as Italy (Protocollo ITACA), Spain (Verde), Portugal (SBTool PT), and Czech Republic (SBTool CZ). In Brazil, a local adaptation was done for commercial buildings in Espírito Santo state (ASUS), but it does not certificate.

Unfortunately, if a certification system is implemented, SBTool will not be free anymore, losing one of its best characteristics. Moreover, from a common methodology (SB Method) it creates multiple versions of a single tool for different regions and different building uses. SBTool can integrate assessment of PROCEL Edifica requirements and fulfil these legal requirements in one single tool.

The biggest challenge is to accomplish economic performance and the need of an accurate local database. Besides, as buildings have a long life cycle, the use period has great importance and impact. The users are important stakeholders in these analyses.

Types of Brazilian public procurement	Characteristic of the mode	Potential for adoption of SBTool
Invitation/*"Carta convite"*	This bidding mode selects the company that will develop the design project.	Can be adopted but must be previously determined in the procurement announcement / "*Edital*". Creating a local benchmark is a difficulty.
Public competition/ *"Concorrência"*		
Live reverse auction/ "Pregão presencial"		The use of SBTool on this modality must be made during the contract supervising phase, after the bidding itself., that is during design phase.
Virtual reverse auction/ "Pregão eletrônico"		
Design competition/ *"Concurso"*	This bidding mode selects the design project.	Can be adopted but must be previously determined in the procurement announcement / "Edital"
		The use of SBTool on this modality must be made during the selection phase, the bidding itself. It could help in the classification of competing projects and could also guide detailing options after the selection has been made.
Differentiated regime of hiring/ *"Regime Diferenciado de Contratação – RDC"*	This bidding mode selects the company that will develop the design project or, in the integrated sub-mode design-build, the one that will both develop and build.	Can be adopted but must be previously determined in the procurement announcement/ "Edital". Creating a local benchmark is a difficulty.
		The use of SBTool on this modality must be made during the contract supervising phase, after the bidding itself., that is during design phase ..
Public companies, Joint stock companies and its Subsidiaries' law	This bidding mode selects the company that will develop the design project or, in the integrated sub-mode design-build, the one that will both develop and build.	Can be adopted but must be previously determined in the procurement announcement/ "Edital". Creating a local benchmark is a difficulty.
		The use of SBTool on this modality must be made during the contract supervising phase, after the bidding itself., that is during design phase.

Table 1: Brazilian public bidding modes and the potential adoption of SBTool

As shown in Table 1, except for the mode Design Competition, which selects the design project, all the other bidding modes aim to select the company that will develop the design project. In this sense, the bidding process must assess the companies' technical-operational and technical-professional capacities, besides their economic, financial qualification and insurance guarantee. That means that, in the majority of cases, the assessment of projects with environmental quality will only be needed in the contract phase, after the procurement process is over.

It must be noted that each country has their own specific legal framework and this paper aims to present the Brazilian legal framework and not to compare Brazilian laws to the ones of any other country. In this sense this paper does not intend to present any parallel to any other country legal framework.

The method allows analyzing a building in its four life cycle phases. In addition, it considers all dimensions defining the sustainability and thus allow a more thoroughly check of the building. The generic SBTool is free, which is a relevant aspect to public bodies and use as reference the best regional construction practice (benchmark) and the impact of local materials in the evaluation process. In this way, it provides an opportunity for continuous improvement.

The first attempt to use SBTool in Brazilian buildings has emerged from a research developed on Federal University of Espírito Santo, that has proposed a similar environmental rating system called ASUS. According to Souza the ASUS method is based on the structure, the evaluation criteria and the grading scale of SBTool. However, the proposed adaptation is restricted to the use of use-operation and maintenance phase of buildings, enabling performance measurement in existing constructions, instead of relying only on simulations. This more restricted

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

version was proposed because, according to the author, the level of coverage and information required by SBTool tool extrapolates the availability of consolidated data in the country, which would make it very sophisticated to be absorbed by the Brazilian civil construction market.

SBTool has a difficult and complex structure that is hampered by the Excel program, since the user needs to fully understand the program in order not to make mistakes that can change the whole assessment system. In addition, file B needs to be synchronized with file A in order to update the information to file B and to allow the system to work properly. Creating a SBTool local benchmark would be difficulty. Another barrier to be considered is the flexibility and the continuous evolution and updating of the generic SBTool method, which may cause differences between the local and the generic tools and may confuse users and companies and create problems. The evaluation through SBTool method requires the use of other tools and methods, such as the assessment of the energy performance of the building or the user satisfaction indicators.

When the procurement announcement is not clear and objective the procurement process itself can be contested by the interested companies or the contracted company. Or, at best, the supervision of future contract will have to deal with the gaps during the contract. These situations have been experienced in bidding and contract supervision by the authors. In a certain way, the most used public bidding modes postpone the results of most problems in the procurement announcements to the contract supervision phase. Design competition is the exception.

5. CONCLUSION

This research deals with the preliminary analysis of the potential adoption of SBTool tool in biddings in order to lead development assessment of sustainable building design. Positive results, as shown, already indicate the potential of SBTool on Brazilian's public procurement process as long as it has been considered since the beginning of design process (pre-design phase) establishing the assessment parameters from the very beginning of the process.

SBTool is a very objective tool, with clear parameters, meeting the needed requirements to guide the development of design projects by contractors and carry out the evaluation of the design projects by the contractor, within the same parameters. But it is a rather complex tool and a more accessible interface would be beneficial.

The present stage of this research shows that SBTool can be applied in all modes of Brazilian procurement, during the procurement phase (in case of its adoption in the competition mode) and during contract phase in other modes. However, it is necessary to consider that the level of coverage and information required by SBTool extrapolates the availability of consolidated data in the country, which will make it very sophisticated and difficult to be absorbed by the Brazilian public buildings.

Despite the challenges, the positive points outweigh the negatives, which, with effort and preparation, can be overcome.

Nevertheless, early measuring the environmental performance and impact of construction along the buildings life cycle, since the pre-design and design phases is absolutely needed. However, LCA data, economic performance and continuous improvement still need to be implemented in order to improve sustainable construction in Brazil.

Finally, it is important to emphasise that, in order to develop a real sustainability assessment local tool that can really help architects and engineers to integrate PROCEL Edifica and economic aspects of sustainable construction in their decisions and design solutions, it is necessary to promote and improve further the research activity in this field of knowledge.

Assessment Tools for The Sustainability Performance of Building - Development of A Sustainability Assessment Method for Small Residential Buildings in Germany

Natalie ESSIG[a]

[a] *University of Applied Sciences Munich (MUAS), Germany, natalie.essig@hm.edu*

ABSTRACT

Several international and national instruments for the assessment of the sustainable building performance have been developed in the last years, such as BREEAM (Great Britain), LEED (USA) and DGNB or BNB (Germany). These methodologies have the same intent - advancement of the sustainable building performance. The focus of this systems are mostly commercial buildings, but also the sustainability rating of the residential sector is getting more and more important. The numbers of certifications with BREEAM, LEED or the Swiss Label Minergie are increasing constantly. In Germany however available systems to certify the sustainability of this type of buildings have so far not achieved widespread due to a complex list of criteria and the costly implementation. In regard that 2.9 million dwellings will be required by 2025 and that 115,000 owner-occupied detached and semi-detached houses are built up per year in Germany, a new assessment method (BNK system) for small residential houses was developed in the context of a research project on behalf of the Federal Ministry for the Environment, Nature Conservation, Building and Nuclear Safety (BMUB). To ensure the suitability of the assessment system the BNK method was tested in a pilot phase involving 18 real case buildings. From 2016 on the BNK method is now available for general use and the assessment is financially supported by public funds (KfW Banking Group).

This paper will show the development and experience with the sustainability assessment of buildings in Germany in general, as well how the new list of criteria, indicators and benchmarks for assessing sustainability of small residential buildings (up to five dwelling units) putting the emphasis on simple applicability and cost-effectiveness in order to achieve widespread application. The assessment system focuses on the category of socio-cultural and functional quality followed by economic quality, environmental quality and process quality.

Keywords: certification of buildings, assessment of the sustainability building performance, assessment and rating methods

1. INTRODUCTION

Several international and national instruments for the assessment of the sustainable building performance have been developed in the last years. Back in the 1990s first sustainability tools such as the British system BREEAM and the American label LEED were developed and introduced on the market. In 2009 the DGNB certificate of the German Sustainable Building Council (DGNB) and the Sustainable Construction Evaluation System (BNB) of the Federal Ministry of Transport, Building and Urban Development (BMVBS) was established in Germany. These methodologies have the same intent - advancement of the sustainable building performance. In contrast to traditional assessment methods the German systems pursue a holistic approach throughout the whole life cycle of a building instead of focusing primarily on ecology and energy efficiency.

The focus of the German DGNB and BNB systems are mostly commercial buildings, but also the sustainability rating of the residential sector is getting more and more important. However in Germany the focus was so far set on building types such as office buildings, schools, industrial buildings or large residential buildings. Small residential buildings in contrast have not obtained enough attention to date although detached and semi-detached houses make up a considerable part of 45 percent of new construction projects within the housing sector. In 2012 the Sustainable Construction Quality Label (NaWoh) was developed with support by the Ministry for Transport, Building and Urban Development (BMVBS). 12 projects have been assessed so far, but the system is only applicable to residential buildings with more than five dwelling units. Furthermore the German Association for Sustainable Building (DGNB) established the system variant “Small Residential Buildings” for houses with less than six dwellings, but only four certifications have been carried out to date. Due to a complex list of criteria and the costly implementation the assessment system is not widespread so far.

The numbers of certifications with BREEAM, LEED or the Swiss Label Minergie are increasing constantly. In Germany however available systems to certify the sustainability of this type of buildings have so far not achieved widespread due to a complex list of criteria and the costly implementation.

In regard that 2.9 million dwellings will be required by 2025 and that 115,000 owner-occupied detached and semi-detached houses are built up per year in Germany, a new assessment method (BNK system) for small residential houses was developed in the context of a research project on behalf of the Federal Ministry for the Environment, Nature Conservation, Building and Nuclear Safety (BMUB).

To ensure the suitability of the assessment system the BNK method was tested in a pilot phase involving 18 real case buildings. From 2016 on the BNK method is now available for general use and the assessment is financially supported by public funds (KfW Banking Group). The objective of the paper is to give an insight into the assessment method and point out the suitability for small residential buildings.

2. SUSTAINABILITY ASSESSMENT METHODS FOR RESIDENTIAL BUILDINGS IN GERMANY

The German Quality Labels (DGNB and BNB) were originally developed for new office and administrative buildings. Today, both the DGNB and BNB systems cater to a huge range of different typologies, from various building types through to entire city districts. For example, there are now lists of criteria covering new, refurbished and existing office and administrative buildings, industrial, commercial and educational buildings, and even sports buildings.

Up until now, it has been almost exclusively buildings such as office buildings, schools, industrial buildings, and large residential buildings (i.e. those containing six or more dwelling units) that have been assessed for sustainability in Germany. Insufficient attention has been given to smaller residential buildings ranging from detached houses to apartment blocks with up to five flats, even though these buildings represent a large (45 %) share of total residential new build. The BMUB is tackling this problem and, together with the Munich University of Applied Sciences has developed a list of criteria specifically for these smaller residential buildings. A wide range of industry players were subsequently called upon to fine-tune this list, which was then subjected to a run to test its suitability for the market. These included housing construction industry associations, architects, engineers, and the prefabricated house industry.

2.1 Why detached and semi-detached houses?

Outside Germany, residential buildings have long since been assessed against sustainability criteria. Some 462,500 dwellings have so far been assessed under the BREEAM “Code for Sustainable Homes” system, for example. This is thanks to the UK government’s decision in 2008 to enshrine in law the sustainability assessment of buildings. More buildings are being assessed all the time, including under the LEED quality label (14,900 dwellings certified) and the Swiss Minergie label (17,850 detached and semi-detached houses certified), In Germany, the Sustainable Housing Construction Quality Label (NaWoh) and individual system variants of the DGNB certificate are available for assessing residential buildings, although the former is only available for structures containing six or more dwellings. 12 projects have been awarded a NaWoh certificate since 2011. To date a total of four buildings have been certified under the “Small Residential Buildings” method for buildings with less than six dwellings. The list of criteria for this method is however currently very complicated and costly to implement, and is primarily only suitable for prefabricated houses. With an average of 410,000 new detached and semi-detached houses being built each year in Germany, a cost-effective, lean, simple assessment system for residential buildings that all clients can apply, and that is designed to encourage sustainability in small residential buildings, is essential. This is confirmed by a survey conducted in 2014 on the topic of “Clients and Sustainability”:

- 96 % of future owners of a detached house would greatly value high energy efficiency, and hence long-term reductions in energy costs.
- For environmental reasons, 85 % would prefer environmentally-friendly building materials.
- 73 % see the value in a certificate that confirms that the house is built in a sustainable, environmentally-friendly, energy-efficient way.

2.2 Housing construction facts and figures

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The latest figures also confirm the need to encourage sustainability in residential construction, particularly in relation to small residential buildings:

- There are currently 18.3 million residential buildings in Germany containing a total of 39.3 million dwellings and 3.6 billion m2 of living space. Of these buildings, around 75 %, i.e. 13.7 million are detached or semi-detached (as per 2011 data).
- In 2013, permits were awarded for the construction of 270,400 dwellings in Germany, 12.9 % more than in 2012.

The number of construction permits granted for dwellings in apartment buildings grew by 22.3 % between 2012 and 2013, which is a considerably higher rate of increase than for dwellings in detached and semi-detached houses. The number of construction permits awarded for detached houses (89,500) represented only a small increase of 1.1 %, whereas the number awarded for semi-detached houses (20,330 new buildings) rose by 13.3 % . According to forecasts by the German Federal Institute for Research on Building, Urban Affairs and Spatial Development, a total of 2.9 million further dwellings will be needed by 2025. This corresponds to an average of 183,000 new dwellings each year. The vast majority of this predicted new build is expected to be owner-occupied detached and semi-detached houses, averaging 115,000 new dwellings per year. However, it is important to note that average living space per capita has doubled in Germany over the last 60 years, and currently stands at 43 m2. This is due to a large extent to detached houses – in which 28 % of Germany's approximately 40 million private households live – because on average these homes contain substantially more living space per person than do apartment buildings that have been built to rent out. And this is the great contradiction surrounding the issue of sustainability in Germany: although the legal thresholds for space heating demand and energy consumption per unit living space are being lowered all the time, and all new buildings need to be ultra-low energy by 2020, the actual amount of energy consumed per person – because of the rise in living space per capita – has remained the same. Making a building sustainable is about more than just improving its energy efficiency: aspects such as emissions of harmful substances, land use, life cycle analyses, and design all have a role to play. It is precisely these topics that form the focus of the list of criteria for small residential buildings.

3. CRITERIA FOR SUSTAINABLE SMALL RESIDENTIAL BUILDINGS

The list of criteria for sustainable small residential buildings is divided up into four overarching categories broken down into a total of 18 criteria (Figure 1,2):

- Sociocultural and functional quality
- Economic quality
- Environmental quality
- Process quality

Figure 1: Sustainability qualities

3.1. Social-cultural and functional quality

Social aspects are particularly important in determining the sustainability of small residential buildings, so the category of “sociocultural and functional quality” comes first in this list of criteria, rather than environmental quality, which comes first in the lists of criteria for the other building types. The quality of life, comfort, safety, security and adaptability that the building offers are all assessed. The level of comfort is determined by measuring building physics characteristics, making calculations regarding thermal, acoustic and visual comfort, and by assessing the inherent level of hygiene inside the building. Because the system takes into account the aspects of safety and security, accessibility, and the user-friendliness of the building services, it helps to enhance residents’ quality of life.

3.2. Economic quality

The goal of the “economic quality” category is to determine selected costs incurred during the building’s life cycle, and to assess its long-term viability. The calculation of life cycle costs is based on the standard DIN 276 (Building costs – Building construction). Long-term viability is based on the assessment results for various criteria such as accessibility and thermal insulation in summer, and the extent to which the building’s energy efficiency figures exceed those demanded by the German Energy Saving Regulation, the extent to which the rooms are designed in a neutral way to allow for alternative uses, and the extent to which the client has been briefed to enable them to maintain the building’s value over time.

Category	Criterium	No.	Indicator
1. Sociocultural and functional Quality	**1.1 Healthy housing**		
		1.1.1	Indoor air quality
		1.1.2	Drinking water hygiene
	1.2 Thermal comfort		
		1.2.1	Summer heat protection
	1.3 Visual comfort		
		1.3.1	Availability of daylight
	1.4 Sound insulation		
		1.4.1	Airborne sound insulation against noise from outside
		1.4.2	Airborne sound and subsonic noise insulation inside the building
		1.4.3	Structure-borne sound insulation
	1.5 Control comfort of building technology		
		1.5.1	Userfriendliness of building control
	1.6 Safety and security		
		1.6.1	Preventive measures against burglary
		1.6.2	Fire protection
	1.7 Design for All		
		1.7.1	Design for All
2. Economic Quality	**2.1 Lebenszykluskosten**		
		2.1.1	Selected life cycle costs
	2.2 Value retention		
		2.2.1	Future viability of the building
3. Environmental Quality	**3.1 Wirkungen auf die Umwelt**		
		3.1.1	Life cycle impact assessment - Global Warming Potential
		3.1.2	Life cycle impact assesssment - Ozone Depleting Potential
		3.1.3	Life cycle impact assessment - Photochemical Ozone Creation Potential
		3.1.4	Life cycle impact assessment - Acidification Potential
		3.1.5	Life cycle impact assessment - Eutrophication Potential
		3.1.6	Harmful emissions into the environment
	3.2 Energy consumption		
		3.2.1	Life cycle impact assessment - Primary Energy demand renewable
		3.2.2	Life cycle impact assessment - Total Primary Energy Demand
		3.2.3	Decentralised energy generation
	3.3 Raw material input and waste generation		
		3.3.1	Recyclability and ease of dismantling
	3.4 Biodiversity		
		3.4.1	Use of local or certified wood
	3.5 Drinking water consumption		
		3.5.1	Use of water-saving valves
	3.6 Land use		
		3.6.1	Land use
4. Process Quality	**4.1 Project preparation**		
		4.1.1	Consultation and goal-setting
	4.2 Object documentation		
		4.2.1	Building record and user manual
	4.3 Quality of construction work		
		4.3.1	Quality assurance

Figure 2: List of criteria and indicators (version V0.0)

3.3. Environmental quality

The environmental quality of a detached or semi-detached house is assessed by carrying out a life cycle assessment (LCA). The LCA is prepared using the online tool “eLCA” provided by the BMUB and the BBSR (German Federal Institute for Research on Building, Urban Affairs and Spatial Development). The LCA looks at the building’s entire life cycle, now including not just the building fabric itself, but also the building services. The most important indicators are Primary Energy Consumption and Global Warming Potential, but it also considers aspects such as recyclability, the use of local or certified wood, measures taken to reduce drinking water consumption, and the efficient use of space in order to minimise soil sealing.

3.4. Process quality

The main aim of the “process quality” category in relation to residential buildings with up to five dwellings is to ensure the quality of planning, construction and documentation, and to provide a building dossier including a user manual. The building dossier includes the latest plans, energy performance certificates, measurement records, safety certificates, data sheets, care instructions, and all documents relevant to the operation and maintenance of the building. Process quality also includes having the quality of construction verified by an external assessor.

4. PILOT PROJECTS

A pilot study involving building owners, developers, project managers, architects and engineers was carried out inorder to check the suitability of the list of criteria, and to test the system out on real detached and semi-detached houses. Following this pilot phase, the list was extended to cover buildings with between three and five dwellings as well. During the test phase a total of 22 projects were assessed, including 15 detached houses, one detached house with a secondary suite, one semi-detached house, four terraced houses, and a building consisting of two flats above a shop unit. The first 12 projects were certified at the BAU 2015 trade fair in Munich. The results of the certification process are expressed as a percentage and a score, and ranged from 61.73 % (score: 2.2) to 85.1 % (score: 1.3). The remaining 10 projects are still being assessed. During the pilot phase, it emerged that the biggest differences between research and reality are in people’s response to the statutory requirements regarding safety, security, accessibility and harmful emissions into the environment. It became clear that, in the real-life construction industry, the applicable standards are not always adhered to as a matter of course. In some areas where the relevant building products and verifications were not yet available on the market, or the costs of implementation would be excessive, the criteria were modified or, in the case of the criterion “harmful emissions into the environment”, were postponed during the pilot phase.

5. OUTLOOK

The list of criteria was being revised on the basis of the results from the pilot phase, and from April 2015 it is available for general use as a simple and cost-effective assessment system. Assessment will in future be carried out by “Sustainability Coordinators” who hold a specialist qualification in sustainable building, and who monitor the project during construction. As a next step, an online platform will be set up to make it easier to generate the necessary building documentation. So far the system has been extended to cover residential buildings with up to five dwellings; in future it is conceivable that it will also allow the assessment of refurbishment work on existing residential buildings.

To ensure that all certificates are of a suitably high quality, assessments should be checked, and the coordinators trained, by an independent body. Therefor the BMUB has announced the Building Institute for Ressourceefficiency and Sustainability (BiRN GmbH). From 2016 the KfW Banking Group is providing financial support to help projects achieve the sustainability certificate for houses with 1-5 dwellings, similar to the support it offers for those seeking to achieve the Efficiency House standard.

Renovation of Sheung Shui Staff Quarters – Green Building Actions Echoed by the Contractor

LI Siu-lung[a]

[a] *Water Supplies Department, Government of the HKSAR, Hong Kong SAR, sl_li@wsd.gov.hk*

ABSTRACT

The Sheung Shui Staff Quarters of Water Supplies Department (WSD), which comprise three low-rise buildings (up to 3-storey high with total construction floor area of 1,027m2), were built in 1985. They were situated along the eastern edge of the Sheung Shui Water Treatment Works (WTW). The Quarters were allocated to the operational staff. However, the demand of the Quarters were no longer required for operational need in recent years with the improved transport to the WTW. WSD decided in 2015 to convert the Quarters into the office of a maintenance depot for use by the waterworks maintenance term contract for more gainful use of the buildings.

The conversion project involved renovation of the buildings to restore their serviceability and to provide new lighting, ventilation and power system for use of the office. In line with the Government's drive for promoting green building, the project adopted sustainable design by using integrated green building disposition and technologies with due consideration for the operational need and cost-effectiveness.

Having preliminarily assessed by the consultant on the design of the office of the maintenance depot against various aspects of environmental performance (including site aspects, materials aspects, energy use, water use, indoor environmental quality and innovations), this project could readily attain a Silver rating under the BEAM plus building environmental assessment system. In addition, the maintenance term contractor who would use the office decided to install a photovoltaic system at the roofs of the buildings at its own cost for energy saving. With this additional feature, the project was eligible to apply for a higher (i.e. Gold) rating.

The project commenced in December 2015 for substantial completion by October 2016.

Keywords: green building, BEAM Plus, building performance

1. PROJECT BACKGROUND

The Sheung Shui Staff Quarters of Water Supplies Department (WSD), which comprise three low-rise buildings (up to 3-storey high with total construction floor area of 1,027m^2), were built in 1985. They were situated along the eastern edge of the Sheung Shui Water Treatment Works (WTW). The Quarters were allocated to operational staff. However, the Quarters were no longer required for operational need in recent years with improved transport to the WTW. WSD decided in 2015 to convert the Quarters into the office of a maintenance depot for the waterworks maintenance term contract for more gainful use of the buildings.

Figure 1: The exterior of the adjoining Block A and Block B of Sheung Shui Staff Quarters before renovation. (Photos taken in October 2015).

Having been used for more than 30 years, the buildings had deteriorated considerably in particular the interior of individual units. Problems such as leaking roof, damaged flooring and defective building fixtures were identified.

Figure 2: The condition of Sheung Shui Staff Quarters before renovation.

To restore the serviceability of the buildings, extensive renovation and improvement work including waterproofing at the roofs, demolition of aged building fixtures, plastering, painting as well as replacement of windows, doors and flooring were required. Re-provision of lighting facilities, ventilation system and power system was also required for converting the buildings for office use.

Figure 3: Scope of renovation works of Sheung Shui Staff Quarters.

After about 10 months for design to construction, the conversion of the three buildings into an office which can accommodate about 45 staff with 1,027 m^2 floor area will be substantially completed in October 2016. Block A and Block B will provide the required office facilities like meeting rooms, printing rooms and a refuse storage and material recovery chamber, and Block C will provide changing rooms with shower facilities.

Project Owner:	Water Supplies Department
Main Contractor:	Chun Wo Construction & Engineering Co Ltd
BEAM Consultant:	Parsons Brinckerhoff (Asia) Ltd
M&E Engineer:	Parsons Brinckerhoff (Asia) Ltd
Project Cost:	HK$10 million

Table 1: Key project team members.

2. COMMITTMENT TO PROMOTE GREEN BUILDING

In line with the Government's drive for promoting green building, the project adopted sustainable design by using integrated green building disposition and technologies with due consideration for the operational need and cost-effectiveness. Following the green building policy formulated by the Development Bureau (DEVB) of the HKSAR Government, the project adopted the framework for refurbishment of existing government buildings as set out in the DEVB Technical Circular No.2/2015 throughout its planning, design and construction stages.

3. BUILDING DESIGN

The buildings spread across generously landscaped space (at least 40% of the site area) in harmony with the nature. Operable windows and perforated grille walls enhanced the buildings' performance in passive energy efficiency aspects such as the use of daylight and natural cross ventilation. Moreover, high emissivity roof painting (i.e. painting material with Solar Reflective Index exceeding 78) was applied to those roof areas where they would not be shaded by the photovoltaic panel systems to be installed at the roofs to minimize the solar heat gain of the buildings. Besides, the occupants could benefit from the natural breeze in the balconies, especially during cool months.

Figure 4: An artistic image of the proposed office of the maintenance depot.

Figure 5: The latest view of the renovated buildings.

To minimize construction waste and the embodied energy of construction materials required for the renovation as well as the associated environmental impact, more than 90% of the existing building substructure and above-ground structural frames were reused (which would also shorten the construction period). Besides, a room of about $4m^2$ at ground floor was designated as the Refuge Storage & Material Recovery Chamber (RS&MRC) equipped with de-odorizing system to improve hygiene.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

In consideration of topography and harmony with the surroundings, the buildings' form and their orientation were checked through simulation to ensure the access to daylight of neighboring sensitive buildings was maintained to the prescribed level (see relevant figures below).

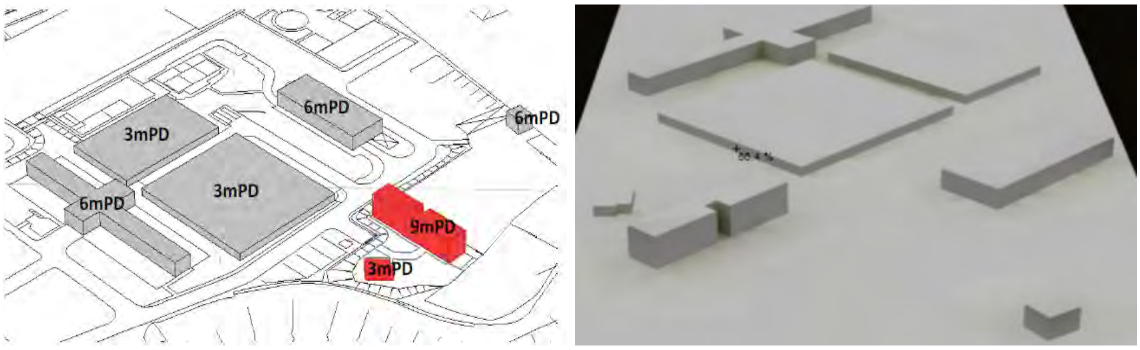

Figure 6: Simulation of neighborhood daylight access.

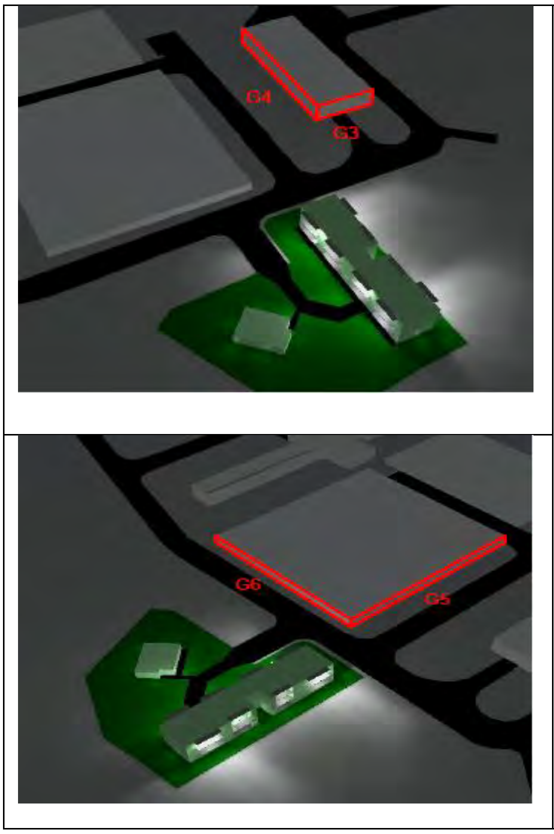
An Environmental Management Plan was implemented on site to control, monitor and mitigate the air pollution, noise pollution, water pollution, light pollution and solid waste production associated with the project.



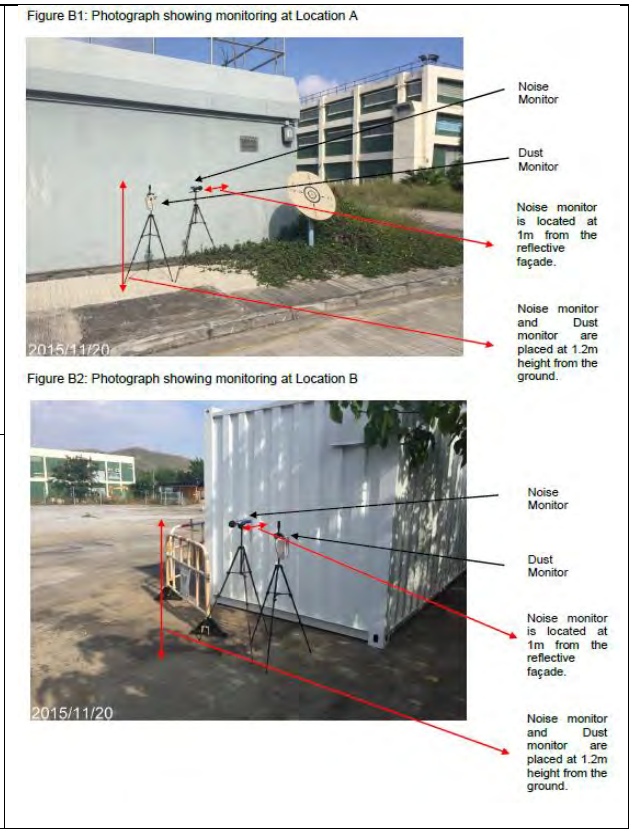


Figure 7: (Left) Simulation of light impact on neighborhood sensitive receivers.
Figure 8: (Right) Baseline monitoring of noise and air quality.

4. MATERIALS ASPECTS

More than 50% of timber and composite timber products used in the project such as those of wooden doors and their frames were from environmentally sustainable source certified by the Forest Stewardship Council (FSC).

The non-structural partition walls were made of chemical gypsum which were recycled materials. They could be easily dismantled and reused elsewhere at the end of the building's life. They, together with most of the other building materials used in the project, were manufactured locally within 800km from the site. That implied the carbon emission associated with the transportation of these building materials was reduced.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 9: Construction of partition walls with recycled chemical gypsum

5. ENERGY EFFICIENCY

The proposed office was designed to achieve an energy performance which outperformed BEC by about 38%. BEC refers to the Code of Practice for Energy Efficiency of Building Services Installation issued by EMSD under the Building Energy Efficiency Ordinance (Cap 610). Simulation of the energy consumption of the office was conducted and some key information is extracted as follows:

Annual Energy Consumption by Enduse

	Electricity kWh (x000)	Natural Gas Btu/h	Steam Btu/h	Chilled Water Btu/h
Space Cool	80.24	-	-	-
Heat Reject.	-	-	-	-
Refrigeration	-	-	-	-
Space Heat	-	-	-	-
HP Supp.	-	-	-	-
Hot Water	4. 38	-	-	-
Vent. Fans	10.99	-	-	-
Pumps & Aux.	4.91	-	-	-
Ext. Usage	-	-	-	-
Misc. Equip.	33.66	-	-	-
Task Lights.	-	-	-	-
Area Lights	40.76	-	-	-
Total	174.93	-	-	-

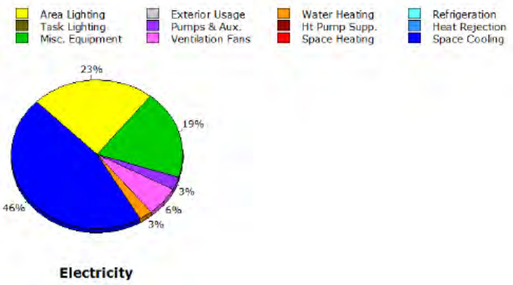

Table 5.1 Comparison of Annual Energy Consumption Reduction

	Energy Source	Energy Consumption
Baseline Case	Electricity	174.93 MWh
Design Case	Electricity	107.96 MWh
% Reduction		38.3%

Table 5.2 Comparison of Annual Peak Demand Reduction

	Energy Source	Energy Consumption
Baseline Case	Electricity	64.58 kW
Design Case	Electricity	43.84 kW
% Reduction		32.1%

Figure 10: Design annual energy consumption and the resulting energy saving.

The energy performance of the office as reflected in the simulation was encouraging and it was achieved through various energy efficient features such as split-type air conditioners and water heaters of Grade 1 energy efficiency under Mandatory Energy Efficiency Labelling Scheme (MEELS), glazing with glass panes of low U-value and shading coefficient of about 5 and 0.68 respectively which offered more heat insulation in the building envelope, and the use of renewable energy by means of the photovoltaic panel system installed on the roofs of the buildings. In addition, LED light tubes were used for lighting to effectively reduce the lighting power density (LPD). Daylight and motion sensors were also installed to switch off the lighting when not required to further lower the lighting energy consumption.

With the total energy saving of 67,000 kWh per annum, the payback period of the additional cost for the aforementioned energy efficient features is just about 9 years.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

6. RENEWABLE ENERGY

The photovoltaic (PV) system installed on the roof of Block A and Block B was the renewable energy (solar power) source for the proposed office. The roof area covered by the PV panels is approximately 200 m^2 (which is more than 40% of the total building footprint). The solar radiation on the designed PV panel area was analyzed and the total annual output from the panels was estimated to be 19,710 kWh which was equivalent to about 11% of electricity consumption for general power and lighting in the proposed office.

Figure 11: Photovoltaic system installed on the roof of Block A and Block B.

7. WATER MANAGEMENT

For water conservation, the design of the office incorporated the use of water saving devices (including low-flow taps, shower heads and other fixture/fittings) at toilets, pantry and changing rooms to reduce potable water consumption beyond the typical BEAM Plus standards, achieving about 40% reduction compared to the baseline.

	Fresh water consumption
Baseline case	466 Litre/Day
Design case	180 Litre/Day
% Reduction	39%

Table 2: Computed reduction in fresh water consumption.

In addition, rainwater was also harvested for non-potable purpose.

8. INDOOR ENVIRONMENTAL QUALITY

The design of the office also aimed at quality indoor environment which would benefit the health, wellbeing and productivity of the occupants. For providing a hygienic refuse collection system, the RS&MRC was equipped with air purifier. Indoor sources of air pollution from toilets and photocopying rooms would be controlled at source with the localized ventilation system. Design considerations were also given to other indoor environmental aspects such as thermal comfort, lighting quality, room acoustics and the provision of building amenities.

9. GREEN BUILDING ACTIONS ECHOED BY CONTRACTOR

The Government encourages the participation in green building assessment scheme. This project has participated in the BEAM Plus building environmental assessment scheme. It provided opportunities for the WSD staff, and project officers, professionals and site personnel of the contractor to learn about the detailed requirements and submission standard for such green building performance assessment. In involving in the exercise, they were motivated with enhanced environmental awareness and job satisfaction brought about by acquainting themselves with the latest trend, technology and best practices relating to green building and sustainability.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

	Overall	SA	EU	IEQ	IA	
Platinum	75%	70%	70%	70%	3 credits	(Excellent)
Gold	65%	60%	60%	60%	2 credits	(Very Good)
Silver	55%	50%	50%	50%	1 credit	(Good)
Bronze	40%	40%	40%	40%	-	(Above Average)

Figure 12: BEAM Plus grading requirements for the 6 categories of building performance.

More encouraging was when we stepped forward to participate in the BEAM Plus assessment, the action became a positive influence to others. Having preliminarily assessed by the consultant on the design of the office against various aspects of environmental performance (including site aspects, materials aspects, energy use, water use, indoor environmental quality and innovations), this project could readily attain a Silver rating. The maintenance term contractor who would use the office decided to install photovoltaic system at the roofs of the buildings at their own cost energy saving. With this additional feature, the project was eligible to apply for a higher (i.e. Gold) rating.

10. CONCLUSION

The renovation of Sheung Shui Staff Quarters into an office of the maintenance depot is one of the recent green building projects of WSD illustrating the Department's devotion in enhancing a green, harmonious and sustainable built environment. When the office comes into operation, they will consume less energy (with energy saving of about 67,000 kWh per annum) and less fresh water (with water saving of about 286 litre per day), representing a reduced carbon emission of 47 tonnes CO2-equivalent per year.

The Department's participation in the BEAM Plus building environmental assessment not only allowed the green performance of the proposed buildings to be evaluated, verified and accredited, the action also reaffirmed the notion "The Best Way of Leading is By Example" in view of the positive echo by the maintenance term contractor who voluntarily introduced additional green feature to this project to make it eligible to apply for a higher (i.e. Gold) BEAM Plus rating.

The joint effort with the industry in supporting green building will surely create a sense of well-being to us and nurture the sustainable livable environment for all.

ABSTRACT

The Government of the Hong Kong Special Administrative Region of the People's Republic of China (The Government of the Hong Kong SAR) is committed to sustainable development. The Central Kowloon Route (CKR) is a 4.7 km long dual 3-lane trunk road linking the Yau Ma Tei Interchange in West Kowloon with the road network in the Kai Tak Development and Kowloon Bay in East Kowloon. The CKR will relieve traffic congestion on existing major east-west corridors, enhance linkage amongst districts and support various developments in Kowloon. The CKR will reduce the number of vehicles using the existing major east-west corridors and alleviate the noise and air pollution arising from the existing traffic thus bringing significant overall environmental benefits. In this paper, the authors will present the environmental impact assessment (EIA) process of the CKR Project and focus on the approaches to protect the environment through early considerations of environmentally friendly designs, advanced air purification systems, and prevention of adverse environmental consequences in order to achieve key decision makings throughout the entire life cycle of a designated project. This paper also highlights the further sustainable development of the Project after the EIA approval including re-use of land-based marine sediments and green building design.

Keywords: design process, green rating tool, high-performance building

1. INTRODUCTION

1.1. The need of the CKR

The traffic on existing major east-west corridors in Kowloon, including Lung Cheung Road, Boundary Street, Prince Edward Road West, Argyle Street, Waterloo Road, Gascoigne Road Flyover and Chatham Road North of central Kowloon is nearing saturation and traffic congestion frequently occurs. The Government of the Hong Kong SAR has implemented local traffic management and improvement measures. However, since the areas on both sides of the existing east-west corridors are highly developed, the options for such measures are limited and therefore can only alleviate localised traffic problems in the short term. A large scale scheme to comprehensively improve the situation and cater for the long term need is thus essential.

CKR is a proposed dual 3-lane trunk road across central Kowloon linking the West Kowloon in the west and the proposed Kai Tak Development (KTD) in the east. Its western end at West Kowloon would connect to the Yau Ma Tei Interchange, via which to connect to strategic road links of the Western Harbour Crossing, West Kowloon Highway, Route 8, and Route 3 and key urban areas of Tsim Sha Tsui and the future West Kowloon Cultural District. Its eastern end at KTD would connect to trunk roads of Kwun Tong Bypass, Tseung Kwan O Tunnel, the future Road T2 and Tseung Kwan O-Lam Tin Tunnel, and urban development areas of Kowloon Bay, Kowloon East and Kai Tak Development. CKR together with Trunk Road T2 and Tseung Kwan O-Lam Tin Tunnel would form the strategic Route 6 highway link connecting West Kowloon and Tseung Kwan O. Figure 1 shows the layout plan and longitudinal section of CKR.

Figure 1: Layout plan and longitudinal section of CKR

CKR will provide an alternative route for the traffic to bypass the congested existing road network thus significantly reducing the journey time. For example, it is estimated that during the peak hours after completion of CKR, the journey time between west and east Kowloon via CKR will take around 5 minutes, compared to 30-35 minutes without CKR. CKR will also substantially reduce the traffic volumes around major east-west corridors in central Kowloon thus relieving their traffic congestion. The improved traffic conditions will also benefit the adjacent areas including Wong Tai Sin, Ho Man Tin and Kowloon City.

1.2. Benefits of the project

- Economic returns

Savings resulted in travel distance and travel time are the primary source of economic benefits from CKR. It is estimated that by 2030, the daily travel time savings will reach 120 thousands passenger hours bringing an economic value of $2.6 billion per annum.

Benefits will also arise from fewer accidents as travellers are diverted to use tunnel from local roads. According to the accident statistics provided by the Transport Department, the accident rate per veh-km for tunnels is 85% lower than local road during 2006 – 2010.

- Environmental benefits

As the traffic on the existing east-west corridors in Kowloon could be diverted by CKR, the traffic volume on these at-grade corridors could be reduced. Pollution resulted from traffic congestion could therefore be reduced to improve the environment in the surrounding areas.

With CKR in place, the traffic conditions (in terms of average travelling speed) along these east-west corridors would be improved and this would lead to a reduction in the substances such as CO_2, NO_x and Respirable Suspended Particulates (RSP) released from vehicles.

Through the adoption of advanced technology like Air Purification System (APS), vehicle exhaust discharged from the 3 ventilation buildings along CKR are largely decreased by the Electro-Static Precipitator and NO_2 removal system.

The following Table 1 summarises the estimated environmental benefits for east-west corridors of Kowloon:

Substances from Vehicular Emission	Reduction by CKR at 2026, Ton / year
CO_2	Approx 20,000
NOx	Approx 18
RSP	Approx 2

Note: Considering key East-West Corridors of Kowloon ONLY

Table 1: Reduction of annual emission for key East-West corridors

- Social benefits

In the future when CKR is completed, there will be a reduction in journey time, which will enhance the connection amongst districts thus supporting social developments.

2. EIA PROCESS OF THE CKR PROJECT

2.1. General approaches

The principle of avoidance and minimization of environmental impacts is the key driving force from the outset of the project planning and development.

Avoidance is the most effective way of preventing environmental impacts and this is primarily achieved through the careful selection of the best options among alternative routes and designs. Environmental considerations are an integral part of the route selection process at the early planning stage of a project, through which adverse impacts on important environmental sensitive receivers could be avoided as far as practicable.

Where adverse impacts on the environment are unavoidable, extensive efforts would be deployed in the planning and design of the project with an aim to achieving minimization of the impacts.

Once the preferred route has been chosen, control of the environmental impacts is mainly achieved by mitigation measures. Mitigation measures involve putting in place measures to reduce the effect of the impacts on the surrounding environment.

2.2. Selection of preferred alignment options

The proposed alignment of CKR evolved through various stages of studies, aimed at minimizing the land resumption/clearance, disruption to the public and impact on the environment. More than 40 alignment options had been considered and screened at each stage of studies, including tunnel and flyover options covering most of the Kowloon Peninsula from the northern Boundary Street to Tsim Sha Tsui. All these studies had concluded that a tunnel (as opposed to flyover) option across central Kowloon would be preferable.

A summary of the configuration of the key road sections of CKR is given in Table 2 below:

Location	Design	Approximate Length (m)
West Portion	Elevated/At-Grade Road	200
	Depress Road	200
	Cut-and-Cover Tunnel	400
Central Portion	Drill-and-Blast Tunnel	2760
East Portion	Cut-and-Cover Tunnel	210
	Underwater Tunnel	370
	Underpass/Depressed Road	320
	Elevated/At-Grade Road	320

Note: Along the mainline of CKR.

Table 2: Overview of key elements of the proposed alignment of CKR

CKR will mainly pass underneath an urban environment. As such, it is important to select an alignment, which can both follow the most favourable geological conditions for adopting mainly the drill-and-blast/break tunnelling method and maximise the rock cover above the tunnel. The selected alignment passes underneath the hills of Kings Park and Ho Man Tin. These areas not only have the advantage of greater rock cover but also have a relatively lower building density than the surrounding low-lying areas. The preferred alignment of the drill-and-

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

blast/break tunnel section also maximises the actual length of drill-and-blast/break and minimises the length of cut-and-cover tunnel. In that way, the adopted alignment will have the least adverse environmental impacts.

2.3. Approach adopted to minimize environmental impacts

Whilst the alignment selection process had avoided many environmental constraints from the outset, extensive efforts were also made to examine every opportunity to minimize environmental impacts.

Minimizing the Size of Reclamation at Kowloon Bay

In order to preserve the precious Victoria Harbour, the method of constructing the underwater tunnel by temporary reclamation using the cut-and-cover method was adopted. The alignment of the underwater tunnel was chosen for it would not involve resumption and/or demolition of private buildings and the extent of temporary reclamation was the minimum for practical construction. Figure 2 shows the layout plan and longitudinal section of the underwater tunnel.

The width of the temporary reclamation is dictated by the highway alignment design of the dual 3-lane trunk road and the minimum working space of 20 m working platform on both sides of the cut-and-cover tunnel. According to the experience of construction of underwater tunnel by similar method in the Central-Wan Chai Bypass project, this 20 m width is just adequate for construction activities. As such, the width of the proposed temporary reclamation is the minimum which requires less filling materials and hence fewer vehicles/barge trips during construction.

Figure 2: Layout plan and longitudinal section of underwater tunnel minimizing the extent of seawall

Conventionally, seawalls are constructed on firm foundations by replacing the soft marine mud in the seabed by sand fill. This process requires dredging and dumping of a large amount of soft marine mud. In order to minimize the extent of seawall for temporary reclamation, the current design is to use pipepile seawall as shown on Figure 3. The adoption of the pipepile seawall approach would significantly reduce the amount of marine-based dredged / excavated sediment from about 357,500 m^3 to 176,600 m^3.

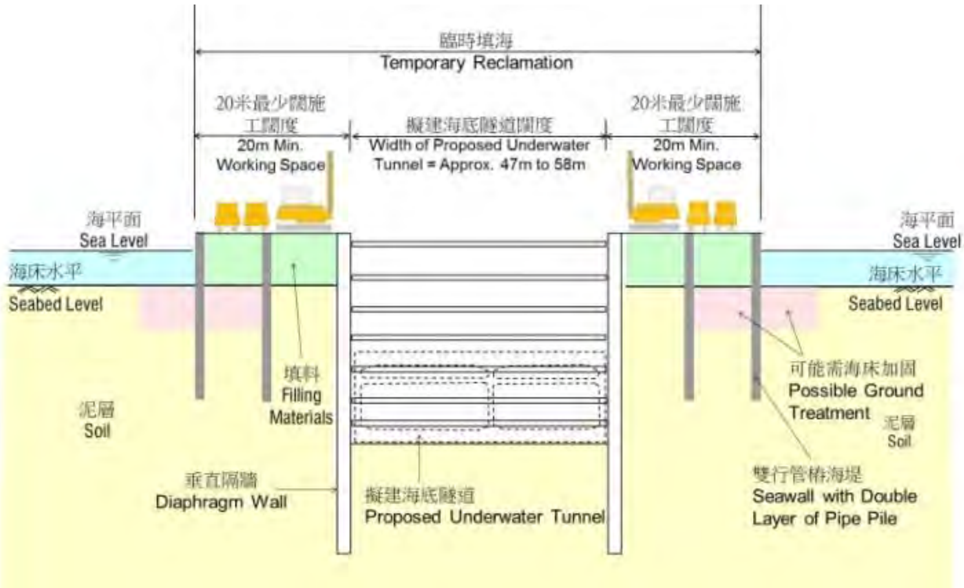

Figure 3: Typical cross section of temporary reclamation

2.4. Approaches adopted to mitigate environmental impacts

- Noise impact mitigation measures

To mitigate operational noise impact, noise mitigation measures including noise barrier / semi-enclosure / full noise enclosure and low noise surfacing are proposed for the project roads. With the provision of the noise enclosures / barriers recommended in the EIA report, there will be significant benefit on reduction in noise level at the noise sensitive receivers at Yau Ma Tei of up to 10dB(A) with an average 3dB(A) reduction. Approximately 1,600 existing dwellings and 85 existing classrooms could be benefited from the Project.

- Air quality impact mitigation measures

Vehicular emission inside the CKR tunnel will be discharged to atmosphere via the three proposed ventilation buildings, i.e. West Ventilation Building located in Yau Ma Tei, Central Ventilation Building in Ho Man Tin and East Ventilation Building in Kai Tak, which are sited away from residential buildings as far as possible. Limited emission from the CKR tunnel portals would be achieved in order to reduce potential air quality impact in these areas. To further reduce the air quality impact, an APS will be adopted to remove the pollutant concentrations before releasing the exhaust to the atmosphere. The APS design aims to achieve a removal efficiency of 80% for both RSP and NO2. Figure 4 shows the schematic layout of the APS.

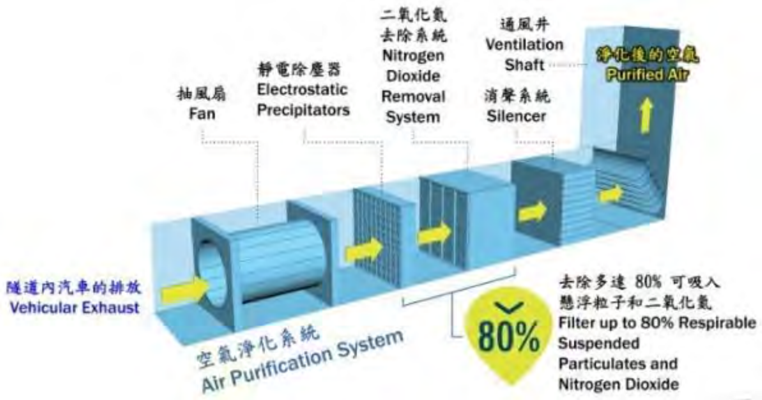

Figure 4: Schematic layout of air purification system enhancement of greening and landscaping

Highways Department (HyD) will make use of the opportunity of constructing CKR to improve the environment through greening and landscaping. A landscape deck with an area of about 20,000 m2 will be constructed at the western tunnel portal of CKR tunnel. A 160 m long and 40m wide waterfront promenade will also be constructed along the waterfront area fronting the Kowloon City Ferry Pier Public Transport Interchange (PTI). The

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

reprovisioned PTI will be covered by a landscape deck with an area of about 9,000 m2. CKR Project will also include the planting of about 1,800 heavy standard trees and 685,000 shrubs, covering a planting area of about 54,600 m^2. Figures 5.1 to 5.2 show the proposed landscape decks and waterfront promenade, which will be provided with multi-function recreational facilities such as jogging trails and pavilions, to be constructed under CKR Project.

Figure 5.1: Landscape deck above yau ma tei interchange

Figure 5.2: ma tau kok waterfront promenade

- Preservation of built heritage

The Yau Ma Tei Police Station at West Portion of CKR is a Grade 2 Historic Building. The proposed side-by-side cut-and-cover tunnel avoids the old wing of the Police Station and the residential buildings at the south side of Kansu Street. For the affected New Wing of the Yau Ma Tei Police Station, we will carry out underpinning to preserve the structure.

- Mitigation measures to be adopted during construction phase

For the construction phase, good site practices would be adopted to reduce various environmental impacts. For example, the implementation of watering in all works areas would substantially suppress the generation of fugitive dust. The use of quiet plant and site hoarding, use of movable noise barriers, etc. will reduce the construction noise. The use of silt curtains and cage curtains will control the release of suspended solids during the reclamation phase.

2.5. Environmental Monitoring and Audit (EM&A) programme

A comprehensive EM&A programme will be implemented to oversee the environmental performance of the Project on various aspects including air quality, noise, water quality, and waste management, etc. on the neighbouring sensitive receivers. It provides a framework to identify and contain potential impacts, and apply appropriate measures to ameliorate them.

In accordance with the requirements of the Environmental Permit (EP) of CKR, an Environmental Team (ET) shall be established and an Independent Environmental Checker (IEC) shall be employed by HyD no later than one month before commencement of construction of the Project. The ET, ET Leader and IEC will ensure full compliance of environmental requirements during construction and operation of the CKR Project according to the EP.

HyD will also set up community liaison groups comprising representatives of affected parties, including local committees, residents and schools in the affected areas along the route alignment, to facilitate communications, enquiries and complaint handlings on environmental issues related to the Project. Respective community liaison teams and designated complaint hotlines shall be set up for the Project to address related concerns and enquiries in an efficient manner. HyD shall also follow up with the respective community liaison groups on the implementation of mitigation measures as necessary.

3. CONTINUING DEVELOPMENT IN SUSTAINABLITY

The Government of the Hong Kong SAR has always been an advocate of sustainable development and has capitalised on the opportunity to steer forward with various green approaches on public works projects. After the approval of the EIA of the CKR Project, HyD continue to incorporate environmental protection and sustainable elements into the Project.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

A tree compensation proposal was developed to justify the need for any tree felling required to facilitate the CKR construction works.

To reduce the volume of disposal of marine sediment generated from the construction of cut-and-cover tunnels, it is proposed to reuse about 30,000 m3 land-based uncontaminated marine sediment with treatment by cement solidification such that the treated sediment is suitable for backfilling of excavated trenches.

The administration building of CKR will be designed as a sustainable building capable of meeting the relevant requirements under the latest "Building Environmental Assessment Method for New Building" (BEAM Plus) of the Hong Kong Green Building Council.

It is confident that through continuing efforts, the CKR Project could be further enhanced in a sustainable way.

4. CONCLUSION

The EIA process is a proactive planning tool to avoid and mitigate adverse environmental impacts that might be caused or experienced by the proposed development. This article highlights the importance of alignment selection of the CKR Project at the beginning of the project planning stage with an aim to avoiding adverse environmental consequences of the proposed Project. Approaches to minimize environmental impacts have also been integrated into the design as much as practicable. For those adverse environmental impacts that could not be fully avoided, measures have been proposed to reduce and control the possible adverse environmental impacts to within established limits or criteria. The environmental performance of the Project during its implementation will then be overseen in accordance with the EM&A programme. Through the EIA process, the Project was planned and designed by striking a balance between development and environmental conservation.

A Comparison on Two Certification Systems: Leadership in Energy and Environmental Design (LEED) And Building Environmental Assessment Method (BEAM) On Green Building in Hong Kong

Ophelia CHU Ka-wai[a], Richard CHEUNG Yun-hing[b]

[a] *City University of Hong Kong, Hong Kong SAR, kwochu2-c@my.cityu.edu.hk*
[b] *City University of Hong Kong, Hong Kong SAR, bhricche@cityu.edu.hk*

ABSTRACT

There are totally 53,432 buildings in Hong Kong, while 25% are public sector and 75% are private sectors, 1.5% of buildings have accredited or registered to BEAM plus certification system and 0.34% have accredited or registered to LEED certification system. And sharp increase of BEAM plus and LEED newly registered projects were record in 2010 and 2013 respectively pointed out the increased concern on green building in the recent years. Variety of research paper were focusing on the credits category and usefulness of LEED building, however there was a research gap showing the usefulness of the BEAM plus system. Therefore, in order to investigate the usefulness of two system, the differences between BEAM plus and LEED systems in the aspect of Water Management, Materials and Indoor Environmental Quality in this dissertation. The research findings based on the difference between two systems indicated the BEAM plus system was more suitable to Hong Kong which because of the BEAM plus has always subjected to adjustment immediately upon to any changes of the regulation of Hong Kong such as Water Quality Objectives due to the LEAD water incident. And the major problem of the government policy was the extra granting of GFA is going to further tightening the land supply in Hong Kong in the future. Therefore, recommendation on reduction of GFA and alternative incentives were presented for the government is also discussed in this paper.

Keywords: green building, BEAM Plus, LEED

1. INTRODUCTION

There was a close relationship between Green Building and sustainability building which has become the talk of the town in recent years, the public awareness was dramatically increased due to promotion in the public media (Zuo & Zhao., 2014). So in other words, green building was no longer a technical term used in the building industry but also well-known in the public (Eichholtz, Kok & Quigley., 2013) The concept of green building was more and more accepted in the public in such a few year, one of the reason should be came from the effort paid by the accreditation organization, the BEAM society and also the Hong Kong Government. Firstly, green building was promoted and encouraged in the building industry by the Hong Kong government in terms of granting gross floor area (GFA) concession ordinance from the building department (BD, 2014). Based on the commercial consideration, there was no argument that why more and more new buildings are adopting green building accreditation scheme in the building process.

Green building is not only the business of engineer but also planner, architecture, interior designer and construction management team yet certification systems are emphasizing the term of integrated process depended on the specialist in different area and considering the operation and maintenance issue in the design stage of the project (Mak, Janet & Dong, 2014). According to the Hong Kong Government, Green buildings different from the others due to efforts are paid on design, operation ecological management, resources management and renovation and building process to minimize the use of energy, water, and other possible resources and so that the overall impacts throughout the life cycle to the environment are therefore reduced (HKSAR Gov., 2015). Green building is also called sustainable building which rely on the simple and low-tech method and strategy such as adopting passive building design, application of highly efficient Mechanical Ventilation and Air Conditioning (MVAC), Electrical (EL), Pump and Drainage (P&D) which aimed in enhancing the energy saving and minimize greenhouse gases emission to protect the health of occupant and enhance productivity also reduce the waste generation at the same time so as to enhance the quality of building, minimize the environmental impacts and cost paid in life cycle and hence achieve sustainable construction (USGBC, 2014, Lockwood, 2006, Fowler & Rauch, 2006). Variety of accreditation schemes were established in all over the world since the late twentieth Century, like Leadership in Energy and Environmental Design (LEED) from United States, BRE Environmental Assessment Method (BREEAM) from

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

United Kingdom, Green Building Council of Australia Green Star (GBCA) from Australia, Green Mark Scheme from Singapore, Deutsche Gesellschaft für Nachhaltiges Bauen e.V. (DGNB) from Germany, Comprehensive Assessment System for Built Environment Efficiency (CASBEE) from Japan, Pearl Rating System for Estidama from Abu Dhabi, Building Environmental Assessment Method (BEAM) from Hong Kong, Green Building Index from Malaysia, 3-star from Mainland China. Among several of green building assessment, LEED and BEAM for new construction or building are going to be focused here.

Basically, various credit focus in different certification system include energy, water, indoor air quality, accessibility, transportation, materials, etc, also there is numerous of researches focus on the energy aspect which because it usually contribute to the largest portion of points in various scheme of certification system. However, relative lesser focus is found on water aspect where it should also play an important role in the sustainability of building as it contribute to the second largest portion of various scheme. Also, due to the scarcity of potable water is increasing in all over the world (Arup, 2014) and based on the Hong Kong situation, the reasonable price of portable water fee made water saving as one of the major public education issue of the government (WSD, 2009), therefore the water aspect should also play equal importance to contribute to the sustainability of building so will be discussed here. In addition, other aspects such as indoor air quality is also important due to the basic purpose of building project is for human beings to live or work and there is no argument that operation phase should be longer than other stage and cost up to 65% of the whole life cycle cost of the building (Dewar, 2004) therefore such aspect will also be mentioned here. Moreover, materials is the one of the most important elements for building project so how selection and management of construction materials made the project into environment friendly way is also trying to be discussed here. So, water aspect, materials aspect and indoor air quality aspect in LEED and BEAM system will be investigated here.

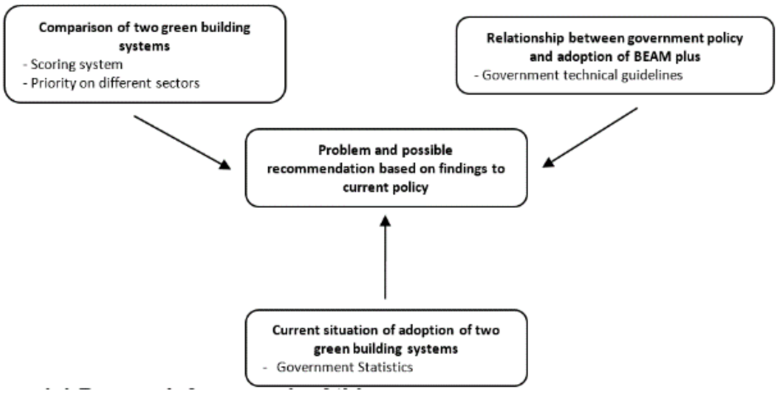

Figure 1.1 Research framework of this paper

1.1. Leadership in Energy & Environmental Design (LEED)

LEED was established in the March of 2000 by the U.S. Green Building council, which was the founded by Rick Fedrizzi, David Gottfried and Mike Italiano aimed in promotion of the concept of sustainability in the construction and building industry for the US department of Energy with strategy of market-driven. In the USGBC Membership Summit held in August 1998, the first version of man ual called LEED 1.0 designed for new building was launched (USGBC, 2014) The latest version now is LEED version 4 (LEED v4) and available for the area of Building design and construction (BD+C), Interior design and construction (ID+C), Operation and Management (O+M), Neighborhood development (ND) and Homes (H) based on the function of the buildings. The decision on rating system based on the proportion of gross floor area by using 40/60 rules. contains base points of 100 which distribute in to five main categories that include Sustainable sites (SS), Location and Transportation (LT), Water efficiency (WE), Energy and Atmosphere (EA) and Indoor Air Quality (IAQ), plus 6 points from Innovation design (IN) and 4 points from regional priority, and 1 to 2 points from integrative process so come to 110 points in each rating system (USGBC, 2009, USGBC, 2016).

1.2. Difference of LEED and BEAM Plus in water management

Based on the credit criteria, both LEED and BEAM plus system on indoor water reduction are based on the specific calculation tool for water by establishing a case of baseline of water consumption and the prerequisites on reduction on water reduction but varied in the threshold. Also the parameter of indoor water reduction in LEED is only 1 credit containing 2 points to be awarded while that is one of the prerequisite requirement. (Arup, 2014). A And for the outdoor water reduction part LEED require 30% outdoor potable water reduction from base line, 50% for 1 points and 100% for 2 points, and for BEAM plus require not using portable water as irrigation sources and ideally reduce 50% water use on irrigation. And for the outdoor water reduction part. Also there is no credits on the fixture specification in LEED system but 1 point if using apparatus with Water Efficiency Labelling Scheme Grade 2 or above.

And the major difference of LEED and BEAM plus certification system is the approach of water management aspects and summarized below. In which LEED is always focusing on the minimizing the amount of the portable water use and also maintain the minimal use of water while the BEAM is comparatively multi-targets that put higher priority on the portable water quality and effluent treatment if available in the projects. Also the category focus of the LEED rating system itself is always stick on the project type while the further divided into residential and non-residential. Extra credits can be gained in the both of the two certification system while in LEED system shall award project with maximum two points for no cooling system as Pilot credits and for the BEAM plus system extra credits shall give to projects with treatment system for waste water as Innovation credits. Also the leakage monitoring is not concerned in the LEED system while BEAM plus pays attention on it.

The apparatus focused in both two system are similar however the LEED system only focus on the flow rate or volume per flush while the BEAM plus system considered the difference needs on water use in female and male so the sex ratio, the frequency is mentioned. Also the majority of estimated baseline value is lower except kitchen water tap data in LEED system compared to the BEAM plus system.

1.3. Difference of LEED and BEAM Plus in materials aspect

Based on the criteria of credits on the materials of LEED and BEAM plus described in the previous paragraph, both LEED and BEAM plus made focus on impacts generated by the raw materials along the life cycle in construction phase and also the management of waste in order to minimize the stress of waste treatment facilitates like landfills and incinerators. The LEED certification system takes focus on the waste management as the basic requirement on materials approach while BEAM certification beside waste management but also the use of Refrigerants that are CFCs based and also the timber not for permanent work. Also the maximum points achieve in LEED certification system is thirteen while twenty-two plus one bonus point in BEAM plus system. Moreover, the BEAM system takes more paragraph on the efficiency on the usage of materials while LEED system focus on the upstream declaration of the products that comprise to the majority of the points in such aspects through encouragement of purchasing products with recognized green labeling. Also both system require the place of product source extraction, manufactured within certain distance from the project site in which LEED system require 160km and where BEAM plus system require 800km from the site location.

1.4. Difference of LEED and BEAM Plus in indoor environmental quality aspect

The achievable point in the IEQ aspect of LEED and BEAM plus are 16 and 32+3B respectively. The major difference of IEQ aspect in LEED and BEAM plus is the credit focus area, both of them pay efforts on the health and comfortability of the occupants in the building but with slightly different focus. Besides LEED and BEAM plus both take the IAQ, lighting, acoustic and ventilation as serious issues, LEED also pay effort to the visual comfort of the environment around the building and BEAM plus decided to take care of the security and amenities facilities as part of IEQ aspect. And the LEED system are not ignoring the issues on amenities facilities and security but those issues are discussed in the Site Aspect (SA) credit category which will not be discussed here. Also the ventilation is one of major concern that directly related to the air quality and therefore pay an important role on transmitting pathogen of respiratory disease, it is found that the major standard for ventilation adopted by LEED and BEAM plus are same, ASHRAE 62.1 but with different version, the LEED system is adopting the 2010 version while the BEAM plus is adopting the 2007 version. Also besides the parameters in IAQ that the special health issues concern are different, while the LEED system straightly control the tobacco smoke in the building and the BEAM plus took the control of Legionnaires' disease as important issue. Moreover, final flush out process is critical for the IAQ of the building and therefore LEED and BEAM plus are both encourage the replacement of filter system/media followed by flush out process after completion of the construction and prior to the occupancy stage to ensure the indoor air quality is not affect by the residue particles in the construction stage.

2. CRITICAL EVALUATION ON LEED AND BEAM PLUS

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

USGBC (2015) pointed out that there was extra effort need to be paid by the developer on additional work procedure and alternative materials purchasing were required so as to build in a green way at the same time there is long term potential saving on the aspect of energy, water and maintenance. It is known that the developers may not concern on the environmental effects from building development so they are not willing to invest large portion into the green building part so according to survey done in the US stated that the maximum investment willing to pay for green building around 15% of total investment while for developer with incent of green building shall took up 0-5% more portion on this sector and their major concern is warranted cost premium through adopting green building measures and certification system (Burnett, et al, 2008). Also, Kats (2003) stated that the higher the level of project gained, the higher the cost of green building paid by the development so if Green building worth its value or just part of the corporate social responsibility (CSR).

In the economic aspect, the cost of green building based on the cost spent on certification system, measures done during design and construction phase and maintenance cost during operation phase while the benefits mainly came from energy reduction, water reduction, rent rate and occupied rate. Burnett et al (2008) concluded the average total building costs of standard was HK$10,600/m2, cost of services is HK$2,550/m2 in average and the estimated cost of fit-out is around HK$5,170/m2 based on the information at 2005. Burnett et al also pointed out that there 10% extra design cost was paid for the indoor environmental quality while Kats (2003) suggested 3-7% extra cost was paid for LEED projects achieving Silver to Platinum level and the average of extra cost on LEED buildings was around HK$248.64 – 414.4/m2 ($3-5/ft2) (Unit transformation based on US$1 = HK$7.7 and 1sq2 = 0.09290304m2) For the performance on energy consumption is similar where LEED buildings conserve 10.5% to 42% energy while BEAM plus buildings conserve 10% to 45% (Lee, 2012). Estimated energy saving for LEED buildings was HK$481.1/m2 (5.8 US$/sq2) and annual cost saving for BEAM plus building for offices and residential were HK$1.6/m2 and HK$0.4/m2. And for the water aspect, additional cost on monitoring was up to HK$2 – 10/m2 however upon appropriate equipment like closets that are valveless cistern and dual flush or Infra-red sensors, the estimate water saving could be 16-50%. The annual saving of water consumption per construction floor area (CFA) for offices and residential are HK$1.8/CFA and HK$20/CFA respectively (Burnett et al, 2008) and HK$3.85 (US$0.5) for LEED buildings (Kats, 2003). Moreover, Miller, Spivey & Florance (2008) pointed out LEED certified building with higher in direct rental rate, higher in occupied rate and lower in maintenance expense therefore resulted 10% positive impact on the sales price per square feet however no such information could be found in BEAM plus buildings.

And based on the situation of Hong Kong, a series of regulation set by the government which include Practice Note for Authorized Persons, Registered Structural Engineers and Registered Geotechnical Engineers APP-151 (BD, 2014) stated the regulation for GFA concession that including the following parts, i) Sustainable building design guidelines (SBD Guidelines), ii) Gross floor area (GFA) concessions, iii) Energy efficiency of buildings. APP-151 work closely with APP 122, APP-152 and Green Features under Joint Practice Notes (JPN 1&2) (BD, 2014). The package of regulation document clearly stated the requirement of earning extra 10% of GFA concession by fully adopting BEAM plus in any new building projects, and therefore developer are able to earn more through selling the addition GFA granted by the government (Fan, 2015). Therefore, the risk of the energy, water efficiency saving not as expected, and the cost is still partially or fully compensated on the GFA concession. Li & Liu (2013) reported the number registered BEAM plus projects from 2010, the year of introduction of GFA concession announced by the government, was 210, then become 225 in 2011 and 300 in 2012, which indicated the successfulness of the GFA concession and related regulation. Also the human working or living in the green building is also benefited through the better control of indoor air quality, and resulted in better health condition of the occupants by reducing respiratory illness, allergies and asthma, symptoms on sick building syndrome and improved performance from the thermal and light regulation done before occupancy stage (Ries et al, 2006) and billions of US dollars was estimated to save by maintain the health of occupants (Fisk, 2002) but lacking of information focusing on BEAM plus buildings on such area in Hong Kong therefore more studies shall be done in the future to investigate the usefulness of BEAM plus certification system.

The retailers companies started to promote green marketing to enhance the socially responsible manner not only for fulfilling the obligations of ethnical and also for enhancement on marketing performance resulted from the response of consumer to corporate social responsibility (CSR) (Ko, Hwang & Kim, 2013). Environmental concerns and the demand for green products of customers in Korea is the pulling force behind the blooming of green marketing (Ko, Hwang & Kim, 2013). In facts, there should be quarter of customers in Hong Kong do concern on the environmental issues, therefore the adoption of green building certification system should definitely increase

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

the attraction of the product such as residential building. Based on the information found, it was found that less statistic information related to BEAM plus building could be found compared to LEED buildings therefore there was room of improvement on information transparency of BEAM plus buildings in the future. Also, large amount of researches were focusing on effectiveness, cost and benefits analysis on LEED system in different aspects than BEAM plus which made difficulty on comparing on the effectiveness of LEED and BEAM plus system. Stronger evidence found on LEED system benefit on both commercial and social way that might be due to the longer history on LEED than BEAM plus system. However, the BEAM plus is also chosen by the Hong Kong Government because of the standard adopted is closely stick to the regulations of Hong Kong, table 3.4 stated the changes of the minimum requirement on portable water in recent year was stick to the WQO of WSD based on the current situation of Hong Kong. No matter which green building certification system was adopted by the building, the sustainability was also fully achieve because both environmental, social and economic were benefited from the effort pay on green building. The major reason on well adoption of BEAM plus was due to the promotion of Hong Kong Government, but it really served as good starting point of green building development in Hong Kong and showed the incentives of the industry but further development will be rely on the professionals in the field to push it forward in the coming future.

3. DISSCUSSION

There must be no argument that, the development of green building system is more competitive than other Asia country as we are the only city having our own certification system, BEAM plus which originated in Hong Kong. The HKGBC has played the most important effort on initiate, modify and promoting the BEAM plus certification system with the green building policy aided by the Government. The initiation of incentives of green building stage is fully done and the next step of the green building policy should be restricted, fine tune and become more aggressive so that more green buildings in Hong Kong to help contributing to positive impacts to the environmental problems in Hong Kong.

In my opinion, the APP-151 is a good measures to introduce, encourage and facilitate the green building development in Hong Kong, and based on the fact that 435 ongoing BEAM plus projects out of 790 total registered projects which meant the ongoing green building projects were almost half of the total projects has proven that the BEAM plus system is well-known and absorbed by the industry. However, Development Bureau (2011) stated that there is extra 40% GFA areas with high density, 67% in area with medium-density, and 57% in area with low-density zone, which further worsen the density situation of Hong Kong. To avoid the worsen situation occurred in the coming future, the APP-151 could considered to be enhanced by step by step to achieve further development of green building in Hong Kong. Taking the example in Singapore, the GFA concession was also based on the level of BCA Green Mark achieved, only project with level higher than gold achieve up to 1% GFA concession (Chong, 2007). Therefore, the gradual GFA concession according to the BEAM plus certification level gained can be adopted, for example 3% for bronze projects, 5% for silver project, 8% for gold projects and 10% for Platinum projects or even totally cut off and compensate by others incentives.

In addition, common adoption of BEAM plus system in the industry should only be one of the milestone of green building development in Hong Kong as it was not yet mandatory. Besides, Fan (2015) pointed out that the Joint Practice Notes (JNP) was also set up by the government to facilitate green building design by encouraging the maximize use of resources on renewable energy and materials for green building so as to minimize the use of energy not renewable and therefore the waste generated by construction can be reduced. The following table 4.1 shows the mandatory regulations on Green building in Hong Kong, in which only part of the BEAM plus system, energy use was restricted by the government. And taking Singapore, the most similar country to Hong Kong in Asia, has already pushed their green building certification system. Green Mark into registration with financial penalty and therefore no longer voluntary adoption since 2008 (Chong, 2007). For every new building projects in Singapore, there was requirement on Minimum Green Mark score and relevant Green Mark Certification and minimum Green Mark standard for existing building stated in the Building Control (Environmental Sustainability) Regulations since April 15 in 2008 so as to achieve 80% of Singapore Buildings with Green Mark by 2030 (BCA Singapore, 2016, Chong, 2007). Therefore that should further encourage the numbers of green buildings in Hong Kong in the future if the adoption of BEAM plus system became mandatory.

Moreover, tax return is also stagey shall be adopted by the government, taking the example in Cincinati, up to 500,000 US dollars of property tax rebate for 15 years was provided building adopting LEED certification system

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

(Miller, Spivey & Florance, 2008), however, the 2015/2016 property tax rate of Hong Kong in was 15% (HKgov, 2016) while in US was 0.55% to 2.38% different in states and that pointed out was the property tax contribute to great income to the Hong Kong government therefore it might not be feasible for all green buildings but for those projects achieving a higher level for example Platinum to increase the incentives of encouragement on achieving higher level in BEAM plus system.

The enhancement mentioned above possibly motivate developer to paid larger investment portion on the green building portion. Therefore, the government is recommend to adjust the percentage on GFA concession and can be changed to property tax rebate instead to maintain the incentive to developer.

In addition, based on the increasing trend of the LEED projects in Hong Kong, and researches stated that 25-30% of energy saving, 10 times of productivity enhancement (Kats, 2003., Miller, Spivey & Florance, 2008) in those buildings, the government shall also consider to adopt the LEED certification system into the GFA concession policy, to serve as another option of certification system can be provided to the construction industry. Also, the BEAM plus certification should be continuously promoted.

4. CONCLUSION

In conclusion, the adoption of green building certification system was now the global trend in the world, the difference between LEED and BEAM plus system are found in scoring system, approaches and priority of different sectors and the target parties. The higher adoption rate of BEAM plus system than LEED system is mostly related to the policy of GFA concession which also tighten the land supply in the future. Alternative concession based on findings and example of Singapore has been suggested to adjust the current policy so as to balance the adoption of green building system and limited land supply in Hong Kong.

ABSTRACT

Under the subtropical climate of Taiwan, indoor building materials have a significant impact on the in-door air quality, which leads to health problems and increased risks of cancer. Currently, the “Green building materials labels” and the Indoor Air Quality Act have been promoted to control the source of pollution, namely the fugitive pollutants of building materials and the air concentration in the indoor space. This study adopted the fugitive emission database of 645 pieces of building materials with a green label, test and verification of fugitive emission of 7 small pieces of building materials, numerical statistics and analysis, and literature analysis to research the emission evaluation classification of fugitive TVOC from green building materials label in Taiwan. The result shows newly emission evaluation classification of Healthy Green Building Materials Label is “E1 (less than 0.005 mg/m^2* hr), E2(0.005-0.06 mg/m^2* hr), and E3(0.06-0.19mg/m^2* hr)”.

Keywords: green construction technology, green building management, indoor environmental quality

1. INTRODUCTION

According to the survey (P.C. Wu, et al.,2003), indoor formaldehyde and VOCs concentrations are relatively high in Taiwan due to the hot and humid climate, emission of chemical substances in interior building materials, and lack ventilation, thus causing high health risk hazards. Formaldehyde and volatile organic compounds (VOCs) are Specifically the main pollutants in indoor, which negatively influence people’s health, comfort and productivity (Kim et al., 2001; Godish,2001). It has been found that various building materials are sources of indoor formaldehyde and VOCs (Cox et al., 2002). Moreover, there is also evidence that building materials can act as a sink of formaldehyde and VOCs by sorption, and the re-emission of sorbed formaldehyde and VOCs can dramatically elevate indoor concentrations for months or even years (Tichenor et al., 1988; Sparks et al., 1994). Under the subtropical climate of Taiwan, indoor building materials have a significant impact on the poor indoor air quality, which leads to health problems and increased risks of cancer. Currently, the “Green building materials labels(GBMLs)” and the Indoor Air Quality Act have been promoted to control the source of pollution, namely the fugitive pollutants of building materials and the air concentration in the indoor space. Emphasis is placed on advanced administrative control of total volatile organic compound (TVOC) to reduce the harm of fugitive pollutants of indoor building materials to health.

4.1 The green building materials label in Taiwan

The Green building material (GBM) labelling system of Taiwan proposed by the Architecture and Building Research Institute was officially launched in 2004 to systematically and effectively evaluate the performance of green building materials. The connotation of the GBM Label is mainly to enhance the built environment and to provide the actual benefit toward the concept of human health and earth sustainability. The system carries out quantitative assessments and laboratory tests based on a variety of measures in different stages of the life cycle of a building. Its criteria and standards are established accommodating with the subtropical climatic condition. In addition, the regulation of at least 45% mandatory green building material utilization has also been involved into Taiwan’s Building Code and become effective since 2011. The GBM system covers four major aspects, including Health, Ecology, Recycling, and High-performance. The Healthy GBM for improving the indoor environmental quality requires low emission, odor free, and no asbestos. The Ecological GBM typically includes low toxicity processing and natural materials without shortage crisis. The Recycling GBM aims to reduce wastes and to reuse abandoned materials and recycling aggregates. As for High-performance, it basically refers to the materials with high permeability and high noise insulation. By the end of July 2016, 1,589 Labels have been conferred covering 11,016 green products. Among these products, the healthy material occupies 74%, and followed by the high-performance category 16%, recycling 9.2%, and ecological 0.8%.

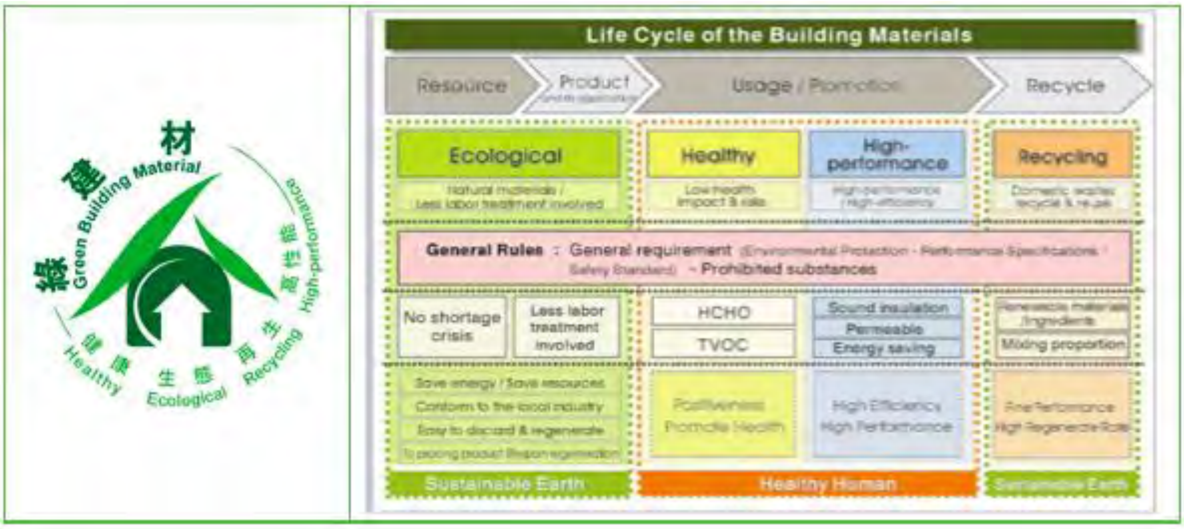

Table 1: The green building materials label in Taiwan

4.2 The emission evaluation classification of healthy green building materials label

Since formaldehyde contained in building materials, and VOCs added during the production of indoor construction materials, application and glue preparation, under the climate condition of high temperature and humidity, harmful chemical substances may be emitted in the air and directly affect human health and indoor environmental quality. Thus, the system focuses on the management and control of the relevant hazards. The test is based on ISO16000, and the standard is HCHO is less than 0.08 mg/m^2˙hr and TVOC less than 0.19 mg/m^2 ˙hr. The Emission Evaluation Classification of Healthy Green Building Materials Label has 3 emission levels (E1, E2, E3).

Health-GBML levels	Emission evaluation Classification TVOC (BTEX substance.)
E1	TVOC ≦ 0.005 mg/m^2*hr
E2	0.005 < TVOC ≦ 0.1 mg/m^2*hr
E3	0.1 < TVOC ≦ 0.19 mg/m^2*hr

Table 2: The health GBMs TVOC emission evaluation classification

2. RESEARCH METHOD AND EXPERIMENTAL

Based on the data from the "fugitive emission database of green building materials" (645 products), this study conducted statistical analysis on normal distribution to learn the distribution of the emission levels (E1, E2, E3) in the green materials and discuss emission evaluation factor control standard and grading method. Test was conducted on fugitive VOCs of 7 small pieces of building materials using the small-scale building materials emissions test method (ASTM D5116-03, ISO 16000) and indoor air quality test methods (NIEA-A715.14B, NIEA-A714.11C, NIEA- A705.11C), in order to verify the "evaluation Classification standard and grading method of TVOC emissions from green building materials".

The small-scale building materials emissions test method	Specifications for the analysis of VOCs	
	Analytical Column	DB-624 GC 30m x 0.25mm x 1.4μm
	Carrier gas	Helium
	GC-MS Condition	Column temp program:35℃ ,10℃/min to 120℃ hold 10min , 10℃/min to 220 ℃ hold 10min,Scan range:50-350 amu (EI)
	ATD Condition	Tube desorption temp:280℃ hold 5min,Cold trap low temp:-20℃, Cold trap high temp:300℃ hold 5min

Table 3: The small-scale building materials emissions test method

2.1 The statistical analysis method

This study adopted the fugitive emission database of 645 pieces of green building materials label. The statistical analysis result shows as Table 4.

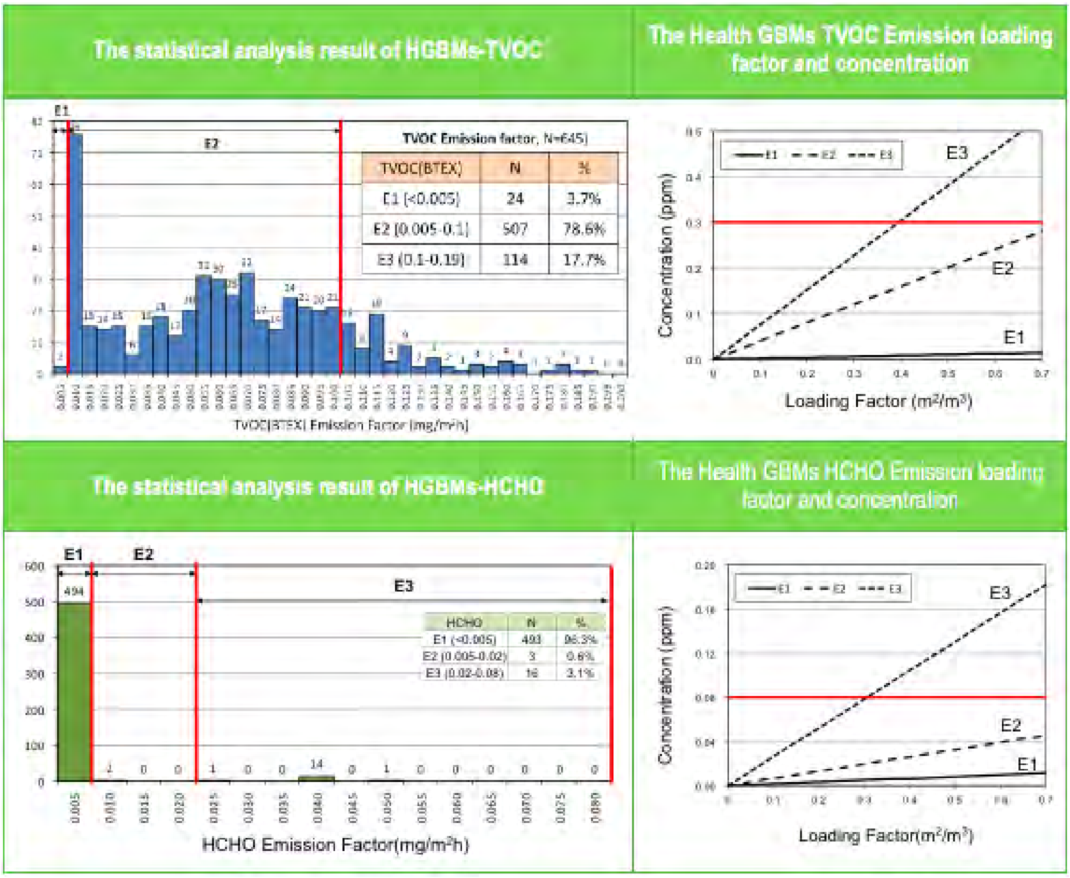

Table 4: The statistical analysis result of HGBMs-TVOC

2.2 Experiments and materials

This study selected paint with a building materials label for analysis, sampled 7 small pieces of paint for an emission test, and conducted a 48-hour qualitative and quantitative analysis. Based on ISO 16000 (part-9,3,6) and ASTM-D5116 standards, this study used the chamber experiment to conduct the building material effusion test. In the 48-hour test under the conditions of temperature of 25°C, relative humidity of 50 %, air exchange 0f 0.5 ACH and loading factor is 0.4 (m^2/m^3)

Specimen NO.	Building Materials	Experiment
S1	water-soluble cement paint	HGBMs Under 25 °C、50%RH、0.5 ACH、L.F. 0.4 (m^2/m^3) for 48hr
S2	latex paint	
S3	Flameproof paint	
S4	Wood paint	
S5	Epoxy paint	
S6	latex paint	Non-HGBMs
S7	Wood paint	

Table 5: The experiment of building materials emission test

The mass concentration of the compound in the reference room air is calculated by means of the following equation:

$$c_R = \frac{SER_A L_{AR}}{AC_R}$$

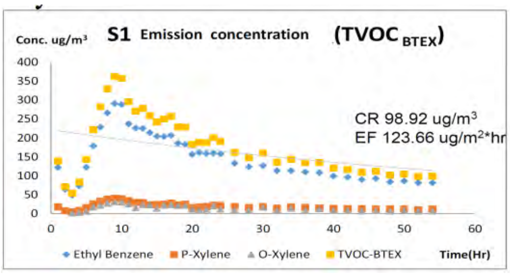
Equation 1

Where, CR is the mass concentration of compound a in the air of the reference room, in micrograms per cubic meter, SERA is the area specific emission rate in m, in micrograms per square meter and hour(emission factor),LAR is the loading factor in the reference room, in square meter sample per cubic meter reference room, ACR is the hourly air change rate in the reference room, in air changes per hour.

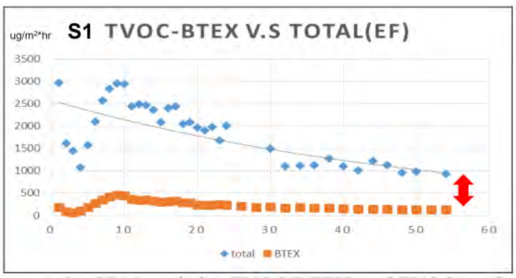
3. RESEARCH RESULTS

Five coating materials obtaining Green Building Materials Mark and 2 general paint materials (with-out Green Building Materials Mark) are sampled in this research for TVOC emission experiment. There 7 coating materials are tested for 48h under standard test conditions (25°C, 50% RH, 0.5 ACH, Loading Factor 0.4 m^2/m^3). Emission test of indoor paint materials shows that evaluation factor BTEX of green paint materials is extremely low and consistent with evaluation reference, however, the other VOCs matters emit largely.

Under the test of S1 building material (water-soluble cement paint) for 48h, the emission matter is used for qualitative and quantitative analysis through GC/MS. Emission concentration and rate of TVOC (BTEX) conform to the standard of Green Building Materials Mark. However, other VOCs matters emit continuously or the posterior concentration of emission increases.



a)



b)

Figure 1: a) S1 BTEX concentration, b) S1 TVOC and BTEX emission factor

Indicated by the evaluation results based on R=CR/LCI of CEN/TS 16516, estimated emission concentration of TXIB is 4.4 times than R value. Estimation factor BTEX of Green Building Mark is extremely low and consistent with the assessment basis, the emission concentration of which is 98.9 (ug/m^2hr), i.e. 123.6(ug/m^3). However, the other TOTAL VOCs matters emit largely and continuously. The two has 10 times difference.

VOCs	48Hr ug/m³	LCI ug/m³	R<1
Nonanal	2.9	1300	0.0022
Benzaldehyde	69	90	0.7667
Acetic acid, butyl ester	24.1	4800	0.0050
Ethylbenzene	83.7	4400	0.0190
2-Propenoic acid, butylester	2.4	110	0.0218
Benzene, (1-methylethyl)	33.7	1000	0.0337
p-Xylene	11.6	2200	0.0053
o-Xylene	6.4	2200	0.0029
TXIB	1982.1	450	4.4047
1-Butanol	13.3	3100	0.0043
2 -Ethanol, 2-(2-butoxyethoxy)	102.38	670	0.1528

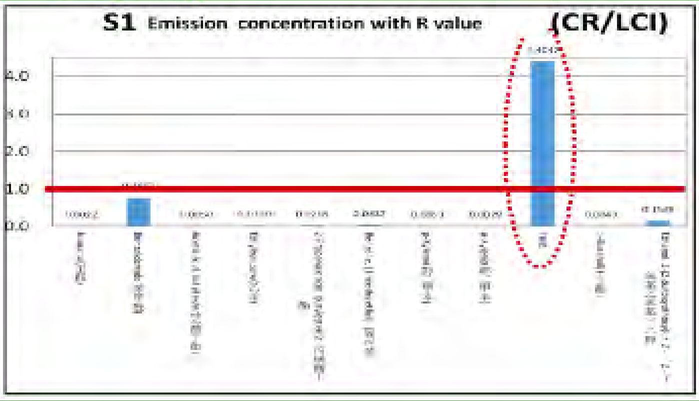


Table 6: The S1-GBMs emission conc. with R value

Test on long-term emission from S1 to S7 building materials showed that the building materials are consistent with emission standard of evaluation factor BTEX for Green Building Materials Mark, the average emission concentration of which is 49.4(ug/m²hr), i.e. 39.5(ug/m³). However, TOTAL VOCs matters emit largely and continuously. The two has 5 times difference, indicating that regarding to the control on evaluation factor of TOTAL VOCs in green building materials, the pollutants shall be controlled.

Specimen NO.	BTEX-CONC. mg/m³	BTEX-E.F. mg/m²*hr	TVOC-CONC. mg/m³	TVOC-E.F. mg/m²*hr
S1	0.187	0.234	1.46	1.83
S2	0.095	0.119	0.82	1.03
S3	0.019	0.025	0.34	0.43
S4	0.018	0.022	0.56	0.71
S5	0.687	0.854	2.55	3.19
S6	0.031	0.039	0.28	0.35
S7	0.028	0.035	0.77	0.96

Table 7: S1-S5 GBMs emission BTEX and TVOC

The evaluation classification of health green building materials mark in this research is in the view of EU and other developed countries' control on indoor air quality and building materials emission. Regarding to TVOC, the quality standard for indoor air by Environment Protection Administration, Executive Yuan can be referred and 12 VOCs in TVOC (i.e. benzene, carbon tetrachloride, chloroform, 1, 2 - dichlorobenzene, 1, 4 - dichlorobenzene, methylene dichloride, ethyl benzene, styrene, tetrachloroethylene, trichloroethylene, methylbenzene and xylene) are evaluated. With regard to simple VOCs, EU-LCI emission control value formulated by EU can be referred to be synonymous with international trade and technical standards and guarantee the health of Taiwanese.

It is suggested to control the evaluation factors of TVOC emissions from green building materials in Taiwan. The TVOC emission standard is: E1 (less than 0.005 mg/m^{2*} hr), E2(0.005-0.06 mg/m^{2*} hr), and E3(0.06-0.19mg/m^{2*} hr).

Health-GBML levels	Newly Emission Evaluation Classification TVOC(with BTEX substance and Carbon tetrachloride、Chloroform、1,2-Dichlorobenzene、1,4-Dichlorobenzene 、Dichloromethane、Styrene、Tetrachloroethylene、Trichloroethylene)
E1	TVOC≦0.005 mg/m^{2}*hr
E2	0.005＜TVOC≦0.06 mg/m^{2}*hr
E3	0.06＜TVOC≦0.19 mg/m^{2}*hr

Table 8: The newly health GBMs TVOC emission evaluation classification

4. DISSCUATION AND CONCLUATION

In the evaluation of emission factor for a GBMs in Taiwan, the main emission control items are dominated by TVOC (BTEX) and formaldehyde, while the TVOC control in the indoor air quality standard includes 12 VOCs. Green building materials label should be used to control TVOC (C6-C16) and cancerogens. The EU's LCI (lowest concentrations of interest) and CREL (chronic respiratory exposure limit) should be adopted as the standard of emissions control from building materials and the grading system of emissions from building materials.

This study selected paint with a building materials label for analysis, sampled 7 small pieces of paint for an emission test, and conducted a 48-hour qualitative and quantitative analysis. The results showed that the VOCs (BTEX) of the tested green building materials was extremely low, meeting the evaluation standard (0.19 mg/m^{2*} hr). However, the emission of other VOCs continues and the TVOC content ranged from 0.073 to 9.071 (mg/m^{2*} hr), indicating that there was still emission of a large amount of unregulated pollutants.

ABSTRACT

Urbanization especially in developing countries is a major driver for economic and social development. However, it has induced major concerns from past urbanization experiences, such as air pollution, traffic congestion, and habitat destruction. Such adverse effects caused by urbanization have generated greater pressures on governments to re-think their urban development policies to be sustainable ones. Within this context, various sustainability assessment methods have been developed by existing studies. Due to the dynamic features of sustainable development, fuzzy logic has been widely used for measuring sustainability performance. However, it is argued that most studies are using pre-defined simple linear membership functions and fuzzy rules which are mostly based on experts' knowledge. The assessment results may not reflect the real sustainability performance. Therefore, there is a need to develop a new approach for induction of membership functions and fuzzy rules. This paper aims to introduce an adaptive neuro-fuzzy inference systems (ANFIS) approach for city level sustainability assessment. The membership functions and fuzzy rules are generated from 185 training samples. The results show that the new ranking of the selected 185 cities in China is close to the original with minor differences. It indicates that the new approach is valid and effective.

Keywords: urban sustainability, ANFIS, fuzzy logic, artificial neural network

1. INTRODUCTION

The urbanization process involves the people migrating from rural to urban areas, which has been recognized as a major driver for economic and social development. However, the rapid urbanization has also posed various problems such as traffic congestion, air pollution and rising crime rates (Shen et al., 2015b; Zhang, 2015). Sustainable urbanization can be defined as "…urbanization practice, which complies with sustainable development principles (Roy, 2009)". Sustainable urbanization is a dynamic process that combines environmental, social, economic and political-institutional sustainability, which complies with sustainable development principles (Zhou et al., 2015b). It has been projected by UNDESA (2014) that, in China, 76% of the population will live in cities by 2050. The figure is already 54% in 2014. This rapid urbanization growth has led to the need to understand urbanization as a major contributor to resource consumption and environmental and social damage (Isendahl and Smith, 2013; Zhou et al., 2015a). For example, the research by Shen et al. (2015b) revealed that during the urbanization process in China, approximately 2.5 to 3.0 million farmers per year lost their farm lands in recent years because of land expropriation, which also adds to the problem of social instability because the majority of these farmers could not find new jobs in cities. It becomes necessary for local governments to re-think related policies for sustainable development of cities.

In line with the promotion of sustainable urbanization, both international institutions and governments at different levels are seeking solutions that integrate, in harmony, environmental, community and economic requirements. With the aim of understanding and monitoring urban sustainability performance, different assessment tools have been developed (Phillis et al., 2011; Singh et al., 2012b; Shen et al., 2011; Shen et al., 2015a; Tan et al., 2015; Tan et al., 2014; Tan et al., 2011; Yao et al., 2011; Zhang, 2015; Zhou et al., 2015b; Zijp et al., 2015). Among them, fuzzy logic is a widely used method to assess sustainability performance. For example, Phillis et al. (2011) introduced the Sustainability Assessment by Fuzzy Evaluation (SAFE) model for assessing the overall sustainability performance at global level. Giordano et al. (2014) applied Takagi–Sugeno fuzzy model to measure the urban ecological efficiency. However, pre-defined membership functions (triangular or trapezoidal) and fuzzy rules are commonly used in existing studies. It is commonly appreciated that the use of pre-defined membership functions and fuzzy rules highly depends on experts' knowledge, which may not reflect a real-world situation (Buragohain and Mahanta, 2008; Naderloo et al., 2012).

Therefore, there is a need to explore new methods for induction of fuzzy membership function and fuzzy rules. This paper aims to apply the ANFIS approach to assess urban sustainability based on work by the Urban China Initiative (UCI) (2011).

2. ADAPTIVE NEURO-FUZZY INFERENCE SYSTEM (ANFIS)

An Adaptive Neuro-Fuzzy Inference System (ANFIS) was firstly introduced by Jang (1993), which incorporates the fuzzy logic concept into the neural networks. Integration of fuzzy logic and neural network is a preeminent idea to overcome the disadvantages of fuzzy-set theory. As mentioned before, the pre-defined linear membership functions and fuzzy rules are commonly used in existing studies. ANFIS constructs a fuzzy inference system (FIS) whose membership function parameters are derived from training examples. Therefore, ANFIS integrates the advantages of fuzzy systems for dealing with explicit knowledge, which can be explained and understood (such as a fuzzy inference system), and neural networks for dealing with implicit knowledge, which can be acquired by learning (such as membership function) (Singh et al., 2012a).

The architecture of a typical ANFIS consists of five layers, which perform different functions in the ANFIS and are described below (Jang, 1993). For example, if an FIS has two inputs (x,y), two if-then fuzzy rules, one output, and each input has two associated membership functions (MFs). The ANFIS structure is shown in Figure 1 (Singh et al., 2012a).

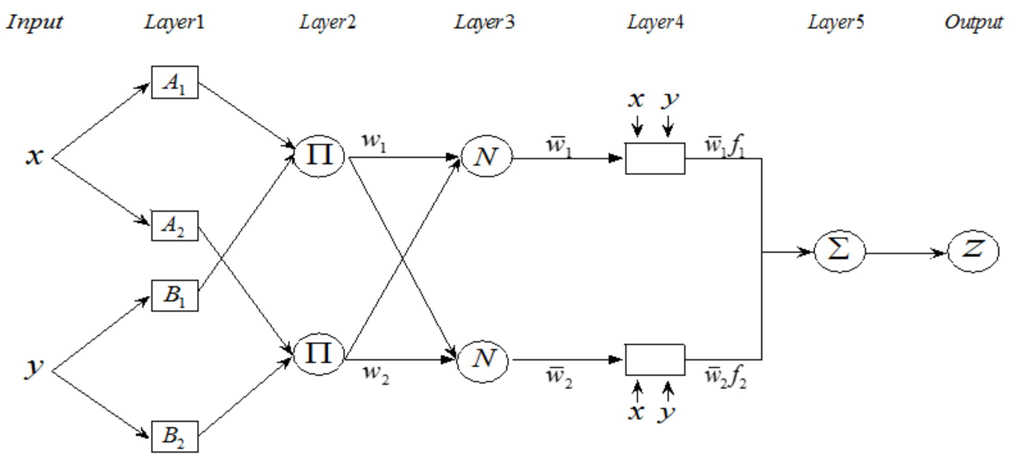

Figure 1: ANFIS structure for a Takagi-Sugeno model with two inputs and two rules

3. URBAN SUSTAINABILITY ASSESSEMENT BY USING ANFIS APPROACH

3.1. Hierarchical structure of ANFIS model

This study is based on the research by the Urban China Initiative (UCI) (2011). UCI is a joint initiative and is led by three major founding institutions: Columbia University, Tsinghua University, and McKinsey & Company. With the ANFIS approach, a bell-shaped membership function will be used because this distribution fits many real-world problems (Ekici and Aksoy, 2011). In their study, a three levels hierarchical structure was established to evaluate urban sustainability in China. Overall urban sustainability performance is the first level. There are four categories in the second level, including social, environment, economy and resource groups. Each category comprises sub-categories. A total of 23 basic indicators are used to describe the sub-category (Urban China Initiative (UCI), 2011). Based on the principle of the ANFIS and the work by the Urban China Initiative (UCI) (2011), the hierarchical structure of ANFIS model is developed, as shown in Figure 2. There are seven ANFIS models for evaluating urban sustainability performance.

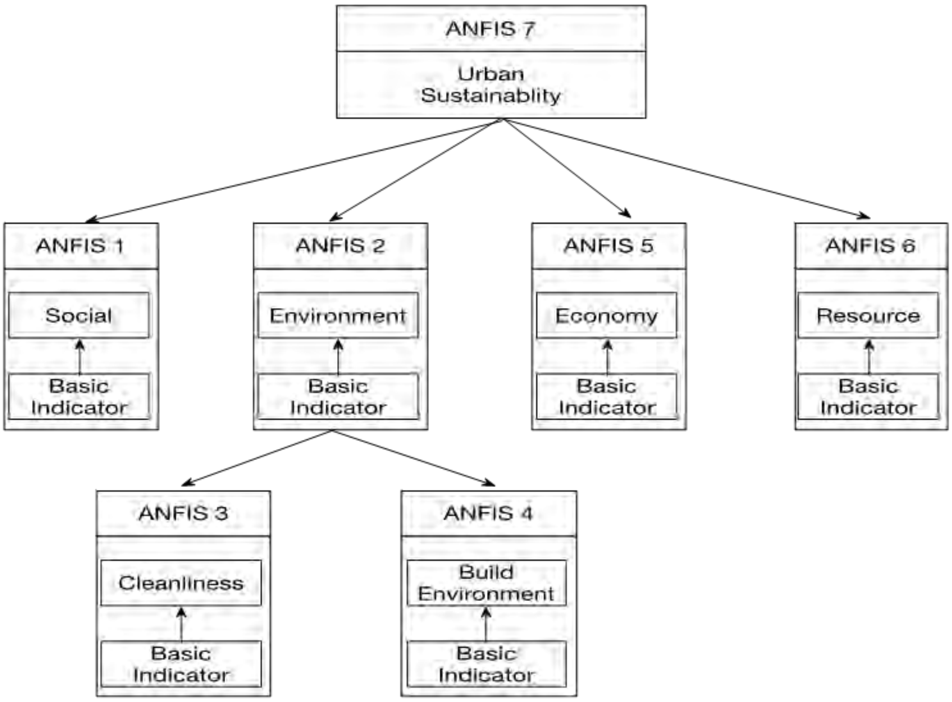

Figure 2: Assessment framework of urban sustainability performance

3.2. Data collection and modelling

The Urban China Initiative (UCI) (2011) has applied the same indicator system to assess the urban sustainability performance of 185 cities in China over the period of 2005-2011. Wang and Elhag (2008) suggested that the reasonable ratio to assume between the training and checking samples is 4:1. In this study, the data from 2005-2008, with the 185*4 = 740 groups, are used as the training samples, and the data of 2009, with the 185 groups, as the checking sample. The data of 2010 and 2011 are used as validating samples.

After collecting the data, the ANFIS model is developed by using the fuzzy logic toolbox of the MATLAB software package. There are five input variables and each variable has three linguistic values with overall 243 if-then fuzzy rules.

3.3. Training and checking

In this part, the developed ANFIS model will be trained and checked using training and checking data. The details of training method including the gradient method and the least-squares estimate method can be found in the study of Jang (1993). Taking ANFIS 1 as an example, there are 740 groups of training samples. The initial epochs are set as 100 in this study, and the training error is 0.033, which is acceptable for the trained ANFIS (Sun et al., 2015). After training, the new membership Functions (MFs) and fuzzy rules are obtained, are shown in Figure 4 and 5.

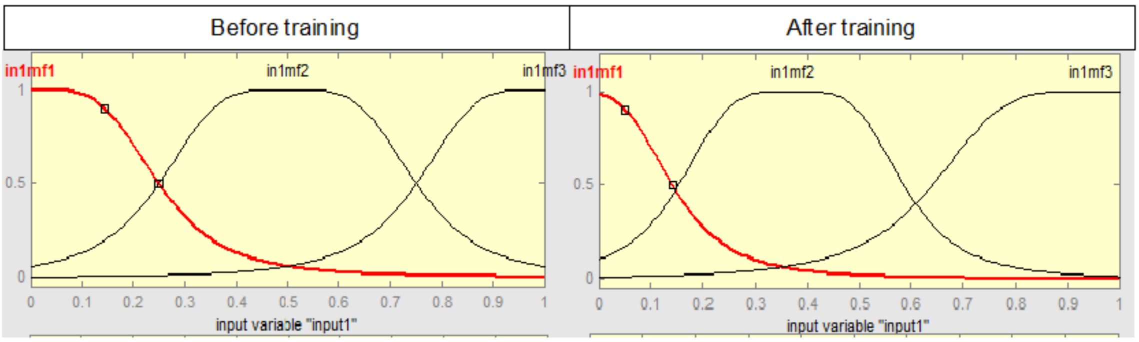

Figure 4: An example of membership function before and after training

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

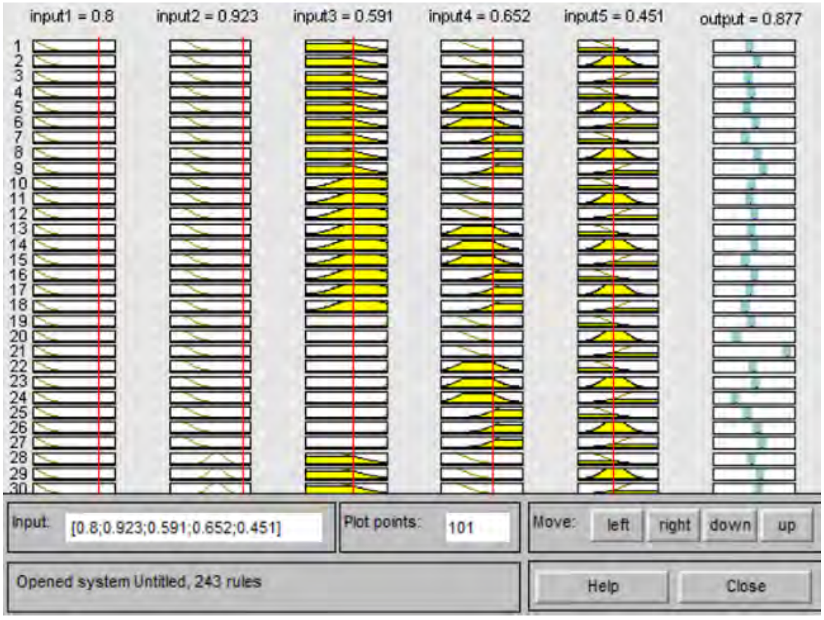

Figure 5: If-then rules after training

After training the ANFIS model, the next step is to check the accuracy of the trained ANFIS model. The checking results show that the outputs from the ANFIS model fit the checking data very well.

4. DISCUSSION

After training and checking, the overall sustainability performance of 185 cites were re-assessed by ANFIS method using the data of years 2010 and 2011. The new ranking is very close to the original. The largest difference is the city “Lanzhou” in 2010, ranking 116 in UCI and ranking 106 in ANFIS. The difference is mainly because the membership functions and if-then rules are from training. The final ranking may be different with different training samples. Therefore, it is important to select appropriate training samples so that the trained membership functions and if-then rules can fit the situation of the real-world. The selection of appropriate training samples will be examined in future research.

5. CONCLUSION

Sustainability is a complex and dynamic issue. Many assessment methods have been developed. Yet the main challenges are still vagueness, subjectivity and dynamics involved in the assessment. To overcome these problems, an adaptive neuro-fuzzy inference system (ANFIS) was introduced in this study for urban sustainability assessment. The membership functions and fuzzy rules can be obtained from training samples rather than from experts’ knowledge. The robust validation process reveals that the ANFIS method is appropriate for urban sustainability evaluation.

One limitation of this study is that there is only one data source, the UCI. The assessment results are very close to those from UCI sources. It indicates that the ANFIS method is effective, but needs to be further improved by using training data from other sources. The Membership Functions (MFs) and if-then rules can be improved in a further study by using training data collected from different sources, such as UN-Habitat, or World Bank. Furthermore, sustainability assessment is a dynamic process. The indicators, benchmarks, or rules may change. However, the ANFIS method can meet the dynamic requirements through new training, with new data and new rules.

ACKNOWLEDGEMENT

This research was fully supported by a grant from the Research Grants Council of Hong Kong Special Administrative Region, China (Project No. F-PP2F). We also would like to thank UCI for providing the training data. The authors would also like to acknowledge the editing by Dr. Paul W. Fox of an earlier draft of this paper.

ABSTRACT

Although urban areas cover only 3% of the earth's land surface, they are responsible for over 70% of greenhouse gas emissions (GHGE) from energy use. Cities are versatile, dynamic and complex. Therefore, implementations of low carbon initiatives at city scale are challenging and at times impractical. From the local administration perspective, the precinct scale represents a manageable operational scale for governance, urban planning and socio-technical innovations. There are various methods for quantification of GHGE at building, precinct, city and national scales, but few target the complexity and dynamics of the urban area, especially at the precinct scale. The aim of this paper is to identify a suitable quantification method for the precinct scale. The method should be able to determine the changes in GHGE due to implementations of low carbon policies and other strategies. This paper reviews the available methods for quantification of GHGE and highlights their challenges and limitations. Since urban areas need a system thinking approach, this review outlines how the methods analyse complex systems, such as System Dynamics (SD).

Keywords: quantification of GHG emissions, low carbon, precinct

1. INTRODUCTION

Urban areas, such as cities, are responsible for a significant portion of greenhouse gas emissions (GHGE) and at the same time, are vulnerable to climate change impacts. Urban energy systems are resource intensive and fossil fuel dependent, contributing to the high concentrations of GHGE released from urban areas. This situation could be exacerbated if the proportion of the global population living in urban areas increases from 50% to 66% as predicted for 2050 (UN 2015). To sustain this urban population growth while reducing GHGE and city's vulnerability, urban areas need to transition from carbon intensive to low carbon practices.

Therefore, measurement and quantification of GHGE in urban areas are vital to develop mitigation, adaptation strategies and to achieve GHGE reduction targets. Quantification methods should be able to capture the changes of GHGE from different low carbon policies and other strategies. These methods have been developed for different purposes such as monitoring, reporting, planning, decision-making, and analysis of land-atmosphere carbon exchange. These methods distinctly define spatial and temporal system boundaries, making their comparison a challenging task. Furthermore, most of the methods, such as rating tools and accounting methods, fail to capture the dynamics and complexities inherently present in urban areas.

There is a need for methods to capture these complexities and dynamics. Therefore, the aim of this review is to identify the most appropriate method to quantify the changes of GHGE from low carbon initiatives in urban precincts. To do so both academic and grey literature in quantification of GHGE were reviewed to identify 1) the techniques for quantification of GHGE in urban areas 2) explain challenges and limitations, and 3) propose a suitable approach to quantify changes of GHGE in a precinct scale when testing low carbon strategies. Since energy systems are an essential part of an urban area and significant generators of direct and indirect GHGE, contribution from review articles on energy methods, tools and models are taken into account in this paper.

Section 2 presents a general overview of the techniques used for quantification of GHGE in urban areas. Section 3 discusses challenges and limitations of current techniques and explains why those in the complex system realm are the most appropriate for the purpose of quantifying GHGE when analysing low carbon strategies at the precinct scale.

2. QUANTIFICATION OF GHGE IN URBAN AREAS

2.1 Complexity, dynamics and scale considerations

Cities have extensive mixed land use areas with distinct characteristics and infrastructures of provision, governed by different authorities and accommodate diverse occupant profiles. Cities and, in general, urban areas should be regarded as complex systems. They are also dynamic. Their dynamics link to different rates of changes of their subsystems, for instance slow land use change compared to fast transport of goods (Simmonds et al. 2013).

These intertwined relationships and different rates of change clearly intensify the implementation challenges for low carbon strategies at a country or city scale. A precinct or neighbourhood, however, represents a more manageable scale (Rauland 2013). In precincts, likeminded communities might easily engage and collaborate with initiatives. Also, a precinct represents an operational unit where low carbon strategies can be developed accordingly to the site characteristics and requirements, taking into account the physical and socio-economic relationships even outside its immediate boundaries. This review investigates different types of quantification of GHGE but focus the analysis at the precinct scale since the idea of targeting an intermediate scale, between the city and the individual building, to implement low carbon initiatives.

2.2 Methods

Quantification methods are developed for reporting, rating, decision-making, design and urban planning, and policy making purposes. In general, urban GHGE quantification methods can be classified as top down, bottom-up or hybrid (Ou 2012; van Vuuren et al. 2009). The characteristics and limitations of these three main approaches have been reviewed before by other authors. This review investigates at more specific models and tools (e.g. bottom-up building stocks).

Different international protocols and standards, developed for the quantification of GHGE since the late 1980's, follow a top-down approach, using econometric models and accounting methods at macro scales. The top-down quantification of GHGE using econometric models emphasizes the analysis on market processes by studying the economy of a country as a whole. This type of approach overlooks sociotechnical detail, it is static and uses highly aggregated historical data.

On the other hand, bottom-up methods look at individual technologies or energy consumption in houses and extrapolate them to the regional or national scale. They use statistical or engineering methods. While these methods capture sociotechnical and other details (e.g. building physics), they overlook their relationship with the economy. Although both methods, top-down and bottom-up, have different applicability, they can be combined to take a hybrid approach.

There are more comprehensive models that take the sustainability triple bottom line perspective, assessing not only GHGE but also other environmental and socio-economic impacts. They use geographical information systems (GIS), optimization algorithms and scenario analysis. These types of models are mostly used by the design and urban planning sectors for decision-making at early stages of a project.

The typical spatial scales used for quantification are building (micro), neighbourhood (local) or city/country (macro) scales. At micro scale (building), the most common and accepted approach for environmental impacts is Life Cycle Assessment (LCA). LCAs can include energy and/or greenhouse gas (GHG) analysis, life cycle eco-footprint, and integrated criteria weighting as part of their methodology (Iwaro et al. 2014). This method has contributed significantly to the analysis of impacts in the built environment.

LCA has also been developed in recent years for local scales. There is sound research on residential configurations and related GHGE (Crawford and Fuller 2011), as well as preliminary work on urban-building life cycle analysis and interactions (Stephan 2013). LCA can incorporate scenario analysis and complement the assessment with GIS techniques. Lotteau et al. (2015) presented a comprehensive review of LCA for local scale. The authors proposed a common definition of a Functional Unit (FU) to improve comparability and analysis. They also claim for a clear contextualization of the neighbourhood and a clear definition of temporal scales to improve decision making.

Another key approach for local scales is the bottom-up building stock models reviewed by Kavgic et al. (2010), where building physics and empirical data can be combined to estimate the energy consumption and related GHGE.

The issues including lack of data transparency, data availability and uncertainty related to how society consumes energy and reacts to changes from energy policies were identified.

Local and macro (City) scales can be also analysed with the urban metabolism (UM) methodology (Codoban and Kennedy 2008; Kellett et al. 2013; Kennedy 2011). UM is applied as an accounting method mainly looking at mass balance and "emergy" of a system. Pincetl et al. (2012) presented how UM can be expanded to allow a more comprehensive and integrative assessment by evaluating electricity, water and solid waste flows plus a LCA of the related infrastructure.

Other accounting methods at local and macro scales are: carbon accounting with input-output models (Wiedmann 2009), GHG footprint, GHG inventory analysis (Chester et al. 2014) and protocols, i.e. The Global Protocol for Community Scale (WRI 2014). These accounting methods of material and energy flows are useful to identify mismatches between demand and supply but they take a static approach.

Allegrini et al. (2015) present a review for the design and planning of district-scale energy systems, highlighting the need for simpler decision making tools, holistic approaches and the opportunity to integrate different models. For decision making and urban planning at this scale, the use of urban simulation models (Rager et al. 2013; Waddell 2002), survey data analysis (Newman and Kenworthy 1989), and material flow (Goldstein et al. 2013), are the most common methods.

All methods described so far are still considering urban areas as static systems. System thinking (ST) is potentially the most convenient perspective that addresses urban areas as complex systems as it is focused on the entire system as a whole, while also accounting for its components and subsystems and how they interact with each other (Waltner-Toews et al. 2008).

However, ST ignores the main relationships with the outside boundary of the system under study. Methods for modelling complex systems following the ST perspective such as System Dynamics (SD) (Feng 2013; Wang et al. 2012), Cellular Automata (CA), and Agent Based Modelling (ABM) (Aschwanden et al. 2012; Natarajan et al. 2011) have the potential to better capture the characteristic features of urban areas.

2.3 Models and tools

A selection of few representative tools is described in this subsection. In general, models and tools for quantification of GHGE build upon one or more methods described before. Rauland (2013) presented a review of typical tools used at precinct scale, including the designing tools eTool and CCap. These tools include quantification of GHGE among other performance metrics for decision making at design stages, but they do not take into account all the subsystems present within an urban ecosystem. The review highlighted the need for a precinct scale GHGE framework using LCA to calculate embodied and operational emissions.

Alternatively, the Australian Stocks and Flows Framework (ASFF) was developed by CSIRO to deal with the processes that support economic and social activities and describe them in dynamic and in physical terms (Turner 2011). ASFF describes the biophysical Australian environment combining different methods such as LCA, and metabolism-based such as mass-flow analysis. All methods are linked as calculators using nationwide databases and simulation processes that complement the analysis tool using what-if scenarios. It is a powerful and comprehensive framework for national and regional scales, but it lacks the finer data resolution needed at the precinct scale.

The urban planning tool, Integrated Resource Management (IRM), is a complex excel spreadsheet (Birch et al. 2013) used as a guidance tool for sustainable urban design and planning. It offers a common framework where urban designers and technical teams can design processes to capture key performance indicators (Page et al. 2008), but they do not capture the urban ecosystem dynamics.

MUtopia is a simulation tool for engineering sustainable systems in local scale. This platform integrates areas such as energy, water supply, waste and transport through spatial data infrastructure. The platform allows testing different scenarios including impacts in GHGE from distributed infrastructure of water or energy supply (Bishop et al. 2008). However, the results are limited due to the assumptions made to simplify the models (Ngo et al. 2014).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

UrbanSim is a simulation software tool for urban planning. It assesses the impacts of infrastructure within a metropolitan area by integrating the interactions and approximating the dynamics between land use, transportation, the economy and the environment. UrbanSim is the only tool within this selection that uses ABM, a method from the complex systems realm. It is a powerful open source simulation tool for local scale, but it lacks the integration of other infrastructures of service such as water, waste, and electricity.

3. DISCUSSION

This section describes the limitations and challenges of the methods and tools reviewed, describing a suitable GHGE quantification approach at the precinct scale.

3.1. Limitations and challenges

All the methods reviewed define different system boundaries, functional units, spatial and temporal scales for analysis, making their comparison challenging. Methods, such as carbon accounting, usually follow a top-down approach, and long temporal and broad spatial scales hindering the identification of potential opportunities to reduce GHGE at the precinct scale. Moreover, reporting and accounting methods are static and do not have the capacity to test future scenarios, diminishing their ability to analyse different policies or interventions.

Most of the methods limit their quantification to operational impacts, while there is a need for tools able to assess operational and embodied impacts simultaneously (Newton 2013). Linked to the need for embodied impact data, is the need for finer data resolution in order to capture the complexity of urban ecosystems. However, balancing complexity and computing costs with accuracy represents a challenging task. Nevertheless, the most important limitation for any method is the availability of representative, complete and consistent data of the urban ecosystem under study.

Also, methods should include the dynamics related to different rates of change of subsystems, which increase the system complexity and uncertainty. Uncertainty analysis should be performed and used to visualise the evolution of different parameters of an urban area, especially when analysing transitions to low carbon futures.

3.2. Appropriate method

Embedded systems and processes in precincts, such as the energy system and related GHGE, have all the main characteristics of complex systems, including agents, networks, path-dependency, emergence and co-evolution (Bale et al. 2015). Therefore, complex systems approaches may better represent transitions to low carbon futures than carbon accounting methods. The sustainability transition modelling community uses ABM or SD to simulate and explore socio-technical transitions in the built environment (Li et al. 2015), mostly assessing the energy area and related GHGE.

ABM is well suited to represent a high degree of heterogeneity across entities assuming there is perfect information about the interaction network. However, this level of detail comes at a high computational cost that limits the use of the model for sensitivity analysis for policy making, increases the complexity of understanding the causes of the results (Rahmandad 2008) and relies heavily on data accessibility which in most real world scenarios is unavailable.

In contrast, SD relaxes the level of detail of the entities through aggregation and lends itself to fast scenario analysis, at the cost of losing track of possible metrics. The design choices when modelling with SD should be made to capture the main metrics accurately, ignoring only the ones that are less important for policy making. Also, Discrete Event (DE) modelling can be easily integrated along with SD to model micro level details that do not involve continuous processes, such as traffic flow, and commuting patterns (Borshchev 2004; Zeigler 2000).

The ST perspective, which analyses the whole system, its subsystems and their interactions, is a valid approach to describe complex systems. However, ST ignores the relationships with the outside boundary of the main urban system under study. Therefore, models driven by the ST approach should be expanded to approximate the main relationships of the system with its outside boundary, especially the ones linked to changes of GHGE.

In terms of tools, ASFF and UrbanSim show the potential for coupling modelling methods, a valid option for assessing possible futures in urban ecosystems (Sheridan et al. 2016). Any successful method for quantification of GHGE changes should include features such as coupled modelling and different time delays (e.g. Urbansim), to better represent the complexity and dynamics of urban ecosystems. Furthermore, suitable methods should be flexible to include data from low carbon initiatives already applied in other contexts as demonstration projects. This data can be used as inputs of the model to examine GHGE reductions from distributed infrastructures, or other technological scenario adoptions (Mohareb and Kennedy 2014).

Moreover, future transitions to low carbon precincts are uncertain in nature, therefore the use of exploratory modelling and analysis represent an opportunity to discover what could happen (Maier et al. 2016), even if the scenarios are generated externally or strategically for decision making (Börjeson et al. 2006).

4. CONCLUSION

The methods for quantification of GHGE in urban ecosystems were reviewed. It highlighted the importance of targeting urban areas at the precinct scale when implementing low carbon initiatives; therefore the review includes quantification models and tools at this specific scale. It summarises the limitations and challenges of different methods and suggests that future work on quantification of urban GHGE should use models with the underlying methodologies from complex systems. The analysis of urban areas, regarded as urban ecosystems, could benefit from the systems thinking approach with a multidisciplinary perspective when quantifying GHGE changes. It is also recommended the use of exploratory modelling and analysis. This would assist representing different future pathways of low carbon transitions and accounting with the inherent system uncertainties.

ABSTRACT

*I*nspired by the increasing urbanization and urban heat island effect (UHI) issues, an innovative concept called Local Climate Zone (LCZ) was developed to standardize and classify various built environment. The LCZ system was use to evaluate the relationship between UHI and urban characteristics which included land cover, sky view factor (SVF), building height, surface albedo and roughness. Due to the previous research had revealed the LCZ system were highly related with the micro-climate condition, this work attempt to apply the LCZ into consideration of adapt the sustainable planning in urban built environment by comprehend the relevance between the thermal load and the LCZ distribution. The Tainan city was selected to be the study area because of the growing thermal stress and the reduction of ventilation path in the rapid urban development. In term of the LCZ classify method, the World Urban Database and Portal Tool (WUDAPT) was applied through the Landsat satellite image to make a wild range LCZ distribution map in an efficient way. In this study, there are two main issues discussed in the study. Firstly, to identify the LCZ by several methods and confirm if it is correct in reality. Secondly, to propose a method to quantify the thermal conditions in different LCZs in the urban area. The analytical results indicated that the WUDAPT may overestimate the building height compared to the actual height by the building digital map. It may due to the resolution in the satellite image is insufficient and the areas with small amounts of tall buildings will be still regards as compact high-rise areas. Concerning the thermal conditions in various LCZ, it is obvious that the highly developed urban areas, such as LCZ2 (Compact mid-rise) and LCZ3 (Compact low-rise) have a higher thermal stress distribution, while the natural areas such as LCZ 6 (Open low-rise), LCZ 9 (Sparsely built), got lower PET value based on the measured data. The result will contribute to the urban climate study and benefit to the sustainable development in the urban areas.

Keywords: local climate zone, WUDAPT, thermal conditions

1. INTRODUCTION

In the urbanization process, the thermal environment of cities has greatly changed due to the reduce of green area and the increase of buildings (Kent, 2011). Urban areas are generally warmer than their rural counterparts. This urban-rural temperature difference is known as urban heat island effect (UHI). Recently, global warming has exacerbated the phenomenon of UHI and threatening the health of urban dwellers. As urbanization is a long-term global trend, understanding how land development is associated with thermal environments becomes an important task for governments to adapt cities to hotter and longer summer.

Previously studies regarding thermal environment distribution in urban areas is highly related to the land use and land cover of the areas, and connected to urban morphology and building typology. However, there are many information required and should be prepared before the analysis. Therefore, this research uses an innovative method called Local Climate Zone (LCZ) (Stewart and Oke 2012) to substitute the traditional land zoning system which was developed for managing land resources by dividing land into various types, such as commercial, residential, and agricultural zones. Furthermore, LCZs can be classified into 17 basic categories, based on ten parameters, including sky view factor, aspect ratio, building surface fraction, pervious surface fraction, and impervious surface fraction, height of roughness element, class of terrain roughness, surface admittance, surface albedo, and anthropogenic heat output.

In this study, there are two main issues discussed in the study. Firstly, to identify the LCZ by several methods and confirm if it is correct in reality. Secondly, to propose a method to quantify the thermal conditions in different LCZs in the urban area. The result will contribute to the urban climate study and benefit to the sustainable development in the urban areas.

2. Method

2.1 Study area

As a high development city (22˚59'N, 120˚11'E) in the south of Taiwan, Tainan is selected to be the study area (Figure 1). The total area of Tainan is 175.6465 km2, including 6 administrative districts. In 2010, Tainan city had been upgraded to a special municipality. However, this transformation results the increase of population and land operations, make it urgently and necessary to consider of microclimate research in order to give local government assistance by making urban development policies. The Tainan city is in tropical areas, the annual mean temperature in this area is 24.6°C. July is the hottest month; the mean temperature is 30.4°C, January is the coldest month; the mean temperature is 17.6°C, and the annual mean relative humidity is 74.4%.

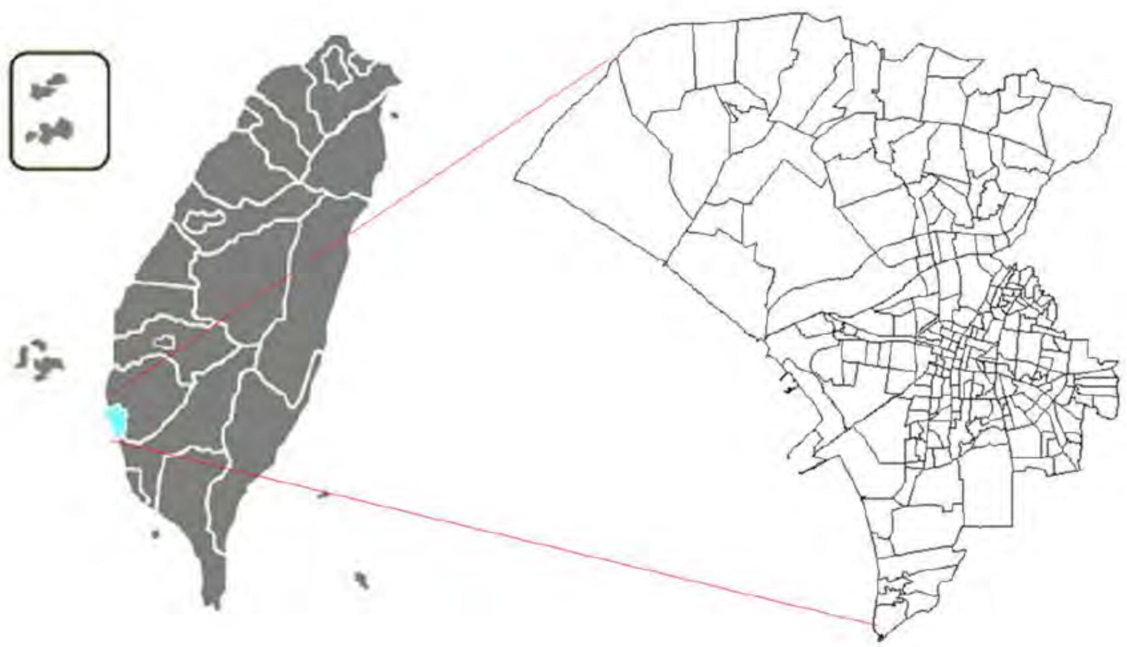

Figure 1: Study areas of Tainan city, Taiwan

2.2 The classification of LCZ

This study applied LCZ, a systematic classification scheme developed by Stewart and Oke (2012), to map land development patterns into climatological related zones. The scheme defines land development patterns according to the structural properties of buildings and vegetation, such as types, height, and density, as well as the types of land cover. Following the instruction on the World Urban Database and Access Portal Tools (WUDAPT), this study prepared the training areas of LCZs in Taipei Metropolis by Google Earth Pro (7.1.5.1557) and utilized SAGA GIS software (2.2.0) to perform classification. Given that LCZ8 and LCZ10 has similar characteristics in Tainan, this two LCZs were combined as LCZ10 for discussion. In total, sixteen LCZs were identified based on the Landsat 8 satellite image acquired on 16 November 2015.

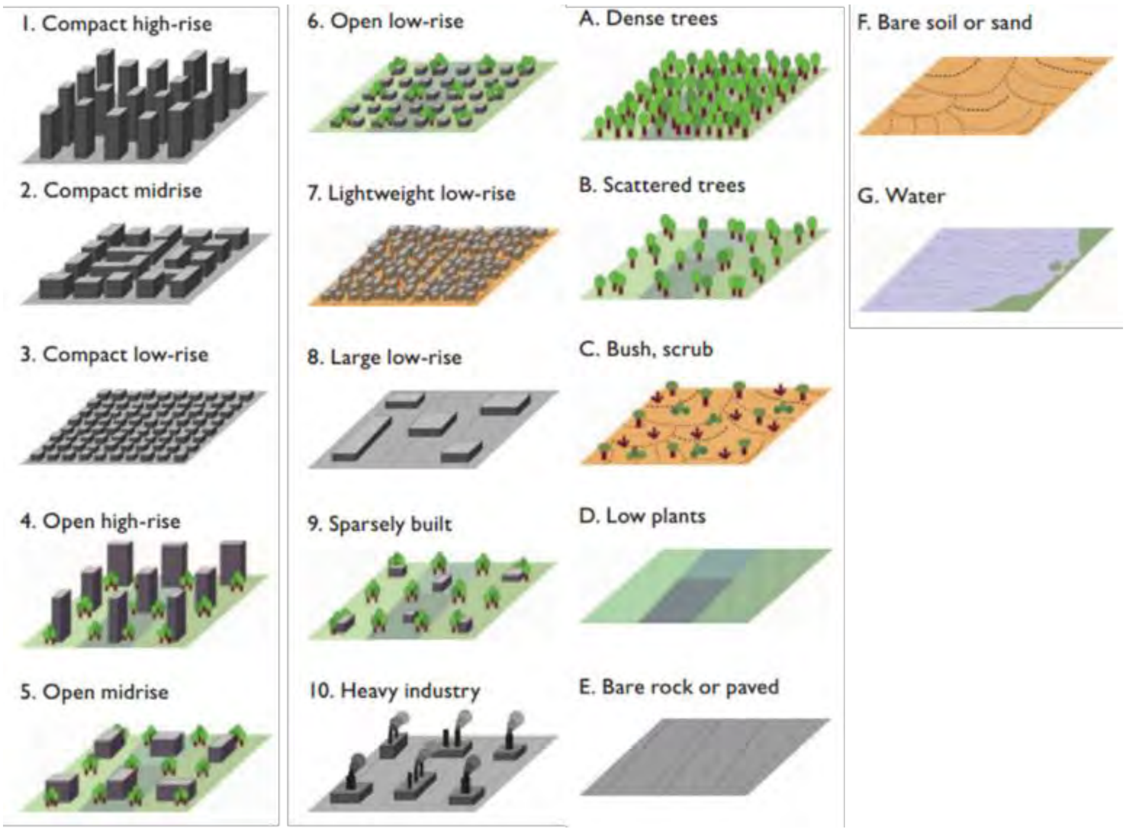

Figure 2: Local climate zone classification

2.3 Thermal conditions data

The thermal conditions data applied in the study is obtained from car traverse measurement on several thermal parameters in the previous project of Tainan cities, named "The development of urban thermal environment climatic map and hotspot analysis." The physiologically equivalent temperature (PET), which has been widely used to evaluate thermal comfort in outdoor spaces, based on the heat balance model of the human body (Höppe 1999; Matzarakis et al. 1999; Mayer and Höppe 1987; VDI 1998), are applied in this study for the evaluation of thermal condition in urban outdoors spaces at pedestrian level.

3. RESULT

3.1 The accuracy of LCZ classification by WUDAPT

Figure 3 shows the level 0 LCZ information in Tainan, it is obvious that the core area of Tainan is consisted of LCZ2 (Compact mid-rise) and LCZ3 (Compact low-rise), and the surrounding suburban areas are consisted of c repented as green area and water areas. In order to examine the accuracy of the LCZ generated by the WUDAPT approach and the land-use/ land-cover and building height in reality, the focus area has been selected and comparted, as show in Figure 4

In the focus area we choose the LCZ1 (Compact high-rise) area which is identified by the WUDAPT method and examine whether the height is correct compared the actual height by the building digital map. Finally, 33 grids (comprising 100m*100m for each grid) is selected for the analysis. Figure 5 shows the frequencies of actual building floors in the LCZ1 group classified by the WUDAPT in focus area in Tainan city. There are totally 2080 buildings in these LCZ1 areas.

In the definition of WUDAPT, it should be higher than 10 floor height. However, Figure 5 shows that more than 1445 building (approximate 70% of the total buildings) are lower than 7 floors, and the average height is 4.2 floors. It indicated that the WUDAPT may overestimate the building height compared to the actual height by the building digital map.

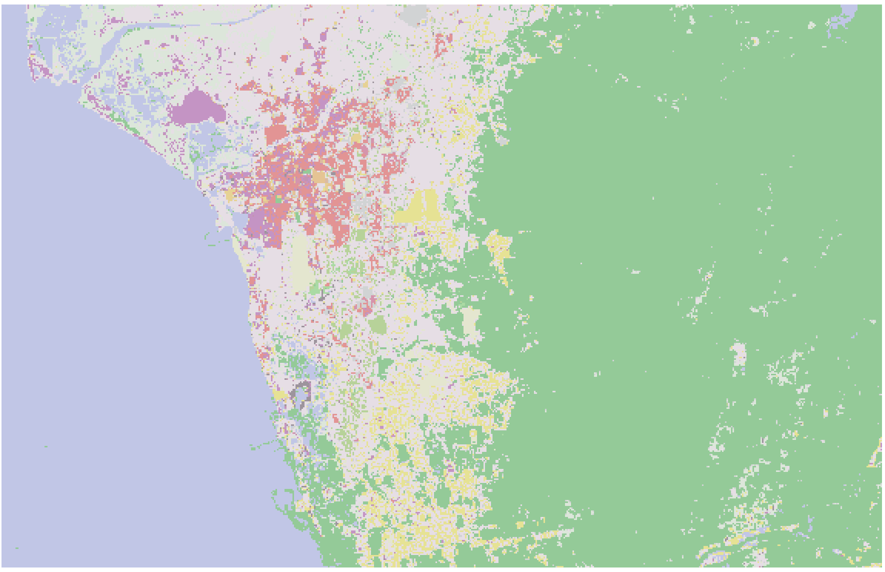

Figure 3: The LCZ map in Level 0 in Tainan city

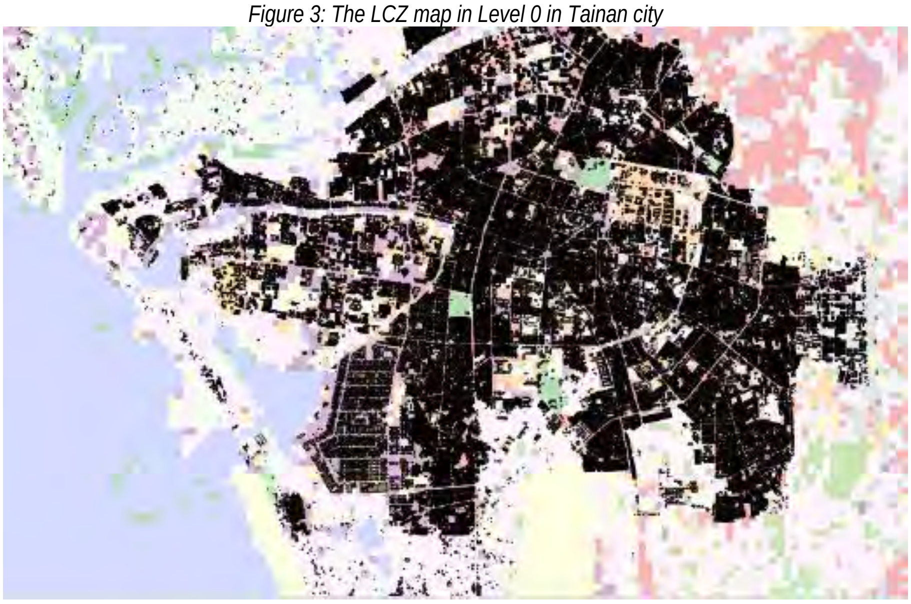

Figure 4: Focus area in Tainan city

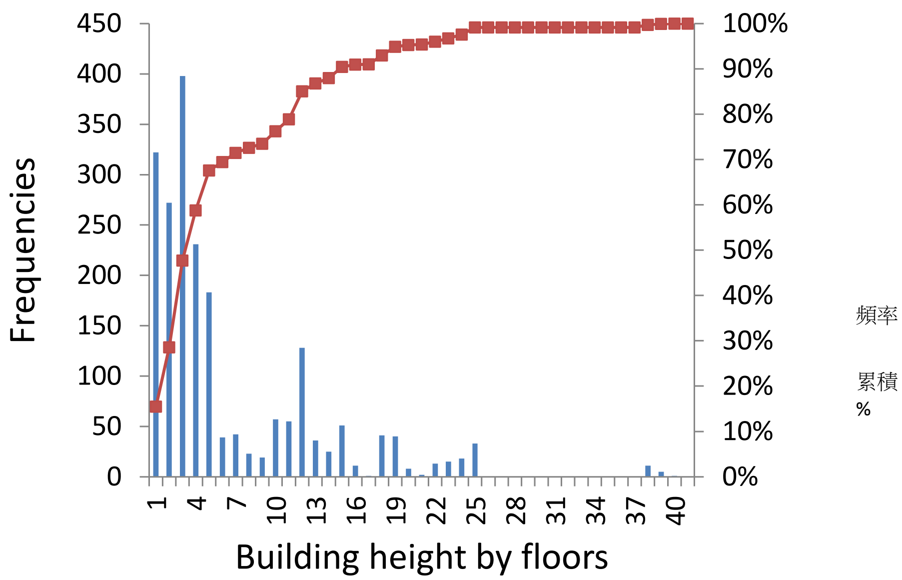

Figure 5: Frequencies of actual building floors in the LCZ1 group classified by the WUDAPT in focus area in Tainan city

3.2 The thermal conditions in various LCZ

Concerning the previous mentioned project on car traverse measurement, the PET of value of each LCZ is analyzed to examine whether the thermal conditions distributions will variate in different LCZs. Figure 6 shows the PET frequency distributions of four types of LCZ that are associated to different distinguishing feature, areas belong to LCZ2 (Compact mid-rise) and LCZ3 (Compact low-rise) have a higher thermal stress distribution, and areas belong to LCZ 6 (Open low-rise), LCZ 9 (Sparsely built) were contrary in low thermal stress. The kurtosis curves for LCZ6 and LCZ9 were higher than those for LCZ2 and LCZ3, revealing that the grids that were associated with LCZ6 and LCZ9 were more likely to have a low thermal load (34 – 35.5°C PET). The grids that were related to LCZ2 and LCZ3 were more likely to suffer from a high thermal load (> 35.5°C PET). Influenced by boundary effects, some grids, such as those associated with LCZ2 and LCZ3, had relatively low kurtosis curves, affecting the performance of nearby grids. The PET values of the LCZ2 and LCZ3 areas have higher variance, indicating that the grids that are associated with LCZ2 and LCZ3 will have a higher thermal load.

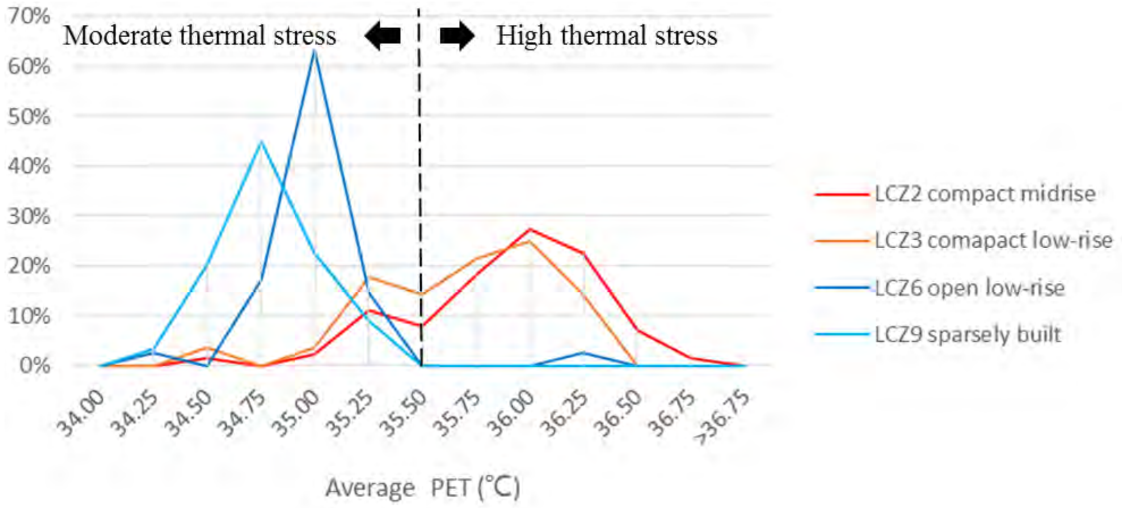

Figure 6: PET frequency distributions of four types of LCZ

4. CONCLUSIONS

Concerning the previous mentioned project on car traverse measurement, the PET of value of each LCZ is analyzed to examine whether the thermal conditions distributions will variate in different LCZs. Figure 6 shows the PET frequency distributions of four types of LCZ that are associated to different distinguishing feature, areas belong to LCZ2 (Compact mid-rise) and LCZ3 (Compact low-rise) have a higher thermal stress distribution, and areas belong to LCZ 6 (Open low-rise), LCZ 9 (Sparsely built) were contrary in low thermal stress. The kurtosis curves for LCZ6 and LCZ9 were higher than those for LCZ2 and LCZ3, revealing that the grids that were associated with LCZ6 and LCZ9 were more likely to have a low thermal load (34 – 35.5°C PET). The grids that were related to LCZ2 and LCZ3 were more likely to suffer from a high thermal load (> 35.5°C PET). Influenced by boundary effects, some grids, such as those associated with LCZ2 and LCZ3, had relatively low kurtosis curves, affecting the performance of nearby grids. The PET values of the LCZ2 and LCZ3 areas have higher variance, indicating that the grids that are associated with LCZ2 and LCZ3 will have a higher thermal load.

Building Envelopes and their Impact on our Urban Thermal Environment

MAING Minjung[a]

[a] *University of Hong Kong, Hong Kong SAR, maing@hku.hk*

ABSTRACT

The way we design our buildings and place them in urban areas, affects our outdoor urban thermal environment through large thermal fluctuations, also described as urban heat island effect. The building envelope is the outer layer of the building that interacts most closely with the outdoor climate conditions and impacts the outdoor through diffuse and reflected radiation off its surface onto pedestrian spaces and streets. How the envelope is designed and positioned can have significant impact and should be considered during the building design process. This paper will discuss the methodology adopted to collect field test data and data analysis findings to describe the effects of different design configurations of building envelopes on pedestrian environment.

Field testing was done in various sites in Hong Kong to measure radiant heat flux of sites of varying amounts of 5 main materials: exterior concrete walls, exterior windows, greenery, adjacent open space areas and visible sky. These materials were then extracted through the dissection of fish-eye photographs to isolate and determine ratio of each of the materials, referred to as view factor analysis. The four main view factors used or developed were: sky view factor, sunlit view factor, green view factor, glass view factor. These view factors were studied against the radiant fluxes to find key discoveries of the relationship between short-wave and long-wave radiation and mean radiant temperature (MRT) which is a thermal index used to understand the thermal comfort of a person from net radiant heat loss and gain. Some of the findings are summarized as the more spread apart building or lower height building envelopes may increase short wave radiation however reduce long-wave radiant heat flux meaning less trapped heat within the buildings. Glass buildings performed badly under direct sun, however under indirect sunlight conditions, performed better than opaque concrete building envelopes.

Keywords: micro-climate, building envelope, view factor analysis

1. INTRODUCTION

The building envelope is the outer-most interface of the building between the outdoor and indoor environment and in contemporary building design, this separation forms clear demarcation between outdoor as public space and indoor as private space. The impact of the building envelope during the design process is typically considered for indoor thermal comfort. More recently, with increased attention to the effects of buildings on urban environment and climate change, the effect of the building envelope on outdoor urban thermal environment is an emerging research topic and this paper describes research conducted on buildings envelopes in a high density city of Hong Kong.

Buildings affect our outdoor environment through large fluctuations of temperature from stored and trapped heat as observed as urban heat island effect. Research has been conducted on studying the impact of building masses and of urban parks in cities using field measurement and computer simulation methods analysing outdoor thermal environment. It is generally agreed that urban configurations play an important role in the urban thermal balance. This paper describes the field measurement methodology used and a new approach of data analysis through a close examination of view factors and radiant flux to investigate the relationship between building envelope and outdoor thermal environment.

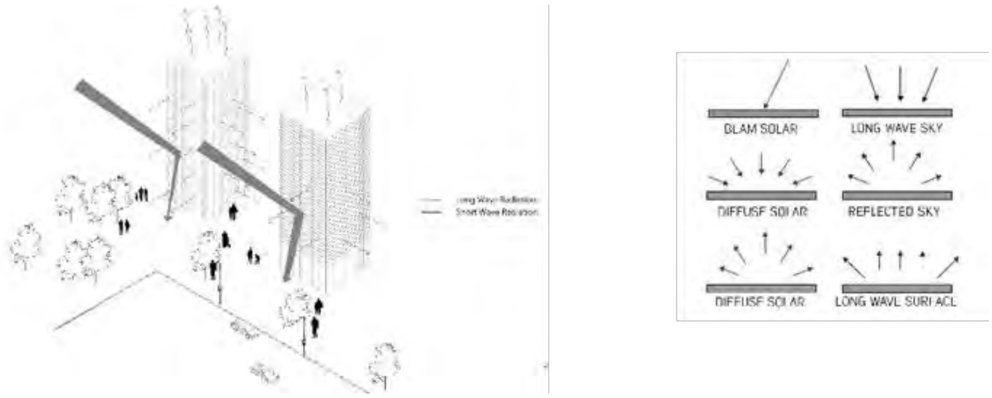
2. METHODOLOGY

2.1 Outdoor thermal environment

The outdoor thermal environment is measured by the parameter of mean radiant temperature (MRT) which can be deduced from simulation or through field measurements of temperature and radiation. There are two types of radiation – shortwave (denoted as 'K') and longwave radiation (denoted as 'L') - that are considered relevant and for reasons diagrammed in Figure 1(a) and (b). Shortwave and longwave radiation is within the thermal radiation spectrum and are important parameters to understand how heat travels in our built environment. Shortwave

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

radiation is a measure of how much thermal energy is radiated from the sun to the earth and longwave radiation is a measure of how much thermal energy is emitted from the absorbed shortwave energy from the earth to the atmosphere. In our field measurements the shortwave radiation measured is mainly the diffused solar energy in the atmosphere, and diffused and reflected solar radiation from the buildings and objects such as trees. Longwave radiation measured is mainly the emitted (re-radiated) radiation from buildings and objects.



(a) (b)

Figure 1: (a) Longwave and shortwave radiation diagram of towers in relation with pedestrian and urban space; (b) Shortwave radiation types (in red) and longwave radiation types (in blue).

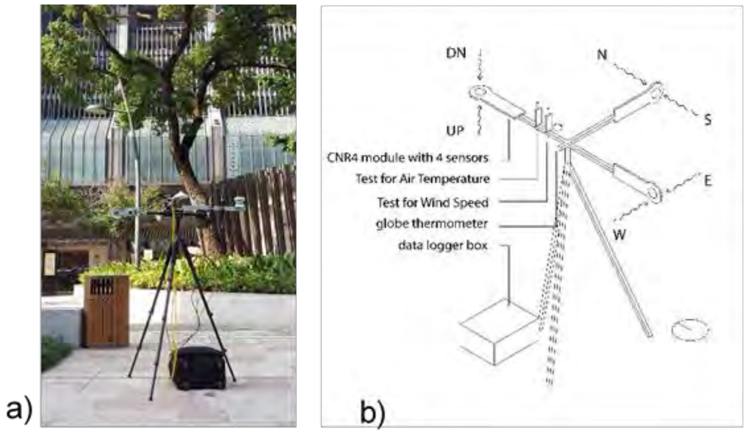


Figure 2: Testing equipment setup for measuring shortwave and longwave radiant flux, temperature, wind speed and humidity.

Thermal comfort parameter – MRT – was calculated based on shortwave and longwave angular factors for a sphere. An integral radiation measurement equipment setup which is one of three common methods of studying the outdoor thermal comfort by researchers was used for this research. A net radiometer (Kipp & Zonen, CNR4) with three integrated pyranometer and pyrgeometer arms was set up at 1.5m above the ground, on a tripod to measure incoming and outgoing shortwave and longwave radiant fluxes within the three-dimension radiation field. The six cardinal points are marked as (N)orth, (S)outh, (E)ast, (W)est, UP and Down where each represents the radiation coming from the noted direction, also shown in the equipment diagram Figure 2b. The Stefan-Boltzmann equation is used to calculate MRT using the measured radiation from six cardinal direction. The CNR4 equipment was used at selected test sites throughout Hong Kong, further described in Section 2.3, and place in shaded conditions to avoid direct sunlight exposure which may cause higher temperature readings due to this exposure.

2.2 View factor analysis

The geometry of the built surfaces and related obstruction of the sky within the city is studied through canyon geometry or sky view factor (SVF), calculated through fish-eye photos, and represents the ratio between radiation

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

received by a planar surface and from the hemisphere radiating environment. Relationships between the air temperature difference and SVF have been studied by means of regression analysis and found to be closely correlated in diverse climates including Hong Kong. For this study, as the focus was identifying how the different vertical building surfaces and materials affected the urban environment, the research began to further dissect the areas related to these factors. The four main view factors identified fundamental were the widely-used SVF, sunlit view factor (SLVF), green view factor (GnVF) and glass view factor (GsVF). SLVF represents the ratio of vertical building surface area receiving direct solar radiation (i.e., cast with direct sun) which then also, inversely counts for the wall areas that are shaded either due to the sun angle or the configuration of surrounding buildings. GnVF, alternately represents the ratio of greenery within the fish-eye lens photo, in order to capture the effect of greenery within the studied hemispheric radiated environment of the urban canyon. GsVF represents the ratio of glass walls receiving radiation within the hemispheric radiated environment. Table 1 shows the visual categorization of these four view factors.

2.3 Site and testing

There were 12 sites selected within Hong Kong for field testing, each site having characteristics of typical and comparable building envelope types and material, and urban configuration (i.e., building layout). To further quantify this range, a design of experiment matrix was developed (Table 2) that represents the range in each view factor for all the sites selected. This method allowed the research team to ensure that the pool of tested sites had conditions to study the effect of the four view factors on the urban thermal environment. From the 12 sites, about 85 data point were collected and multiple regression analysis was conducted to study the relationship between the various view factors and longwave, shortwave radiation and MRT. Most of the testing was conducted in the months of April to September 2015 and during clear to overcast days.

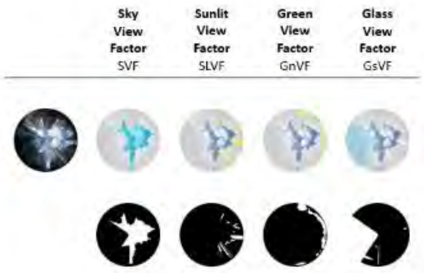

Table 1: Segmentation of the fish-eye lens photo into sky view factor, sunlit view factor, green view factor and glass view factor.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. RESULTS AND DISCUSSION

The multiple regression analysis of shortwave (K) and longwave (L) against the four view factors: SVF, SLVF, GnVF and GsVF are shown in the following Tables 3, 4, 5, and 6 respectively. Five minutes mean values were used to determine the data points from 4 to 6 sites per view factor regression analysis.

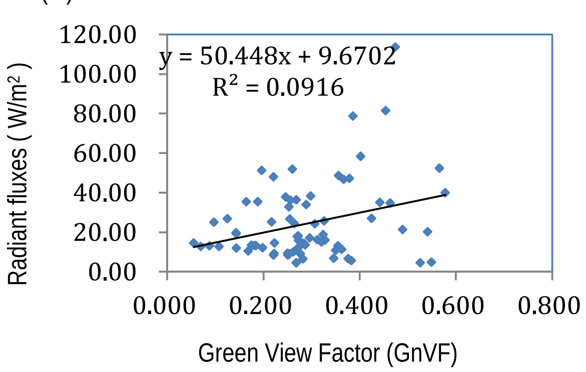
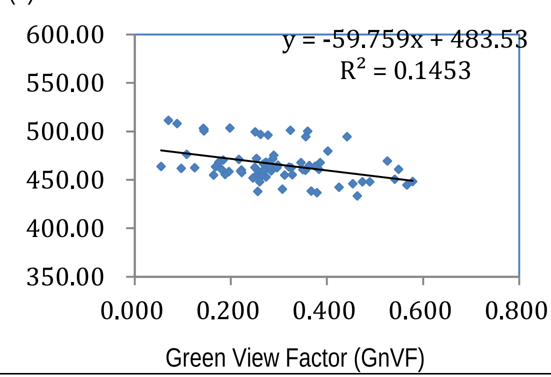
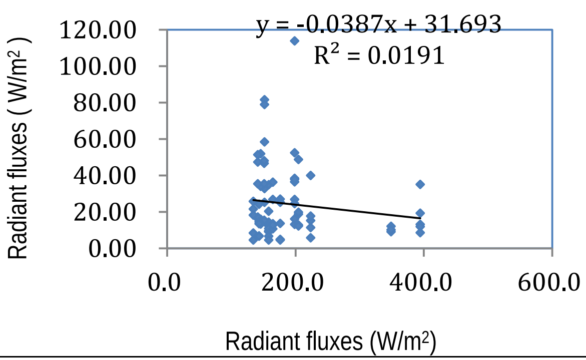
(m) Ki vs GnVF



(n) Li vs GnVF



(o) Ki vs Ko



(p) Li vs Lo

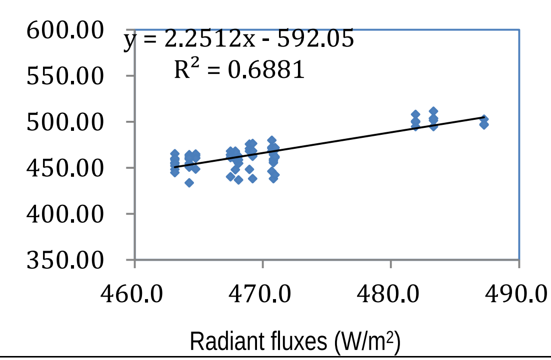


Table 6: Scatter plots for radiant fluxes using 5-min mean values against GnVF

To summarize the regression analysis above in terms of shortwave and longwave radiation, the relative strength table (Table 7) was produced to get a better comparison insight of how sunlit area (SLVF), greenery density (GnVF) and glass wall surfaces (GsVF) can affect shortwave radiation effects (K) and longwave radiation effects (L) for every increase or decrease in visible sky (SVF).

Shortwave radiation increases by all four elements of sky, sunlit wall area, greenery and glass independently by a ratio factor of 1, 0.7, 0.1 and 0.3 respectively. However, the effect of greenery seems to be quite minimal and can be considered negligible in respect to shortwave radiation reflected and diffused from building envelope wall areas receiving direct sun exposure. Shortwave radiation is more significantly affect and increased by:

- More visible sky
- More concrete wall area receiving direct sunlight
- More glass wall area

Although shortwave radiation is considered a significant factor, longwave radiation results provide a better conclusion of how building envelope impacts the thermal environment.

Longwave radiation is affected differently from shortwave radiation in that increases in sunlit wall area causes increase in longwave radiation by ratio of 1:0.5. For elements of sky, greenery and glass decreases in these ratio factors by –1, -0.2 and -0.5 respectively causes increase in longwave radiation. This means that more densely packed built environments where sky visibility is reduced will increase longwave radiation. Reducing the amount of greenery will increase longwave radiation. Reducing glass within the building envelope surface (therefore increasing the amount of concrete building envelope material) in shaded conditions, will increase longwave radiation. To reduce longwave radiation the following could be deduced:

- More visible sky
- Reduce amount of concrete wall area receiving direct sunlight
- Increase greenery
- Increase glass wall area in shaded orientations (i.e., such as north, northeast and northwest facing walls).

Increasing the amount of sky visible in an urban open space between buildings is a positive attribute for psychological human comfort and reducing longwave radiation, therefore although it increases the amount of shortwave radiation due to the direct sunlight entering the open space, the key is to reduce the allow space to let the shortwave radiation reflect and diffuse away beyond the open space.

	SVF (+1 unit)	SLVF (+1 unit)	GnVF (+1 unit)	GsVF (+1 unit)
Shortwave radiation, K	1 1 1	0.7	0.1	0.3
Longwave radiation, L	-1 -1 -1	0.5	-0.2	-0.5

Table 7: Relative strength of view factors and their effect on increases in shortwave and longwave radiation.

The final relative strength matrix summarizes the effects of thermal radiation on pedestrians due to orientation and layout of building envelope, cast sunlight on building envelope, greenery and glass envelopes.

4. CONCLUSION

The results indicate that the thermal environment is mostly affected by the positioning of the building envelope in respect to the canyon geometry and amount of direct solar radiation received by the building envelope. This can be translated to mean that having more sky visible between buildings where building envelopes are smaller masses (lower building) or more spaced apart will allow for relief of shortwave and longwave radiation trapping, which in turns means the MRT will experience less rise. Allowing more sky to be experienced by the pedestrian, also alleviates the urban heat island effect. The wall area receiving direct solar has significant impact on affecting both shortwave and longwave radiation. Greenery affects longwave radiation and should be considered a material to

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

combat the effects of large thermal mass (concrete) receiving direct solar and re-radiating out to the environment increasing MRT.

Urban Geometry and Wind Simulation Studies for Comfort in Bangkok Street Canyon

Pattaranan TAKKANON[a]

[a] *Kasetsart University, Thailand, pattaranan.t@ku.th*

ABSTRACT

The increase of densely built-up areas in Bangkok aggravates Urban Heat Island phenomenon. Urban geometry as formed by the relationship of building height and street width or height-to-width ratio is a contributing factor to UHI. While the street canyon can provide self-shading during the day which is good for hot-humid regions, the deep street canyon influences heat absorption and airflow in the city, resulting in trapping air pollutants especially at the pedestrian level. Therefore, it is important to find optimum urban geometry for thermal comfort and enhancing airflow for public health. Wind studies were conducted using CFD simulation for uniform urban block arrays. Height-to-width ratios were varied for 95 cases. Results show that height-to-width ratios ranging from 1 to 2 can generate turbulence for heat mitigation and air pollution dispersion. The minimum height-to-width ratio recommended is 0.5 while the minimum building height is 9 meters. The minimum road width recommended is 12 m. However, the width of 34 m is preferable for heat mitigation and promoting air circulation.

Keywords: urban geometry, wind simulation, street canyon

1. INTRODUCTION

Urbanization has a significant impact on shaping the city. The densely built-up areas trap the heat within urban canopy causing urban environments to be warmer than their surroundings especially during the night time. This phenomenon is known as Urban Heat Island (UHI). There are many factors contributing to UHI including canyon geometry, thermal properties of materials, anthropogenic heat released from combustion and metabolism, and lack of green spaces. Among these factors, the canyon geometry has an impact on the type and magnitude of urban airflow as well as the short and long wave radiation balance in the canyon. It is also suggested that the urban geometry is much more important at the microscale than the thermal behaviour of materials and the albedo effect.

The urban canyon is considered very critical for UHI investigation since the canyon is formed with buildings along roadsides. The geometrical characteristics of the urban canyon are defined by height-to-width ratio, (H/W ratio) or aspect ratio which has been found to correlate significantly and directly with the UHI effect. It influences urban shading and ventilation for passive cooling and air pollution dispersion, thus affecting people's thermal comfort and health.

The temperature distribution in the canyon is influenced by the canyon surface temperatures and energy transfer depends on convective process. A study in Athens concluded that air temperature in the canyon is not greatly influenced by street orientation either during the day or during the night but is mainly controlled by the airflow process.

Whilst UHI has been studied extensively in many countries especially in temperate climates, there is still a need for more research in the tropics. It is also the case of Bangkok where only a few studies were found. At macro-scale level, urban heat island intensity of Bangkok was studied based on meteorological data. Nonetheless, at micro-scale level, there is still a big gap of knowledge on urban geometry in relation to UHI effect. Even though airflow is crucial for heat mitigation, the overheating conditions in urban areas of Bangkok are affected by the lack of airflow to enhance outdoor thermal comfort and air pollution dispersion. Therefore, the study is an attempt to investigate effect of height-to-width (H/W) ratio on airflow at pedestrian level in the street canyon. The research is supported by the National Research Council of Thailand and results from the study will be taken into consideration for establishing urban geometry design guidelines to promote wind for heat and air pollution mitigation in urban area of Bangkok.

2. LITERATURE REVIEW

2.1 Air movement and thermal comfort in hot-humid climate

Environmental factors of thermal comfort include air temperature, humidity, mean radiant temperature, and air velocity. The air movement produces physiological cooling effect by increasing evaporation from the skin. For hot-humid climate, the desirable wind speed at body's skin is 1-1.5 m/s or within the limit of 2 m/s. This is in accordance with results from field studies in the sub-tropical climate of Hong Kong as under summer condition, air velocity of 1.0-1.5 m/s would likely satisfy 80% of building occupants thermally. The studies in India and Iran show a reduction in thermal discomfort at 32-40˚C with air velocity greater than 0.25 m/s. Field studies in the warm and humid climate of Bangladesh also present an increase in comfort temperature with air velocities greater than 0.3 m/s.

Providing channels for airflow distribution is a way to promote thermal comfort in the city. Urban design requires Air Ventilation Assessment (AVA). The assessment height for pedestrian level is 1.5-2 meter above ground. To evaluate the effect of wind speed on outdoor thermal comfort, wind speed classification is derived based on Physiological Equivalent Temperature (PET).

2.2 H/W Ratio and urban airflow

Densely built-up areas tend to have street canyons with high aspect ratios. In general, the canyon has ratio approximately equal to 1 without major openings on the walls. An aspect ratio below 0.5 defines shallow canyon while a value of 2 represents the deep one.

Urban wind flow conditions can be improved by providing ventilation paths, mixing building heights, and increasing building height while decreasing land coverage. The latter strategy was found most efficient as it can increase wind velocities by up to 2.4 times of the real case.

An investigation in Singapore shows that placing a few high-rise towers will enhance the airflow inside the canyon thereby reducing the air temperature. An optimum H/W ratio for the canyons can increase the velocity by up to 35% and reduce the corresponding PET by up to 0.7oC.

2.3 CFD numerical simulation

Wind flow in the city is commonly studied using field measurement and numerical simulation methods known as Computational Fluid Dynamics (CFD). Even though the measurement method gives quantitative information about ambient air temperatures and velocities at specified locations and times, it cannot identify causes of the problem. Air modeling is, on the other hand, widely used for parametric studies in order to determine cause and effect from individual and combined parameters influencing airflow conditions.

In order to verify results from field measurement and CFD simulation, most models created are non-uniform to simulate real situation. Nevertheless, uniform modeling is generally used to study effect of individual parameter as it is more controllable. Two-dimensional and three-dimensional models are commonly produced for the studies.

3. BANGKOK'S CHARACTERISTICS

Bangkok is situated at 13.44oN latitude. It is in the central region of Thailand covering total area of 1,568.74 sq.km. The city has approximately registered population of 5.7 million and a hidden population of 2.6 million (in 2010). It has a diurnal temperature range of minimum 22.5oC to 26.9 oC and maximum 32.1 oC to 36.3 oC. A mean annual temperature is 27.8 oC and a mean annual RH is 79.9%. The minimum RH is 74% in January and the maximum RH is 85% in September. Bangkok experiences only moderate wind speed. The average wind velocity at 10 meters above ground is 1.7 m/s. The street canyons in densely built areas of Bangkok are blocked by tall buildings, therefore calm periods and stagnant conditions possibly occur.

4. STUDY METHODS

The research adopts CFD method to study urban airflow conditions influenced by H/W ratios or aspect ratios ranging from 0.1 to 2 as the maximum permitted by Thai regulation. Road widths are 12, 18, 24, 34, 64, and 94 meters, respectively. These widths include the actual road width and possible 6-meter setback distance. Building heights are then calculated according to the relationship between H/W ratios and road widths. There are 95 simulation cases possible for the specified range of H/W ratios as shown in Table 1. The simple geometry with aspect ratios above 1 are expected to produce a skimming flow regime in the street canyon.

The commercial CFD simulation program, DesignBuilder is employed for calculation. The numerical models are uniform regardless of the effect of building's length and width. Domain size is 1000 m × 1000 m. All buildings are square shape and areas considered are at intersection providing identical street canyons on the direction parallel and perpendicular to prevailing wind. In the studies, the wind direction is set to come from the south. The reference wind velocity is 1.7 m/s as it is the average wind velocity at 10 meters above ground in Bangkok. Wind profile is specified for urban area. The computational domain is k-ε which is for turbulence modeling. Area for consideration on horizontal plane is 1.5 meters above ground to investigate airflow at pedestrian level while sectional area across the canyon is made vertically to investigate air velocities on leeward and windward sides.

Table 1: Simulation cases

5. RESULT ANALYSIS

Since urban canyon has an impact on airflow characteristics, whether to generate vortex and turbulence, the areas considered in the studies are on leeward and windward sides in the canyon as specified in Figure 1.

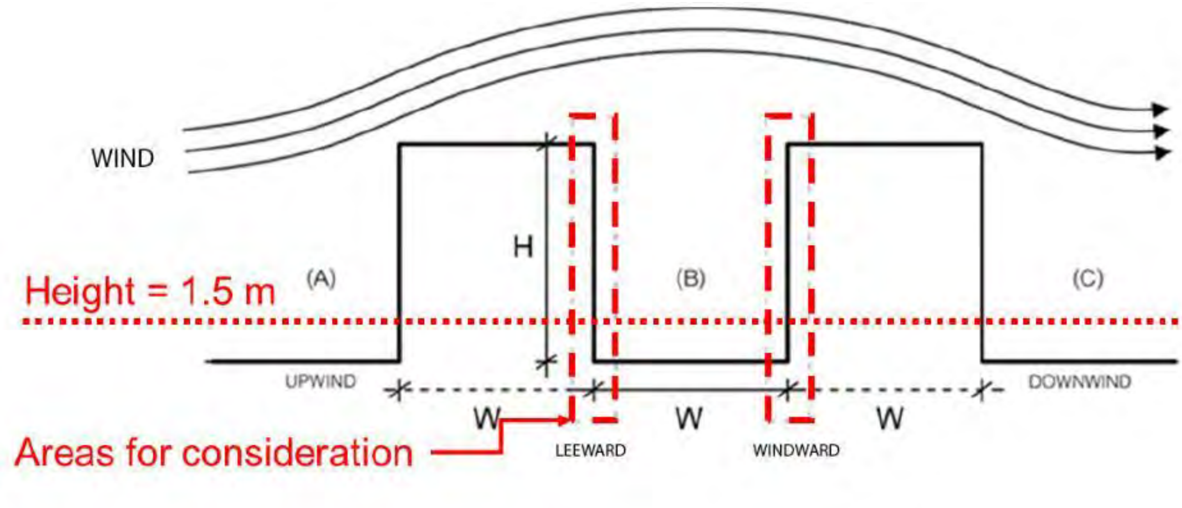

Figure 1: Areas for investigation

Results from the simulation show that wind velocities at pedestrian level in the street canyon perpendicular to the prevailing wind range from 0-0.18 m/s which cause still air. In the canyon parallel to the prevailing wind, the velocities range from 0.73-0.91 m/s which can enable thermal comfort and enhance air pollution dispersion. However, laminar flow occurs when building heights do not exceed 9-9.4 m (3 storeys).

Turbulence and vortex are profound on building's edges and downwind area when H/W Ratios are not less than 0.2 and building heights are above 9-9.4 m (3 storeys). Turbulences is likely to occur with increasing building height in association with increasing road width. The increase in pressure difference between the upwind and the downwind areas is noticeable for the cases with H/W = 0.4 and W = 64 meters. Turbulent flows are distinct. Wind velocities on windward side are generally higher and more distributed in the area than those on leeward side as the radar chart in Figure 2 shows percentages of areas on leeward and windward sides with the frequencies of low, medium and high velocity occurrence.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

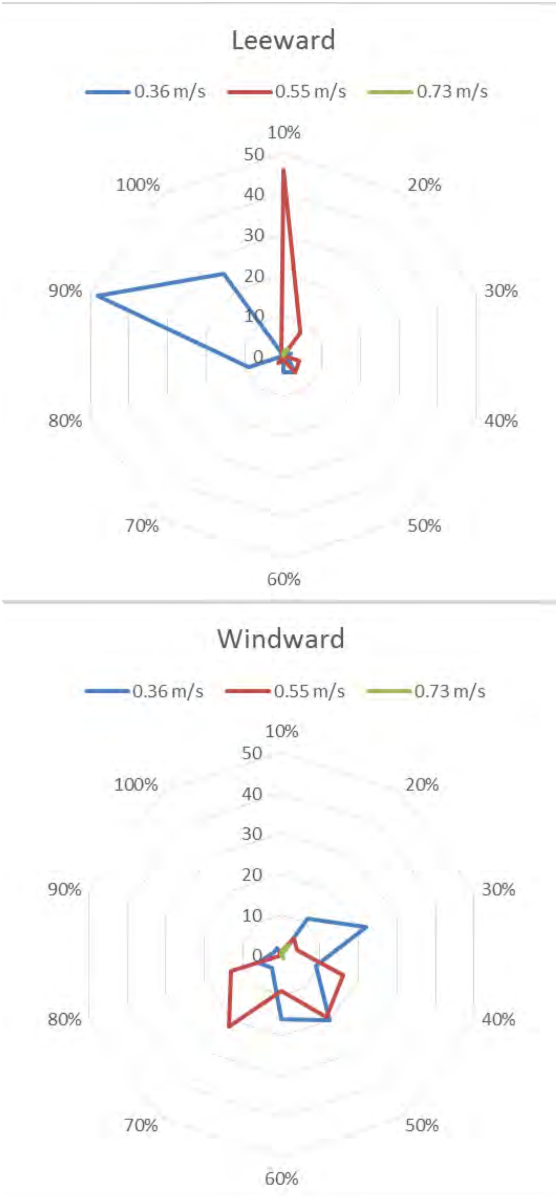

Figure 2: Percentage of area covered with 3-level wind velocities on leeward and windward sides

	Plan	Section
H/W Ratio = 0.1; H = 6.4 m.; W = 64 m.		

	Plan	Section
H/W Ratio = 0.3; H = 28.2 m.; W = 94 m.		H/W Ratio = 0.5; H = 47 m.; W = 94 m.		H/W Ratio = 0.7; H = 65.8 m.; W = 94 m		H/W Ratio = 0.9; H = 84.6 m.; W = 94 m		H/W Ratio = 1.5; H = 96 m.; W =64 m		
Table 2: Examples of simulation cases

Table 2 show examples of simulation results of low (less than 0.5), medium and high values of H/W ratios (above 0.5). Wide roads greatly influence turbulence as shown in models with H/W ratios higher than 0.5.

H/W Ratios range from 1-2 can generate turbulence for heat mitigation and air pollution dispersion. The turbulent flow can occur even when the road width is only 12 meters. However, the influences of high H/W ratio are profound when width = 34 meters. For the road of 12, 18, 24 and 34 meter wide, airflow patterns remain the same with increasing potential of turbulence. However, in cases of road width greater than 64 meters, the pattern is different.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

On downwind side, vortices occur in the middle of street canyon as shown in the example case of 1.5 H/W ratio with 64-m road width. H/W ratios ranging from 0.5-1.1 potentially promote wind distribution in wider area especially when associated with wide roads: 34, 64, and 94 meters. Based on the overall simulation cases, it is found that the minimum H/W ratio should be 0.5 while the minimum building height should be 9 meters. The optimum road width is 34 meters.

6. CONCLUSION

Results from the study show that medium to high H/W ratios tend to increase air velocities and create turbulence in the canyon, thus promoting cooling effect for pedestrians. Therefore, it is possible to promote high density development for Bangkok. Nonetheless, it is required to balance between high H/W ratio and road width to avoid too deep canyon that traps heat during the night. It is recommended that stagnant conditions in the canyon can be improved by providing wind channel on ground level of buildings especially those that are situated along narrow roads. The recommended H/W ratios range from 0.5-2 while road width should not be less than 12 meters and not less than 34 meters is preferable.

Research of Urban Heat Island (UHI) in Shenzhen Based on Climatic Design and Urban Planning Strategies

YU Wenjuan[a]

[a] *Ronald Lu and Partners (Hong Kong) Ltd., Hong Kong SAR, yuwenjuan26@gmail.com*

ABSTRACT

Urbanization with growing population and economic development in China has resulted in fast expansion of urban areas with rapidly land use change. The newly constructed high density city pattern is to meet the development of cities and at the cost of urban environment. Shenzhen, which regarded as the most rapidly urbanizing city in China in the last three decades is taken as an example to study the urban heat island (UHI) effect. As the urban heat island effect is the most common environmental issue associated with the urbanization and influence the sustainable development of Shenzhen, understanding the urban heat island in Shenzhen is highly important. In this paper, the climate condition of Shenzhen will be presented. Moreover, the performance of urban heat island in relation to urban planning and land use change will be analysed and discussed. Besides, several urban planning strategies are put forward. The conclusion presented in this paper can made available to the designer and used as a reference guideline for achieving sustainable urban planning for Shenzhen.

Keywords: urban regeneration, urban heat island, urban planning strategies

1. INTRODUCTION

1.1 Geography and climate condition of Shenzhen

Shenzhen, which regarded as the fastest developed city in China, is a coastal city belongs to the Pearl River Delta and located at the southeast of Guangdong Province (Huasheng, 1991). It is a liner city surrounded by hills and seas with a total area of 1992 km2 hilly terrain (Chen, et al., 2014). The topography condition of Shenzhen is undulating, the southeast part is hilly with mountains which may block the typhoon in summer while the northwest part of Shenzhen is relatively low along the west coast (Ng, 2003). In this case, the land use pattern in Shenzhen is various including cropland, woodland, built up area, water body and unused land and there are four major rivers run through the city (Tianhong, et al., 2010).

Shenzhen enjoy a humid subtropical marine monsoon climate and belongs to the hot summer and warm winter climate zone (Song & Somasundaram, 2009). Influence by the East Asian monsoon, the summer in Shenzhen is wet and hot while the winter is comparatively dry and mild. The climate data for Shenzhen shows that the annual mean temperature is 22.55°C with monthly averages temperature ranging from 11.7°C in January to 32.2°C in July, the city enjoy 1933 hours sunshine per year and the annual rainfall in Shenzhen city is about 1966mm (China Meteorological Administration). In this case, the temperature in summer is high and cause the heat generate in the city which may lead to urban heat island effect.

1.2 Urbanization development of Shenzhen

Within 30 years, Shenzhen has experienced a tremendous change from a small fishing village to a modern city (Che, et al., 2011). Study shows that the population for Shenzhen is only 0.31 million in 1979 (Ng, 2003). With the Open Door Policy in China and the setting up of Special Economic Zone (SEZ) in 1980, the total population of Shenzhen was 4.69 million until 2001. And the urban population was increased to 10.37 million in 2010 (Shi & Yu, 2014). In this case, in order to balance the population grow, the expansion of urban areas with built up zones is needed. As a liner city, the rapid urban sprawl in Shenzhen was developed along several cores to the surrounding areas and there are four main axes for urban develop along west, middle, east and south (Xie, et al., 2013).

The urbanization of Shenzhen shows that the built up areas has extended to the middle of Shenzhen city and the western part along the coast from 1990 to 1994. From 1994 to 2005, the built up areas growing ever faster which occupied west of Shenzhen and expand to north part of Longgang district. The built up space increased from

0.63% to 33.42% while forest decreased from 38.71% to 29.96%; water bodies decreased from 7.41% to 5.64% and wetland decreased 0.21% (Che, et al., 2011).

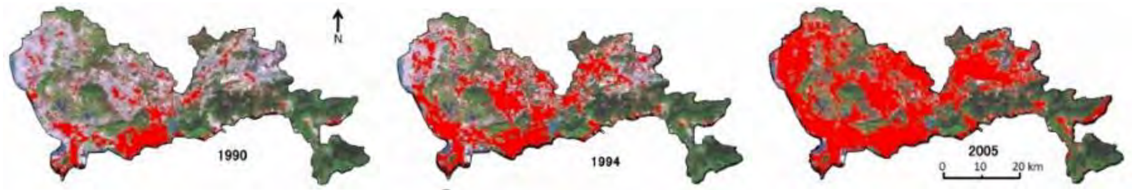

Figure 1: Urbanization pattern in Shenzhen (Che, et al., 2011).

As a result of fast urbanization, Shenzhen is toward a shortage of land and resources, facing high density urban pattern and several environmental problems (Shi & Yu, 2014). For example, stress between industrial, residential and natural land, traffic jam, air population, reducing of green open space and urban heat island effect. Among them, urban heat island (UHI) issue is highly relevant to the urbanization process and has huge impact on the sustainable development of Shenzhen.

2. UHI ISSUE OF SHENZHEN

2.1 The special distribution of UHI in Shenzhen

Urban heat island effect is performed that the urban area temperature will be higher than the surrounding countryside (ZHANG, et al., 2011). Study shows that the temperature in Shenzhen is keeping increasing during the past 50 years reaching 28°C in 2005 and the extremely hot day in summer is also increase which gradually heat up the city, the temperature in the city center is approximately 3°C higher than the suburban area (Lin, 2011).

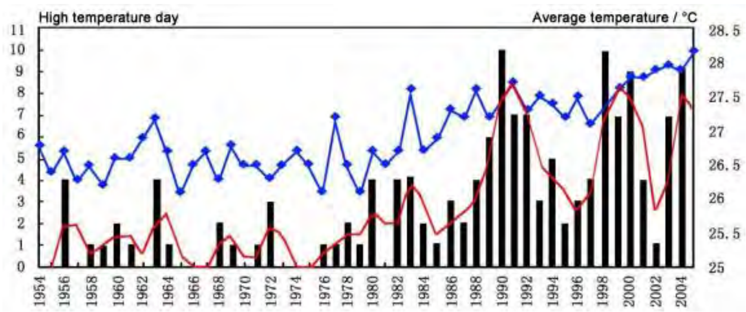

Figure 2: Temperature in Shenzhen (1954 – 2005) (Lin, 2011).

By using regional boundary layer model (RBLM), the studies illustrated that during the daytime, the UHI intensity can reach around 4°C at the western part of Shenzhen (ZHANG, et al., 2011). And the strong UHI effect is happened in Nanshan, Futian and western Bao'an district with temperature higher than 33°C while other part of Shenzhen are also facing obvious urban heat island effect with the temperature between 31°C to 33°C (ZHANG, et al., 2011). However, during the nighttime, the high value of UHI happened in the city center with high density in western Nanshan, western Luohu and western Bao'an district with temperature more than 27°C (ZHANG, et al., 2011). When it compared with the urbanization pattern of Shenzhen, it can be seen that the high value of UHI intensity happen in the construction areas which means that the urban planning with high density buildings areas will generate urban heat island effect.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

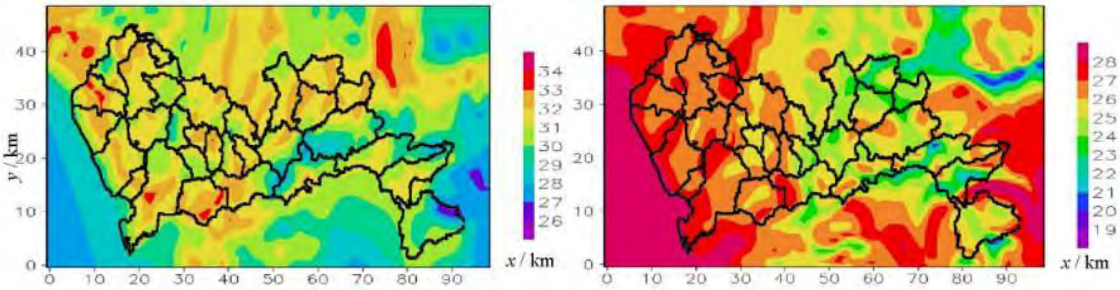

Figure 3: Air temperature during daytime and nighttime (ZHANG, et al., 2011).

2.2 The formation of UHI in Shenzhen

2.1.1. Land use change

Land use change is one of the key factors that generate UHI in Shenzhen. A study indicates that the land use pattern in Shenzhen has toward significant change during 1990 to 2008. The urban land is growing faster along the western coast and main road while the natural land with greenery is decreasing (Chen, et al., 2014). The UHI spatial distribution is highly match the urban land expansion pattern. For land use type of Shenzhen, the developed land dominate most part of the city land while the green land is limited to the mountain areas (Xie, et al., 2013). In this case, the constructed land will increase the surface roughness and have relatively high surface temperature thus generate the urban heat island effect in this areas.

As UHI is characterized by land surface temperature (LST) and land cover and landscape patterns are the two main factors that influence the LST, the vegetation fraction and impervious surface areas of Shenzhen are illustrated below to show the relation between land use and UHI issue (Xie, et al., 2013). It can be concluded that the higher vegetation fraction areas the lower surface temperature and the higher value of impervious surface areas the higher the surface temperature due to the cooling effect of the vegetation. In this case, the reduction of greenery space was one of the reasons that cause UHI effect in Shenzhen.

2.1.2. High density built up areas

From the above analysis, it can be seen that Shenzhen has experienced a rapid urbanization and urban expansion period. The develop pattern of Shenzhen is toward a high rise and high density city like Hong Kong. A study of the greening space in Shenzhen shows that the forest land is quite large (Che, et al., 2011). However, within the urban built up areas are lack of greenery and open space. The zoning for street network of the most densely populated area of Shenzhen indicated that the street network is closely linked to each other without space for urban greenery (Wang, et al., 2013). And the planting of greenery cannot catch up with the construction of buildings and highways in the city. The existing trees planted along the streets may be too small to effectively reflect the solar radiation and cooling down the local temperature.

Besides, another study shows that among the high density areas of the city, wind cannot easily ventilated the region because the wind speed will reduce when passing the high density building areas. The wind speed will decrease from 2.7m/s to 1.2m/s when entering the urban districts (Lin, 2011). In most areas, the wind speed is only 1m/s or even create the stagnate zones. In this case, the heat will generate and stay in the urban areas due to the poor urban scale ventilation which will greatly increase the potential for UHI effect in Shenzhen.

2.1.3. Reduction of water bodies

The reduction of water bodies in Shenzhen is regarded as another factor that forming the UHI. Study shows that the river network of Shenzhen has toward a decrease from 1980 to 2005 (Zhou, et al., 2010). It can be seen that the river network complexity is decreased from 36.1 to 31.6 and the number and length of the river are also decrease during the urbanization with the total length of the rivers in Shenzhen shortened 355.4km (Zhou, et al., 2010). It can be concluded that with the fast development of urban areas, the water bodies have been influenced and the cooling effect of the rivers are also reduced. In this case, the surface temperature of Shenzhen is keep increasing with the decrease of water bodies therefore generate the UHI effect.

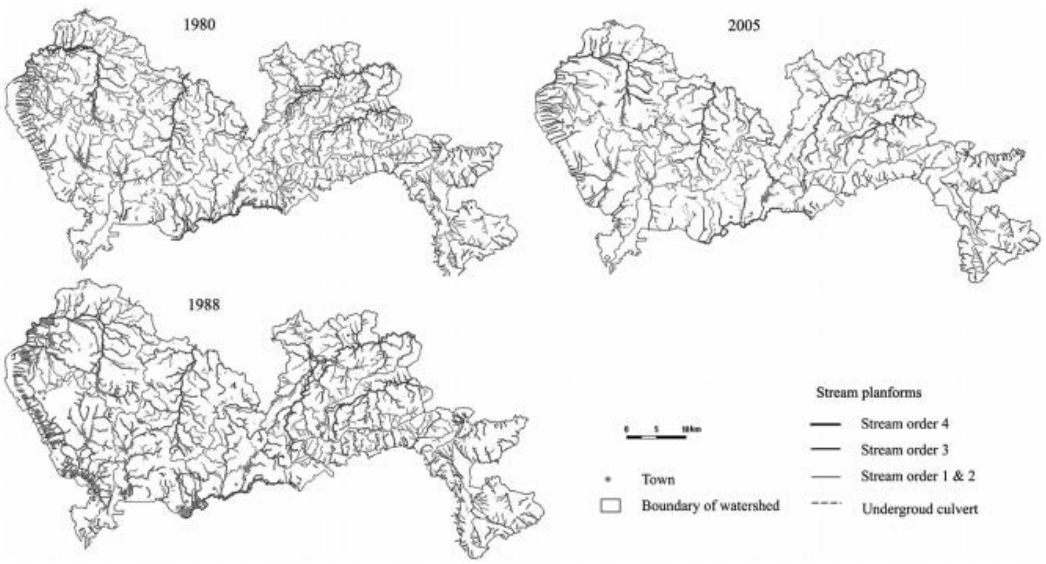

Figure 6: River network change in Shenzhen (Zhou, et al., 2010).

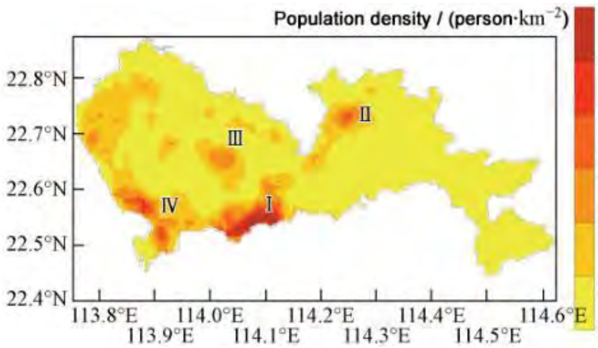
2.1.4. Anthropogenic heat

Anthropogenic heat is another reason that forming UHI in Shenzhen. From the UHI distribution pattern, it can be concluded that the strongest UHI areas appear with high population density (Zhang, et al., 2011). Human's activities will significant increasing the energy consumption thus generate unwanted heat of those regions. Besides, study shows that the total number of motor vehicles and private car in Shenzhen are increasing. Reaching 2.72 million in 2014 with the annual growth rate of 16.2% and the vehicle density in Shenzhen is 440 per km which is much higher than the international standard (Zhang, et al., 2011).



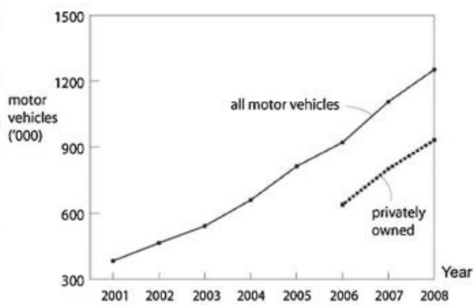


Figure 7: Population density of Shenzhen (Zhang, et al., 2011)

Figure 8: Motor vehicle and private car tendency. in Shenzhen (Zacharias & Tang, 2010).

Besides, according to the studies of industrial and commercial zone location and the road network of Shenzhen indicates that the UHI effect is highly related to the anthropogenic heat generated by industrial and commercial activities and transportation. The western part with distribution of industrial and commercial districts and the central part with main road network are found to have higher UHI value in Shenzhen. Therefore the built up of buildings and the emission of the private cars are one of the key reason that forming the urban heat island.

3. URBAN PLANNING STRATEGIES TO CONTROL UHI

3.1 Ventilation corridors

In order to reduce the urban heat island effect in Shenzhen, ventilation corridors should be created both on city scale and district scale. On the city scale, as the dominate wind direction of Shenzhen is northeast, east and southeast, the wind path should be arranged northeast to southwest and northwest to southeast. And the wind corridors may follow the major roads and green lands and link to each other. Besides, the air path should prevailing

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

to the dominate wind direction and should be long and width enough to effectively ventilate the whole community. On the district scale, a new district known as the Low Carbon City locates in Pingdi district which can represent the future urban planning model of Shenzhen is designing the wind corridors according to the dominate wind direction to reduce the urban heat island effect. In this case, the wind can penetrate into the urban built up areas and bring away the urban heat.

3.2 Linkage of open space and increase greenery

Increase open space with greenery is another useful strategies to reduce urban heat island effect in the city due to the cooling effect of vegetation. A greenway has been built up which went through the whole Shenzhen city to increase greenery in the city and bring wind into the urban construction areas. In this case, the surrounding urban areas can be benefit from the greenway and the land surface temperature will to some extent decrease. The greenway can not only provide a space for people to enjoy nature and do exercise but also is a process toward sustainable urban planning for the future of Shenzhen.

Besides, several strategies are needed on the district scale to improve the local environment as microclimate play an important role in the whole urban climate condition. In order to build up the Low Carbon City, several strategies are put forward. Buildings are setback to widen the streets; open spaces are design within the high density built up areas for better ventilation and provide outdoor thermal comfort; trees are planting at the sidewalks at the initial stage of urban planning to improve the environment at the pedestrian level. What's more, the green belts are closely linked with the surrounding nature land to make sure the cooling effect. In some really high dense areas where building setback and open spaces are hard to design, vertical planting and roof gardens are needed to increase the greenery in this areas.

3.3 Building design toward sustainable urban planning

Buildings which take up the biggest parts of urban built up areas should be design properly to reduce the urban heat island effect in Shenzhen. As Shenzhen is locates at the hot summer and warm winter climate zone the same as Hong Kong, the urban planning guideline published by the Hong Kong Planning Department can also applied in Shenzhen. For building orientation and disposition, in order to catch wind, the building orientation and disposition is very important. Building should be oriented to face the prevailing wind with large openings, the main street should parallel or up to 30° with the dominate wind and the length of building façade along with the prevailing wind should be longer to reduce stagnant zone behind the building (HK Planning Department, 2014). For building height, a mix of low-rise and high-rise building will benefit the wind movement. Increase the building height of the behind building along with the prevailing wind direction can enhance the ventilation and allow the wind to reach the building behind (HK Planning Department, 2014). Besides, for building permeability, better ventilation pattern can be achieved by creating gaps and openings on the buildings.

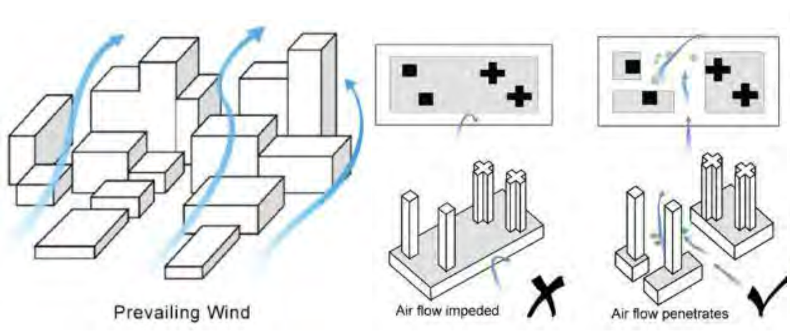

Figure 11: Building height and podium separation (HK Planning Department, 2014).

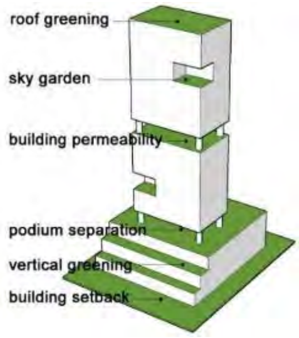

Figure 12: Building permeability (By author).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.4 Green transportation system

Green transportation system is highly recommended in Shenzhen in the form of green subway system and electric vehicles. By encouraging people to use public transportation, the number of private cars can be greatly reduce therefore the anthropogenic heat generate by cars can also decrease. Besides, the electric vehicles are green because it uses electricity instead of burning gasoline. In this case, the heat release by the transportation can be reduced and thus make great contribution to the control of urban heat island effect in Shenzhen.

4. CONCLUSION

Urban heat island is considered as one of the most important environmental issue as it influences the sustainable urban development and living environment directly. The urban heat island effect in Shenzhen is becoming much more obvious since 1980 with the rapid urbanization process. From the analysis of spatial distribution of UHI and land surface temperature, the strong UHI appeared at the urban construction areas with high density building pattern. Land use change during the urbanization process, high density built up areas, reduction of water bodies and anthropogenic heat generated by human activities are the main factors that forming UHI in Shenzhen. Shenzhen which locates in the hot summer and warm winter climate zone in China, has huge potential to reduce UHI effect and achieve sustainable urban planning in the future. Several climatic based design and urban planning strategies such as ventilation corridors, linkage of open space and increase greenery, building design toward sustainable urban planning and green transportation system are put forwarded to control the UHI in Shenzhen. Therefore, the urban planning strategies presented in this paper can made available to the designer and used as a reference guideline for achieving sustainable urban planning for Shenzhen and any other cities with similar urban climate condition.

ABSTRACT

The occurrence of “crazy bad” air pollution in many cities of China often hits the international headlines. In Hong Kong, the outdoor air quality faces great challenges as well. According to the report released from the Environmental Protection Department of the Hong Kong Government, vehicular emissions and street canyon effects are the two main contributing factors to roadside air pollution. This paper outlines the findings from our numerical investigation of the dynamic pollutant dispersion as induced by moving vehicles within the street canyon environment of Hong Kong. The integrative computational fluid dynamics (CFD) models, including the standard k-ε model for airflow turbulence, the species transport model for gaseous pollutants, and the dynamic mesh model for moving vehicles, were validated by wind tunnel measurements as well as reported data from published literatures. Our findings confirm that moving vehicles could generate secondary airflow, and hence introduces additional ventilation effects. This leads to continuous interaction between the wind flow and the wake of vehicles, and in addition, promotes the mixing and transportation of the vehicle exhausted pollutants. Dynamic impacts of the moving vehicles on the airflow field (such as the flow velocity) and the pollutant dispersion (such as the concentrations of CO from a stationary line source and NO_2 from the moving point source) were found highly dependent on: (i) The geometrical configuration of the street canyon; (ii) The mode of vehicular movements, such as in single- or multi-lanes and their travelling directions, and (iii) The position of the monitoring site, i.e. near the leeward/windward wall, at the middle of the street canyon, or near the two street end openings.

Keywords: micro-climate, sustainable neighbourhood, roadside air quality

1. INTRODUCTION

The occurrence of “crazy bad” air pollution in many cities of China often hits the international headlines. In Hong Kong, the outdoor air quality faces great challenges as well. According to the report released from the Environmental Protection Department of the Hong Kong Government, vehicular emissions and street canyon effects are the two main contributing factors to roadside air pollution, which is often associated with high pollutant concentrations exceeding current air quality standards. Therefore, air quality in urban street canyon has garnered great interest and numerous studies have been conducted to enrich our understanding of the airflow field and the mechanisms of pollutant transport, dilution and removal in street canyon. Several parameters that dominate the pollutant dispersion process can be classified as geometrical, meteorological related, and traffic related.

It is undeniable that traffic is one most dominating risk for the urban atmospheric environment. However, the influence of on-road vehicles on the air quality of urban canyon is far more complicated than just simply considers it as the source of diverse atmospheric pollutants. Previously, theoretical studies, field measurements, wind tunnel experiments, as well as computational fluid dynamics (CFD) techniques were used to interpret the detailed processes of airflow and pollutant distribution under the influence of moving vehicles. In general, the rapid running vehicles on-road can themselves introduce secondary airflow and additional ventilation effect due to the continuous interactions between the natural wind and vehicle wakes. Consequently, in the presence of moving vehicles, the normal airflow pattern and pollutant distribution profile within a street canyon will be broken up, and both micro- and large-scale mixing and dispersion processes will take place. The complexity in predicting the pollution distribution and in the assessment of air quality will considerably increase.

In this present work, dynamic impact of the moving vehicles on the airflow and pollutant dispersion within the idealized deep and uniform canyons were investigated by innovatively adopting the dynamic mesh model based on the FLUENT software platform. As to the model validation, the wind tunnel test section was modified to incorporate the Moving Model Rig for the vehicle movement. Research outcomes are expected to help narrowing

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

the knowledge gap in understanding the influence of traffic on the transport characteristics of pollutants, and to help identifying spots vulnerable to be polluted.

2. NUMERICAL METHODOLOGY

2.1 Studied cases

The size of the computational domain in all studied cases is X = 600m, Y = 290m, and Z = 150m (Figure 1). The idealized urban street canyon is formed by two parallel aligned blocks—the upstream and downstream building blocks. Each has the dimensions of LB = 90m, WB = 30m, and HB = 30m. Both the deep (aspect ratio=3) and the uniform (aspect ratio = 1) street canyons were investigated. The approaching wind was set perpendicular to the long axis of the street canyon. The double-decker-bus model (Lv = 12.5m, Wv = 2.5m, and Hv = 4.5m) run through the street canyon at a moderate speed of 36 km/h. Each bus model has a 0.1m diameter exhaust tail-pipe at its rear end. Traffic pollutants from the constant traffic fleet and from the moving vehicles were investigated separately. The vehicular emissions from the steady traffic fleet are simplified as: (i) a ground-level continuous pollutant area source of Carbon Monoxide (CO) in the deep street canyon, and (ii) the line source(s) of CO in the uniform street canyon. The emission from the exhaust tail-pipe of a moving vehicle is taken as a moving point source of Nitrogen Dioxides (NO_2). The dynamic impact of the moving vehicles are studied in four different scenarios: (i) Scenario#1: Single vehicle runs on the one-lane street of the deep canyon (Figure 2a); (ii) Scenario#2: Two vehicles run in the same direction of the two-lane street of the deep canyon (Figure 2b); (iii) Scenario#3: Two vehicles run in the opposite directions of the two-lane street of the deep canyon (Figure 2c); and (iv) Scenario#4: Four vehicles run on the four-lane street (two-way traffic) of the uniform canyon (Figure 2d).

2.2 Numerical models

The standard k-ε model was used in this airflow study due to its simplicity, low computational cost, robustness and relatively good accuracy. The species transport model was employed to simulate the dispersion and distribution of the tracer gases. The dynamic mesh model was adopted to deal with the influence from a moving object on the airflow field and the pollutant concentration field. The integral form of the conservation equation for a general scalar Φ, on an arbitrary control volume V with moving boundary can be written as:

$$\frac{d}{dt}\int_{V} \rho\Phi dV + \int_{\partial V} \rho\Phi(\vec{u} - \overrightarrow{u_m}) \cdot d\vec{A} = \int_{\partial V} \Gamma\nabla\Phi \cdot d\vec{A} + \int_{V} S_{\Phi} dV$$

Equation 1

where ρ is the fluid density, $\vec{u}$ is the flow velocity vector, $\overrightarrow{u_m}$ is the grid velocity of the moving mesh, ∂V represents the boundary of the control volume, Γ is the diffusion coefficient, S_{Φ} is the source term of Φ. The computational domain should be divided into two separate sections: (i) the dynamic mesh zone for the moving vehicle model, and (ii) the static mesh zone for the rest domain. The interface data exchange between the two sections was implemented by the grid interface principles of sliding mesh theory. The dynamic layering method was employed to update mesh only in the dynamic mesh zone. User-Defined Functions (UDFs) served to define and track the motion of vehicle model. In our previous studies, the dynamic influence of human walking movement on the airflow and particle concentration in ventilated room have been successfully modelled and investigated. On this technical basis, the linear movement of on-road vehicles can be appropriately modelled.

Accordingly, the inlet of the computational domain was set as velocity inlet with a power-law wind profile. The mean velocity u_H at the top of the building was set 2.5m/s and with the exponent α at 0.4 for urban terrain. The temperature of the approaching wind was 303.15K. The outlet, the top and two side surfaces of the computational domain were defined as the Outflow Boundary Condition and Symmetric Condition. The bottom of the computational domain, and all surfaces of the two buildings as well as the vehicle models were defined as No-slip Wall. After the time step independent tests, the time step of 0.02s for Scenario#1 and 0.01s for Scenario#2-#4 are selected for dynamic simulation. The SIMPLE algorithm was used to solve the Pressure-Velocity coupling equations. The Pressure was discretised using the second order scheme. For the discretization of the governing equations, the second-order upwind scheme was used for the convection terms, and the central differences scheme with second order accuracy was for the diffusion terms. The scaled residual criteria for all the flow properties were set at 10-5.

Extensive tests on the independence of the meshes were carried out with increasing mesh numbers until further refinement was shown to be insignificant. Finally, the Moderate Mesh for each scenario (about 2 million cells) was adopted for the following simulation.

2.3 Model validation

Good performance of the standard k-ε model coupled with the species transport model in modelling the airflow pattern and the tracer gas concentrations within street canyons was demonstrated by comparing the computer outputs with the wind tunnel database of CODASC. The competence and performance of the adopted models for capturing the initial pollutant dispersion from a diesel vehicle were also validated by comparing with the measured data from Chan et al., 2001.

To validate the dynamic mesh model for vehicular movement, a series of tests was carried out in the wind tunnel laboratory of the City University of Hong Kong. The wind tunnel was modified to accommodate a moving model rig, which allowed the scaled vehicle model to be fired across the test-section of the wind tunnel. A gas supply system was specially designed for the continuous releasing of tracer gas (Propane) during the forward movement of the vehicle model. SWEMA03 Anemometers and HRF 400 fast FID systems were appropriately installed and tuned preceding to the measurement of the transient and time average features of wind flow and tracer gas concentrations. Close agreements were found between the measured and modelled data (results are not shown here), which strongly indicates that the integrative model adopted in this study can provide a reasonable description of the transient flow physics under the dynamic influence of vehicular movement.

3. RESULTS AND DISCUSSION

For the convenience of making comparisons amongst the different scenarios, airflow velocity, concentrations of CO and NO_2, and time series were normalized to become Vel*, CO*, NO_2*, and Time* respectively. Time* = 0 stands for the start of the vehicle movement; Time* = 0.5 represents the arrival of vehicles at the middle of the street canyon, and Time* = 1.0 indicates that the vehicle reaches the terminal end of the moving path and stops moving forward. Moreover, the sampling time is much longer than the whole moving duration of the vehicle in order to include the recovery process after the pass of moving vehicle. In this study, the contours of Vel* and CO* are first presented to help capturing the general features and rules of the dynamic influence. Then, detail effects of the potential influencing factors are discussed by analysing the temporal variation of NO_2*.

3.1 General characteristics of dynamic impact

Dynamic impacts on the Vel* and CO* distributions at the adult breathing height (z/Hv = 1/3) within the deep street canyons (Scenario#1 - #3) when the vehicles are at the mid-point of the street canyon (Time* = 0.5) are illustrated in Figure 3 and Figure 4 respectively.

Take Scenario#1 in Figure 3 as an example: the most striking features of the dynamic influence on the airflow pattern are the generation of the "Propelling effect" in the form of a relatively high Vel* in front of the head of the moving vehicle, and the "wake effect" characterized by a stripe of high Vel* following its rear end. Within the semi-confined space (i.e. the train tunnel), the train movement would generate the "piston effect". For the street canyon environment, the combined effect of "propelling effect" and "wake effect" of each individual vehicle can be taken as the equivalent "piston effect". Similar dynamic impacts on pollutant (CO*) distribution within the deep street canyon can be found in Figure 4, where the polluted air in front of the vehicles is pushing forward due to the "Propelling effect" and the relatively clean air is entrained into the vehicle wake due to the "Wake effect". Moreover, we expected that vehicles running in the same direction (Scenario#2) would enhance the combined influence of "piston effect". Such influence would be attenuated when the vehicles running in the opposite directions (Scenario#3).

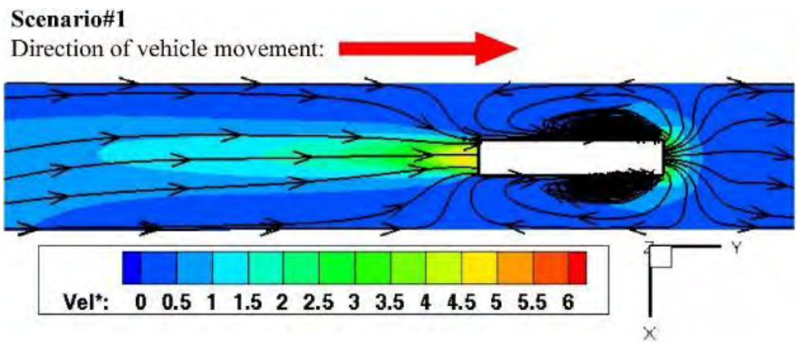

Figure 3: Contour of Vel and airflow streamlines at the height of adults' breathing zone (z/Hv=1/3) for Scenairo#1 within deep street canyon*

3.2 Effects of influencing factors

In this section, the temporal variation of NO_2* is analysed to help figuring out the detailed effects of potential influencing factors.

Figure 5(A) presents the time series of NO_2* at the adult breathing height near the leeward and windward walls for the above four scenarios. The dynamic variation pattern and magnitude of NO_2* in the deep canyon (Scenario#1 - #3) are found quite different from that in the uniform street canyon (Scenario#4), even though Scenario#3 shares similar mode of vehicle movement with Scenario#4. This indirectly demonstrates that geometrical configuration of the street canyon has an important role on the influencing range and the extent of the dynamic impact induced by the moving vehicles. Compared with the uniform street canyon, air ventilation is less effective in the deep street canyon, leading to a relatively stronger transient influence of vehicle movement. Secondly, the dynamic impact is found in close association with the mode of the moving vehicles — the number and the travelling direction. Take the deep canyon (Scenario#1 - #3 in Figure 5A) as an illustrating example. NO_2* in Scenario#1 is much lower than those in Scenario#2 and #3, which strongly indicates that single moving vehicle would release less amount of pollutant, while multiple moving vehicles would generate stronger dynamic influence on the transportation and dispersion of vehicular pollutants. Moreover, vehicles running in the same direction (Scenario#2) would reinforce the combined “piston effect”, enhance the disturbance on the airflow, and promote the transport of pollutant. However, individual “piston effect” would offset by one another when the vehicles run in the opposite directions (Scenario#3). This results in a reduction of dynamic disturbance at the far field, but at the same time, generates a “mixing effect” which would promote the dilution and mixing of local pollutant around the moving vehicles. Therefore, NO_2* in Scenario#2 is relatively higher than that in Scenario#3. Thirdly, the difference in transient distribution of pollutant can be observed between the leeward and windward sides due to the joint effect of vehicle induced airflow and the ambient wind field. Generally speaking, in the deep street canyons (Scenario#1 - #3), the variation trends of NO_2* near both sides share the similar pattern but carry remarkable different peak values. For the uniform street canyon (Scenario#4), NO_2* peak value on the windward side is much higher than that on the leeward side. However, long-lasting influence is actually found near the leeward wall.

Dynamic variations of NO_2* at the adult breathing height at different horizontal positions near the windward wall in Scenario#2 is shown in Figure 5(B), where 0 LB, 1/4 LB and 1/2 LB are at the opening, the quarter, and the centre of the street canyon, respectively. It can be seen that NO_2* at the street openings (0 LB) is lower than that in the internal space of the street canyon (1/4 LB and 1/2 LB), due to the outside clean air fills in through these two openings. Also, the occurrence time of the NO_2* transient variation is found in tight relationship with the time instance when the moving vehicle passes by the adjacent monitoring site.

Figure 5(C) gives the temporal variations of NO_2* at different vertical heights of the street canyon (z = 1/6 HB, 1/3 HB, 2/3 HB and 1 HB) for Scenario#2. NO_2* at the lower level of the street canyon is found much higher than that at the upper level, and the occurrence time of concentration peak at the lower level is prior to the upper level. However, certain amount of pollutants can still reach the upper height of the street canyon. Such enhanced vertical dispersion of vehicular pollutant induced by the moving vehicles might call for extensive research efforts on dynamic simulation, because there might be unexpected exposing risks at some places (i.e. higher level of the street canyon), which may not be predictable by the conventional steady state simulation.

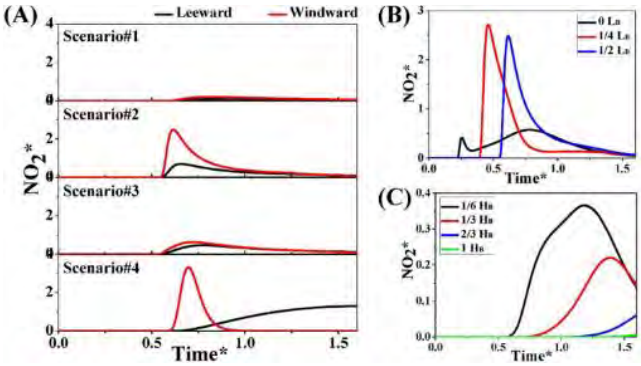

Figure 5: Time series of NO2 (A) Near the leeward and windward wall for the four different scenarios; (B) At different horizontal positions for Scenario#2; and (C) At different vertical heights for Scenario#2*

4. CONCLUSION

Dynamic impacts of the moving vehicles on the airflow and pollutant dispersion within both the deep and uniform street canyons were numerically investigated under four different scenarios. This was by employing the standard k-ε model for the airflow turbulence, the species transport model for the dispersion of tracer gas, as well as the dynamic mesh model for the vehicle movement. These adopted numerical models were validated by wind tunnel measurements and reported data from the published literatures. Dynamic simulation results clearly confirm that moving vehicles could generate secondary airflow and hence introduce additional ventilation effects, in the form of the combined effect of "Propelling effect" and "Wake effect". This leads to a continuous interaction between the wind flow and the wake of vehicles, and also promotes the mixing and transport of vehicle exhaust pollutant. Dynamic impact of the moving vehicles on the airflow field and the pollutant dispersion are found highly dependent on: (i) The geometrical configuration of the street canyon; (ii) The mode of vehicular movements, such as in single- or multi-lanes and their travelling directions, and (iii) The position of the monitoring site, i.e. near the leeward/windward wall, at the middle of the street canyon, or near the two street end openings. Finally, a deductive conclusion can be made based on this dynamic simulation study. There might be unexpected exposing risks at some places (i.e. at higher level of the street canyon), which may not be predicted by the conventional steady flow simulation. Hence, more research efforts are needed for investigating the urban air quality under dynamic impact of moving vehicles.

ABSTRACT

In recent years, with the global trend of greenhouse gas reduction and sustainability, the development of nearly zero energy building (nZEB) and zero carbon building (ZCB) becomes international consensus. However, some ZEB design technologies in Europe and America may not be entirely applicable to Taiwan where air condition costs a lot of energy in summer for the hot-humid climate. To face these challenges, this study provided appropriate architectural design technologies and conduct feasibility assessment of nZEB in Taiwan.

Firstly, three-oriented energy-saving technologies, including passive design, active design and renewable energy were analyzed. Then "Building Carbon footprint Method (BCF)" was used for nZEB quantify and feasibility of Taiwan's residential building. The main research results are as follows:

- In "Residential standard situations," through operating the optimizing design of building envelope and other ventilation and equipment efficiency factors, the EUI could be by 50 (kWh/ m^2.yr) down to 33 (kWh/ m^2.yr) . The total energy efficiency could rise up to 34%.
- If photovoltaics were chosen as the main renewable energy source, a single-family house with 150m2 floor areas would have the potential of reaching nZEB. However, if the house had larger scale, it needed more BIPV design and improve the conversion efficiency of solar cells to increase it s nZEB potential.
- The key point to aim at nZEB is to set specific near-zero energy targets, it not only to encourage innovative building energy efficiency design techniques, but also to promote the construction and upgrading of industrial technology.

Keywords: green building management, energy saving, ZEB

1. INTRODUCTION

The Nearly Zero-Energy Buildings (nZEB) refers to a low energy-consuming green building, using the renewable energy system for the building to attain the goal for energy neutralization zero energy consumption. The European Union (EU) has declared that the energy conservation standard of all of new buildings must conform to the standard of "nZEB" in 2020 . The United States Department of Energy (DOE) specified that the new commercial buildings should reach zero energy consumption by 2030, and attain the goal for zero energy consumption thoroughly by 2050. Taiwan has a mature green building evaluation system at present, but Taiwan is located in subtropical zone with wet hot climate, it depends on air conditioning energy a lot in summer, this is a big challenge to the development of zero-energy buildings in Taiwan. This study aims to appraise the feasibility of zero-energy design for green buildings under the precondition of developing nZEB in Taiwan.

2. RESEARCH PURPOSES

The main purpose of this study is to use appropriate building energy saving design technique to appraise the feasibility of nZEB, and the house building with relatively low "Energy Use Intensity (EUI)" is taken as research subject. In order to simplify the complex building energy consumption pattern, this study uses the " Standard Scenario " set by the "Building Carbon Footprint Evaluation Method (BCF)" of the Low Carbon Building Alliance (LCBA) to "standardize" the complex user, time interval and equipment by dynamic simulation of energy, and then calculates the reduction of building energy consumption with different building energy saving techniques.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. RESEARCH METHOD

3.1 BCF method and application

The Building Carbon Footprint Evaluation Method deduced by LCBA uses a series of building materials, the statistics of building energy use and theoretical prediction equation of carbon emission to simulate the carbon footprint of buildings in 60-year life cycle, including the evaluation of five stages of life cycle, (1) building materials production and transportation; (2) construction; (3) daily use; (4) repair and renovation; (5) demolishment and discarding. The BCF uses a series of "Standard Scenario "to simulate the building carbon footprint. As the BCF method is completely established on the carbon investigation data of Taiwan's building industry, the building energy consumption analysis is developed according to Taiwan's meteorological data, the standard scenario of building use and architectural space classification are derived from precise local industry survey and academic research findings, which are indigenous, reproducible, effective and reliable.

General nZEB uses primary energy as baseline value, and only considers the energy consumption of lighting equipments, air-conditioning equipments and hot water supply equipments in "daily use" stage, the energy consumption of household appliances depends on the boundary of calculation, not always brought into calculation. At present, the studies of Taiwan's residential building energy consumption mostly use EUI (kWh/ m^2) as calculation unit. As the electricity, carbon emission and primary energy can be converted, and the routine energy consumption of BCF method is estimated by using the unit EUI of electricity (kWh/ m^2), without converting the electricity into carbon emission equivalent, this study uses the "routine energy consumption" evaluation method of BCF method to calculate the energy consumption of ZEB, which is a rapid and accurate method. Therefore, this study uses electricity (kWh) and EUI (kWh/ m^2) as the quantization units of ZEB.

3.2 "Standard Scenario" setting for residential routine energy consumption

The "Standard Scenario" means the complex users, time intervals and equipments are "standardized" by dynamic simulation of energy. The standard population of each household is set as two adults and two children, who have standardized work and rest. There is a standard situation for the service hours of household equipments (Table 1). The standard situation of residential energy consumption is: air conditioning energy consumption accounts for 20%, lighting energy consumption accounts for 30%, the energy consumption of the other household appliances accounts for 50%, the average EUI is 50 (kWh/m^2.yr) (Table 2).

Hours of operation (hr)	Annual service hours (hr/yr)		
	Air conditioning	Lighting	Business equipment
8760	1132	2920	2555

Table 1: Standard scenario of household equipments

Residential Type	Subitem EUI reference (kWh/m^2.yr)			EUI (kWh/m^2.yr)
	Air conditioning	Lighting	Electrical appliance	
Single house, townhouse, housing	10	18	22	50

Table 2: Standard residential EUI

4. BCF METHOD FOR QUANTITATIVE EVALUATION OF TAIWAN'S NEARLY ZERO-ENERGY HOUSES

4.1 Air conditioning energy conservation potential of house envelope energy conservation design

The first step of ZEB design is to use the passive energy conservation design of building envelop to reduce the indoor air conditioning heat load and the overall energy consumption of building. In the BCF method, if the energy consumption is not converted into carbon footprint equivalent (kgCO_2e), and the energy consumption (kWh/ m^2.yr) is calculated only, the estimation of the air conditioning energy consumption of specific air-conditioning system space is expressed as Equation 1:

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

$$\text{Annual energy consumption of specific AC system} = (\Sigma EUIai \times AFIi) \times Vac \times Bac \times SEL$$

Equation 1

$$Bac = 1.0 - (2/d) \times (1.0\text{-}EEV)$$

Equation 2

where, EUIai= Air conditioning EUI of residential space (kWh/m^2.yr)
AFIi= Indoor floor area (m^2)
Vac = Air conditioning energy consumption reduction ratio by natural ventilation
Bac= Air conditioning energy consumption reduction ratio by building envelop energy conservation
EEV= Building envelop energy-saving efficiency
SEL= Air conditioning energy label correction coefficient
2/d= Depth factor, where d is the mean depth in short direction of building (m)

The "natural ventilation air conditioning energy consumption reduction ratio Vac" means the building uses natural ventilation condition, so that the air conditioning is stopped in winter, spring and autumn to reduce the ratio of annual air conditioning energy consumption. If Vac=0.7, the natural ventilation can save 30% of air conditioning energy. The "natural ventilation air conditioning energy consumption reduction ratio Vac" is related to the "natural ventilation potential VP (Ventilation Potential)". The VP is the ratio of "naturally ventilated floor space" to "total floor space". According to the study of Building Research Institute, Cheng Kung University, Taiwan's "natural ventilation potential VP" is 0.9~0.3 . The residential spaces mostly use air conditioning at night, the maximum air conditioning energy-saving benefit is set as 70%, so the maximum Vac of residential type is 1, the VP is 0.9~0.7. The residential air conditioning energy conservation potential is discussed below by "passive energy saving technique" and "active energy saving technique".

- Discussion about passive energy conservation design benefit

According to Equation 1 and Equation 2, the "passive design" factors related to the air conditioning energy consumption estimation of specific air-conditioning system space include "building envelop energy-saving efficiency EEV", "mean depth d in short direction of building" and "natural ventilation air conditioning energy consumption reduction ratio Vac". As the BCF method encourages using natural ventilation to reduce the air conditioning energy consumption, if the EUI and total floor area are identical, this study assumes the energy-saving scenario baseline values to be VP=0.7, Vac=1, EEV=1, SEL=1 without using any shell energy conservation design technique.

The natural ventilation potential is the best when VP = 0.9, the Vac is 0.85. If EEV = 0.8, approaching the daily energy saving design value of most Taiwan's green buildings, the air conditioning energy-saving benefit increases to 22%. If EEV = 0.6, it is approximately the optimum performance value of shell energy saving of current green building design, the air conditioning energy-saving benefit is 29%, about 30% of air conditioning energy consumption can be reduced. (Figure 1).

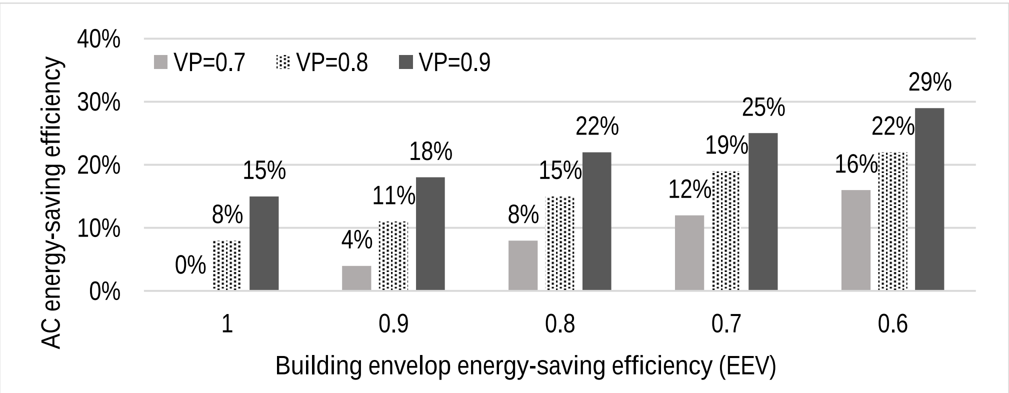

Figure 1: AC energy-saving efficiency and building envelop energy-saving efficiency EEV

- Discussion about active energy conservation design benefit

In Equation 1, the "active design" factor related to the annual energy consumption of specific air-conditioning system is the "air conditioning energy label correction coefficient SEL", the coefficient uses five "air conditioning energy label efficiency grades" of Bureau of Energy, Ministry of Economic Affairs for air conditioning energy consumption reduction. According to Figure 2, under the precondition of excellent passive energy conservation design (VP=0.9, EEV=0.6, d=5), the maximum air conditioning energy-saving benefit of different "air conditioning energy label efficiency grades" is 43%.

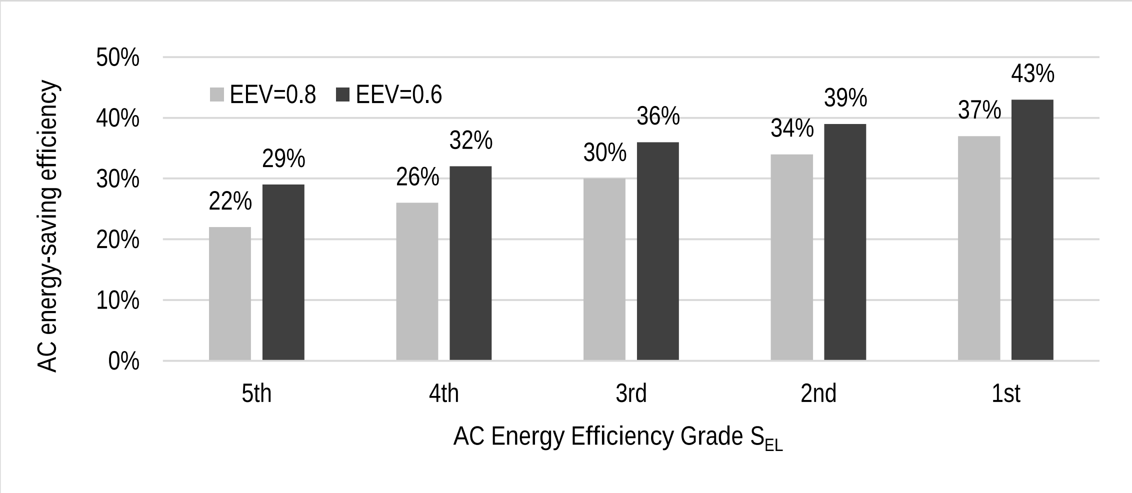

Figure 2: AC energy-saving efficiency and AC energy efficiency grade SEL

- Discussion about overall energy conservation design benefit

According to the pilot calculation of the aforesaid design influencing factors, the excellent passive design and excellent air-conditioning equipment (VP=0.9, EEV=0.6, d=5m, SEL=0.85), under the existing house design conditions of Taiwan, can reduce the routine energy consumption of residential air conditioning by 43%. Therefore, if the annual EUI of residential air conditioning is 10 (kWh/ m^2.yr), the minimum annual energy consumption is 10*0.6=6 (kWh/ m^2.yr).

4.1 Energy conservation potential of residential lighting design

The second factor influencing the residential energy consumption is the "lighting energy consumption". The BCF method estimates the lighting energy consumption as Equation 3. The EL index is the combined lighting energy-saving index about energy-saving lamps, lighting system and on-off control in Taiwan green building label EEWH.

$$\text{Annual energy consumption of lighting} = (\Sigma EUIai \times AFIi) \times EL$$

Equation 3

where, EUIli=Lighting EUI (kWh/ m^2.yr)
AFIi= Indoor floor area (m^2)
EL=The lighting system energy-saving efficiency follows the green building assessment manual EEWH - BC daily energy saving index specification

Referring to EEWH system, this study uses minimum 0.4 of EL for evaluation, namely, the minimum annual energy consumption of lighting can be 40% of standard lighting energy consumption. Therefore, if the annual EUI of residential lighting is 18 (kWh/ m^2.yr), the minimum annual energy consumption is 18*0.4=7.2 (kWh/ m^2.yr).

4.2 Energy conservation potential of household electrical equipments

The electrical equipments refer to household electric equipments with plugs, such as computer, washing machine and so on. The BCF method regards the water heater, hot drinks machine and household sauna as household appliances. The energy consumption of electrical equipments is estimated as Equation 4:

$$\text{Annual energy consumption of electrical equipment} = (\Sigma EUIai \times AFIi) \times Uei$$

Equation 4

where, EUIli=Lighting EUI (kWh/ m^2.yr)
AFIi= Indoor floor area (m^2)
Uei= Electrical equipment service management efficiency, using effective night standby power off management technique is 0.9

As the standby power consumption of household appliances accounts for about 10% of total power consumption of home, the BCF method privileges 10% of total energy consumption of electrical equipments for night standby power off management technique. Therefore, estimated by Equation 5-8, minimum value of Uei is 0.9, if the annual EUI of household electrical equipments is 22 (kWh/ m^2.yr), the minimum annual energy consumption is 22*0.9=19.8 (kWh/ m^2.yr).

4.3 Total residential energy conservation potential

According to the aforesaid subitem evaluation, under current condition of general techniques, if the residential planning and design use the optimum energy conservation design technique, the residential air conditioning EUI can be reduced from 10 (kWh/ m^2.yr) to 6 (kWh/ m^2.yr), the lighting EUI can be reduced from 18 (kWh/ m^2.yr) to 7.2 (kWh/ m^2.yr), the electrical equipment EUI can be reduced from 22 (kWh/ m^2.yr) to 19.8 (kWh/ m^2.yr), the total EUI can be reduced from 50 (kWh/ m^2.yr) to 33 (kWh/ m^2.yr), the maximum energy-saving benefit is 34%.

Title	Subitem EUI (kWh/ m^2.yr)			Total EUI (kWh/ m^2.yr)
	Air conditioning	Lighting	Electrical equipments	
Original standard value	10	18	22	50
Optimum energy-saving technique applied	6	7.2	19.8	33
Maximum energy conservation potential	40%	60%	10%	34%

Table 3: Energy-saving technique, residential EUI and maximum energy conservation potential

4.4 Substitution potential of residential renewable energy technology

The renewable energy is estimated by using photovoltaic in this study. First, local daily average solar radiation quantity (kWh/ m^2.day) is obtained from meteorological data, multiplied by photovoltaic installed capacity (kW), number of days, service life and correction coefficient 0.8 (m^2/ kWh), the annual electricity generation design value can be obtained (Equation 5).

$$\text{Photovoltaic panel electricity generation (kWh/year)} = \text{daily average solar radiation quantity (kWh/ } m^2\text{.day)} \times \text{Correction coefficient 0.8 (} m^2\text{/ kWh)} \times \text{Photovoltaic installed capacity (kW)} \times 365 \text{ (days)}$$

Equation 5

This study refers to the statistical data of Directorate General of Budget, Accounting and Statistics, Executive Yuan in 2015 , the nationwide average area per household is about 150 m^2, the EUI is 33 (kWh/ m^2.yr), the annual total power consumption is 4950 kWh. Mounting 1kW crystalline silicon photovoltaic panel needs about 10 ㎡, the annual electricity generation of 1kW photovoltaic panel in the north is about 803 kWh, that in the midland is about 949 kWh, that in the south is about 1095 kWh. Therefore, one household in the north needs at least 62 m^2 photovoltaic panel, that in the midland needs at least 52m^2 photovoltaic panel, and that in the south needs at least 45 m^2 photovoltaic panel. The specific payback period of investment is 14~19 years (Table 4).

If the individual house is a two-story building, 60%~80% of rooftop area shall be reserved for mounting photovoltaic panels. If it is a three-story building, as the rooftop area decreases, all the rooftop area shall be used, the shortage will be made up by ground area or upright space, so as to meet the goal for nZEB.

Besides the excellent energy conservation design of buildings, the application of renewable energy is the key to the success of nZEB. According to the aforesaid pilot calculation result, if a general-scale household (floor area 150 m^2) is used for nZEB design in Taiwan, under the precondition of disregarding the equipment investment cost, using the rooftop and partial area within the site to mount photovoltaic panels is potential to implement nZEB. However, the actual residential pattern is much complex, especially in large metropolitan areas, the residential pattern is mostly high density amalgamated dwelling, only using rooftop to set up photovoltaic panels to reach the balance of nZEB is hardly feasible. Therefore, only if the solar cell efficiency is further increased in the future, the concept of "Building Integrated Photovoltaic (BIPV) system" is used actively, and the photovoltaic panels are set up thoroughly on at least 70% of rooftop area, 20% of open area and the building elevation, the nZEB may be implemented.

Site	Daily average solar radiation quantity (kWh/m^2.day)	Annual power generation per unit capacity (kWh/kW)	Total installed capacity (kW)	Mounting area (m^2)	Cost recovered years (yr)
North	2.75	803	6.2	62	19
Midland	3.25	949	5.2	52	16
South	3.75	1095	4.5	45	14

Table 4: Photovoltaic substitution potential calculation (area per household 150 m^2)

5. CONCLUSION AND SUGGESTIONS

This study uses the BCF method of the "Low Carbon Building Alliance", controls the building envelop design, ventilation, lighting and household appliance factors in "residential standard situation", and calculates the "building EUI" under various energy-saving techniques, to evaluate the feasibility of nZEB. The results show that under the present general energy-saving techniques, the total residential EUI can be reduced from 50 (kWh/ m^2.yr) to 33 (kWh/ m^2.yr), the maximum energy-saving benefit is 34%.

This study uses "photovoltaic" as main renewable energy to evaluate the nZEB feasibility. The dwelling level is about 150 m^2 per household in Taiwan, under the precondition of EUI 33 (kWh/ m^2.yr), the small-scale "individual house" is potential to implement ZEB at present. However, in the case of amalgamated dwelling, the full elevation BIPV design and high conversion efficiency solar cell shall be developed, then it is potential to be ZEB.

In the promotion of related policies in the future, it is suggested to enhance the existing building energy saving reference, establish building energy label system, promote the improvement of the existing building efficiency, reward excellent green building design, and encourage the application of BIPV, so as to attain the goal for nearly ZEB.

ABSTRACT

Urban-scale policy, planning and development decisions can have significant resource use and environmental impacts. The energy consumption and related greenhouse gas (GHG) emissions of residential households, in particular, are mostly due to their housing and transport energy consumption. At the metropolitan scale, the type and location (or distribution) of housing can have a significant impact on the region's total energy and emissions profile. This paper presents a bottom-up methodology for assessing the impacts of alternative urban forms on the urban energy and GHG emissions footprint, combining housing and transport energy consumption across all households in the study area. The integrated assessment is built around a common household typology, and then extends separately towards housing energy consumption (based on sub-typologies of housing type and age, end-use demand categories and supply) and transport energy consumption profiles. The impact of the spatial distribution of households can be assessed from small geographical levels (comprising of about 200 - 250 households) to the whole municipality or Local Government Area (LGA), and to the whole metropolitan scale (i.e. all of the 31 LGAs in Metropolitan Melbourne). We present herein the calculation and validation of the total baseline energy consumption, and related GHG emissions of all households in Metropolitan Melbourne in the census year 2011. This approach can be used in the next stage to assess the impacts of alternative urban forms into the future.

Keywords: urban form, building energy simulation, transport energy

1. INTRODUCTION

More than 75% of the world population are expected to live in cities in the next 10 years (UN Habitat, 2013). These agglomerations exacerbate existing urban challenges and bring new ones. The nature and diversity of stakeholders' decisions to address the increasing population and housing density and the changing demand and patterns of human mobility have a significant impact on resource consumption, particularly energy, and on the environment, particularly through the greenhouse gas (GHG) emissions caused by human activities (Jenks & Burgess, 2000). This has become even more important and urgent in the light of the global agreement (during the recent Conference of Parties, COP21, in Paris) to scale up the implementation of ambitious actions towards the "below 1.5 or 2°C" pathways. Different levels of government and stakeholders in urban governance and the building and construction sector need to map-out the most cost-effective options to contribute to this goal.

The assessment of urban energy includes the energy used in buildings, transport, industry, water management and wastes (Kennedy, 2012). Since the building and transport sectors have the largest contribution to energy consumption (SoE, 2014), the present study focuses in these two areas, but excluding their embodied impacts. Previous studies have traditionally looked at transport (e.g. Alford and Whiteman, 2009) and building stock (Foliente and Seo, 2012) separately.

Broadly, there are two general methods for modeling building stock energy use and associated GHG emissions: the bottom-up and the top-down approaches. Previous work by Crawford & Fuller (2010) and Rickwood (2010) integrated building and transport energy assessment based on a hybrid Input-Output (I-O) and Life Cycle Assessment (LCA) methodology considering urban form, housing types and residents' travel behaviour. These studies, like others that use aggregated data (i.e. the top-down approach), are useful to understand the impacts of broad policy, econometric or technological options, but are not practically useful to guide and assess the impact of specific decisions and/or actions of stakeholders. They could provide macro understanding of the entire housing sector, but are not concerned with individual end-users.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The bottom up approach is built from disaggregated data and analysis then combined according to the needs of the specific sector (Kavgic, 2010). Bottom-up studies that combine energy consumption in buildings (stationary energy) and transport (non-stationary energy) are very rare. In the Energy Efficiency Cities Initiative in the City Model (CiMo, 2014)) Project, bottom-up engineering models of energy demand, supply, and emissions from buildings and surface transport at the city scale were applied to the City of Westminster. This UK approach is similar to separate studies that have been undertaken separately for these sectors in Australia (Foliente and Seo 2012; Ren et al. 2013).

Considering household travel needs and activities from their place of residence, there is a need for a similar intermediate approach in this area that builds on disaggregated travel data and/or detailed transport modelling and simulation results but simplified for application to practical planning scenarios impact assessments based on selected household typologies. This paper integrates the residential households' location and mobility patterns with their housing stock characteristics to establish the combined energy consumption from the bottom up to metropolitan scale.

2. METHODOLOGY

The cross-typology bottom-up building stock energy assessment framework proposed by Foliente and Seo (2012) to assess the impacts of different technology, investment, policy instruments and actions by different stakeholders into the future provides a starting platform for this type of intermediate approach. This provides a systematic and detailed classification (or sub-typologies) of variables that impact the total energy consumption and GHG emission of building stock in a given area (e.g. building characteristics, space conditioning system, lighting, hot water system, plug-in appliances, occupancy type and pattern, and local energy supply system); different options at these sub-typologies can be assessed at different scales and level of details The cross-typology capability refers to a separate classification of intervention schemes.

The overall research has two main phases: (a) Calculation of a baseline building and transport energy profile, its validation at micro and macro scale (from Statistical Area 1 or SA1 level to SA3 and then metropolitan level); and (b) Application into future scenarios for the growth of Metropolitan Melbourne (business as usual vs alternative urban form scenarios) (Figure 1). This paper deals with the first phase only.

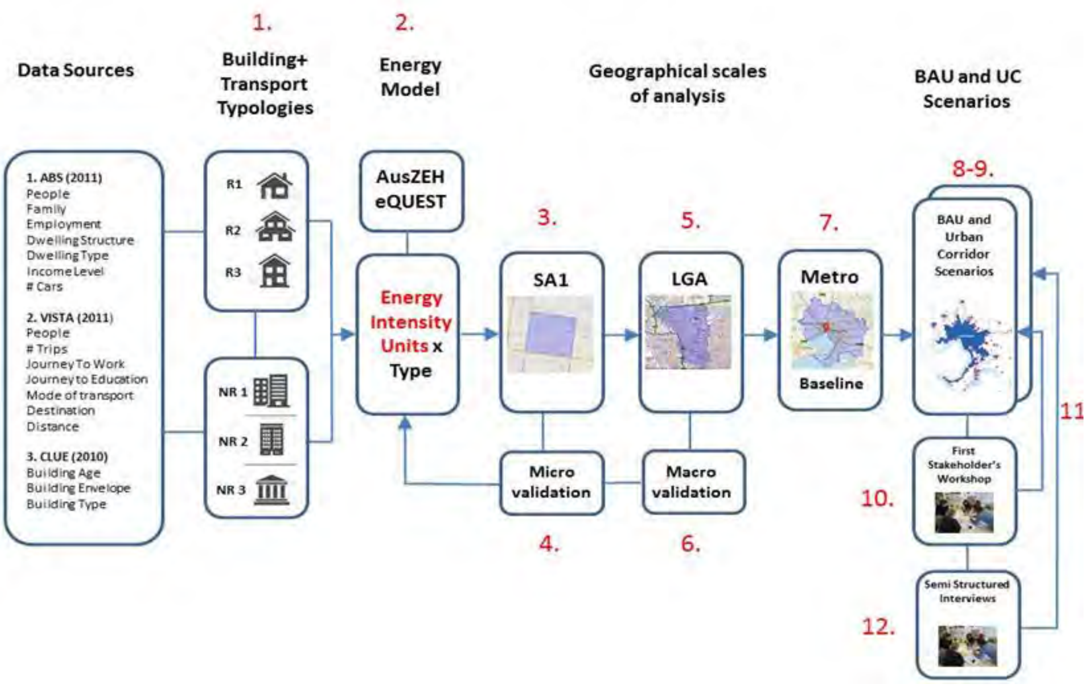

Figure 1: The research methodology's overall scheme; the present paper covers only the first phase of the planned work program (i.e. up to item/ step 7 only)

The residential building energy is modelled following the bottom-up building typology approach by Foliente and Seo (2012) and using the AusZEH software developed by CSIRO (Ren et al. 2012). The results were processed for distribution in the geographical scale using Microsoft Access and SQL queries to obtain the values per meshblock and per SA1. The Energy Intensity Units (EIU) and associated GHG emissions will take into consideration: a) Demand (Building, Load and Household type) b) Supply (Energy system: gas, electricity, solar, wind) and c) Consumption (Gross Energy and Energy Intensity Units x annum) with the Household type as integrating element (see Figure 2):

Figure 2: Integration between residential building and transport energy consumption

The smallest unit of building stock energy aggregation is at SA1 level (comprising of about 200 - 250 households) and the results are displayed within these boundaries. This is the smallest geographical unit that have available census data for modeling from the Australian Bureau of Statistics (ABS), mainly for dwelling type, household type and labour force. In addition, it is also compatible with the other datasets on dwellings, such as those from the Geoscience National Exposure Information System (Geoscience Australia, 2014)) database and property data from the Valuer's General for the State of Victoria. The SA1 scale also allows a finer grain visualization of the whole Metropolitan Melbourne, than other geographical scales that have been used previously by others.

For household travel related energy consumption, the smallest unit of analysis used is the meshblock level, as it was possible to request the Victorian Integrated Survey for Travel and Activity (VISTA, 2009) at this small geographical level. The survey sampled meshblocks covering all 31 LGAs in Metropolitan Melbourne and geographically distributed in an even form to cover equally all territory. The transport consumption was modelled from the household level, then summated up to meshblock level, and finally aggregated at SA1 level to match the unit of analysis used for the residential dwelling's operational energy consumption.

The processing of input data from various sources (left most part of Figure 1) and the modelling results/output data was facilitated by a script coded in Python which extracted and processed the information from the databases used in the research ABS, NEXIS, Valuer's General and IMAP) and distributed the IMAP building typologies and their associated Energy Intensity Units (EIU) at SA1 level using the information from the requested datasets (ABS, NEXIS, Valuer's General and IMAP) and automated the aggregation and mapping in ArcGIS. The goal is to analyze patterns of energy consumption at the report neighborhood level scale (SA1), and their main difference according to distribution of dwellings types, household types and location at LGA scale and the metropolitan scale. GHG emissions were calculated using the emission conversion factors for different fuel types for housing and transport from Australian Energy Market Operator (AEMO, 2012) and Australia Energy and the Australian Energy Institute (AEI, 2012).

3. MODELING RESULTS AND DISCUSSION

Figure 3 shows the results of the residential building stock energy consumption calculations mapped at SA1 level for the whole Metropolitan Melbourne area. As expected, the most intense consumption areas are those associated with larger population density. However, many SA1 areas with lower population density showed larger residential energy consumption than the average, mainly related to dwelling type and household type variables including occupancy type (hours of use) and household size.

These results were verified and validated though different data obtained in surveys, government reports, energy providers and residential energy bills. Verification of the model results was undertaken by comparing the results obtained by the model with the results obtained using the same bottom-up building typology approach proposed in the Inner Melbourne Energy Consumption Report 2011 - 2016 (Seo et al., 2014). In this report, they modeled the energy consumption of residential and commercial operational energy for the four inner city councils: the City of Melbourne, City of Port Phillip, City of Yarra, and City of Stonington. The unit of analysis in this report was the meshblock geographical unit, as the information needed for the modelling was available at this fine grain unit, and the city officials wanted to see small variances between meshblocks in the different councils (IMAP, 2014).

The results of the IMAP work aggregated to a comparable SA1 level of geography were compared with the results of the model developed in the present research using the same energy modeling engine (AusZEH developed by CSIRO) but the latter energy mapping effort using a code developed in Python to automate the typologies distribution process. Figure 3 shows the comparisons of the percentage of difference between the IMAP results and the results obtained with the script developed in Python:

Model validation was undertaken using government reports, surveys and reports from energy providers and residential energy bills. The average consumption for the different sources was compared with the average operational energy results from the energy model. A micro validation (at building level) and a macro validation (SA1 level) were undertaken. The sources for the validation were selected depending on the availability of information for Victoria, as results can vary greatly between different states in different geographical zones. It is important to mention that some of the sources used for validation are surveys, and as such, they do not cover the whole population, instead only samples of the selected areas.

The main sources for the validation were:

- Victorian household energy survey report, May 2014
- Residential energy bill average (Lumo Energy, Brunswick) 2014
- Ausgrid report energy bill prices 2012 (medium size dual fuel household Melbourne)
- Energy Consumption Survey, ABS, 2012 (results for state of Victoria)

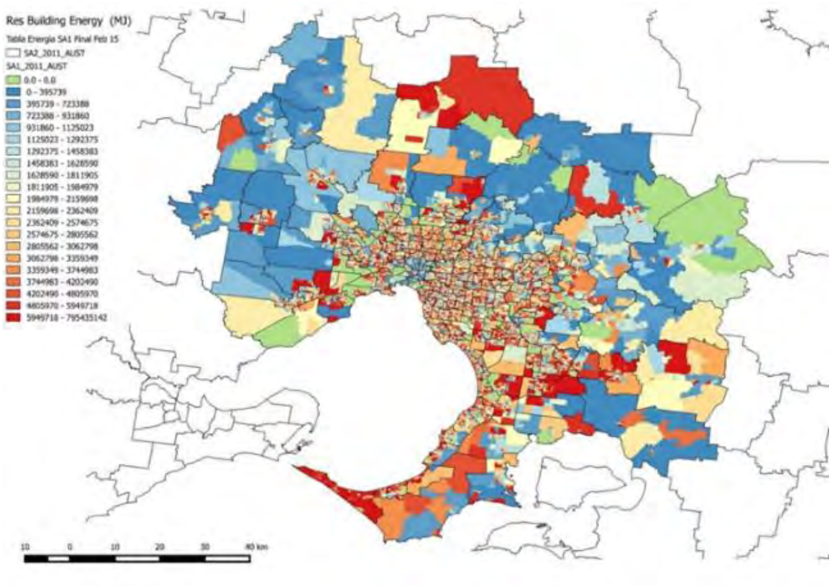

Figure 3: Metro-wide distribution of the residential building stock energy consumption (by SA1)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

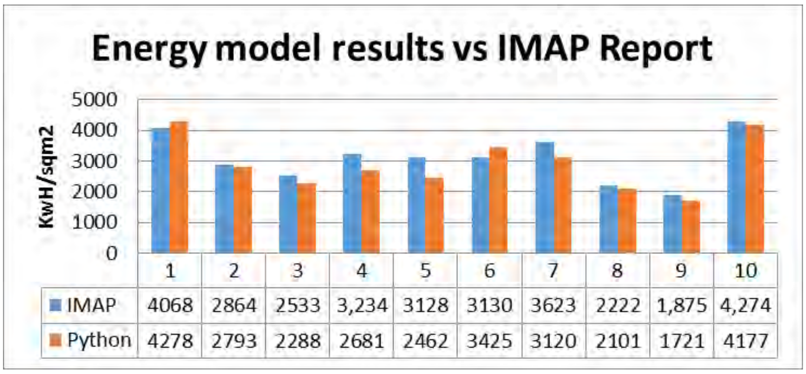

Figure 4: Comparison of IMAP vs. script model results for residential energy (by SA1)

Results show that the average consumption for a medium size dwelling type in this report was 19.671Kwh per annum for the micro validation level (residential building). For comparison, a random set of 10 SA1 from the simulated energy consumption were selected and its overall result per annum was divided in the number of dwellings reported in the ABS 2011 Census (see Figure 4). The results of the residential building average per dwelling of the selected SA1s was 20.003 KhW per annum, showing a difference of 3.5%, and generally a deviation of less than 10% is considered good for studies of this kind (IMAP, 2014).

Another type of macro-validation was undertaken using information from the Water and Energy Supply and Consumption (WESC) protocol or data standard developed by AURIN and CSIRO (combined monthly Meter Readings for aggregated electricity consumption by postcode for 2004 - 2012 in Jemena provider areas). The dataset is broken down into commercial, industrial, residential or unmetered uses, from postcode regions in the northwestern parts of Melbourne. Using this WESC information on residential energy, we compare the total residential operational energy consumption at a larger geographical scale (postcode), by aggregating the consumption of each SA1 conforming the Post Code area in the areas where Jemena Energy supplies energy. With the dataset in postcode 3058 (Coburg), our residential energy calculation under-predicted the actual aggregated data by 18.8% (estimated to be 2,692,638KwH vs Jemena's reported figure of 3,198,113kwH).

Overall, the Inner Melbourne area variations in residential energy consumption are related with the Household Type and Dwelling and Occupancy type variables. Building age also has an impact on the efficiency of the building envelope to reduce heating and cooling energy consumption; a large part of the residential building stock in Metropolitan Melbourne is more than 35 years old (Sustainability Victoria, 2013).

Regarding the residential transport energy consumption, analysis of the 2011 VISTA survey data shows that large households (Hh_structure) tend to use more private transport for everyday activities, although households located near the transport corridors (train and tram lines) showed a smaller proportion of private car use in the modal split. A Pearson's correlation analysis with the variable Distance (Sum_Dist) as dependent variable and other variables selected (Distance from CBD, Main transport mode, dwelling type, Household Structure, Income, and Number of cars). The relationship between dwelling type and household type and private car VKT (Vehicle Kilometer Travel), shows only a small impact of these variables on the overall residential transport energy consumption.

	Correlation with Sum_Dist	Significance (R squared)
Hh_structure	0.0408	0.0017
Dwell type	-0.0952	0.0091
Income	0.0965	0.0093
Distance to CBD	0.2114	0.0224
Nr of cars	0.1628	0.0265

Figure 5: Pearson's correlation analysis residential transport energy model

Correlation analysis of the residential transport energy model shows a correlation between the dependent variable Sum_Dist (household Total VKT per mode) and the Nr of cars (# cars) and Distance to CBD (distance to CBD in Km) (Figure 5). Income and other socio economic variables were also considered, but in the case of the transport behaviour in Metropolitan Melbourne the correlation between income levels and use of private cars is not as strong as shown in other residential transport studies (Grosee et al, 2015).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

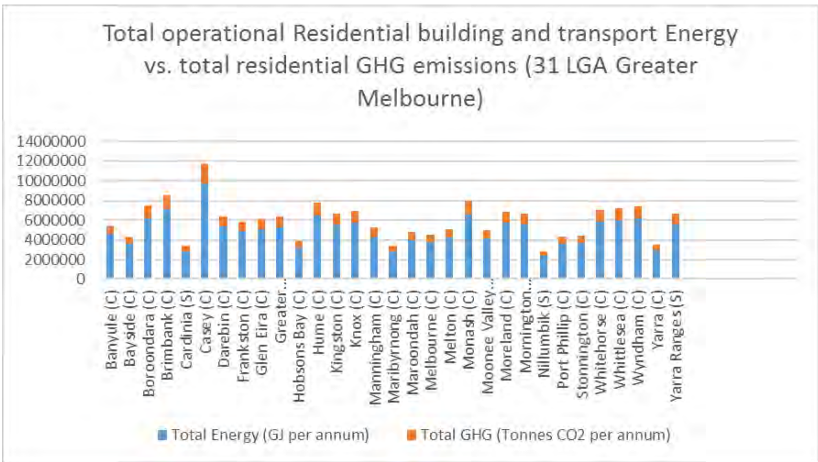

Figure 6: Combined residential building and transport energy and associated GHG emissions for 31 LGA Greater Melbourne

Once the residential buildings and transport energy was modelled, we calculated the GHG emissions based on the energy supply ratio established in the IMAP typologies (70% households with electricity+gas, 30% households with electricity only and 5% households with all sources installed); this also corresponds with the building stock report for residential energy supply from ABS (Households Energy Use and Cost, 2012). The Greenhouse Emission factors applied were the coefficient values reported by the Australian Institute of Energy (AEI, 2012) and the Australian Energy Market Operator (AEMO, 2016) for electricity and natural gas for the State of Victoria.

The residential transportation fuels emissions factors were provided by the Environmental Protection Authority (EPA, 2006) Assuming that 60% of private cars use petrol and 40% diesel (ABS, 2014) and the public transport (trams, trains) use electricity providing from coal energy plants, except for buses (100% Diesel).

Figure 6 shows the results of the combined residential building energy (in GJ x annum) and combined total GHG emissions (in Tonnes CO_2 x annum) at LGA level (31 LGA) for Greater Melbourne. the areas with higher dwelling density and car ownership have the largest impact on the operational energy (GJ per annum) and $CO_{2\text{-equiv}}$ emissions, and the distance to the CBD and car ownership density are clearly showing a larger $CO_{2\text{-equiv}}$ emission impact that the areas of Melbourne's Inner City.

4. CONCLUSIONS AND FUTURE WORK

We developed a new energy modeling methodology for calculating the total residential household energy, combining housing and transport energy consumption across all households in Metropolitan Melbourne. The integrated assessment is built around a common household typology, one branch was focused on housing energy consumption (based on sub-typologies of housing type and age, end-use demand categories and supply) and the other was on transport energy profiles (based on household and dwelling type information from VISTA 2011). The GHG emissions for residential buildings and residential transport have been modelled and distributed geographically at SA1 level, facilitating a spatial comprehension of consumption patterns in Metropolitan Melbourne. The distribution of household energy intensities was mapped from small geographical SA1 level to the whole municipality or Local Government Area (LGA), and to the whole metropolitan scale (i.e. all of 31 LGAs or 9650 SA1s across all of Metropolitan Melbourne). The total baseline energy consumption was spot-validated using various sources for the census year 2011. These capability and results bring us to the next stage of analyses considering the environmental impacts of alternative urban forms to accommodate the expected population growth in Melbourne.

Building Life Cycle Carbon Emissions: A Review

TENG Yue[a], PAN Wei[b]

[a] The University of Hong Kong, Hong Kong SAR, tengyue@hku.hk
b The University of Hong Kong, Hong Kong SAR, wpan@hku.hk

ABSTRACT

Buildings are responsible for a substantial percentage of energy use related carbon emissions that contribute to global warming. Examination of buildings' carbon emission has been one of the key issues for the sustainability. As a high-density city, Hong Kong has increasingly advocated the use of prefabrication for high-rise residential buildings. However, although life cycle carbon emission assessment has been widely applied to buildings, its implications on high-rise prefabricated buildings remain unclear. Therefore, this paper aims to contribute to a better understanding of the life cycle carbon emission assessment of high-rise prefabricated buildings in Hong Kong.

The review was carried out through a meta-analysis of relevant previous studies and a more focused examination of research in the context of Hong Kong. The meta-analysis was conducted from the temporal, spatial, functional and methodological dimensions using seven variables, namely, life span, life cycle phase, research area, research scope, building type, building height, and life cycle assessment method. The focused examination reveals a severe gap in knowledge of the life cycle carbon emissions of high-rise prefabricated buildings in Hong Kong. A lack of understanding was also identified of the operational stage and indirect implications of prefabricated buildings. Furthermore, there is absence of consistent life cycle carbon assessment method in addressing the gaps. A systemic model of examining the carbon emissions of high-rise buildings is suggested to address the full building life cycle.

Keywords: life cycle assessment, carbon emission, high-rise prefabricated building, Hong Kong

1. INTRODUCTION

The excessive releasing of greenhouse gases (GHGs) is the largest cause of global warming, which has created risks worldwide (Soetanto et al., 2014). Carbon dioxide (CO_2), produced by consumed energy, has been the primary component of the GHG (Li et al., 2016). According to Sadineni et al. (2011), buildings are responsible for almost one third of the energy-related CO_2 emissions. In Hong Kong, this figure can be as high as 60% (EPD, 2010). Research into the environmental impact of buildings is thus important to Hong Kong.

Being a high-density city, Hong Kong has increasingly advocated prefabrication for high-rise buildings. Although relevant studies have widely applied life cycle carbon assessment ($LCCO_2A$) method for evaluating carbon emissions from the construction industry, the use of this method for high-rise prefabricated buildings remains unclear. Therefore, it is vital to explore consistent method of $LCCO_2A$ for prefabricated high-rise buildings. This paper aims at contributing to a systematic understanding of $LCCO_2A$ of buildings in Hong Kong. There are three research objectives: (1) to reveal the profiles of previous studies on $LCCO_2A$ of buildings; (2) to investigate the implications of $LCCO_2A$ for high-rise prefabricated buildings in Hong Kong; and (3) to explore the research gaps and recommendations.

2. THE CONCEPT OF LCA AND $LCCO_2A$

According to International Organization for Standardization (ISO, 2006), life cycle assessment (LCA) was defined as "compilation and evaluation of the inputs, outputs and the potential environmental impacts of a product system through its life cycle". As a simplified version of LCA, $LCCO_2A$ only focuses on CO_2 relevant emissions (Chau et al., 2015). The building's life cycle can be divided into four main phases: production, construction, operation and end-of-life (Kamali and Hewage, 2016). However, previous studies examined the building's life cycle carbon emissions in different interpretations of the building life cycle: e.g. from "cradle to gate" (Din and Brotas, 2016), from "cradle to site" (Gardezi et al., 2016), from "cradle to grave" (Blengini, 2009), and from "cradle to cradle" (Sinha et al., 2016). Subsequently, the various concepts of $LCCO_2A$, coupled with inconsistent data collection methods, boundaries, and calculation methodologies, call for a critical review of previous research.

3. REVIEW METHODS

The research was carried out through a meta-analysis of previous relevant studies and a focused examination of research within the Hong Kong context.

In the meta-analysis, a commonly applied search engine, Scopus, was firstly selected to identify relevant articles published in peer-reviewed journals during the period from 1996 to 2016. The keywords were identified as: “Life Cycle” and “Carbon Emission” and “Building” in undertaking the analyses. Papers with these specific terms included in the Title/Abstract/Keyword were considered to have fulfilled the requirement of this review. The search was further limited to subject areas such as “engineering”, “environmental science”, “energy”, “social and management” with the document types of articles. Through the process, the search limited the data sources to a list of representative 13 journals. Subsequently, a total of 173 articles were identified (Table 1).

	Journal	Number of articles
1	Applied Energy (AE)	14
2	Building and Environment(BE)	31
3	Building Research and Information (BRI)	8
4	Energy (EN)	7
5	Energy and Buildings(EB)	44
6	Energy Policy (EP)	6
7	Environmental Impact Assessment Review(EIAR)	4
8	Habitat International (HI)	2
9	International Journal of Life Cycle Assessment(IJLCA)	21
10	Journal of Cleaner Production(JCP)	21
11	Journal of Environmental Management (JEM)	3
12	Renewable Energy (RE)	4
13	Renewable and Sustainable Energy Reviews(RSER)	8
	Total	173

Table 1: Selected journal and articles for analysis

The meta-analysis method, prompted by Pan and Ning (2015), was then applied to the 173 articles identified to investigate the $LCCO_2A$ of buildings. Seven variables were selected drawing on literature, from temporal, spatial, functional and methodological dimensions (Table 2).

Dimensions	Variables	Description of variables
Temporal	Life span	The service life of the buildings
	Life cycle phase	Full life cycle or not
Spatial	Research area	Location of the buildings
	Research scope	Building as a whole; components; materials; system; others
Functional	Building type	Residential buildings; non-residential buildings
	Building height	High-rise; medium-rise; low-rise buildings
Methodological	LCA Methods focus	Input-output; process based; hybrid method

Table 2: Dimensions and variables for review

In the focused examination, six papers focusing on $LCCO_2A$ of buildings in Hong Kong were identified. The analysis was carried out from the dimensions of case study, building type, life cycle phase, LCA method, research method and key data input.

4. REVIEW RESULTS AND ANALYSIS

4.1 Results of meta-analysis

4.1.1 Profile of research in the temporal dimension

- Buildings’ life cycle phase examined

Among the 173 articles, 134 indicated the life cycle phase of the cases studied, of which 43.3% (58) focused on the examination of LCCO2A from the full life cycle. The other LCCO2A studies of the partial life cycle (76; 56.7%) mainly included those articles examining the “cradle to end of construction” (23.7%; 18), “cradle-to-gate” (19.7%; 15), and the “operation” (18.4%; 14). There were also some articles addressing “cradle to site” or “cradle to grave” (both of 13.2%; 10), and some others studying “cradle to operation” (10.5%; 8).

- Buildings’ life span studied

Among the 173 articles examined, 69.9% (121) addressed particular building cases and clearly specified the service life span of the cases. However, the life spans addressed in these 121 articles were inconsistent: falling in three groups (1) between 25 (exclusive) and 50 years (inclusive) (50.4%), (2) 25 years or less (22.3%), and (3) greater than 50 years (27.3%). In particular, 27.3% and 19.0% of the 121 articles adopted 50-year and 100-year life span, respectively.

4.1.2 Profiles of research in the spatial dimension

- Research area studied

The majority (89%; 154) of the identified articles specified the cases’ locations in text, whereas the rest did not explicitly describe them. Among these 154 articles, the largest category (26.6%; 41) addressed the examination of LCCO2A in Europe, followed by the categories addressing U.S. (13.6%; 21), Mainland China (12.3%; 19) and Korea (10.4%; 16). However, only a few (3.9%; 6) examined the cases in Hong Kong. For the 41 articles focused on the Europe, Sweden was the most researched (31.7%; 13). These results reveal a lack of studies into the life cycle carbon emissions of buildings in Hong Kong.

- Research scope examined

The research scope in relation to the LCCO2A of buildings exists at four layers: materials, components, systems, and buildings as a whole. Nearly three quarters (130; 75.1%) of the 173 identified articles clearly pointed out their research scopes. For the 130 articles, the largest category (57; 43.8%) studied LCCO2A of buildings from the perspective of “Materials”, followed by 28 articles (21.5%) studying “Components of buildings” (Table 3). The number of articles examined from the perspective of “Systems” (23; 17.7%) and “Buildings as a whole” (22; 16.9%) nearly remains the same.

Group	Description	Number
Materials	Focusing on the materials (concrete, cement, wood, steel, etc.) in the buildings	57
Components	Focusing on components (envelope, floor, foundation, interior, etc.) in buildings	28
Systems	Focusing on the system (fuel and heating system; household biogas system; rainwater systems, thermal system, etc.) in the buildings	23
Buildings as a whole	Focusing on the whole buildings	22
Others	Macro analysis; No case studies; Not concentrating on specific buildings, etc.	43

Table 3: Articles of buildings’ $LCCO_2A$ by research scope

4.1.3 Profiles of previous research in the functional dimension

- Building type studied

Buildings are divided into residential and non-residential buildings (e.g. industrial, commercial, educational and health buildings) (Wong et al., 2000). Among the identified 173 articles, only 61.3% (106) definitely showed the buildings’ types of the cases. The results illustrate that the majority of the articles (73; 68.9%) studied the LCCO2A of residential buildings, whereas merely 33 articles (31.3%) addressed that of no-residential buildings. Under the category of non-residential buildings, nearly half (16; 48.5%) studied office buildings, followed by those studying educational buildings (8; 24.2%) and commercial buildings (7; 21.2%); very few examined the cases of health

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

buildings (1; 3.0%) and historic buildings (1; 3.0%). The salience of research on residential buildings illustrates the clear focus of previous research on examining the life cycle carbon emissions of domestic buildings.

- Building height examined

According to Jan et al. (2004), buildings are divided into four types based on the stories: low-rise (less than 3 stories), medium-rise (4 to 6 stories), medium-to-high-rise (7 to 9 stories), and high-rise (greater than 10 stories). Among the identified 173 articles, only 97 articles specified the height of the cases. The majority of the $LCCO_2A$ articles (43; 44.3%) studied low-rise buildings, followed by the group addressing medium-rise (22; 22.7%) and high-rise buildings (25; 25.8%), with a marginal amount of studies addressing medium-to-high-rise buildings (7; 7.2%).

4.1.4 The Profile of previous research in the methodological dimension

Three LCA methods, i.e. process-based analysis, input-output analysis and hybrid analysis, have been advocated by previous studies to calculate the carbon emissions of buildings (Ries and Mahdavi, 2001). Only 41.6% (72) of the identified 173 articles implemented the calculation process and adopted one of the three methods. The results show the majority of the studies adopted input-output and process-based methods in their $LCCO_2A$ examination, namely 34 (47.2%) and 31 (43.1%) of the articles. Only about one in ten (7; 9.7%) used hybrid analysis method.

4.2 Results of focused examination within the Hong Kong context

Despite several studies have examined $LCCO_2A$ of buildings, little research has been undertaken into high-rise prefabricated buildings in Hong Kong. To address this gap, six identified papers which are relevant to Hong Kong were investigated thoroughly (Table 4).

	Authors	Case study	Building type	Life cycle phase	LCA method	Research method	Key data input
1	Chau et al. (2012)	CB [a]	HR office	cradle-to-end of construction	process-based	Monte Carlo method	First hand data; Reference; Published information.
2	Zhang et al. (2013)	CB	a thirty-story commercial	Full life cycle	process-based	inventory analysis; case study	Report by the Electrical Mechanical Service Department of Hong Kong; Literatures.
3	Chiang et al. (2014)	CB	residential	cradle to site	NA	NA	ICE database
4	Jaillon and Poon (2014)	review	HR residential	deconstruction phases	NA	Questionnaire survey	Questionnaire survey; Face-to-face interviews; Site observations.
5	Dong et al. (2015)	CB and PB	HR residential	cradle-to-end of construction	process-based	SimaPro	Questionnaire survey; Semi-structured interview; Ecoinvent.
6	Pan et al. (2016)	NA	PRH	NA	Simulation	BEA software	Literature review; Technical analysis; Case study;

[a] CB means the conventional buildings and PB means the prefabricated buildings.

Table 4: Previous studies of buildings' $LCCO_2A$ in Hong Kong

Chau et al. (2012) conducted Monte Carlo method to predict CO_2 emissions of the superstructure of thirteen high-rise office buildings in Hong Kong. It provided a method to evaluate the emissions reduction impacts by using different materials. However, operational stage was not considered in this research. Zhang et al. (2013) analysed a thirty-story high commercial building to examine eight types of air emissions in Hong Kong, using an inventory analysis method. It contributed to identify the optimal solution of minimizing the air emissions in early stage. However, this paper used a second data that needed to be improved in further studies. Chiang et al. (2014) proposed an optimization model from environmental, economic, and social criterions. A residential building, with a 75 years' life span in Hong Kong, was used as the case study. It helped decision makers choose a reduction method both from economic and social aspects. However, the operational stage was not included in this analysis. Jaillon and Poon (2014) proposed a review on design for deconstruction and a case study on industrialized building.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Findings from the case studies shows there are several advantages when adopting prefabrication in Hong Kong. However, this article just focused on the deconstruction phases. Dong et al. (2015) compared the carbon emissions of precast and traditional construction methods from the “cradle-to-end of construction” life cycle phase, based on a high-rise private residential building in Hong Kong. Results showed reduction of carbon emission could be 10% due to precast concrete. Pan et al. (2016) developed strategies for modelling carbon emissions in 40-story public residential buildings in Hong Kong. It helped to achieve efficient and accurate building energy simulation and carbon emission estimation of high-rise buildings in Hong Kong. These studies show LCCO2A of traditional high-rise buildings have been carries on by some scholars, whereas very few studies worked on LCCO2A of prefabricated buildings in Hong Kong.

5. DISCUSSION

The results of the meta-analysis reveal some general trends of previous studies. First, it reflects the inconsistent of cases’ service life span. In the identified articles, 50-year and 100-year life span are the relatively most widely accepted life span. Second, despite some studies have emphasised the analysis from the full life cycle aspect, the non-full life cycle was carried on by more scholars, especially the phase of “cradle to end of construction”, “cradle-to-gate”, and the “operation”. The reason may lay in the statements by some researchers that carbon emissions in the use and end-of-life phases were insignificant and could be neglected (Flower and Sanjayan, 2007). Third, although there are abundant LCCO2A articles in Europe, U.S., Mainland China and Korea, very few studies have been conducted in Hong Kong, which reveals the demand for further research. Fourth, the majority of articles addressed the LCCO2A studies from the materials’ aspect, which manifested the importance of changing materials for reducing the carbon emission (Wu et al., 2014, Ingrao et al., 2015). Fifth, residential buildings were demonstrated as the main research objectives of previous LCCO2A cases. This finding supports the statement of Li et al. (2013) that residential buildings’ carbon emissions are rather prodigious. Among the no-residential buildings, nearly half of them studied office buildings. However, the majority of LCCO2A analysis just focused on low-rise buildings. Therefore, the lack of understanding on the mid high-rise and high-rise buildings needs to be optimised in further research. Sixth, the input-output and the process-based methods have been widely advocated in previous research. Nevertheless, the articles adopting hybrid method are inadequate, albeit the demonstrated efficiency of it (Zhang and Wang, 2016).

The in-depth examination of the identified six articles reveals research problems. First, although studies on the carbon emissions from the upstream phase of buildings are abundant, the operation phase has been overlooked in Hong Kong. This finding is in line with the observation of Kamali and Hewage (2016) that the evaluation of CO2 emissions from the upstream phase was increasingly common in recent years. However, the operational phase can occupy 80% of all life cycle carbon emissions (Mao et al., 2013), which should not be ignored. Second, studies on high-rise prefabricated buildings in Hong Kong are inadequate. One reason might be that prefabrication has not yet been a recognised phase in the building life cycle. Another reason appeared to be the insufficient adoption of precast concrete components within the precast yard (Dong and Ng, 2015), which leads to the limited applications and analyses using real projects. Third, the direct implications were considered while the indirect ones were ignored. For example, the improved quality of buildings can reduce the carbon emission from full life cycle aspect, which should be taken into consideration in the calculation of carbon emissions.

6. CONCLUSIONS

Drawing the results and discussion, this paper concludes that uncertainties and inconsistency in the adoption of LCCO2A methods contribute to a fragmented understanding of the LCCO2A of high-rise prefabricated buildings. These uncertainties and inconsistency are caused by the differences in system boundaries, assumptions, chosen life span, building types and locations in LCCO2A. The paper also concludes that there is a lack of understanding of LCCO2A relevant to the building’s operational stage and prefabricated buildings’ indirect implications. There is a severe gap in the knowledge of the LCCO2A of high-rise prefabricated buildings in Hong Kong. To bridge this gap, a systemic model of examining the carbon emissions of high-rise buildings is suggested, which addresses the inconsistency of LCCO2A method. By this systemic model, the carbon emissions generated from the full life cycle will be accounted. The life cycle will cover eight phases: cradle-to-gate (P1), transportation (P2), prefabrication (P3), construction (P4), operation (P5), maintenance and refurbishment (P6), deconstruction (P7) and recycling/landfill (P8). First, data in the phase of cradle-to-gate (P1) will be primarily collected from Carbon Labelling of Construction Products in Hong Kong and Life Cycle Inventory worldwide, being calculated using process-based method. Second, carbon emissions in prefabrication (P2- P3) and construction (P4) phases will be examined using data from resource and energy consumption during transportation and installation in the construction yards and site. Third, operational carbon emissions (P6-P8) will be determined using EnergyPlus software, based on the simulated energy consumption. Last, data in the after-use phase (P9-P10) will be obtained through LCA inventories and literature review subject to their compatibility with available LCA inventories. The adoption of this systemic model will help to achieve a better understanding of the life cycle carbon emissions of buildings within high-rise contexts.

ACKNOWLEDGMENT

The work described in this paper was supported by a grant from the General Research Fund of the Hong Kong Research Grants Council (RGC GRF Project No.: 17207115).

ABSTRACT

The authors have collaborated to develop the new international standard on carbon metric (CM) of a building during the use stage (ISO 16745-2015). Carbon metric (CM) is a partial carbon footprint. It implies the sum of annual greenhouse gas emissions and removals, based on the real energy consumption and expressed as CO_2 equivalents. CM is relevant for snapshot measurement in the operational stage of building. It does not require professional knowledge about methods such as overall environmental performance assessment and life cycle assessment (LCA). Carbon metric is usable also in those countries where experts' services are limited.

The paper presents how the standard sets out a globally applicable common method of the calculating, reporting and verification of CM, including an explanation of the different system boundaries and preconditions. It focuses on how the standard simplifies and clarifies the method to make it globally applicable.

The paper discusses on how the standard could facilitate innovation for reduction of GHG emission from buildings. It is applicable in actions and policies for reduction of greenhouse gas (GHG) emission that includes the benchmarking for property management strategy, energy management service contract, post-occupancy evaluation, and education. The standard also provides the basis for cap and trade program. It also enables monetizing for international carbon trading (CDM in building related sectors)

Keywords: carbon metric, energy measurement and verification, carbon finance

1. INTRODUCTION

Measurement and reporting of greenhouse gas (GHG) emissions from existing buildings are critical for enabling significant and cost-effective GHG mitigation. Currently, there has not been a globally agreed method established to measure, report, and verify potential reductions of GHG emissions from existing buildings in a consistent and comparable way. If such a method existed, it could be used as a universal tool for measurement and reporting of GHG emissions, providing the foundation for accurate performance baselines of buildings to be drawn, national targets to be set, and carbon trading to occur on a level playing field.

In view of the context above, UNEP-SBC has proposed the idea of Common Carbon Metric of Building as a globally agreed method to measure, report, and verify potential reductions of GHG emissions from existing buildings (UNEP 2009). Following up the initiative by UNEP-SBCI, the authors have collaborated to develop the new international standard on the metric of GHG emission of a building during the use stage (ISO 16745-2015: Environmental performance of buildings — Carbon metric of a building during the use stage). It aims to set out a globally applicable common method of measuring and reporting of associated GHG emissions (and removals) attributable to existing buildings, by providing requirements for the determining and reporting of a carbon metric(s) of a building.

This paper presents how the standard sets out a globally applicable common method of the calculating, reporting of CM, including an explanation of the different system boundaries and preconditions.

2. WHAT IS CARBON METRIC OF BUILDING?

2.1 A measure that focuses on use stage of a building

In principle, accurate and precise reporting can only be achieved if GHG emissions from all life cycle stages of buildings are measured and quantified. However, not all countries in the world have sufficient capacity or resources to use and apply life cycle assessment (LCA) methodologies. Besides, we need to bear in mind that operational energy use in buildings typically accounts for 70 %–80 % of energy use over the building life cycle. Therefore, the operating stage of the building's life cycle could be the focus of measurement and reporting of direct and indirect GHG emissions.

Respecting the need for collaboration on a global scale, the need exists for a metric that is usable not only in countries with a sufficient number of experts and a precise database but also in those countries where experts' services are limited and databases have considerable gaps. The idea of carbon metric has emerged in consideration of 70 %–80 % share of energy use over the building life cycle as well as the need of simple metric that is usable by non-LCA-expert. Carbon metric is a measure that is based on energy use data and related building information for an existing building in operation.

ISO 16745 defines carbon metric (CM) as "sum of annual greenhouse gas (GHG) emissions and removals, expressed as CO_2 equivalents, associated with the use stage of a building". CM is measured by kg CO_2e/ year. CM is, in a sense, a partial carbon footprint. While a product carbon footprint includes all possible GHG emission over the all life stages of a product, CM is based on energy use data and related building information for an existing building in operation.

Associated with carbon metric, the standard defines carbon intensity as "carbon metric expressed in relation to a specific reference unit related to the function of the building." Here reference units include per unit area, per person, per kilobyte, per unit output, and per GDP. Thus, carbon intensity is measured by kg CO_2e/ year/ m^2, or kg CO_2e/ year/ occupants etc.

2.2 Principles in determining the carbon metric

To ensure that GHG-related information represents a true and fair measure, ISO16745 indicates the following principles in the determination of carbon metric.

- Completeness: Include all relevant GHG emissions that provide a significant contribution to the carbon metric.
- Consistency: Apply assumptions, methods, and data in the same way throughout the carbon metric determination to arrive at conclusions by the needs of the intended user and intended use.
- Relevance: Select the GHG sources, GHG sinks, GHG reservoirs, data, and methodologies appropriate to the needs of the intended user and the intended use.
- Coherence: Select the methodologies, standards, and guidance documents already recognized and adopted for energy measurement and consumption to enhance comparability between carbon metrics calculated by different system boundary definition (See 2.3).
- Accuracy: Ensure that the carbon metric quantification and communication are accurate, verifiable, relevant, and not misleading and that bias is avoided and uncertainties are minimized.
- Transparency: Address and document all relevant issues in an open, comprehensive, and understandable presentation of information.
- Avoidance of Double Counting: Avoid counting of greenhouse gas emissions that have already been allocated within other carbon metrics.

2.3 System boundaries of a carbon metric

A consistent definition of system boundary is essential to satisfy the principles shown in 2.2. ISO 16745 indicates the following three types of carbon metrics of a building:

- Carbon metric 1 (CM1) is the sum of annual GHG emissions, expressed as CO_2 equivalents, from building-related energy use;

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Carbon metric 2 (CM2) is the sum of annual GHG emissions, expressed as CO_2 equivalents, from building- and user-related energy use;
- Carbon metric 3 (CM3) is the sum of annual GHG emissions and removals, expressed as CO_2 equivalents, from building- and user-related energy use, plus other building-related sources of GHG emissions and removals.

The system boundary for the CM1 and CM2 of a building is shown in Figure 1. It consists of the equipment to operate the building fulfilling the demand as energy end use and the technical building system(s) to deliver, convert, and generate energy for the energy end use. All building-related energy end use (as indicated by the pale gray boxes in Figure 1) shall be taken into account for the carbon metric (CM1).

User-related energy use (as indicated by the dotted box in Figure 1) shall be included in the CM2, including energy for supplementary lighting installed by building users. It is NOT necessary to separately measure the amount of energy generated, converted, or consumed within the system boundary by each system, piece of equipment, or machine. Exported energy is outside the system boundary but may be reported as additional information where appropriate.

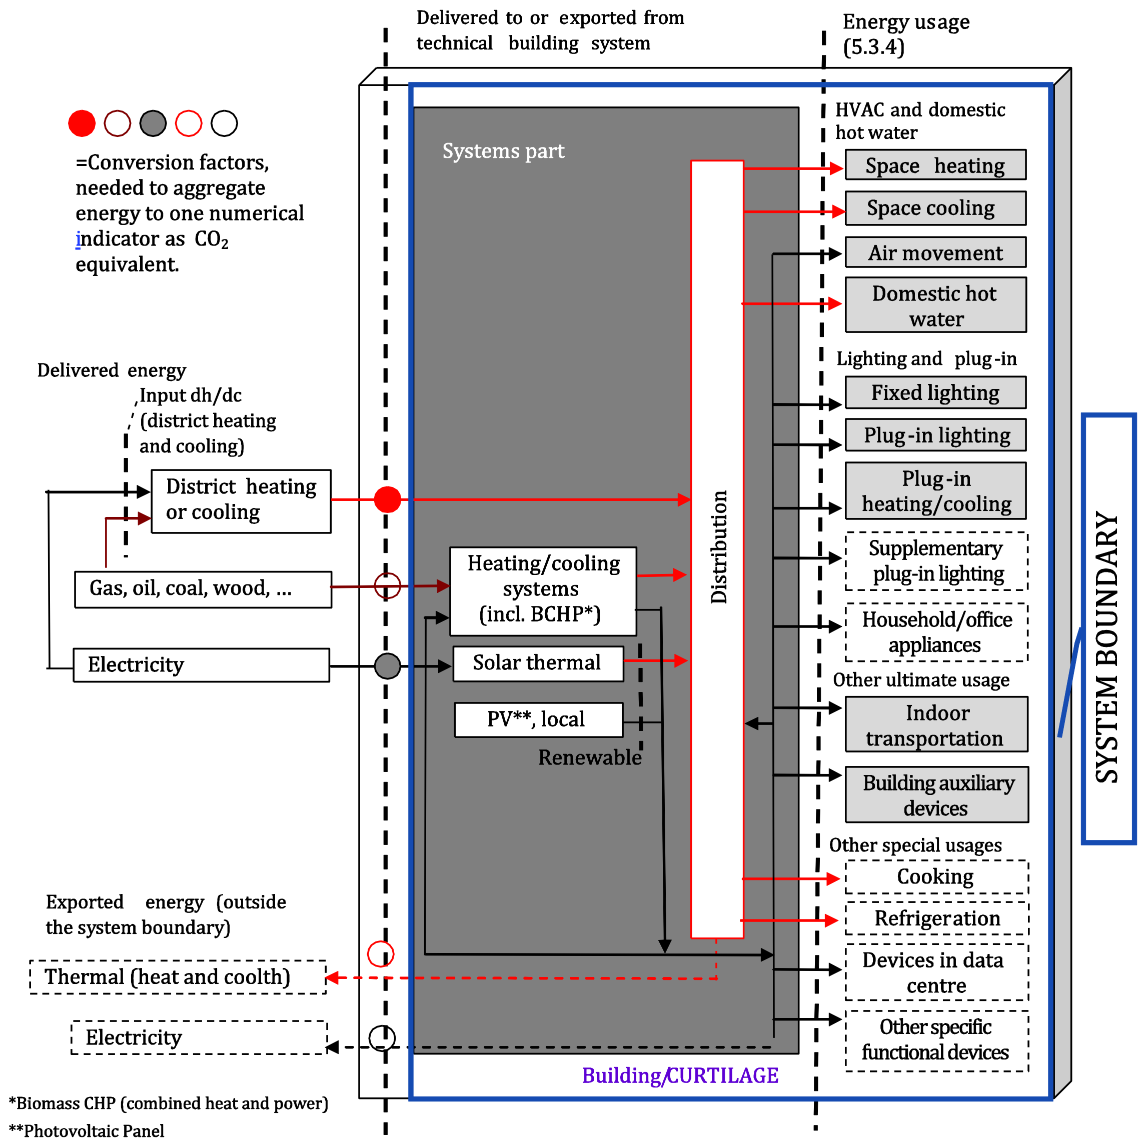

Figure 1: Boundary and energy flows - Main energy flows within and crossing the boundaries for energy use of a building (Source ISO16745)

Figure 2 show examples of the system boundary for CM1. Here only the energy carrier for the delivered energy and energy generated by the PV panels and used within the system boundary are required to be measured for CM1.

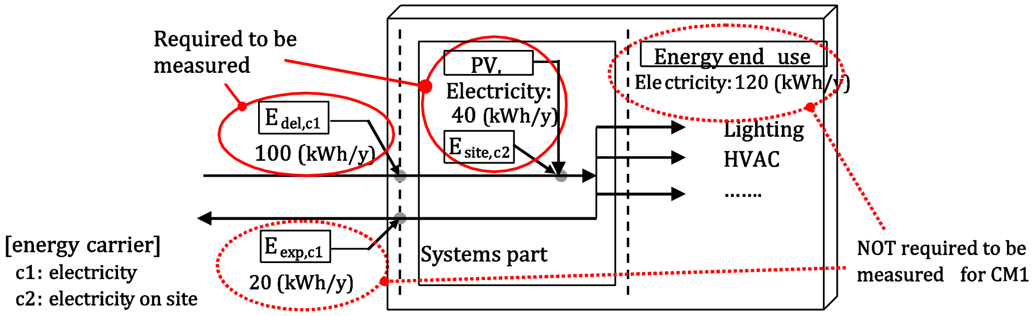

Figure 2: Examples of energy flow measuring by energy carriers

3. CALCULATION OF THE CARBON METRIC

3.1 Equation to calculate the carbon metric

ISO16745 indicates that carbon metric of a building is given by the following equation.

$$m \cdot co_{2eqv} = \sum \{ (E_{del,ci} \times K_{del,ci}) + (E_{site,ci} \times K_{site,ci}) \}$$

Equation 1

Where $m \cdot co_{2eqv}$ is the carbon metric of a building, i.e. the emitted mass of GHG, expressed as kg CO_2 equivalent per kg emission,

$E_{del,ci}$ is the delivered energy for energy carrier del,ci;

$E_{site,ci}$ is the energy produced onsite for the energy carrier site,ci;

$K_{del,ci}$ is the GHG emission coefficient for delivered energy carrier del,ci

$K_{site,ci}$ is the GHG emission coefficient for on-site energy carrier site,ci.

Equation 1 implies that carbon metric of a building hall be calculated from the delivered energy for each energy carrier plus the on-site energy, if any, produced without using delivered energy and used in the building and/ or for other energy use within the building's site, multiplied by the respective GHG emission coefficient. In view of ISO 16745 suggests that where the sum of energy produced on-site is estimated to be is less than 2 % of the total energy, $E_{site,ci}$ should be ignored.

3.2 Measurement of energy carrier

ISO16745 requires that measurement of the energy carrier shall take account of all the sources delivered to and generated within the system boundary including electricity, fuels (e.g. gas, oil, wood, and other biomass waste), and imported coolth/ steam/ heat. Data for nominal delivered energy is available from utility provider reports and contracts, electricity bills, invoices for fuel deliveries, gas bills, meter readings, pipeline measurements, energy management software.

3.3 GHG emission coefficients

ISO16745 requires that the choice of the source of the GHG emission coefficient used for calculating a carbon metric shall be appropriate for the intended use of the carbon metric. The standard demands that GHG emission coefficients shall be obtained from, in the following order of priority:

- Nationally agreed data;
- Independently provided information;
- Internationally agreed data.

4. REPORTING OF THE CARBON METRIC

The carbon metric study report is essential to assure fairness, universality, and traceability of measurement of GHG emissions from existing buildings. For that purpose, the report shall include the information on; a) building identification, b) type of the carbon metric (e.g. CM1, CM2, or CM3), c)value of the carbon metric(s), d) value(s) of the carbon intensity(ies) determined, e) purpose of the reporting, f) reporting period, g) whether the CM has been normalized to average annualized conditions such as local climate, h) date of the evaluation, i) name of the organization or individual doing evaluation, j) client of the evaluation, k) description/ illustration of the system boundary, l) list of energy end use included in the CM in relation to the type of CM, m) whether delivered energy end uses are measured or estimated, n) inventory of energy carriers, o) source of GHG emission coefficient (publication, organization, year of the coefficient measured), p) year of construction of building, q) year of latest major renovation affecting energy use, r) year of any (latest) change in use, s) total site area of the building, and t) location.

Table 1 illustrates an example of a table in carbon metric study report to present whether delivered energy end uses are measured or estimated.

	Energy consumption related service		Present in the building (a)	Included in the CM(b)	Separately metered(c)	Measured or Estimated (d)	Energy carrier(e)
1	Building-related energy use	Space heating					
2		Space cooling					
3		Air movement					
4		Domestic hot water					
5		Lighting for basic building function (fixed lighting etc.)					
6		Auxiliary energy (e.g. for heat pumps)					
7		Indoor transportation					
8		Building auxiliary devices					
a	Use “P” to indicate if services are present in the building.						
b	Use “I” to indicate if the energy end use for the service is included in the carbon metric.						
c	Use “X” to indicate if energy end use for the service is separately metered.						
d	Use “M” or “E” to indicate if delivered energy end use is based on either measurement or estimation.						
e	Report may indicate the energy carrier for each energy end use, if known						

Table 1: List of energy end use included in the carbon metric for CM1

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

5. COMMUNICATION OF THE CARBON METRIC

ISO16745 provides two types of communication that may be used to make the carbon metric publicly available.

- A carbon metric declaration
- A carbon metric claim

5.1 Carbon metric declaration

A carbon metric declaration is the communication of a carbon metric that has been verified by an independent third party. Assumptions made to create the declaration shall be included in the documentation of the organization or individual determining the carbon metric, which shall be referenced in the declaration and made available upon request.

5.2 Carbon metric claim

A carbon metric claim is the communication of a carbon metric that has not been verified by an independent third party. When an organization decides to make a carbon metric claim publicly available, the communication of the evaluation of the carbon metric shall be supported by a carbon metric disclosure report Assumptions made to create the claim shall be included in the documentation of the organization or individual determining the carbon metric, which shall be referenced in the claim and made available upon request. ISO 16745 describes the requirement to verify the calculation of carbon metric.

6. THEN HOW CM FACILITATE INNOVATION FOR REDUCTION OF GHG EMISSION FROM BUILDINGS?

ISO16745 provides globally agreed method to measure, report, and verify reductions of GHG emissions from existing buildings in a consistent and comparable way. Due to its simplicity, the method is usable not only for building profession and LCA expert but also for a wide range of stakeholders who commit in economic transactions, business activities, and governmental policy making. Thus, the metric and its protocol defined by the standard is usable both in the developed world and in developing countries as a reference and as a baseline for benchmarking.

It implies that CM defined by the standard provide the foundation for national targets to be set, a contractual agreement to be prescribed, and carbon financing to occur on a level of varieties of playing fields. Therefore CM could provide the basis to initiate and facilitate social innovation that considerably reduces GHG emission from existing buildings. The following are the possible examples of initiative for such innovation.

6.1 CDM in building sectors

In general, Clean Development Mechanism (CDM) is an effective instrument to globally rationalize investment for GHG reduction by transferring technologies from knowledgeable groups and countries to less capable or less experienced. However, so far, there are very few examples of CDM in building sectors because Certified-Emission Reductions (CER) had not been available due to a lack of globally agreed method of measurement, reporting and verification of GHG reduction from existing building. In principle, burden shifting via CDM should be assessed and verified by LCA basis. However, operational energy use in buildings typically accounts for 70 % to 80 % of energy use over the building life cycle. Therefore, CM and its protocol defined by the standard sufficiently enable to introduce CDM in buildings sectors by providing the basis of CER to the investment for the improvement of energy efficiency of buildings. Therefore CM and its protocol are expected to trigger off the innovation by creating new services and technologies associated with CDM in building including global scale cap-and-trade in buildings.

6.2 Green investment fund for building sector

By the dissemination of socially responsible investment (SRI), green investment fund has been grown globally in the last decade. The current target of the funds is large-scale green infrastructures such as renewable energy generation plant regarding which green performance is measurable, reportable and verifiable. CM and its protocol by the standard open up the possibility that groups of buildings could be the target of a green investment fund. It is notable that building sector has the highest GHG reduction per investment efficiency. It is probable that

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

investment on energy performance improvement of groups of buildings could have considerable better performance than investment on green infrastructures. CM could be the basis such comparative study in investment strategies. If the energy performance of buildings is included in the target list of a green investment fund, it facilitates technology innovation that reduces GHG emission from operations of buildings.

6.3 Green lease

Green leases are contracts between the landlord and the tenant to share the financial benefit of energy savings of a rented building. The practice of green lease requires measurable, reportable and verifiable energy performance which is the basis of mutual contractual obligation. Thus, CM and its protocol defined by ISO16745 could be the essential elements to make the green lease contract feasible. So far most of the precedents of the green lease in Japan aims to replace existing artificial lighting to LED, simply because energy use and GHG reduction are predictable and measurable. In case CM and its protocol are applied, replacing of HVAC and building services could be included in green lease practice because such actions would become measurable, reportable and verifiable. It implies CM and its protocol could broaden the scope of the green lease, thus facilitate social innovation including behavioral changes of stakeholders that have significant impact on GHG reduction.

6.4 Innovative intervention by governments

Any government policies (legal control, intervention to activities in market place and provision of information) for GHG reduction require a fair and comparable reference for benchmarking and baselining. CM and its protocol by ISO16745 satisfy such requirement. Thus CM and its protocol could make the contribution to the innovation that is triggered by benchmarking and baselining policy by the governments.

7. CONCLUDING COMMENTS

The paper summarizes the idea of CM and its protocol that are prescribed in ISO16745 documented by the authors. The protocol assures internationally agreed method of calculation of GHG emission from buildings in operation. CM and its protocol provide the measurable, reportable and verifiable reference for GHG emission based trading, contracts, financing and policies that could be the sources of social and technological innovation in building sectors.

CM and its protocol are, in a sense, a simplistic approach among a set of possible holistic approaches against the complex crisis of global climate we are facing. The authors wish that the appropriate and effective usage of CM and its protocol would be identified and enhanced through “learning by using of CM and its protocol” in trading, contracts, financing and policy-making.

Climate Action Planning Strategies for Achieving Carbon Neutrality and Net Zero Campus Operation

Vuk VUJOVIC[a]

[a] *Legat Architects, United States of America, vvujovic@legat.com*

ABSTRACT

Scientists, business leaders and heads of government around the world are in agreement: climate change is one of the most serious issues facing our global society today. Colleges and universities have an opportunity to exercise leadership in their communities by providing the knowledge, research, practice, and informed graduates that can create a positive and more sustainable future.

The process of Climate Action Planning, used by over 680 colleges and universities in the U.S., provides a useful template for sustainable campus operation, incorporating deep energy efficiency and reduced carbon emissions. The planning includes on-site renewable energy and retro-commissioning aimed at achieving carbon neutrality and net-zero campus operation within the conceivable future.

This paper will explore Climate Action Planning implemented on several higher education campuses in the Midwest, including two recent case studies completed between 2011 and 2015. The tools and processes for carbon footprint inventory will be discussed to inform other institutions and professionals pursuing similar goals.

The planning process starts by conducting a carbon emissions inventory, compiled using scope-based methodology: Scope 1 (equipment on campus), Scope 2 (off-site energy production) and Scope 3 (transportation). The carbon emissions data is then translated into a set of actionable goals and strategies, while the planning process continues through a series of workshops including representatives of the institution's administration, operations, students and faculty.

The proposed goals and strategies are envisioned as complementary tools for achieving carbon neutrality and net zero campus operation. The final plan consists of four complimentary strategy areas: Mitigation, Renewable Energy, Adaptation and Resilience, Engagement. These strategies are broken down into actionable, quantifiable and measurable goals that will be implemented through standard campus operation.

The Climate Action Planning process reduces the likelihood of unmanageable change, helps manage the risks, and takes the advantage of new opportunities created by our changing climate.

Keywords: climate change, sustainable neighbourhood, energy measurement and verification

1. INTRODUCTION

Since 1993, over 4,000 faculty and administrators at hundreds of U.S. colleges and universities collaborated with Second Nature1 to coordinate their joint response to global warming and climate change, and make the principles of sustainability essential to every aspect of higher education. In late 2006, twelve visionary college and university presidents initiated the American College and University Presidents' Climate Commitment (ACUPCC)2, a reporting system which was later expanded into Second Nature's Climate Leadership Commitments, consisting of the Climate Commitment, the Carbon Commitment and the Resiliency Commitment.

Today, over 680 higher education institutions in the U.S. have signed the Second Nature's Climate Leadership Commitments. The Commitments are requiring them to implement annual tracking and planned reduction of their overall CO_2 emissions and related carbon footprint. As the current number of signatories reached hundreds of institutions nationally, many participating colleges and universities are faced with a significant dilemma: if unchecked, needed campus expansion and building modernization would increase their existing building area and in turn, simultaneously increase overall energy use, long-term utilities and maintenance costs and resulting carbon emissions. This realization opened the path to tighter integration on previously not closely related areas of academic programming, building design, energy use and campus planning and operation, which often had competing or mutually conflicting goals.

1.1 Opportunities for climate action on higher education campuses

This paper will briefly review Climate Commitment requirements, the process of initiating and implementing Climate Action Plans. Additionally, two case studies will be explored to illustrate how similar issues could be addressed by integrating climate action into campus operation and sustainable master planning process. The case studies also showcase the new sustainable master plan model which incorporated the Climate Action planning into traditional master planning process.

Resulting hybrid approach evaluated and proposed climate action strategies and technologies designed to improve campus-wide energy efficiency, reduce greenhouse gas emissions and firmly integrate sustainability into campus operations and the academic curriculum.

2. CLIMATE ACTION PLANNING PROCESS

The Carbon Commitment defines climate neutrality as having no net greenhouse gas (carbon) emissions by a certain date selected by each reporting higher education institution. The process of climate action planning starts by conducting an institutional carbon emissions inventory, compiled using three-scope-based methodology based on Scope 1, Scope 2 and Scope 3. While the energy use, size and campus operation model of each institution varies, the Scope based-carbon emissions inventory allows for easier comparison and benchmarking between campuses. Scope 1 emissions are a result of equipment located and used on campus and operated by the institution. Scope 2 emissions represent carbon generated during the energy production derived from non-renewable sources, typically energy purchased from the utility grid. Scope 3 emissions are generated by transportation of students and faculty to and from the campus.

The collected carbon emissions data is translated into a set of actionable goals and strategies, while the planning process continues through a series of workshops including representatives of the institution's administration, operations, students and faculty.

2.1 Carbon footprint data collection

Participation in Second Nature's Climate Commitment requires detailed greenhouse gas (carbon emissions) accounting, which describes the ways to inventory and audit greenhouse gas emissions produced by the reporting entity. The accounting of greenhouse gas generates data used to create annual carbon emissions inventories.

Educational institutions can use carbon emissions inventories for a variety of reasons: to better understand the sources and trends in emissions on their campuses, as well as to plan how to mitigate and reduce them through proper building design and construction. Carbon emissions are calculated and reported over a 12-month period, as is standard practice, while climate action plans are devised to eliminate greenhouse emissions by a given date, selected by each participating institution.

A greenhouse gas inventory is a process of accounting for all carbon emissions resulting from a university or community college's operation. To simplify the data collection process, institutions may choose to calculate their emissions according to their fiscal year rather than by calendar year. All emissions data is reported in metric tons of carbon dioxide equivalent (CO_2e). The emissions data is further categorized based on scope.

3. CLIMATE ACTION STRATEGIES

The proposed goals and strategies are envisioned as complementary tools for achieving carbon neutrality and net zero campus operation. The final plan consists of four complimentary strategy areas: Mitigation, Renewable Energy, Adaptation and Resilience, Engagement.

These strategies are broken down into actionable, quantifiable and measurable goals that will be implemented through standard campus operation. Each of the proposed strategies was reviewed by several of the committees instituted to guide, advise and inform strategy formulation and the climate action planning process. Administration, Operations and Maintenance, Faculty and Students are some of the typical committees recommended as the best representation of all interested parties on a given campus.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.1 Mitigation strategies

Mitigation strategies include various energy-efficiency measures, reduction of transportation related to student and faculty commute, improvements in operation and maintenance and overall reduction of waste generated on campus (Figure 1).

Figure 1: Mitigation strategies – Waste reduction and handling

3.2 Renewable energy strategies

Renewable energy strategies relate to on-site clean energy generation. Systems to be considered include wind-generated energy, solar, geothermal, renewable energy purchases and offsets. (Figure 2).

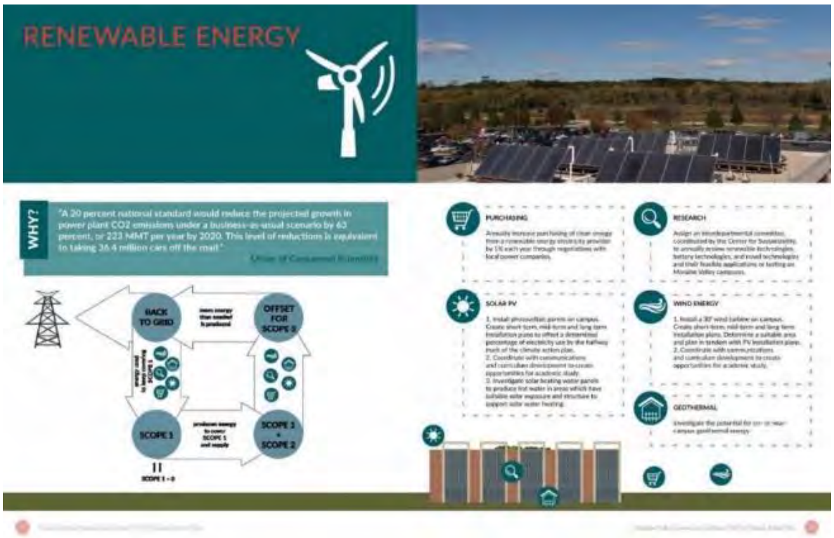

Figure 2: Renewable energy strategies – Wind, solar and geothermal

3.3 Adaptation and resiliency strategies

Resiliency strategies aim at increasing ability of the institutional systems to respond and resist impact of man-made and natural disasters. (Figure 3).

Figure 3: Adaptation and resiliency strategies

3.4 Engagement strategies

Community engagement and internal culture change are critical to communicate goals of Climate Action Plan and its strategies to students and faculty (Figure 4).

Figure 4: Community engagement strategies

4. CASE STUDIES

This section explores Climate Action Planning process implemented on two higher education campuses located in the U.S. Midwest region and completed in 2011 and 2016, respectively.

4.1 Case study 1: Joliet Junior College - 2011 Climate Action Plan

In 2009, Joliet Junior College (JJC) took a significant step in setting sustainability goals by committing to the former ACUPCC compact. This created an opportunity for the higher education institution to take the lead in reducing greenhouse gas emissions, achieving climate neutrality, applying sustainable practices and integrating sustainability into college curricula to ensure that future generations are equipped with the knowledge necessary to be environmentally responsible.

Historically, sustainable practices have been an integral part of JJC's culture. Between 2008 and 2010, various sustainability initiatives and practices culminated in the implementation of JJC's Sustainable Master Plan, later integrated with the Climate Action Plan, completed in 2011.

The JJC's Climate Action Plan sets goals for future action and develops a timeline for goal achievement. In order to determine the initial level of impact, an inventory of carbon emissions was conducted for fiscal years 2009-2010 and 2010-2011. Through this, strategies were developed to address the most significant sources of carbon emissions. Incorporated with these strategies are educational efforts intended to promote awareness about climate change and carbon emission throughout the College. These strategies will be open to constant updates and revisions, as greenhouse research and sustainable technology further develop.

It should be noted that JJC GHG calculations for FY 2010-2011 include projected emissions resulting from six new buildings that were going to be added by the end of 2013. In absence of historic data, design energy and GHG emissions data were used to project total GHG emissions. All new buildings on campus have been designed to achieve LEED-NC certification. Significant CO_2 footprint reduction came from JJC's vast, well-preserved natural areas. Some estimates indicate that as much as 600 metric tons of CO_2 emissions could potentially be mitigated by maintaining, improving or expanding existing natural areas.

Additionally, as a result of new building construction, the overall building area was increased by 43.95% between August 2010 and August 2011, while net GHG emissions have risen by only 30.77% during the same period. This data clearly demonstrates the benefits of energy efficient building design and construction. The data also suggest that implementation of the energy-efficient building systems can result in significant decreases in both overall campus energy use and GHG emissions per square foot of area.

JJC continues with the carbon emissions tracking and inventory data collection after initial Climate Action Plan was compiled in 2011. Their goal is to integrate sustainable campus master plan, climate action plan with the institutional sustainability plan,

4.2 Case study 2: Moraine Valley Community College - 2015 Climate Action Plan

In 2013, Moraine Valley Community College (MVCC) made a significant commitment by signing the Second Nature Carbon Commitment3. The goal of the commitment was to begin the process toward achieving campus carbon neutrality, support greater community resilience and provide structured climate change education and global citizenship opportunities for their students. MVCC further integrated their climate action with the goals of the current sustainable campus master planning process, making building energy efficiency, renewable energy integration, resiliency and adaptation integral part of their five-year campus master planning process.

The college implemented several key steps aimed at facilitating the climate action planning process: set up the institutional structure (committees, task force, office of sustainability; completed an initial inventory of greenhouse gas emissions; created and implemented the Climate Action Plan (completed during 2015-2016); defined target date and interim milestones for achieving campus carbon and climate neutrality. MVCC carbon emission inventory data was benchmarked with several other higher education institutions pursuing similar goals (Figure 5).

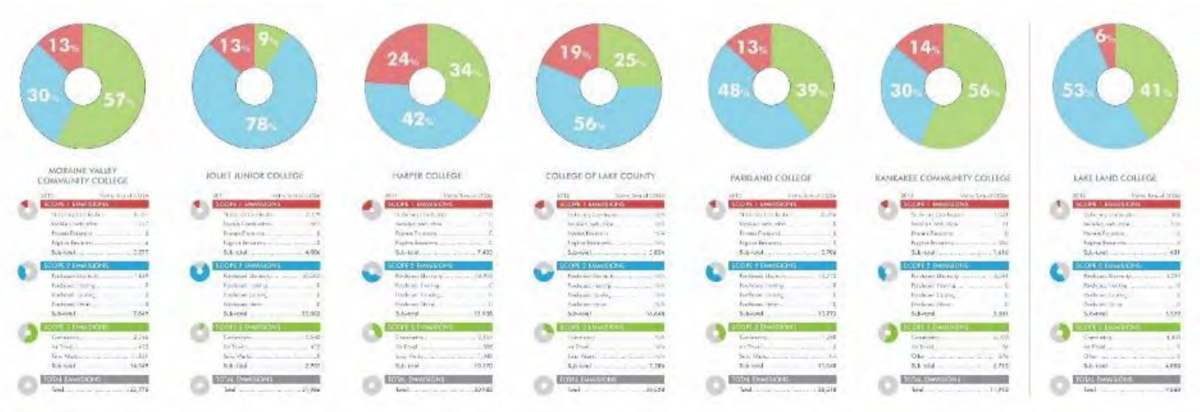

Figure 5: Carbon emissions inventory benchmarking between higher education institutions

5. CARBON NEUTRALITY AND NET ZERO CAMPUS OPERATION

The institutional progress toward carbon neutrality is measured through annual greenhouse inventories, climate action plan updates and implementation of selected strategies. To simplify the planning process and implementation of strategies over time, the individual strategies are identified as short-term (0-5 years), mid-term (5-15 years) and long-term (15-25 years), depending on projected time horizon.

It is recommended that climate action planning should be fully integrated with the sustainable campus master planning process, which typically following the five-year planning and implementation cycle. In order to achieve carbon neutrality and achieve eventual net-zero campus operation, the Climate Action Plan envisions gradual replacement of grid-based fossil fuel electrical energy supply with on-site generated renewable energy. The remainder of carbon emissions that, cannot be displaced by clean (renewable) energy sources will be mitigated by carbon offsets (Figure 6).

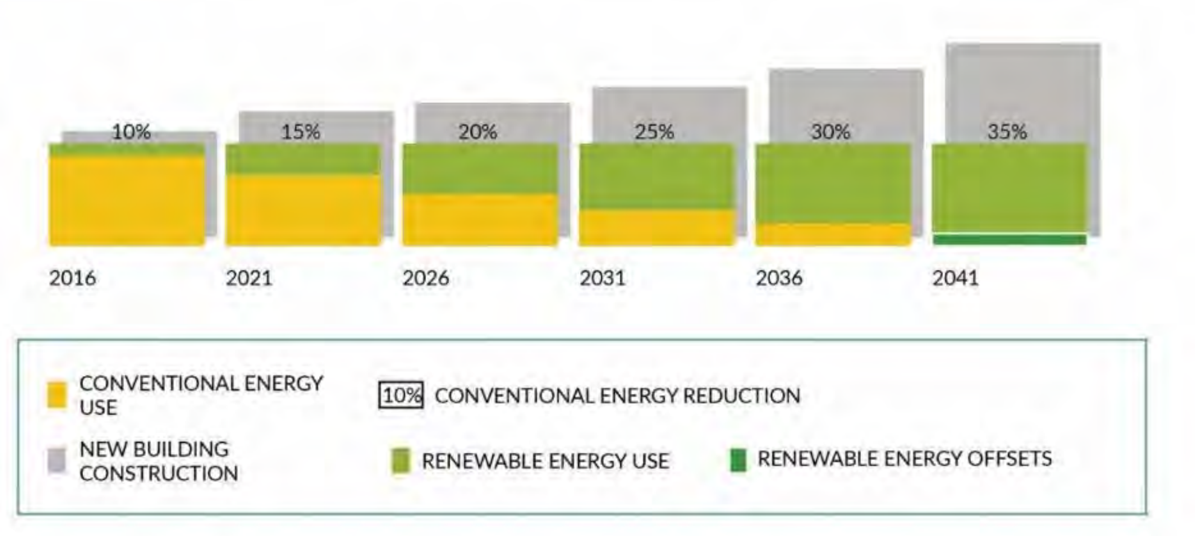

Figure 6: Climate Action Plan implementation process – Gradual energy source replacement

6. CONCLUSION

Achieving carbon-neutral or net-zero operation in a college campus education environment requires appropriate funding, continuous implementation of identified carbon emission mitigation strategies, planning flexibility to address future technological developments, and time to create meaningful culture change, implement necessary building upgrades, install renewable energy systems, and plan for and secure the necessary funding.

The short-term strategies on individual projects are easier to identify and implement, mid-term and long-term strategies that involve entire campuses or communities will be need to remain flexible and allow sufficient room for adaptation for future changes in the political, social, economic and natural environment. The critical element for securing success will be proper integration of carbon action plan goals and strategies into all subsequent sustainable campus planning, operations, and maintenance activities on college campuses. While some of the GHG emission will be difficult to completely eliminate, such as those related to commuting or air travel, sufficient funding should be allocated for carbon offsets, parallel to budgets developed for the implementation of the entire Carbon Action Plan.

Session 3.6: Innovations Driving for Greener Policies and Standards – Practices Review

Leap Forward or Snail Speed? Examining Radical Sustainable Innovation

Christian KOCH[a]

[a] *Chalmers University of Technology, Sweden, kochch@chalmers.se*

ABSTRACT

Sustainable building appear to progress rapidly these years. The new technological possibilities could be interpreted as radical, but the objective of this paper is to critically examine, whether some parts of sustainable building technology can be understood as radical or whether we rather witness a continued slow and emergent development. The framework of understanding includes concepts of radical innovation, inventions and sustainability. Radical sustainable innovation (RSI) should break away from the customary and be characterized by high degrees of newness in the entire life cycle. RSI should offer significant enhancements of known benefits, entirely new benefits, or substantial cost reductions, leading to the transformation of existing markets, the creation of entirely new possibilities for sustainable balanced growth and RSI should contribute to a sustainable globe. Serious limitations are addressed. For example buildings are large complex products realised through complex processes and with a considerable lifecycle. It appears impossible that an entire building should/could be radically new. the certification standards represent a possible low denominator for measuring radicality, as criteria for newness related to inventions are found not to be instrumental. Methodologically a selection of international cases of office buildings with very high scores of BREEAM, LEED and DGNB are examined. "Protected economy" cases are sorted away in line with the developed criteria for radical innovation. The result shows that a portfolio of office buildings have reached substantially higher level of sustainability than contemporary building regulations (such as those in EU). There is indeed a gap between a few, substantially more sustainable buildings and the majority of buildings, indicating some radicality, yet not identified as radical innovation here.

Keywords: radical innovation, sustainability, office buildings

1. INTRODUCTION

The current global development of, not only new products, components and renewable technologies for sustainable buildings, but also methods, approaches and tools to support design, production and operation of sustainable buildings are quite breathtaking for anyone trying to establish an overview and take sensible choices. The opportunities are accelerating and are multifaceted. Yet clients and their suppliers largely continue to do business as usual, building and renovating mostly to comply with merely legal requirements. The unrealized potential creates a possibility to take a quantum leap in of sustainability by transcending existing norms beyond legal requirements such as Building Research Establishment Environmental Assessment Method (BREEAM 2016), Leadership in Energy and Environmental Design (LEED 2016), Cradle to Cradle, Deutche Gesellschaft für Nachhaltiges Bauen, (DGNB 2016) and other present day certifications. And to do this on a business basis. There is in other word room for something else than the usual stepwise incremental innovation often seen in buildings. This opportunity coincide with an increasing renewed interest in radical innovation in other industries (Hartman 2005, O'Connor et al. 2008). Radical innovation scholars have developed quite extensive and explicit models for managing such innovations within large companies. These scholars would define radical Innovation as innovation that break away from the customary and are characterized by high degrees of newness (Christensen 1997 Hartmann 2015, Leifer et al 2000). Radical innovations offer significant enhancements of known or entirely new benefits, or substantial cost reductions, leading to the transformation of existing markets or the creation of entirely new possibilities for growth. It is worth noting that radical innovation, as innovation in more general, is firmly embedded in a market and business economy thinking.

On this background this paper ask whether some parts of sustainable building technology can be understood as radical? It conceptualize what radical sustainable innovation is and develop an explorative method for measuring it. And as counterquestion it problematized whether we rather witness a continued slow and emergent development.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Also the bodies developing and operating certifications has sensed the development and has speeded up their continual renewal of the measures of sustainable performance. Here we focus on Building Research Establishment Environmental Assessment Method (BREEAM, BREEAM 2016). BREEAM is a sustainability assessment method for masterplanning projects, infrastructure and buildings. It addresses a number of lifecycle stages such as "new construction", "refurbishment" and "in-use" (BREEAM 2016). Globally there are more than 550,000 BREEAM certified buildings, and more than 2,250,000 buildings registered for assessment since 1990 (BREEAM 2016). Why selecting office buildings? When interested in innovation and radical innovation the focus is not on what is technically possible per se, as in buildings realized on university campuses or other experimental contexts to test future techniques. Rather innovation is embedded also in markets and economical feasibility. Our original position was that office buildings are tested by the market, paid by private companies. Moreover many radical ideas in buildings have over the years been realized by fiery souls using their private houses as testbed. Through loads of entrepreneurial effort by the designer, owner and constructor in one realize radically new villa concepts. However such projects often never got beyond that. What surface when looking at office buildings is the marketing and publicity effect of certain enterprises operating in and from a sustainable building. The category include utility company, building component manufacturer, building service suppliers etc. One might cynically observe, that they merely want to show off. We have chosen to include those here as after all even these companies operate in our present markets.

The paper is structured in a traditional manner. It commence by developing the theoretical understanding and continue to posit the methods that can answer to the objectives of the research. The follows case descriptions of our found candidates for radical innovations. The paper analyse these and finalise the argument through a discussion and a conclusion.

2. FRAMEWORK OF UNDERSTANDING

The framework commence by the concept of innovation, moving on to radical innovation. Sustainability is then introduced and inserted into our tentative definition of radical sustainable innovation.The Oslo Manual (OECD 2005) defines innovation as follows: "An innovation is the implementation of a new or significantly improved product (good or service),or process, a new marketing method, or a new organizational method in business practices, workplace organization or external relations". This definition distinguishes in a linear manner between invention and innovation, believing that invention are globally new and not necessarily implemented in a practice, whereas innovation is only counted as such if the change is implemented. This implies that radical innovation at a time needs to be almost as new as inventions yet is required to have experienced implementation. Also innovation is normally measured up against its context, i.e. innovation is new in relation to a specific contextual and not necessarily globally new. We suggest to depart from this contextual criteria for innovation below. Radical Innovations break away from the customary and are characterized by high degrees of newness. Radical innovations offer significant enhancements of known benefits, entirely new benefits, or substantial cost reductions, leading to the transformation of existing markets or the creation of entirely new possibilities for growth. These innovations are also referred to as "breakthrough", "discontinuous", or "paradigm-shifting" (Christensen 1997 Hartmann 2015, Leifer et al 2000). It is important to note that disruptive innovation is different from radical. Disruptiveness may occur from wellknown elements of innovation reshuffled. Disruptive innovation can be defines as "a process were a smaller company with fewer resources is able to successfully challenge established incumbent businesses" (Christensen et al 2015). Disruptive innovation originate in the low-end of new-market footholds and only compete with mainstream when quality catch up to their standard (Christensen et al 2015). We adopt the position that innovations within sustainability should comply with certain special rules. Where innovation concepts are embedded in market economy concepts, sustainable innovation needs to depart from this unambiguous embeddedness and rather refer to a sustainable economy. Sustainability was originally defined as "development that meet the needs of the present without compromising the ability of the future generations to meet their own needs" (Brundtland 1987).The notion of sustainability has undergone signification development even if still ambigious. As many other societal goals it is a moving target, and should be. This goes for the content and weight of the original Brundtland dimension of environmental, social and economic sustainability (Chathara et al 2015). On this background a tentative definition of radical sustainable innovation:

- RSI Break away from the customary and are characterized by high degrees of newness. In the entire life cycle and in all elements, financial, process, product, client relations, organisation management

- RSI offer significant enhancements of known benefits, entirely new benefits, or substantial cost reductions, leading to the transformation of existing markets or domains or the creation of entirely new possibilities for growth and sustainable balances encompassing at least an environmental, social and economic aspect
- RSI contributes to a sustainable globe

We suggest that within radical sustainable innovation in office buildings a global convergence has meant that it makes sense to move from a contextual definition to a worldwide covering definition, which resembles the demands of patented inventions, whose novelty is tested in a broader region like Europe or US. In fact we suggest that radical sustainable innovation should be measured by a global novelty criteria.

3. METHOD

We draw on innovation and radical innovation literature to conceptualise these parts and combine these with sustainability. This approach is chosed because of a paucity of contributions conceptualizing radical sustainable innovation. In an initial phase radical examples were sought for outside the certified portfolio. This approach however quickly was abandoned because we did not have resources to follow up on promising, yet poorly documented cases. Compared to these potential radical cases, the certified were far better documents. On this basis we then use sustainable building certification schemes. The literature comparing certification schemes within sustainable building, show large similarities between tools (Chathana et al 2016). The emphasis are on environmental sustainability (roughly 70% of the criteria points), and less on social sustainability (roughly 25 % of the criteria points), and very little emphasis is assigned to economic sustainability (Chathana et al 2016). Several consecutive searches have been made in BREEAM, LEED, DGNB and Cradle to Cradle certification databases from 2012-2016. Case studies of remarkably sustainable building has been collected over this time period. Cradle to Cradle certification is however only covering building components as is therefore a supplement. LEED platinum buildings were examined on an exemplary basis. According to LEED there are 852 certified platinum buildings (LEED 2016), however based on the exemplary evaluation they appeared less performative than the BREEAM "outstanding" certification which was therefore selected.

BREEAM is an entire suite of certifications targeted different phases of a building's life and different sectors of buildings (domestic, offices, public institutions etc, BREEAM 2016). There are certifications for four different phase/stages: Master planning, new construction (incl. design), refurbishment, in-use. They include up to ten aspects related to energy and water use, the internal environment (health and well-being), pollution, transport (access to public transport and bicycle facilities), materials, waste, ecology (including biodiversity), management processes and innovation. In total there are typically 80 evaluation points. The criteria dimension are typically the following: Management, health and wellbeing, energy, transport, water, material and waste, landuse and ecology, pollution and innovation. The scores at these evaluation points are summed up in a score card, with a score from 1 to 100%. The scores are translated into stepwise categories: "Passed", "Good", "Very Good", "Excellent", "Outstanding". Outstanding means scoring more than 85 points out of 100 and around 1% of all ratings do that (BREEAM 2016). For example in the BREEAM 2014, the energy dimension Excellent is 37-52,5% reduction of energy consumption compared to national building regulation and Outstanding is 60-82,5% reduction (BREEAM 2014b). Although BREEAM is increasingly international, it is 96.4% of its certifications of non domestic buildings (including offices), that are placed in the United Kingdom. The figure for 2012 was 92.5% showing the gradual grow in internationalization (BREEAM 2014). Using our latest searches in the greenbook data base we were in april 2016 able to identify 256 cases of BREEAM certified buildings in class "outstanding". This figure had grown to 281 in october 2016. Out of these 76 were categorized as office building, but our search also covered mix-use buildings. The certification were according to BREAAM 2009 or 2011. None referred to BREEAM 2014 which is presently a draft (BREEAM 2014). In the further selection the more recent and highest scores (meaning more than 90%) were selected, and thus deselecting even relative high scores. Also some examples of "protected economy" cases, such as experimental buildings on university campuses were sorted away in line with the developed criteria for radical innovation. We ended up with a sample of five building which are described below.

There are several limitations to our approach. Our analysis here rely on preliminary comparisons between the certifications and exploratory searches. As for patented sustainable products and processes, although preliminary searches were made into patented sustainable building components, it has not been established whether the patented products constitute a more radical innovation than cradle to cradle certified products. Our preliminary position is that the patent approval process do not evaluate the products as systematics as a cradle to cradle certification would. It is merely newness that are the central criteria.

4. CASES

Below the five cases found with the highest score is presented.

The Air Street building is placed in central London UK and part of a larger project carried out by Crown Estate. The building was certified after BREEAM 2011 New Construction, Office and scored 94,16 % after finalizing in autumn 2015. An earlier interim certification was rated slightly lower. The project is a combination of preservation of an existing listed building, and demolishing and new built of the two upper floors aiming at delivering office facilities.The stronger part of the evaluation were energy, waste, materials and management. The weaker health, transport, water and innovation. On energy for example the building scored 25 credits out of 27 due to the low carbon energy strategy adopted, provision of monitoring facilities, use of district heating, LED lightning and solar panels. Also the wall insulation used reduces heat loss by 65%.

The Bentley Works, Doncaster UK building was rated outstanding with a score of 92,5 % in BREEAM interim in 2015. The owner, SKANSKA UK, a contractor, also used the company's internal "Color Palette" certification tool. The Colour Pallette tools is organized in economic, green and social dimensions. Skanska describe the economic scores like this; a total green payback period of 11 years and creation of 70 new full-time positions. The green scores points are the following: Net zero primary energy site, office building uses 67% less energy than UK building regulations, 11% reduction in embodied carbon, zero construction waste materials to landfill, zero hazardous materials, net zero potable water & 70% less water than BREEAM benchmark. In the social dimension SKANSKA highlights a healthy indoor and outdoor environments for building occupants and workers. In other words it derives that the building substantially surpass BREEAM outstanding criteria in one dimension, water use, yet operate a very limited social sustainability perspective.

Le Hive, Ile de France, Paris, is Schneider Electric's headquarters in France. Schneider is a large global electricity installations supplier. The building scored 93,8% in the BREEAM In-Use certification in 2013. The building complex is at 35.000 m2 and energy consumption level at 78 kwh/m2 per year was achieved from the double level of 150 kwh/m2 per year. The BREEAM In-Use rating included Asset performance 'Excellent', 75%; Building management performance 'Outstanding', 88%; Occupier management performance 'Outstanding,' 92%. The energy use for Heating Ventilation and Air Conditioning (HVAC) and lighting have been halved over three years through active energy efficiency, without changing the structure of the building and without energy production, according to Schneider. Other dimensions of sustainability include recycling and sorting of 12 kinds of waste (0% to landfill), efficient management of water – rain sensors, real time leak detection, health and well-being services on site, consultation with occupiers, acoustic comfort improvement, innovative comfort measurement. Greenhouse gas emissions study, use of 100% eco-labelled products for cleaning. Closely managed energy consumption and centralised control and monitoring using innovative tools. Conservation of green outdoor areas, improvement of bio-diversity, establishment of beehives on site. Thus the Hive stays within the BREEAM outstanding category.

The Angel Square building in Manchester, is the headquarters of the Co-operative Group. The building provides office facilities for 3,000 employees. The Co-operative Group is owned by 8 million members. The building scored 95,16%, outstanding, in the BREEAM (2008) offices certification in 2013. Some of the dimension highlighted were: The building is powered by a pure plant oil fed Combined Heat and Power (CHP) system and utilizes rapeseed oil which is grown on the Co-operative's own farm land. Surplis energy is sent back to the grid. Other features include LED lighting and a system to recycle waste and rain water. Apart from its unusual architectural qualities, the building's sustainable solution do appear to go beyond BREEAM certification at the CHP system and the recycling of water.

The 50 person large new office building for the Dutch company Geelen Counterflow, that manufacture industrial coolers and driers, obtained two BREEAM certifications at the level Outstanding in autumn 2015. "Design" at 94.19% and "Post construction" at 99.94% (Greenbook 2016). The building's structure is prefabricated walls and floors of 100% unglued and non-chemically treated wood, grown in sustainably managed forests in Germany. Where possible "Cradle To Cradle" certified building materials will be applied. The garden includes a variety of local plants, flowers and nesting sites for birds, bugs, bats and amphibians. By building according to the "Passive

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

House" guidelines and powered with 330 solar panels on the roof, the office will produce 50% more renewable energy than the total energy consumption for heating/cooling, ventilation, lighting and accessories. The extra energy will power machinery in the company's factory. Adjustable daylight infiltration, air quality, and indoor lighting, imply that the office contribute to a healthy work environment and employee productivity according to the owner Geelen Counterflow. Some materials used: The basement made by "ecocrete" concrete and also (partly) prefabricated via a hollow-wall system made of 100% recycled granules. Building structure (beams, pillars) supplied by NurHolz. Facade Accoya wooden battens (cradle to cradle certified). Window frames Accoya. Glass AGC (cradle to cradle goal and transport minimizing). Paint Drywood woodstain semi-transparant water based lack. Roof Derbipure vegetal (cradle to cradle certified). Insulation Roof Kingspan Unidek EPS. Insulation cellar DOW XPS (cradle to cradle certified). More sustainable than mentioned here is included. Through producing more 50% energy that it consumes and adopting the policy of adopting "as many as possible" cradle to cradle certified building material, the building clearly transcend the BREEAM outstanding certification, apart from scoring almost 100%. Nevertheless some elements in the building appear to be of more traditional kind, such as the electricity cabling and the cloak system. There is no mention of any social sustainability dimensions apart from what is incorporated in the BREEAM certification.

5. DISCUSSION

The intention is scrutinize the concept of RSI through these cases of outstanding performance. It is therefore important to discuss where the cases surpasses the scale of BREEAM or not. As we have suggested that RSI should surpass the certification standards of sustainable buildings. In general the cases scored high, yet they did not surpass the scale. There are few exceptions: Bentley works surpassed the BREEAM outstanding certification in one dimension, water use. The Angel square building features a CHP system feed by rapeseed oil and recycling of water. The Geelen Counter flow case has a number of cradle to cradle certified building components inbuilt, yet still misses others. The cases mention little about social sustainability. The actual measures in the outstanding cases rarely relate to "outside" building stakeholders and focus one's own employees. In this dimension we thus find no elements addressing a broader understanding of what social sustainability is defined as (Colantinio and Dixon 2010). It does appear that the certified companies go "hunting points" inside the certification rather than pursuing a comprehensive sustainability agenda (Chathera et al 2016). As mentioned we found 852 LEED certified platinum buildings (LEED 2016) and 281 BREEAM outstanding in 2016. Out of the BREEAM 76 were categorized as office building, but our search also covered mix-use buildings. These numbers does raise an issue whether sustainable buildings that perform just above these many certified building can be understood as radical sustainable innovations? As our concepts requires a substantially improved product or process, the distance to this portfolio of very well performing sustainable building does appear marginal and thereby in contradiction to being radically different. Yet the distance to the majority of building regulation compliant buildings at snail speed are still substantial. The outstanding certified building is thereby a rare exception.

6. CONCLUSION

This paper set out to critically examine, whether some parts of sustainable building technology can be understood as radical or whether we rather witness a continued slow and emergent development. We conceptualise radical sustainable innovation, RSI, as innovation that break away from the customary and characterize RSI by high degrees of newness. In the entire life cycle and in all elements, financial, process, product, client relations, organisation and management. We posited that RSI offer significant enhancements of known benefits, entirely new benefits, or substantial cost reductions, leading to the transformation of existing markets or domains or the creation of entirely new possibilities for growth and sustainable balances encompassing at least an environmental, social and economic aspect and that RSI contributes to a sustainable globe. Methodologically a selection of international cases of office buildings with very high scores of BREEAM, LEED and DGNB were examined. Even if certified "outstanding", "platinum", some buildings with lower performance (including some slightly older), and "protected economy" cases were sorted away in line with the developed criteria for radical innovation. The result shows that a portfolio of office buildings have reached substantially higher level of sustainability than contemporary building regulations. There is indeed a gap between a few, substantially more sustainable buildings and the majority of buildings, indicating some radicality, yet it is not identified as radical innovation. Buildings are complex products and the certification schemes are useful as measurement of this complexity and the certifications given also demonstrate that the buildings studied do arrive at some radical elements, yet still possess a number of more traditional elements. Future research will include a more systematic comparison of certification systems and highest rated buildings.

The Progress of Energy Renovations of Housing in the Netherlands

Henk VISSCHER[a]

[a] *Delft University of Technology-Faculty of Architecture and the Built Environment, The Netherlands, h.j.visscher@tudelft.nl*

ABSTRACT

The European Union formulated high ambitions of energy reductions to be realised in the built environment. The existing housing stock covers a major share of energy use and is seen as high potential to contribute to the savings. This should be realised in the first place by reducing the energy demand for heating by renovation of the existing stock and bring the dwellings to a higher energy performance standard. The targets, policies and programmes are already applied for several years now and the question arises of what progress can be seen in renovation activities and energy saving results. This paper is based on data on improvement rates of the Dutch non-profit housing sector and insight in the relation with actual energy reduction. It shows that the renovation progress is limited and that the actual energy reduction is less than is expected according to theoretical models. Furthermore, the paper presents some promising innovative approaches to realise nearly zero energy renovated residential buildings, the so called Net-Zero-Energy-Renovation programme (Stroomversnelling). Will it be possible to reach the energy saving goals with the current approach?

Keywords: energy efficiency, housing stock, renovation, energy labels, actual energy use

1. INTRODUCTION

Climate change mitigation is maybe the most important driver for the ambitions to reduce the use of fossil fuels. There are also other reasons for implementing energy efficiency policies in the EU and its Member States. These include the wish to decrease the dependency on fuel imports, the increasing costs and the fact that fuel resources are limited. The European building sector is responsible for about 40% of the total primary energy consumption. To reduce this share, the European Commission (EC) has introduced the Energy Performance of Buildings Directive, the EPBD (2010/31/EC) and the Energy Efficiency Directive (EED – 2012/27/EU). These frameworks require Member States to develop energy performance regulations for new buildings, a system of energy performance certificates for all existing buildings and policy programmes that support actions to reach the goals like building only 'Nearly Zero Energy Buildings (NZEB)' by 2020 and realizing an almost carbon neutral building stock by 2050. Formulating ambitions and sharpening regulations are relatively easy to do. These goals and programmes were already formulated back in 2008 for the Netherlands. Since then the renovation of the stock started and data was collected to monitor the progress as well as data about the (theoretical) energy performance of houses and actual energy use figures.

This paper presents some insights in the implementation of energy renovations in the Netherlands and the effects on actual reduction of CO2. Section 2 presents the data on progress of energy renovations in the Dutch social housing stock. In section 3 the relation between modelled energy use according to the labels for existing housing and the actual energy use are described. Section 4 describes an innovative programme for Net Zero Renovations of housing in the Netherlands and the pros and cons of this approach. This all leads to some conclusions about the challenges and required innovations for the housing stock to meet the formulated energy reduction ambitions in section 5.

2. THE PROGRESS OF ENERGY RENOVATIONS IN THE SOCIAL HOUSING STOCK

The largest energy saving potential is in the existing building stock. New dwellings add about one per cent per year to the housing stock in Europe. The most important policy tool required by the EPBD in the European Member States is the issuing of Energy Performance Certificates (or EPCs). These EPCs give a hypothecated indication of the required energy to provide a certain average temperature in the building and depend on physical characteristics of the building. The certificate has no mandatory implications in the sense that owners could be forced to improve their buildings to certain levels. Nonetheless it is a crucial instrument for benchmarking and formulating policy goals. Building owners in all EU Member States have to obtain an EPC for a building at the moment it is sold or rented out. This is not yet current practice everywhere, mostly due to lack of enforcement. This especially applies to the private housing stock.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The social housing sector in the Netherlands agreed with the government and the national tenants' union to a covenant about energy renovation goals. This was initiated in 2008 and updated in 2012. Most important goal is to initiate renovations that lead to average energy label B in 2020 for the whole sector, which comprises 2.3 million dwellings (35% of the total stock). Energy labels are the Dutch Energy Performance Certificates that express the energy performance of existing houses as required by the European EPBD.

The whole social housing stock is already labelled for many years. Since 2010 most of the stock has a label. Every year AEDES, the national umbrella organisation of the housing associations, wants to collect the energy label data of all housing associations. Every year more associates really do so. In 2015 the data of more than 60 % of the whole social housing stock was collected in this way. This database is called SHAERE. Research with the SHAERE data base enables to show the progress in renovation. Figure 1 demonstrates the label steps over the years 2010 to 2014. It can be noted that most of the renovations lead to small improvements. If the current figures are extrapolated to 2020, we can see that the goals of an average label B will not be reached (see Figure 2). The label indexes relate the calculation of the Energy Index, which is for label B 1,25.

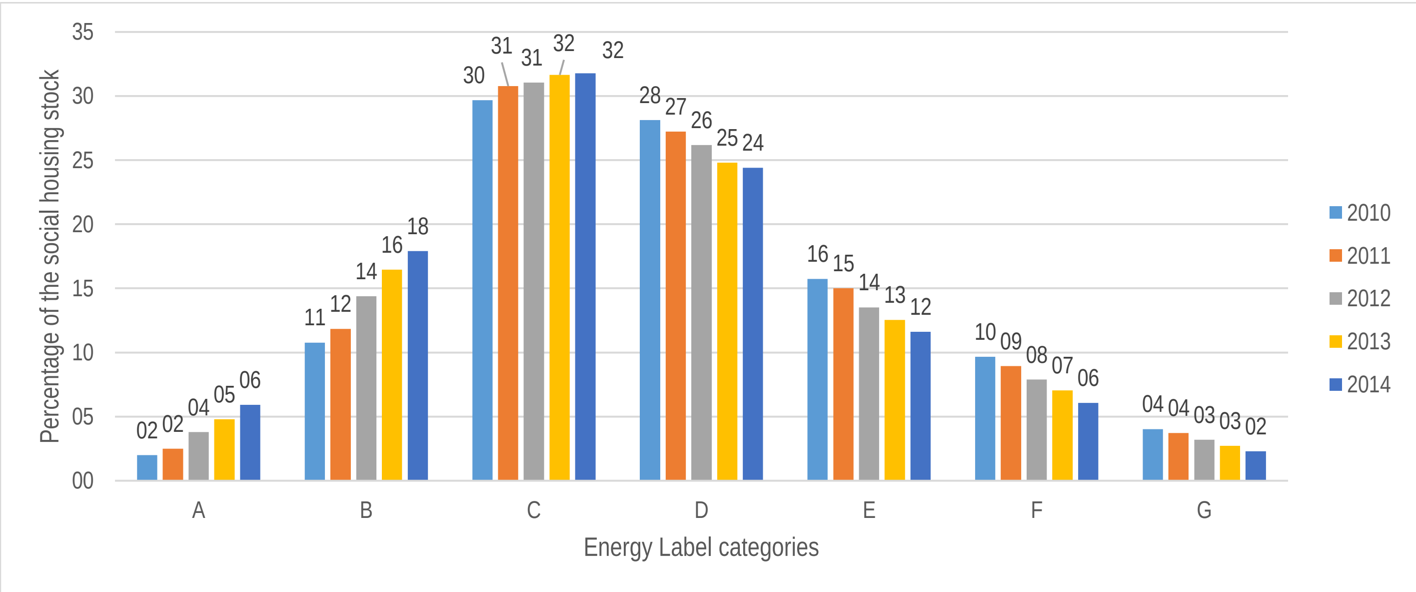

Figure 1: Distribution of the energy labels of the non-profit rented housing sector in SHAERE database (Filippidou, F, et al., 2014)

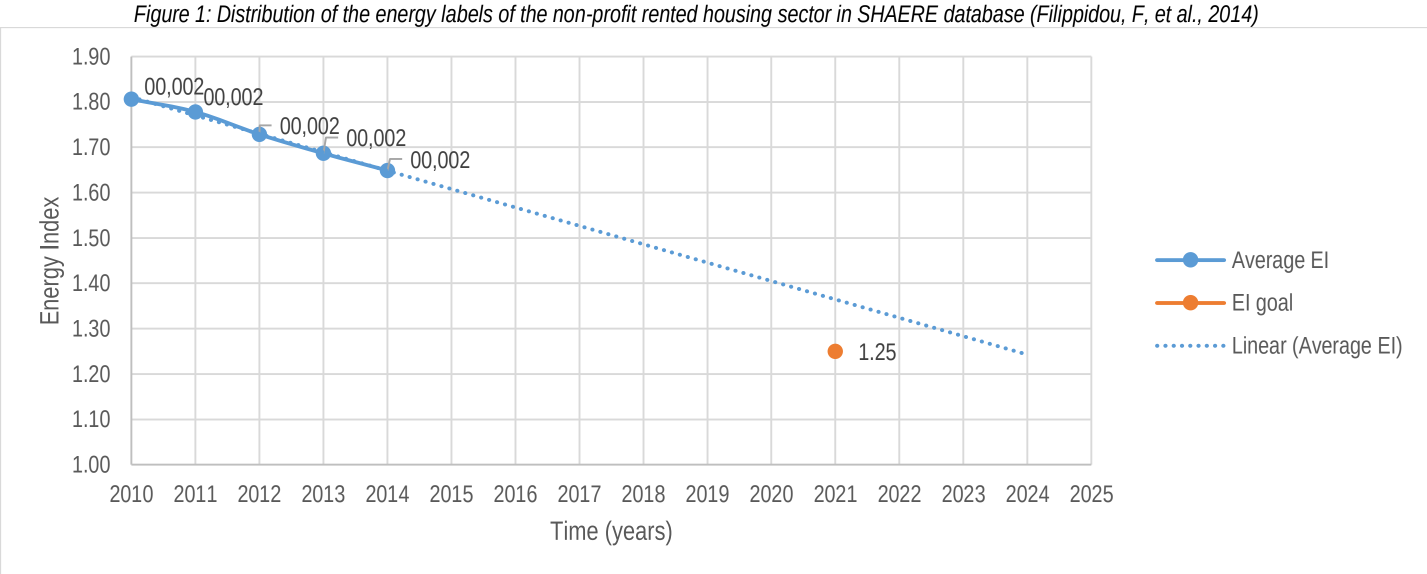

Figure 2: Development of the EI in the Dutch non-profit housing sector since 2010, (Filippidou, F, et al., 2015)

3. THE ENERGY PERFORMANCE CERTIFICATES FOR EXISTING DWELLINGS AND THE RELATION WITH ACTUAL ENERGY USE

The actual domestic energy use is besides the physical characteristics of a dwelling, largely influenced by the use and behaviour of the tenants. Some preliminary figures demonstrate the difficulty in 'forcing' reduced energy use by improvements of dwellings. The dwellings with the worst EPC (G) in practise use far less energy as expected, while the most advanced dwellings (A) use much more. This is probably due to a combination of the rebound effect and an increase in comfort level of the dwellings (Majcen et al 2013a, 2013b, 2015) and underperformance of the buildings and installations. The large difference between theory and practice is called the performance gap and is recognised in more and more international studies.

In a research project by Majcen (2013a, 2013b) the actual energy consumption was compared with the theoretical use according to the EPC's (see Figure 3).

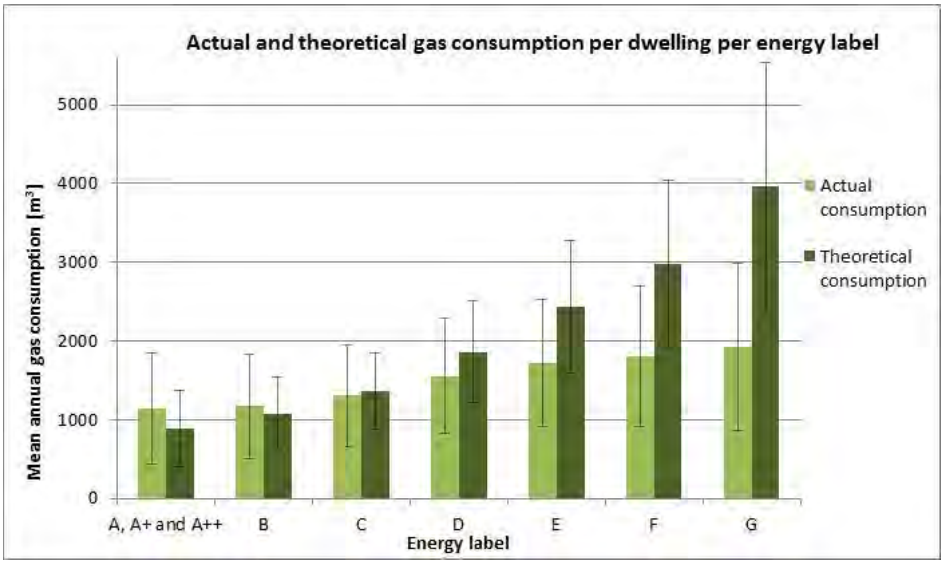

Figure 3: Actual and theoretical gas consumption in Dutch dwellings - per m2 dwelling area
Source: Majcen et al., 2013a

This research was based on the Dutch energy labels issued in 2010 - a total of over 340,000 cases with 43 variables (regarding building location and technical characteristics, the properties of the label itself etc.). This data set was derived from the publicly available database of the EPCs. This data was, on the basis of the addresses of the households, linked to actual energy use data. The energy data was provided by the CBS (Statistics Netherlands), which collected this data from the energy companies. The combined data file was then cleaned by deleting incomplete or obvious incorrect EPCs. This resulted in 193,856 usable cases. This still large sample proved to be representative for all housing types and energy label classes.

To understand how the energy label relates to the discrepancies, the gas and electricity consumption in various label categories were examined and analysed. The actual and theoretical gas use per dwelling was compared and then analysed per m2 of dwelling (Figure 5). Little difference exists between the actual and theoretical energy use calculated per dwellings and per m^2, except the difference in actual gas use between label A and label B. At the level of individual dwellings, the actual consumption was identical, but at the level of m2 the dwellings in category A use less gas than dwellings in category B. This may relate directly to the fact that dwellings in label category A were found to be considerably larger than all other dwellings. From these figures it is clear that although better labels lead to higher actual gas consumption, there is a clear difference between the mean theoretical and mean actual gas consumption for each label. For the most energy-efficient categories (A, A+ and A++) and for category B, Figure 5 shows that the theoretical calculation underestimated the actual annual gas consumption. This is in contrast to the rest of the categories for which the theoretical calculation largely overestimated the actual annual gas consumption. This research indicates that the energy label has some predictive power for the actual gas consumption. However, according to the labels, dwellings in a better label category should use on average significantly less gas than dwellings with poorer labels, which is not the case.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4. NET ZERO ENERGY RENOVATION PROGRAMME

Stimulated by government policies in 2013 an agreement was made by a group of 27 housing associations and buildings and the Dutch government to work on a programme for 111,000 houses to Net Zero Energy (E=0) levels (Munckhof et al, 2015). This was called Energiesprong (Energy leap). E=0 means, annually a house does not consume more energy for heating, hot water, lights and appliances than it produces. The concept is based on refurbishments financed by the energy cost savings; a refurbishment executed within 10 days and a 40-year energy performance warranty from the builder. The approach is further based on organizing a massive demand for a Net Zero Energy (E=0) refurbishments, making financers and governments tune their financing offerings and regulations towards this product and challenging the construction sector to start an ambitious innovation process. Since the take of of the programme several projects have started and some houses are yet already taken into use and even some monitoring results are yet available (Energiesprong 2016). Recently Energiesprong is working also in the UK and France to get an independent market development team set up to drive a similar approach as in the Netherlands.

The costs for Net Zero Energy refurbishment are substantially more than the net present value of today's energy bill. Therefore, an intensive innovation process in the construction sector is needed focused on reduction of costs and process time and energy performance guarantees. This will require moving from doing one-off projects towards developing mass-produced refurbishment packages with a performance standard. And then the idea is that these packages will be sold in shops, which are cosy and have helpful staff. To catalyse that innovation process, a large demand volume this new product is needed.

The financing of the refurbishment is done by giving the tenants an "energy plan" including a guarantee for a hot house (22o), warm water (certain amount of shower time per day) and an electricity bundle for electric appliances for which they together pay a fixed monthly fee. If they exceed that agreed amount of energy performance, they pay the additional electricity consumption to the utility. The bundle fee is paid to the housing association (HLM). This pays of the investment. In the private sector it works similarly, with an increase in mortgage installments to finance the investment covered by the reduction in energy costs. In the Dutch case, the cost of living stays therefore the same for tenants or private homeowners. Investing in factories are required to pre-fabricate these refurbishment solutions with a view to scale. It helped the government to change regulation (i.e. ability for associations to collect the energy plan money) and it made the financier revalue the properties that would be refurbished in order to free extra room to borrow money. The first 200 prototypes and test houses have been built. By the end of 2016, there should be 10000 Net Zero Energy refurbishments completed. Following that deal, Energiesprong is now working to bring these refurbishment packages to the private homeowner sector.

A common question is whether this only works for certain houses that all look the same. In fact, it is mass customization. Houses are all 3D scanned and refurbishment packages are individually produced because even a set of row houses are not all exactly the same, even if it looks like they are. The focus until now has been on the most prevalent typologies of houses in the Dutch market of which 2.3 million houses in the Netherlands exist, but flexibility will increase over time with the number of possible solutions. The first designs will establish whole new supply chains based on prefabricated industrially production methods providing new platforms for further, interactive innovation process (very much like the car industry).

5. CONCLUSION

Without any doubt there is a necessity to drastically reduce the use of fossil-fuel energy sources by reducing the demand for energy and switching from fossil to renewable sources. Buildings account for 40% of Europe's energy consumption and three-quarters of the floor area of the building stock is residential. The targets are clear and the technical solutions are available. Good insulation and product innovations can reduce the energy demand for heating and cooling for a large part. The remaining energy demand can be delivered by renewables like sunlight and heat, district heating, heat pumps, etc. The remaining electricity demand for appliances can in the first place be reduced by further product innovation and then be provided by photovoltaic panels. There are no reasons not to apply these solutions in new buildings at a large scale on the short term. Evaluations of the current practice show however that there is a lot to be gained here. To improve this situation, it has to be assured that constructions and installations are installed properly and in such way that they are not vulnerable for unpredictable or misuse by the occupants. This will set demands on both the construction industry as on the control and enforcement process (and the parties responsible).

The improvement of the existing building stock forms a big challenge. The potential energy savings are large, but the barriers to overcome are also high. As stated before, almost three quarters of the future housing stock (2050) has already been built. Studies show however that it is hard to increase the rate and depth of energy renovations of the existing stock. Actual energy (and financial) savings in renovated dwellings stay behind expectations because of rebound effects. There are important barriers. Many owners believe that the benefits of the measures do not outweigh the costs. Besides that, the cost of improving the energy performance of a dwelling does not (proportionally) increase the value of the dwelling.

We are faced with the difficult task to increase the energy renovation pace. The question is how this process can be accelerated. Maybe there is still room for further smart product development. Innovative products that that contribute significantly to the reduction of energy demand, that are cheap, easy to apply and to handle by occupants and users. The fast decrease of the price of PV cells is promising.

ABSTRACT

As with many other countries, Hong Kong has experienced severe social and environmental problems because of construction waste. Therefore, promoting resource conservation and implementing waste reduction measures are a priority in the building industry's attempt to achieve sustainable construction goals. Green building construction must be underlain by the consideration of net positive contributions to urban environments, the avoidance of waste generation and the promotion of the material life cycle concept. Sustainability in the industry is also strongly driven by the use of environmental assessment tools for buildings. Accordingly, there is a need to evaluate the effectiveness of such tools in promoting waste reduction.

Since 2011, certification under the Building Environmental Assessment Method (BEAM-PLUS) has been amongst the prerequisites for the granting of gross floor area concessions for Hong Kong's development projects. This research was aimed at evaluating the effectiveness of BEAM-PLUS in facilitating waste reduction in the building construction sector. It assessed the appropriateness of the waste reduction criteria in BEAM-PLUS and the waste reduction level achieved when such criteria are adopted. A questionnaire survey, a case study of recently completed buildings and face-to-face interviews were conducted to collect data. The findings reveal that although waste control awareness has increased in recent years, it remains neglected by the stakeholders of building construction. Incentives provided in the Material Aspect (MA) criteria of BEAM-PLUS can serve as an effective motivation for reducing waste, although some credits may be difficult to achieve. MA credits should be divided into sub-credits to encourage the wider adoption of MA in the building industry. BEAM-PLUS should incorporate additional waste reduction measures to increase the awareness and adoption of life cycle thinking in the construction industry.

Keywords: BEAM PLUS, green building assessment, waste reduction

1. INTRODUCTION

Hong Kong is an extremely dense region with a population of about 7.3 million (Censtatd, 2016). It is currently confronted with a shortage of reclamation sites and landfill spaces because of limited available land. The construction industry of Hong Kong accounted for 4.4% of the country's GDP in 2014. It exerts a major effect on economic and environmental issues given that it consumes substantial energy and other resources and generates a significant amount of construction waste. Construction waste accounted for 25% of the total intake at landfills. In 2015, nearly 66,000 tonnes of construction waste were generated each day. With the current waste generation trend, the three existing landfills in Hong Kong will be full by the late-2010s, and public fill capacity will be depleted in the near future (EPD, 2014).

To address the critical issue of construction waste, the Hong Kong government has enacted various regulations, codes and initiatives that promote waste reduction. Amongst these measures, the Construction Waste Disposal Charging Scheme is recognised and proven to be effective at reducing waste that is discharged to landfill sites (Tam, 2008; Lu and Tam, 2013; Yu et al., 2013). Similarly effective regulations are the 3R principles (reduce, reuse and recycle) and the 'polluter pays' principle. Adherence to the 3R principles have become common practice amongst policy makers and practitioners of sustainable solid waste management (Memon, 2010; Napier, 2012).

Amid these achievements, however, an important consideration is that effective construction waste management (CWM) does not depend solely on government efforts but also on collaboration amongst industry players. Poon et al. (2004) reported that on-site waste sorting and recycling are regarded as a low priority by contractors mainly because of low environmental awareness within the industry and because of the constraints represented by limitations in site areas. In an investigation of stakeholders' willingness to apply waste minimisation strategies, only the government showed a positive attitude, whereas clients, contractors and designers remained neutral (Tam, 2008). In recent years, contractors' attitudes and behaviours towards on-site sorting and recycling have improved; such improvement has led to more effective reuse and recycling of resources given that waste sorting is implemented on-site at the source (Yuan et al., 2013). Interestingly, public projects exhibit better on-site sorting performance than do private projects (Lu et al., 2016). Yuan et al. (2013) pointed out that stakeholders' attitudes towards waste sorting in construction sites are still regarded as the most critical factors for enhancing Hong Kong's CWM. As Hong Kong's green building tool, BEAM-PLUS incorporates waste reduction and recycling criteria in the assessment of sustainability in building construction. However, Ng's (2014) examination of 23 platinum projects revealed that Material Aspects (MA) only achieved 50% among all four categories. This percentage was the lowest amongst all the four categories of the evaluation method.

Given this backdrop, the current research was conducted to assess the use and achievability of waste-related MA credits and their effectiveness in reducing waste generation in Hong Kong projects. Data were collected through a questionnaire survey and interviews. An in-depth case study was also carried out. On the basis of the results, recommendations for the construction industry were formulated.

2. METHODS

As previously stated, data were collected through a survey and individual face-to-face interviews that were targeted towards various professionals in the construction industry. The survey was designed to assess the appropriateness of the waste reduction criteria in BEAM-PLUS. The face-to-face interviews served as supplementary avenues from which to investigate the issues addressed in the survey. These issues included challenges and opportunities and recommendations for strengthening waste reduction through BEAM-PLUS. A total of 32 respondents participated in the survey, and 20 professionals participated in the interviews.

The survey respondents and interviewees were asked to assign Likert scale rating that reflects the perceived importance or effectiveness of each item studied. The rating ranged from –2 (e.g. lowest importance) to 2 (e.g. highest importance). The data collected were then analysed using statistical methods, and presented in tables with rankings.

The in-depth case study involved a project-oriented survey and a face-to-face interview. The project-oriented survey consisted of questions regarding the BEAM-PLUS criteria that practitioners have attempted to satisfy, and detailed information related to the perceived relevance and achievability of the criteria within the MA category. The examined project was completed in 2015 (Table 1). The survey data were collected from a Hong Kong building industry contractor who was involved in the project. Additional data were derived via a face-to-face interview with the contractor to substantiate the survey data.

Project description	3 towers with around 27 floors 2-level podium
Year of construction	2013-2015
Site area (m^2)	8,250
CFA (m^2)	66,000
BEAM Plus version	BEAM Plus New Buildings version 1.1
BEAM Plus rating	Provisional Gold
Podium construction	Cast-in-situ (Timber formwork)
Tower construction	Prefabricated non-structural elements and cast-in-situ (95%Steel formwork and 5% Timber formwork)
Precast % (by volume per typical floor)	15%
Type of prefabricated elements	Precast external facade walls and curtain wall
Design characteristics	Repetition on every typical floor Variations of layout on each towers

Table 1: Details of Hong Kong BEAM-PLUS case study

The total amount of construction waste generated and the total amount of construction waste recycled in the project were recorded by the contractor in tonnes per month, as reflected in the landfilling documentation (by truck) and receipt from the recycling company. The waste quantity was calculated with the same method adopted by Jaillon et al. (2009) and expressed in Equation 1. The data were then compared with those on the projects constructed under Hong Kong's Joint Practice Notes (JPN) policies of 2001 and 2002 (see Jaillon et al., 2009). The average waste quantity generated by the JPN-regulated residential building projects of the private sector was 0.23 tonnes/m^2. The calculation method for comparing our case project with the projects investigated in previous research is shown in Equation 2. The calculation method for comparing the recycled construction waste is indicated in Equation 3.

Ratio of Waste Quantity: Cw (ton)/ CFA (m^2)

Equation 1

Where Cw = Construction waste generated; CFA = Construction floor area

Level of reduction: (Pn - Po)/ Po x 100%

Equation 2

Where Po = Waste quantity from the average of projects using prefabricated technology from the private sector (Jaillon et al., 2009); Pn = Waste quantity from the project in this research.

Rate of recycled construction waste: Wr/ Cw

Where Wr = Recycled construction waste; Cw = construction waste generated

Equation 3

3. RESULTS

The survey findings reveal that factors 4, 9 and 15 were the most frequently attempted MA credits (Table 2). The results also reflect that, overall, MA credits are satisfied to a lesser extent than are other credits. Ng's (2014) study confirms these results.

Factor No.	Factors	Rank
1	MA 1,1 credit for the reuse of 30% or more of existing sub-structure or shell	10
2	MA 1,2 credits for the reuse of 60% or more of existing sub-structure or shell	13
3	MA 1,1 additional BONUS credit for use of 90% or more of existing substructure or shell	16
4	MA2, 1 credit for demonstrating the application of modular and standardized design	2
5	MA3, 1 credit when the manufacture of 20% of listed prefabricated building elements has been off-site	4
6	MA3,2 credits where the manufacture of 40% of listed prefabricated building elements has been off-site	14
7	MA 4, feasible and at least 50%of the listed items in the relevant BEAM checklists could be achieved in residential development	10
8	MA 4, feasible and at least 70% of the listed items in the relevant BEAM checklists could be achieved in other building types	9
9	MA 6, 1 credit for demonstrating at least 50% of all timber and composite timber products used in the project are from sustainable sources/ recycled timber	3
10	MA 7, 1 credit for the use of recycled materials contributing to at least 10% of all materials used in site exterior surfacing work, structures and features	6
11	MA 7, 1 credit where at least 10% of all building materials used for facade and structural components are recycled materials	8

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

12	MA 7, 1 credit where at least 10% of all building materials used for interior non-structural components are recycled materials	6
13	MA 10, 1 credit for demonstrating that at least 30% of demolition waste is recycled	5
14	MA 10, 2 credits for demonstrating that at least 60% of demolition waste is recycled	15
15	MA 11, 1 credit for demonstration that at least 30% of construction waste is recycled	1
16	MA 11, 2 credits for demonstration that at least 60% of construction waste is recycled	12

Table 2: Frequency of MA credit attempted in respondents' company's BEAM-PLUS NB projects

3.1 Appropriateness of MA credits

The MA category of BEAM-PLUS can be regarded as a guideline for measuring waste reduction in the construction industry. Appropriate requirements for acquiring MA credits should be practical and efficient to promote construction waste reduction. These credits are key to encouraging the increased adoption of waste reduction measures and advancing the implementation of BEAM-PLUS measures.

As shown in Table 3, the survey respondents identified factors 1 and 2 and factors 6 to 8 as having appropriate percentage levels. However, for factors 1 and 3 to 5 and 9 and 10, the respondents suggested reducing the required percentage levels. Most of the interviewees opined that some of the credits are difficult to achieve because of high requirements and limitations with respect to building types, land area restrictions and material specifications. In factors 9 and 10, (MA 10 - Demolition Waste Reduction and MA 11 - Construction Waste Reduction), which directly affect the waste diverted to landfills, 1 and 2 credits are awarded for at least 30% and 60%, respectively, of demolition/ construction waste recycled. Most of the respondents expressed a preference for lowering the percentage levels to 10% to 20% given that the original levels are ambitious. That is, they are difficult to achieve because of time limitations (demolition and sorting of waste/ materials require additional time) and lack of on-site storage and sorting spaces (small sites in dense urban areas). With regard to the second credit for the recycling of demolition/ construction waste, the majority of the respondents prefer lowering the percentages to 10% to 40% because satisfying a 60% recycling rate is laborious. The interviewees also mentioned that most existing buildings are demolished prior to the awarding of construction projects. Some architects pointed out that waste recycling may be difficult for them to control/ monitor given that contractors take the lead in handling both demolition and construction waste. Additionally, most of the contractors stated that recycling companies accept only some recycled materials and may be the primary handlers of waste at construction sites located near recycling points. Furthermore, the labour cost associated with sorting waste into recyclable material is high. To conclude, the recycling rate at construction sites can be increased if sufficient time and space are provided and if the market for

Factor No.	Factor	Decrease the level	Remain the level	Increase the level
1	MA2, 1 credit for demonstrating the application of modular and standardized design (over 50%)	✓	✓	✕
2	MA3, 1 credit when the manufacture of 20% of listed prefabricated building elements has been off-site	✕	✓	✕
3	MA3,2 credits where the manufacture of 40% of listed prefabricated building elements has been off-site	✓	✕	✕
4	MA 4, feasible and at least 50%of the listed items in the relevant BEAM checklists could be achieved in residential development	✓	✕	✕
5	MA 4, feasible and at least 70% of the listed items in the relevant BEAM checklists could be achieved in other building types	✓	✕	✕
6	MA 7, 1 credit for the use of recycled materials contributing to at least 10% of all materials used in site exterior surfacing work, structures and features	✕	✓	✕
7	MA 7, 1 credit where at least 10% of all building materials used for facade and structural components are recycled materials	✕	✓	✕

8	MA 7, 1 credit where at least 10% of all building materials used for interior non-structural components are recycled materials	×	✓	×
9	MA 10 and 11, 1 credit for demonstrating that at least 30% of demolition and construction waste is recycled	✓	×	×
10	MA 10 and 11, 2 credits for demonstrating that at least 60% of demolition and construction waste is recycled	✓	×	×

Table 3: Appropriateness of percentage level in MA credits to promote construction waste reduction

3.2 Effectiveness of MA credits in reducing waste

The examined project attempted to achieve the following MA waste-related credits:

- MA2 modular and standardised design: Over 50% of building elements are designed as modular and standardised components to minimise construction cut-off waste.
- MA4c adaptability and deconstruction: A total of 50% or more of the structural design is created for flexibility in future use to reduce demolition waste from future changes.
- MA6 sustainable forest products: A total of 50% or more of timber and composite timber products are obtained from sustainable sources or recycled timber to help reduce resource extraction and protect forest ecology.
- MA7b recycled materials: A total of 10% or more of the building materials used in façade and structural components are recycled materials to encourage waste to be recycled and indirectly reduce waste disposal.
- MA11 Construction Waste Reduction: Approximately 35% of construction waste is recycled to help reduce the disposal of construction waste.

According to the data, the waste generated from the case project was 0.21 tonnes/m^2 (all construction waste generated per CFA). Data from Jaillon et al. (2009) show that the quantity of waste generated per CFA for high-rise residential buildings in the private sector was 0.23 tonnes/m^2 when prefabrication techniques were used and 0.30 tonnes/m^2 when conventional methods were adopted. The construction waste generated in the project examined in the present study was 30% lower than those produced with conventional techniques (Jaillon et al., 2009). As indicated in the interview data, the recycled waste in our case project were mainly steel (95.5%) and paper/ cardboard packaging (4.4%). Steel formwork was reused on typical floors, whereas timber formwork was reused only two to three times.

As shown in the survey, 45% of participating professionals believe that BEAM-PLUS cannot promote waste reduction, whereas 34% expressed neutral attitudes. These findings may be attributed to the achievability and appropriateness of the BEAM-PLUS credits. They also reflect that the BEAM-PLUS credits still have room for improvement in terms of promoting waste reduction. A necessary requirement is to compel contractors to quantify generated waste for practitioners to effectively reduce waste.

4. CONCLUSION

The effectiveness of waste reduction via BEAM-PLUS was assessed on the basis of a survey, face-to-face interviews and a case study. The waste reduction criteria in BEAM-PLUS were evaluated as insufficient given that waste reduction is not regarded as a priority in the Hong Kong building industry and that practitioners rarely satisfy MA criteria owning to low overall weighting, lack of required minimum thresholds and difficulty in achieving credits. Furthermore, the MA category provides no criteria for enhancing cooperation between builders and designers in waste reduction, and no accurate figure reflects the amount of waste reduced after attempts to acquire MA credits. On the basis of the interview findings, the following recommendations were developed:

- Break down credits into sub-credits and provide detailed explanations and more specific environmental measures for easier attainment of MA credits.
- Provide a criterion that enables requests to reduce waste generation (tonnes/m^2), on the basis of total waste generation data collected over the last few years through BEAM-PLUS (MA 11) and EPD (trip ticket system).
- Providing a ratio of MA aspects according to the scope of BEAM-PLUS as a minimum threshold may be un-suitable.

ABSTRACT

The planning and construction of highly energy-efficient buildings is one of the most ambitious challenges of the building industry worldwide. Especially in Europe the topic of Nearly Zero-Energy-Buildings is very present because of the legal requirements of the European Parliament on buildings. All relevant stakeholders, scientists as well as practitioners, are looking for successful strategies to achieve that goal.

In 2010 the planning phase for the first Net-Zero-Energy-Building of the German Federal Government started. The building should cover its total final-energy demand by the use of renewable energies solely. At the same time the building should have the highest standard of sustainability regarding to the assessment system used for buildings of the Federal Government (BNB). The building went in operation in 2013 and since than the building operation has been monitored.

First experiences and results of the monitoring of the energy performance, the thermal comfort and assorted aspects of the sustainability will be presented and general recommendations for improvements of details and processes are given. Furthermore a strategy for the optimization of the performance, energy and comfort as well as costs, will be introduced. Therefore a building model was created and calibrated on basis of the measured data. By varying different parameters like energetic quality and changes in the sizes of different building parts or the inclusion of new devices in the energy supply concept the influences on the total building costs but also on the energy and comfort balance were investigated in dynamic simulations.

Keywords: high-performance building, building energy simulation, energy measurement and verification

1. INTRODUCTION

In the framework of the last European Directives concerning the energy performance of buildings, all EU Member States enacted legislations in matter of a low-carbon future of the building sector with increasingly stringent prescriptions for the next years. Following the 2010/31/EC Directive, public administrations and Institutions have to play a leading role in the field of energy efficiency in the building sector. The Directive concern both new and existing buildings. One of the most relevant aspects is the target of “nearly zero-energy buildings”. Member States in particular are requested to guarantee high quality buildings with a minimized energy demand and mainly using renewable energies according to the following time schedule (Article 9 of the 2010/31/EC Directive):

- For new buildings owned and or occupied by public administration and authorities, the nearly zero-energy standard is requested from January 2019;
- Starting from January 2021, all new buildings shall fulfill the nearly zero-energy standard.

In 2010 the planning phase for the first Net-Zero-Energy-Building of the German Federal Government started. The building is located in Berlin and used as office building for approximately 30 persons. Destined for the German Federal Environment Agency (UBA) and aspiring the fulfillment of the EU-requirements of 2019 the building is called UBA 2019. The building concept was oriented toward the Gold-standard of the Assessment System for Sustainable Building (BNB; www.nachhaltigesbauen.de), the rating tool for sustainable buildings of the German Federal Government (Federal Buildings).

The difference between “nearly” and “net” zero energy buildings (nearly ZEB and net ZEB) is the share of renewable energies which is used to cover the energy demand of the building. While in a nearly ZEB the energy

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

demand is covered predominantly by renewable energies that share is 100 % in a net ZEB during a certain time period (mostly one year).

2. PRESENTING THE BUILDING CASE STUDY

The building UBA 2019 has a compact square shape (Figure 1). The gross dimensions - width and length - are 25 m, even if the east-west façade has a longer aspect, due to the anterior porch on the south and north exposure. Most offices are for single persons. The building has three meeting rooms; two of them can be connected. Other spaces are used for services (as kitchen and toilettes), technical rooms and common areas. In Figure 2 ground and first floor are shown.

Figure 1: UBA 2019; view from south (left), view from west (right)

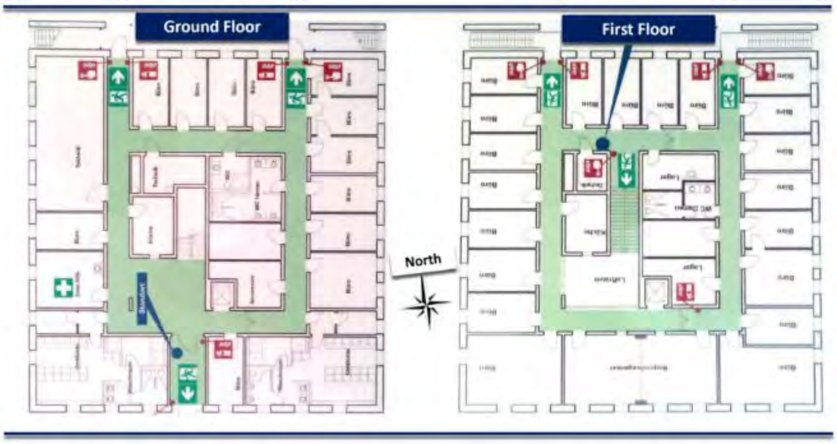

Figure 2: Schemes of ground floor (left) and first floor (right)

In order to reduce the energy need for heating (e.g., cooling demand can be covered almost without energy costs by using groundwater and natural ventilation), the envelope structures were strongly thermally insulated by thick layers of cellulose fiber. The structure of the thermal envelope is the following:

- External wall: The overall thickness is 0.46 m (inclusive of 36 cm of cellulose insulation). On the inner side, there is an OSB plane with a coating of drywall. Externally an air permeable wooden fiberboard is installed. The thermal transmittance (U-value) is 0.12 W/m²K.
- Flat roof: The overall thickness is 0.96 m, with 53 cm of cellulose fiber insulation. The structural elements are wooden box beams, with a thickness of 28 cm. On the outer side, there are 10 cm of mixed sand, gravel, chippings, covered with extensive sedum vegetation. Other intermediate layers are two OSB boards, a vapor barrier on the inner side, a waterproofing layer on the external side. The thermal transmittance is around 0.05 W/m²K.
- Floor on the ground: Wooden box beams are insulated with 16 cm of poly-urethane and 12 cm of foam glass. On the inner side, a light concrete layer of 6 cm is covered with the parquet floor. The thermal transmittance is 0.09 W/m²K, with a total thickness of 0.71 m.
- Windows and skylights: Are triple-glazed systems, with certified overall U-values respectively equal to 0.70 and 0.86 W/m²K. The windows are equipped with shading systems (horizontal slats). The shadings are

located externally to the third glass. A fourth pane is installed in the frame as protection of the shading device. This pane can be opened separately.

Already after finishing the air-tight sealing a first blower door test was performed in order to guarantee a certain quality of the construction. After completion the building air-tightness was measured by a second test. The testing involved a series of under-pressure and over-pressure measurements. The measured rates of air change per hour (ACH), at a differential pressure of 50 Pa (i.e., n50), ranged between 0.30 h-1 and 0.35 h-1. The calculated average value is 0.33 h-1.

For heating and cooling the offices built in capillary tube systems and handled ventilation air are installed. For heating, the capillary tubes are embedded in the inside of the external walls. The water for the wall integrated heating system as well as for the heating coil of the ventilation system is heated by a water-to-water geothermal heat pump. Conversely, the capillary tubes for cooling are embedded in the partition walls. No chiller is required. Only for pumping the ground water electric energy is needed. The temperature of the ground water is directly used for cooling the building by passing a water-to-water heat exchanger. In each office a dew point sensor prevents condensation by stopping the cooling system. The cool ground water also is used for cooling in the air supply system.

The mechanical ventilation system - designed for achieving the comfort Category II according to the Standard EN 15251 in each room - is equipped with a sensible flat plate heat recovery system.

Beyond the use of ground water for cooling and heating the building is equipped with a solar thermal energy system, with an overall solar collector area of 11 m² and two 970 l thermal heat storage tanks. The inclination angle of the solar thermal collectors is 37°, with a slight deviation, around 8°, from the south exposure. Furthermore a large photovoltaic system is installed on the building roof. In order to reduce the system visibility a tilt angle lower than 10° was chosen. The total installed capacity is approx. 66 kWp. The designed specific yield is 790 $kWh_{ELECTRIC}$/(kWp*a). Compared to the calculated annual demand of electricity for all processes in the building in the amount of approx. 46,000 kWh/a it means a surplus in generation of electricity of approx. 10 %.

The building cost around 4.2 million Euro (net), including all building categories identified by the German standards DIN 276 and DIN 277 . The specific price per gross floor area is about 3,325 €/m².

Looking solely on the costs of architectural works and indoor technical equipment, the specific price is about 2,350 €/m². An average value for Germany, with reference to highly equipped office buildings, is around 1,730 €/m². Compared to that, the costs of UBA 2019 are 36 % higher. Regarding that point it should be noted that the building meets extraordinary requirements in matter of energy, accessibility, and sustainability.

3. RESULTS OF THE MONITORING

UBA 2019 is equipped with a full monitoring apparatus, thus continuous metering of all energy flows is possible. In detail, there are 83 electric meters, 26 heat counters, 4 meters for cold and hot water installed. Moreover, an outdoor weather station measures the outside air temperature and relative humidity, wind direction, wind speed, global solar radiation, CO_2 concentration, illuminance. To get information about the indoor climate a fixed and a mobile measurement system are used. In particular, the indoor air temperature is measured in each room and, for four representative spaces, further 18-27 sensors are installed for measurements concerning the thermal comfort, the indoor air quality (CO_2 concentration), peoples presence, illuminance and lighting level, status of use (e.g., window contacts, use of shading devices). The mobile system - that can be installed for some days in any place in the building - measures the thermal comfort by means of 8 sensors as well as the presence of persons.

Figure 3 is showing a comparison between expected data from the planning phase and the monitored data in the first 3 years of operation of UBA 2019. In all years of operation the electricity generation by PV-system is higher than the consumption of electricity. That means that the aim of a net ZEB is achieved. The installed PV-system is more efficient than planned and the solar irradiation was higher compared to a standard year. In detail one can see that the energy demand for each single process is different from the expected one. The reasons for that are mainly the reduced occupancy of the building and the existing potential for optimizations. The decrease in generation in the 2nd year of operation was caused by an accidental shutdown of the PV-system.

The monitoring of the indoor microclimate showed that the building achieved the highest categories in terms of operative temperature and air velocity regarding Standard DIN EN ISO 7730:2006 . For relative humidity the results differ. In summertime the highest category is met but in wintertime the air is too dry. Interviews with users confirm these results. Furthermore the answers gave indications for further optimization. As example malfunctions of the heating and cooling devices in some offices could be detected.

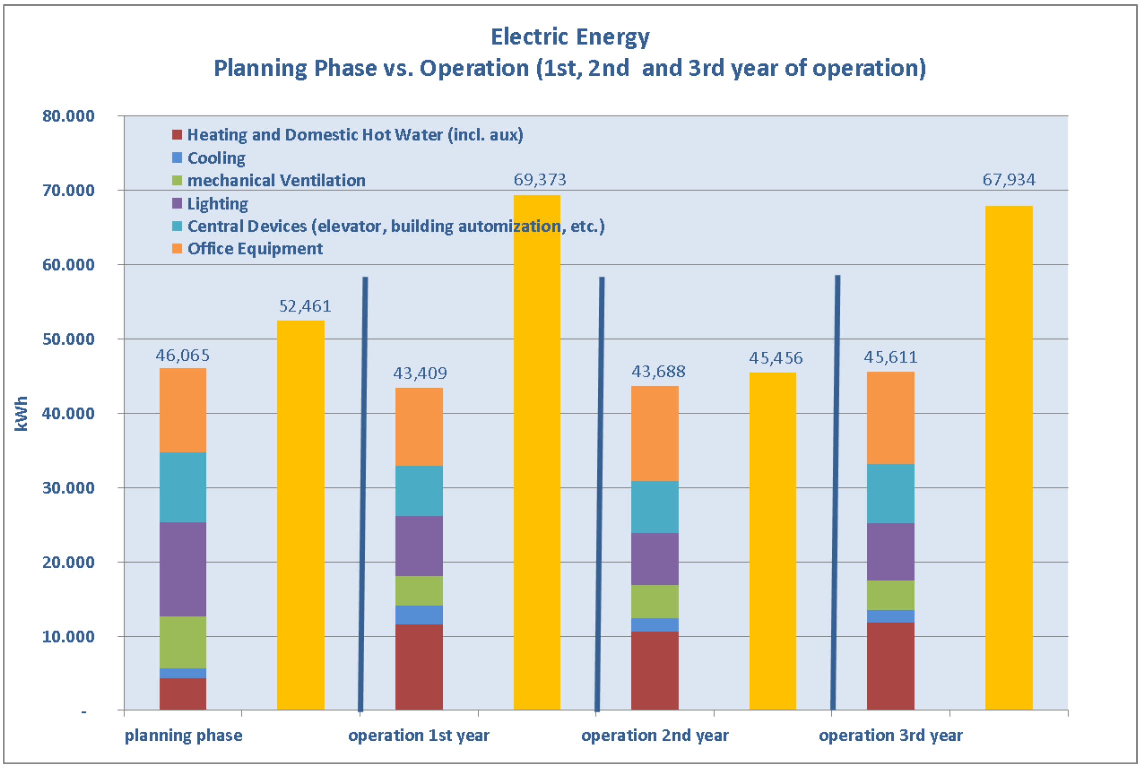

Figure 3: Results of the monitoring UBA 2019 – Planning phase vs. operation

4. EVALUATION OF THE BUILDING MODEL

Transient energy simulation, when validated based on proper calibration with monitored data is a powerful tool to understand gaps between design and operation, inefficiencies of building systems as well as to test potential energy efficiency measures aimed at improving building performance. Methods and protocols for calibrating energy models were developed by FEMP and ASHRAE [6,7 and 8] and these are applied in the investigations.

The building geometry and the general boundary conditions of the several functions of the building were implemented with DesignBuilder 3.2.0 [9]. EnergyPlus 7.2.0 [10] was used for numerical calculation and here also the materials and constructions for reproducing the real thermal-physical properties of the building envelope, such as provided by the design documentation (i.e., layers orders, materials' thermal conductivity, density, specific heat, etc.) have been defined. In the Appendix some key parameters affecting the energy simulation as the climate boundary conditions and other relevant data are reported there (Tables 1 and 2).

The relative differences between designed and simulated annual energy performance for each process based on hourly energy balances show a span between -1.2 % and 1.9 % (see Table 3).

Nevertheless, the differences between monitored energy usage and expected values from the planning phase suggested the definition of a new building model, calibrated on the present building operating conditions and patterns of use, in order to verify reasons and causes of differences in energy performance.

In order to verify a suitable calibration of the model, statistical indexes, as proposed by the M&V Guidelines "Measurement and Verification for Federal Energy Projects" [7] of the U.S. Department of Energy have been calculated. In our study the option D, suitable for the comparison of measurements of energy meters and output of numerical simulations, has been used. To understand deeply the reliability of our investigation, the indexes have been calculated not merely for the whole facility, but also with reference to every system (heating, cooling, ventilation, auxiliaries, lighting).

In particular, the followings indexes have been calculated:

- Mean bias error (MBE): It allows to estimate the fit between the simulation and the measured data. Positive values testify an overestimation of the numerical model. Conversely, negative values reveal an underestimation.
- Coefficient of variation of the root mean square error (CV(RMSE)): The overall uncertainty of the prediction, and this refers to the whole energy usage of a building. The value of CV(RMSE) is always positive.

According to [6] and [7] the following values for MBE and CV(RMSE) are acceptable, when a month is the reference calculation period over the whole time horizon investigated:

- MBE_{month} (%) ≤ ± 5%,
- $CV(RMSE_{month})$ (%) ≤ + 15%.

The MBE_{month} for the single processes in the building is in a span between -1.16 % and 1.95 %. The $CV(RMSE_{month})$ for the overall energy use is equal to 7.96 %. Thereby the calibration of the building model is completely satisfactory.

5. BATTERY STUDY

The building has an overproduction and at the same time a mismatch between electrical energy demand and generation The economically most appropriate use of on-site produced electricity is on-site consumption. Therefore, a further investigation looked at the optimization of an electric storage system under both technical and economic points of view. Presently, the on-site energy yield is about 69,000 $kWh_{ELECTRIC}$ a year, and thus the target of net zero energy building (i.e., the energy balances consider the energy flux on the basis of one year of observation period) is achieved. At the moment the grid on the property is used for supplying into the grid the surplus electricity and for getting electricity if demand is higher than production. Presently, the building uses only 27 % of the on-site generated electricity while the bigger part of the total electricity need is covered by the grid.

The energy demand for the microclimatic control in summer - the peak time of energy generation - is very low (only auxiliary devices are needed no use of chillers, low use of lighting because of the diurnal high radiation). Based on these considerations, an Electrical Energy Storage (EES) has been designed by optimizing energy capacity, discharge rate, and the costs (taking into account the feed-in tariff, the price of purchased energy, investment - 1.000 €/kW and 1.500 €/kWh - and maintenance of the battery system). The aim was to find the lowest costs of the stored kWh of electric energy while maximizing the on-site use of the PV-generated electricity.

With costs of the stored kWh similar to the price of the one bought from the supplier a battery system with a capacity of 10 kWh and a discharge power of 39 kW can rise the on-site-use up to 42 %. The costs per stored kWh can be decreased to 0.21 €/kWh if the maximum discharge power is limited to 16 kW. In this case the on-site-use is slightly reduced to 38 %. This system is characterized by the optimal performance in terms of technical and economic constraints.

6. COST STUDY

The present surplus of electricity and the very high insulation of the building indicates that there are alternative configurations with reduced investment costs and/ or reduced lifecycle costs. Therefore a further study was carried out on alternative solutions for the building energy concept. The aim of that study was to find ways for a reduction of the building costs (investment cost as well as lifecycle costs) while the existing qualities in terms of energy performance, sustainability (BNB Gold level) and indoor comfort are maintained. Only the level of natural lighting could be increased because the windows of the building only take approx. 16% of the surface of the external walls. Also in this case, the calibrated building energy model has been used.

Several assorted measures and packages of these measures have been taken into account. They consist of widening of window areas from 16 % to 24 % of the external wall surface, reducing the thickness of insulation of

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

external walls, roof and bottom slab. Moreover, two different types of thermal glazing for windows (double and triple glazed) and a change in the control of the shading system have been investigated. The feasibility study has been performed according to the cost optimal methodology. For each package the global costs of the re-designed building were calculated and compared with the base case to find the package that represents the optimal level between costs, consumption and generation.

From all of the investigated measures and packages in the study the optimal one consists of changes in the size of the windows, change of insulation (i.e. 20 cm of mineral wool for both roof and external wall insulation, double glazed windows and reduced thickness of polyurethane for the bottom slab) and a different shading control system. In the simulation the measures are leading to a negligible lower annual primary energy consumption of 1.4 %. At the same time the global costs in the lifecycle for the certain measures decreased by approx. 46,000 €. In relation to the base case it means a reduction of the global costs of approx. 11 %. Regarding the total costs of the project (investment costs), the investigated improvements would led to a reduction of less than 2 %.

7. CONCLUSIONS

After a 4-year-phase of planning and construction the first Net-Zero-Energy-Building of the German Federal Government went in operation in 2013. The sustainability of the building was certified regarding to the Assessment System for Sustainable Building for Federal Buildings (BNB). It achieved the highest degree of performance and therefore it obtained a certificate in gold.

The monitoring of energy usage, sustainability, indoor air quality and thermal comfort shows that the ambitious aims of the project were achieved almost totally. In order to access the left potential of optimization, a building model was developed and evaluated besides onsite measurements and user surveys. The model is used for investigations of different operation strategies or the installation of additional equipment. Furthermore it is an instrument for investigations regarding the cost-optimality of the building and thereby a tool for the development of general conclusions to that topic. First investigations in possible improvements of the building envelope were already carried out. A second study identified optimal design values for electric battery storage to improve the share of self-used electricity generated by the PV-system. The next step will be the implementation and monitoring of this device.

ABSTRACT

Future population growth is estimated to be concentrated in urban areas of the developing world. This growth and demographic shift will require a large amount of construction materials and generate Greenhouse Gas emissions. The present study is motivated by the lack of a holistic approach to understand how urbanization affects resources and the environment. A framework is established, which links population increase and the associated material flows devoted to construction of additional housing units as well as densification of the existing building stock. Different political scenarios as well as alternative construction techniques and building materials are used to explore the potential for reducing material requirements and embodied GHG related to urban growth in Johannesburg, South Africa. Stock dynamics modeling techniques are applied with the use of building typologies and uncertainty quantification. The bottom-up approach allows identifying appropriate solutions for decarbonization by localizing embodied GHG with a revisited Sankey diagram. The results of the dynamic model over time indicates that only a combination of densification of the building stock with multi-story buildings and the use of alternative construction materials and techniques shows a real potential to decelerate embodied GHG while aiming to provide adequate and sustainable housing.

Keywords: urban metabolism, scenario analysis, embodied energy

1. INTRODUCTION

Countries of the developing world are facing an increase in population and accelerated urbanization. 60% of the built environment required to accommodate the earth's urban population by 2050 remains to be built (UNEP, 2013). While construction materials are already the single biggest form of material flows (Schandl and West, 2010), the coming urbanization wave will increase even more the pressure on resource extraction and its deleterious environmental impact. The objective of this paper is therefore to explore potentials to reduce material requirements and Greenhouse Gas (GHG) emissions caused by urban growth.

To do so, Urban Metabolism (UM) is used as it is a common method to understand how human and economic development affects the natural environment (Pauliuk et al., 2015). Studies on UM are subject to quality and amount of accessible data. This issue is raised in standard literature reviews (Broto et al., 2012; Zhang et al., 2015). Furthermore, studies at the urban scale in developed countries are data intense and go into great detail. In cities of developing and emerging countries, where this type of information does not exist, data mining remains a big challenge and data on the national level is used. Recent urbanization in most African cities has been largely informal (Cobbinah et al., 2015). In consequence, national or city data are of little help to grasp the material flows of these new settlements. There is a need for a finer granularity analysis whilst keeping a large-scale approach in order to extract sound and relevant data in a time-effective way.

The present paper wants to combine bottom-up accounting and demand-driven modelling of the building stock. By applying a combined approach, the advantages of the different modeling techniques can be employed for the specific situation in an emerging country: data scarcity can be overcome, information on the city scale can be modeled dynamically over time and the influences of socioeconomic indicators are taken into account. Different scenarios for the identified determinants of the building stock's embodied GHG emissions are proposed. The scenario compares and combines these potentials to minimize future impacts.

2. DATA AND METHODS

2.1 Typologically driven stock dynamics model

The framework for the model was adapted from a current stock dynamic approach developed by Hu and colleagues (2010). The method makes use of building typologies to model a whole urban residential building stock by simply using averages. The relevant service unit of the present study is floor area in use. This process is determined by the population size and per capita floor area (PCFA). PCFA is dependent on the dwelling type, it is one parameter considered to define building typologies. Actually, for each building typology, the household size is modeled. This includes people per household and habitable space per household. These characteristics are then translated to the PCFA as an expression of the population's lifestyle.

The floor area in use of the residential building stock is described with a state variable (in m^2) and a derivative, which represents the net stock accumulation. A density of materials is defined (in kg/ m^2), which depends on building type, the volume of its elements and the density of used construction material. The material density controls the input of materials by linking it to the floor area. Equivalent to floor area, materials in use have a state variable (in tons of material) and derivative. The output of floor area and materials is determined by lifetime of dwellings and material respectively. Inflows are controlled by simple balance relations as a sum of in stock and outflow of mass and floor area.

The environmental impact of the production of each building material is defined as an embodied GHG intensity. The combination of this embodied GHG intensity with the input of materials in use allows to calculate the additional embodied GHG required for the additional floor area. Equivalent to the processes floor area and materials, embodied GHG in use is also modeled with a state variable (in tons of CO_2 equivalents), and a derivative.

2.2 New visualization tool

To visualize the allocation of the resources in the building stock, a diagram resembling a Sankey flow diagram is developed. The diagram helps to easily track the embodied GHG when modelling in a data scarce environment. It is a vital way of disentangling the building stock since the incorporation of typologies in the model makes it more complex to grasp and interpret. Furthermore, it allows comparing different technological and political options to decarbonize urban areas.

Often a huge number of line and bar charts are used to show the contribution of different types of infrastructure elements and their characteristics regarding material and energy intensity. These ways of presenting material stocks and flows make it difficult to grasp the entire information because results are shown in various tables and charts. The proposed revisited Sankey diagram makes it easier to see the link between different composites and processes and to visually identify the main drivers of material and energy consumption. The diagram highlights optimization potential, mainly from a structural engineering point of view. The proposed visualization does not show continuous flows like a classic Sankey diagram does. It is revisited so that the width of links indicates the proportion from one node to the next, but the illustrated flows change in terms of units from one step to the next.

2.3 The city of Johannesburg

The City of Johannesburg Metropolitan Municipality (referred to as Johannesburg in this article) is chosen as a case study. Johannesburg is a sprawling city composed of dispersed residential, industrial and office developments (Economist Intelligence Unit, 2011). As a result, it is less dense compared to other major African cities, leading to a particular interest of examining the challenges that arise from urbanization. The present study used national censuses for 1996, 2001 and 2011 (Statistics South Africa, 2011).

Building typologies

The building typologies are based on definitions of dwelling types from the South African census in 2011 and were gathered in 5 dwelling typologies: (1) house on a separate stand, (2) flat in a block of flats, (3) house/ flat/ room in backyard, (4) informal dwelling in backyard, and (5) informal dwelling in settlement. These 5 dwelling types represent around 87.5% of the residential building stock in Johannesburg (Statistics South Africa, 2011). The

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

model is run for a period from 1975 to 2040. Starting in 1975 allows creating reasonable initial conditions as the service life of buildings is relatively low and a large part of the urbanization linked with population growth happened at that period.

Material sets of building typologies

For each building typology a specific material set in kg per floor area and kg per building element is defined. Building elements considered are load bearing walls, roof, slabs and the foundation. The inventory is based on floor plans and images of representative buildings that can be allocated to each typology.

As it can be seen from Table 1, the two informal dwelling types (4 and 5) are identical in terms of material requirement but they were modeled separately in order to implement changes in the share of dwellings from political decision.

Element	Type (1)	Type (2)	Type (3)	Type (4)	Type (5)	Other
Walls	12,505	21,780	7,441	218	218	15,597
Foundation	16,432	18,751	2,548	-	-	17,205
Ceiling	-	17,120	-	-	-	5,707
Roof Trusses	310	1,117	268	-	-	579
Roof Tiles	1,905	6,222	1,163	71	71	3,344
Amount	31,152	64,990	11,419	289	289	42,431

Table 8: Amount of material in kg per building element for building typologies

GHG intensity of building materials

The current study focuses on GHG emissions related to the production of the different building materials. The maintenance can be neglected as we focused on structural elements (Hoxha et al., 2014) and the demolition and landfill phase of the life cycle are not the main responsible of the climate change related impact compared to the production phase of building materials (Lasvaux, 2012).

Future scenarios

Finally, future scenarios for the evolution of the building stock are considered. Engineering and policy measures were considered. For the engineering side, changes in the structural design as well as changes in the type of materials are considered. For the policy aspects, the focus lies on a change in building typologies.

Two structural design options are considered: a conventional structure of reinforced concrete slabs for multi-story buildings and an optimized one where a vaulting system is used allowing to drastically reduce the amount of materials for slabs (Block et al., 2010; Hebel, 2015). This innovative system was implemented by Hebel (2015) in Ethiopia in the “SUDU - Sustainable Urban Dwelling Unit” project.

For the alternative construction materials, the building materials low carbon concrete and earth are considered. Low carbon concrete is a concrete made with a cement containing a low proportion of clinker and therefore associated with smaller GHG emissions. This is the current trend in the cement industry where at the global level the clinker substitution is currently around 20% and the extreme scenario considered in the present study assumes that the substitution could reach 50%, which is a technical limit from the cement chemistry (Habert and Roussel, 2009). Concerning earth materials, earth based construction has been used for more than 10,000 years and a revival of this material can be observed in recent years (Landrou et al., 2016; Scrivener et al., 2016). The environmental impact associated with this material is extremely low and, if not stabilized, can be reduced to the impact associated with extraction and transport of the raw material. However, a stabilization of the material would lead to higher emissions per m^3 and per MPa compared to traditional concrete.

Three different policy scenarios are considered. One scenario represents an elimination of informal settlements, which is in line with UNEP’s recommendation to eliminate existing housing backlog in South Africa. The second scenario considers a densification of the city through an increased share of apartment buildings in the building typologies. This is strongly encouraged by UNEP who considers that the existing urban density of 15-20 dwelling units/ hectare should be increased to a minimum of 35-45 dwelling units/ hectare via smaller plot sizes and multi-story buildings (UNEP, 2011).

3. RESULTS

3.1 Total embodied GHG emissions for political and technological scenarios

The different scenarios considering alternative structures and materials are combined with the policy scenarios to examine the potential impact of each respective scenario and are compared to the current situation (2011 data) and the Business as Usual (BAU) trend scenario in 2040.

The bar chart in Figure 1 shows how a change in policy, indicated by pattern, and different combinations of material and technology, as shown as groups on the x-axis, affect the embodied GHG intensity of Johannesburg in 2040. The diagram indicates that the different political scenarios alone do not have a primary importance in the future of GHG emission reductions. The same goes for singular improvements in technology. When considering low-carbon-concrete and optimized ceiling structure, the difference between the technical scenarios is small for the single policy scenarios (BAU or no informal settlements). However, the promotion of flats allows to increase the leverage effect of the optimized ceiling structure compared to the technical solutions where only low carbon concrete is used. Finally, it is also clear that the use of radical alternative materials and smart structure shows the potential for significantly reducing embodied GHG of the residential building stock by 2040. If these radical technical shifts are additionally combined with policy making which promotes a denser building stock by moving people from freestanding houses into apartment buildings, then the GWP linked with construction materials could stay within range of the 2011 value in in 2040.

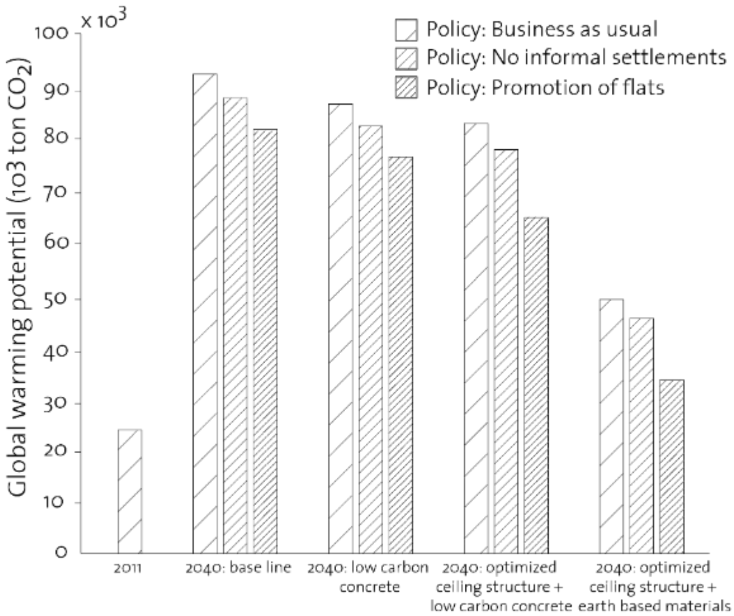

Figure 1: Total embodied GHG released in 2040

3.2 Visualization of building stock in 2040: comparison best and worst case

The proposed representation method helps to localize and track embodied GHG by breaking down the building stock into its components and small scale elements. It is important to note that the modified Sankey diagram developed in Figure 2 does not show one consistent unit but that from the first node to the second number of people per building typology are shown. From the second to the third node the links indicate mass of material per building element. This unit remains the same for the next step, a translation to type of construction material. The last links show amount of embodied GHG.

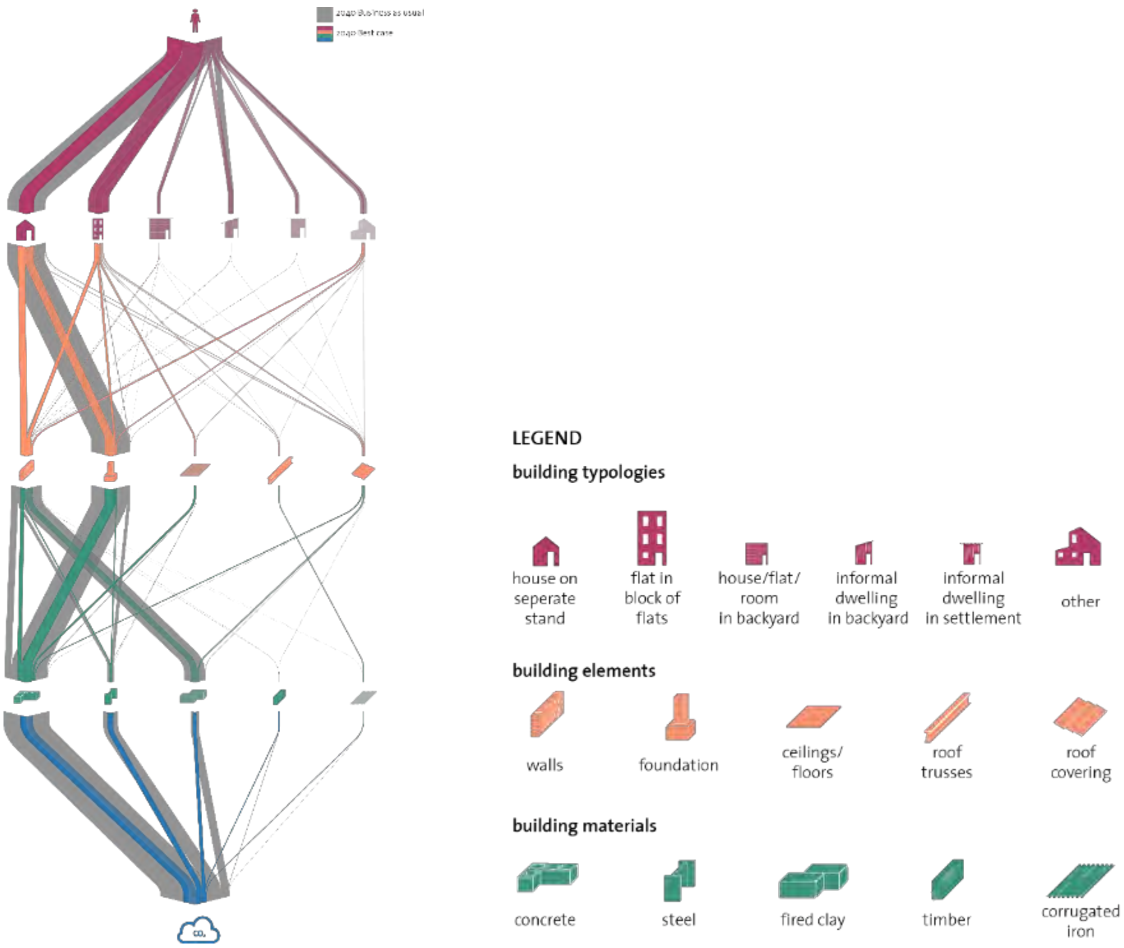

Figure 2: Revisited Sankey for the best (combination of promotion of flats with optimized floor structures and alternative building materials) and worst (BAU) case in 2040

Figure 2 shows the structure of the building stock for two extreme scenarios: the BAU and the one where optimized radical change in structure and materials are used as well as a shift towards multi-story buildings. The enormous amount of saving potential is clearly visible in the final GHG quantification. At the same time it can also be clearly explained that this is mainly due to the drastic reduction of the concrete for the foundation due to the shift from single houses to apartment. This is linked with two components. The first one is that there is less requirement of foundation per m^2 built in an apartment than in a freestanding single family house, and the second is that much less multi-story buildings need to be built to accommodate the growth of the population compared to when accommodated in single houses. This double effect induces that embodied GHG of the residential building stock could be reduced to one third compared with the BAU trend of current building techniques and housing habits.

4. DISCUSSION

The revisited Sankey diagram visually tracks construction material and associated embodied GHG of the built environment. There could be other types of visualization if we want to improve and understand, for example waste management or the potential for refurbishment. In that case, the focus would probably lie on the quality of construction and the age of buildings. However, these issues seem to be more relevant in developed countries where the current policy often wants to enable closed-loop material systems in the construction sector due to the fact that their cities are already built. Wiedenhofer and colleagues (2015) state that large share of material inputs are required for maintenance of existing stocks in the European Union and recommends that proper management of already built infrastructure will be crucial for future resource use. The Sankey-like diagram proposed in this study could help to understand the potential for refurbishments in such a context by linking age of the building, quality of construction and need for renovation with required amount of materials and energy.

5. CONCLUSION

The main purpose of this study was to propose a simple representation of the building stock and its drivers (population, building types, and materials) to be able to clearly understand the consequences of different potential actions. These actions being at the technical levels (type of materials, type of structure) as well as at the policy or urban planning level (building typologies). It is possible to use this representation and the results for transdisciplinary discussions and co-construction of pathways for decarbonization with all stakeholders involved in the production of the built environment.

Furthermore, the initial results show that urban planning actions will not have a significant impact if they are not combined with technical changes (materials and structure). Also, focusing on technological changes alone can only result in little action. It is the combination of both that can potentially stabilize greenhouse gas emissions related with the construction of the built environment in a context of a dramatically fast increase of the floor area demand in cities.

ABSTRACT

The significance of the construction and real estate sector for sustainable development is broadly recognized in Europe. Reflecting this recognition, systems for the description, quantification, assessment and certification of sustainable buildings have already been developed in many countries. The European horizontal standardized methods for the assessment of the sustainability aspects of construction works have been developed in CEN/TC 350 "Sustainability of construction works", a committee that has been working already since 2005.

CEN/TC 350 standards provide the basis for carrying out life cycle based environmental, social and economic performance assessments for buildings in a transparent and performance based way. Therefore, e.g. the environment related indicators included in these standards demonstrate the level of environmental performance against the desired functional and technical requirements for a building over its life cycle. Considering sustainability aspects in the design and construction of buildings will motivate manufacturers, contractors and service providers to seek out ways to provide better quality products and services.

The assessment according to the CEN/TC 350 standards at the building level can be used for comparing solutions or choices of a construction project involving different materials and products and creating the most sustainable overall solution.

The paper presents and discusses available standards and outlines current developments.

Keywords: standards, sustainability assessment, life cycle approach

1. INTRODUCTION

For those not already familiar with the European standardisation work in the field of construction works, the Committee for European Standardization (CEN) is the body responsible for developing and overseeing harmonized European construction standards. A little more than a decade ago, CEN/TC 350 group was given a mandate by the European Commission to develop voluntary horizontal standardized methods for the assessment of the sustainability aspects of new and existing construction works (buildings and civil engineering works), as well as standards providing guidance for the development of environmental product declarations of construction products. Part of the progress achieved has already been reported. Figure 1 shows the current work program of CEN/TC 350.

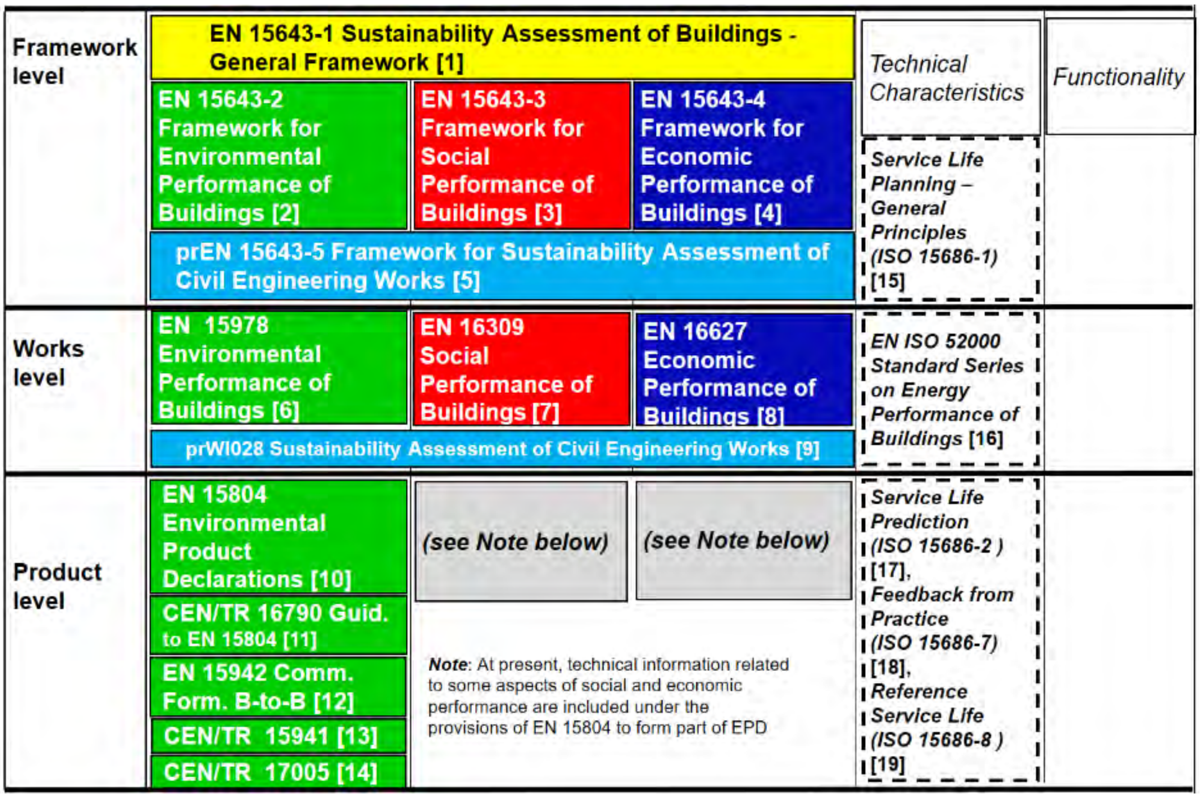

Figure 1: Work programme of CEN/TC350. (Source Ari Ilomäki, chairman, CEN/TC350)

The standards developed under the framework of CEN/TC350 provide a harmonized European system for the assessment of environmental, social and economic performance of construction works based on a life cycle approach. The standardised application of a life cycle approach means that the assessment of environmental performance presented in EN 15978 is based on the Life Cycle Assessment methodology defined in ISO 14044 and the assessment of economic performance presented in EN 16627 is based on the Life Cycle Costing approach according to ISO 15686-5 methodology. At the same time, the rules for the handling of service life issues are based on the guidance of Service Life Planning described in ISO 15686 standard series]. Further information on the Performance-Based Building concept can be found in [23].

The final goal is to develop and implement a system of an integrated building performance assessment allowing the assessment of the environmental, social and economic performance of a building or constructed asset to be made concurrently and on the same equal footing, in view of its technical quality and functionality / serviceability.

The results of such an assessment help designers, investors or other actors understand the impact a building has on the environment on the one hand, and on the occupants and other users on the other. Social performance assessment as described in EN 16309 includes amongst others the building related aspects that can influence users' health, comfort and safety, as well as aspects related to the resilience of buildings to climate change.

2. A LIFE CYCLE APPROACH TO SUSTAINABILITY ASSESSMENT

2.1 Object of assessment and system boundaries

In this European standardised system of CEN/TC 350, when it comes to the sustainability assessment at the building level, the object of assessment (and therefore the source of life cycle impacts) is the building, including its foundations and external works within the area of the building site. This clarification means that in order to assess the environmental, social and economic performance of a building, the physical system boundary for the assessment excludes impacts of non-building related appliances, since the object of assessment is only the building and not the processes carried out in the building. Non-building related appliances are domestic, commercial and industrial appliances and other non-building related equipment e.g. entertainment electronics, washing machines, refrigerators, cooking appliances and office electronics. The impacts of building related appliances or integrated technical systems are included in the assessment, since they are part of the building

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

system. This covers e.g. systems for heating, cooling, domestic hot water supply, ventilation and lighting, as well as integrated building automation and controls, including systems for transport of building users, such as elevators and escalators. It is recommended to present and check the completeness of the description of the building and its life cycle.

Figure 2 shows that the fulfillment of the technical and functional requirements is a prerequisite. What is new for the building owners/clients is that they should be able to provide requirements for the environmental, economic and social performance already in the task formulation (client's brief).

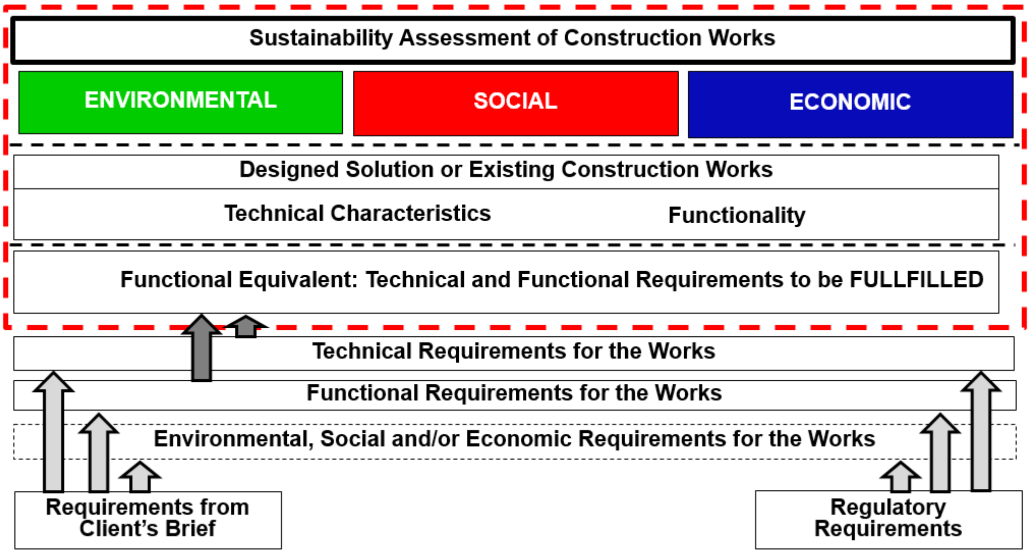

Figure 2: Concept of sustainability assessment. (Source Ari Ilomäki, chairman, CEN/TC350)

The suite of standards within CEN/TC 350 is only dealing with the analytical part of the building assessment system, and not with the valuation part. For this reason, these standards do not provide valuation methods and do not set levels, classes or benchmarks for any measure of performance. It is clear that appropriate valuation methods for interpreting the results are also needed. However, due to their nature being always subjective to value choices and "political" decisions, the development of valuation methods has been left to the developers of rating tools or national assessment systems. In recognition of the need for global guidance on this matter, a new standardization initiative within the scope of ISO TC 59 SC 17 WG2 deals with the principles guiding the development and application of benchmarks.

2.2 Performance based approach with the basket of indicators

In order to have a transparent and truly performance based European system for assessing sustainability, CEN/TC350 standards have only taken into account performance aspects and impacts that can be expressed with quantifiable indicators. The environmental and economic indicators used in EN 15978 and EN 16627 are purely quantitative, while the indicators used in EN 16309 for the assessment of social performance of buildings can be considered semi-quantitative. These quantifiable indicators are defined in the framework level standards (as indicated in Figure 1).

The determination of characteristic values for the indicators at the building level requires that this information is first made available at the level of construction products. The use of identical indicators for buildings and construction products is therefore required.

The indicators are derived from protected goods (areas of concern). In the case of environmental performance, the protection goals are the "protection of the ecosystem" and the "protection of resources". Indicators measuring the impacts on the global environment (e.g., global warming potential) are used among others.

Figure 3 shows environmental indicators used in the standards

1) Indicators for environmental impacts:
1. Global warming potential
2. Destruction of the stratospheric ozone layer
3. Acidification of land and water resources
4. Eutrophication
5. Formation of ground level ozone
6. Abiotic depletion potential (fossil fuels)
7. Abiotic depletion potential (elements)

2) Indicators for use of resources:
8. Use of non-renewable primary energy
9. Use of renewable primary energy
10. Use of non-renewable primary energy resources used as raw materials
11. Use of renewable primary energy resources used as raw materials
12. Use of secondary materials
13. Use of non-renewable secondary fuels
14. Use of renewable secondary fuels
15. Net use of freshwater resources

3) Indicators for other environmental information:
16. Components for re-use
17. Materials for recycling
18. Materials for energy recovery
19. Non-hazardous waste to disposal
20. Hazardous waste to disposal
21. Radioactive waste to disposal
22. Exported energy

Figure 3: Basket of environmental indicators in EN 15978. (Source Ari Ilomäki, chairman, CEN/TC350)

2.3 Consistency, modularity and transparency at different levels

Figure 4 shows the interactions between the building and the product level and explains the subdivision of the life cycle into modules A-C, including an additional special module D. The same rules, modules and set of appropriate indicators are employed for products and construction works in CEN/TC350 standards, e.g. EN 15978 for the building level and EN 15804 for the product level. This allows the product-related environmental performance information declared in an EPD (Environmental Product Declaration) according to EN 15804 to be applied for the assessment of the environmental performance of construction works.

Furthermore, Module D is used to demonstrate on building level the net benefits (avoided impacts, avoided primary material use, avoided energy use and avoided waste generation) beyond the building life cycle, resulting from recyclability, recoverability and reusability of construction materials and products. Module D, in the sense of a recycling potential, must be separately reported as additional information.

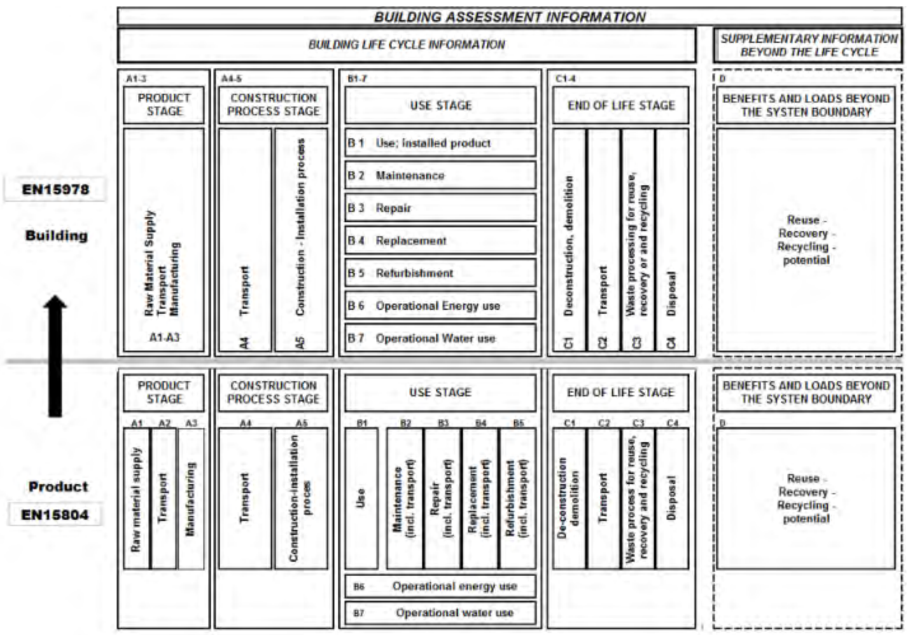

Figure 4: Building life cycle and modular information. (Source Ari Ilomäki, chairman, CEN/TC350)

The assessment according to EN 15978 can be used for comparing solutions or choices involving different materials and products at the building level.

2.4 Technical and functional requirements as a prerequisite

To effectively communicate the assessment results and comparisons of those results between alternative design options in the design stage or between finished buildings, a "fair basis" must be always secured. For this purpose, the concept of "functional equivalent" was established in the CEN/TC 350 standards. In addition to the reference area, also the type and intensity of use must be specified among others. The functional equivalent allows the assessment results to be provided in a systematic and comparable way. Communication of the assessment results for the environmental performance, social performance and economic performance of a building follows the same requirements.

The functional equivalent should be derived from the requirements for technical performance and functional performance of buildings to form the basis for comparison. The technical and functional performance requirements can include, for example, requirements for the structural safety, fire safety, health and comfort, security, adaptability, de-constructability, durability and required service life of a building. These requirements become fixed when they are prescribed in the client's brief or in the project specification. This means that each design option must fulfil these technical and functional performance requirements set for the building.

3. SUMMARY AND OUTLOOK

The series of standards developed under CEN TC 350 provide the basis for assessing the environmental, social and economic performance of construction works – or, in a broader sense, they form the basis for a uniform sustainability understanding in the construction and real estate sector, as well as for assessing the contribution of buildings to sustainable development. The standards correspond to the European context. They are interacting with the results of ISO TC 59 SC17, but are in part more detailed. In addition to technical and functional quality requirements, clients and investors are advised to integrate their objectives to be achieved with regard to an environmental, economic and social performance from the beginning into the description of the project (client's brief). When it comes to the developers of the next generation building sustainability assessment and certification systems, it is now possible for them to orient their work more strongly towards the state of standardization. This is a way of promoting the process of streamlining the content of such systems, while maintaining their independence.

CEN/TC 350 standards encourage freedom to design for better environmental, economic and social performance and support innovation. They can also be used to tackle related macro-level political targets.

The experts working within the framework of CEN TC 350 are currently discussing possibilities for further refinement and development. This concerns the development of B2C communication formats, the specification of scenarios for deconstruction and recycling, the handling of generic data in early design phases as well as issues related to the consideration of impacts on the economic value.

The authors would like to thank all those who have actively participated so far, and will participate in the future, in the standardization process.

ABSTRACT

Serious carbon mitigation in the building sector requires full consideration of life cycle energy consumption (both embodied and operating energy), and their related greenhouse gas (GHG) emissions, over the life span of the dwelling stock. We analyse herein the life cycle energy and related GHG emissions of the pre-2005 residential housing stock in the Greater Melbourne Area (GMA), comprising of 31 municipalities or Local Government Areas (LGAs), considering various retrofit options that range from relatively cheap and easy (e.g., draught sealing) to relatively expensive (e.g., double glazing of windows). Operational energy savings are calculated based on representative performance of energy-rated detached and semi-detached dwellings using the Australian residential rating scheme (i.e., a bottom-up approach), while the embodied energy and GHG emissions are calculated using a multi-regional input-output analysis (i.e., a top-down approach). If all the buildings are improved to the level of a 6-energy rated dwelling across GMA, we can save about 25.5 TWh/year in heating and cooling energy, which translates to 6.25 million tons of GHG reduction every year. However, the retrofit program will consume 4.75 TWh of embodied energy or 1.89 million tons of embodied GHG emissions, which is equivalent to 50% of the annual heating and cooling energy or 81% of the operational GHG emissions due to heating and cooling of dwellings. The energy reduction in building operations will remain to be the dominant driver for retrofit, but the contribution of the embodied impacts cannot, and should not, be ignored.

Keywords: urban regeneration, climate mitigation, residential buildings.

1. INTRODUCTION

The minimum energy efficiency requirement in Australian housing has only been in place since 2005 (minimum of 5-star rating then, and now 6-star rating from 2011 in the State of Victoria). The Building Code of Australia (BCA) administers compliance through modelling (using an approved house energy rating software such as AccuRate) and energy efficiency rating under the National House Energy Rating Scheme (NatHERS)]. Existing residential buildings that have been built before 2005 do not comply with the current building energy efficiency standards, and thus have significant potential to cut energy use and enable the government to achieve its energy and GHG reduction goals. This has become even more important now with the recent global agreement to scale up the implementation of ambitious actions towards the "below 1.5 or 2°C" pathways (known as the COP21 Paris Agreement).

Various retrofit strategies have been recommended to reduce demand and increase energy efficiency (e.g. improving the thermal energy performance of building envelope [Horne and Hayles, 2008]). But many studies on energy efficiency measures to improve existing dwellings have only focused on a specific retrofit measure, or on a single or several building types rather than the whole stock at urban or regional scale aggregated from individual dwelling types (i.e. bottom up approach). Also, most have exclusively focused on operational energy use in buildings. While it is recognised that many retrofit packages can effectively reduce energy and GHG emissions during their service life, the embodied energy and GHG emissions of different retrofit options are usually ignored. The production of building products and technologies for retrofit requires energy and generates corresponding GHG emissions in their manufacture, transportation and installation. These may contribute a significant portion in the total life cycle energy and GHG emissions in buildings, and thus, should be included in the analysis and decision-making. Without the whole life cycle considerations of environmental impacts, building designers, developers or policy makers can make sub-optimal or potentially even detrimental decisions.

This paper examines the environmental impacts (energy and GHG) and the economic aspects of different retrofit options for pre-2005 dwellings in the Greater Melbourne Area (GMA), comprising of 31 municipalities or Local Government Areas (LGAs), considering both building operations and embodied impacts.

2. METHODOLOGY

Two different methodological approaches are integrated in this study: a top-down Input-Output (IO) analysis, and a bottom-up approach of energy performance assessment based on results of a building energy modelling software.

Leontief's IO method is employed to quantify the embodied environmental impacts (energy and GHG emissions) due to the building works and new/replacement products to upgrade or retrofit existing dwelling stocks. With combined national energy and GHG emission accounts by industry sectors, unit energy consumption and GHG emissions are quantified based on unit monetary based economic activities (per million $). Then, the benefits due to improved energy performance of residential buildings are quantified using the energy performance data for different energy-rated houses. In this analysis, the energy and GHG reductions are considered only for heating and cooling of buildings (as covered in the NATHERS rating scheme), and other end-use categories (such as plug-in appliances) are not taken into account.

2.1 Embodied impacts (energy and GHG emissions) for retrofit

Embodied impacts, which include raw material extraction, material manufacture, processing and transport to the site, were quantified using the comprehensive analysis based on IO datasets. In the IO data table, the total economic output of industry sector *i* is the sum of intermediate input of each industry sector to satisfy the intermediate demand and final product to satisfy the final demand of industry *i*. In the IO table, if import *m* is excluded in the endogenous set by deducting it from the column direction as a lump sum, then the domestic output can be expressed as;

$$X = \{I - (I - M)\,A\}^{-1}\ \{(I - M)\,F_D + F_E\}$$

Equation 1

where, X is the domestic total output of product ($/year); {*I* – (*I* – *M*) *A*}-1 is the Leontief competitive import type inverse matrix, which captures the supply chain inputs to satisfy one unit of final demand in monetary value; *I* is the identity matrix; *A* is the intermediate input coefficient (a_{ij}) (input coefficient from industry *i* to *j*). *M* is the import coefficient diagonal matrix (import coefficient, $m_i=M_i/C_i$); C_i is the domestic demand for product *i* ($/year); F_D is the domestic final demand value ($/year); F_E is the export value ($/year).

Total energy intensities are then calculated by multiplying the direct energy intensity matrix with the Leontief inverse matrix (Equation. 1) of the corresponding IO table. Embodied energy (or GHG) in a region can be calculated by multiplying total energy (or GHG) intensity with a final demand including export of a region.

With this energy intensity of industry *i* and Equation. (1), we can obtain the direct and total energy consumption of industry *i*. Embodied energy and GHG, which is the total energy requirement (or GHG emissions) of the economy directly and indirectly in supporting one unit of monetary value final demand, can be quantified by the following:

$$EE_k = E_i \cdot \{I - (I - M_k)\,A\}^{-1} \quad or \quad EGHG_k = (E_i \cdot C_j) \cdot \{I - (I - M_k)\,A\}^{-1}$$

Equation 2

where, EE_k is the embodied energy intensity of industry *k* (*MJ/$*); E_i is the direct energy requirement per dollar worth of final demand for industry *k* (*MJ/$*). Similarly, embodied GHG intensity of each industry *k* (*tonCO_2eq/$*), $EGHG_k$, is obtained by multiplying the GHG intensity of energy *j*; $EGHG_k$ is the embodied GHG intensity of industry *k* (*ton CO2eq/$*); C_j is the GHG conversion coefficient of energy *j*.

2.2 Recurrent embodied energy and GHG emissions

The energy consumption and GHG emission associated with repetitive product replacement or related action(s) during the building's service life is called the recurring embodied energy or carbon. This is estimated using the following equation:

$$EI_{REC} = \sum_{Mat=1}^{M} \left(\frac{SL_{Bldg}}{SL_{Mat}} - 1 \right) \times \left(Q_{Mat} \times EI_{Mat} \right)$$

Equation 3

where, EI_{REC} is the recurrent impact (embodied energy in GJ or embodied carbon in ton CO_{2eq}); SL_{Bldg} is the service life of building (year); SL_{Mat} is the service life of material/product (year); Q_{Mat} is the quantity of material/product to achieve an improved energy rating (A$m); EI_{Mat} is the embodied intensity of material (embodied energy in GJ/$m) and embodied carbon in ton CO_{2eq}/$m which can be obtained by Equation. (2)).

2.3 Operational energy and GHG emissions

2.3.1 Building stock in the greater melbourne area

Melbourne is the capital of Victoria, which has a population of about 4.1 million. The Australian Bureau of Statistics (ABS) shows that Greater Melbourne is one of the largest and fastest growing capital cities in Australia. From 1973 to 2013, Melbourne has increased its population by 62%. More than 70% of Victorians live in GMA, which consists of 31 LGAs out of a total of 79 in the whole state.

Five-star minimum energy requirement was introduced in 2005; the minimum requirement was raised to 6-star from 2011 in Victoria. In GMA, there are 1.43 million dwellings. More than 96% of the dwelling stock were built before the introduction of the minimum 5-star rating requirements. The average energy efficiency rating for existing dwellings is 1.57 stars for buildings built prior to 1990 and 3.14 stars for those built between 1991 and 2005. We used these survey data as the base case for quantifying the heating/cooling energy for existing dwelling stocks in GMA.

In GMA's existing dwelling stock, detached houses represent the most dominant building type, with more than 90% share, and semi-detached houses with 8.8% share of the total stock. Compared to these two, others such as flats or apartments show a relatively small part (1.6% of the total stock, although we note that this is currently a growing category). Thus, this study is focused on the upgrade or retrofit of detached and semi-detached houses which were built prior to 2005.

2.3.2 Prototype of existing buildings and energy retrofit options

The national average floor sizes of 114 m^2 and 57 m^2 are applied for detached and semi-detached, respectively. The average floor areas of detached and semi-detached that were built between 1991 and 2005 are larger than those of pre-1990 dwellings: 182 m^2 for detached and 132 m^2 for semi-detached. The annual energy consumption and GHG emissions due to heating and cooling for existing dwelling stocks in the GMA are quantified as follows:

$$ERG_{OPR} = \sum_{i=1}^{4} \left(\left(\frac{ERG_{i,h}}{COP_{i,h}} + \frac{ERG_{i,c}}{COP_{i,c}} \right) \times HH_i \right) \; or \; GHG_{OPR} = \sum_{i=1}^{4} \left(\left(\frac{ERG_{i,h}}{COP_{i,h}} \times cf_k + \frac{ERG_{i,c}}{COP_{i,c}} \times cf_j \right) \times HH_i \right)$$

Equation 4

where i is the index of the dwelling prototype; $ERG_{i,h}$ (MJ/m2/year) and $ERG_{i,C}$(MJ/m2/year) are the space heating and cooling energy requirement for building type i calculated by the AccuRate software; HH_i is the floor area of dwelling type i in m^2, which sum up over the 31LGAs in GMA. GHG_{OPR} is the total GHG emissions due to heating and cooling energy requirements in GMA in ton CO_{2eq}; COP_h and COP_C are the coefficient performance of the heating and cooling systems, which are chosen from the AccuRate database for this study; cf_k is the GHG emission factor of energy type k.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The retrofit scenarios considered ranged from relatively cheap to expensive measures. By grouping different measures based on costs and difficulties of installation, a total 16 retrofit cases (4 cases for energy improvements x 2 types of dwelling x 2 different age group) are set up to improve energy efficiency of existing dwellings from 3 to 6 Stars (Table 1).

3. RESULTS AND DISCUSSION

3.1 Operational energy and GHG reduction

The heating and cooling energy demand for existing (pre-2005) dwelling stock in GMA is shown in Figure. 1(a); the total heating and cooling energy consumption is 34.9 TWh per year. Most of this energy demand is for detached houses, which accounts for more than 95% of the total. Semi-detached houses account for less than 5% of the total demand.

As intended by the energy efficiency rating scheme, the heating/cooling energy demand decreases as the energy rating increases from 3 to 6 stars. If the existing dwelling stock is upgraded from the current business-as-usual (BAU) average energy performance level into 3 stars (as shown in the 2nd bar in Figure.1(a)), 12.6 TWh of heating/cooling energy can be saved. If the existing BAU dwelling stock is upgraded to 4 stars, 16.4 TWh of heating and cooling energy load can be saved. This represents a 52% energy reduction from the BAU case (before retrofit). Deeper energy retrofits (i.e. up to 5- and 6-star levels) bring further reductions, Figure 1(a).

The associated GHG emissions due to heating and cooling for dwelling stock in GMA is estimated at 8.57 million tons of CO_2eq per year (Figure.1(b)). As in the total energy demand, detached houses contribute more than 95% of the total GHG emissions. Semi-detached house account for only 4.7% of the total (0.4 million tons of CO_2eq). With all residential buildings built after 2005 in GMA rated at 6 stars (minimum), if we assume that all existing dwelling stock is upgraded from 3 to 6 stars, then the total GHG reduction can be up to 6.25 million tons of CO_2eq (i.e., a 73% reduction).

For each of the local governments in GMA, Figure. 2 shows the energy and GHG emissions reduction due to the upgrade of existing dwellings to 6 stars.

	Stocks built Pre 1990								Stocks between 91~2005

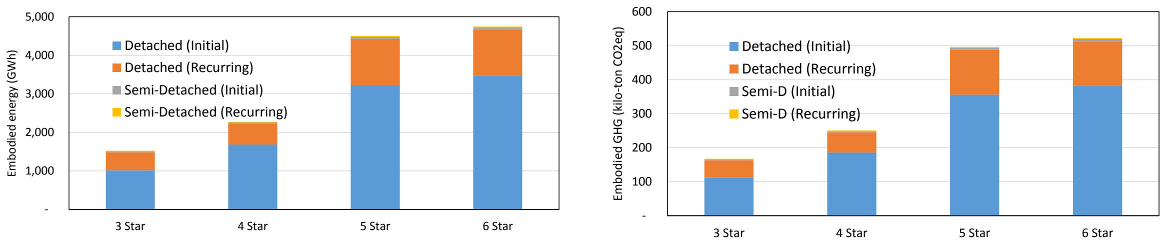
Figure 2: Energy and GHG emissions reduction by LGA due to the increase of energy efficiency of existing dwellings to an equivalent 6-star rated dwelling in GMA

3.2 Embodied energy and GHG emission impacts

Figure. 3 shows the embodied energy and GHG emissions due to the upgrade of existing dwelling stocks to 3, 4, 5 or 6 stars. To retrofit existing dwellings in GMA into an equivalent 3-star house, a total of 1,523 GWh embodied energy is required. This is the combined initial and recurrent embodied energy over its assumed 25-year life span. The initial embodied energy, which accounts for 68% of the total, is the upfront embodied energy required to upgrade the existing dwellings into 3-star buildings, and the rest (471 GWh or 32% of the total) is the embodied energy required to maintain that performance level over the next 25 years (i.e. the recurrent embodied energy). Similar to operational heating/cooling energy demand, most of the embodied energy come from retrofitting of detached houses (in this case, 98% of the total).

Similar patterns are observed when retrofitting to meet 4, 5 or 6-star efficiency levels. In the 6-star retrofit case, the total embodied energy required is 4,748 GWh, which is 212% more than the energy required for the 3-star retrofit case. But in the 6-star retrofit case, the initial embodied energy is 75% while the recurrent is 25% of the total.

As shown Figure.3(b), the embodied carbon reductions follow a similar trend to those for embodied energy.



(a) Embodied energy (GWh) (b) Embodied carbon (kilo ton CO_2eq)

Figure 3: Embodied energy and GHG emissions due to retrofit of existing dwellings to meet 3, 4, 5 or 6-star efficiency levels

3.3 Life cycle impacts of energy retrofits in existing dwellings

Life cycle energy combines the operational heating/cooling energy with the embodied energy for the assumed life span of the retrofitted buildings. Figure. 4 shows the decrease in operating energy with increasing star-rating compared to the BAU, but accordingly also the increase in embodied energy. For example, retrofitting of existing dwellings to 3-star level results in a 36% heating/cooling energy reduction (12.6 TWh); at 6-star level, the reduction is to 73% less than the BAU case. Correspondingly, the embodied energy increases by 1.53 TWh for the 3-star retrofit and up to 4.7 TWh for the 6-star retrofit. These embodied values are equivalent to 12 to 20% of the annual operational heating/cooling energy of the whole dwelling stock in GMA.

Embodied carbon follows a similar pattern to that for embodied energy. The existing dwellings in GMA that were built before 2005 release 8,571 kilo tons of CO_2eq for heating/cooling. By improving the energy efficiency of the existing stock (up to 6-star level), GHG emissions can be reduced up to 73% (6,252 kilo tons of CO_2eq). However, the embodied carbon to install and maintain the retrofit packages for existing dwellings increases – e.g. to 5-star level, the embodied carbon goes up to 32% of annual operational heating/cooling carbon emissions.

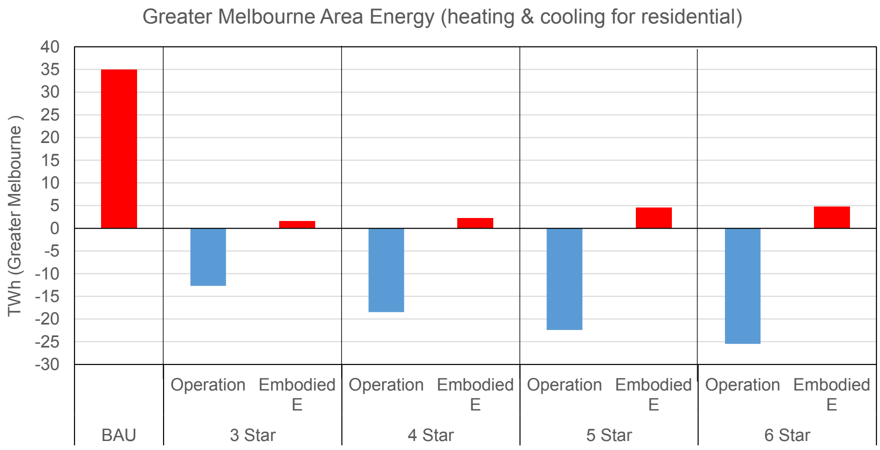


Figure 4: Life cycle energy to increase energy efficiency of existing dwellings in GMA

3.4 Cost analysis of energy retrofits of existing dwellings

The results of retrofit cost analysis and energy saving for 3-star to 6-star retrofit levels, at each LGA, are shown in Figure.5. Each bell shape represents energy savings (left, in $million) vs retrofit cost (right, also in $million) from a dwelling stock with 3-star performance level to a stock equivalent with a 6-star level. The City of Melbourne (top), with a predominance of flats and apartments, has the least cost for energy saving and upfront and maintenance cost of the 31 local governments in GMA.

At the bottom, the City of Casey shows the largest amount of heating and cooling energy savings and upfront/maintenance costs. Interestingly, the Cities of Hume, Melton, Whittlesea and Wyndham show high upfront costs but not much energy saving for heating and cooling. These are all the fastest growing local governments in Victoria (7.8% for Wyndham, 5.6% for Melton and Whittlesea, and 2.6% for Hume). Dwelling stock built between 1990 and 2005 take a relatively high proportion of the total stock: 62% in Melton, 52% in Wyndham, 33% in Hume and 30% in Whittlesea.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

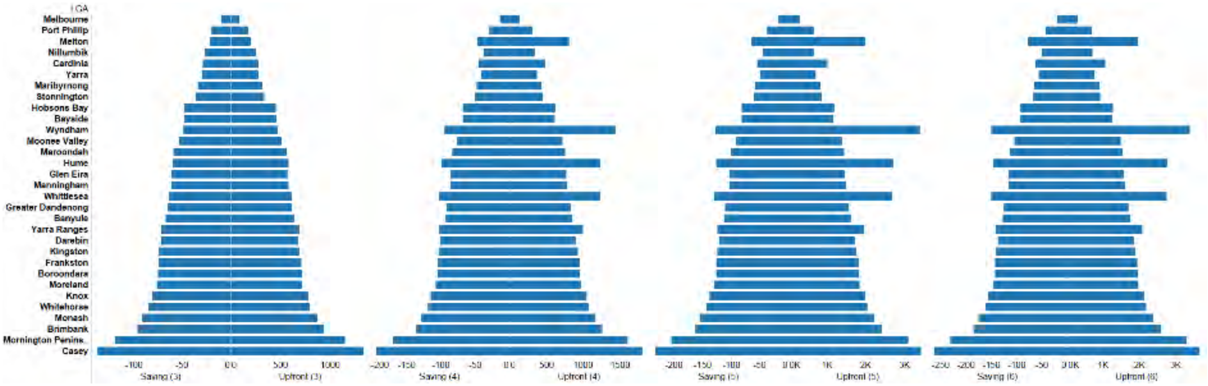

Figure 5: Cost balance between upfront cost ($million) and benefits ($million) due to energy upgrading of existing dwellings in each local government in GMA

4. CONCLUSIONS

We presented a combined bottom-up and top-down methodology that investigated the life cycle energy and GHG emissions of the residential housing stock for each of the 31 LGAs in GMA, considering various retrofit options that range from relatively cheap and easy (e.g., draught sealing) to relatively expensive (e.g., double glazing of windows). The operational energy savings were based on representative energy ratings for detached and semi-detached dwellings, while the embodied energy and GHG emissions were calculated using input-output analysis.

The total heating/cooling energy for the pre-2005 dwelling stock can be reduced by 12.6 TWh to 25.4 TWh by wholesale retrofit of the stock to 3-star and 6-star efficiency levels, respectively. These are equivalent to 36% to 73% of energy reduction compared to the BAU case, and come mostly from detached houses, which account for more than 95% of the total reduction.

The embodied energy associated with the retrofit package to improve the stock to a 5-star level is more than 36% of the annual heating and cooling energy for existing dwellings in GMA. If all the buildings are improved to the level of a 6-energy rated dwelling across GMA, savings are 25.5 TWh/year in heating and cooling energy, which translates to 6.25 million tons of GHG reduction every year. However, the retrofit program will consume 4.75 TWh of embodied energy or 1.89 million tons of embodied GHG emissions, which is equivalent to 50% of the annual heating and cooling energy or 81% of the operational GHG emissions due to heating and cooling of dwellings.

Although energy savings during building operations will likely remain to be the main driver for retrofit, the contribution of the embodied impacts cannot, and should not, be ignored. This will only likely grow in importance in the coming years as the implementation of net-zero (operating) energy and emissions concepts become more commonplace. Urban decision makers, at individual LGAs or across the metropolitan area, where to focus and select their most cost-effective options to contribute to the global efforts towards the "below 1.5 or 2°C" future climate pathways.

ABSTRACT

Turkey has developed legislation to improve energy efficiency in buildings and promote the uptake of renewable energy sources (RES). The Renewable Energy Technologies Economic Analysis Tool is developed to assist building designers and developers. This tool aims promoting and enhancing the effective and rational utilization of renewable energy resources in buildings and thereby to reduce the final external energy consumption and associated greenhouse gas (GHG) emissions in the buildings sector of Turkey. For this purpose, the tool aims to demonstrate the feasibility and benefits of renewable energy technologies (RET) in a more quantitative and comparable manner by:

- Calculating the energy savings potential, economic and environmental benefits from RET for buildings,
- Calculating associated investment costs of the renewable energy technologies for economic analysis and also to check if it complies with the minimum investment costs of the current regulations and bylaws of Turkey,
- Comparing possible RET implementation scenarios and base building scenarios.

Keywords: renewable energy technologies, buildings

1. INTRODUCTION

As populations expand, living standards improve and consumption rises, total global demand for energy is expected to increase by 21% by 2030. At the same time, growing concerns over climate change are prompting governments worldwide to seek ways to supply energy while minimizing greenhouse gas emissions and other environmental impacts. Renewable energy benefits therefore play a critical role in informing policy decisions and tipping the balance in favor of low-carbon investments. Renewable energy resources are inexhaustible and offer many environmental benefits compared to conventional energy sources. Each type of renewable energy also has its own special advantages that make it uniquely suited to certain applications. Turkey has developed legislation to improve energy efficiency in buildings and promote the uptake of renewable energy sources (RES). According to current regulation in Turkey, renewable energy technologies and cogeneration system use should be analysed for new buildings which are larger than 20.000 m^2 and it should be implemented equal at least % 10 of total construction cost. To assist building designers and developers meet their obligations, developing of “Renewable Energy Technologies Economic Analysis Tool (RET-EAT)”, which will identify the feasibility of technology options, and evaluate the economic, environmental and efficiency benefits of technologies and their combinations.

The RET-EAT is developed to promote and enhance the effective and rational utilization of renewable energy resources in buildings and thereby to reduce the final external energy consumption and associated greenhouse gas (GHG) emissions in the buildings sector of Turkey. For this purpose, the tool aims to demonstrate the feasibility and benefits of renewable energy technologies (RET) in a more quantitative and comparable manner by:

- Calculating the energy savings potential, economic and environmental benefits from RET for buildings,
- Calculating associated investment costs of the renewable energy technologies for economic analysis and also to check if it complies with the minimum investment costs of the current regulations and bylaws of Turkey,

- Analyzing possible RET implementation scenarios and base building scenarios.

Two different calculation approaches with different data requirements are used in the tool:

- The Detailed Approach requires hourly inputs of different forms of energy demand (space heating, space cooling, domestic hot water, and electricity), which are exogenous user-inputs obtained through the use of a third party software.
- The Simplified Approach calculates different forms of hourly energy demand of the building using limited user inputs (compared to the Detailed Approach) and is likely to be more suitable for preliminary design work and other situations in which hourly energy demand data is lacking and a detailed assessment of renewable energy options is not desired.

2. MODELLING METHODOLOGY AND SCOPE

The establishment of the baseline energy demand can be done in two modes: a simpler 'Simplified Approach' and a more complex 'Detailed Approach'. The detailed flow-charts are presented in Figure 1 and 2 respectively. The modelling analysis is based on the energy demands of a single building, including electricity, space heating, space cooling and domestic hot-water demands. Industrial processes (e.g. energy/ steam demand for industrial processes, power plants, etc.) are not in scope. The user defines a mixed set of renewable and conventional technologies each of which will partially satisfy the building's energy demands. The model calculates the fuel, CO2 and financial breakdown of meeting the user energy requirements for a suite of user specified technology installation options, which can then be compared to determine return on investment and levelised costs of energy. It is as such concerned only with the energy supply and end uses, and is not a point-to-point, or building spatial simulation model.

For the Simplified Approach where hourly energy demand is modelled within the tool, heating and cooling gains/ losses are assumed to be only through the building envelope exposed to outside air and for meeting ventilation requirements. This means that walls shared with neighbouring buildings are assumed to be in thermodynamic equilibrium and therefore no heat transfer is assumed through them. Furthermore, only space heating/ cooling and hot water energy demands are calculated in this approach, with annual lighting and equipment electricity demands being provided as a user input. Annual electricity demands for lighting and equipment are broken down into approximate hourly values based on a simplified algorithm.

For the Detailed Approach, hourly inputs of energy demand (heating, cooling, hot water and electricity), are an exogenous user-input, calculated through the use of a third party software, such as EnergyPlus etc. For the heating, if the building has steam demand for space heating purposes, steam demand should be included as "heating demand" and an appropriate technology (e.g. boiler) should be selected to meet the required heating demand. The conventional and renewable energy technologies included in the model are as follows:

- Combined Heat and Power (CHP), including micro CHP and Combined cooling, Heating, and Power
- (Tri-generation) based on, turbine or engine
- Heat pump (air source, ground source, water source)
- Heat driven chillers (absorption and adsorption),
- Solar PV,
- Solar thermal,
- Combined: Solar PV-thermal or thermo-electric systems,
- Wind Turbine
- Hot water storage,
- Cold water storage,
- Ice storage
- Space heating storage
- Electricity storage (battery),
- Gas and biogas Boilers,
- Direct heat and hot water sources (e.g. geothermal, district heat or waste heat)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The detailed method or the simplified method is used to calculate the utilisation of user-selected technology mixes for each scenario and for the counterfactual "base" scenario. Based on these, the following metrics can be calculated. Mathematical functions used to calculate these outputs are presented in the next chapter.

- Annual energy demand met by the selected technology mix scenario
- Annual fuel savings (kWh) by the selected scenario including exergy analysis (optional)
- Annual CO2 savings (tCO2) by the selected scenario
- Energy efficiency of the system
- Rational Exergy Management Efficiency (optional)
- Increase in initial investment compared to baseline (% fraction of total building cost)
- Annual fuel/ bill savings (TRY) by technology
- Payback duration by technology (years)
- Net annualised cost over lifetime by technology (TRY/ y)
- Levelised cost of CO2 reduction over lifetime by technology (TRY/ tCO2)
- Levelised cost of CO2 reduction over project lifetime for building (TRY/ tCO2)
- Net present value of scenario

2.9 Simplified approach

This approach calculates hourly energy demand using limited user inputs. The hourly heating and cooling demands are calculated using a simplified analysis of heat losses through fabric for exposed walls and resulting from ventilation. The degree hours are calculated based on occupancy (The use of only degree hours and U values results in overestimation of the heating loads as it does not include some of the heating gains such as appliance, metabolic and solar gains. Furthermore, it will not be able to distinguish different occupancy patterns for different buildings - e.g. commercial buildings might not be heated or cooled over the weekend, schools might be unoccupied for more than 2 months), internal design temperature and hourly outside air temperature data. In proposed methodology, using hourly temperature data and default occupancy timing (based on the type of buildings) will enable a more accurate calculation of heating and cooling loads.

The internal gains are estimated based on occupancy, lighting and appliance use, while solar gains are calculated using the glazing ratio and the dimensions of the exposed walls. The hot water demand is also based on the occupancy and typical requirements per person based on building type. The annual electricity consumption, split by lighting and other appliance use, is a user defined input. Electricity consumption will be broken down into hourly demand in the tool using a simplified algorithm. Similar to the detailed approach, dispatching algorithms determine the order in which the technologies are deployed to meet the electrical, heating and cooling demands. This ranking defines the merit order of preference in which technologies are used and therefore share of the energy demands that are met by renewables. The proposed simplified approach is "simplified" compared to detailed engineering simulation tools; however, it still provides relatively accurate and robust energy demand data. Although the algorithm performs an internal hourly calculation, it will be straight-forward for the user to use the model. Some of the required inputs will be included in the "Default building parameters database", and the user will only need to choose the simplified building type. Target heating and cooling temperatures will also be included in the database. Simplified approach (i.e. performing an internal hourly calculation) also results in better estimates of utilization of renewable technologies. Even in the preliminary design work, the user will be able to apply a dispatching algorithm for the bundling scenarios. The flowchart for the simplified approach is given in Figure 1.

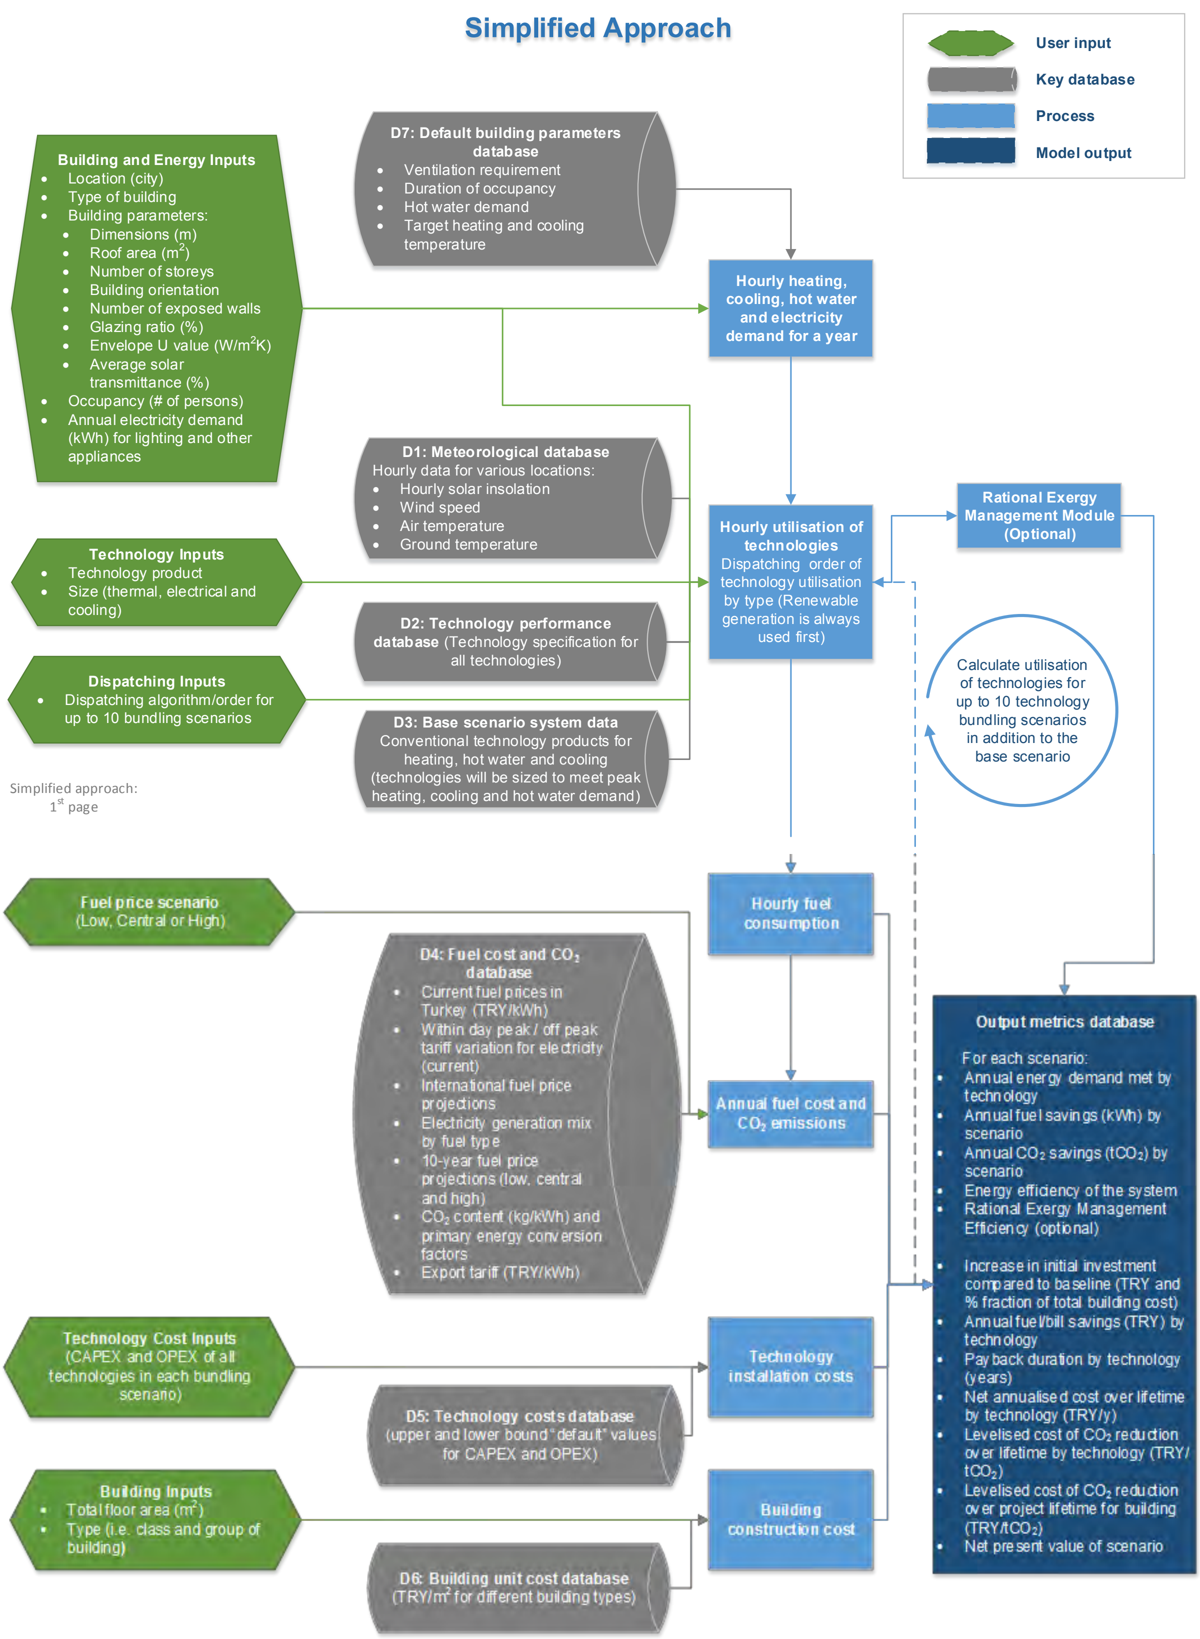

Figure 1: Flowchart for the Simplified Approach

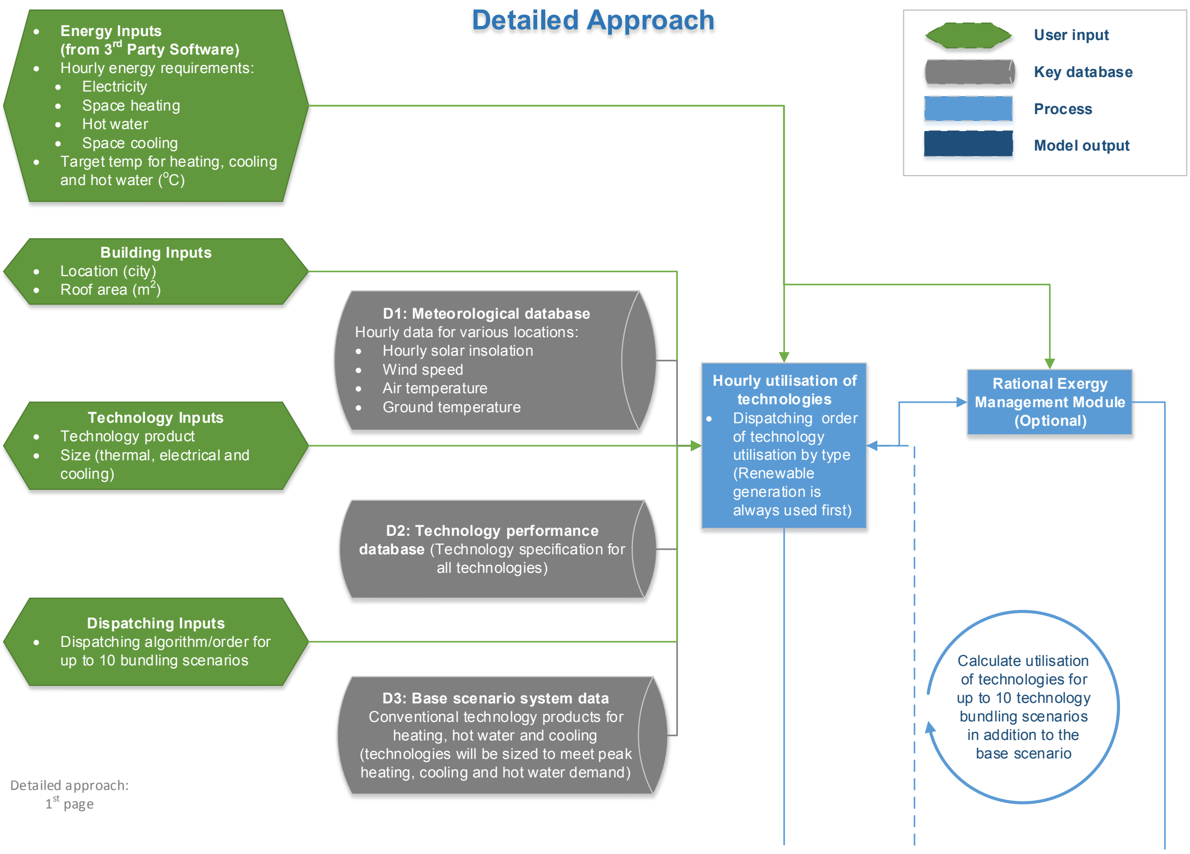
From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.10 Detailed approach

The detailed hourly approach uses pre-calculated energy demand profiles from third-party software, output and converted as needed to produce hourly electricity, heating, cooling, and hot water use figures. This approach requires fewer user inputs regarding the building performance as hourly energy demand does not need to be calculated by the tool. It should be noted that, the user will need detailed data on the building to generate the input file using a third-party software such as EnergyPlus. Dispatching algorithms determine the order in which the technologies are deployed to meet the electrical and thermal (heating, cooling and hot water) demands based on a technology 'ranking'. This ranking defines the preference order in which technologies are used and therefore the share of the energy demands met by renewables. As a general principle, renewable generation in the form of heat, hot water and/ or electricity from solar and wind is always used first. Any residual demand is reduced by storage, heat pump, CHP and if still required the conventional technologies such as boilers. The main objective constraint is the minimum required RET investment cost as a fraction of the total building cost. RET mix scenarios may be included in the tool but can be created or amended by the user. Compared with the Simplified Approach, the Detailed Approach produces a more accurate assessment of the dispatch of the available technologies and therefore provides a more accurate feasibility assessment. Where an accurate assessment is desired, and data is available, this will be the preferred approach. The flowchart for the detailed approach is given in Figure 2.



From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

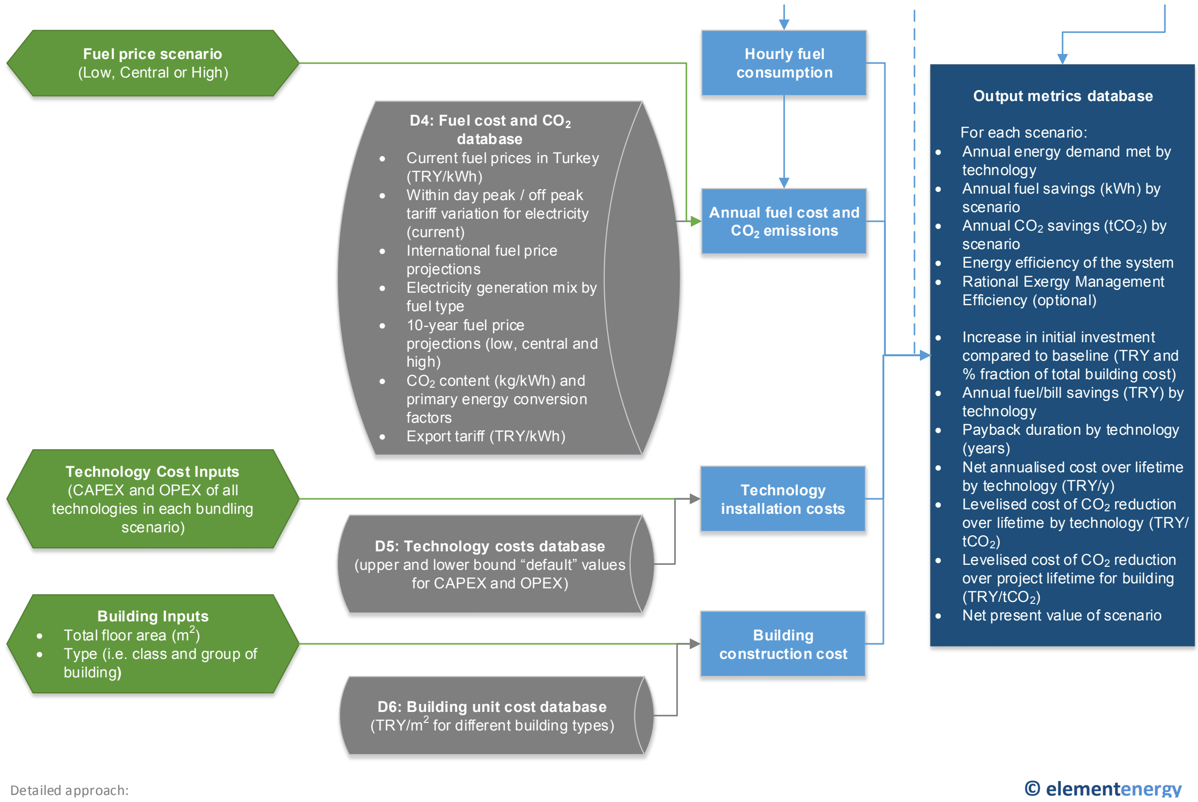


Figure 2: Flowchart for the Detailed Approach

3. CONCLUSION

RET-EAT methodology developed as a subpart of "Promoting Energy Efficiency in Buildings in Turkey" Project. National software will be obtained by using this methodology. This web-based software can be used as a decision support tool for designers and investors about the cost optimality of the renewable energy technologies.

Renewable energy technologies diversify the nation's generation portfolio away from fossil fuels. The magnitude of the renewable energy can play depends role on how much cost reduction projections materialize. Investments in renewable energy systems should result in comparable reductions of investments in traditional energy technologies. Although incorporating costly renewable resources into the generation portfolio mix might increase the expected costs, fuel price risk is lower and will offset by increased export of petroleum and less consumption of natural gas. Also, exergy analysis is a very useful tool which can be successfully used in the performance evaluation of renewable energy resources as well as all energy-related systems.

ABSTRACT

One of the strategies for decarbonizing of the energy mix is to increase the use of district heat networks, for distribution of waste heat or heat produced by renewable energy sources. However, planning of such networks needs a geo-dependent energy database concerning demand and supply, incorporating their dependency on space and time.

The present paper concerns the development of a bottom up statistical extrapolation model for estimation of the heat demand of the Swiss building stock. The database is constructed on top of the Swiss building register, which contains basic data on building category, age, ground area and number of floors, as well as area devoted to dwellings. The model itself concerns: (i) estimation of the heated area of each building; (ii) estimation of the heat demand of each building, with disaggregation in terms of space heating (SH) and domestic hot water (DHW).

The model is calibrated by way of recorded data concerning actual yearly energy consumption of around 27'000 buildings, with a classification by buildings category and age. The disaggregation in terms of SH and DHW allows for climatic correction of the observed data within a common climate basis. In a second step this calibration data is used for extrapolation of the demand on the entire Swiss building stock, for which the SH component is corrected by taking into account local climate characteristics.

Finally, statistical methods tend to quantify the uncertainty inherent to the use of average demand values by age and category, in relation with the level of spatial aggregation.

Keywords: energy use, energy measurement and verification, building energy simulation

1. INTRODUCTION

During the year 2013, the Swiss final energy consumption for space heating of buildings and domestic hot water production is estimated to 330 (PJ/Year) by [1]. According to the national energy statistics this represents approximately 40% of the total final energy demand. Within the Swiss Energy Strategy 2050, it is foreseen to reduce this demand by 63%, while increasing the share of renewable energy. Local renewable resources are numerous, however characterized by specific spatial availability, as well as temporal dynamics and quality (e.g. temperature), which limit their compatibility with demand. Hence, for assessing the potential of these resources and designing of adequate infrastructure like district heating systems, geo-dependent energy databases concerning demand and supply are needed. We focus here on the development of a geo-dependent heat demand model of the Swiss building stock.

Previous work in this direction was done by [2], where hectare raster statistics on dwelling surface and number of working places serves to estimate the heat demand of the Swiss building stock. However, latter model supposes that all building categories have the same specific heat demand of 120 (kWh/m2 year). At European level, [3] uses population density for estimation of the heat demand on a 1x1 km raster. As an alternative to such statistical extrapolation methods, other authors try to simulate the energy demand of buildings in urban area by way of models based on building physics. However, such an approach requires detailed information on the building geometries as well as on the envelope components and associated U and g values. This turns out prohibitive at national level, as well in terms of access to such data as in terms of computational time.

As a response to preceding questions and state of the art, this paper outlines the development of a statistical bottom-up extrapolation model, which is based on measured heat demand and heated surfaces values of a representative set of about 27'000 individual buildings. As a result, and as an improvement to previous work such

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

as [2, 6], we estimate the heat demand of each building of the Swiss national building register (GWR) as a function of its category, age and location, and its heated surface as a function of its category, gross surface and/or dwelling surface. Furthermore, a bootstrap resampling algorithm allows to quantify the uncertainty inherent to the use of average demand values by age and category, in relation with the level of spatial aggregation. This kind of approach could be applied to other countries or communities having a GIS database containing basic information of their building stock as for example the Austrian address and building register (AGWR).

2. GEO-DEPENDENT HEAT ESTIMATION MODEL

The general structure of the model is shown in Figure 1. The combination of basic information for each building from the GWR with average statistic indicators from the calibration sets allows estimating the heated surface A_E (m2) and the specific heat demand E (MJ/m2 year), from which we derive the final energy demand E_B (MJ/year).

For each pixel of territory, the estimated heat demand is summed over all buildings, and a bootstrap algorithm allows to estimate the confidence interval around the average value given by the model.

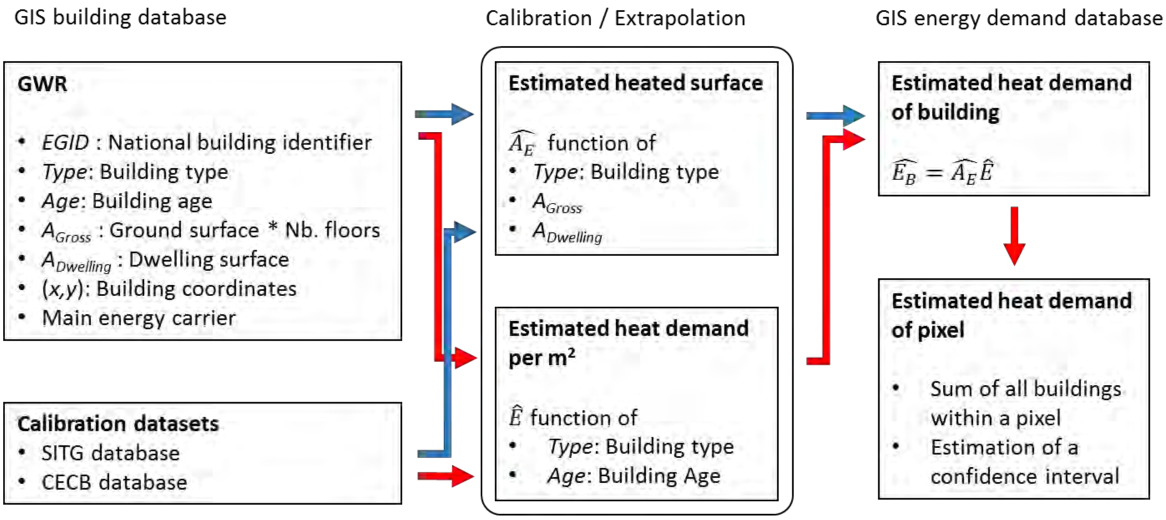

Figure 44: Model overview

2.1 Datasets

The model uses the following datasets:

- The Swiss national building register (GWR) maintained by the Swiss Federal Statistical Office contains basic building information such as: geographical coordinates, category, age, ground and dwelling surface as well as the main energy carrier for around two millions of buildings. This database is not exhaustive for buildings without residential purpose. A comparison with the Swiss building footprint data layer [9] shows that around 400'000 buildings are missing. A unique federal building identification number (EGID) identifies each building, allowing to link this data with other databases.
- The Geneva SITG database contains measured energy consumption as well as heated surface A_E defined according to norm SIA 416/1, for residential buildings and buildings used for non-residential purpose. This declaration is mandatory and is updated each year by a network of trained agents.
- The CECB database contains energy consumption averaged over three years. This is a certification covering buildings spread over the whole Swiss territory.

2.2 Estimation of Heated Surface

For each building of the GWR database, the heated surface A_E is estimated by way of the gross surface (number of floors x ground surface) and/or the dwelling surface.

The estimation is based on a set of linear regressions, on ten different building categories, given by 8'951 observations from the SITG database. As an example, Figure 2 shows the linear regression for the category of residential multi-family buildings.

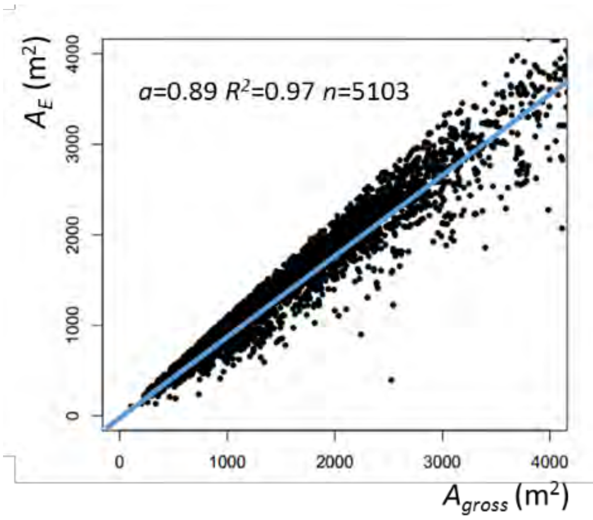

Figure 45: A_E as a function of gross surface (multifamily buildings)

Note that the CECB database, which is anonymised, could not be linked to the gross and dwelling surface of the GWR, reason why it is not used in this part of the process.

2.3 Estimation of Specific Heat Demand

For each building of the GWR database, the specific final energy for heat demand E_B is estimated by way of its age and category, on hand of average values given by the SITG and CECB datasets, which are normalized on a common reference.

Normalization of calibration data to a common reference

Since heat demand data of CECB and SITG concern a variety of energy carriers and locations, it has first to be normalized on a common reference. Therefore, for each building of these datasets, the measured final energy demand E (MJ/m² year) is converted into useful heat demand for space heating:

$$Q_{SH} = \eta_{EC}E - Q_{DHW}$$

Equation 1

η_{EC} is the transformation efficiency factor estimated by [10] and Q_{DHW} the useful heat demand for DHW production according to the SIA 380/1 norm. Since some very low-energy buildings may have thermal solar panels, leading to very low Q_{SH} values, we further add following constraint:

$$Q_{DHW} = \min(Q_{DHW}^{SIA}, 2/3\,\eta_{EC}E)$$

Equation 2

The space heating values are further normalized on a common climatic reference (arbitrarily Geneva):

$$Q_{SH}^{GE} := Q_{SH}\frac{DJ(GE)}{DJ(Origin\ of\ measure)}$$

Equation 3

DJ(Origin of measure) stands for the norm SIA 2028 heating degree days from the climatic station associated to the building.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Finally, the SITG and CECB data sets allow computing 15'588 and 11'499 Q_{SH}^{GE} values normalized to Geneva's climatic reference.

Statistical analysis by building category and age

For the sake of statistical analysis, preceding data is grouped in four building categories (multi-family residential, individual residential, non-residential, mixed purposes). For each of these categories, the data is further divided into 12 construction periods, and analysed in terms of statistical distribution Figure 3. At this stage, it is worthwhile noticing that the variability within each construction period is much higher than between the periods, as previously put forward by [10].

Finally, for each of the building categories and construction periods, we define the average space heating demand which is used for extrapolation on the GWR database:

$$\overline{Q_{SH}^{GE}} := \frac{\sum_{\{\}} Q_{SH}^{GE} A_E}{\sum_{\{\}} A_E}$$

Equation 4

This analysis is done separately for the SITG and CECB datasets, the respective values being used for reconstruction of the entire GWR building stock located in Geneva, respectively in the rest of the Swiss territory.

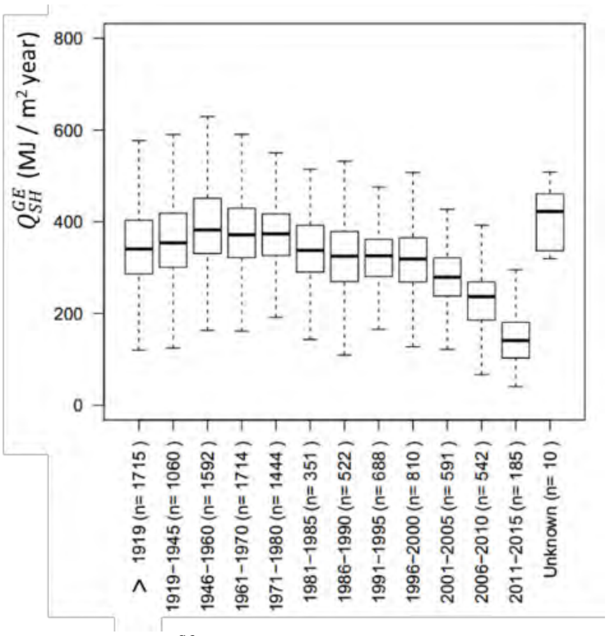

Figure 46: Boxplot distribution of q_{sh}^{ge} by construction period (multifamily buildings, SITG database)

2.4 Heat Demand at Building and Pixel Level

For each building of the GWR database, the specific heat demand is estimated by the average demand of its corresponding category and construction period with

$$\hat{E} = {}^{1}/_{\eta_{Agent}} \left(\overline{Q_{SH}^{GE}} \frac{DJ(b)}{DJ(GE)} + Q_{DHW} \right)$$

Equation 5

On this basis, we compute the sum of the heat demand of all buildings contained in a pixel of territory:

$$\hat{E}_{Pixel} = \sum_{B \in Pixel} \widehat{E_B} = \sum_{B \in Pixel} \widehat{A_E}\, \hat{E}$$

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Equation 6

The procedure is repeated on the entire Swiss territory, on square pixels of scalable sizes, ranging from 100 (m) to 1.6 (km).

2.5 Confidence Intervals

For each of the above pixels, we compute a confidence interval around the estimated heat demand value. It is computed by way of a bootstrap resampling algorithm, which consists in generating a heat demand distribution, which replicates the dispersion of the calibration datasets.

Therefore, for each building of the pixel, a new $\hat{E}$ value is generated by replacing the $\overline{Q_{SH}^{GE}}$ value of (5) by a randomly picked value of the corresponding calibration dataset (same building category and construction period). Similarly, the heated surface $\widehat{A_E}$ is replaced by

$$\widehat{A_E}^* := \left(1 + \Delta\widehat{A_E}\right)\widehat{A_E}$$

Equation 7

where $\Delta\widehat{A_E}$ is a randomly picked relative error of the corresponding linear regression model, defined as:

$$\Delta\hat{A}_E := \frac{A_E - \hat{A}_E}{\hat{A}_E}$$

Equation 8

The replicated $\hat{E}$ and $\widehat{A_E}$ values are fed into (6), generating a replicated heat demand of the entire pixel. Repeating of this procedure a 1000 times per pixel generates the heat demand distribution of each pixel. Finally, the limits of the 10% level confidence interval are the 5% and 95% percentiles of this distribution.

2.6 Results

At national level: Around 90% of the 1.93 million buildings listed in the GWR have sufficient data for applying of the appropriate regression model. Summing up all $\hat{A}_E$ values leads to a total heated surface estimation of 706.2 million of m^2. The total aggregated final energy demand is 340 (PJ/Year) for a reference climatic year.

At pixel level: The results of the model, which cover the entire Swiss territory, are made available by way of a dedicated web service.

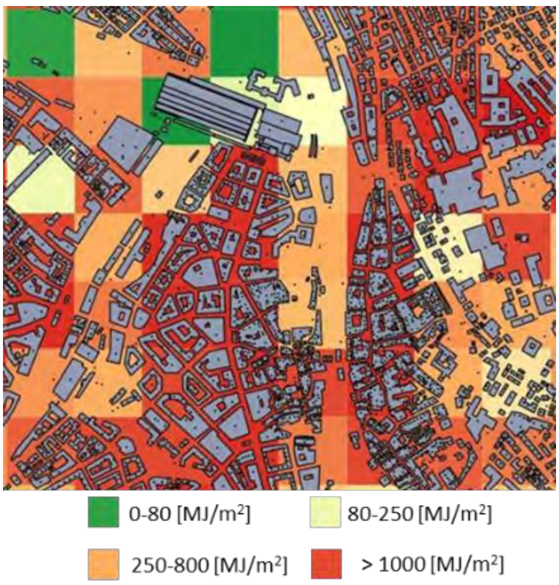

Figure 47: Sample map of a district of zurich

We finally build heat demand GIS maps, with more or less aggregated information, depending on the zoom level. Figure 47 shows an example of such a heat density map for an urban district. A colour ramp indicates the final energy consumption per square meter of territory, for each pixel of 200 (m) size.

3. DISCUSSION

Model variables: In this model, the variables used for determination of the specific heat demand have been limited to building category and age. In principle, the model could be refined with the use of additional factors, like building size or floor area ratio, which could be estimated on hand of the data contained in the GWR. However: (i) a rapid analysis of the SITG calibration dataset shows that, although statistically significant, these factors remain of secondary order; (ii) further subdivision of the calibration datasets would lead to statistically small subsets and related representativeness issues.

Due to similar representativeness issues within the calibration datasets, following finer categorizations were also abandoned (but could be introduced once more calibration data is available): (i) subdivision of the buildings in a larger number of categories, in particular for the non-residential sector; (ii) categorization of the heat demand by Canton, for tracking and taking into account of local specificities (other than the degree day issue, which is included in the model). As seen in section 2.3, and due to the high level of information of the SITG database, Geneva is the only exception to this uniform territorial categorization.

Comparison with national statistics: The total heated surface estimation is 6% below the estimation of 754 million of m^2 given by [1]. The fact that the GWR is not complete for industrial and services buildings can explain part of this gap. When focusing on the residential sector, the model yields 580 million m^2, against 509 million m^2 in [1].

The total aggregated final energy is in line with national demand statistics as [1]. This good concordance speaks in favour of the quality of the model, which was not calibrated for this purpose.

Confidence intervals: A strong added value of the model is the generation of a confidence interval around the estimated heat demand of each pixel. Due to the high dispersion of the specific heat demand within each building category and age class (Figure 46), the confidence interval can turn out quite large for pixels containing only few buildings, and reduces when more buildings are aggregated (averaging of the dispersion effect). A forthcoming paper will expose the relationship between aggregation level and estimation uncertainty in more details. The main outcome is that the uncertainty decreases proportionally to $1/\sqrt{Nb.\ buildings}$ as predicted by the central limit theorem.

4. CONCLUSION

The strength of this bottom-up model is to allow estimation of geo-dependent heat demand at any aggregation level for the Swiss territory. The estimation of consumption based on the distribution of measured consumptions bears the advantage of including the variability between buildings of same category and age. As a result, a bootstrap resampling algorithm allows to quantify the precision of the aggregated heat demand, which is an added value compared to previous approaches. Finally, the good concordance of the total aggregated final energy demand with national demand statistics speaks in favour of the quality of the model.

ACKNOWLEDGMENTS

This research is being financed by CTI within the SCCER FEEB&D (KTI.2014.0119) project. The authors thank the Swiss Federal Statistical Office, for free access to the GWR database. We also thank Professor Martin Kumar Patel of the University of Geneva for giving us access to CECB database (exchange of information within the scope of a collaboration with SCCER CREST).

ABSTRACT

Nowadays municipalities are facing an increasing commitment regarding the energy and environmental performance of cities. In order to answer this increasing demand, municipalities need integrated methodologies and tools which make possible take into account the specific boundaries, strengths and barriers and assess their impacts (environmental, economic and social) at current stage and allowing the evaluation of low carbon refurbishment scenarios with life cycle approach. Considering these needs, Tecnalia is working by different tool and methodologies, allowing the assessment of direct and indirect environmental, economic and social impact of new and existing districts. Using one of these tools, NEST (Neighbourhood Evaluation for Sustainable Territories) within the research projects ESSAI URBAIN and OptEEmAL, authors of this work have carried out the evaluation of several existing districts in the city of Donostia. This evaluation has firstly consisted in analyzing the baseline scenario in terms of energy performance, environmental and economic impacts; and social "well-being" of these districts. Then, with the objective of improving the energy performance and reducing the global impacts, authors have proposed several refurbishment scenarios based on specific actions from the SEAP (Sustainable Energy Action Plan) of Donostia municipality. This study has been performed in close collaboration with the city of Donostia which enabled the identification and selection of the most relevant and feasible scenarios from social perspectives. Results from this study have been used for comparing theoretical values extracted from the Donostia SEAPs, for developing a critical view of the achieved results and for proposing a prioritization process between different refurbishment strategies.

Keywords: decision support tool, refurbishment scenarios, environmental impacts

1. INTRODUCTION

Energy security and climate change are driving a future that will require significant improvements in the energy performance of the building sector. The 28 Member States of the European Union (EU) have set an energy saving target of 20% by 2020, which will need to be reached mainly through energy efficiency measures. The EU has also committed to reduce greenhouse gas (GHG) emissions by 80-95% by 2050, as part of its roadmap for moving to a competitive low-carbon economy in 2050 (Directive 2010/31/EU, 2010).

In order to support the energy transition of Europe towards a low carbon economy, municipalities have a key role to play. Launched the Covenant of Mayors for Climate & Energy brings together thousands of local and regional authorities voluntarily committed to implementing EU climate and energy objectives on their territory. Signatories now pledge to reduce CO_2 emissions by at least 40% by 2030 and to adopt an integrated approach to tackling mitigation and adaptation to climate change and to endorse and support the efforts deployed by local authorities in the implementation of sustainable energy policies. A Sustainable Energy Action Plan (SEAP) is the key document in which the Covenant signatory outlines how it intends to reach its CO_2 reduction target by 2020. It defines the activities and measures set up to achieve the targets, together with time frames and assigned responsibilities. These cities have signed the Covenant of Mayors on a voluntary manner and are committed to implement sustainable energy policies to meet and exceed the EU 20% CO_2 reduction objective through increased energy efficiency and development of renewable energy sources. However, there is a lack of connection between global objectives at city level and the implementation of energy strategies at district level. Specific solutions implemented at district level often ignore global issues, failing in the consideration of mid-term and long-term

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

scenarios. Besides, measures defined at global scale usually underestimate boundaries and barriers at district level.

In order to be effective in their energy and environmental transition, cities need specific tools to coordinate local stakeholders' information, provide detailed and relevant diagnosis of their city; identify boundaries and barriers of each district and their potential for energy measures implementation, considering technical and social issues. Using NEST (Neighbourhood Evaluation for Sustainable Territories) (Yepez, 2011), the authors of this work carried out an environmental and social evaluation of three districts in the city of Donostia. The evaluation firstly consisted of analysing baseline impacts. Then, with the objective of reducing environmental impacts and increasing social well-being, the authors proposed several refurbishment scenarios for the studied districts, in line with Donostia's strategies for energy efficiency.

2. NEST: NEIGHBOURHOOD EVALUATION FOR SUSTAINABLE TERRITORIES

Neighbourhood Evaluation for Sustainable Territories (NEST) was developed through a PhD thesis (Yepez, 2011) in Nobatek and the Groupe Recherche Environnement, Confort (GRECAU) laboratory, and focused on the environmental assessment of eco-neighbourhoods. Currently, the development of this software is carried out between Nobatek and Tecnalia, French and Spanish research centers with extensive experience in assessing environmental, economic and social impacts of buildings and districts. NEST is a plugin for Trimble SketchUp, which is the most used 3D modeler among urbanists and architects. NEST analysis is performed directly on the 3D master plan of the neighbourhood, and performs the assessment of a set of indicators that was developed through a scientific approach to operational urban planning objectives.

In terms of system boundaries, four major neighbourhood components are taken into account by NEST: buildings, land use, infrastructure (public lighting), and daily mobility of neighbourhood users (inhabitants and non-resident workers). Furthermore, NEST is one of the first tools that aims at assessing environmental impacts of neighbourhood scale projects, based on Life Cycle Assessment (LCA) methodology (social impacts currently are not evaluated with the life-cycle approach). NEST is based on the EN15978 (EN, 2011) standard, which defines the evaluation scope of a building's assessment with a life-cycle approach. Based on the conclusions obtained in the study carried out by Oregi (Oregi, 2015), NEST is focused on the assessment of the environmental impact of some of the life-cycle stages. The length of the NEST analysis is 50 years. Regarding the components of the district, the service life of the buildings is 50 years (Malmqvist et al., 2001), of land use is 50 years and of infrastructure is 30 years (Fthenakis et al., 2009).

3. PROJECT

3.1 Goal and scope

The goal of this study is to develop a methodology in order to promote resource conservation, reduction of environmental impacts and also to improve social conditions, adopting a life cycle approach. Using NEST, where studied the historical part of the city ("Parte Vieja"), the centre of the city ("Ensanche Cortazar") and the new part of the city ("Amara district") (see Figure 1). In this paper, we will present and discuss how the NEST tool was used in order to support the decision making process of urban refurbishment projects in order to implement the SEAPs measures into the three districts under study.

Figure 1: Screenshots of the three areas studied with the ESSAI URBAIN (Essai Urbain, 2009-2013) framework ("Parte Vieja" – "Ensanche Cortazar" – "Amara").

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.2 Case studies: Presentation

The three districts studied (see Figure 1) were chosen for their representativeness of the city of Donostia. As in most European cities, due to urbanism characteristics, construction age, buildings use, thermal properties, mobility infrastructure, building protection level, etc., the improvement potentials and constraints are quite different for each district. The historic centre of Donostia, founded in 1180, is protected by various regulations, reducing the number of conceivable options in terms of refurbishment strategies. The "Ensanche Cortazar" was designed in 1864. The architectural quality of some of these buildings turns them into catalogued or protected buildings, disabling their energy rehabilitation through strategies such as ventilated facades or window replacement. However, due to the high amount of energetically inefficient buildings, the potential of improvement is very high. In the second half of the 20th Century, Donostia city was enlarged and new urban areas had been created to make room for the increasing population ("Amara" district). The use of buildings in Amara is mainly residential and there is no building architecturally or urbanistically protected. Consequently, the energetic improvement potential of this district becomes very.

3.3 Evaluation methodology

A classical LCA process, similar to the one recommended by ISO standards on LCA was implemented beginning in the early stages of the study. To start, the goals and scope of the project were defined. As a result, it was decided that interest in the energy refurbishment strategies selected by the SEAP would be assessed, and would encompass each studied area over several time horizons. Next, the inventory analysis phase was carried out. This stage was critical as well as time consuming, because it required the collection of a large amount of data. The third phase consisted in running assessment calculations.

Primarily, a baseline analysis was done for the three districts. The baseline was defined in 2009, and corresponds to the starting point for Donostia with regard to municipal ordinance implementation (called "eco-ordenanza") (Gipuzkoa, 2014). This ordinance aimed at optimizing energy efficiency of new and renovated buildings. After that, three assessments were performed in order to evaluate the efficiency of the measures taken by the city of Donostia: municipal ordinance, horizon 2020 and horizon 2030. Finally, the results provided by NEST were interpreted and compared to the baseline, taking into account three indicators: Primary Energy (PE), Global Warming Potential (GWP) and Air Quality (AQ). It must be noted that because mobility aspects have already been deeply studied by the municipality, it has been excluded from the calculations.

3.3.1 Baseline

The information obtained in close collaboration with the city of Donostia the definition of a vast majority of the inputs required for modelling the baseline scenario of each of the studied districts. Based on this information, Table 1 shows some of the results obtained after inserting the input data in the tool. Ninety-three percent and 91% of PE and GWP impact, respectively, are related to the impact generated during the operational stage of the buildings. During this stage, 43% of PE and 75% of GWP are related to heating consumption. With regard to the air quality impact and with the exception of the historic district, in which mobility is limited mainly to pedestrians, more than 95% of the AQ impact is related to individual and public transport. In terms of comparison among the three districts, it appears that the Ensanche Cortazar has the highest impacts related to buildings.

This is explained by the significant number of buildings without insulation, as well as by its lower density. With respect to public lighting, the Parte Vieja district has the highest impact due to the relatively low efficiency of its public lighting system. And finally, in terms of mobility, the Amara district has the highest impacts mainly because of the district's transportation model, which relies more on energy-consuming and GHG-emitting transportation modes than the two other districts.

Impact indicator	Sector	Life Cycle Stage	Parte Vieja	Ensanche Cortazar	Amara
PE (MJ/year/user)	Buildings	A1-5, B2, B4, C1-4	0.0E+00	0.0E+00	0.0E+00
	Buildings	B6, B7	4.4E+04	9.7E+04	4.7E+04
	Public lighting	A1-3, B4, B6	1.9E+03	1.5E+03	1.3E+03
	Mobility	A1-4, B6, C1-4	1.2E+00	1.7E+03	2.1E+03

GWP ($kg_{eq}CO_2$/year/user)	Buildings	A1-5, B2, B4, C1-4	0.0E+00	0.0E+00	0.0E+00
	Buildings	B6, B7	2.5E+03	3.4E+03	1.5E+03
	Public lighting	A1-3, B4, B6	1.4E+01	1.1E+01	9.8E+00
	Mobility	A1-4, B6, C1-4	0.4E+00	9.7E+01	1.2E+02
AQ (m^3/year/user)	District		6.6E+03	2.9E+05	6.3E+05

Table 1: Baseline results for each studied district (per year and user)

NEST models also provided the "well-being" profile (see Figure 2) of each district through the social indicator assessment, which provides a better understanding of the district structures, highlighting their main features.

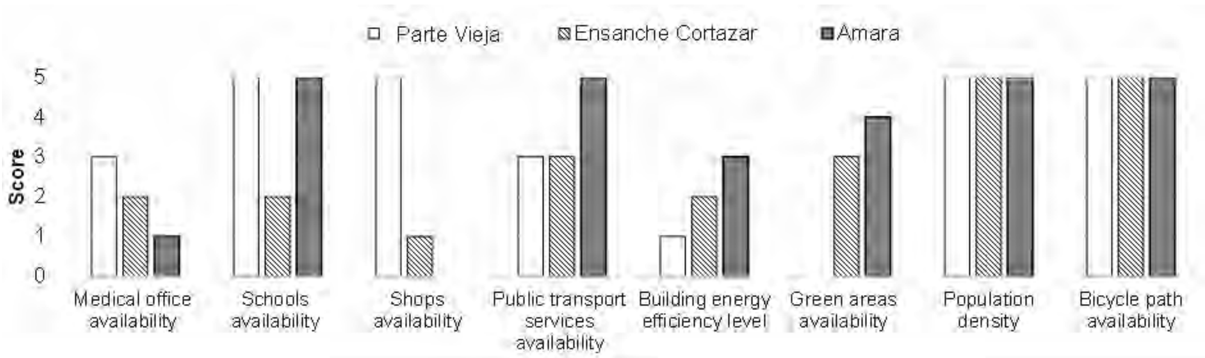

Figure 2: NEST social indicator results assessment of the three baseline scenarios.

3.3.2 Refurbishment scenarios

After evaluating the impacts of the baseline scenario, the second phase of the project was focused on the assessment of different energy refurbishment scenarios. The refurbishment scenarios are divided into three different temporal evaluations:

- Municipal ordinance of energy efficiency (2009-2014 years) (Gipuzkoa, 2014).
- Scenario 2020: Scenario based on the SEAP of Donostia (Minuartia Enea et al., 2011).
- Scenario 2030: Scenario based on Hiri Berdea document (ENEA, 2014).

Based on the information provided by these documents and through direct collaboration with the municipality, Table 2 shows the different energy refurbishment strategies for each aforementioned period.

Refurbishment strategy		<2009 (Baseline)	Eco-ordenanza	2020	2030
Public lighting	Luminary	Mercury vapour		Low pressure	LED
Public buildings	Boiler	Natural gas	No improvements		Condensation
	Lighting	No improvements			
	Cooling system	Standard		Efficient	
	Heating reduction	No improvements		15%	15%
Residential buildings (RB) boilers	Oil (PV, EC and A)	20%	10%	0%	0%
	Natural gas (EC)	80%	90%	90%	75%
	Natural gas (A)	80%	90%	90%	60%
	Condensation (PV)	0%	0%	10%	50%
	Condensation (EC)	0%	0%	5%	15%
	Condensation (A)	0%	0%	10%	30%
	Biomass (PV)	0%	0%	0%	0%
	Biomass (EC)	0%	0%	5%	10%
	Biomass (A)	0%	0%	0%	10%
RB replacement	Windows (PV)	No improvements		5%	15%
	Windows (EC)	No improvements		10%	20%
	Windows (A)	No improvements		15%	40%
	Façade (PV)	No improvements		0%	0%
	Façade (EC)	No improvements		5%	10%

Table 2: Refurbishment strategies proposed for "Parte Vieja" (PV) – "Ensanche Cortazar" (EC) – "Amara" (A) districts

From Figure 3, it can be seen that results vary among the three districts. The "Ensanche de Cortazar" and "Amara" districts evolve in the same way, with reductions in terms of PE demand and GWP for the three scenarios (between 1% and 28%, depending on the scenario and the indicator).

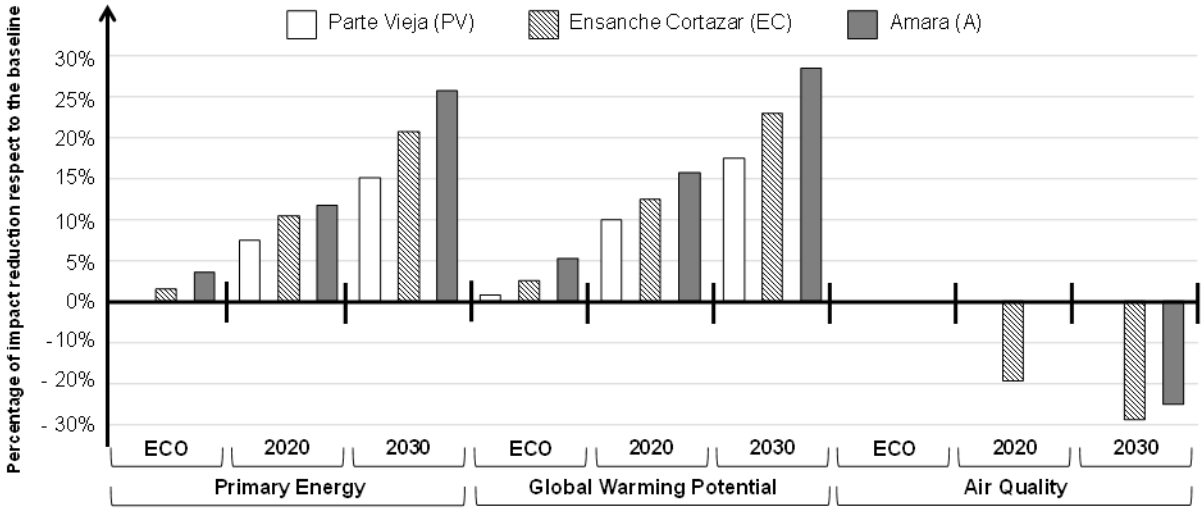

Figure 3: Impact variation (%) for the three districts studied in relation to the baseline.

However, the air quality indicator increases in the 2020 and 2030 scenarios due to the implementation of wood boilers (instead of gas boilers), leading to higher particulate emissions. It must be noted that this analysis should be deeply investigated while the precise type of wood boiler to be implemented is known. For the "Historic city" district, the impact reduction in terms of PE demand and GWP is lower due to historical constraints, which limit the implementation of energy refurbishment strategies. Also, the less frequent use of biomass boilers leads to a reduction in particulate matter, and thus reduces the influence on the air quality indicator.

4. DISCUSSION

Results provided by NEST allow quantifying the performance of the three districts at different time horizons in terms of primary energy demand, GHG emissions and air quality. This evaluation permitted to set the position of the studied districts with respect to the Donostia city objectives in terms of GHG emissions reduction for 2020 and 2030. As indicated in Table 3, results of the simulations show that the envisaged scenarios are not sufficient to reach the city objectives. Consequently, these results shed light on the improvements still needed to reach the defined objectives. However, it has to be noted that the proposed scenarios only tackle the built environment and associated impacts. One of the next possible areas of work in terms of methodology could be related to the influence of historical restrictions in designing energy refurbishment strategies at the city scale. Discovering new paths when designing refurbishment plans for such areas could significantly increase the refurbishment potential of cities.

(Impact indicator: GWP)		ESSAI URBAIN results (Essai Urbain, 2007–2013)	SEAP (Minuartia Enea *et al.*, 2011) & Hiri Berdea (ENEA, 2014)

5. CONCLUSION

As mentioned, the work carried out during this study aimed at positioning the envisaged energy refurbishment scenarios and associated environmental impacts in relation to the city's objectives. The results showed some differences between the three districts studied, and helped the city of Donostia answer some critical questions. First, the assessment performed has allowed for the identification of GHG emissions hotspots in the baseline, and thus for the definition of key areas of action both in terms of geography (which districts) and items (which elements). For instance, it was highlighted that the Historical centre, due to architectural restrictions, will not be able to reach the same performance levels as the Amara or Ensanche districts. Also, building heating has been identified has the main contributor to district GHG emissions in the baseline. Finally, this exercise has provided important information regarding the envisaged energy refurbishment plan and its corresponding role in reaching the city's objectives. This has been particularly useful for the municipality to justify the need for additional efforts to reach their GHG emission objectives.

ACKNOWLEDGEMENTS

Part of this work was developed from results obtained during the ESSAI URBAIN (project number EFA287/13), POCTEFA program and "Optimised Energy Efficient Design Platform for Refurbishment at District Level" (OptEEmAL) project, Grant Agreement Number 680676. Another part of this work was developed with financial support from the French State, managed by the French National Research Agency (ANR) in the frame of the "Investments for the future" Programme ITE for the project INEF4 (ANR-10-IEED-0013).

ABSTRACT

Quantifying the sustainability of buildings is a complex and very challenging task. Three interdependent factors: society, economy and environment need to be considered. It requires a systematic assessment of all these three factors for the entire life-cycle of the building. Full cost assessment (FCA) is an accounting method that monetises direct, indirect and external aspects. Since external aspects are considered, FCA provides a systematic approach to monetise the current and future impacts of decisions which may cause environmental and social impacts. The oil and gas industry was the first to apply the FCA approach in their decision-making processes. Recently, applications of FCA have been expanded to many areas such as energy supply, waste management, chemical process, transport system, and urban development. This paper aims to identify the benefits and limitations of FCA on the evaluation for the sustainability of buildings. The concept of FCA, the relevant methods available and the applicability of FCA to buildings are discussed.

Keywords: environmental product, life-cycle assessment, affordable housing

1. INTRODUCTION

The today's market demands the delivery of more affordable and sustainable buildings globally. However, the construction industry is facing many challenges to tackle this issue. The definition of sustainable development (SD) by the Brundtland Commission's Report considers three principal factors: society, economy and environment (WECD 1987; Bourdeau 1999). Sustainable construction is an important component and a direct output of sustainable development (Bourdeau 1999). Environment, economy and society are primary aspects of sustainable construction and public participation embraces this concept 'along with all their features throughout its life cycle' (Aye & Mirza 2006, p.386). Four principles denotes a notion that sustainability should include future, equity, environment and public participation in a wider perspective (Aye & Mirza 2006; Bourdeau 1999). Despite many different tools being available for quantifying sustainability in buildings, the lack of consideration given to the impact of external aspects is a major concern in the available sustainability assessment tools of buildings (Aye & Mirza 2006; Xing et al. 2007). Also, inaccuracy or misjudged assessments of sustainability identified in existing valuation tools may lead to further investments constrains and/or result in the mispricing of assets (Warren-Myers 2013). Therefore, economic appraisals shall provide means to support decision-making by quantifying economic, social and environmental values and lifetime benefits with impacts on the economy and society (Smith, Brown & Saunders 2016).

1.1 Full cost assessment

Full cost assessment (FCA) is an accounting method for identifying and quantifying costs of environmental, social and economic aspects in a lifecycle perspective (Bebbington 1998, p.7). It was developed to adjust the existing prices of goods and services by monetising and incorporating both positive and negative sides of internal and external aspects (Jasinski et al., 2015, pp. 1124). The "full cost" terminology was appeared in the oil and gas sector, seemingly as an environmental accounting approach to capitalise productive and non-productive expenditures, and produce data for predicting future earnings (DuBois 1974, p.1). The social sphere was incorporated into the definition of FCA in 1980 (Burchell et al. 1980). However, FCA focused mainly on environmental issues up until 1990's (Huizing & Dekker 1992) and faced challenges to meet companies' interest due to a high level of resources required and complexity (Naggar 1975; Buchanan 1982; Antheaume 2004). Since then, environmental impacts

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

has been incorporated into accounting-based information for private decision-making and environmental considerations into public decision-making (Milne 1991; Figge & Hahn 2005). Based on accrual accounting principles, revenues and expenses are recorded and costs incurred in the past and future costs are annualised.

FCA has been applied in many sectors for quantifying externalities and their uncertainties in projects and organisations (Bebbington et al. 2001; Jasinski, Meredith & Kirwan 2015). The FCA approaches vary in a range from narrowed to comprehensive applications, accordingly to its objective (Jasinski et al. 2015). For instance, the oil and gas sector, waste management, energy supply, water service, transport, urban development, and agriculture has applied FCA approaches to internalise externalities and increase the level of sustainability of products and organisations. Externalities or costs bear by external parties are viewed as not accountable costs or costs from impacts organisations are not responsible for (Antheaume 2004; Roth & Ambs 2004). Assessing external factors provide an opportunity to assess costs at the whole-society level, bringing the real economic effects of externalities as well as potential costs and prices changes (Smith et al. 2016; Bebbington et al. 2001). Therefore, FCA considers externalities rather than outlays as internal costs (Bebbington et al. 2001). Contingent or intangible environmental costs and externalities are accounted in a lifecycle perspective (Smith et al. 2016).

Environmental impacts can be divided into four categories such as impacts on atmosphere, hydrosphere, pedosphere and biosphere. Air pollutants, greenhouse gas emissions, soil depletion, contamination and noise are examples of negative environmental externalities which may arise from processes and activities in a lifecycle perspective, affecting the human health. Examples of positive economic externalities are higher workforce productivity, travel time savings, reduction in mortality and morbidity. Other effects may cause positive or negative impacts, for instance, community perception of economic equality, collective sense of uncertainty about the future, and standard of living. Social externalities may relate to environmental impacts (Phelan et al. 2017). Some studies included human health impacts as social externality (USEPA 2008; Kerr 2004). Many other negative social impacts may arise from environmental pollutants such as cancer cases.

The consideration of the three spheres of sustainable development has been partially included for quantifying externalities in project and organisations as the FCA concept, frameworks, methods and tools evolved over the time. However, Smith et al. (2016) acknowledged that there is still a lack of clear and established methodology approach (Xing et al. 2007; Liu 2014). Also, few studies have focused in quantifying externalities related to buildings (Xing et al. 2007; Liu 2014). Therefore, this paper aims to identify the benefits and limitations of FCA for the evaluation of sustainable buildings. The concept of FCA, the relevant frameworks available and the applicability of FCA to buildings are discussed.

2. CASE STUDIES

Twenty one FCA studies were selected from the literature for the identification of available FCA frameworks and the applicability of its concepts to buildings. The FCA frameworks found in the selected studies were categorised in five approaches as per Antheaume (2004) and Jasinski et al. (2015). The FCA approaches and externalities were discussed in this section. Table 1 provides detailed information about the selected case studies.

2.1 The avoidance and remediation cost control

The avoidance/remediation cost control approach estimates external aspects by the costs to be incurred, and cost which has not been incurred to prevent or avoid its emissions and meet existing or future regulatory standards (Bebbington et al. 2001). These case studies were selected for avoidance and remediation cost control through the Forum for the Future Framework (FFF). This approach can be utilised as cost control for environmental and social external impacts, avoiding damages to the environment and society. Liabilities are measured for the whole accounting year and impacts are translated into a sustainable operating income. The FFF utilises cost benefit analysis (CBA), sustainable cost calculation (SCC) and SCC combined with multi-attribute accounting are the methods available for the avoidance and remediation cost control approach. The Ontario Hydro utilises market methods whereas the value of damages applies contingent valuation.

2.2 Opportunity cost

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Opportunity cost is a form of capital costs for omitted future returns that would have created benefits by alternative investments (Figge & Hahn 2005). The Sustainable Value (SV) concept combines social and financial capitals plus natural capital and applies opportunity cost for the evaluation and allocation of future assets (Figge & Hahn 2005). In this approach, the companies need to adjust their net profit to further receive a value-added indicator (Jasinski et al. 2015). Different from SCC, corporate genuine saving (CGS) is based on abatement costs rather than damage costs.

2.3 Damages cost

Damages are quantified through mathematical models or on-site measurements for reducing future external impacts (Bebbington et al. 2001). Through a multi-criteria analysis, decision-making alternatives are made to reduce future damages to the environment and society. For instance, the ExternE project-series focused on energy-related external and environmental and social impacts and combined with life cycle assessment (LCA) and impact pathway analysis (IPA) to fully quantify sustainability (Bickel & Rainer 2005). This method has certain limitations as it mainly focuses on energy-related external and environmental issues (Lai et al. 2014).

Sustainable Assessment Model (SAM) is the most used approach for the consideration of damages in projects/organisations. SAM enables to take a broader assessment, including many aspects of the evaluation (Jasinski, Meredith & Kirwan 2015). Despite multi-criteria analysis being used as a decision-making tool, CBA is the most applied method for the evaluation of sustainability. CBA has been widely used for assessing social, environmental and economic impacts as all the case studies include internal and external aspects. External costs are estimated through the monetary value of the damage and willingness to pay (Antheaume 2004). However, the use of CBA for FCA does not consider life cycle perspective. Therefore, recent studies have integrated CBA with other valuation methods to provide a comprehensive quantification of internal and external aspects.

2.4 Multiple approaches

Despite the popularity of FFF and SAM in FCA applications, there is a progress towards the utilisation of integrated models/methods. The concept of multiple approaches regards the integration of methodologies, frameworks or methods for achieving a comprehensive FCA (Jasinski, Meredith & Kirwan 2015). Multiple approaches adapt with the context of its implementation, providing means to tackle specific issues related to externalities.

Different from the first FCA applications, the recent case studies which utilised multiple approaches considered an extended life cycle period of about 30 years. Kerr (2004) utilises Damage Function Approach (DFA) and Value Estimated Damage (VED) in industrial processes. Liu (2014) combines Life Cycle Cost (LCC), LCA and Value Score (VS) for quantifying sustainability. The principle component analysis/factor analysis (PCA/FA) was utilised to identify sustainability index in the transport area (Reisi et al. 2014). Although combining methods provides the consideration of a reasonable amount of impacts, some studies acknowledge there are restrictions on quantifying a large number of impacts due to the limitation of tools and methods (Reisi et al. 2014; Mutavchi 2012). A novelty in the selected FCA case studies is the inclusion of Wider Economic Benefits (WEBs), which can be translated as gains to the society. In Australia, many sectors such as transport, communications, energy and water have applied full cost-benefit analysis (FCBA) to assist the decision-making process. The consideration of externalities, WEBs provides means to quantify indirect social benefits, which are usually not assessed. Lai (2015) applies this concept by integrating the traditional CBA and WEBs and, therefore, having a full quantification of positive external aspects.

Table 1: Selected case studies

FCBAs consider elements of agglomeration economies, imperfect competition and economic welfare benefits of optimised labour supply (Department of Transport 2012). Such benefits can be transferred to others and therefore add an external social and/or environmental value to the project or organisation, according to the type of its application. Even though FCBA has been applied in infrastructure and transport projects, this concept is relatively new to building constructions.

3. APPLICABILITY TO BUILDINGS

FCA provides means to quantify costs of external factors, which are usually not identified or are outside the responsibility of companies and/or organisations. Xing et al. (2007) acknowledged current FCA applications available for buildings absence in recognising external social and environmental impacts which are not reflected by the market. Therefore, there is a clear need of identifying, estimating and allocating potential shadow prices of buildings in a life cycle perspective. As most stakeholder easily understands monetary values, an approach for increasing the level of sustainability of buildings may be the inclusion of external impacts in monetary terms by using an economic appraisal.

The benefits of FCA for the evaluation of sustainability of buildings are many. The FCA approach allows measuring costs which may arise from external factors that are usually not considered. We observed that most the studies focused on internalising environmental impacts to, then, reduce, eliminate or avoid the effects of its external aspects considering financial aspects, at the same time. Also, some external impacts can be quantified while others have limitation to be appropriately monetised due to limited availability of relevant information.

Few studies have focused on quantifying externalities in buildings considering its entire lifecycle. No evidence of a FCBA for conventional or prefabricated houses was found in the literature as this approach has not been applied to the residential buildings. Therefore, we propose the utilisation of an integrated SAM by combining the quantification of externalities and WEBs. Not only externalities but also WEBs should be considered for FCBA in buildings and, therefore, decisions will not be made only based on the cost of the damage or externalities, but also by considering indirect benefits. There is a wide range of sustainable indicators which could be used in further FCA applications in the building sector. For instance, impacts on atmosphere, hydrosphere, pedosphere and biosphere, higher workforce productivity, value of time, human health, wellbeing and reduction in mortality and morbidity. Positive and negative impacts of social, economic and environmental externalities need to be carefully identified, analysed and quantified or monetised.

The FCA related to construction and urban development may guide further potential applications in the building sector as some externalities may be very challenging to be monetised. Also, the size of the project or organisation and objectives needs to establish the boundaries of the application. There is a lack of consideration of full costs and benefits to the society in current decision making relevant to buildings. The quantification of social costs and benefits must be considered as it may influence significantly the outcomes of the decision.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

4. CONCLUSION

Quantifying externalities in buildings requires, firstly, a thorough understanding of effects on economy, environment and society in a lifecycle perspective to achieve better sustainability. This paper reviewed 21 FCA case studies from literature to identify the benefits and limitations of applying FCA for the evaluation of sustainability of buildings. Many different methods/techniques are used for this propose. However, it was observed in recent studies that the inclusion of both externalities and benefits of external impacts should be considered. We propose the application of an integrated SAM (or FCBA) by inclusion of externalities and WEBs in CBA for quantifying sustainability of buildings. Since the integrated application of CBA and WEBs was first applied in other sector, there is a clear need of adaptations of its concept to buildings. As further studies, we acknowledged limitations may be found as adjustments may be necessary, according to the data availability. We suggest the use of FCA studies in the urban development and building sector as a reference and guidance to identify potential external aspects related to its context.

ABSTRACT

The main purpose is the design and development of an integral system for the energy inspection and energy evaluation for buildings with high energy-saving potential, which will make possible the proposal of effective rehabilitation actions towards the reduction of the CO^2 footprint and the conversion of those buildings into zero-consumption buildings.

First of all, all the typologies of buildings have been studied to choose which one is the ideal model. A multidisciplinary approach has been applied to deal with this task, including the design of an indoor unit mounted on a trolley and a UAV drone unit for the complete, geometric and thermographic, measurement of the building's envelope. All processed data have been compiled in Building Information Models (BIM) containing also all the information required for the energy evaluation of the building. These models were made with all the data georeferenced so they could be automatically incorporated into the energy analysis software. Several of this energy analysis software were used to evaluate the model and the results have been compared, focusing on the complexity and the percentage deviation of results.

A methodology for evaluating the energy generated by buildings has been developed, and it also includes the creation and evaluation of innovative building solutions that would lead us to reduce energy consumption. These solutions have been gathered in a manual for use in several similar buildings.

Keywords: energy efficiency, integrated design, laser scanner

1. BACKGROUND

Energy consumption in buildings accounts for approximately one third of the EU energy consumption and CO^2 emissions, this is more than the consumption of industrial activity or transportation. Therefore, the rationalization of energy consumption in this sector has become a priority on the national and European energy policy, manifested by the appearance of specific regulations. Particularly noteworthy is The Spanish Strategy for Science and Technology, under the "Horizon 2020" of the EU, that states the challenge of producing safe, clean and efficient energy. In the case of existing buildings (in Spain there are 13 million homes most households amenable to be intervened, most of them from the years 1940-80, with non existent rules and scarce resources that difficult their intervention), energy rehabilitation works can bring savings of up to 75% in energy consumption, and a reduction in CO2 emissions of most of 34% with respect to 2001 (WWF, 2012).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2. OBJECTIVES

2.1 Main objectives

The objective of this research is the development and creation of an integrated system that allows simplify the process of data collection, analysis of the situation and application of energy-saving solutions to a building rehabilitation as much as possible.

The rehabilitation leads to the recuperation of the interior thermal comfort and the reduction of maintenance costs, with a return period of investment assumable. Each building is a unique case, with its particularities in geometry, composition and construction (Celis et al, 2012), as well as its occupation and use, typology, facilities and management. The availability of comprehensive, unified and consistent information is a key factor to do a proper diagnosis and optimal decision making.

2.2 Election of study case

The study case is located in the south-western Galicia region. It has been chosen as a model for this investigation because in the 70's there were a great expansion of the construction sector, which had to built many new schools, but with low climatic requirements. Once there were analyzed a number of existing typologies with the previous conditions, it was chosen an educational building located in the south-western Galician region. In the 70s it was experienced a big construction expansion that led to the construction of new schools across Spain but with low climatic requirements. This model has been replicated frequently throughout the national territory (in this area, the same school project was built 35 times), and the study of this unit will provide data to know other similar centers in the area. The study building is the childhood education center of San Roque Elementary in Cangas, Pontevedra, (1972), (Figure 1).

Figure 48: Study Case. San Roque elementary school in Cangas, Pontevedra, Galicia, España. West Facade

2.3 Data collection

Regarding to geometry, the original drawings of the existing buildings aren't always available are not related with the constructed reality. For digital geometric modeling or 3D reconstruction, the laser scanners have an increasing acceptance, with specialist literature (Huber et al, 2011) pointing to its utility in the generation of 3D models BIM architecture.

Within the integrated system designed has been used a technology to acquire the geometry using a moving measuring device without GPS assistance, as the international reference research groups, such as the Video and Image Processing Lab, University of California Berkeley, and the Robotics Lab at the City College of New York, USA, has been developed. It has been also developed an unmanned aerial vehicles (UAV) model, with thermographic and geomatic sensors located in multi-rotor helicopters type (drones), which can fly at slower speeds and even maintain a fixed position (Fernández-Hernández et al, 2012).

BIM (Building Information Models) technology appears as the solution to compile all the information needed for the energy modeling process: 3D geometry, thermographic inspection and boundary environmental and technical conditions of the building (Lagüela et al, 2013; Vanlande et al, 2008). BIM does available to the energy inspector all the information and energy efficiency studies obtained of from the building (Raheem et al., 2011). The benefits from of this technology have been demonstrated by reducing costs and errors in the construction process, making a substantial improvement in the energy modeling of buildings (GSA, 2009) thanks to its large amount of data and faithful reproduction of constructed reality (Wang et al., 2011). However, advances in software on BIM and energy assessment takes focus on the early stages of life in the building: its design and endowment. Thus, the main commercial architectural design software tools offer BIM (© Autodesk, Bentley Systems ©, CYPE ©), but the energy assessment of as-built BIM is still under investigation.

2.4 Energy simulations

Within the integrated system that allows simplify the process of data collection, analysis of the situation and application of energy-saving solutions to a building rehabilitation as much as possible, this article will focus specially on energy simulations on the model of study and its connection with compliance with official regulations, (CTE, 2006) (Spanish Technical Building Code/Código Técnico de la Edificación).

3. ARQUITECTURE AND CLIMATE IN GALICIA

The climate of the village where the school is located under study is a mild, regular and humid climate. Temperatures range between 5 and 17 ° C, in winter and 15 and 25 ° C in summer, with humidity all year between 70 and 95%.

On the current regulation, the determination of climatic zones are given by the CTE, according to topographic height of each municipality, in the form of numerical table. It has developed a mapping with data versions CTE 2008 and 2013, with notable differences and several doubts regarding the correct climate distribution.

In this situation, it is very important for this research to obtain real climate data. Thus, the first step in the research is the realization of a new climate map of Galicia based of a proven methodology and set (da Casa, 2000), with the following phases:

- Consultation of weather information available through the official website of the autonomous community www.meteogalicia.es; all available stations with updated information are analyzed (Figure 2);
- There is established which weather stations are updated frequently, with no more than ten years in between;
- Monthly data of maximum and minimum temperatures, average data of maximum and minimum temperatures and relative data humidities are collected;
- The data are applied to Givoni diagram and bioclimatic strategies are established monthly;
- All the data obtained are arranged in a map and doubted zones are identified, data are analized even if the data are less than ten years, completing monthly distributions;
- Ultimately, there are obtained a map of monthly strategies, analyzed and verified the existence of potential clusters of great similarity, establishing zones with common data.
- With the mapping created, it is possible to establish the policy needs on each of the selected schools (35), with the same characteristics of the study case.

4. ANALYSIS OF CURRENT STATUS AND PROPOSED IMPROVEMENTS

As already mentioned in this article has focused attention on the comparison of results between different simulation tools. To analyze the current status and proposed improvements of the building will be used several computer simulations tools:

- HULC: (Herramienta Unificada LIDER CALENER -Unified Tool LIDER-CALENER). It is the official tool provided by the CTE in Spain for energy assessment of buildings. Last version 26/07/2016. (view of results on Figure 5);
- ECOTECT: One of the best simulation tools. It is currently unavailable because it is no longer provided by AUTODESK. (Figure 3, 4);
- REVIT: It's the BIM of AUTODESK suite, and allows to obtain direct 3D image from the robotic entries and is associated with ENERGY PLUS engine analysis;
- CASANOVA: It is a free software. Very accessible and intuitive, It has operative limitations and data input;
- SEFAIRA: It is a plugging for SKETCHUP. It has now been bought by the owner of SKETCHUP, ISCAR. Easy to shape but very simple.

Not all the computer simulations tools allows to use the same starting parameters. In some cases (REVIT, CASANOVA and SEFAIRA), there are not taken into consideration the hours of daily or monthly activity. In other cases, is not possible to use the real thermal data of the enclosures (it is only possible with ECOTECT) because they are much lower than the software admitted.

There are established three starting points:

- Case 0: No timetables or schedules of use are applied. External walls data correspond to the CTE. It can be applied to all analysis tools used in this research;
- Case A: Applying schedules and calendars. Using actual data of transmittance obtained "in situ" with measurement devices. It is only applicable with ECOTECT;
- Case B: Same as Case A, but introducing building materials data from the CTE database. It is applicable with HULC and ECOTECT.

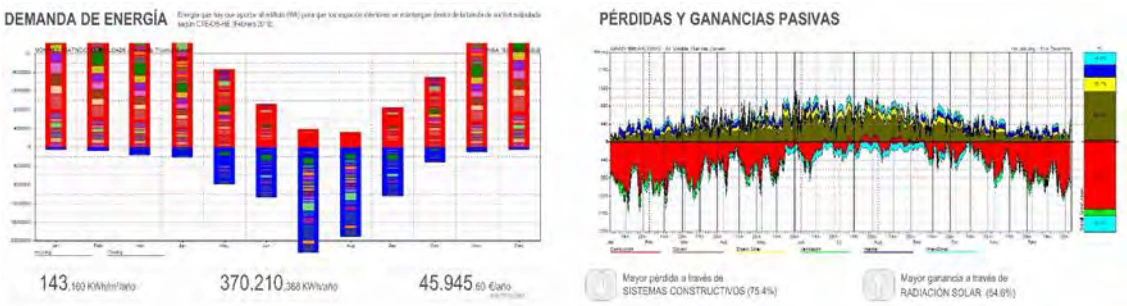

Figure 50: CASE 0 – Current status. Monthly demand for energy. Passive lost and gains.

5. IMPROVEMENT PROPOSALS

The simulations made with the different tools can be seen as requirements are isolation and uptake of radiation. They are used the same premises to discuss the results with all the tools, based on constructive solutions verified by the CTE. Three changes have been proposed but it would be possible to extend the application to many other combinations, using the speed of the simulation analysis:

- Option C: application of a new 15 cm insulation inside the facades is proposed;
- Option D: application of a new 15 cm insulation on the roof/deck is proposed;
- Option E: replacing existing windows by others with thermal break and double low emissivity glazed is proposed;
- Option F: It is the sum of all previous proposals (op. C+ op. D+ op. E).

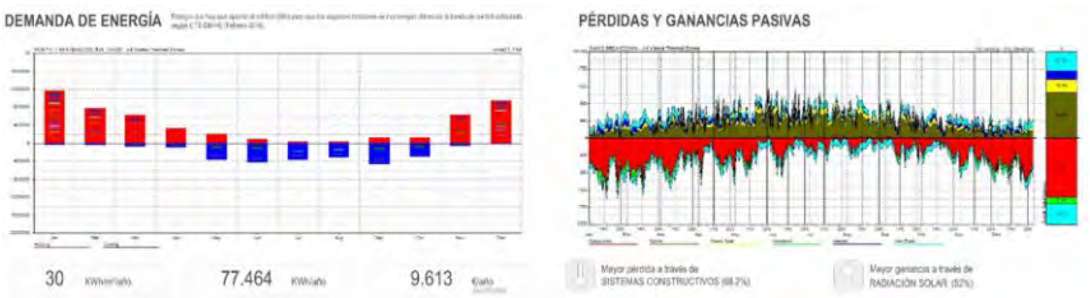

Figure 51: OPTION F- Monthly demand for energy. Passive lost and gains (ECOTECT)

	Verificación Límite de consumo				Certificación			
	Consumo EP no renobable edificio Objeto kWh/m2.año	Consumo EP no renovable edificio Referencia kWh/m2.año	Porcentaje respecto al edificio de referencia % maximo 65	Califica. EP	Consumo EP no renovable kwh/m2 año	Indicador kgCO2/ m2 año	Letra	Etiqueta energética

6. INTEGRATED DESIGN FOR ENERGY-EFICIENT HOUSING

In addition to improve the energy efficiency of the building, according with the theories of integrated design, the other objective of the research is to get the most effective way to find the best solutions in building energy efficiency. This strategy aims to promote a more sustainable architecture through early multidisciplinary collaboration, achieving reductions of up to 80% of operating costs (Miotto et al, 2012).

The integrated design includes among others the following features:

- Motivation of participants;
- Prior establishment of measurable goals and project requirements;
- Holistic Business vision with extensive information: site, climate, use, culture, materials, systems;
- Internal coordination of the team work, establishing the direction and aids.
- Multidisciplinary team covering all trades that, in one way or another, are involved;
- Evaluations and simulations of the prototypes from the first sketch in order to take focus on the better solution.

7. CONCLUSIONS AND ACKNOWLEDGMENTS

The following conclusions have been obtained:

- Using the same parameters, there are obtained very different answers depending on the analysis tool used. The differences are both in absolute values and in the type of results that can be obtained.
- There are many differences in each tool or system between the form to input the data and the response received, and in the time spent entering data and the calculation process of the application itself.
- However, as can be seen despite the dispersion of absolute values, the relative values are similar improvement in the tools where these constructive solutions are applied.
- Once the system model is implemented it is very easy to propose a wide range of combinations of improvements over the model.

The procedure suggested for improving the conditions of energy consumption of buildings is, in the first instance, the usage of easier operation tools that can even support the direct import of 3D models from laser scanning tools within the integrated system proposed in this research.

Subsequently, and once channeled the energy solution, it will require a specific modeling using the official simulation tool "HULC", since this introduces data numerically, without modeled complex.

Alongside these simulations the study of the most efficient facilities also arises to improve overall performance and includes calculating the relative cost of each.

The development of this research is conducted within the project "ENE2013-48015-C3-2R" (Integrated system for energy optimization and reduction of building CO^2 footprint: BIM, indoor mapping and advanced energy technologies UAVs simulation tools) funded by the Ministry of Economy and Competitiveness and executed by the Geotechnologies group applied - University of Vigo, the Technology group information for scanning and 3D modeling in engineering and architecture - University of Salamanca and the Intervention group in the heritage and sustainable architecture - University of Alcala.

ABSTRACT

A monitoring system with environmental indicators has been developed to monitor the environmental impact from the construction and real estate management sector in Sweden, at a national level and from a lifecycle perspective. The indicators are based on the Environmental accounts from Statistics Sweden and are updated every year from 2016. Data is so far available for the period of 1993-2014.

Environmental indicators enable to follow the development of the environmental impact of the sector. Seven indicators are selected to monitor the most significant environmental impact:

- Air emissions - Greenhouse gases, nitrogen oxides, particulate matter
- Use of energy - Fossil fuels, renewable fuel
- Use of health and environmentally hazardous chemicals
- Waste generated (planned)

The environmental indicators show the following results: The construction and real estate management sector emitted 11.6 megatonnes of CO_2e in Sweden in 2014. In comparison with total annual greenhouse gas emissions in Sweden the sector accounted for 19 percent. The total fuel usage of the sector accounted for 79 TWh, which is 31 percent of total fuel use and 17 percent of total use of fossil fuels in Sweden, from a life cycle perspective. The sector also contributes to emissions in other countries through imported products. An estimate of greenhouse gas emissions linked to imported products show that the emissions are big outside Sweden, about 8.7 megatonnes CO_2e. The sector import more environmentally hazardous chemicals than those produced in Sweden.

The environmental indicators show that the environmental impact from the construction and real estate management sector is significant from a life cycle perspective. The indicators will be used to evaluate improvement and inform policy and practice.

Keywords: life-cycle assessment, policy and regulation, environmental indicators

1. INTRODUCTION

The Swedish building authority is responsible for building up and disseminating knowledge about the impact on the environment from the construction and real estate management sector, hence the sector. Environmental indicators have been developed in order to measure and track the progress of the environmental impact from the sector. The method used was developed during the years 2009-2014 and has been presented in two studies (Toller et.al, 2011, and Toller et al. 2013) and in three reports (Boverket, 2009, Boverket, 2011, and Boverket 2014). It is developed by Royal Institute of Technology, in cooperation with Statistics Sweden.

The environmental indicators are selected to reflect the national Environmental Quality Objectives (EQO) in Sweden, covering the most significant environmental impact from the sector. They are intended to be communicable and based on available data. The indicators to monitor the environmental impact are as follows:

- Air emissions - Greenhouse gases, nitrogen oxides, particulates,
- Energy - Fossil fuels, renewable fuel
- Use of health and environmentally hazardous chemicals
- Generated waste

The Environmental indicators show the environmental impact from the sector from a lifecycle perspective. A starting point was to describe the environmental impact based on activities during a building's life cycle, and translate it to a sector level. This includes the environmental impact of all construction activities that occur during a year in the sector. It applies to activities during the manufacturing stage, construction stage, in the finished building, from the demolition phase and transport within and between the various stages. The statistics on waste are under development. The reporting of this indicator differs so far compared to the rest, as it does not emanate from a life cycle perspective.

Emissions from imported construction products are shown separately. Export of building products and household energy is not included.

Environmental indicators show:

- How much is emitted/ used in the sector
- The share of Sweden's total emissions/ usage in the sector
- Development over time – However they are dependent of the economic situation and the temperature

2. METHOD

The basis for the environmental indicators is the National and Environmental Accounts produced by Statistics Sweden. The method used is a so-called input-output analysis (IOA), adjusted for the special needs from the Swedish building authority to illustrate the environmental impact from the sector from a lifecycle perspective.

This adjusted method of an IOA for the construction and real estate management sector was developed by the Royal Institute of Technology in collaboration with Statistics Sweden on behalf of the Swedish building authority. It is based on similar analyses previously made for the energy sector and the agricultural sector. The used method is described in two papers (Toller et.al, 2011, and Toller et al. 2013) and three reports (Boverket, 2009, Boverket, 2011, and Boverket 2014). It has been improved in the past years and the method described below differs slightly on some points.

The National Accounts is an internationally comparable accounting system. Environmental Accounts are based on National Accounts and aims at describing the relationship between economic activities and the impact on the environment. Economic data from the National Accounts is expanded with environmental statistics for each industry such as emissions, fuel usage and chemicals.

An input-output table from the National Accounts describes the relationships between different industries within an economy. It shows how output from one industry is used as input in other industries and vice versa. An environmentally extended input-output analysis therefore enables estimating the impact on the environment from a certain industry, both through direct and indirect effects.

The adjusted input-output method used aims to capture environmental impact throughout a life cycle perspective from the sector, i.e. from the production of material used as input in the building process until the building is demolished. It differs from a traditional IOA regarding industry classification, redistribution of space heating, renovations and additions for imports.

2.1 Industrial classification

In National and Environmental Accounts industries are classified according to EU:s recommended standard, NACE. The building authority's definition of the sector is represented well by the industries Construction of buildings (NACE 41), Specialised construction activities (NACE 43) and Real estate activities (NACE 68).

In National and Environmental Accounts, however, the Construction industry normally is presented as an aggregate, (NACE 41-43), which also includes Civil engineering (NACE 42). One reason for this is that the requirements from the European Commission on reporting input-output statistics within the EU are on this aggregated level. To enable analysis of the environmental impact only from the construction of buildings, i.e. NACE 41 and NACE 43, and from the real estate management, NACE 68, a special partition of the official statistics has been made in this project.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The method used for disaggregating the Construction industry has been improved compared to the previously used method. Further improvement of the disaggregation method would be useful and our hopes are that the official statistics will be presented on this disaggregated level.

To sum up, by disaggregating the construction industry and by analysing chosen parts of the construction industry together with the real estate management industry our approach differs from an ordinary input-output analysis.

The environmental indicators are available from 1993-2014. However, due to the change in the industrial classification from NACE Rev.1.1 to NACE Rev.2 the time series is only consistent for the periods 1993-2007 and 2008-2013 separately.

2.2 Redistribution of space heating

In National and Environmental Accounts the major part of the space heating is excluded from the real estate management industry (NACE 68), due to European praxis. Only a minor part of the space heating is included in NACE 68, such as heating of stairwells. The major part, however, is included in other sectors, such as other service industries, the household sector, the government sector and non-profit organisations.

Capturing the lifecycle perspective of the sector therefore requires a redistribution of the energy used for space heating, with the intention to burden the real estate management industry with the environmental impact linked to space heating.

Compared to National and Environmental accounts the redistribution of space heating involves a so-called extended system boundary. The redistribution of space heating implies that information from different industries is combined. The life cycle perspective of the sector is captured in a better way, but comparison with statistics on other industries will be misleading.

A corresponding redistribution is done for environmental impacts from for example repairs and renovation of existing buildings.

2.3 Additions for imports

The products used as input in the sector are either produced within the country or imported from other countries.

The environmental impact of imports does not take place in Sweden, but in the countries where the products are manufactured. Environmental indicators should highlight the total environmental impact of the sector from a life cycle perspective. Hence, emissions from the production of imported products must be taken into consideration.

Different countries have different modes of production. Our experiences are that if emissions from imported products are handled as if they were produced in Sweden, they are underestimated. When it comes to greenhouse gas emissions, Statistics Sweden has improved the method and estimate emissions from imports by assumptions regarding the production in different countries, which would give a more accurate result.

3. RESULTS AND DISCUSSION

3.1 Environmental impact from the sector

The environmental impact from the sector was between 4-31 percent of the total impact in Sweden, see Table 1. The contribution from imported products is considerable. See especially the greenhouse gas emissions which are nearly doubled when emissions from imported products are included in the total emissions from the sector. For the greenhouse gas indicator, the estimation of emissions from imports is improved compared to the method presented in the paper from 2013 (Toller et.al 2013).

Environmental indicators for the sector 2014	Emissions from the sector, domestic production	The share of the sector, total domestic emissions in Sweden	Emissions from domestic production and imported
Greenhouse gases *(tonnes CO_2-e)*	11 568 305	19 %	20 248 149
NO_x *(tonnes)*	28 840	11 %	43 114
SO_2 *(tonnes)*	8 333	13 %	12 713
Particles *(tonnes)*	12 871	25 %	14 653

Table 1: The total emissions and use for the chosen indicators during 2014

Environmental indicators, the sector 2014	Use in sector, domestic production	The share of the sector, domestic use in Sweden	Total use domestic and imported
Total use of fuels *(TWh)*	79	31 %	88
– *Bio fuels*	50	58 %	52
– *Fossil fuels*	28	17 %	36
Chemicals hazardous for the environment (tonnes)	65 385	4 %	230 494
Chemicals hazardous for the health *exclusive cement* (tonnes)	991 326	10 %	1 837 646

3.2 Greenhouse gases

The total greenhouse gas emissions from the sector were 20.2 megatons of carbon dioxide equivalents in 2014, including emissions from imported products (Figure 1). Of those, 11.6 megatons were released in Sweden. Compare with total annual greenhouse gas emissions in Sweden this amounts to about 19 percent. The indicators are dependent of the actual climate, e.g. in 2010´s the higher emissions is explained by the colder temperature that year.

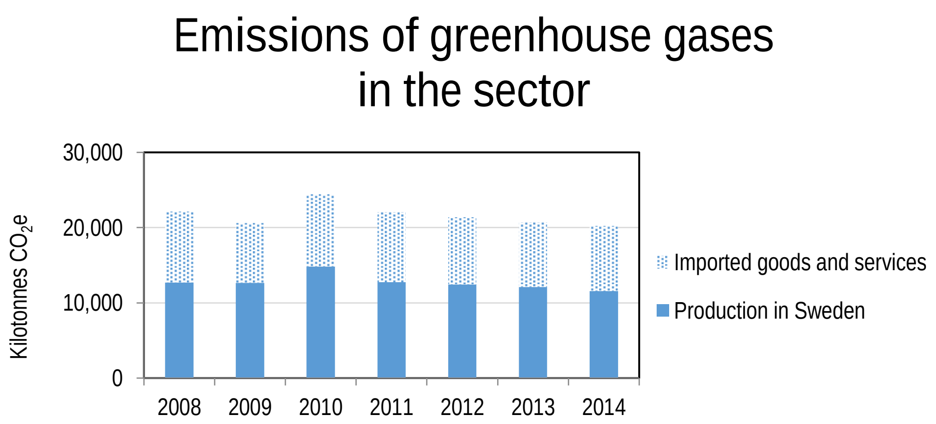

Figure 1: Total greenhouse gas emissions from the construction and real estate management sector in kilotonnes of carbon dioxide equivalent (CO_2e) released in Sweden (domestic emissions) and from imported products, viewed from a lifecycle perspective

3.3 Use of fuel

The total use of fuel in the sector amounted to 88 TWh in 2014, including imported products. Of these, 79 TWh was used in Sweden, equivalent to about 31 percent of Sweden's total use of fuel. Out of the 79 TWh, 50 TWh was from biofuel and 28 TWh from fossil fuels. The total use of fuel in the sector varies from year to year, depending on how the temperature varies; this applies to the energy for heating. Cold years the use of fuel increases.

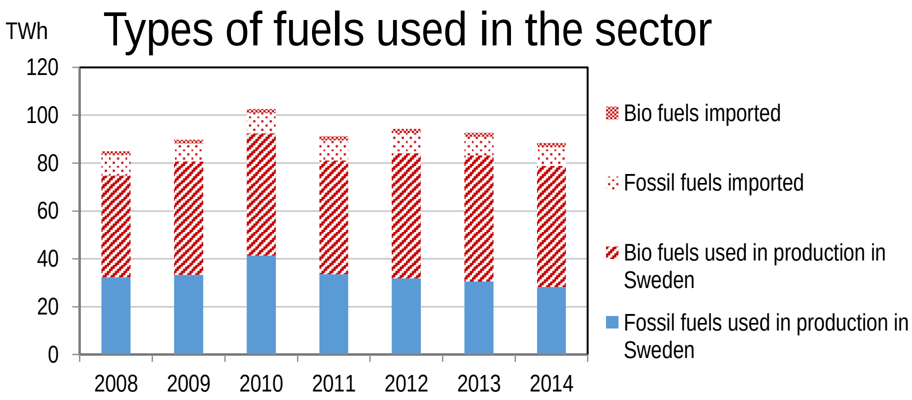

Figure 2: Total use of fuels between 2008 and 2014 in the construction and real estate management sector divided in domestic use and from imported products, and also in bio fuels and fossil fuels. The use of fossil fuels includes coal and coke, petroleum and petroleum products, natural and town gas and peat, fossil waste, etc. The biofuels are solid biomass, liquid biomass, biogas and biogenic waste.

3.4 Use of hazardous chemicals

In 2014 the use of chemical products hazardous for the health in the sector amounted to nearly 1.8 megatonnes if cement was excluded and approximately 3.1 megatonnes if cement was included (see Figure 3). Chemical products hazardous for the environment amounted to a much lower level, 230 kilotonnes in 2014.

The results include the use of chemical products that are classified as health or environmental hazardous in the sector. Examples of such products are paint, thinners and insulation. Products not included in the analysis are for example tar, asphalt and bitumen, as these are not classified and therefore not included in the Environmental Accounts. However, the quantitatively smaller amounts of additives in the asphalt are classified according to the Regulation (EU) No 1272/2008 on classification, labelling and packaging of chemical substances and mixtures (CLP), and are therefore included in the calculations.

The manufacture of cement, lime and gypsum accounts for a large proportion of the use of hazardous chemical products. These products are mainly classified as corrosive (C) and/ or irritating (Xi) according to the CLP Regulation. Products of cement are primarily a health and safety problem in the work environment. After the product has hardened it has no longer these properties. In order to avoid other hazardous chemicals to "disappear" in the statistics we have chosen to present cement separately.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

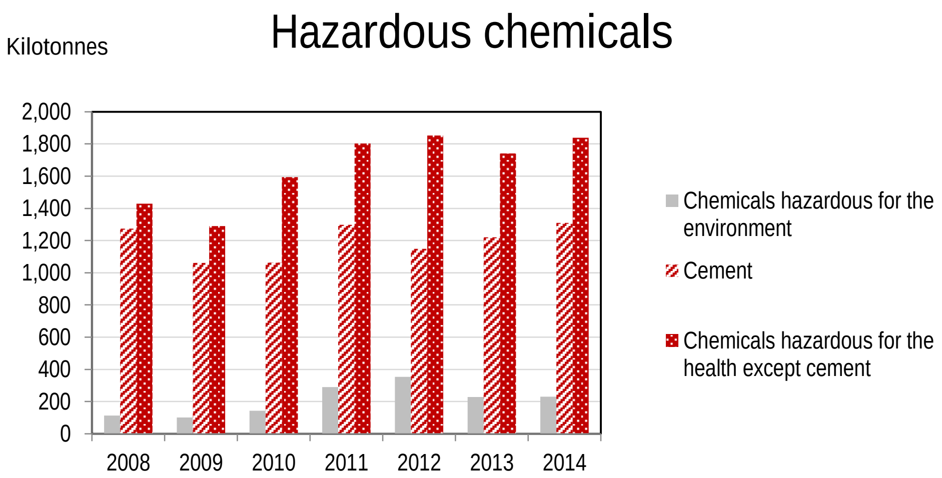

Figure 3: Total use (incl. imports) of health and environmentally hazardous chemical products (kilotonnes) from the construction and real estate management sector during 2008-2014

4. DEVELOPMENT NEEDS

Even though the method is ready to be used as it is presented in this paper, there are needs of further development of the indicators, according to the Swedish building authority. For example a better estimation of the emissions from import is needed for the rest of the indicators (the greenhouse gas indicator has a better estimate). It is a big difference in accounting as if the products were produced in Sweden or in the actual country, due to different modes of production.

The indicators are dependent of the economic situation and temperature. This will be visualized in the figures in the future. The indicators are also possible to regionalize. That's of interest for the evaluation of the EQO. The waste indicator is based on official waste statistics and there is an ongoing development of them since the data is inadequate.

5. CONCLUSIONS

The Swedish building authority's environmental indicators show the following about the sector environmental impact: The sector emitted 11.6 megatonnes of carbon dioxide equivalent (CO_2e) in Sweden in 2014. Compared to the total annual greenhouse gas emissions in Sweden this is about 19 percent. The sector´s total fuel usage in Sweden is 31 percent. Both from a life cycle perspective. This means a 4-31 percent sector if we keep to the emissions/ use in Sweden.

The sector also contributes to emissions in other countries via imports. An estimate of greenhouse gas emissions linked to imported products show that they are big outside Sweden, about 8.7 megatonnes. The sector import more environmentally hazardous chemicals than those produced in Sweden.

The results show the importance of having a broader perspective in the analysis of environmental impacts. For example the constructions phase (material manufacturing) and the contribution of imports is important to include. You miss a large part of the environmental impact if only domestic emissions are reported.

The method can be used for follow-up. Several countries could use the method as statistics are available. The European requirements for international reporting cover the entire construction sector. It is desirable to have a finer breakdown of the sector. Sharp focus on the environmental impact of buildings creates a need for better statistics/ finer division.

ACKNOWLEGEMENT

The authors thank the Royal Institute of Technology and Statistics Sweden for developing the method.

ABSTRACT

People are spending more and more time in indoor, especially for highly populated cities like Hong Kong. Prolong exposure to the indoor air pollutants can induce harmful effects to occupants' health and lower their productivities. Full indoor air quality (IAQ) assessment is the best way to diagnose unsatisfied IAQ and to identify the sources for mitigation and remediation to maintain a comfortable and safe indoor environment. However, without the initiative and support provided, high implementation cost and manpower lower the incentives for conducting IAQ assessment as well as managing the IAQ of a premise voluntarily. With growing concerns regarding the possible health problems and illnesses caused by exposure to indoor pollutants, territory-wide IAQ screening is urged to improve the overall IAQ situation in Hong Kong. In this study, feasibility of implementing IAQ index in Hong Kong is evaluated. Two approaches are suggested: i) IAQ index with surrogate indicators (IAQSI) and ii) IAQ health index (IAQHI). Proposed indices shall be easily understood by general public and thus can serve as an indicator of perceived IAQ of an indoor environment.

Keywords: Indoor Air Quality (IAQ), IAQ index, IAQ policy, screening

1. INTRODUCTION

Nowadays, people spend over 85% of their time indoor (Robinson and Nelson, 1995; Burroughs and Hansen, 2011). Workplace indoor air quality (IAQ) has always received focuses since poor IAQ can impede business. In recent years, IAQ in other indoor environments, for example residential buildings and sports centres, has gained social attentions and concerns regarding the potential health effects caused by poor IAQ. Indoor air pollutants are originated from the infiltration of ambient air pollutants from the outside and the generation from indoor sources. Indoor sources include indoor fixtures, building materials, operating machines and even occupants in the premises. IAQ concerns focus mainly on the potential health threats and the economic consequences of unsatisfied IAQ. Problematic IAQ has been correlated to health effects ranging from mild allergic reactions to adverse cancerous and fatal consequences. It also impedes working performance and causes discomfort to the occupants. Other than health problems, inadequate IAQ management can lead to economic consequences. Decrease in productivity and increase in sick absentees resulting from poor IAQ increase labour and production cost (Fisk, 2000a; Fisk, 2000b; Raw and Leaman, 1990). Costs arose from IAQ-related health problems pose burden on medical sector. In long-term, poor and unsatisfied IAQ creates negative effects to not only the building users and management but also the society as a whole.

IAQ problems in well-developed cities like Hong Kong are relatively complex, and therefore difficult to deal with. While most of the research efforts, legislations and policies in Hong Kong focus on mitigating and controlling the ambient air pollution, little development has been done in managing IAQ. In fact, indoor air pollution can be a greater problem than the ambient one because indoor environments are mostly enclosed with limited ventilation. Conducting full IAQ measurement to identify the root problems and the need for mitigation or remediation is no doubt the best way to manage and improve the air quality of an indoor environment. Yet, recourses and time involve can be a burden to small businesses and parties, which lower their incentives in tackling the IAQ problems they are facing.

To minimize the resources needed to be put onto IAQ management, extensive research has been carried out to develop diagnostic tools for identifying poor IAQ, which is the foremost and an essential step in preliminary IAQ screening strategies. IAQ index, proposed by Wong et al. (2006), provides an easy and understandable screening tool especially useful for IAQ management over a large area of interest. This study investigates the feasibility of implementing the IAQ index as a surveillance tool for managing the overall IAQ in Hong Kong.

2. IMPLEMENTION OF INDOOR AIR QUALITY (IAQ) INDEX IN HONG KONG

Pre-assessment tools have been proposed in two approaches: i) Surrogate indicator approach; and ii) Health-risk approach. Surrogate approach reduces the efforts by conducting a less complicated but still highly representative assessment, while health-risk approach relates assessment result directly to human well-being. Proposed IAQ index with these two approaches are the IAQ index with surrogate indicator (IAQSI) and IAQ health index (IAQHI).

2.1 IAQ Index with Surrogate indicator (IAQSI)

Indicator approach has also been widely used in a variety of studies, since it is a practical, efficient and economical way to investigate the status of a subject without huge investment of resources. In disease control and medical diagnosis, health indicators, also known as bio-markers, are often used to identify potential diseased patients. For example, HLA-B27 is an antigen with positive linkage to autoimmune diseases (Jenisch et al., 1998; Cauli et al., 2002; Monnet et al., 2004). In the field of sustainable built environment, research has also been done on the investigation of using surrogate indicators for preliminary IAQ assessment, which is believed to be successful in minimizing the implementation cost of IAQ management.

Assessment using IAQSI looks at high fractional quantities of the common indoor air pollutants. The proposed IAQSI θ uses the average fractional dose φ_j^* of the average level φ_j to the exposure limit $\varphi_{j,0}$ of N parameters j. Exposure limit selected can be from any standard, with the selection criteria depending on the management strategies. High value of θ indicates a higher probability of unsatisfied IAQ in an indoor environment. Equation 1 shows the calculation of the IAQ index (Wong et al., 2006).

$$\theta = \frac{1}{N}\sum_{j=1}^{N}\varphi_j^* ; \qquad \varphi_j^* = \frac{\varphi_j}{\varphi_{j,0}}$$

Equation 1

Surrogate indictors as indication of the quality of an indoor environment are selected based on their respective representative natures, which reflect the performance of the building systems and the occupant situation. Carbon dioxide (CO_2), particulate matter (PM10) and total volatile organic compound (TVOC) are proposed to be the most indicative IAQ parameters, since they represent the occupants load, indoor activities and ventilation rate, system filtration performance and indoor activities, and building emission, finishing and human activities accordingly, at the same time are independent to each other (Wong et al., 2006).

The effectiveness of IAQSI in identifying premises with problematic IAQ can be evaluated using likelihood ratio, where likelihood ratio $Lr > 1$ suggests a high risk of having an unsatisfied IAQ, vice versa. Equation 2 illustrates the computation of Lr, where TP and TN are the number of fail and pass counts, nTN and nTP are the total pass and fail counts.

$$L_r = \frac{TN}{TP}\frac{n_{TP}}{n_{TN}}$$

Equation 2

Different combinations of the abovementioned surrogate IAQ parameters are tested to evaluate and illustrate the possible baseline IAQ control strategies in Hong Kong air-conditioned offices (Wong et al., 2016), i.e. how effective the IAQSI is in identifying problematic IAQ with minimum resources invested in the screening process. The difference between using 1) CO_2 only, 2) CO_2 and PM_{10}, and 3) CO_2, PM_{10} and TVOC, (IAQSI θ_1, θ_2 and θ_3 respectively), is investigated. To facilitate the understanding of IAQ screening results among general public, corresponding likelihoods of experiencing poor IAQ are expressed verbally with the proposed expression below.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

1. Very improbable ($P'_d \leq 0.05$),
2. Improbable ($0.05 < P'_d \leq 0.2$),
3. Possible ($0.2 < P'_d \leq 0.4$),
4. Probable ($0.4 < P'_d \leq 0.7$),
5. Very probable ($0.7 < P'_d \leq 0.9$); and
6. Almost certain ($P'_d > 0.9$).

P'_d is the post-test probability, which can be calculated using Equation 3. P_d is the pre-test probability, O_d and O'_d is the pre-test and post-test odd, N_d is the number of unsatisfied IAQ in N regional IAQ samples.

$$P_d = \frac{N_d}{N}; O_d = \frac{P_d}{1 \; P_d}$$

$$P'_d = \frac{O'_d}{1 + O'_d}; \; O'_d = O_d \times L_r$$

Equation 3

2248 office IAQ data undergo screening process using IAQSI θ1, θ2 and θ3, in which offices are categorized into respective ranks (verbal expression) according to the post-test probability P'd (Reagan et al., 1989; Vick, 2002). Result shows that IAQSI θ1 can already screen out office samples that have relatively less chance of experiencing poor IAQ, while θ2 and θ3 offer better resolution over θ1, and are effective in identifying lower and higher risk groups among tested subjects. Ranks of the offices generally fall into the same category when they are subjected to full IAQ test (HKEPD, 2003). This part of the feasibility study shows that even with the measurement of just CO_2 as the indicator pollutant in IAQSI, the screening test already contains substantial usefulness and accuracy in reflecting the general IAQ in a premise with justified resources invested. The proposed IAQSI might be a useful tool for setting up a public IAQ surveillance programme and baseline control policy in Hong Kong.

2.2 IAQ Health Index (IAQHI)

Well-develop cities like Hong Kong should protect the health of general public, therefore maintain good IAQ to ensure good quality of life is essential and shall be incorporated in the management policy. Health-risk approach in risk management emphases in the effectiveness and the balance between cost for risk reduction and the benefits gained, and any strategies shall be set as low as reasonably practicable (ALARP) (H.M.S.O, 1974). Health risk-based air pollution index has been adopted in Hong Kong for ambient air pollution. The Air Quality Health Index (AQHI) provides the estimated combined excess health risk by using the sum of the percentage added health risk (%AR) of daily hospital admissions attributable to the average concentration of sulphur dioxide (SO2), nitrogen dioxides (NO2), ozone (O3) and PM10. Equation 4 exhibits the calculation steps of AQHI (Wong et al., 2013; HKEPD, 2013).

$$\%AR = \sum \%AR(c);$$

$$\%AR(c) = \{\exp[\beta(c) \times C(c)] - 1\} \times 100\%$$

Equation 4

Concept of IAQHI takes into the consideration that the effects of air pollutants to health are the same regardless the environment one is in. Therefore, expanding the AQHI by incorporating common indoor air pollutants into the calculation can make AQHI more comprehensive in predicting the total health risk of a person when he/ she breathes in the surrounding air in an environment. The proposed health index is named as IAQ Health Index (IAQHI).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Addition of health risk of a certain indoor air pollutant into the calculation of IAQHI shall be carefully considered due to the complication induced by potential chemical reaction between multiple air pollutants. Dominant or representative IAQ parameters (CO_2 and TVOC), or IAQ parameters which are confirmed to impose health risks (e.g. Formaldehyde (HCHO)) can be included in the calculation, yet linkage between the pollutant itself and the health effects, i.e. relationship between pollutant levels and hospital admissions rate, shall be determined through extensive survey and data collection.

Further consideration of integrating the well-developed risk assessment approaches, for example Disability-Adjusted Life Years (DALY) for quantifying the burden of mortality and morbidity due to the exposure to certain level of air pollutant (Murray and Lopez, 1996), with IAQHI to compute the %AR may expand the coverage of the application of the index to international level.

It is noteworthy that unavoidable difficulties must be encountered in evaluating the health risks regarding the effect of combined exposure to multiple pollutants. No currently available guideline is suggested to deal with such issue. Another uncertainty in identifying health effects is the fact that individuals respond differently to the same exposure of a pollutant. Susceptibility to chemicals can be largely influenced by the conditions of each individual such as gender, ethnics and health history. IAQHI takes hospital admission as the health risk, which is justified enough to minimize such concerns.

In addition, identifying the health risks related to evaluation of some indoor air pollutants such as CO_2 can be difficult, since the related health effects confirmed by far are only general and mild. Correlation between actual hospital admission and pollutant levels may require extensive and long-term health research conducted by national organizations like World Health Organization (WHO).

3. CONCLUSION

Sustainability has always been the main focus of developing Hong Kong into a world-class city. In the context of sustainable city development, provision of a healthy and comfortable environment shall be taken into consideration. IAQ has grown popular in research field in the past few decades. The establishment of statutory region IAQ control and management policy to safeguard the well-being of residents is essential. Extensive regional IAQ database has been developed in Hong Kong which is comprehensive to provide IAQ profile of Hong Kong. Collaborative work between the government, research institutes and the business sector shall be established to put the research efforts into practical use. With incentive measures and resource support by the authority, the proposed IAQ indices: IAQSI and IAQHI might be useful, practical and economical diagnostic tools for setting up a public IAQ surveillance programme as well as IAQ management policies and legislations in Hong Kong.

Integrating Capital Cost with Energy Efficiency: Cost@Work

TANG Chee-khoay[a]

[a] CK@Work Sdn Bhd, Malaysia, ck@gbeet.com

ABSTRACT

It has always been a perception that implementing energy efficiency in buildings increases capital cost for developers. Passive features such as additional roof insulation, wall insulation, high performance glazing, daylight harvesting and etc. increases capital cost in new buildings. Active features such as variable flow, radiant cooling system, desiccant dehumidification and etc. are also seen as additional cost to developers. Compounding on to this perception is that the architects and engineers often works independently of one another, with each party often ignoring the benefits implemented by the other party.

A software was developed to integrate both the passive and active features within a simple shoe-box building scenario to provide peak cooling load computation, annual energy consumption prediction, while computing the building material/equipment capital cost at the same time. The most interesting part of this software is its ability to automatically run through a database of building material and equipment to calculate the building energy consumption and peak load of each combination. It then hunts for the lowest capital cost and/or lowest lifecycle cost of the project by calculating the combined capital cost for each of the tested combination of building material, equipment and air-conditioning selection.

A version of this software is in operation since early 2016 and has been providing indications that that in almost all cases, energy efficiency in building can be improved while reducing capital cost. In fact, capital cost reduction up to 7% of total building construction cost has been regularly demonstrated with this software, while at the same time improving energy efficiency in building.

The output from this software is a clear demonstration that a truly integrated design strategy that combines passive, active and costing features within a single platform will yield better energy efficiency at a lower capital cost for the building industry.

Keywords: building energy simulation, lifecycle assessment, energy saving

1. INTRODUCTION

There exist many buildings today that are claimed, designed to be energy efficient. However, it is still very much a market perception today that an energy efficient building is more expensive to build. One of the early successful demonstration of low energy office building in Malaysia was even documented, in 2005, to have an additional cost of 10% above the base total building construction cost.

Additional cost in an energy efficient building is largely fuelled by the increased complexities of air-conditioning equipment and better building fabric on a building. Examples of such items are:

- Variable air volume instead of constant air volume
- Variable speed chiller instead of conventional chiller
- More efficient lighting system instead of conventional light
- High performance double glazing with low emissivity instead of typical single glazing
- Increased building fabric insulation
- And more.

However, improving energy efficiency also reduces the building cooling load. A reduction in cooling load reduces the capacity (size) of air-conditioning system for a building. This lead to a reduction in capital cost. Unfortunately, there is hardly any actual case study of the actual amount of capital cost reduction due to implementation of energy efficiency in building. This leads to the perception that energy efficiency in building is expensive.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

A software, Cost@Work, was developed recently that is able to address this missing link between energy efficiency and capital cost. This software is currently based on Malaysian climatic conditions and building construction practices. The software computes both capital cost and running cost instantly based on a shoe-box model allowing important decision related to energy efficiency and capital cost to be made instantly. These information, provided upfront, allows the design team to set the design direction of a building at the onset of the design stage, to optimize both capital and running cost of a building.

Finally, the benefit in being able to demonstrate a reduction in capital cost while implementing energy efficiency is immense in the engaging developers to consider sustainability in all buildings.

2. ENERGY EFFICIENCY IS COMPLEX

Energy efficiency in building design involves the selection of building fabric, lighting system, air-conditioning system, operational practices, passive cooling strategy and more. And within each major element, there are even more elements that can to be optimized. For example, a building fabric will need to optimize its insulation, thermal mass, solar absorption, emissivity, shading (as in a double roof) and more. There are at least hundreds, if not thousands of opportunities for energy efficiency in a building. Due to the near limitless possibilities of energy efficiency in buildings, the task of finding the least cost and/or best lifecycle method of addressing and optimizing energy efficiency in a building is not simple.

3. ENERGY EFFICIENCY AND COOLING LOAD

An energy efficient building is often the combinations of many energy efficiency features that is implemented on a building. The Passive and Active Design Guideline provided by the Building Sector Energy Efficiency Project (BSEEP) has shown that most energy efficiency feature provides an improvement in energy efficiency in a building by an average of 1% in Malaysian conditions. The impact on peak cooling load is even less per feature wise. An energy efficiency case study made for a high-rise office tower in Malaysia showed a possibility of reducing building energy consumption over 60% with the implementation of approximately 50 energy efficiency features in the building. However, the peak cooling load reduction is only 30%. This indicates that on average the peak cooling load reduction is less than 1% per implemented energy efficiency feature.

Due to this, many (if not all) air-conditioning engineers have subliminally learned that impact of a single element or product on the cooling load is marginal at best, and therefore are always reluctant to reduce the initial design capacity of the air-conditioning system. Unintentionally, many existing energy efficient buildings have an oversized cooling system installed.

4. BUDGETING OF CAPITAL COST

Budgeting of capital cost in the development of Malaysian buildings are split into 2 categories; the building cost and; the mechanical and electrical equipment cost.

A quantity surveyor will estimate the building cost based on the architectural and structural engineer's drawings and specifications; while the mechanical and electrical equipment cost are estimated by the appointed trade engineering consultant. These parties often do not communicate with one another well enough. Products such as roof and wall insulation; and better glazing properties that are specified by architects and quantity surveyors are often not considered by the air-conditioning engineers.

However, these items have an influence on a building peak cooling load. And the peak cooling load of a building is the key determination of the air-conditioning equipment cost. The larger the capacity, the higher the cost will be. With the average installed cost of air-conditioning system today ranging between 10% and 20% of a building total construction cost, air-conditioning represents one of the highest single element cost in a building construction.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

5. LACK OF COMMUNICATIONS

Building construction is a very complex process. It involves many parties because it is impossible for any one party to be able to design every part of a building. Over the years, the building industry has fine-tuned this process into a very lean linear system of communication between the different parties.

Putting it simply, the architect provides the drawings and specifications; and the design engineers size the necessary equipment for the building, with very little integrated design opportunity.

Most architects have little knowledge of an air-conditioning system. They have little understanding of the building fabric impact on the air-conditioning load, capital cost and running cost. However, they are the primary decision maker in charge of specifying building fabric. Meanwhile, most air-conditioning engineers have little to no interest in building fabrics, leaving the selection entirely to the architects.

6. BUILDING ENERGY SIMULATION

Building energy simulation studies have often been touted as the solution to the issues raised. Energy simulation enable studies to be made, to optimize building design on energy efficiency and cooling load. However, there are 2 major barriers that needs to be overcome for this solution to work in practice:

- Building simulation studies are complicated.
- Capital cost has not been made as part and parcel of building analysis.

6.1 Complexities in building energy simulation

Building energy simulation study is a fairly complex matter. Even with the most user friendly software in the market today, efforts are required to ensure that the defaulted values and assumptions made by the software matches with the conditions of the building and site location. This is not often the case. All of these software defaulted the values and assumptions based on the standard of practice of their primary market, such as US, UK or Europe. Buildings in other location requires significant changes to the defaulted values. It often takes up to several weeks of intensive work to ensure that the building was even modelled correctly.

Getting a building modelled correctly is not a simple process at all. A 3D model of a building is only the beginning of energy studies in a building. Information is also required on the details of the building envelope for each wall, glazing and roof; occupant's load and profile; equipment's load and profile; lighting load and profile; type of air-conditioning system used; climatic data; phantom load assumption, elevators and controls power consumption; ventilation in car park; ventilation in toilet; outdoor air quantity; infiltration assumption and more.

Sometime, part of basement wall is buried under the earth, part of it not. Part of the building is naturally ventilated and part of it is not. Part of a floor may be directly connected to the earth, while part of it is exposed to outdoor air. Standards on construction for walls, roof and glazing is also different from country to country. Thermal breaks requirements are different depending on the climate. Typical working hours, operational practices on lighting, air-conditioning and type of system available is also different based on site location. In short, there are thousands of numbers that need to be reviewed for each simulation study.

Furthermore, a good building energy simulation analysis requires knowledge of multiple trades. For example, a building energy simulation practitioner need to know the different types of building fabrics that is available in the market for wall, roof and glazing. This person also has to understand the properties of insulation, solar absorption, emissivity and more to be able to give good advice to a project. Information provided by manufacturer datasheet can sometimes be wrong or have units mislabeled. There is also a need to understand outdoor air requirement for each spaces and infiltration possibilities based on the construction practices at that location. There is also a need to know about the availability of various types of lighting system based on the building location.

Finally, an air-conditioning system is an extremely complex beast even for an experienced engineer. For example, the available fan and motor efficiency is different for different types of fan and flow rate. The total pressure drop of a fan is different for different types of cooling coil, air filter, distance of duct, duct size and more. Performance of a chiller efficiency at peak and part load is strongly dependent on the selected capacity of the chiller. Small chiller typically has lower efficiency than larger chiller. Cooling tower optimization of control is different for different wet bulb condition at different location. Even developers of energy simulation software themselves do not have full understanding of the intricacies of each and every equipment. And yet there is a very unrealistic expectation in the building industry that any building architect and engineer can conduct building energy simulation studies accurately for any building in this world with the use of such complicated tool.

6.2 Lack of integration of capital cost within energy simulation

There is hardly any building energy simulation tool today that integrates capital cost into building energy simulation studies. This is a drastic loss of opportunity for these software to provide quick answers to the most important question for a building developer – which building product or strategy of operation will yield the best return on investment on this development?

Typically, the person conducting the simulation study provides the results for different options of design; other trades are than required to provide the costing on these options. This process often takes up several weeks to arrive at the final answer. The long duration of such a process poses a major limit on the number of studies that can be carried out.

7. COST@WORK

Initial version of Cost@Work was a tool called BEET, short for Building Energy Estimation Tool. It was developed in 2005 in Excel, to allow general building design practitioner an easy method to estimate building energy consumption with minimum inputs. The simplicity of input on this software encouraged the tool to be adopted by Association of Consulting Engineers Malaysia (ACEM) for Malaysian building industry. By entering easily understood data into approximately 50 cells, the software is able to make a general estimate of the yearly energy consumption for a building in Malaysia.

The annual cooling load of a building was computed using the definition of Overall Thermal Transmission Value (OTTV). The OTTV is a familiar term in South East Asia and is used by Malaysian Standard, MS 1525, since 1990s. It provides a manual method of calculating the average thermal transmission value through a building fabric over a period of a year. The original form of OTTV was developed for ASHRAE Standard 90 in 1975 and was refined again in 1980 [6][7].

An enhancement of BEET was performed in 2015 under Building Sector Energy Efficiency Project (BSEEP) in Malaysia. A stakeholder consultation was made with the building industry practitioners to seek feedback on how the new software should work. Feedback received was to make the software ‘idiot proof’ rather than enhancing the software computational features. It was highlighted that many architects and engineers do not know the correct value to enter into the software such as U-values, shading coefficient, fan efficiencies, fan total pressure, system coefficient of performance and etc.

Based on the feedback received, BEET made changes to the cooling load computation method to Ashrae Radiant Time Series Method (RTSM). The use of RTSM, allowed the software to estimate the peak and average cooling load of a building instead of just the average cooling as provided by the older version. The peak cooling load allowed an early estimation to be made by the software on the type of fan, pumps and chillers that may to be used without any the need of an expert to provide input. This prevented users from entering values that are not realistic into the analysis. In addition, input data for all technical inputs were fixed to a pull down menu to select the types of wall, glazing, roof, lighting system and etc. using well-known generic terms that is easily recognized in the building industry. Most of the pull down menu was provided based on the selection of 4 options; inefficient, typical, efficient and very efficient scenarios. These features limit the potential error a person can make by ensure that all values entered are within reasonable range, thereby, ‘idiot proofing’ the software.

In 2016, BEET version 2 was developed into Cost@Work with the primary objective of optimizing building design based on capital cost, running cost, payback period, return in investment and lifecycle analysis. A product cost database of building material, lighting and air-conditioning was added into the software. With the inbuilt cost database, Cost@Work able to run a subroutine to test each and every design option that is available in the software

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

to provide an estimate on net capital cost and running cost of it. A net capital cost refers to the total cost of air-conditioning system together with the building material or product selected.

The software is able to compares all options of wall, glazing, roof and etc. that is available in the database. For each element type in the database, it computes the total element capital cost, building running cost and cooling equipment cost (from the peak cooling load). The net total capital cost of the element with the cooling equipment are then analyzed together to find the best design option for the building and at the same time computing the running cost.

For example, it may compute that the use of a 100mm thick concrete wall will cost the building RM 300k for the wall and RM 17.5 million for the air-conditioning system. An insulated wall option will cost the building RM 900k for the wall and RM 16.6 million for the air-conditioning system. Analyzed individually the additional cost for an insulated wall is 300%, while the air-conditioning cost was reduced by 5%. However, when these numbers are analyzed together in absolute values, the insulated wall reduces the capital cost of the building by RM 300k, while improving energy efficiency at the same time.

This analysis is conducted for the entire database of building envelope and lighting system within minutes by the software, providing a roadmap of design options for the lowest capital cost, highest energy saving and lifecycle analysis of 5, 10 and 20 years.

In short, Cost@Work is able to provide instant documentation with engineering calculation that it is possible to improve energy efficiency in building while reducing capital cost at the same time. It provides an output that is easily understood by the building investors that are focused at their rate of return on investment.

8. VERIFICATION

While, the financial computation in Cost@Work is easily verified using a manual calculator, the verification of the software is required on its cooling load computation engine that was based on Ashrae Radiant Time Series Method.

A verification work was conducted under BSEEP project using IES<VE> and BEET version 2 software, which Cost@Work was developed from. The verification procedure follows similar methodology as Ashrae Bestest 140: Test Procedures “Building Energy Simulation” Tools, where a range of identical design options were tested on both software and its results compared with one another.

The verification study compares the predicted Building Energy Intensity (BEI), building yearly energy consumption in kWh/(m^2.year) and peak cooling load in kW of cooling power. Results of the study showed good agreement between the 2 software as shown in Figure 1 below. A detailed report on the verification study can be found within the BSEEP project.

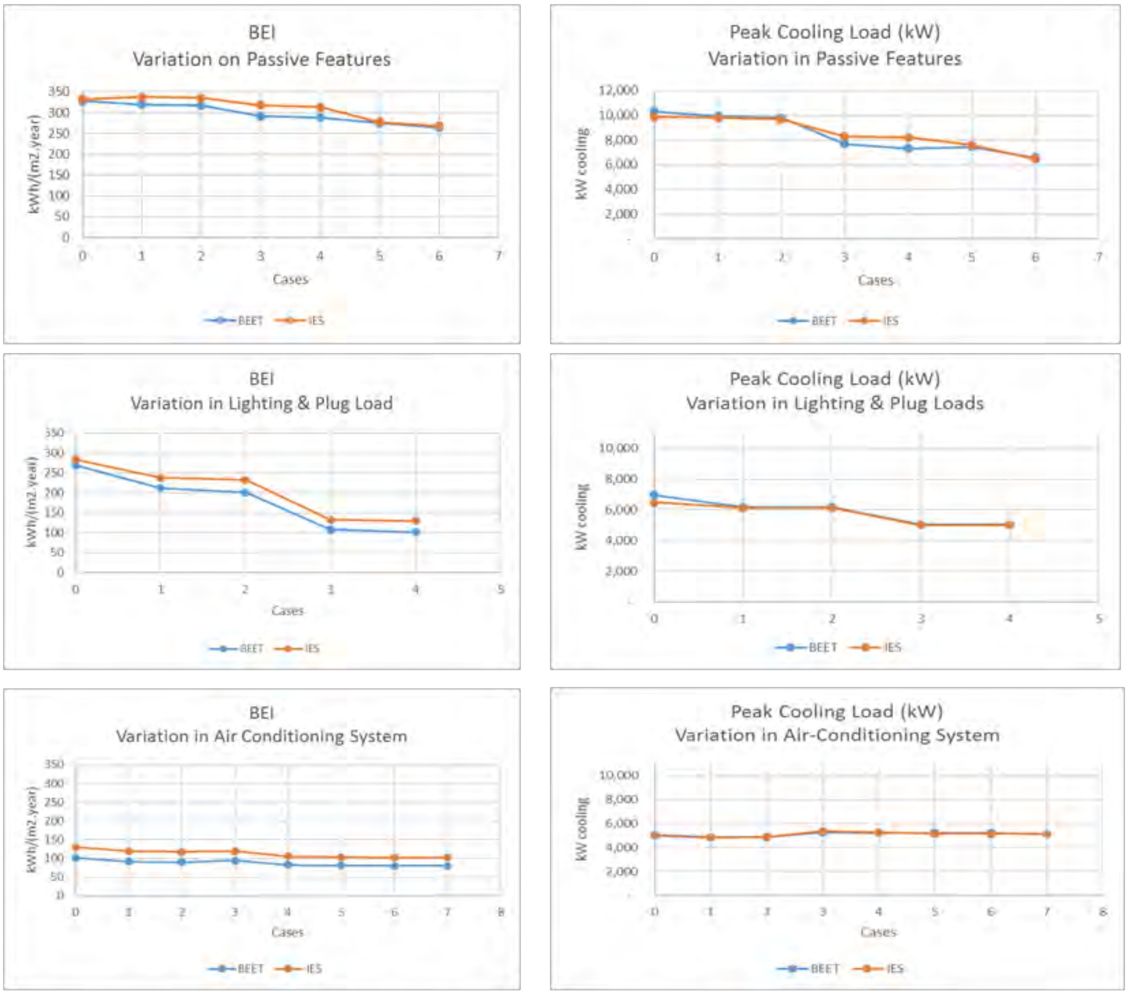

Figure 1: Verification results between IES<VE> and BEET

9. SUMMARY

Cost@Work was deliberately made simple for quick initial analysis to be conducted easily at an onset of building design development while minimizing the risk of errors in data entry. It gives immediate computation of the estimated running cost, peak cooling load and capital cost of building elements and air-conditioning system. This allowed the software to provide immediate comparison of payback, rate of return and lifecycle analysis of various design options in a building.

In addition, the language of the software was kept simple and easily recognizable by building design practitioners. This will encourage better communication between the different trade discipline, allowing consultants to understand each other easily.

As a pre-design tool, the accuracy provided by Cost@Work is more than adequate for key decision to be made early on in the design process to optimize a building capital cost and energy efficiency.

Finally, such a software encourages the building industry to pursue energy efficiency in buildings, as it can now be proven from the earliest stage of design that energy efficiency is capable of reducing capital cost when it is done right.

ABSTRACT

Since 2007, urban cities have become the main living environment of humanity, as opposed to rural areas. Thus, with the increase of urban areas, it is appropriate to develop techniques for the orderly and integrated growth of the cities. The concept of Smart City arises in this context. Considering the particular challenges of each city to become a Smart City, it is necessary to select specific indicators to meet these different requirements. This article aims to select the most adequate indicators to measure Vitória's performance as a Smart City. The European Smart Cities assessment tool was selected and studied to serve as a reference for the selection process of indicators. Afterwards, the indicators were selected based on suitability, clarity and availability criteria, and weights were assigned by their relevance, based on their compliance with the strategic goals of the city. This study suggests the indicators to measure Vitória's performance and reveals the need to improve the tool with the addition of indicators that are more suitable to local needs.

Keywords: smart city, indicators, green rating tool

1. INTRODUCTION

In 2007, the world's urban population surpassed the rural population for the first time in history. Currently, 54% of the world population live in urban areas, and the forecast is that by 2050 this figure will reach 66%. In Brazil, the urbanization rate is even higher. Currently, 85% of the Brazilian population lives in cities, and it is estimated that by 2050 this figure will reach 91% (United Nations, 2015). Increasing urbanization inflicts obstacles to cities, as it contributes for the emergence of infrastructure, mobility, and environmental problems, and consequently affect the quality of life of the population. In this context, the Smart City concept arises, as an urban planning model aimed at the development of cities through a combination of human and technology capital (Angelidou, 2014).

Although there is no consensus about its definition, it is widely held that Smart Cities are characterized by the use of Information and Communication Technologies (ICT) in order to help cities to make better use of its resources (Neirotti *et al.*, 2014). However, despite the importance of technology, there is a need for investment in human capital for the development of an efficient strategy for Smart Cities. (Angelidou, 2015; Monfaredzadeh and Krueger, 2015). The adopted Smart City concept is based on Caragliu *et al.* (2011), who state that a city is considered to be smart "when investments in human and social capital and traditional (transport) and modern (ICT) communication infrastructure fuel sustainable economic growth and a high quality of life, with a wise management of natural resources, through participatory governance".

According to Neirotti *et al.* (2014) there is some difficulty in establishing worldwide definitions and trends for Smart Cities, since the initiatives are implemented under different contexts and realities. The Smart indicators of the cities should consider specific variables that capture particular characteristics, such as local culture, political leadership, population density, economic development and climate conditions. Therefore, it is noteworthy that each city faces specific challenges, hence its Smart indicators must be particularized. In this context, the focus of this research is on the city of Vitória, Brazil. The choice of this subject matter is because this municipality has a 100% urbanised territory and a high population density, with more than 3,000 inhabitants/ km^2 (Oliveira *et al.*, 2014).

This study aimed to select and assign weights to assessment indicators for Vitória, according to the Smart City concept. This set of indicators should measure the city's progress and be periodically updated. Thus, it is assumed that it is possible to evaluate Vitória's evolution in relation to the selected indicators, by providing data to the government assisting the development of specific policies and guiding investments. It is therefore expected that

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

the local population be positively affected, since the Smart City attributes are aimed at sustainable development and the improvement of the population quality of life.

2. METHODOLOGY

After a literature review to establish the state of the art theme, this research was developed in three main stages. The initial stage consisted of select an assessment tools, based on specific criteria, which served as reference for the choice of indicators for Vitória (Tab. 1). The selected tool was thoroughly studied, seeking a clear understanding of its conceptual guidelines, specific goals and methodologies associated with the indicators. In the second stage, the reference tool indicators were selected, based on suitability, clarity and availability criteria. In the third stage weights were assigned to the selected indicators, judging their relevance based on their compliance with the strategic goals of the city.

There is currently no unanimity on a methodology or indicators to assess a city in relation to the Smart City concept. In order to select the reference tool for choosing Vitória's indicators, the main urban area assessment systems were identified, specific for Smart Cities or related to the sustainability concept. The score was given by evaluating the relevance of the criteria for the research and suitability of the tool to the criterion. For each tool, the values assigned to the evaluated items were added up, and the one with the highest score was selected as reference for the research, according to Table 1.

This research is based on the first version of the tool European Smart Cities, released in 2007. The assessment system was created in order to assess European medium-sized cities, with populations between 100,000 and 500,000 people, comparing them and identifying their strengths and weaknesses. It presents a total of 74 indicators, divided into six key features: economy, people, governance, mobility, environment and living (Giffinger *et al.*, 2007). According to Giffinger *et al.* (2007), the indicators have their values standardised by z-transform. The score of each domain is given by the simple average of the corresponding indicators. The same goes for the key features, obtained by the simple average of the domains. Thus, the indicators have equal weights.

	Selection Criteria					
Assessment Tool	Developed for assessment of Smart Cities	Free access to assessment methodology	Developed in Brazil	World-wide recognition	Academic relevance	Total sum
European Smart Cities	6	3	1	1	1	12
Connected Smart Cities	6	1	3	0.5	0.5	11
CASBEE for Cities	4	3	1	1	1	10
AQUA Bairros	2	3	3	1	1	10
Green Star Communities	2	3	1	1	1	8
LEED ND	2	1	1	1.5	1.5	7
BREEAM Communities	2	1	1	1.5	1.5	7
HQE UPD	2	1	1	1	1	6

Table 1: Selection of reference tool

In the second stage of the research, the reference tool was used as a source for the acquisition of indicators for Vitória's Smart assessment. Each item proposed by the structure was analysed according to the following criteria:

- Suitability – considers whether the indicator is adequate to assess Vitória;
- Clarity – evaluates whether the purpose of the indicator or data related to its acquisition is understandable;
- Availability – amongst the defined research sources – IBGE and City of Vitória websites – it identifies if there are similar available data.

The indicators that not fulfilled simultaneously these criteria were not eligible for the following step. After the selection of indicators for Vitória, it was deemed necessary to assign weights in order to provide a hierarchical reading of the items, facilitating the analysis in investment decisions. Thus, in the third stage of the research, the proposed system classifies each indicator according to its relevance, which is based on the relationship with the strategies presented in the 2008-2028 Agenda of the City of Vitória. Each indicator is evaluated under the perspective of the Agenda themes, and its relevance is judged based on the type of relationship they establish with them, whether direct or partial.

The Agenda is the third revision of the strategic plan drawn up according to the 1992 Rio Summit, and it was developed by a multidisciplinary technical team and representatives from various social sectors of the city. The population participated in the Agenda development through debates in seminars and surveys, signalling their main demands and expectations to the City. Thus, the document proposes strategic goals in line with the local reality. The strategy is based on three main themes that steered the plan's guidelines (Agenda Vitória, 2016):

- Economy – involves issues related to the dynamics of labour and production, productive investments, Science and technology, innovation, workforce qualification, specialized activities, labour market, ports and airports;
- Urban-Environmental – prioritizes issues related to the environment and urban infrastructure, such as mobility, sanitation, housing, clean energy and urban planning legislation;
- Sociocultural – addresses areas related to citizenship, human rights, social welfare, culture, education, health, security, employment and income and population dynamics.

Considering the above-mentioned criteria, weights were assigned to the indicators. First, we evaluated the relationship of each indicator with the Vitória 2008-2028 Agenda themes, considering its direct or partial affinity (Eq. 1). Then, its weight was calculated in contribution percentage for the scoring of each key feature (Eq. 2).

$$CM_i = ADR_i \times 2 + APR_i \times 1$$

Equation 1

where ADR_i = sum of the amount of themes directly related to indicator i; APR_i = sum of the amount of themes partially related to indicator i

$$IW_i = \frac{CM_i}{\sum_i^n CM}$$

Equation 2

where $\sum_i^n CM$ = sum of CM of all indicators of the key feature.

3. INDICATORS FOR VITÓRIA'S SMART ASSESSMENT

The second stage of the research has resulted in the identification of 39 indicators (Tab. 2). Among the excluded indicators, it is noteworthy that about 63% received a negative response only to the data availability criterion, which was the main cause of exclusion of indicators.

The third stage of the research consisted in assigning weights to the selected indicators based on the strategic themes of the Vitória Agenda. We highlight the indicator Social Welfare Return Index (Índice de Retorno de Bem-Estar à Sociedade - IRBES), which stands out with the highest relative weight in the context of its category (Governance dimension), with 46.15%. This indicator compares the tax burden to the Human Development Index (HDI), thus is directly related to the three strategic themes of the Agenda and establish a direct relationship with them. Next, with the relative weight of 27.27%, are the indicators Ratio of Students Enrolled in High Quality Courses, Percentage of Population with 13 or More Years of Schooling, and Ratio of Workers in STEM Occupations, components of the People dimension.

Table 2 presents the set of indicators for Vitória's Smart Assessment, their adaptation based on locally available data and respective weights.

	Factor	Indicator	Adapted Indicator	DR	A DR	PR	A PR	CM	IW
ECONOMY	Innovative spirit	R&D expenditure in % of GDP	State government investment in C&T/State budget	E	1	S	1	3	13.64 %
		Employment rate in knowledge-intensive sectors	Proportion of workers in STEM occupations (Science, Technology, Engineering, Mathematics)	E	1	S	1	3	13.64 %
		Patent applications per inhabitant	Patents registered in ES year/100,000 Inhabitants	E	1	-	0	2	9.09%
	Entrepreneur-ship	Self-employment rate	Self-employed workers/Total workers	E	1	-	0	2	9.09%
		New businesses registered	New companies registered	E	1	-	0	2	9.09%

4. FINAL CONSIDERATIONS

This article is the first step to develop an assessment tool for Vitória under the Smart City concept. The development of a consistent assessment tool requires the selection of relevant indicators, aligned with the defined goals and targets (Hák *et al.*, 2015). Amid a large number of indicators, it is assumed that the first step in the development of the assessment framework is to define the city's strategy, in accordance with the adopted concept of Smart City and Sustainable Development Goals. The importance of defining city level strategies is stressed, due to the relevance of local characteristics and challenges (Shen *et al.*, 2010). The Vitória Agenda defines the strategy at the local level and displays important diagnostics and considerations. However, it is not clear as to setting goals and targets to be achieved, hindering the selection of indicators.

The main challenge of the research was the access to reliable information, especially at the local level. In some cases, the use of the metropolitan region or state data was accepted, in order to not hinder the work, since the percentage of excluded items for lack of similar data was high. The data sources used for this research are public databases, and their publication, in general, does not occur on an annual basis, which also makes it difficult to obtain updated data.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The high weight assigned to the indicator IRBES may have occurred because the Governance dimension has a lower amount of items when compared to the others. Thus, for a proper assessment, the need to add new indicators to this dimension is clear, in order to achieve a better balance in the allocation of weights.

By analysing the proposed indicators for the European medium-sized cities, the authors emphasise the difference between their development levels compared to the Brazilian cities. The tool used as reference does not address issues that correspond to recurring problems in Brazil, such as illiteracy and infant mortality. Thus, the need to continue the research is realised, in order to, once again, supplement the list of indicators with new items according to the local reality, grounded on other existing assessment tools.

Establishing Smart Cities for Sustainability: An Analysis of the Japanese Innovation System and Implications for Asia

Masaru YARIME[a]

[a] *City University of Hong Kong, Hong Kong SAR, yarimemasa@gmail.com*

ABSTRACT

Smart cities are considered to be one of the key areas in which innovation is expected to play a crucial role in making a transition towards urban sustainability. They require effective integration of a variety of science and technological knowledge through collaborating with various stakeholders in academia, industry, and the public sector. Smart cites, based on advanced systems of hardware and software for mutual exchanges of energy and information between supply and demand sides, will play a crucial role in implementing sustainability in Asia. Innovation systems of smart cities exhibit a significant degree of diversity in knowledge, actors, and institutions. In this paper, we examine technological innovation systems of smart cities in Japan and discuss its implications for Asia. Bibliometric analysis of scientific and project documents in Japan reveal that knowledge domains basically concern renewable energy, energy storage, community energy management, and applications for home appliances and electric vehicles. Network analysis of actors suggests a concentrated structure dominated by large actors, particularly government organizations and electric and electronic companies. Policies and regulations influencing the innovation system include economic incentives to promote renewable energy, liberalization of energy markets for new entrants, participatory road-mapping on key component technologies, demonstration projects incorporating local conditions, platform creation for stakeholder partnerships including academia, industry, government, and end users, and standard setting for smart meters and equipment. Policy for facilitating communication and engagement with end users would be particularly important for implementing innovation on smart cities.

Keywords: smart grid, innovation system, stakeholder collaboration

1. INTRODUCTION

Smart cities are considered as a key area where innovation plays a critical role in making a transition towards urban sustainability. A smart city involves an advanced technological system for efficient, flexible, and resilient energy supply and applications, incorporating the behavior of the actors including generators, distributors, technology developers, and consumers through an intelligent network. Improvement in the efficiency of energy consumption will reduce emissions coming from energy generation, particularly those from coal power plants. Flexibility in balancing energy supply and demand through smart meters and affiliated technologies will facilitate the introduction of renewable energy sources such as solar and wind, substituting pollution-laden fossil fuels. Electrification of urban infrastructure will also support the deployment of electric vehicles, which do not emit pollutants unlike the conventional vehicles driven by internal combustion engines. In these ways smart cities are expected to make a significant contribution to coping with the serious issue of air pollution currently observed in many urban areas.

As a diverse mixture of hardware as well as software are involved in a complex way, however, a variety of approaches would be possible to implementing the concept of smart cities in practice, depending on the economic, social, and environmental conditions. In-depth examination is not yet conducted on the processes of creating innovation on smart cities in different national contexts. Policy and strategic implications of the experiences of the industrialized countries will be particularly important for many countries in Asia, where urbanization is proceeding rapidly in many major cities, posing a formidable challenge of tackling air pollution.

This research is aimed at examining the processes of implementing innovation on smart cities in different countries, particularly focusing on Japan and the United States. Detailed analysis is conducted on what actors are involved at which stages of innovation, what factors influence the behaviour of the actors, and what effects and impacts are made by policy interventions. Projects on smart cities in Japan are analyzed with regard to the actors involved, the technological areas emphasized, and the processes in which the actors collaborate with each other. Information was collected through various sources, such as project reports, academic articles, corporate reports, trade journals,

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

and web sites, and interviews were conducted with relevant stakeholder, including academia, firms, industry association, and government organizations. The framework of technological innovation systems (TIS) is applied for analyzing smart cities, in terms of the functions identified for TIS, including knowledge development and diffusion, guidance of the search, resource mobilization, entrepreneurial experimentation, market formation, legitimation, and development of positive externalities. Based on the analysis of Japan's experiences, implications are discussed for policy options and approaches for making a transition towards urban sustainability in Asia.

2. TECHNOLOGICAL INNOVATION SYSTEM OF SMART CITIES

The concept of smart city hence would vary, used by a variety of actors and scholars to describe different kind of technological assemblages. As such, it is not surprising that there are differences in the nuance of the concept in different contexts. In Europe a focus is given on creating an infrastructure that can use information collected and distributed among all connected users, to ensure that the various objectives of the electricity grid are achieved in a more intelligent way. In the United States there is a specific emphasis on security, involving key features such as self-healing and resilience against physical and cyber threats. Because the functionalities discussed as part of the smart city are many, there is also a breadth of benefits envisioned for society when a smart city is implemented. Potential benefits include higher overall energy efficiency, lower cost of operating the electricity grid, lower environmental impact, higher resilience of the energy system and more empowerment to end-users in the energy system. Given the desirability of these benefits for societies facing climate change and increasing energy prices, and the high hurdles such a complex systemic technology area faces, it is important that governments facilitate the introduction of smart cities. Many efforts towards this end have been taken, and this study aims to take a macro-level view of efforts in two countries, Japan and the United States, to extract valuable lessons for governments and entrepreneurs seeking to promote smart cities.

Macro-level studies of innovation on smart cities are very few, given the short time span in which smart cities have evolved, with only a few studies taking policy perspectives (Lin, Yang, and Shyua, 2013). This study, instead, aims to create a holistic view to smart city innovation. One of the major analytical approaches to studying innovation processes is the approach of technological innovation system (TIS). The TIS framework emerged from the innovation systems field, which itself was created upon the notion that not only activities by firms and researchers determine the character of technological change, but also broader societal structures. The idea of the system of innovation was originally developed to examine the functioning of national systems of innovation, particularly how governments could actively promote innovation through linking different stakeholders in the national context. Traditionally, researchers working on the system of innovation have focused on the role of firms, government and knowledge institutes within the innovation system. The experience of the last decades, however, has shown that other influences, such as activities by end users and discourses in society, can also have an important role in driving innovation.

In an attempt to investigate such broad societal structures, TIS aims to capture the activities directed toward development, diffusion and use of a particular technology (Bergek, Jacobsson, Carlsson, Lindmark, and Rickne, 2008). A TIS is defined as "a network or networks of agents interacting in a specific technology area under a particular institutional infrastructure to generate, diffuse, and utilize technology" (Carlsson and Stankiewicz, 1991). It is stressed that it is the analysis of the functions that should receive the most attention, as the aim of a TIS is to fulfil its functions, rather than to achieve a structure. TIS is often regarded as a problem-solving discipline, and many scholars in this field are preoccupied with finding ways to accelerate and enhance innovation processes. Therefore, TIS has mostly been applied to the study of green innovation, which is taken to have a clear positive societal value. Examples include wind turbines in the Netherlands and Denmark, renewable energy systems in Germany, Sweden, and the Netherlands, and renewable vehicle fuels.

A smart city involves an advanced technological system for efficient, flexible, and resilient energy supply and applications, incorporating the behavior of the actors including generators, distributors, technology developers, and end users in a complex way. To capture a broad understanding of the processes of introducing and implementing innovation on smart cities in Japan and the US, interviews were made with experts from different stakeholder groups, including academia, firms, industry association, and government organizations. Each interview explored the seven sub-processes of a TIS, focusing on an appraisal of the existence of drivers or obstacles in the different sub-processes. These are knowledge development and diffusion, guidance of the search, resource mobilization,

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

entrepreneurial experimentation, market formation, legitimation, and development of positive externalities. A case study approach was adopted because of the exploratory nature of the study.

3. ANALYSIS OF THE JAPANESE INNOVATION SYSTEM ON SMART CITIES

The Japanese government interest in smart grid grew out of the government's promotion of renewable energy sources, an area in which Japan was an early champion. In the first decade of the millennium the New Energy Development Organisation (NEDO), a governmental agency under the Ministry of Economy, Trade and Industry (METI), promoted domestic projects aiming at developing grid-connecting technologies for renewable energy projects. Projects supported included clustered photovoltaic (PV) generation, mega solar generation, wind power stabilizing and power quality management, and micro grids. These projects were not carried out under the label of smart grid, but touched upon some of the functionalities now associated with smart grid. In 2010, smart grid innovation efforts started when METI launched four large-scale smart grid demonstration projects in different areas of Japan. These were called "Next-Generation Energy and Social Systems Demonstration Areas," later known as "Smart Cities." The projects are all based on a strong role of local authorities and one coordinating corporation per project, which receives support from METI and coordinates with other partners, and focus on creating practical examples of different smart grid technologies. Other smart grid innovation efforts in Japan have been mainly conducted by potential vendors of smart grid technology, often in collaboration with other enterprises, such as supermarket chains and real estate developers.

Many government organizations are involved in smart grid innovation in Japan. Among them, METI is the most prominent actor, having a broad portfolio of relevant policy areas. Traditionally characterized by a strong relationship with the business sector, METI's main mission has been to support the development of the Japanese industry. Situated under METI, the New Energy and Industrial Technology Development Organization (NEDO) is Japan's largest public R&D funding and management organization. As one of the responses from the government to the oil crisis of the 1970s, NEDO was formed in 1980 to promote the development and diffusion of new energy technologies in Japan. Prior to the year 2000, NEDO-supported research on electricity grids focused on extending grid connection to single producers of renewable energy. In the first decade of the new millennium, NEDO shifted its focus to inclusion of large-scale, multiple renewable energy producers. Since 2010, a broader focus has been made on the concept of "smart communities," with more attention to consumer-domain technologies (Morozumi, 2010).

METI and NEDO conduct their smart grid innovation efforts in close collaboration with the business sector. Local governments, especially the cities that were allocated financial resources through the Japan Smart Cities project and the Future Environment City project, are very active in the smart grid activities. Several cities have partnered with private companies or universities; for example, Fujisawa is partnering with one of the largest electronic companies in Japan, Panasonic, and Toshima ward in Tokyo has collaborated with the Tokyo Institute of Technology.

The most important actors in Japanese smart grid efforts are large firms with strong corporate networks, such as Hitachi, Toshiba, and Mitsubishi. The size of these companies and their networks with other firms provide them with access to expertise in various aspects of smart grid technologies (Office of Energy and Environmental Industries, 2012). Because of their large portfolios of business activities, these companies tend to take a broader definition of smart grid, referring to it as part of smart communities, with many products and services available for residential end-users of electricity. Companies and consultancies in the information and communication technology sector are also active, mostly in the development and provision of software components and services. Residential developers and department stores are also important stakeholders, as they aim to provide customers with additional services and potential for cost reduction through installing smart grid technologies.

While regional monopolistic utilities still control most of Japan's electricity system, they are currently operating in a very uncertain and economically difficult situation since the Fukushima nuclear accident. TEPCO, the largest of the utilities in Japan and one of the largest utilities in the world, previously did not show much enthusiasm about smart grid. Prior to the Fukushima disaster, it was argued that Japanese grid was based on the world-class technology and thus smart grid would not be very necessary (Dasher, 2012). In the post-Fukushima era, the financial standing of the utilities would make it difficult for them to make much engagement.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Japan Smart Community Alliance (JSCA) was formed by METI and NEDO, which hosts the secretariat, in April 2020, following the recommendation of a roadmap produced internally that international standardization efforts were needed. By February 2013, 408 companies have joined the organization, with Toshiba serving as the president (Japan Smart Community Alliance, 2013).

The Energy Conservation and Homecare Network (ECHONET) Consortium is a network of private companies in the area of smart housing. Active since 1997, the consortium has developed communication standards for smart appliances, which are open and universal, to promote the emergence of home networks connected to these smart appliances (ECHONET Consortium, 2013a). As of January 2013, the consortium has eight core members representing some of the largest electronics producers in Japan, including Panasonic, Sharp, and Toshiba, as well as Japan's largest utility company, TEPCO (ECHONET Consortium, 2013b). After its establishment, ECHONET experienced a steady decline of activities in the early 2000s, as consumer interest in smart appliances remained quite low, and a proliferation of communication protocols meant high cost and uncertainty for vendors. In 2011, the consortium released an enhanced and WiFi-based standard, ECHONET-lite, which was swiftly endorsed for the home energy management system (HEMS) by the Japanese government, with financial support provided to HEMS adopting the standard. This led to a sharp spike in interest and membership in the ECHONET consortium.

In some areas, local associations have been established for private companies and research institutes involved in smart grid or smart house developments. One example is the Yokohama Smart Community Association, which was created following the beginning of the Yokohama Smart City project. It is an association of local small and medium enterprises (SMEs) working in collaboration with smart grid initiatives and acting as suppliers for some of the corporations involved.

To examine the network structure of the actors in the field of smart cities, data on projects and consortia related to smart grid was collected through trade journals, research reports, web sites, and interviews with relevant stakeholders. As a result, a database was constructed with 22 projects and two consortia. Network analysis was conducted to identify key stakeholders in Japanese smart grid innovation and to analyze the relationships between them. In the network, when multiple organizations join the same joint project, they are connected with each other.

The key actors identified from the network analysis are mainly large conglomerates with broad portfolios, covering both electronics and infrastructure areas. They are also members of both JSCA and ECHONET and are participating in several demonstration projects. The top two, Hitachi and Toshiba, are of particular importance, and the government funding agency NEDO also plays a prominent role in the network. The large electric utilities, on the other hand, are not centrally connected in the smart grid network, and their presence is relatively invisible. This is a distinctive feature of the Japanese network of the actors involved in the network on smart grid, in comparison to the U.S. network.

Knowledge creation and diffusion is considered to be one of the key functions of a TIS. It encompasses the creation of different kinds of knowledge concerning scientific, technological, market, and institutional dimensions. In Japan, the respondents overall rated the situation on the knowledge creation and diffusion process as moderately positive. The Smart City projects are regarded as especially important collaborative platforms in which novel technological functionalities could be tried out. While the tightly knit groups involved in the Smart City projects are producing valuable knowledge, the sharing of that knowledge is still limited. Within the smart house and appliances sector, knowledge creation has proceeded further and diffusion platforms have seen as better developed, especially since the Fukushima disaster, after which the government started to promote standardization and to provide financial support to consumers for purchasing home energy management systems (HEMS).

The function of guidance of the search refers to the way in which society creates incentives for a certain type of technology to emerge from a TIS. If this function is performing well, there is a clear common understanding of the expectation and probabilities of technology development and diffusion, shared by industry actors, the government and consumers. This is particularly important as it addresses the often-overlooked phase of interactions among different groups of interest and power within innovation processes. While a more vague vision could be helpful to mobilize a broad coalition, if the interpretative flexibility is too great, the innovation system will not be pulling in the same direction and therefore will not be effective as a system. In Japan the process of the guidance of the search has been performing relatively well, as there is a shared understanding about the basic concept and acceptance of smart grid, although the emphasis varies to a certain extent between different stakeholders. NEDO has been regarded as the most important actor in facilitating consensus building. As NEDO manages the financial resources for many of the demonstration projects on smart grid, it has a significant amount of capacity to influence the focus and direction of the development of smart grid technologies.

Innovation requires different kinds of capital and assets in order to proceed. Financial and human capitals are the most important among these, and resource mobilization is crucial in enabling innovation. The financial resources provided by METI and NEDO to smart grid projects has functioned as an important stimulus for smart grid innovation, especially through funding the Smart City projects. After the Fukushima accident, in particular, many of the electric utilities have very low financial capabilities to initiate and implement new technological development. This has directly affected their engagements on smart grid that had already existed. The activities of the electric utilities that are still on-going are mostly funded by government grants, which illustrate the significant role played by this function for keeping the momentum on innovation.

Entrepreneurial experimentation refers to experiments carried out by the actors who intend to utilize smart grid technologies to implement something novel for achieving their aims. Their activities would be indispensable for a process to be innovative. From a societal perspective, the experimentation of entrepreneurs would make uncertainty about the development and use of technology lower, as they create hard evidence for the likelihood of success or failure of certain types of technology. In Japan this function has been performing relatively poorly. While established manufacturing firms are making efforts to tap into new markets, the current monopolistic structure of the electricity market and the uncertainty about future policies and regulations discourage ambitious activities of entrepreneurship. Moreover, the membership in the smart grid projects remains relatively closed, with new entrants very limited, and smart grid tends to be regarded as a field giving advantage to the established industrial giants. The smart house and appliance sector sees more involvement and engagement by smaller firms, in addition to the large electronic companies.

For the benefits of innovation to become widespread, a market for technologies needs to be created and developed. As an emerging TIS often has only a very small and weak market, particularly at an initial stage, a strong expectation of market formation in the future with ample possibilities and opportunities for profit making will accelerate the process of innovation. The creation of a market for smart grid technologies in Japan is at this moment considered to face many problems and challenges. While there exists a very limited market, it is still in a very early stage, and the uncertainties surrounding the current environment and future development of the electricity market make potential investors wary. In the smart home and appliances sector, the market has developed further and some demand has already been emerging. Residential developers have played a key role in popularizing various applications for smart home and appliances. The residential developers, however, while actively engaged with the concept of smart home and appliances, only cater to the upper-income groups, with HEMS remaining relatively expensive. The high prevalence and popularity of residential photovoltaics in Japan has also been an important driver for the smart house market.

The creation of legitimacy refers to the process in which technologies become socially accepted and institutionally incorporated into the legal system. When this function is not fulfilled, search guidance and market formation would not be effective ultimately, and regulatory barriers can create obstacles to innovation. In the case of Japan the creation of legitimacy has not been a serious problem for facilitating innovation on smart grid. Although knowledge about smart grid is not necessarily shared in the general public, energy efficiency has basically been understood as an area to be supported since the oil crises in the 1970s. Particularly the planned outages by the electric utilities following the Fukushima accident received strong criticisms, as regions of less economic importance had to endure more blackouts. Accordingly, through smart grid technologies that are considered to contribute to reducing energy consumption are socially accepted, without much resistance based on concerns about privacy or health effects. In the smart house and smart appliance sector, the situation has been less problematic, as smart appliances are generally appreciated by consumers for the benefits to be provided by these technologies.

Empirical studies have shown that the existence of complementary innovation systems is important for a TIS to be successful. For example, the success of civilian nuclear power technology benefited greatly from the advances in nuclear weapon technology, even though they basically belong to two distinctive innovation systems. Similarly, the development of positive externalities has also been observed in the evolution of technologies on smart grid. A crucial area of co-evolutionary development is the fast-developing field of smart home and appliances. The appliance manufacturers who also have interests in the grid equipment market have been the most active

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

stakeholders in the technological innovation system on smart grid. The electric vehicle (EV) has also been an innovation area of critical importance, and while being at a too early stage to contribute significantly, EV will benefit considerably from smart grid innovation. Renewable energy development has also been an adjacent innovation area. The influence of renewable energy is still relatively small, however, as the electric utilities currently allow only limited amounts of electricity to be connected to the grids, because of the concern about the grid capacities to absorb the fluctuation and interruption of the electricity produced by renewable energy sources, particularly solar power.

ABSTRACT

Buildings in an urban context can hardly achieve positive primary energy balances throughout a year due to the relative high density in the neighbourhood: low ratio roof area to floor area (low active use of solar energy) and shading through other buildings (low passive use of solar energy). For this reason, renovations on individual buildings shall be assessed in an overall concept at neighbourhood scale, expanding thus the considered system boundary. The aim of the project is to evaluate the additional benefit of specific typological, user-specific and technical interventions in terms of maximal thermal and electrical loads for the neighbourhood compared to a single house.

A typical Swiss urban neighbourhood with a representative utilisation mix has been chosen in Cham in the canton of Zug to analyse the change of its thermal and electrical loads for different scenarios.

- Utilisation mix: Substitution of 20% and 50% office buildings into residential buildings.
- Densification: Increase of 20% and 50% space heating area in the neighbourhood.
- Efficiency (Renovation): Renovation of 20% and 50% of the actual building stock.
- Decentralised production: Impact of 0% up to 100% roof coverage of photovoltaics.
- Storage: Benefit of an ideal daily thermal or electrical storage.

The criteria used to define the additional benefits of each scenario were the highest yearly average daily load and the ratio between daily maximum load and daily mean load.

The results show that the technical measures clearly have most impact on the peak load reduction, but due to their high costs, resulting in the present low retrofit rates, spatial planning measures present a good option to help mitigate thermal (-10%) and electrical (-17%) loads without major effort.

Keywords: smart neighbourhood, transformation building park, load management

1. INTRODUCTION

Buildings in an urban context can hardly achieve positive energy balances throughout a year due to the relative high density in the neighbourhood: ratio roof area to floor area (low active use of solar energy) and shading through other buildings (low passive use of solar energy). Depending on their location, plus energy buildings are not even desirable, since they unnecessarily stress the electricity grid. For this reason, renovations on individual buildings shall be assessed in an overall concept at neighbourhood scale, expanding thus the considered system boundary.

The aim of the project is to evaluate the additional benefit of the neighbourhood compared to a single house for specific typological, user-specific and technical interventions.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2. METHOD

2.1 Choice of the neighbourhood

The following requisites were set in order to define the typical neighbourhood of the suburban agglomeration of Switzerland:

- Frequent typology in urban areas.
- High share of residential buildings with a retrofit potential.
- Potential to change the utilisation mix in the neighbourhood or in the surrounding area.
- Potential for densification of the neighbourhood.

After analysing more than hundred neighbourhoods, “Cham Ost” near Zug has been chosen (Figure 1).

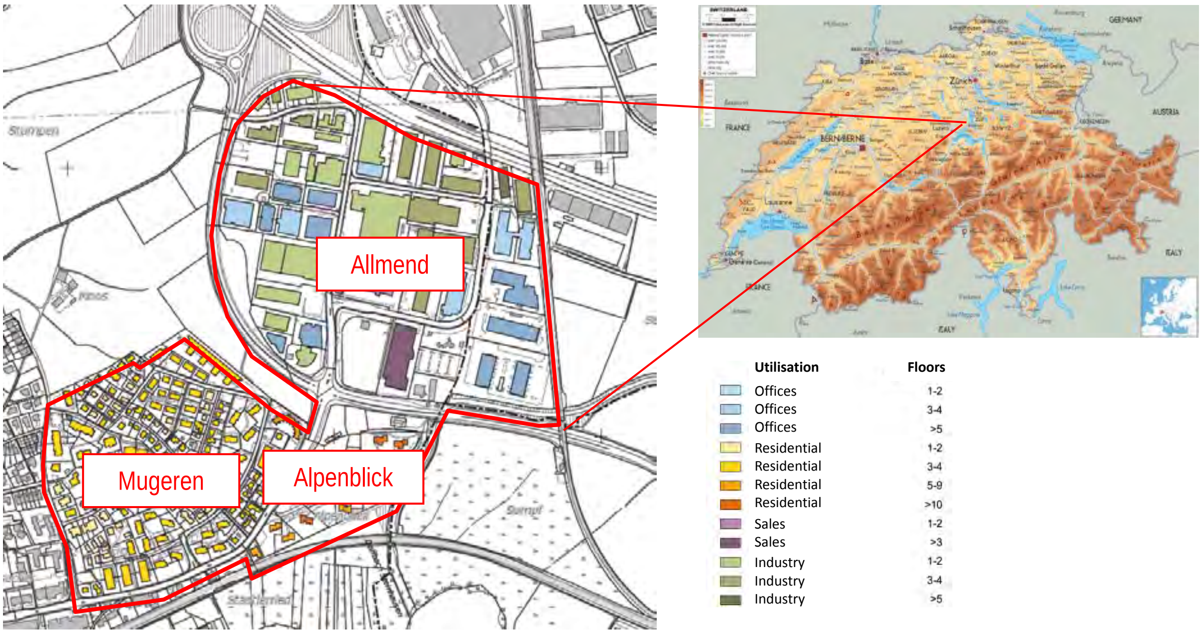

Figure 1: Neighbourhood “Cham Ost” near the city of Zug divided into three subareas, Allmend (offices, sales and industry), Mugeren (residential buildings) and Alpenblick (high-rise buildings)

2.2 Criteria for the evaluation

The criteria used to define the additional benefits of the intervention measures were the highest yearly average daily load and the difference between energy demand and energy supply (= energy consumption) (Figure 2).

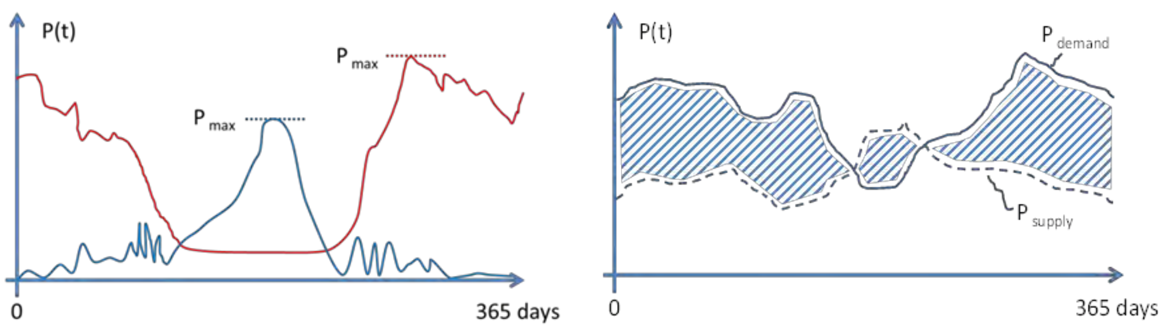

Figure 2: Criteria for the evaluation of the scenarios in the neighbourhood

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

2.3 Thermal and electrical loads of the neighbourhood "Cham Ost"

The thermal loads of the neighbourhood were determined by means of thermal simulations in IDA-ICE. 16 representative buildings were chosen, modelled and simulated to reproduce the entire neighbourhood. The electrical loads of the neighbourhood were assessed by using measured data on buildings of the same type in the same region. The profiles were then proportionally summed up accordingly to their surface share in the neighbourhood.

Figure 3: Thermal loads of the neighbourhood "Cham Ost" (upper graph) and electrical loads (lower graph) of the neighbourhood "Cham Ost"

2.4 Scenarios

Different scenarios were analysed in order to assess their potential according to the defined criteria. The scenarios were not set equally in relation with their economic investment, but according to their technical feasibility in the neighbourhood.

- Networking: Potential of connecting buildings electrically and thermally.
- Utilisation mix: Substitution of 20% and 50% office buildings into residential buildings.
- Densification: Increase of 20% and 50% space heating area in the neighbourhood.
- Efficiency (Renovation): Renovation of 20% and 50% of the actual building stock.
- Decentralised production: Impact of 0% up to 100% roof coverage of photovoltaics and combined heat and power technology.
- Storage: Benefit of an ideal daily thermal or electrical storage.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. RESULTS

The most important results are briefly presented for two scenarios, efficiency and decentralised production of photovoltaic panels.

3.1 Efficiency (Renovation)

The results show that in order to reach the goals of the SIA 2040 (target value for operation), 50% of the building stock shall be renovated to actual standard and 100% of the fossil fuel heating system shall be replaced by heat pumps with a yearly COP of at least 3.5 (Figure 5).

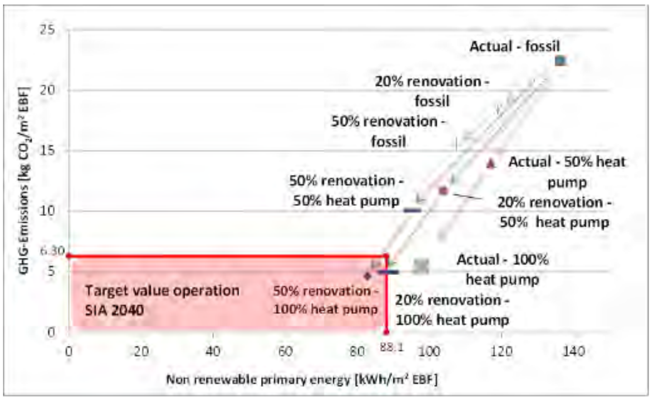

Figure 4: Renovation strategies on buildings for the neighbourhood and environmental impact according to SIA 2040 (target value in operation)

3.2 Photovoltaic production

The results show that even if 100% of the roof surface of the whole neighbourhood is covered by photovoltaic panels, the transmission lines not additionally stressed, i.e. the maximum grid supply load does not exceed the maximum grid demand load. Without demand side management, decentralised production of electricity can only reduce up to certain percentage roof coverage (40% of the roof area = about 50'000 m²) the grid demand peak.

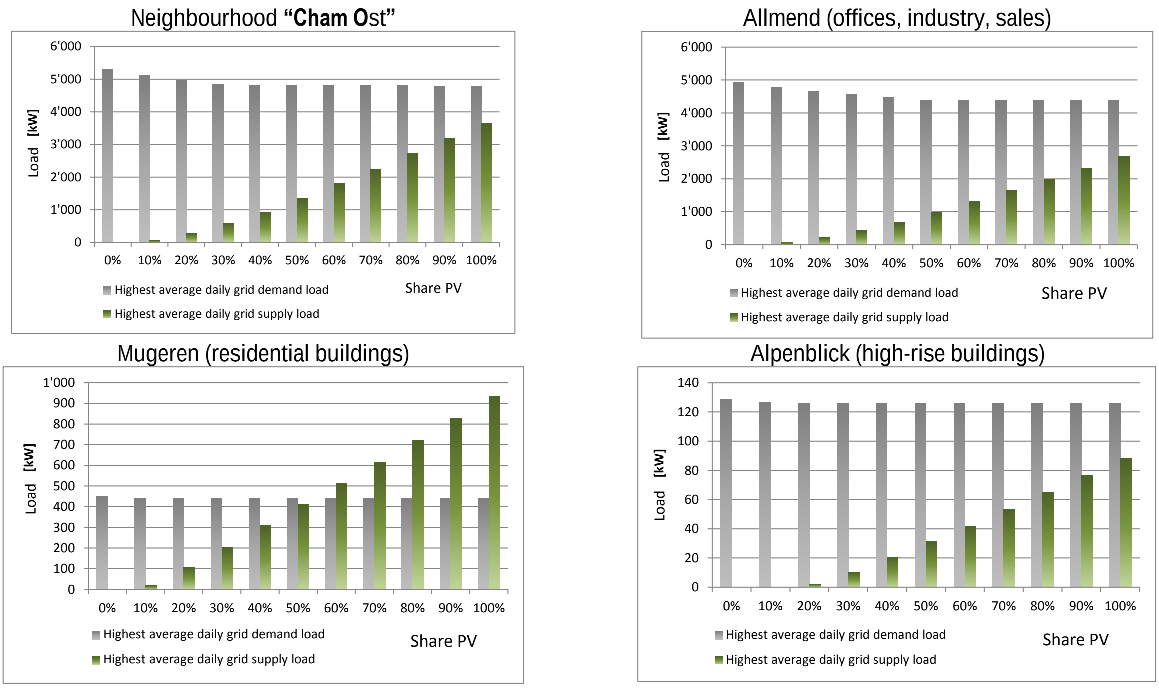

Figure 5: Maximum grid demand (grey) and grid supply peak from PV (green) of the whole neighbourhood and the three subareas when 0% up to 100% of the roof surface is covered by photovoltaics

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3.3 Summary of the scenarios

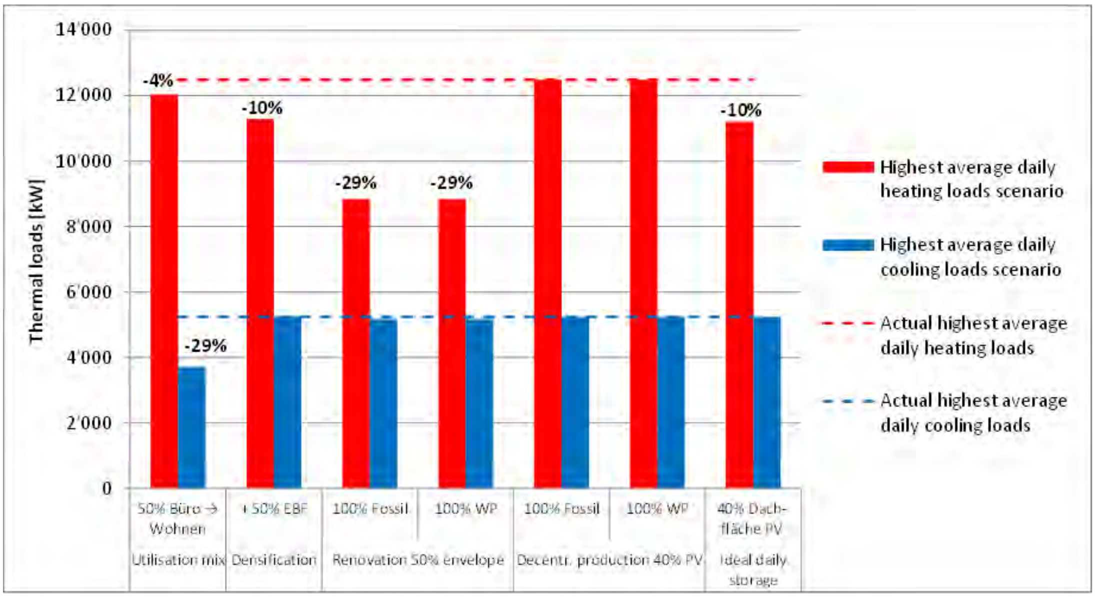

Figure 6: Highest daily average during the year of the thermal loads of the different scenarios (histograms) compared to the actual state (dashed line) by the same surface

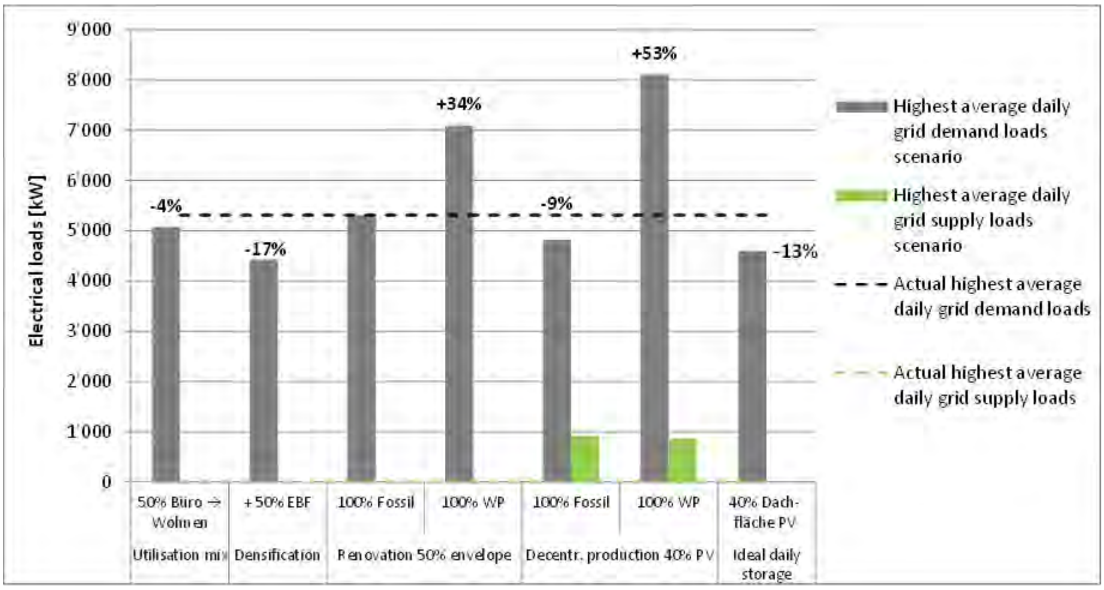

Figure 7: Highest daily average during the year of the electrical loads of the different scenarios (histograms) compared to the actual state (dashed line) by the same surface

The scenario that has most impact on the thermal loads, without increasing the cooling loads, is the renovation of 50% of the building stock in the area. The conversion of offices into residential buildings reduces both heat and cooling loads, since residential buildings carry a higher specific storage mass than offices. If all internal waste heat would be reused for heat purposes on site, final energy demand could be reduced by 3.5 GWh and maximum heat loads can be reduced by around 10%. Densification of the neighbourhood with residential and office buildings reduces the specific electric loads of the neighbourhood, since the present specific electricity demand due to industry is high. Decentralised production of photovoltaic reduces down to 9% the grid demand peak, while increasing the grid supply. The substitution of fossil fuels with heat pumps increases grid demand load by 34% resp. 53%, according to the renovation state. The ideal daily storages have limited potential to reduce yearly peaks, since on the days with highest energy consumption, low thermal and electrical excess energy is generated.

4. DISCUSSION

The overall results show that the technical measures on individual buildings clearly have most impact on peak load reduction, but due to their high costs, resulting in the present low retrofit rates, spatial planning measures still present a good option to help mitigate thermal and electrical loads without major effort. A densification in the neighbourhood (+ 50% surface) brings a yearly specific reduction of the thermal peaks of 10% and a yearly specific reduction of the electrical peaks of 17%. The peak loads engendered by the use of heat pumps shall be considered as a major issue for the future electricity network capacity and cannot be drastically reduced without any demand side management or long term batteries.

ABSTRACT

The Anderson Road Quarry is an important facility for supplying aggregate, asphalt and concrete for construction industry in HK since 1956. Following the accomplishment of its historical mission, the vacated 40 hectare site will take up another new mission – land supply for residential development with 25,000 planned population to address the housing shortage problem in the territory.

In view of the unique geographical location and as a piece of precious virgin land in the urban area, it gives us the opportunity to develop the site to an exemplary, sustainable and spongy living area. Smart initiatives are considered for adoption throughout the development process. Smart initiatives including pedestrian walkable network, cycling network with shared/ rental bikes, interactive bus-stop concept, smart phone Apps, etc. will be considered to encourage the residents to use convenient and healthy ways of active mobility for commuting within the area and help reducing vehicular transportation and emission.

Furthermore, integration of total water management with low impact development (LID) concepts has been derived to create a new leisure, healthy, socially integrated and harmonious community. To better utilize the water resource, we study the feasibility of using the first public grey water recycling system in ARQ site. LID as a kind of blue-green infrastructure, integrating water planning with landscape and urban design, comprises an artificial flood attenuation lake cum park, an underground storm water storage tank, rainwater harvesting system, bioretention system, porous pavement, etc, with some of them firstly introduced in HK. The retained rainwater also offers a water source for revitalization of the downstream Tsui Ping River in Kwun Tong area for environmental, ecological and landscaping enhancement.

Keywords: smart initiatives, low impact development, total water management

1. BACKGROUND

In the last 50 years, the economy of Hong Kong grows extraordinarily rapid. Accompanying with the rapid economic growth, a lot of large scale infrastructures works and building structures have been constructed and erected to support the development of Hong Kong. Since 1950s, Anderson Road Quarry (ARQ) has been an important facility and plays a significant role in construction industry for supplying aggregate, asphalt, stone and concrete in Hong Kong.

Following the accomplishment of the historical mission of ARQ, its 40 hectare vacated quarry site will take up another new mission – land supply for future residential and commercial development to accommodate 25,000 planned population with the aim of addressing the acute housing shortage problem in the territory.

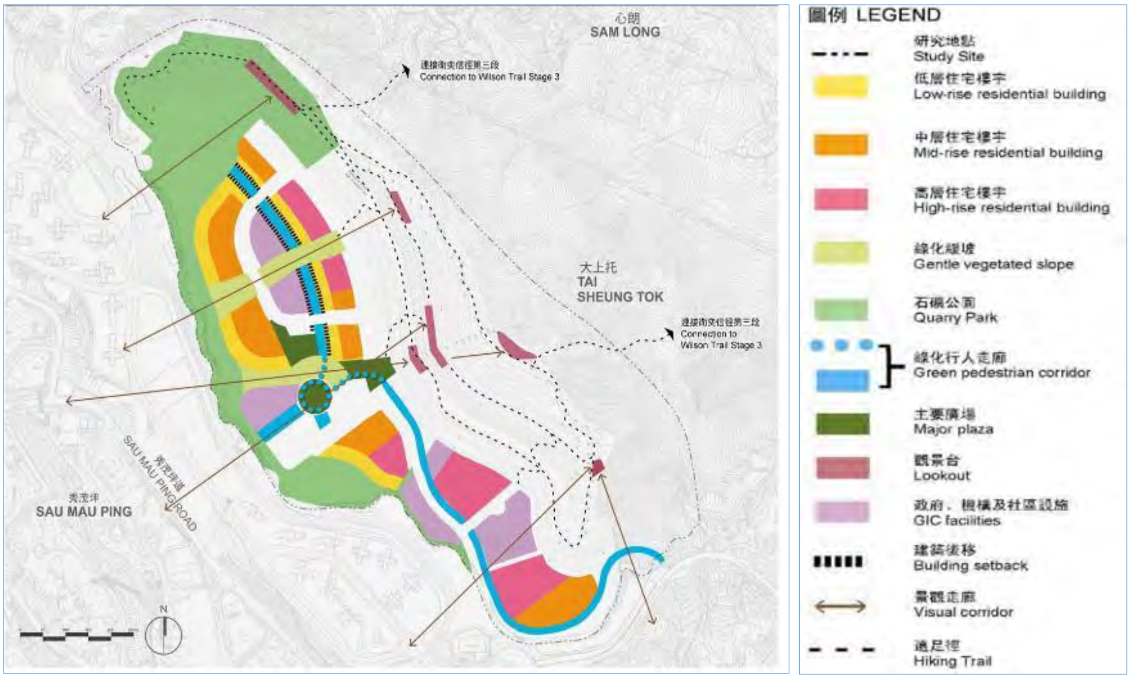

Figure 1: Conceptual development layout of ARQ Sites

2. SMART INITIATIVES ADOPTED FOR THE ARQ SITE DEVELOPMENT

The ARQ Site is a precious piece of virgin land of 40 hectare platform and another 40 hectare slope face in urban area of Hong Kong. It situates at the eastern side of Kowloon Peninsula in the vicinity of Tai Sheung Tok. In view of its dominant geographical location semi-detached with other current users and less conflicts with existing utility undertakers, it gives the opportunity to develop the site into an exemplary and sustainable community for people living there with more smart, green and resilient living environment.

In general, three main categories of smart initiatives will be implemented in the Development of ARQ Site, namely, integration of total water management (TWM) with low impact development (LID); smart energy; and smart mobility.

TWM is a modern concept for managing water resources in all aspects. It seeks to achieve an optimal balance between water demand and water supply in order to ensure sustainable use of water resources. To align with the TWM strategy, grey water recycling system, water intelligent network and automatic meter reading system will become pioneer initiatives for adoption under the Development of ARQ Site. LID initiative here refers to the best practice of stormwater management that integrates flood attenuation planning with landscape and urban design by blue-green infrastructure. The overall aim of adopting LID initiatives is to make urban hydrological systems function more like natural systems. The LID initiatives recommended for implementation in the Development of ARQ Site include artificial flood attenuation lake; underground stormwater storage tank; bioretention system; porous pavement and green roofs.

2.1 TWM – Grey water recycling

Grey water from the sources of bathroom wash basins, baths, shower, kitchen sinks, clothes washers, etc. of residential premises in the ARQ Site will be collected via dedicated grey water collection pipework system. These grey water collection pipes will be laid underneath and along public carriageways and convey the collected grey water to the proposed grey water treatment facilities underneath the regional open space of the ARQ Site. The treated effluent, known as reclaimed water, will be pumped to the flushing water service reservoir located at high level of the ARQ Site.

Use of reclaimed water as flushing water for public has not yet been implemented in Hong Kong so far and this will be the first grey water system if successfully implemented. There are still quite some challenges ahead to facilitate successful implementation of this grey water recycling system - amendment of existing legislation, incorporation of new land lease conditions, adoption of new building design, public education, etc.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 2: Schematic diagram for grey water recycling

2.2 TWM – Water intelligent network and automatic meter reading

With the advancement of the telemetry and sensing technology, it is planned to set up a smart water network in Hong Kong, namely Water Intelligent Network (WIN). Under WIN, an intelligent network management computer system will be established for collecting and analyzing the tremendous amount of time-series flow and pressure data to be collected from the some 2000 District Metering Areas (DMAs) and Pressure Management Areas (PMAs) in Hong Kong. The analyzed results by the system will be displayed in a dashboard and the abnormalities spotted by the system will be reported in the form of alarm so that the attention of the system operators can be drawn easily for timely follow-up action. The water network within the ARQ Site will be the first batch of its kind in Hong Kong for upgrading to WIN.

In addition, the water network at ARQ Site will be equipped with Automatic Meter Reading (AMR) system, which will collect metering data automatically and transmit it to the master station in Water Supplies Department through 3G/ broadband networks. The AMR system will disseminate useful information to customers for raising their awareness on water conservation. Moreover, the data will be imported to the WIN system to enhance water loss management analysis.

2.3 LID – Artificial flood attenuation lake

In order to reduce the loading of existing stormwater drainage system at the downstream of the ARQ Site against potential flooding at low-lying areas, measures have been developed to attenuate the peak flow at upstream. The idea of an artificial flood attenuation lake not only serves the function of flood attenuation during rainfall period, but also serves for recreational and irrigation uses during dry weather period. The proposed artificial flood attenuation lake will become a key landscape feature of the proposed Quarry Park and is the first of its kind in Hong Kong.

The lake is designed to cater for 1 in 200 year return period rainfall intensity with climate change factor incorporated such that the flood attenuation capacity would be around 24,000 m^3 and the lake surface area would be 10,000 m^2 at flooded condition. The lake can attenuate the peak flow from 7.4 to 1.7 m^3/s and hence, plays a key role in improving the drainage capacity of the downstream drainage facilities from the worst of less than 1 in 10 year to the average of 1 in 50 year.

Part of the collected rainwater will be drained away immediately while some will be retained inside the lake with proper treatment for recreational and irrigation functions for the Quarry Park. At normal condition, the volume of stored water would be around 7,000 m^3 and the depth of water would be around 0.7 m.

The non-submerged area or exposed surface of the artificial flood lake will become an open space in form of gentle sloping lawn area and landscape features for public enjoyment. To ensure the water quality suitable for the recreational uses such as water children play area facilities, an active water treatment facility is required to provide secondary treatment to the stored water, which will include chlorination and possible neutralization and aeration to fulfill the current rainwater harvesting standard.

Figure 3: Photomontage of artificial flood attenuation lake

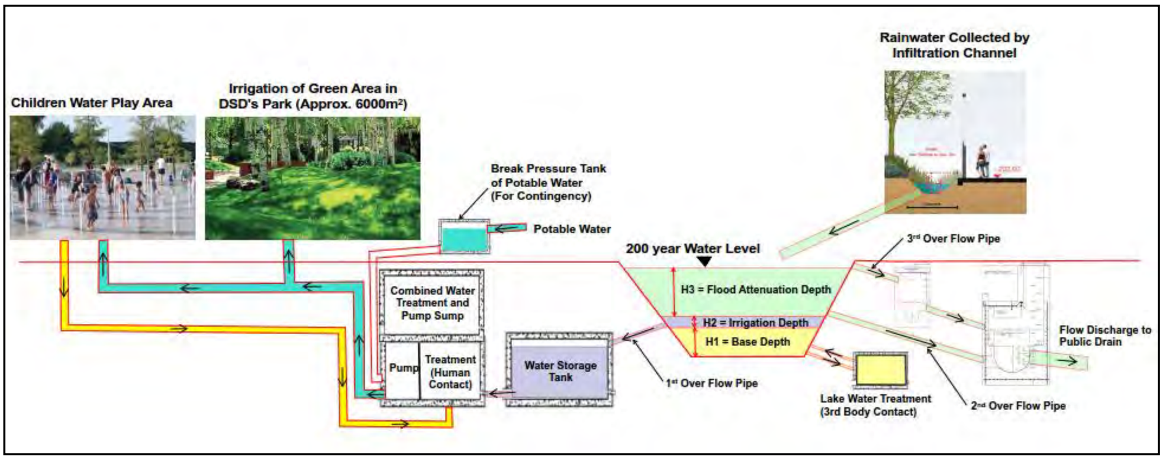

Figure 4: Flow Concept of artificial lake, irrigation and water treatment systems

2.4 LID – Underground stormwater storage tank

In addition to the artificial flood attenuation lake, another underground stormwater storage tank is proposed at the southern portion of the ARQ Site serving the similar function as the artificial flood lake for flood control. This retention tank will be situated underneath the regional open space. It will have a flood attenuation capacity of 60,000 m^3. The stormwater collected from the surface runoff of the ARQ Site during rainfall period will be temporarily stored in the tank. After each rainstorm, the stored water will be discharged to the downstream drainage system and then to the Tsui Ping River in a controlled manner. This discharge of collected stormwater serves as a reliable source of water supplement for the revitalization of Tsui Ping River downstream for environmental, ecological and landscaping enhancement for Kwun Tong area, especially in dry weather condition.

2.5 LID – Bioretention system

The first flush of surface runoff in urban/ developed area usually contains high concentration of pollutants such as petrochemicals. Bioretention channels are used to convey stormwater in lieu of, or with, underground drainage systems, and to remove coarse and medium sediments as well as pollutants and nutrients from the stormwater.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Bioretention system is proposed in the Development of ARQ Site as a pilot scheme. Bioretention system will be adopted at two locations within the ARQ Site – one is located alongside the footpath of the main road. Surface runoff from footpath flows into the bioretention channel of which its catchment area is around 4,000 m^2. The filtered water will be discharged into the natural water course at downstream. Another location for biorentention system is within the Quarry Park area catering for about 120,000 m^2 catchment area of the ARQ Site. The proposed bioretention system will collect the surface runoff from adjacent rock slopes. After filtering by the bioretention channels, the filtered stormwater will be conveyed to and stored in the artificial flood attenuation lake.

2.6 LID – Porous pavement and green roof

Use of porous paving material is one of the green infrastructure provisions in the Development of ARQ Site. The porous pavers would increase stormwater infiltration, improve groundwater recharge and reduce ponding from surface runoff. Another benefit is to reduce the heat island effect for the site which in turn reduces the temperature of the site. The porous paver would be applied on most of the major pedestrian footpath within the site.

Furthermore, green roof system will be provided at the proposed fresh and flushing water service reservoirs and fresh and flushing water pumping stations to enhance the environment and reduce the heat island effect.

2.7 Smart energy

Provision of conventional salt water supply facilities for toilet flushing will require significant amount of pumping energy for ARQ Site owing to its high altitude – platform level at +200mPD approximately. The adoption of the grey water recycling system as described above to replace the salt water flushing facilities in another way reduce the energy consumption. From energy saving point of view, the new system will also be a smart initiative to reduce energy consumption for the ARQ Site.

The LIW infrastructure including the artificial flood attenuation lake; bioretention system; porous paving and green roofs discussed above also play a role in energy saving by reducing the heat island effect.

Furthermore, solar panels will be installed on the cover for the Public Transport Terminus (PTT) and the roof of the ventilation room of the underground stormwater storage tank. Operation for the pumping stations and treatment facilities for the flood attenuation lake, road lights and illumination for signs of public carriageways within the ARQ Site will be the main features to be powered by electricity generated from the renewable source. Considering ample space available from the eye-catching rock faces of the ARQ Site and the favorable orientation of absorbing sunlight, feasibility of installing solar panels at the rock faces is also under study. If this idea could be put into reality, it can not only bring much improvement to the original eyesore but also be an energy producer.

2.8 Smart mobility

The concept of smart mobility is to create and promote a walkable city and to adopt environmental friendly transportation mode for residents commuting within the development area. It also fosters public transit oriented transportation by using information and communication technology in order to improve the quality of transportation service. There are two main elements of smart mobility for implementation in the Development of ARQ Site, including Pedestrian and Cycling Mobility; and Interactive Urban Mobility.

2.8.1 Pedestrian and cycling mobility:

To position the Development of ARQ Site as a smart model community, a well-planned pedestrian and cycling network with associated ancillary facilities is essential for providing a convenient and healthy method of active mobility on a daily basis.

Provision of cycling network and ancillary facilities helps to encourage residents to use bikes for internal circulation within the community of the ARQ Site so as to reduce the reliance of vehicular transport. This cycle track to be placed alongside the main roadways of the Development of ARQ Site with single-two lanes ensures cyclists to be able to reach important nodes within the community blocks efficiently while maintaining a safe level of segregation between motorized vehicles and pedestrians, which is regarded as "dedicated cycle track".

Apart from the implementation of the cycling mobility within the ARQ Site, off-site pedestrian connectivity facilities including escalator and lift systems as well as access to the proposed bus-bus interchange station at Tseung Kwun O tunnel toll plaza will be provided to reduce the demand for short vehicular trips for relieving the pressure on the existing road network in Sau Mau Ping area.

A bike share program is also being considered at the ARQ Site that boosts the community's health by shifting people from passive to active transportation at a relatively low cost. Daily commuters, cyclists, young riders, and inexperienced cyclists are all welcomed to use the shared bikes. An operator of the bike share program will be required to monitor the bike share stations and re-allocate the shared bikes at areas with low stock. Smartphone Apps is a possible tool to enable the monitoring.

Demarcation of management and maintenance responsibilities of the facilities; and administrative control and regulatory measures are always crucial issues to be resolved for implementation. Operation of the shared bike program and provision of private bike parking are also challenges for the successful implementation of this smart mobility initiative. It is believed that there are possible solutions to tackle the difficulties by making reference to those successful precedent cases locally and overseas.

2.8.2 Interactive urban mobility:

Hong Kong, as a city with a substantial number of public transit ridership and an intricate transportation system, has not yet formed a comprehensive interactive mobility system that brings together all travel modes, transport-related services, and mobility concepts in Hong Kong. Well-developed system of providing travel information helps building a smart community.

When future residents move around the community of the ARQ Site, real time travel information gathered from different travel modes can be accessed through the use of smart apps or interactive signage at the bus stops to enhance overall transportation efficiency. Synchronized city-wide information will also be available for residents travelling outside the ARQ Site.

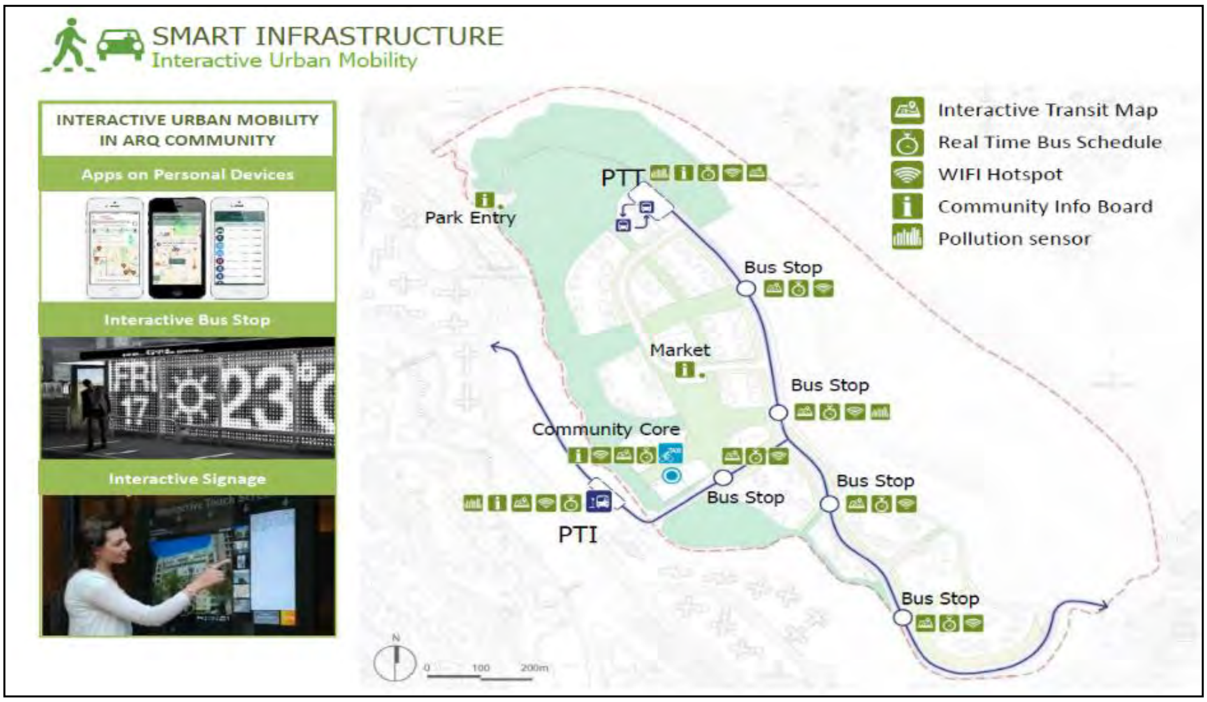

Figure 5: Interactive mobility features

3. CONCLUSION

The Development of ARQ Site will demonstrate Hong Kong as a place that builds exemplary communities for its residents. A community that even more than "smart" is "wise" by engaging both the future and the past. A community that seamlessly integrates new technologies in support of timeless world class urbanism to efficiently promote the safety, pride and well being of its residents.

Revolution and evolution always face a lot of resistance and challenges. For instance, to achieve success in the implementation of bike share program and grey water recycling system within the ARQ Site, it is paramount important to foster culture change in the community by collaborating with each other within the government to undertake the responsibilities for operation, management and maintenance and to review the need for legislation amendment, the existing design guideline, the current policy of development and the existing organizational structure.

With devoting collaborative efforts to building smart new community, it is expected that even more smart initiatives could be implemented in other new development areas like Yuen Long South, Kwu Tung North, Fanling North, Hung Shui Kiu and Tung Chung East and West under planning, and could build up Hong Kong to be a more green and smart city.

ABSTRACT

Increasing emission of greenhouse gases intensifies global warming. Pollution control, energy conservation and deployment of renewable energy being the core strategies to combat climate change are also the very fabric of sewage treatment. On the one hand, sewage treatment processes are energy intensive endeavours, and on the other, sewage is normally high in calorific value. For the past two decades, the sewage treatment industry has worked assiduously to develop energy efficient and recoverable processes to treat sewage and harvest the treasure trove of resources found in sewage. Studies conducted on major sewage treatment processes reveal that the conventional aeration system for oxidation of organic and inorganic contaminants contributes to 40-60% of the energy consumption of a sewage treatment plant. Smart aeration, frictionless-bearing air blowers, short cut denitrification, sidestream sewage treatment and mainstream anaerobic sewage treatment followed by ammonium oxidation (anammox) are promising energy saving technologies that can significantly reduce the aeration demand. Adoption of advanced sludge treatment processes such as biological hydrolysis process, thermal hydrolysis process, co-digestion of sewage sludge and other organic waste, etc. are measures to boost up the biogas yield in sewage treatment works with the anaerobic digestion process. Intertwining aforementioned energy saving and resources recovery approaches into the design and operation of sewage treatment works paves the road to energy neutrality. Looking above and beyond, biogas fuel cells and novel technologies, such as extraction of the energy content of ammonia from the nitrogenous pollutants with significant specific heat in digestate, are opportunities worth further exploration and may lead to the ultimate paradigm shift – from Energy Intensive Sewage Treatment Works to Net Energy Gain Energy Recovery Centre.

Keywords: sewage treatment, energy budget, energy neutral sewage treatment works

1. INTRODUCTION

Sewage treatment shifting paradigm recognises sewage energetic budget and the treatment capability to meet the stricter regulations for effluent and emissions related to the environment and human health. The energetic budget refers to the energy stored in the chemical bonds and the nutrient content from organics and inorganics compounds, such as nitrogen (N), and phosphorous (P) contained in sewage. In fact, previous estimation for internal energy content in domestic sewage, considering 6.8 billion people in the world producing 60-120 gCOD/person/day and 14.7 kJ/gCOD as energy content value, showed there is 2.2-4.4 x 10^{18} J of energy per year available (Heidrich *et al.,* 2011). Those calculations were based on raw sewage, but during the sewage treatment process, the initial energy content is distributed into the water and solids streams. Several studies have used bomb calorimeter to measure the calorific value for the sewage treatment process (Tomkins *et al.,* 1985; Shizas and Bagley, 2004; Heidrich *et al.,* 2011). Raw sewage intrinsic energy ranged around 1.9 -10.1 kJ/L, 18 - 94 kJ/L for primary sludge, 1,265 – 1,695 kJ/L for thickened combined sludge, 254 - 306 kJ/L for anaerobic sludge, and 1.9 - 2.5 kJ/L for primary clarifier effluent. In general, the energy content values combined with the flow of a sewage treatment works (STW) represent the energy flow at that respective treatment process.

The energy budget for energy production within a STW has been proved to meet, or even exceed, the energy demanded by the treatment process (Remy *et al.,* 2014). By using the appropriate technologies, a STW can achieve energy neutral, or even positive, operation. Researchers have reported their findings of energy neutral technologies, including energy saving and energy production strategies, adopted in full-scale STW; [e.g. Austria (Nowak *et al.,* 2011), Czech Republic (Jenicek *et al.,* 2013) and USA (Proctor, 2010)]. Strass wastewater treatment plant (WWTP) in Austria has even become energy positive. The energy saving strategies mainly present in the energy neutral STW aforementioned are anaerobic ammonium oxidation (Anammox), smart aeration, chemical enhanced primary treatment (CEPT) completed with anaerobic digestion. The energy production strategies mainly are anaerobic digestion with co-digestion, combined heat and power (CHP), generators and solar panels. The objective of this study was to review literature and to identify state-of-the-art energy efficient technologies that could be implemented to achieve energy neutral operation in a typical sewage treatment works (STWs). The energy flows from Sha Tin and Shek Wu Hui STWs in HK were performed in a R&D project supported by Drainage Services Department (DSD). Results are interpreted to overlook their application niches, and thus, recommendations were made in achieving energy neutral operation in the short- and long- term.

2. ENERGY NEUTRAL STRATEGIES

The current research and development of STWs provides a wide range of options to recover the intrinsic energy in the sewage. Some of those options are the energy production strategies presented in this study. Yet, not only energy production, but energy conservation within the plant is essential to achieve energy neutral operation. Aeration is the focus of the energy conservation due to its significant share in the plant power usage which commonly is around half of the plant power usage (WEF, 2009). Then, this study presents energy saving strategies, which are focused on efficient aeration system and anaerobic/ anoxic biological treatments. In addition, the energy production strategies refer to the making use of the biogas produced by anaerobic digestion in the water and solid stream.

2.1 Energy saving strategies

The energy saving strategies identified in this study include some recent technologies such as shortcut denitrification, smart aeration, and anaerobic treatment followed by Anammox.

2.1.1 Shortcut denitrification

Shortcut denitrification is a strategy evolution from the conventional nitrification-denitrification process. The typical nitrification-denitrification process consists in two steps. In the nitrification step, reduced nitrogen compounds (ammonium, ammonia and nitrite) are first oxidised by ammonia-oxidizing bacteria (AOB), which convert ammonia to nitrite (NO_2^-). Then, nitrite-oxidising bacteria (NOB) further oxidise the intermediate product to nitrate (NO_3^-). In the denitrification step nitrate is then transformed back to nitrite, and further to nitrous oxide, nitric oxide, and finally to nitrogen gas (Jianlong and Ning, 2004; Ruiz *et al.,* 2006).

Nitrite is the key intermediate for both nitrification and denitrification. Thus, a partial nitrification (ammonium oxidation into nitrite, but not further to nitrate) can be followed by denitrification (Ruiz et al., 2006; Jianlong and Ning, 2004). Partial nitrification requires the inhibition of NOB activity, while enhancing AOB activity through appropriate regulation of free ammonia (FA) by manipulating pH, temperature, DO, and sludge retention time (SRT) (Jianlong and Ning, 2004; He et al., 2013). The optimal operating parameters for partial nitrification have been well-studied and its ammonia-nitrogen removal efficiency and nitrite accumulation rate were well-reported (Jianlong and Ning, 2004; Ciudad et al., 2005; Ruiz et al., 2006; He et al., 2013). Literature showed that low DO concentration ranges from 0.7 mg/L to 1.5 mg/L could achieve ammonia-nitrogen removal efficiency over 90% and nitrite accumulation of 67.6 to over 95%.

Low DO supply results in energy savings associated with aeration during nitrification, reduction of organic matter requirements in denitrification, reduce in reactor footprint, decrease in surplus sludge production from reducing growth of NOB, and low cost implementation due to the change of only operational conditions (Ciudad *et al.,* 2005; Ruiz *et al.,* 2006). In addition, Jianlong and Ning (2004) reported that nitrogen-rich high-strength wastewaters with a C/N ratio of over 3 are ideal for application of the shortcut biological nitrogen removal process. Therefore, the dual system for flushing toilets of Hong Kong could be treated through this process.

2.1.2 Smart aeration

In addition to low DO concentration levels for energy saving in the aeration system, efficient mechanical devices for smart aeration highly contribute to energy conservation. The main mechanical elements in the aeration system are the blowers, valves and diffusers.

Åmand *et al.* (2013) reviewed the most efficient technologies for each mechanical element. Centrifugal blowers were presented to have the highest efficiency of about 65-85%. Blowers (not considering influent pumping) are the largest single user of energy at a traditional activated sludge system. The valves and their actuators energy saving strategies are most-open-valve (MOV) principle and direct flow control. Valves and their actuators are closely related to complementary elements such as sensors, and control structures with algorithms. The last element, the diffusers, can be categorised by their porosity or bubble size. Fine bubble aeration has higher oxygen transfer efficiency than coarse bubble aeration. Hence, the fine bubble diffuser could represent energy savings if adapted appropriately.

In overall, Åmand *et al.* (2013) presents the main mechanical elements should include centrifugal blowers, most-open valve (MOV) strategy, and fine bubble diffusers. Yet, the mechanical and complementary elements of the aeration system should be tested and further evaluated to determine their energy efficiency. Upgrade of the aeration elements has been adopted in Strass and Wolfgangsee-Ischl WWTPs in Austria, and Gresham WWTP in the US (Proctor, 2010; Nowak *et al.,* 2011).

2.1.3 Anaerobic treatment followed by Anammox with sewage

The technology termed staged fluidised-bed membrane bioreactor (SF-MBR) is a hybrid system covering both strategies of energy saving and energy production. This technology consists of an anaerobic fluidised-bed bioreactor (AFBR) and a fluidised-bed membrane bioreactor (F-MBR). The SF- MBR omits the use of aeration due to its anaerobic nature, while producing biogas during the process. Strass WWTP in Austria has already adopted the similar concept, leading an energy gain (Nowak *et al.,* 2011).

The AFBR treats the organics through anaerobic conversion to methane and/ or hydrogen sulfide depending on sewage characteristics of high or low saline content. The next stage, the F-MBR, combines biofilm and membrane design configuration for autotrophic nitrogen removal via coupling nitritation and Anammox (Kwak *et al.,* 2012). The coupling occurs by integrating completely external DO supply for stable nitritation, membrane filtration and biofilm fluidised-bed media design configuration in a single stage (Wang *et al.,* 2010; Ni *et al.,* 2010; Lee *et al.,* 2013; Kwak *et al.,* 2012). The oxygen supplied externally through aeration of a recycle stream is then mixed with the influent ammonia-containing wastewater to achieve a given DO to ammonium nitrogen ratio. By this complete DO supply an observation of nitrate formation equalled no more than 2% of the ammonium removed by Anammox, which has usually been reported as around 10% by research (Lee *et al.,* 2013). On the other hand, the produced nitrite by nitritation in this F-MBR would be consumed immediately by Anammox microorganisms which ensure less nitrous oxide formation, thus a reduction in greenhouse gas (GHG) emissions (Kwak *et al.,* 2012). In addition, the F-MBR has good mass transfer and high biomass retention with the traits of effective fouling control (Ni *et al.,* 2010; Kim *et al.,* 2011).

The SF-MBR system has several advantages. First, the system has less direct GHG emissions due to the fast consumption of nitrite by Anammox diminishing nitrous oxide formation. Also, less sludge production from microorganisms associated with anaerobic organic treatment and autotrophic nitrogen removals which have the feature of low yield (McCarty *et al.,* 2011; Kwak *et al.,* 2012). The good effluent quality comes from the use of membrane filtration process. Also, polishing residual organics either by Anammox or integration with denitrification has been found through the limited DO supply (Wang *et al.,* 2010; Lan *et al.,* 2011). The secondary anaerobic biofilm treatment of organics with low or high saline sewage either by AFBR or upflow anaerobic sludge blanket (UASB) has recently been proved to be able to meet the effluent standard of 30 mg/L for BOD (Wang *et al.,* 2009). Regarding resource recovery, the SF-MBR effluent could be sent to a commercialised phosphorous recovery process producing a plant nutrient fertiliser (Rittmann *et al.,* 2011). Additionally, the dissolved hydrogen sulphide and methane contents from the anaerobically-treated effluent could be recovered as elemental sulphur and electricity, respectively (Bandara *et al.,* 2012; Cookney *et al.,* 2012).

2.2 Energy production strategies

The energy production strategies identified in this study include some recent technologies such as co-digestion, solid oxide fuel cells (SOFC), and energy recovery from ammonium in digestate.

2.2.1 Co-digestion

Anaerobic digestion (AD) is a biochemical process for the treatment of organic substrates in the absence of molecular oxygen. The anaerobic pathway to CH_4 formation involves the degradation and stabilisation of complex organic matter by a consortium of microorganisms leading to a methane-rich biogas. Anaerobic treatment for a sole substrate has demonstrated to encounter difficulties to breakdown rigid cell walls and extracellular polymeric substances which lead to poor hydrolysis (Zhen *et al.,* 2014). To tackle these limitations, co-digestion is a strategy that has been developed in recent years. Co-digestion is the simultaneous digestion of a homogeneous mixture of two or more substrates. Co-digestion has unique benefits over the traditional AD including: balances C/N ratio and nutrient, increases pH buffering capacity, decreases ammonia toxicity and accumulation of VFAs, results in better quality of a digested product, and increases loading of readily biodegradable organic matter, which translates in enhanced biogas production (Zhang *et al.,* 2014; Zhen *et al.,* 2014). This technology is of interest to this study, due to its potential adaptability to existing digesters at WWTPs (Zhang *et al.,* 2014). In fact, energy neutral plants have adopted co-digestion with fat, oil and/ or grease (Proctor, 2010) food waste (Adelman and Gill-Austern, 2011) and dairy waste (Shen *et al.,* 2015).

2.2.2 Solid oxide fuel cells

Unlimited by the Carnot cycle, solid oxide fuel cell (SOFC) is a promising technology used to electrochemically convert the chemical energy of fuels to electric power with high energy efficiency and negligible impact on environment. A typical SOFC is composed of a porous cathode, a dense electrolyte and a porous anode. The cathode serves as an electrocatalyst for reduction of molecular oxygen to oxygen ions, a process commonly known as oxygen reduction. And then the electrolyte (assuming oxygen-ionic conducting oxide) allows oxygen ions to transport through continuously and solely under a gradient of chemical potentials of oxygen. Finally, the anode accepts oxygen ions delivered by the electrolyte and converts them into H_2O, CO_2 and electrons by reacting with hydrogen or hydrocarbon fuels, while the electrons transport through an external circuit from the anode to the cathode to realise the production of electricity.

The most attractive feature of SOFCs is their flexibility in selecting types of fuels due to the high operating temperatures, which can effectively activate the processes of reforming and electrochemical oxidation of hydrocarbon fuels (Xuan et al., 2009). The excessive heat produced from the electrochemical oxidation of fuels can be utilised by the highly endothermic steam reforming reaction simultaneously occurring, which makes internal on-cell fuel reformation possible. Such integration has advantages in terms of energy conversion efficiency and system simplification.

The composition of biogas can vary depending on its origin; however, it always includes as major constituents CH_4 and CO_2. With such a composition, CH_4-CO_2 gas mixtures can be also regarded as a relevant biogas fuel for SOFCs. The biogas produced from sludge digestion contains a significant amount of CH_4, which can be an energy source (Van Herle *et al.,* 2004). When CO_2 and CH_4 mixture is used in SOFC, CH_4 can be reformed by CO_2 at high temperature to produce CO and H_2. The CO and H_2 can be used as fuel in SOFC for power generation. The efficiency of SOFC (typically 50-60%) is significantly higher than conventional heat engines with typical efficiency of about 35% (Adams *et al.,* 2013). Thus, SOFC produces less pollutant for unit power generation than that of heat engines. Moreover, SOFCs can generate considerable power even at 20% CH_4 to CO_2 while the combustion engines cannot be applicable under this situation. Finally, SOFC contains no moving components thus it is quiet during operation.

2.2.3 Energy recovery from ammonium in digestate

Coupled Aerobic-anoxic Nitrous Decomposition Operation (CANDO) is a process that recovers energy from nitrogen in three steps: (1) partial nitrification of NH_4^+ to NO_2^-; (2) partial anoxic reduction of NO_2^- to N_2O, and (3) N_2O conversion to N_2 with energy recovery by either catalytic decomposition to N_2 and O^2 or use of N_2O to oxidise biogas CH_4. Scherson *et al.,* (2012) demonstrated through stoichiometry calculations that the oxidation of CH_4 with N_2O, rather than with O_2, lifts approximate 30% more energy. In principle, this N_2O is a more powerful oxidant than O_2 due to the release of an additional 82 kJ/mol from N_2O to N_2. The intermediate step- reduction of NO_2^- to N_2O may be accomplished abiotically with Fe (II) or biotically with polyhydroxybutyrate (PHB) storage granules as the source of electrons. Myung *et al.* (2015) studied the biotic strategy and found that the type II methanotrophic enrichments can mediate step two by coupling oxidation of poly (3-hydroxybutyrate) (P3HB) to NO_2^- reduction. The potential advantages of this process include the decrease of oxygen requirements by 20%, decrease of biomass production by 40%, mitigates the release of N_2O, increase of organic matter available for recovery as biogas methane, and enable energy recovery from nitrogen by 60% (Scherson *et al.,* 2012).

3. DISCUSSION

The energy flow done by Garrido *et al.* (2013) shows that 70% of the initial calorific energy (MJ/day) is present for biological treatment. In contrast, other studies affirm that 40-66% of the initial energy content is concentrated in the sludge (Shizas and Bagley, 2004; Gyobu *et al.,* 2015). In this context, we recommend shortcut denitrification for the biological treatment, with an upgrade of the aeration mechanical systems in the short-term. For the sludge stream at the anaerobic digesters, co-digestion is recommended. These strategies can be implemented by other similar plants aiming to achieve operational energy neutral. In a long-term planning considering infrastructure construction, change in the treatment, and higher investment; then, anaerobic treatment followed by Anammox for the water stream, and SOFC and ammonium in digestate for the sludge stream, can be implemented. Yet, further study is needed to determine if the organic matter should follow the water stream into the biological treatment or if the organic matter removal in the primary clarifier should be enhanced to obtain higher chemical oxygen demand for the solid stream in the anaerobic digester for biogas production as suggested by Flores-Alsina *et al.,* (2014).

ABSTRACT

Education is an important element to bring about social, economic and technological changes in any country. The physical infrastructure of schools is however seldom part of education improvement strategies in countries like Brazil. Public school buildings in the state of São Paulo are managed by its Foundation for Education Development (FDE). In 2010 FDE required that all new buildings were certified under AQUA, the French HQE environmental rating scheme adapted to Brazilian contexts. Building certification was devised as an opportunity to decrease environmental impacts, while improving indoor environment quality, among other performance aspects. Our research goals were to investigate if the certification requirements have a tangible positive impact on building quality, induce climate responsive architecture and provide adequate and comfortable environments for education. Nineteen FDE projects currently seeking AQUA certification were studied. First, we analysed the sample regarding climate responsiveness and critical performance aspects for learning environments. Then, we ran thermal and daylight simulations for a representative classroom to assess contribution from the designed shading devices. Our analysis revealed that orientation of school buildings to suit local climates is neglected. Double loaded corridor floor plans are typically adopted even though they prevent cross-ventilation in classrooms. Solar absorptance of external walls is not compliant in half of the cases. Finally, typical shading device design improves thermal conditions of optimally oriented classrooms, but impairs daylight harvesting in over half of the occupied time. The hypothesis was that AQUA certification of public school buildings would have significant effect on design elements which contribute to environmental comfort conditions. This was not confirmed. The certification had limited capacity to induce climate responsive architecture. For this reason, besides certifications the design process needs enhancement. Design decisions impact must learn from assessment loops, simulations and inputs from users and specialists alike. Finally, building assessment data should inform new school building projects, to guarantee that we are actually advancing in the right direction.

Keywords: building energy simulation, climatic responsive architecture, educational building facades

1. INTRODUCTION

Education is an important element to bring about social, economic and technological changes. Improving school buildings design to attain minimum sustainability indicators should contribute to enhance not only the quality of physical learning environments, but of education as a whole.

The State of Sao Paulo Foundation for Education Development (FDE) manages the public school building construction process. FDE is responsible not only for the design and construction of new schools, but also for the management and maintenance of around 5000 primary and secondary education facilities in the state. An example of FDE schools is shown in Figure 1.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

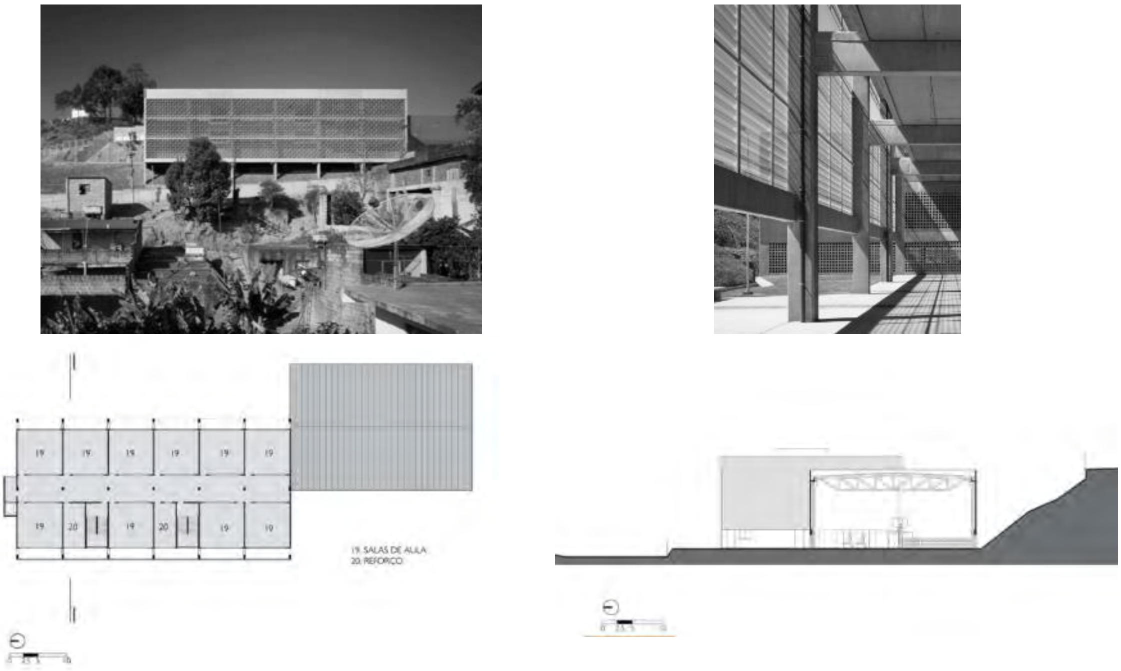

Figure 1: FDE school design example: "Escola Várzea Paulista". Courtesy of FGMF Architects

FDE school buildings are based on prefabricated reinforced concrete elements, similar to those used in other countries, like Spain. Designs are no longer stock-plans, but based on provision of a standardized short brief, minimum design requirements and a catalogue of architectural elements. This linear design process lacks evaluation loops at various stages. A sustainability milestone was established in 2010, when FDE required that all new school buildings must be certified under AQUA, the French HQE environmental rating scheme adapted to Brazilian contexts.

This paper is part of an on-going research project on school building design conducted at the University of Campinas (UNICAMP). Our research goals were to investigate if the certification requirements had a tangible positive impact on building quality, induced climate responsive architecture and provided adequate and comfortable environments for education. Nineteen FDE projects currently seeking AQUA certification were studied. First, we analysed the sample regarding climate responsiveness and critical performance aspects for learning environments. Then, we ran thermal and daylight simulations for a North-facing representative classroom to assess contribution of the designed shading devices.

2. METHODOLOGY

2.1 School building survey

Our surveyed database comprises 19 FDE projects designed between 2002 and 2014. All projects currently seek certification in one of the different AQUA process phases: concept design (13 schools), design (5 schools) and construction (1 school). Surveyed buildings accommodate from 8 to 27 FDE standard classrooms (7.2m x 7.2m) distributed over 2 to 5 floors and built areas ranging between 2,000 m² and 5,000 m². The floor-to-ceiling height varies between 2.7m and 3.0m. All sampled school buildings use the same construction materials and components, and all classrooms have acoustic ceilings.

Once this database was selected, five certification requisites were assessed, according to different sections of the AQUA reference guide:

- Building configuration and solar orientation, analysed according to sections 1.2.1 (Building orientation for solar and wind optimization) and 4.1.1 (Bioclimatic design strategies, including building dimensions and solar orientation of glazed areas);
- Building materials and components, analysed according to section 4.1.1, which demands compliance of the building envelope with level C of RTQ-C, a national energy efficiency label for buildings;

- Daylight and views, analysed according to AQUA's specific recommendations for classrooms and school buildings. All classrooms should be day lit (section 10.1.1) and have access to outdoor views (section 10.1.2). A minimum daylight factor of 1.2% must be achieved for 80% of the total number of classrooms (section 10.1.3), while higher values achieve extra points in the certification program. Though not a prerequisite, Section 10.1.4 also assigns certification points for avoiding glare, by protecting sitting and desk areas, as well as black or white boards from direct sunlight.
- Exterior solar protection, analysed according to Sections 4.1.1 and 8.4.3. The guide does not mention any specific recommendations for the design of exterior shading devices. Section 4.1.1 relates the solar orientation of glazed surfaces to the activity developed in a specific room. Section 8.4.3 states that spaces with a probability of being influenced by direct solar radiation (especially glazed areas) must have thermal comfort conditions controlled.
- Natural ventilation: Section 8.3 deals exclusively with thermal comfort of naturally ventilated spaces. There are no specific requirements for window opening dimensions. Section 8.3.1 requires that all naturally-ventilated, regularly-occupied spaces demonstrate, by computer simulation, that the percentage of occupied hours that achieve comfort conditions comply with RTQ-C requirements: between 60% and 70%, for level C (prerequisite); between 70% and 80% for level B (3 points); and above 80% for level A (4 points). Rooms with operable windows must ensure natural ventilation according to Section 8.3.2.

2.2 Computer simulations

One case study was chosen from the 19 schools of the database. Selection criterion was recurrence within our surveyed sample, regarding: building configuration, solar orientation, natural ventilation and exterior solar protection. The selected case study was School Jardim Santa Rita II, in a sub-tropical climate city near Sao Paulo, classified as bioclimatic zone 3, according to NBR 15220-2005. This 3-floor school has eight classrooms and combines a double-loaded corridor plan, with North-South classroom orientation and exterior horizontal fins (25% of perforation and reflective top coating) shading typical louvered windows. A North-facing classroom was selected for the simulation runs (Figure 2). Two models were created (Figures 3a and 3b), following the input parameters listed in Table 1. Sefaira and Energy Plus simulations respectively supported daylight and thermal comfort analyses.

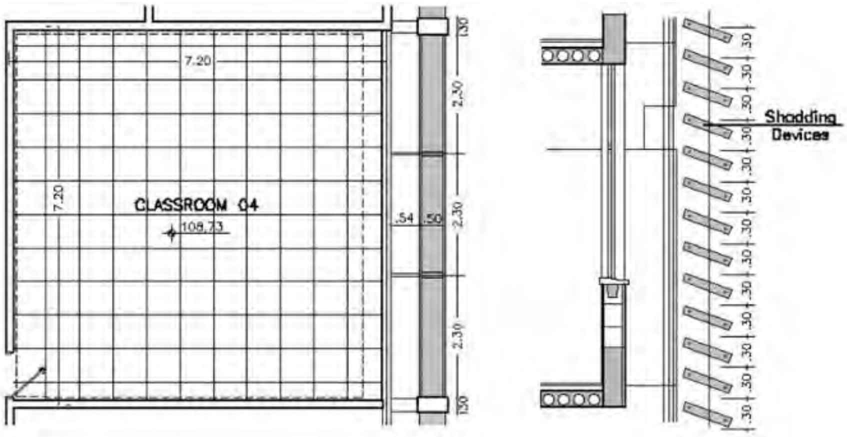

Figure 2: Simulated classroom floor plan and façade section

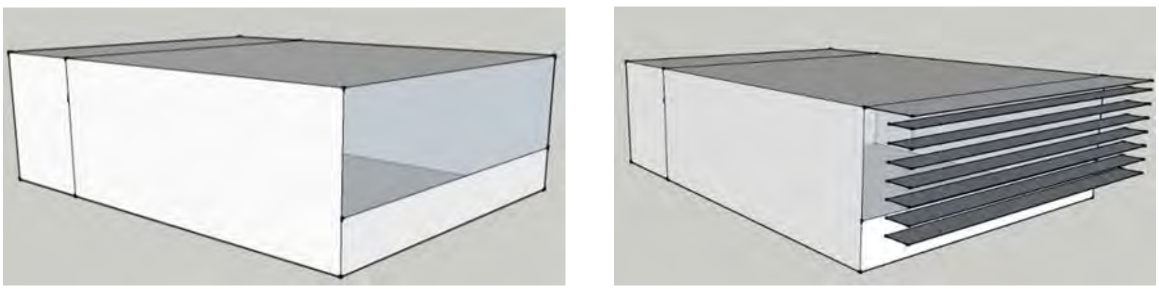

Figure 3: Classroom simulation models (a) without and (b) with shading devices

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Daylight and views evaluation was based on AQUA criteria that demand simulation: Daylight factor (DF) and Useful Daylight Illuminance (UDI). DF relates the amount of illumination available indoors and outdoors at the same time, under overcast skies. UDI measures the well lit occupied time (illuminance between 100 lux and 2,000 lux), as well as the underlit and overlit occupied time percentages. UDI also considers the probability of glare for results over 2,000 lux.

Thermal comfort analyses considered ASHRAE 55:2013 adaptive model for occupant-controlled naturally conditioned spaces, which establishes acceptable monthly indoor operative temperature ranges, considering an 80% acceptability limit.

Parameter	Value
Ratio of width to length (building)	0.54
Solar orientation	N-S
Floor-to-ceiling height (m)	2.8
U-value - exterior wall (W/(m².K))	2.7
WWR (%)	70
U-value - roof (W/(m².K))	0.7
Glazing U-value (W/(m².K))	5.5
Glazing SHGC (%)	87
Exterior shading devices	Horizontal fins (North façade)
Solar absorptance –walls (%)	0.3
Lighting Power Density (W/m²)	12
Electric Power Density (W/m²)	16
Building operation	7am to 6pm (weekdays)

Table 1: Simulation modelling parameters

3. RESULTS

3.1 School building survey

3.1.1. Building configuration and solar orientation

All surveyed buildings have a rectangular shape, which can be thoughtfully oriented to expose the long facades towards North-South for passive solar strategies optimization (Figure 4b). However, only 32% of the schools are actually best oriented, whist 26% are oriented East-West (Figure 4a).

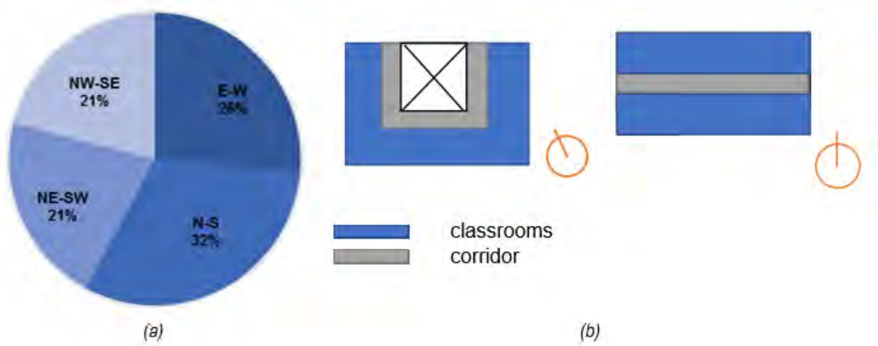

Figure 4: (a) Distribution of long facades orientation within the school buildings sample; and (b) Schematic ground floor plans of courtyard and linear schools

3.1.2. Building materials and components

All analysed schools have 20 cm-thick concrete blocks and plaster walls. Roof construction consists of insulated metal roofing panels over a reinforced concrete slab. Window-to-wall-ratio (WWR) for the two longitudinal façades is between 70% and 74%. Average window U-value in our sample is 5.5W/(m^{2}K), which corresponds to single 4 - 6mm glazing.

To comply with level C of RTQ-C, building façades and roofs in bioclimatic zone 3 must have U-values lower than 3.7W/(m^2.K) and 2.0W/(m^2.K), respectively. U-values of walls (2.7W/m^2.K) and roofs (0.7W/m^2.K) fall within RTQ-C's limits. AQUA does not have any specific requirements for solar absorptance, but rather refers to RTQ-C, which limits it to 0.5 for external walls and roofs, as a prerequisite. Even so, in the analysed sample, roughly half of the external wall surfaces are not compliant (Figure 5a).

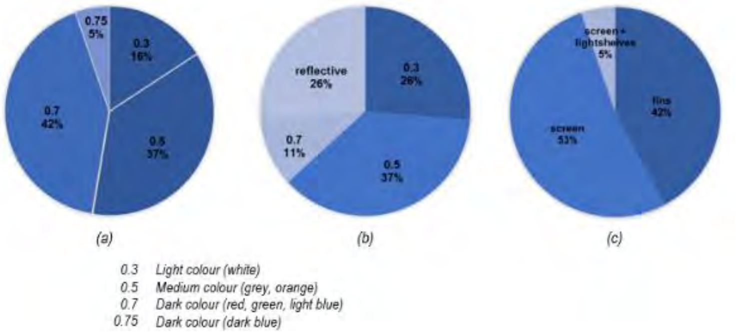

Figure 5: Distribution of (a) Solar absorptance of external walls; and of (b) Colour and (c) Type of exterior shading devices within the studied sample

3.1.3. Daylight and views

Classroom internal surfaces are painted white, to reflect daylight and ensure natural light distribution. While about 37% of the exterior shading devices have a solar absorptance of 0.5 and positively contributes to glare avoidance, one third (26%) of the cases have a reflective topcoat, which would actually provoke an opposite effect (Figure 5b). Windows are large in area, have transparent glass and the sill height permits views when sitting. Simulated results are presented in section 3.2.1.

3.1.4. Exterior solar protection

Classrooms in all buildings in our database have concrete or metallic exterior shading devices. Most designs include a perforated steel plate screen to protect classroom windows while allowing for daylight (Figure 5c). If adequately designed and adjusted, the provided exterior shading devices can potentially avoid glare. Simulated results are presented in sections 3.2.1 and 3.2.2.

3.1.5. Natural ventilation

As the majority of surveyed buildings follows the same floor plan model (central corridor with classrooms on both sides), cross ventilation in classrooms is impaired. In four schools this effect is alleviated by attaching the classroom access corridor to a courtyard (Figure 4b). Louvres (90%) and top hung windows were the fenestration types found in the sample. Classroom façade window height ranges from 1.8m to 2.2m, and totalize between 13.0m^2 and 15.8m^2, with approximately 71% of operable area. On the corridor side, classroom windows are smaller: window height between 0.35m and 0.8 and area varying between 2.5m^2 and 5.8m^2. Natural ventilation was out of our scope, but contributes to the overall thermal comfort conditions presented in Section 3.2.2.

3.2 Case study

3.2.1. Daylight simulation results

The simulated average Daylight Factor (Figures 6a and 6b) confirms that only the model without exterior shading devices (DF = 3.29%, Figure 6a) would comply with AQUA requirements, but users would experience 28% of overlit occupied time (Figure 7), and glare issues should be adequately addressed by design. UDI simulation (Figure 7a) shows that underlit conditions did not occur in this case.

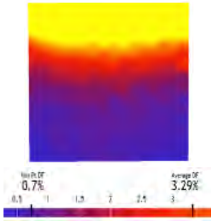

Figure 6: DF simulation (a) Without and (b) With shading devices

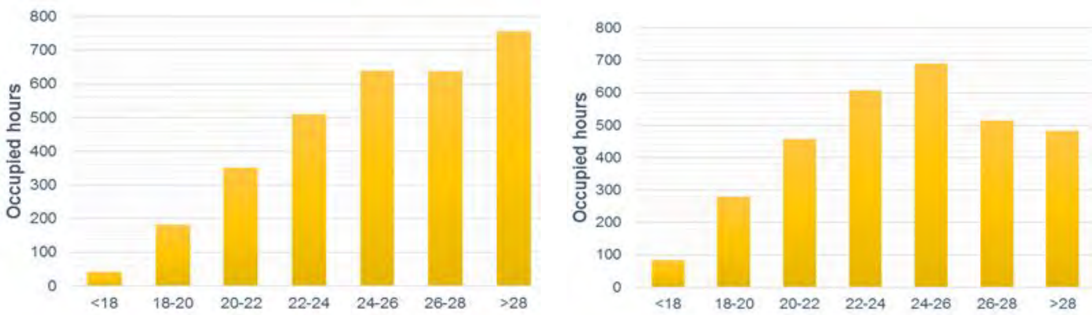
Figure 7: UDI simulation (a) Without and (b) With shading devices

For the model with shading devices, DF is much lower (0.85%, Figure 6b) and such classroom would rarely experience possible glare (overlit conditions = 1%), but rather be underlit for 55% of the occupied time (Figure 7b).

3.2.2. Thermal comfort simulation results

The model without shading devices provided satisfactory thermal comfort conditions for 64% of the occupied period. Such performance is compatible with level C of RTQ-C, and meets the corresponding AQUA certification prerequisite. When shading devices were added, the comfortable period was increased to 71% of the occupied time. The improved performance would comply with level B of RTQ-C, and grant 3 extra points (Figures 8a and 8b).



Figures 8: Results of thermal comfort simulations (a) Without and (b) With shading devices

4. CONCLUSION

Compelling school architecture comprises a series of spatial qualities and positive user experiences, such as fit of architectural brief, educational methods and perceived socio-cultural values. Certification of school buildings, as required by FDE, is an opportunity to decrease environmental impacts while improving indoor environments, among other performance aspects. Conversely, our analysis revealed that, among building designs seeking AQUA recognition, orientation of school buildings to suit local climates is surprisingly neglected. Double loaded corridor floor plans are typically adopted, though they prevent cross-ventilation in classrooms. Solar absorptance of external walls is not compliant in roughly half of the cases. Finally, typical sun-shading device design improves thermal conditions of optimally oriented classrooms, but at the cost of impairing daylight harvesting in over half of the occupied time.

Though rating systems like AQUA can potentially contribute, the certification per se seems to have limited capacity to induce climate responsive architecture or delivery of adequate indoor environments for educational activities. Aiming for better design outcomes demands design process enhancements. Old, inefficient school models – as well as the design processes that generated them - should be revised. Design decisions impacts must be carefully reflected upon and continuously learn from assessment loops, simulations and inputs from users and specialists alike. Finally, building assessment data should inform new school building projects, to guarantee that we are actually advancing in the right direction.

ABSTRACT

In today's materialistic society, there is a constant pressure to consume goods and services without taking into account that this unbridled acquisition will lead to an increase in the generation of solid waste that, in most cases, will not be properly disposed of, culminating in the proliferation of vectors for Zika, Dengue, Chikungunya, Leptospirosis, and Meningitis, as well as structural problems such as flooding and contamination of soil and groundwater. However, most wastes contains organic materials with the potential to produce biogas that can be used to generate electricity. When sanitation is not properly managed it can cause incalculable damage to the environment, to public health, to the population, and to the urban order. This study presents projectual guidelines for sustainability of low income communities in urban areas through the installation of biodigesters as an alternative for the proper disposal of their organic solid waste and sewage in order to improve sanitation and enable the generation of biogas and power for such communities. The guidelines were elaborated based on interviews with community leaders, the socioeconomic profile of community residents, the amount of waste generated, sewage drainage problems, availability of open areas adequate for the installation of biodigesters, the post-installation maintenance manual, as well as an analysis of the Brazilian laws and regulations that standardize the construction aspects. The proposed guidelines are intended to assist managers in decision making with regard to sanitation and generation of biogas from waste, which is currently a problem for local development.

Keywords: biodigesters, low income communities, sustainability in urban areas.

1. INTRODUCTION

In large Brazilian cities, innumerable informal dwellings, also known as needy communities, lack basic sanitation, safety, transportation, decent housing, and the means to enable the development of infrastructure that could improve the quality of life for the population. According to Fantinatti et al. (2015), informal dwellings arise spontaneously, as in the cases of invasions or irregular settlement in difficult-to-access areas that are established because of proximity to work or availability of open land. Faced with this problem, the need to apply engineering knowledge in support of low-income communities with projects that bring sanitation, leisure, education, sustainable housing, and generation of energy to the population becomes evident.

In Brazil, basic sanitation is defined by Law 11.445/2007 as the set of services, infrastructure, and operational installations for drinking water supply, sewage, street cleaning, solid waste management, floodwater management, and urban drainage. According to etymology, sanitation is the act or effect of sanitizing, disinfecting, deodorizing; it refers to the application of measures to improve hygienic conditions of a place or region, especially drainage, making it suitable for habitation and bringing improvements to health. (Weiszflog, 2016).

Therefore, sanitation implies a determining factor and condition for public health, and must be regarded as of interest to social policy for the protection of the population. According to Embrapa (2010), 75% of hospital admissions in Brazil are associated with the lack of basic sanitation, often related to informal housing combined with the absence of three basic services: running water in at least one room, sewage network or septic tank, and trash collection. (Observatório das Metropolis, 2010)

Faced with these sanitation problems, the objective of this article is to bring alternatives through project guidelines and a proposed layout for biodigesters, considering economic viability and ease of installation and maintenance,

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

that can be used to channel sewage and solid waste in needy communities, improving the local basic sanitation and public health, as well as contributing to the improvement of sewage spilled into bodies of water.

1.5 The city of Recife and basic sanitation

In middle- and upper-class neighborhoods of large Brazilian cities, it is not common for the populace to stop and think about how many times they turn on faucets or the shower, or flush the toilet. It is not a habit to analyze the consumption of water by families, the neighborhood, the city, or the state where one lives, much less to think about the collection, treatment, and maintenance of its sewer systems. (Revista Proteção, 2012).

According to the latest census from the Brazilian Institute of Geography and Statistics, the City of Recife has a population of 1.5 million. Recife is a coastal city surrounded by rivers and marshes. Its unplanned territorial occupation, associated with poverty and misery, has spurred the growth of informal housing with innumerable socio-environmental problems, lack of basic sanitation, and numerous clandestine connections of sewage to the city's drainage network. (Picarelli, 2016).

The municipality of Recife covers 220 km^2 of area and is divided into six (6) Politico-Administrative Regions (RPA's) for the purposes of forming, executing, and evaluating the policies and plans of the government. Each RPA is subdivided into three (3) micro-regions, which define local-level municipal interventions and coordination with the populace. These micro-regions are subdivided into neighborhoods, and within them can be found the Special Zones of Social Interest (ZEIS), which are "portions of territory to be given priority in urban recovery, land regularization, and social housing projects, including the recuperation of degraded properties, the provision of social and cultural amenities, public spaces, services, and locally-based businesses." (Fonseca et al., 2014, p.1).

The ZEIS were integrated in the City Master Plan in 2008. Today, Recife has 66 ZEIS distributed throughout 94 neighborhoods. Such neighborhoods show symptoms of urban land use exhaustion. Many of these neighborhoods are located in riparian areas, near drainage canals, or in sensitive hillside areas highly restrained from expanding and installing urban infrastructure, resulting in a wide range of structural and socio-environmental problems for their low-income residents, who have no other housing options.

The Brazilian reality is that 35% of the population (reaching over 60% in Recife) relies on inadequate solutions for their sewage removal. Only 20 million habitants in Brazil have sewage disposal systems or septic tanks that are considered suitable for the disposal of wastes. (Ministério das Cidades & Secretaria Nacional de Saneamento Ambiental, 2014; Ministério das Cidades, 2014).

1.6 Use of biodigester systems in rural and urban areas

According to the United Nations Development Programme (PNUD) and the Ministry of the Environment (MMA) (2010), a biodigesteris a closed chamber that provides appropriate conditions for the fermentation of organic material carried out by methanogenic bacteria. This decomposition process generates biofertilizers and biogas, which is formed from the following gases in these proportions: methane 50-70%, carbon dioxide 25-40%, hydrogen 1-3%, hydrogen sulfide 0.1-0.5%, and other trace gases.

According to Peres (2010), 1 m^3 of biogas with 60% methane has a calorific value of 19.52 MJ.m^{-3}. The advantages of treating waste in a biodigester are a reduction in the amount of waste, the generation of a renewable energy source (biogas), and the production of biofertilizers with little odor and rich in nutrients that can be used in agriculture.

The study made by Turdera and Yura (2015) in the city of Dourados in Mato Grosso do Sul, Brazil, simulated the home use of biogas, where 8.93m^3 of biogas per day was able to provide for the cooking of meals, illumination of four light bulbs for three hours, refrigerate food, and provide a hot bath for a family of five people.

Despite being a reality for many years in other countries of the world, the use of biodigesters remains in its infancy in Brazilian urban areas. However, a few examples of research and development can be seen at Brazilian universities (Pimentel et al., 2015). In urban areas, specifically ZEIS where there is disorderly settlement and high population density, large-scale projects are not applicable due to the absence of free space within the communities, necessitating a new compact design that is simple to install, operate, and maintain.

2. METHODOLOGY

Initially, a literature review was conducted on the political-administrative distribution, neighborhoods, and ZEIS, as well as the sanitation infrastructure of the city of Recife. Subsequently, a descriptive Field study was conducted through photographic registry and informal interviews with community leaders in the ZEIS of Borborema, Vila Arraes, and CarangueijoTabaires with the goal of identifying, mapping, and observing the flow of sewage and the disposal of Municipal Solid Waste (MSW), discovering the locations of open areas for installation of biodigesters, tracing the socio-economic profile of residents, and estimating the electrical current necessary to supply homes, residents associations, or community centers open to all local residents.

Using the ESIG program, Geographic Information of Recife, it was possible to visualize the proximity of the communities visited to bodies of water, and to map rivers, drainage canals, lakes, basins, and the sea, as well as to store information necessary for a potential study of environmental impacts caused by improper sewage disposal.

Project guidelines were proposed to channel sewer water to a “homemade” biodigester based on laws and technical standards, international and national case studies in urban and rural areas, technical manuals from biodigester manufacturers, a survey of the average wastewater volume produced per family, and the Pernambuco Solid Waste State Plan (PERS), generating as output biofertilizers, and biogas that can be utilized within the local community. The proposed guidelines also take into account the use of low-cost construction materials and the ease of installation and operation by the local community residents.

3. EXPLORATORY STUDY IN A ZEIS OF RECIFE

The exploratory field visits were conducted in 2015 and 2016 at three ZEIS communities in the Recife Metro Area: Borborema, Vila Arraes, and Carangueijo Tabaires. The visits were performed to collect data for a pilot project biodigester proposal and note the existing possibilities for the implantation of biodigesters in needy communities. In the ZEIS of Borborema, a potential area for the biodigester installation was identified, capable of attending the needs of a few homes and whose biogas could be channeled to community centers.

ESIG (Geographic Information of Recife), was used to map the ZEIS and visualize their proximity to bodies of water. With use ESIG, and photographic records, it was possible to identify the irregular and inadequate disposal of waste and sewage in the community of Caranguejo Tabaiares, Figure1 and its interconnection with the Capibaribe River, with the ABC drainage canal, and with the Nature Conservation Unit (NCU) Zeca Island.

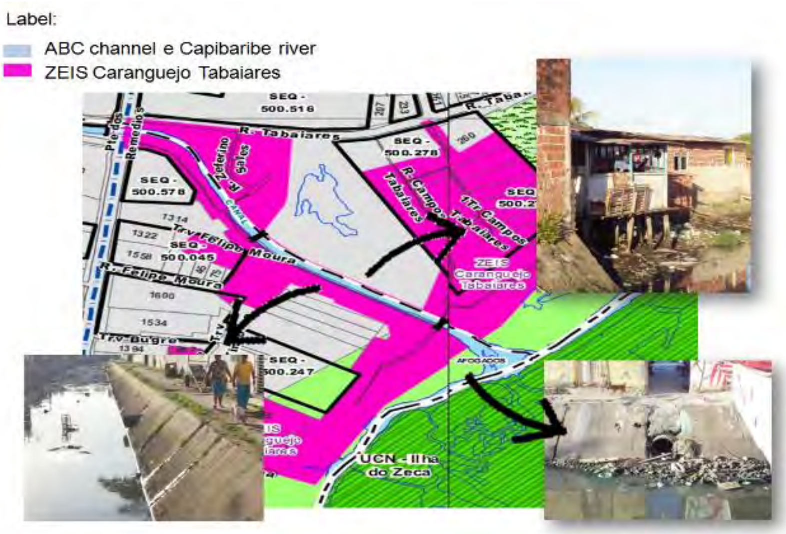

Figure 1: Location of inadequate waste and sewage treatment in the visited ZEIS. Source: Author, 2016

According to the informal interviews with local residents during the exploratory visits, respiratory illnesses, meningitis, leptospirosis, hemorrhagic dengue, chikungunya, zika, and scorpion bites have been reported and have been the cause of death for many children in the poorest communities due to the unsanitary conditions to which they are subjected.

4. DEFINITION OF GUIDELINS FOR THE PREPARTION OF PROJECTS AND LAYOUT PROPOSAL FOR URBAN BIODIGESTERS

The guidelines were divided into four sub-items: (1) basic elements, (2) minimum distances from areas of influence, (3) choice of location and (4) specific elements to establish criteria for the development of biodigester projects in needy communities. Based on current local legislation, technical standards relevant, guidelines from manufacturers' manuals, as well as on data obtained from the exploratory visits to needy areas of Recife, the criteria are detailed on the following flowchart:

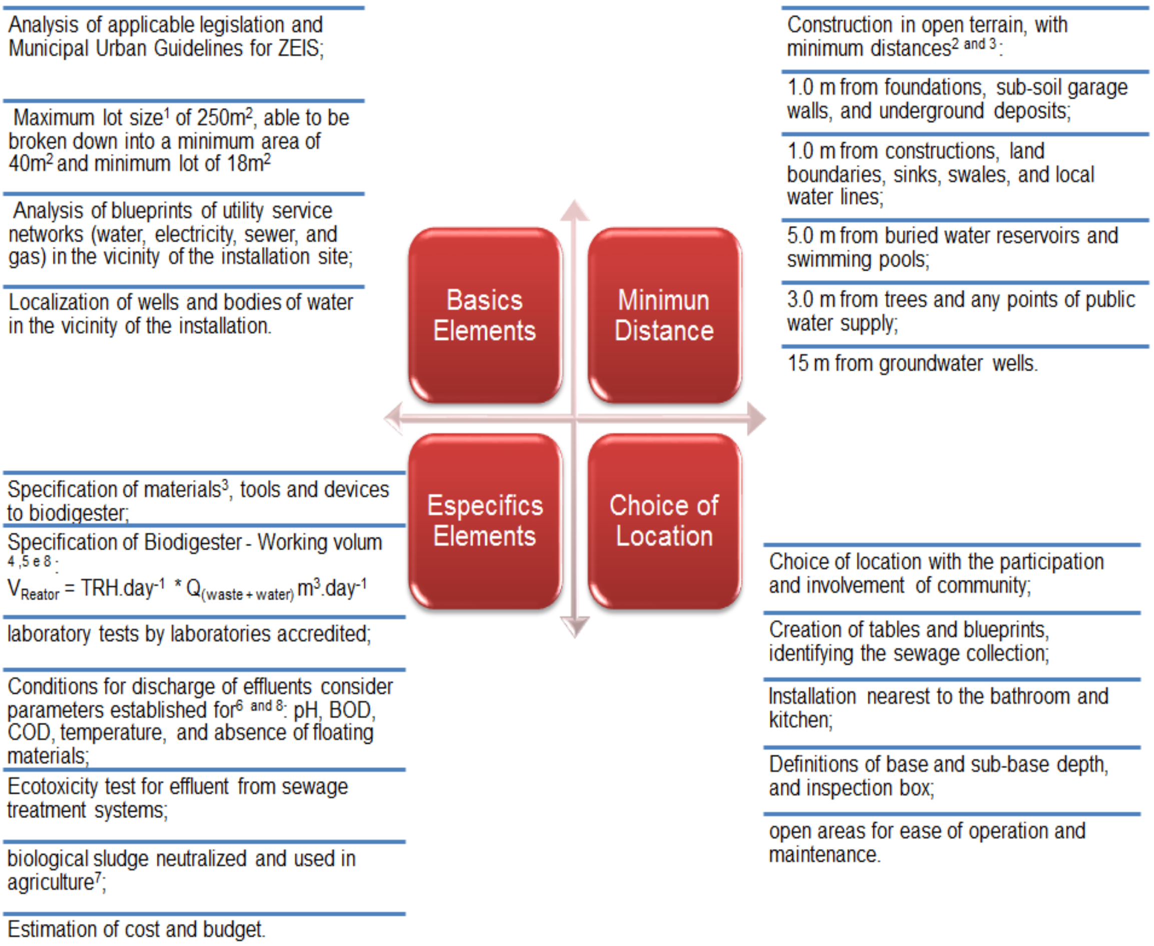

Figure 2: Guidelines for project preparation. source: created by the author based on [1]Recife (1995); [2] CPRH (2004), [3] Creder (2006); [4] ABNT (1993); [5]ABNT (1997); [6]CONAMA (2011); [7] CONAMA (2006), [8]ONUDI (2016).

The Total Waste (RT) value was calculated in accordance with Equation 1, considering the value of Organic Waste (RO) added to the waste water (NA) produced per person.day^{-1}. The RO value 0.9924 kg per person.day^{-1} was calculated from the PERS (SMAS & ITEP, 2012). For toilet waste water (WW), the value of 0.2 kg feces+urine per person.day^{-1} was considered, according to NBR 7229:1993. The total waste feeding into the biodigester daily can be calculated by the expression below:

$$RT = Pop.*[(RO + WW)]$$

Were, RO in kg per person.day^{-1}, WW in kg per person.day^{-1}.

Equation 1

The dimensions of the system were calculated according to ONUDI (2016), and using Equation 2 below. The process was considered to be mesophilic with fermentation in 30 days and the average temperature of Recife around 30°C, obtaining a reactor volume (fiberglass box) of 5.97 m³. For the gasometer, a PVC tarp attached to the base of the fiberglass reactor that stores the biogas generated, a volume of 30% of the $V_{Reactor}$, 1.791 m³, was estimated.

$$V_{Reactor} = TRH * Q\ (RT + Water)$$

Equation 2

were $V_{Reactor}$ in m^3 for the biodigester, Q = total contribution RT sun Water in $m3.day^{-1}$ and TRH = Water Retention time, in days.

To create the Urban Biodigester prototype (Figure 3), materials available in the market were considered and a family made up of five (5) residents was contemplated. The prototype will use a 6000 L fiberglass box (to fit the estimated waste according to Equation 2); 3.40m² of PVC canvas, shown in Figure 3 and indicated by the letter (a); 100 mm PVC pipes shown by the letter (b) to transmit waste water (AN), for the output of biofertilizer (c), and for receiving organic wastes (d). To operate the biodigester, a slope of 5% should be used for the waste water pipes. For the biogas output, the installation of a 4" Spin pipe connection is suggested, as well as a gas filter (g) and a meter to measure the biogas output (h).

A commercially available inspection/interconnection box must be installed and adapted with an interior grid having a minimum diameter of 30 cm, illustrated by the letter (f) in Figure 3, before the input pipes to the biodigester in order to hold accidental discards of non-biodegradable material in the toilet, such as wipes and plastic packaging that can clog the system. It`s necessary a complementary treatment of the liquid effluent through the use of a buried sand filter (ABNT, 1993) is indicated, as shown in Figure 3 (f).

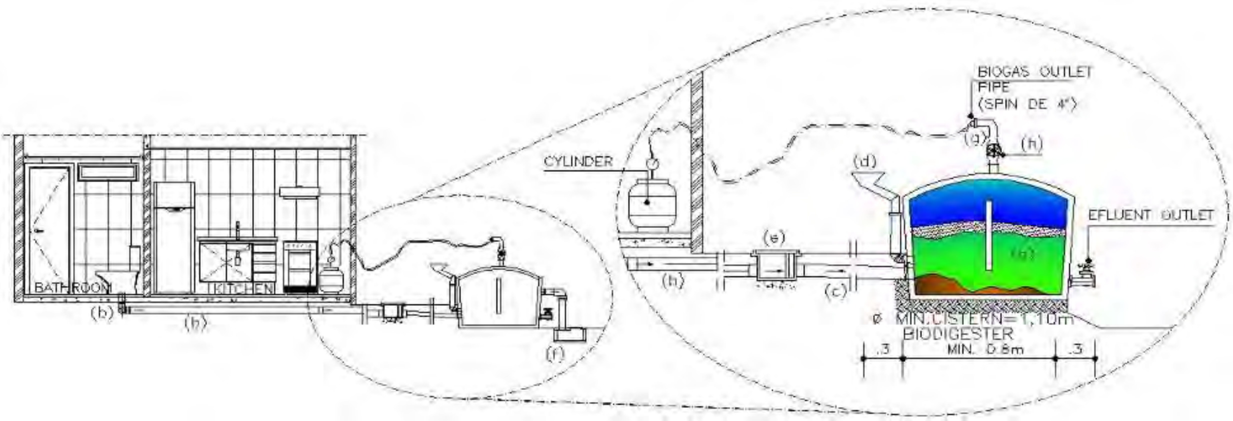

Figure 3: Proposal for prototype urban biodigester to be in Recife. Source: Autor, 2016

This system is expected to generate ¼ bottle of $LPG.month^{-1}$ and 20 L of biofertilizer/month, considering that the first withdrawal during the production period should occur after approximately 30 days have passed. The average time to recoup the initial investment was estimated to be 2.6 years, from the sale of biofertilizer and savings from the reduced purchase of cooking gas.

5. CONCLUSIONS

Large Brazilian cities, just like cities in other developing countries, have suffered because of the close link between lack of efficient public policies, unequal income distribution, disorderly settlement, and environmental degradation, which threaten the preservation of remaining natural areas located in protected areas and compromise the quality of life of the general population, and especially that of excluded communities. From this study, it can be concluded that:

- With the use of the ESIG tool correlated to photographic records, it is possible to evaluate the presence of environmental impacts in the areas, identifying affected water bodies.
- Considering local limitations, social Technologies must be invested in (products, techniques, and low-cost equipment that can be replicated anywhere in the country).
- Public policies that encourage residents and don't create bureaucratic barriers to implementation are needed, as well as training in the operation and maintenance of the equipment, providing autonomy for the families involved.

- The average time for the recovery of initial investment is estimated at 2.6 years, considering the profit obtained through the sale of the by-products generated by the process.
- The implantation of urban biodigesters is consistent with Law 11.445/2007, contributing to the management of sewage and solid wastes, by using them as fuel for the biodigester itself. They also bring technological advances related to the generation of electricity from biogas.
- The implantation of social Technologies for the treatment of sewage, beyond the direct effects of protecting the environment, improving water quality, scenery, and public health, can above all bring dignity to the families who live in informal housing and the surrounding neighborhoods.

ABSTRACT

Hong Kong is a high density living environment. With scarce land sources, residential developments, including public housing developments, may be located in close proximity to heavily trafficked roads or other noise sources. Embracing a caring attitude to create a healthy living environment to our residents in public housing estates, the Hong Kong Housing Authority has applied a host of noise mitigation measures to reduce the impact and nuisance. Depending on the individual site characteristics, noise mitigation measures can be applied at source, at propagation path and/ or at receiver end. Apart from these measures, where the noise impact is too severe for these mitigation measures to be adequate, more innovative building design in a cost effective manner becomes essential particularly for difficult public housing sites. This paper will highlight our recent research and development of innovative building designs on noise mitigation by making reference to some public housing projects in Hong Kong. A detailed case study will be presented holistically on the evolution of the acoustic balcony from its conceptual arc-screen form to the first generation of acoustic balcony and lately to an enhanced configuration to tackle the most severe noise challenge without compromising the performance of natural ventilation for the flats.

Keywords: noise mitigation measures, high-performance building, acoustic balcony

1. INTRODUCTION

Under the land use planning mechanism, the public housing development need to have noise assessment conducted to demonstrate compliance with the criteria under the Noise Control Ordinance and Hong Kong Planning Standards and Guidelines (HKPSG), especially for sites requiring rezoning to residential use.

Many public housing sites are subject to severe noise impact from the environment such as roads, railways and mechanical plants at industrial/ commercial buildings. Various design measures like single-aspect design, optimized block disposition, architectural fins, noise barriers, non-noise sensitive podiums and buildings such as multi-storey car parks or retail facilities as noise buffers will be applied to address the traffic noise impact. While each measure has its own merits and demerits, site constraints often restrict their full application, and more innovative measures are required at particularly difficult sites. In recent years, we have carried out research and development on innovative mitigation measures under collaborative approaches with our stakeholders in tackling severe noise issues in our developments.

2. SPECIFIC DESIGN TO TACKLE NOISE ISSUES

In general, mitigation at source and mitigation on the path of propagation are the most effective ways of easing noise problem. The choice of mitigation measures at source depends on site constraints and the acoustic performance required for individual housing projects.

2.1 Special noise cover for public transport interchange (PTI)

A number of our public housing sites are located very close to PTIs. Noise barriers are sometimes ineffective in blocking the line-of-sight to the noise source at the PTI as recommended in the HKPSG. Noise cover has to be used instead. To avoid the use of mechanical ventilation and fire services installations in association with a full

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

cover which will increase the future maintenance costs, we designed a special cover with appropriate openings and orientation with minimal maintenance requirement for the PTIs at Hung Fuk Estate (Figure 1) and Shui Chuen O Estate, allowing the use of natural light and ventilation to minimize energy consumption.

Figure 1: Special noise cover with openings for PTI at Hung Fuk Estate

2.2 Specific building block design

While noise impact is more effectively mitigated at source, such mitigation measures may not always be practical for reasons such as lack of space for noise barrier erection. Hence, mitigation measures at the receiver end need to be considered to overcome the noise impact. These measures are based on three types of acoustic principles – screening, setback and reducing view angle.

For some specific sites, the building blocks may be designed to set back from noisy roads and disposition at a skewed angle and farthest away from the noise source to reduce the impact on the building façade. Sometimes, vertical fin walls may also be added adjacent to windows to reduce the view angle towards the noisy roads, thus lower the noise levels at the flats. Single-aspect building design with non-sensitive receivers, such as kitchen and bathroom, facing the noise sources could be a very effective measure to solve severe noise issues. Long Ching Estate in Yuen Long (Figure 2) is an example of successfully mitigating noise impact with passive design and planning.

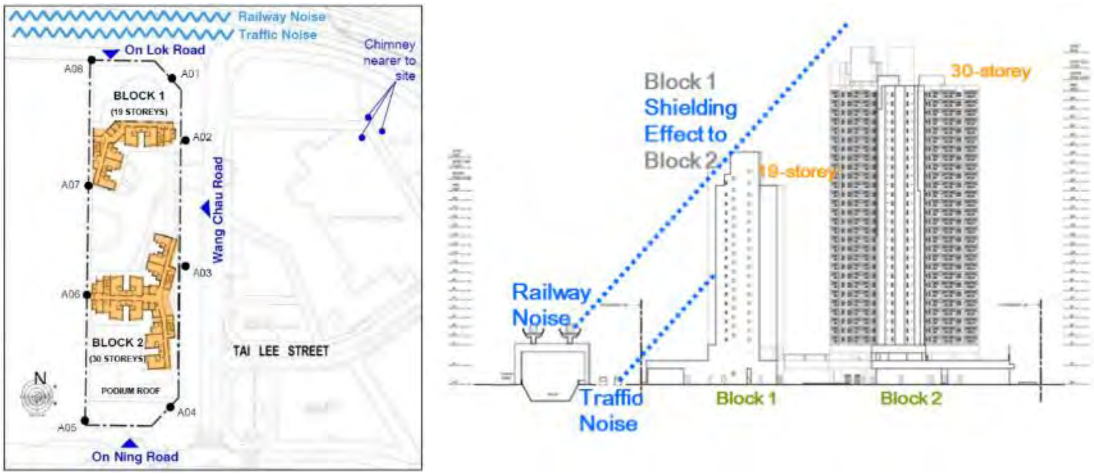

Figure 2: Long Ching Estate

Under extremely severe conditions, indirect mitigation measures in the form of window insulation and air conditioning could be considered as the last resort. However, it would be at the expense of natural ventilation.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

3. INNOVATIVE MITIGATION MEASURES

Apart from the above specific noise mitigation measures, we have recently developed more innovative measures at the receiver end for mitigating road traffic noise in order to maximize site development potential and improve the living environment. These are described in details as follows:

3.1. Acoustic window

For San Po Kong public housing development which abuts heavily trafficked Prince Edward Road East, the unmitigated noise level at the site boundary was anticipated at 85 dB(A). Apart from other conventional measures, the project team needed to work out innovative measure to further attenuate 8 dB(A) in order to meet 70 dB(A) noise standard as a rezoning requirement. Hence, we collaborated with Environmental Protection Department (EPD) and the Hong Kong Polytechnic University (HKPolyU) to form a Research Team to work out the design of acoustic window, which would function as a modified double-glazed window with offset openings to allow natural ventilation (Figure 3). In mid 2009, we commenced our exploration by conducting laboratory tests on this window design concept with various window configurations, noise source orientation, use of sound absorption material in the window system etc. to verify the noise attenuation performance of the design. The laboratory testing provided very promising results.

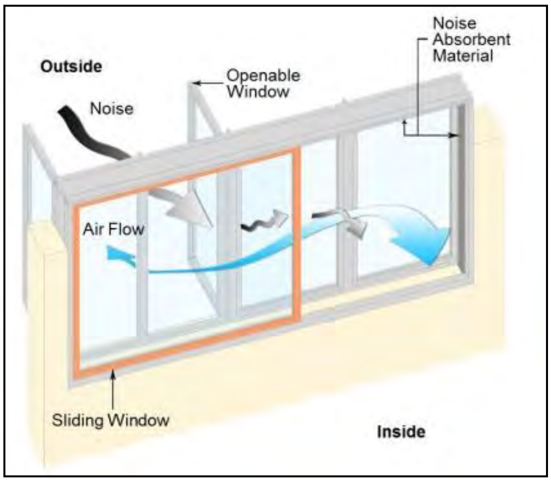

Figure 3: Configuration of acoustic window system

Subsequently, full scale mock-up flats installed with prototype acoustic window was set up on site for in-situ acoustic monitoring (Figure 4). Upon testing of the acoustic window for direct comparison of performance against conventional window, it was established that the acoustic window could achieve noise attenuation up to about 8 dB(A).

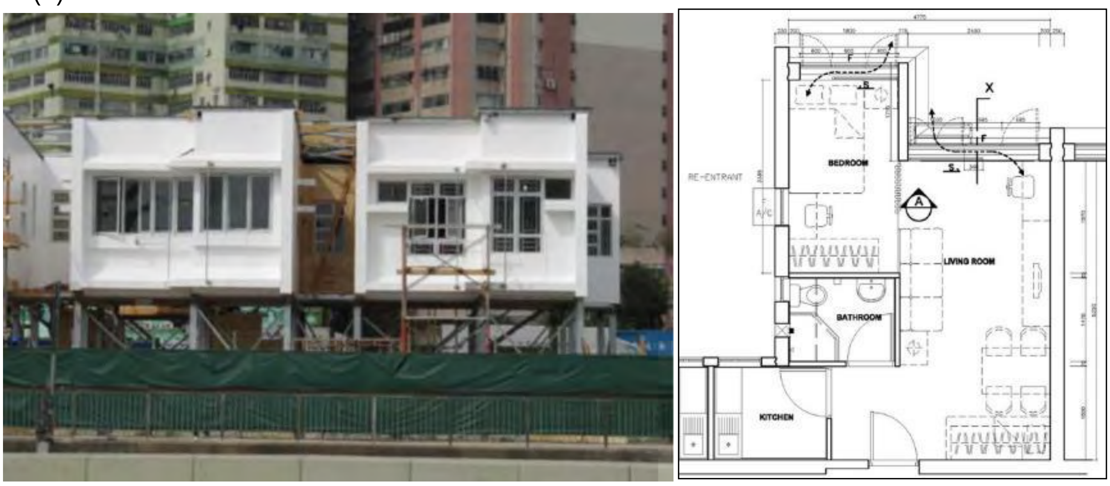

Figure 4: Mock-up flats for comparison of the performance of conventional window and acoustic window

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

With the employment of acoustic window system, 100% predicted noise compliance with the noise standard can be achieved to enable the San Po Kong project to proceed. Upon completion of the project, further noise monitoring would be arranged in completed flat for verification. During the design process, ventilation and other operational factors like window cleansing, clothes hanging and long term maintenance have been carefully considered from the residents' perspectives.

4. A CASE STUDY OF ACOUSTIC BALCONY

4.1 Acoustic balcony (Arc-screen to first generation)

Wing Cheong Estate development, abutting the elevated West Kowloon Corridor, is exposed to severe road traffic noise impact. Since the site and road configuration rendered conventional noise measures impractical, the project team came up with an innovative arc-screen design concept for shielding noise impact in front of the windows.

Desktop numerical analysis was first conducted to explore the effectiveness of the measure. With the promising desktop results, the project team subsequently proceeded with a 3-storey full scale model prototype installation for the in-situ noise measurements. Various arc-screen options, different materials and test scenarios have been worked out for testing (Figure 5). Results demonstrated the effectiveness of noise attenuation by the arc-screen.

Figure 5: Site mock-up model at Dongguan and measurement scenarios

Upon further consultation with various stakeholders, this arc-screen design concept finally evolved in the form of an acoustic balcony for use in the project, as shown in Figure 6.

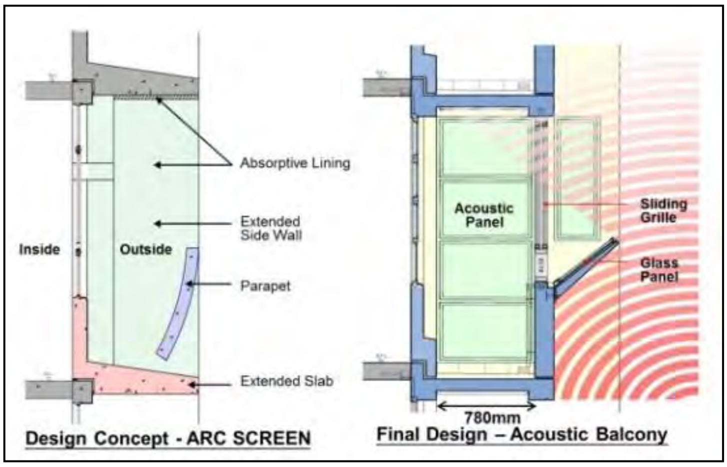

Figure 6: Initial arc screen design concept and first generation of acoustic balcony design

Together with the application of noise absorptive linings, the Acoustic Balcony could achieve maximum noise reduction up to 6.4dB(A). After completion of the building works in July 2013, on-site noise verification has been conducted, confirming the predicted noise reduction could be achieved.

Use of Acoustic Balcony has enabled the Wing Cheong Estate development to proceed amidst the severe noise impact. Consideration has been given to facilitate associated daily operation such as clothes hanging and window cleaning as well as long term maintenance. According to the resident survey taken after its occupation in 2013, this Acoustic Balcony design which could effectively reduce noise by about 2 to 6 dB(A) were much to the satisfaction of the tenants.

4.2 Acoustic balcony (Enhanced design)

Although successful in developing the innovative measures of acoustic window and acoustic balcony (Arc-screen to First Generation), we are not complacent. We looked into an enhanced Acoustic Balcony design (Figure 7), which amalgamates the acoustic window concept in the first generation of Acoustic Balcony. To ameliorate the incidence of noise through the balcony door into the flat, a sliding screen is installed in front of the balcony door in the balcony. This arrangement allows the ventilation path to be of decent width. Other auxiliary feature like noise adsorptive material at the wall and ceiling of the balcony and inclined panel projecting from the parapet would be provided on a site-specific basis for further noise mitigation enhancement. Apart from the noise aspect, other factors such as natural ventilation have to be carefully considered in the enhanced version.

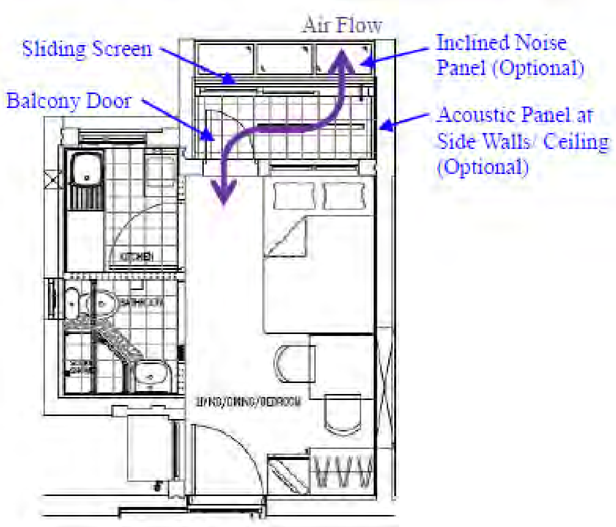

Figure 7: Layout of enhanced acoustic balcony design

In July 2015, we set up full-scale mock-up flats for the test case unit with prototype acoustic balconies and the base case unit with conventional window inside an existing vacant school building at Yue Wan Estate to verify the effectiveness of the noise reduction effect by in-situ acoustic measurements (Figure 8). The existing vacant school building would be demolished and the site would be developed for a public rental housing development providing some 800 flats for 2019/2020. This housing development is the first pilot project adopting the enhanced Acoustic Balcony design. Both in-situ traffic noise source and loudspeaker noise source had been used for the measurements.

Figure 8: Mock-up flats for comparison of the performance of enhanced acoustic balcony and conventional window

At least 20 microphones were employed to measure simultaneously the exterior and interior noise levels of the mock-up flats under 23 scenarios of different flat/ enhanced balcony settings. Besides, loudspeaker arrays at different offset distance representing different inclination angle of noise source were employed to simulate the flats at various levels. Upon testing for different flats and enhanced balcony scenarios, it was established that, the enhanced Acoustic Balcony with the fittings as stated above could achieve relative noise attenuation up to around 10dB(A), which was even higher than Acoustic Window and the first generation of Acoustic Balcony. It would be an effective design for noise mitigation whilst at the same time allow desirable natural air ventilation for the habitable area of the flat. At the moment, we are still refining the design to meet other aspects like buildability and other balcony orientation with respect to road alignment. But this noise mitigation design feature is now being adopted in some of our housing projects with acute noise issue.

5. COLLABORATION WITH EPD AND OTHER STAKEHOLDERS

Over the years, we have been working in close collaboration with EPD and other stakeholders of expertise such as environmental consultants and tertiary educational institutes in the exploration of various innovative measures to mitigate noise impact to our public housing developments. During the research and development of Acoustic Window and Acoustic Balcony, EPD gave valuable advice on the knowledge and experience in similar research projects together with the regulatory requirements of noise control whereas the environmental consultants and tertiary educational institutes were capable of providing acoustic expertise in the investigation and testing. Experience indicates that collaboration approach with other stakeholders is essential and practicable to develop innovative measures for the benefit of the community.

6. CONCLUSION

The HKHA's mission is to implement the subsidized public housing programme in meeting the housing needs of those who cannot afford private housing in Hong Kong in support of the Government policy on housing. Yet land has always been a precious and indispensable ingredient in HK's housing, economic and social development. Owing to the limited land supply, we need to make the best use of every piece of land, optimise the development potential and provide as much as domestic flats as practicable within the shortest possible time. All the mitigation measures discussed above, enable us to build more in areas with undesirable noise environment, without compromising the environmental quality of housing estates.

Gaining from past experience, through the development of various innovative noise mitigation designs and measures, we have optimised the development potential of several difficult public housing sites, and holistically improved the environmental quality of these estates at the same time. Looking ahead, we will continue working closely through close collaborations among stakeholders in the academic institutes, regulatory authorities and construction industry to overcome these challenges.

ABSTRACT

On November 2013, there was widespread devastation over the Visayan Region due to the onslaught brought by Typhoon Haiyan, which was hyped as the strongest landfalling cyclone. Despite of that, a new benchmark for future disaster preparations cannot be established due to the discrepancies between various weather bulletins on how strong Haiyan really was, as well as the loss of vital meteorological data during Haiyan's passage. To remedy the shortage and discrepancy of Typhoon Haiyan's meteorological data, a forensic structural analysis was done on windicators through a field survey done on Leyte and Samar Island. Windicators are structural objects of interest whose structural failure will lead to estimating the magnitude of the winds that brought the failure, in this case, the strength of Typhoon Haiyan, which in turn was used to determine and re-assess the wind vulnerability of the regions affected, using also the historical wind data from Tacloban and Guiuan station, comparing with that to the current design wind speeds prescribed by the NSCP. The study determines through the analysis of four windicators, that before its landfall at Leyte Island, Typhoon Haiyan has 1-minute sustained winds of 351 kph, 10-minute sustained winds of 290 kph, and through the analysis of the reamining surface data, which corresponded well into forming a model of the storm, Typhoon Haiyan, before its landfall at Guiuan, Eastern Samar, has 10-minute sustained winds of 317 kph and 1-minute sustained winds of 352 kph, with minimum central pressures of 868.5 mbar and 872.2 mbar at 4:10 am and 5:10 am respectively. Statistical analysis determined that the existence of a storm like Typhoon Haiyan, regardless whether it would make landfall has a minimum recurrence period of 500 years and the event that such storm makes landfall has a minimum recurrence period of 5600 years on the areas affected.

Keywords: windicators, typhoon haiyan; forensic structural analysis, computational fluid dynamics, wind engineering, geophysical fluid dynamics

1. INTRODUCTION

Last November 8, 2013, Super Typhoon Haiyan (PAGASA Designated Name: Yolanda) struck the Visayan Region leaving catastrophic damages and record fatalities along its path, most notably the Eastern Visayan Region where the storm made landfalls at its peak intensity.

The storm was immediately hyped as the strongest storm to make landfall. But amidst the devastation and misery upon those affected, they were in confusion on how strong Typhoon Haiyan really was, with Joint Typhoon Warning Center (JTWC) estimating the 1-minute sustained winds to be about 315 kph through the Advanced Dvorak Technique (ADT) and Japan Meteorological Agency (JMA) and Philippine Atmospheric, Geophysical and Astronomical Services Administration (PAGASA) estimating the 10-minute sustained winds to be about 235 kph using the Doppler effect estimations. Taking into account the differences in the time-base of the wind averaging, using the recommendations of World Meteorological Organization (WMO) on the conversion factors between 10-minute averages and 1-minute averages, there was still a 55-kph difference between these estimates.

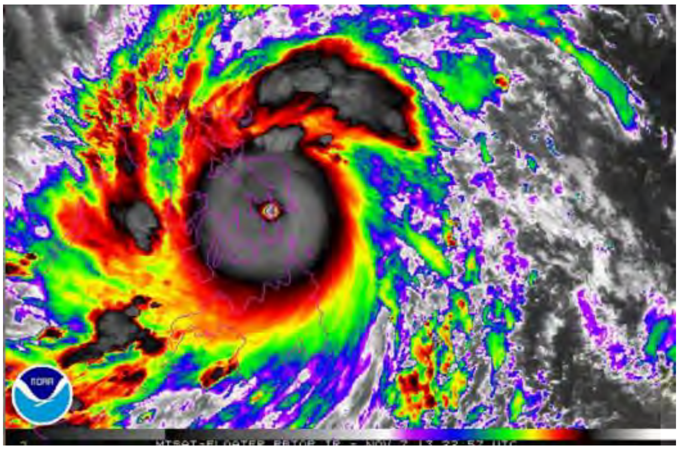

Figure 1: Infrared Image of Typhoon Haiyan

In-situ meteorological measurements were necessary to clear the discrepancy but unfortunately most of the weather instruments were damaged during the passage of TY Haiyan with only the barometric pressure readings from some areas remaining intact which were recorded during the full onslaught of Typhoon Haiyan at peak intensity namely: the 955.6 mbar barometric pressure reported at Tacloban Airport at 7:15 am, the 910 mbar barometric pressure reported at Guiuan Station at 5:10 am and the pressure readings from the barometer of the iCyclone team stationed in Hotel Alejandro in Tacloban City.

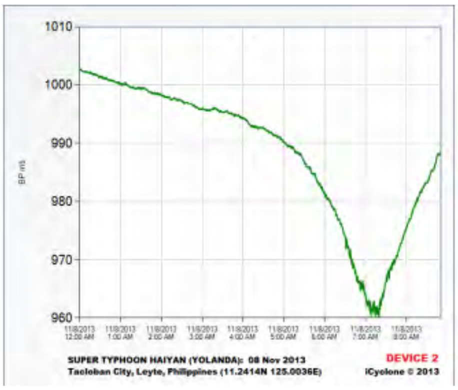

Figure 2: Barograph Reading on Tacloban City. A storm chaser team from iCyclone.com stationed at Hotel Alejandro in Tacloban City recorded the lowest pressure of 959.9 mbar at 7:20 am.

The flux of wind speed reading on weather stations was halted due to the fact that these stations were suffered physical damages from the winds of Typhoon Haiyan. Bantayan Island recorded winds of 77.4 m/s (278.6 kph) at 9:30 am (Nov 8, 2013, PST), which was recorded after Haiyan weakened considerably.

Tacloban Station, before being damaged by the storm surge, recorded winds of 77.7 m/s at 6:45 am. Guiuan Station, before halting its wind speed recording, recorded 10-minute sustained winds of 43 m/s (154.8 kph) peak winds of 53 m/s (190.8 kph) at 4:10 am, hours before its first landfall at Guiuan.

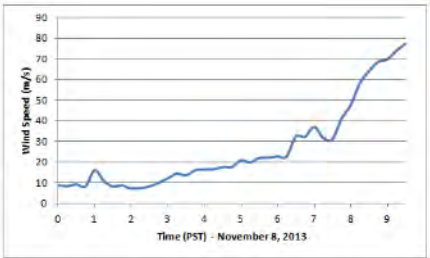

Figure 3: Wind Speed Reading – Bantayan Island

With these following premises given, a forensic structural analysis was performed to estimate the intensity of Typhoon Haiyan by the time it was making its landfalls to settle the discrepancy.

The forensic structural analysis performed on Windicators. Windicators, which were coined from terms 'wind' and 'indicators', are simple structural objects of interest whose failure leads to the computation of the wind speeds that brought the failure. Figure 5 shows the research framework using windicators.

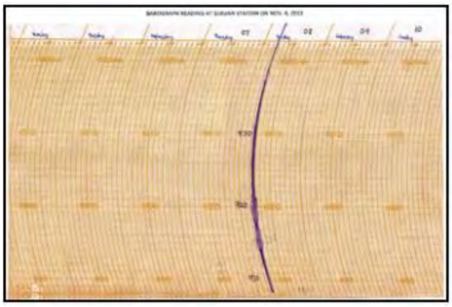

Figure 4: Barograph Reading – Guiuan Station (November 8, 2013). The lowest barometer reading of 910 mbar was recorded at 5:10 am. (Source: Climate Data Section - PAGASA and Guiuan Station Chief Marianito Macasa)

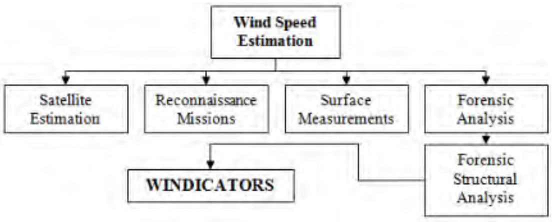

Figure 5: Conceptual Framework for Windicators

2. FORENSIC ANALYSIS

2.1 Field survey

Figure 7: Windicators (L to R: #4, #10, #9 and #8)

A field survey was performed on the affected areas. Non-inundated areas were surveyed to look for windicators. The area was further narrowed down to the area between Brgys. Guindapunan and San Jose in Palo, Leyte.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Figure 8: Windicators (L to R: #4, #10, #9 and #8) These were lamp posts installed in 2010 at Palo, Leyte. Windicator #9 was included in the study for verifications whether it was tampered or not.

The geogprahical coordinates, the geometric properties and samples trimmed from the structures were taken.

2.2 Material testing

The samples were taken back to the lab for material testing. Per ASTM A370-21419, a tensile test was performed on the samples.

Figure 9: Tensile test (right) on the sample (left)

Sample	Coupon #1	Coupon #2
Picture		
Gauge Length (in)	2.00	1.8125
Area ($\times 10^{-3}$ m^2)	0.00616	0.00777
f_{ult} (lbs)	6560	6800
σ_{ult} (MPa)	473.71	389.29

Table 1: Tensile test results

Based on the ultimate strengths of the samples and referring to AISC Table 2-1, the material is determined to be A36 steel.

2.3 Computational fluid dynamics (CFD)

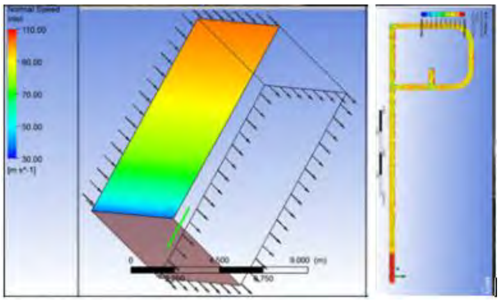

Figure 10: Wind simulation (left) and external pressures (right)

Using a finite-element modeler, winds were simulated over the structure following a logarithmic profile:

$$\bar{U}(z) = \bar{U}_{10}*\ln(z/z_0)*C_{SD}^{0.5}/0.4$$

$\bar{U}(z)$ – average wind speed at height z

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

z_0 – roughness length [1]

C_{SD} – surface drag coefficient [1]

$\bar{U}_{10}$ – average wind speed at height z=10 m

Equation 1

in order to obtain the external pressures applied on the structure using static wind load analysis. Using the external pressures caused by the wind, the internal forces in the member were determined. The von Mises stresses were used as the failure indicator, which was progressive yielding.

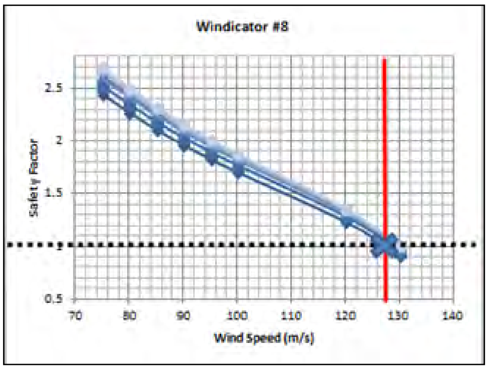

Figure 11: Wind speed v safety factor - #8

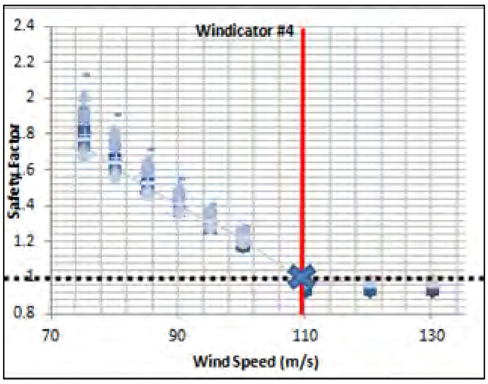

Figure 12: Wind speed v safety factor - #4

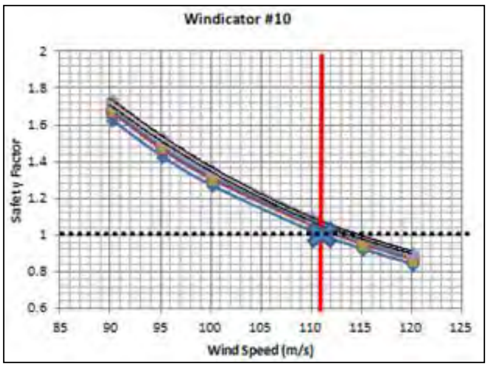

Figure 13: Wind speed v safety factor - #10

The terrain was considered a rough terrain (z_0 = 0.5 m and C_{SD} = 0.019) for the analysis. On Figures 11 to 14, the safety factor (Yield Stress/von Mises stress) on leeward elements and the wind speed were plotted. The winds simulated were considered to be a 3-second gust and therefore must be converted to 10-minute sustained averages using the conversion factors recommended by WMO. (Table 2)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

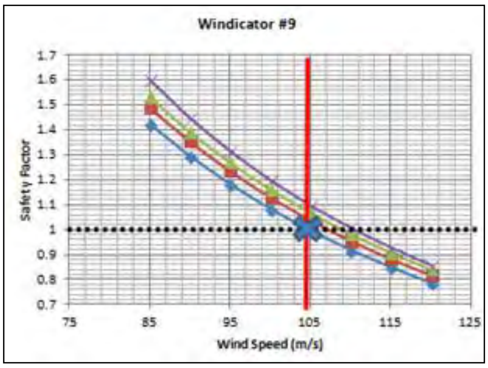

Figure 14: Wind speed v safety factor - #9

Windicator	Gust (m/s)	10-min sustained wind (m/s)
#4	109.43	65.95
#8	127.4	76.77
#9	104.77	63.11
#10	**113.48**	**68.36**

Table 2: Results of CFD analysis

2.4 Geophysical Fluid Dynamics

To determine the time of arrival of the winds, the direction of failure of the structures was estimated from the location of the compressive elements, which were considered to be on the leeward side of the winds, and the tensile elements on the structure's cross-section.

Next was to consider the effect of the Ekman Spiral, which is the change in direction of the winds as it descends from the boundary layer, where:

$$u\ (z) = U_{gr}*(1-(e^{-\beta}\cos(\beta))$$

Equation 2

$$v\ (z) = U_{gr}\ e^{-\beta}\sin(\beta)$$

Equation 3

$$\beta = z * (f/(2*v_e)$$

u – magnitude of the wind tangential to the pressure isobars.

v – magnitude of the wind n to the pressure isobars.

f – Coriolis parameter

v_e – Eddy viscosity (constant on rotating bodies)

The height of the boundary layer (H_{abl}), which is dependent on the roughness length (z_0) and the Coriolis parameter (f), is determined by using (1) on the equation of Lettau (1959) :

$$H_{ABL} = e^{(2.5(f z_0{}^{-0.09})+\ln(z_0)}$$

Equation 4

The height of the Ekman layer (H_{ekman}), which is dependent on the roughness length and the Eddy viscosity (v_e), is determined by equating (3) to zero:

$$H_{ekman} = \pi * (2*v_e/f)^{0.5}$$

Equation 5

Due to the circular geometry of Typhoon Haiyan, which had a Dvorak rating of T8.1, the gradient winds were assumed to be parallel to the pressure isobars. At 4:10 am in the morning, the direction of the gradient wind over Guiuan – Station was estimated to be N 42.08ºE. The PAGASA Station recorded the direction of the surface wind at that time to be at N 30ºE. Using the directional differences of the wind at that time and coinciding the Ekman layer to the Atmospheric Boundary Layer, the eddy viscosity (v_e) was computed to be equal to 0.719144 m^2/s.

Typhoon Haiyan's storm track was interpolated from 6-hour intervals into 1-minute intervals. Using the computed eddy viscosity, Equations (2), (3), (4) and (5), the time of failure was estimated based on the direction of failure and the windicators' location (Figure 14). With the time of failure being estimated the distance from the storm's center at the time of failure was estimated on each windicators.

Windicator	Gust (m/s)	10-min sustained wind (m/s)	Time of Failure	Distance from the storm's centre (km)
#4	109.43	65.95	7:50 AM	30.57
#8	127.4	76.77	6:41 AM	35.93
#9	104.77	63.11	7:20 AM	24.41
#10	**113.48**	**68.36**	**7:02 AM⁺**	**27.31**

Table 3: Time of failure and storm's proximity

2.5 Maximum Wind Speed Estimation

An analytical model of Typhoon Haiyan was formulated using the equations of Holland (1980) for the gradient wind profile and the pressure profile, the pressure (p) vs radial distance (r):

$$U_{gr} = -\frac{|fr|}{2} + \sqrt{\left(\frac{fr}{2}\right)^2 + \frac{(p-p_0)AB}{\rho_{air} r^B}\exp\left(\frac{-A}{r^B}\right)}$$

Equation 6

$$\frac{p-p_o}{p_n-p_o} = \exp\left(\frac{-A}{r^B}\right)$$

Equation 7

Using the pressure points discussed at section A and from Figure 2, and assuming the pressure on the outer edges of the storm to be at 1000 mbar based on the RDAP of the Haiyan from JTWC, on (7), the values of A and B were determined to be equal to 2445717313577890000 and 4.14868822191798 respectively. Using (6) to the data from Windicator #10 yielded a value of 68.39 m/s, relatively close to the 68.36 m/s 10-min sustained wind speeds on Windicator #10.

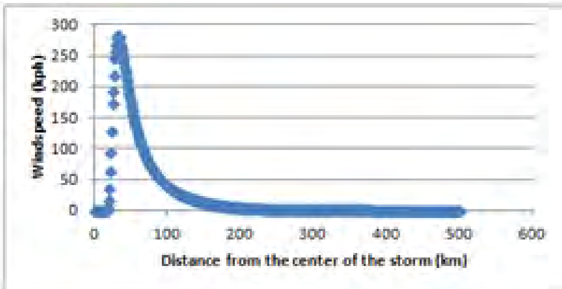

Figure 15: Velocity profile of TY haiyan (7:02 am)

Equation (6) was used not only to determine the maximum wind speeds and the minimum central pressure of Typhoon Haiyan at the time of failure of the windicators (Figure 13).

	#4	#8	#9	#10
Time of Failure (UTC)	2350	2241	2320	2302
10-minute sustained winds (kph)	**239.6**	**290.81**	371.82	**281.67**
1-minute sustained winds (kph)	**289.91**	**351.87**	449.90	**340.83**
Percent Deviation from JTWC(1-min)	**8.65%**	-10.48%	-	**-7.58%**
Percent Deviation from JMA/PAGASA(10-min)	19.17%	71.55%	-	23.57%
Minimum Central Pressure	922 mbar	888 mbar	500~ mbar	895 mbar

Table 4: Summary of values

The data from Windicator #9 returned erroneous values from the model. Windicator #9, before the survey was conducted, was being used as an anchor to the residents' clothesline, therefore the direction of failure may be compromised thus causing errors on the comparison to the model.

Using the 910 mbar pressure reading on Guiuan station at 5:10 am on (7), the minimum central pressure of Typhoon Haiyan at that time was estimated to be equal to 872.2 mbar, corresponding to a 10-minute maximum sustained winds of 317 kph and 1-minute sustained winds of 352 kph. The 10-minute sustained winds of 43 m/s and the peak gust of 53 m/s from the Guiuan Station taken at 4:00 am and 4:10 am respectively both returned 10-minute maximum sustained winds of 325 kph and 1-minute maximum sustained winds of 352 kph, corresponding to a minimum central pressure of 868.5 mbar, for Typhoon Haiyan.

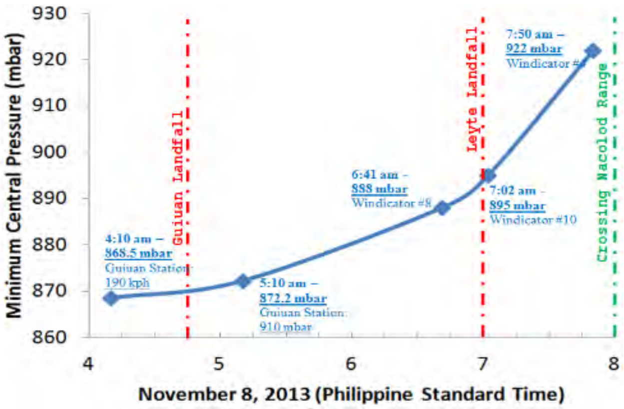

Figure 16: Minimum central pressure vs time

The conversion of the 77.7 m/s data from Tacloban Station, which was located at an isthmus which account for a sea type exposure, at 6:45 am to 10-min sustained winds, and putting it to the analytical model returned 10-minute maximum sustained winds of 290 kph, almost the same as Windicator #8 which failed around the same time.

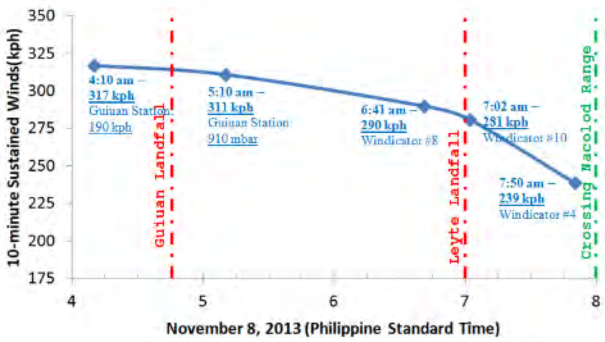

Figure 17: Maximum sustained winds vs time

Summing up the data on the timelines of Figure 16 and Figure 17 showed how Typhoon Haiyan drastically weakened over time. Terrain analysis reveals the limits of the analytical model which was valid until Typhoon

Haiyan crossed the Nacolod Range (a mountain range with 1000+ m mountains) of Leyte, causing disruption of the storm's structure as shown by the comparison of the analytical model and the synthesis of the data from Bantayan Island at Figure 18.

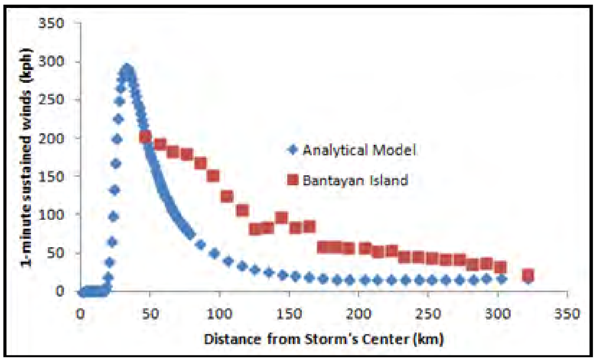

Figure 18: Bantayan island vs the analytical model

3. STATISTICAL ANALYSIS

The study analyzes the historical data from the PAGASA Synoptic Stations in the Visayan Region as shown in Figure 18 and Table 5.

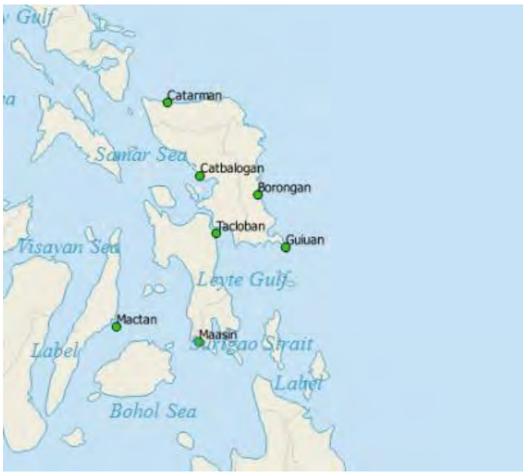

Figure 19: Location of the PAGASA stations analysed

STATION	PERIOD OF COVERAGE	HISTORICAL MAXIMUM WINDS
Borongan	1963-2010	52 m/s
Catarman	1951-2010	54 m/s
Catbalogan	1951-2010	59 m/s
Guiuan	1973-2012	72 m/s
Maasin	1972-2010	52 m/s
Mactan	1972-2010	55 m/s
Tacloban	1973-2012	62 m/s

Table 5: Details about the pagasa stations

Using the historical data, extreme value functions are formulated using the methods of Gumbel (Type I) and Gringorten (Type II) :

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Table 7: Largest winds on the following return periods (in kph)

Using largest winds over the return periods of 10, 25, 50 and 100 years, basic wind speed maps are made :

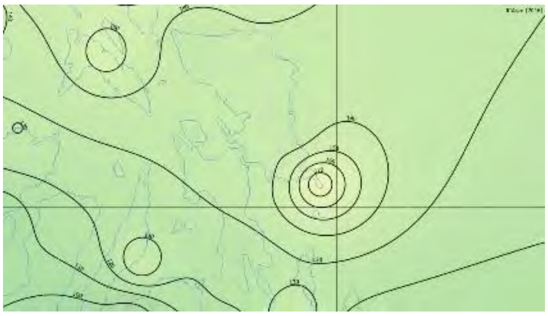

Figure 27: Basic Wind Speed Map – 10-year return period (Values are in kph)

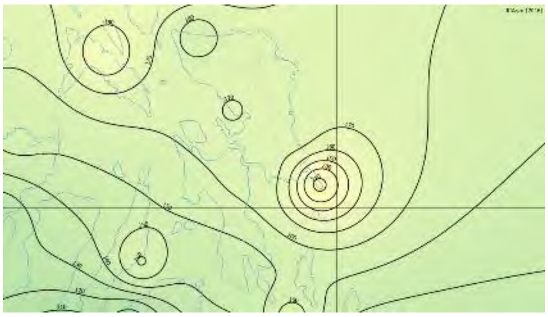

Figure 28: Basic Wind Speed Map – 25-year return period (Values are in kph)

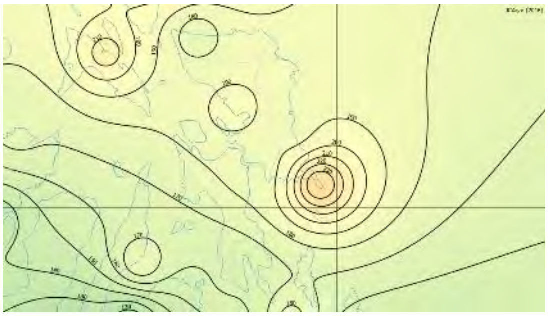

Figure 29: Basic Wind Speed Map – 50-year return period (Values are in kph)

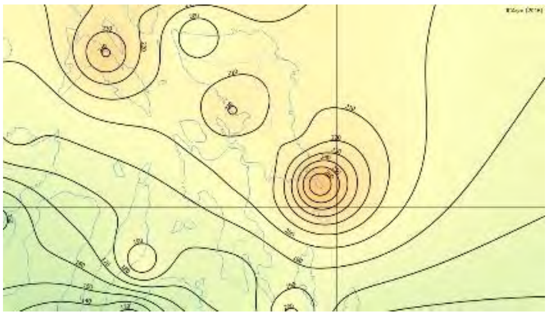

Figure 30: Basic Wind Speed Map – 100-year return period (Values are in kph)

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

The estimated and recorded wind speeds were also used to produce a wind exposure map brought by Typhoon Haiyan.

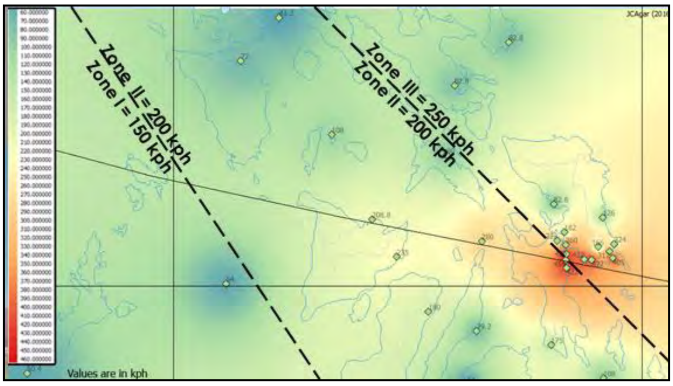

Figure 31: Wind Vulnerability Map of Typhoon Haiyan compared to the wind zones on NSCP (Values are in kph; Lower bound – 60 kph; higher bound – 460 kph)

Many of the areas had exceeded the basic design wind speed recommendations in the National Structural Code of the Philippines with the areas under Zone II experiencing gust more than 300 kph and areas under Zone I experiencing gust more than 400 kph, therefore, even engineered structures built in accordance to the NSCP were damaged.

Also using the values on Table 6, the return period of the winds experienced by Windicator #8 is obtained. Through the Type I extreme value functions, the 127 m/s winds experienced by Windicator #8 give return period values with the least being from the extreme value function from Guiuan Station which is approximately 5600 years. The return period is greater than the design life of the engineered structures.

Furthermore, using the least value expected for the highest pre-landfall wind speeds, highest wind speed recorded after the Leyte landfall in Bantayan Island, 77.4 m/s (278.6 kph), the return periods were computed to be at least 1650 years for Tacloban, and 140 years for Guiuan, also exceeding already the prescribed design life for engineered structures on the areas affected.

In terms of typhoon strengths, a statistical analysis was also done on the historical data of typhoon strength using the data from Japan Meteorological Agency, spanning from 1977-2014, excluding Typhoon Haiyan.

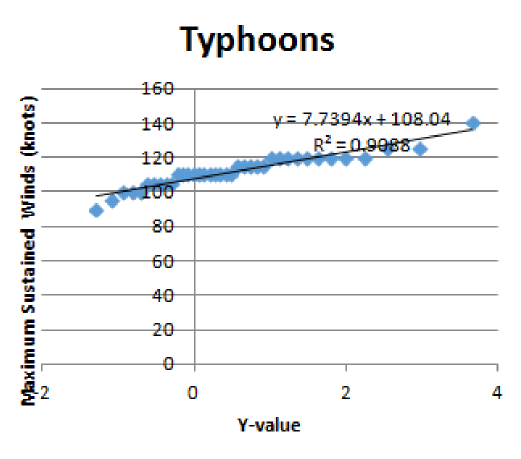

Figure 32: Type I analysis (Gumbel)

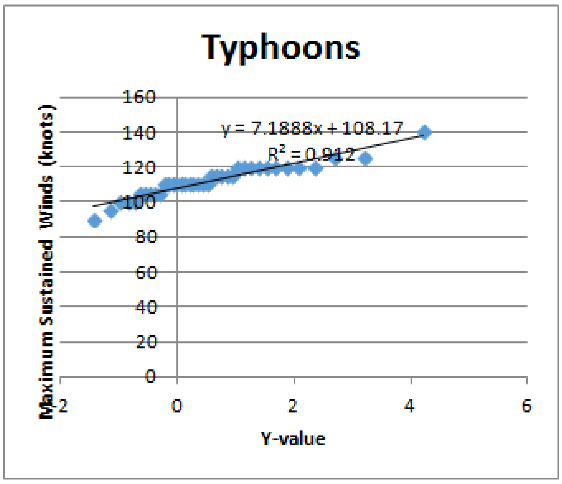

Figure 33: Type II analysis (Gringorten)

4. CONCLUSION

The study concludes that Typhoon Haiyan, before its landfall at Guiuan, has 10-minute sustained winds of 317 kph and 1-minute sustained winds of 352 kph. At its landfall at Leyte, Typhoon Haiyan has 10-minute sustained winds of 290 kph and 1-minute sustained winds of 351 kph. The minimum central pressures were determined to be 872.2 mbar at 5:10 am and 868.5 mbar at 4:10 am.

The wind vulnerability map during the passage of Typhoon Haiyan revealed that the current wind design specifications were not enough to prevent damage to structures.

Using statistical analysis over the historical data of Typhoon strengths and using the maximum sustained winds estimated in the forensic analysis, the existence of storms with the same intensity, whether it will hit land or not, on the Northwestern Pacific Basin as Typhoon Haiyan was analyzed to have a return period of 500 years.

Using statistical analysis over the historical data on weather stations in the Visayan Region, the winds brought by Typhoon Haiyan has a return period of possibly more than 5600 years over the affected areas.

ABSTRACT

There are many community parks use the improper lighting creates light pollution. The study aims to address the issue of glare reduction for outdoor lighting as well as to encourage the installation of lighting with fitting design and style. These eight community parks located in Taichung City were selected for the study, the information collected on-site allows for an analysis of the lighting quality at night-time community parks.

The present absence of proper light shade lead to the problems of glare, uneven illumination and excessive brilliance. An analysis based on the field data reports that all community parks share similar background luminance. In terms of glare rating, Taichung Wen-Hsin Park has the highest outdoor glare rating at 53.56 for the area along the walking trail adjacent to the in-park facilities. The average illumination on the ground of walking trails in some parks are two to four times more intense than the regulation standard because the lighting installations are not properly shaded, and the distance interval between the street lamps are overly concentrated. In terms of brilliance, Taichung Park and Wen-Hsin Park has the highest brilliance index at 1.5 times in excess of the regulation standard. The high brilliance is a sign of excessive spill light, frequently leading to glare. Finally, use the DIALux, a lighting design program, is used to simulate lighting along the trail with various lighting conditions and types of installations.

Light shades are recommended to reduce brilliance so the park users do not feel harsh on the eyes. For those areas with insufficient illumination, direct lighting is recommended to enhance illumination to the ground. For the types of installations, direct and indirect lighting installations are recommended to create a properly-lit night-time environment and prevent light pollution.

Keywords: sustainable neighbourhood, community park, glare rating, background luminance

1. RESEARCH ORIGIN AND PURPOSES

The light hazard, like noise or air pollution, can cause adverse effect on physiology and ecology, so it is also known as "light pollution". The trails in the community parks in Taiwan are universally provided with excessive lamps, but the light environment quality is poor, resulting in glare, ecological disturbance and energy waste. At present, the evaluation of light environment quality is still neglected in the selection and setup of park trail lamps in Taiwan, this study is expected to provide reference for the future planning of park trail lamps.

- The night-time light environment quality of community parks is measured, so as to know the community park lighting design quality in Taiwan.
- The night illumination problem in Taiwan's community parks is analyzed, the improvement method and lamp selection strategy are proposed.
- The lighting evaluation software DIALux is used to simulate the effect of the lamps of different specifications and setup modes for park trails on the light environment quality and glare index of park trails, to provide reference for the future park lighting design.

2. LIGHT ENVIRONMENT QUALITY ASSESSMENT METHOD

2.1 Outdoor lighting glare rating evaluation

The outdoor glare discomforts the user's eyes and increases the danger. The glare evaluation is to establish the glare rating for different lighting occasions, for example, the unified glare rating (UGR) assessment method is applicable to indoor lighting environment; whereas the park lighting is of outdoor lighting, in order to know the lamp glare rating in the community parks in Taichung City, the outdoor glare rating (GR) is used for assessment. According to the International Commission on Illumination CIE 112-1994, the GR represents the glare level, the

GR lower than 50 means the glare is acceptable, that higher than 50 means the glare is unacceptable. Therefore, the lower the glare rating is, the lower is the glare degree, unlikely to discomfort vision (Table 1).

GR	Glare degree	GR	Glare degree	GR	Glare degree
90	Severely glaring	60	Disturbing	30	Slightly sensible
80	Intolerable	50	Slight discomfort	20	Noticeable
70	Glaring	40	Acceptable	10	Unnoticeable

Table 1: Glare rating evaluation relationships (CIE 112-1994)

2.2 Outdoor illumination evaluation

The illumination is most frequently used to evaluate the outdoor lighting environment, for evaluating the brightness in different places, so as to meet the optimal activity requirement. As the light source type, pattern and spacing of lamps can influence the pavement illumination, the "illumination meter" is used to measure the illumination of trails in various community parks, and the illumination in the parks is evaluated according to CNS15015 outdoor landscape lighting lamp specifications to check whether it is proper or not (Table 2).

Object of lighting		Average illumination (lux)	Illumination standard (lux)
Passageways	Trail	5	1~10
	Green corridor	3	1~10
	Recreation trail	3	1~10

Table 2: Illumination standard for various zones in outdoor space (CNS 15115)

2.3 Outdoor lighting brightness evaluation

The brightness is the brightness degree of the light source or the illuminated surface perceived by human eye, its unit is [cd/m^2]. The brightness depends on the area of the illuminated surface and the intensity of light reflected from the illuminated surface to the naked eye. A good brightness is closely related to the lamp cut-off design. This study uses "brightness meter" to measure the brightness of lighting fixtures in various community parks, and evaluates the lamp brightness in the parks according to IS Z 9111 road lighting standard. The brightness of trail lighting fixtures is supposed not to exceed 6,000 [cd/m^2], the brightness at the visual center can be reduced, so as to avoid discomforting the pedestrians.

3. FIELD MEASUREMENT OF LIGHT ENVIRONMENT QUALITY

As the community park is the minimum park for recreational activity and social gathering, this study takes eight 4~20 ha community parks in service radius of 1.5km in "Taichung City" in central Taiwan as the subjects investigated (Table 3). There are three types of arrangement of the lamps in the parks, unilateral arrangement, bilaterally opposite arrangement and bilaterally staggered arrangement (Table 4). The trail width, lamp type and setup spacing are investigated, and the trails frequently used by common people are taken as analytes. The "image color analyzer, illuminance meter and brightness meter" are used to measure the lamp glare, pavement illumination and lamp brightness data in parks at night, so as to know current park trail lamp setup situation and quality of lighting, contributing to proposing the way of improvement in the future.

Code	Parks Name（Brief Name）	Construction Year	Area [ha]	Measured Zone
A	Bei-Tun Park（BT Park）	1983	4.6	4
B	Jiu-She Park（JS Park）	1994	4	5
C	Chong-Zheng Park（CZ Park）	1975	7.3	4
D	Taichung Park（TA Park）	1977	10.5	5
E	Museum of Art's Park（MU Park）	1982	10.1	4
F	Wen-Sin Park（WS Park）	2006	7.6	6
G	Chong-Lun Park（CL Park）	1990	6.2	3
H	JianKang Park（JK Park）	1991	5.6	4

Table 3: Community park sample data

Unilateral arrangement	Bilaterally opposite arrangement	Bilaterally staggered arrangement

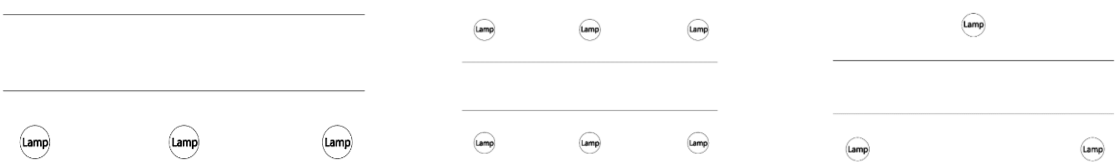

Table 4: Arrangement modes of park road lamps

3.1 Glare rating measurement method and result

In order to measure the glare quality received by the eyes when the pedestrian is walking on the trail, the "DIC image color analyzer (laboratory corrected lens and single lens camera)" is used to take two digital images in front of and behind the measuring point, the images are imported into the DIC analysis program to calculate the average glare rating at the measuring point. As the glare rating is influenced by the lamp brightness and environmental background brightness, but if the difference in background brightness is slight, in unilateral arrangement, bilaterally opposite or bilaterally staggered arrangement of lamps, the glare rating does not vary too much with the arrangement mode, it is mainly influenced by the lamp pattern. For the spot-light well controlled lamps, for example, CZ Park-C Zone keeps the glare rating at 23.92. Only the maximum and minimum results of glare rating in different lamp arrangement modes are listed (Table 5).

Arrangement modes	Park/ Zone	Trail width	Lamp form	Light distribution curve type	GR	Lb
Unilateral arrangement	WS Park C Zone	2			53.56 (Max)	1.47
	CZ Park C Zone	3			23.92 (Min)	1.59
Bilaterally opposite arrangement	BT Park C Zone	9.6			45.07 (Max)	1.85
	WS Park D Zone	5			30.17 (Min)	1.69
Bilaterally staggered arrangement	BT Park B Zone	4.6			50.06 (Max)	1.79
	JS Park E Zone	4			40.62 (Min)	0.51

Table 5: Relationship between community park trail lamps and glare rating

3.2 Illumination measurement method and result

The horizontal illumination of trails is measured by using high precision illumination meter. In this experiment, five measuring points are arranged between two lamps on average, and a train of measuring points is taken along the center line of the trail in width less than 3M; there are two rows of measuring points on the trail in width of 3~10M; there are three rows of measuring points on the trail in width greater than 10M. According to the field measurement, the average illumination value of most of the present trails can reach the minimum illumination 5[lx] required by CNS15015, but the illumination of 21~38 [lx] is too wasteful. A few zones below 5[lx] are related to the trail width, lamp spacing and tree shading. Sparse lamps and trail width will result in insufficient illumination of trail. Only the maximum and minimum results of illumination in different lamp arrangement modes are listed (Table 6).

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Arrangement modes	Park/ Zone	Trail width	Lamp form	Light distribution curve type	Lux
Unilateral arrangement	MU Park C Zone	2			38.18 (Max)
	MU Park B Zone	3			0.47 (Min)
Bilaterally opposite arrangement	WS Park D Zone	5			29.94 (Max)
	BT Park C Zone	9.6			20.20 (Min)
Bilaterally staggered arrangement	BT Park B Zone	4.6			21.24 (Max)
	JS Park A Zone	3.4			4.01 (Min)

Table 6: Relationship between community park trail lamps and illumination

3.3 Brightness measurement method and result

According to CNS 5064, the brightness meter is mounted at the measuring point at 1.5m above the ground, at vertical included angle of 85° to the observed lamp light source to measure the lamp brightness value. If the lampshade is transparent, unable to resist the horizontal projection effectively, there will be high brightness value. The lamp brightness situation in the parks is evaluated according to JIS Z9111 road lighting standard, the brightness of lighting fixtures for trails should not exceed 6,000 [cd/m^2]. However, it is found in this survey that if the projecting angle of the lamps for park trails is improper, the brightness is 7500~9200 [cd/m^2] which is likely to cause discomfort. Only the maximum and minimum results of brightness value in different lamp arrangement modes are listed (Table 7).

Arrangement modes	Park/ Zone	Trail width	Lamp form	Light distribution curve type	Brightness
Unilateral arrangement	WS Park B Zone	6			8854 (Max)
	CZ Park C Zone	3			1413 (Min)
Bilaterally opposite arrangement	BT Park C Zone	9.6			7567 (Max)
	WS Park D Zone	5			3422 (Min)
Bilaterally staggered arrangement	WS Park A Zone	6			9221 (Max)
	TA Park D Zone	15			1937 (Min)

Table 7: Relationship between community park trail lamps and brightness

4. SIMULATION OF CONFIGURATION OF PARK ROAD LAMPS

4.1 Lighting simulation mode

Due to the limitations of the measured objects, the lighting situation of all park trails cannot be obtained, the quality of lighting in different cases can be known by computer program simulation. This study uses DIALux software for lighting simulation, which is a lighting design software developed by Germany lamp manufacturer DIAL. It has been approved by many lamp manufacturers and lighting designers in the world. The lamp data files provided by lamp manufacturers are installed in the software for simulation. According to current condition of trail lighting, the light distribution curves of lamps in Taiwan's community parks are divided into five classes, and 135 lighting combination modes are studied out according to the road width, lamp spacing and lamp arrangement mode (Table 8), the quality of lighting of park trails is calculated one by one as reference for the selection and arrangement mode of park trail lamps in the future.

Simulated item	Simulation type	Description	
Lamp type	A Type: Direct	A Type 3200 (lm)2800 (k)	
	B Type: Semi-direct	B Type 1200 (lm) 3000 (k)		C Type: Perfect diffusion	C Type 950 (lm) 3200 (k)	
	D Type: Semi-indirect	D Type 1800 (lm) 3500 (k)		E Type: Indirect	E Type 1497 (lm) 4000 (k)	
Trail width	3m, 5m, 10m	The park trails in width of 3m~10m and over 10m are main passageways.	
Lamp spacing	10m, 15m, 20m	The three spacings are the major road lamp spacings	
Lamp arrangement mode	The three modes are the major road lamp arrangement modes - Unilateral arrangement - bilaterally opposite arrangement - bilaterally staggered arrangement		
Simulation combinations:5 lamp types, 3 trail widths, 3 lamp spacings, 3 arrangement modes=5*3*3*3=135 simulation combinations			

Table 8: Park road lamps simulation conditions

4.2 Analysis of park road lamps lighting simulation results

Road lamp type-based comparison

- Semi-direct lamp: 27 situations of this type of lamp are simulated, the trail width or lamp arrangement mode results in glare rating of 51~69, which is an uncomfortable glaring environment.
- Direct lamp: Whatever the trail width or lamp arrangement mode is, the glare rating is about 50, mostly acceptable (Figure 1). When the trail width is 3m and the lamp spacing is greater than 20m, the illumination is 2.1~4.4 [lx]. When the trail width is 5m and the lamp spacing is greater than 15m, the illumination is 1.5~3.9 [lx]. When the trail width is 10m and the lamp spacing is greater than 10m, the illumination is 0.7~3.3 [lx].

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

- Perfect diffusion and semi-indirect lamps: In whatever configuration mode, the glare rating of the two types of lamps is 51~61, which is likely to cause uncomfortable glare. The illumination of this type of lamp varies with the light source capacity. The types selected for this study generate low illumination of 0.63~4.6 [lx].
- Indirect lamp: Whatever the trail width or lamp arrangement mode is, the glare rating is acceptable 36~49, the pavement illumination is quite high, almost higher than 5[lx] (Figure 2).

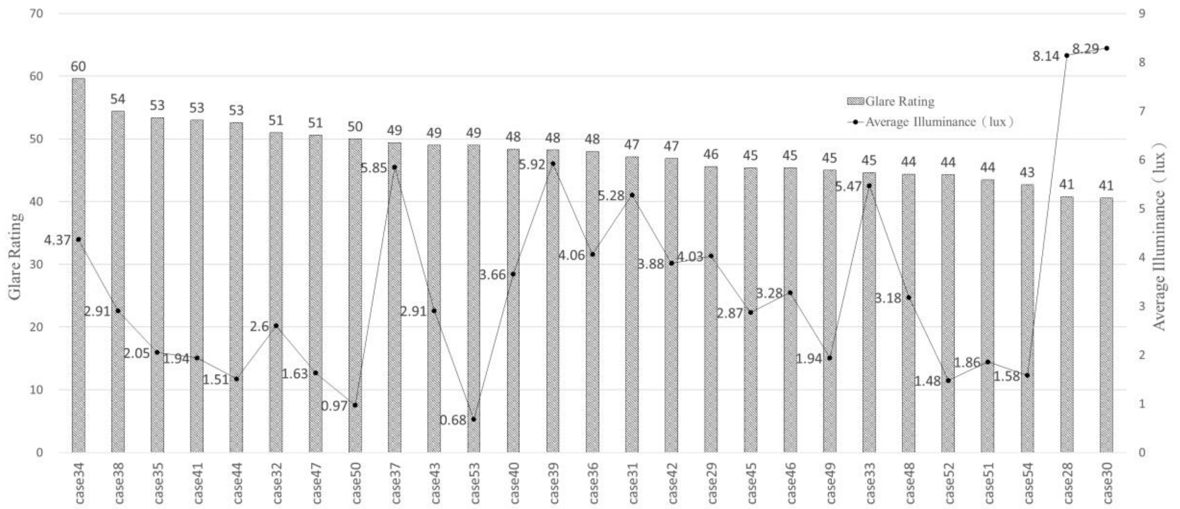

Figure 1: Semi-direct lamp simulation results

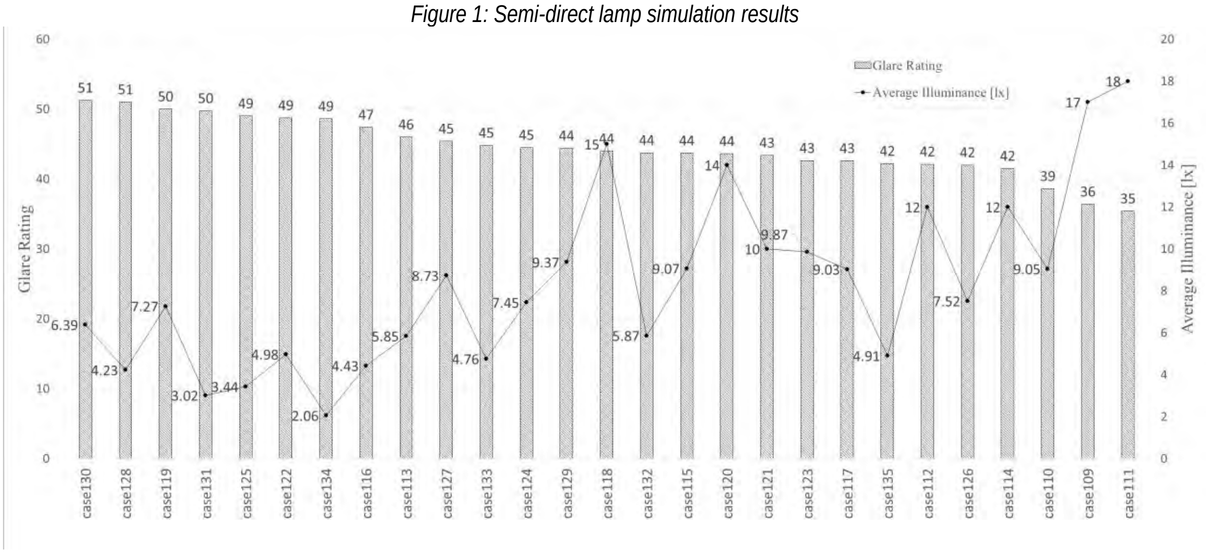

Figure 2: Indirect lamp simulation results

Park trail width-based comparison

- In terms of trail width 3m, the recommended lamp spacing is 15m, and the direct lamps are used for bilaterally staggered arrangement and bilaterally opposite arrangement.
- In terms of trail width 5m, the recommended lamp spacing is 10m, and the direct lamps are used for bilaterally staggered arrangement and bilaterally opposite arrangement.
- In terms of trail width 10m, the recommended lamp spacing is 10m, the direct lamps are used for bilaterally staggered arrangement and bilaterally opposite arrangement, but the pavement illumination is likely to be insufficient, the lamp spacing shall be shortened.

5. CONCLUSION

- A few lamps in the community parks have high brightness and glare problems. The glare level of most lamps in the eight community parks investigated by this study is acceptable. In unilateral arrangement, bilaterally opposite or bilaterally staggered arrangement of lamps, the glare rating does not vary too much with the arrangement mode. The lampshades are transparent in a few zones, which cannot shield light source effectively, so the brightness is relatively high, generating uncomfortable glare.
- The trail illumination is sufficient but relatively high: The average pavement illumination is related to the lamp setup density, the average illumination value of the trails in current community parks is higher than 5[lx], conforming to CNS 15015, but generally speaking, the illumination of 21~38[lx] is too wasteful. Although it is required to avoid too long lamp spacing causing insufficient average illumination, the excessive illumination and energy waste resulted from short spacing shall be noticed.
- The glare rating of park trails using direct or indirect lamps is relatively ideal: This study simulates 135 lighting combinations according to common lighting conditions of the parks in Taiwan, the findings show that when the "direct lamp" or "indirect lamp" is used, whatever the trail width or lamp arrangement mode is, the glare rating is 50 and 36~49 respectively, which is acceptable.

The setup of park trail lamps shall be evaluated carefully, in order to provide an appropriate park lighting environment, the lamps shall refer to the light distribution curve at the design stage, selecting the types which can prevent light rays from dissipating effectively can reduce visual and ecological impacts.

ABSTRACT

Considering we spend about 90% of our time in built environments, it is crucial to understand how buildings have an enormous impact on the health and well-being of its occupants. Regarding the workplace, studies demonstrate that indoor air quality and ventilation, thermal comfort, noise and acoustics, daylighting and lighting, interior layout and active design, views and biophilia, look and feel, location and access to amenities, may have a significant influence on the employee's productivity. Such concerns, particularly in large business offices, have already led to considerable investments thus creating a new market with new business opportunities.

Although the scientific community is yet to agree upon consolidated wellbeing metrics and measuring methods, a few alternatives have presented themselves with promising results. Among them, the Green Building Council ´s Brazil (a nongovernmental organization founded in 2007) in partnership with IPT (Instituto de Pesquisas Tecnologicas – Technological Research Institute), indicates a path by applying the perceptual and physical metrics, based on the report about Health, Wellbeing and Productivity developed by the World Green Building Council (WGBC).

Throughout this session, the authors aim to present the results of the Survey conducted with the occupants of office buildings in Brazil. In order to obtain the perceptive metric, an online questionnaire was applied on LEED CI (commercial interiors) certified buildings, collecting about 300 answers anonymously, considering the topics: indoor air quality and ventilation, thermal comfort, acoustics, lighting, layout and ergonomics, biophilia and views, look and feel, location, transportation and access to amenities. Regarding the physical metrics, the survey demonstrates measurements of illuminance in the workplace, measurements of the acoustic quality of both internal and external noise, and temperature measurements of air, mean radiant, humidity and air velocity. From the gathered data, important evidence of the relationship between the subjective wellbeing and physical concepts are brought to light.

Keywords: green building, wellbeing, acoustic

1. INTRODUCTION

In 1987 during an United Nation Organization meeting, Brundtland comission has defined sustainable development as: 'Satisfy present needs, without compromising capacity for future generations to satisfy their own needs." The green movement and assessment science has begun during the beginning of ninetys all over the world. (Marcovitch, 2012). ISO 14000 regulations were created from Agenda 21 decisions during the United Nations international congress for the environment and sustainable development, known as ECO 92. The concern about the sustainability in buildings and the built environment had an advance when the United States Green Building Council USGBC was founded in 1993.The Green Building Council Brasil, GBC Brasil, has been founded just in 2007.

The sustainability concept is based on the equilibrium of three spheres, or the triple bottom line: Planet, People and Profit, known as the 3 P! Basically, all assessment tools were created also based in three contents: Structure, Process and Results. Structure is related to the physical area, space, form, function, installations and maintenance. (Sommer, 1969) Process is consisted on an evaluation of all data, records, orders, protocols and indicators. Results can be assessed comparatively as financial results, costs per unit and productivity. Total quality management and continuous quality improvement are examples. LEAN and Six Sigma are also assessment methods focusing on reducing waste in all building sectors, from industrial to healthcare.

From the Conference Proceedings of World Sustainable Built Environment Conference 2017 Hong Kong - ISBN 978-988-77943-0-1 www.hkgbc.org.hk

Nowadays there are many sustainable certification systems in Brazil, like: Leadership in Energy and Environmental Design LEED the American model, AQUA- HQE based on a French model, 'Procel Edifica', 'Selo Caixa Azul', both Brazilian systems; besides international systems: the American Living Building Challenge LBC, the German system DGNB, the British system BREEAM, the Japanese system called CASBEE and others. The tendency is that all these quality tools are going to be more challenging, not only to reduce the impact on the planet, but also to be restorative, like the Restorative Design.

It is inevitable to compare the 3P with the health, wellbeing and productivity. Health is inside the Planet and environment, wellbeing is part of the People, the social sphere and productivity is related to Profit. (Wolff, 2013) According to World GBC report, we spend about 90% of our life time in built environments. These built environments should be healthy and collaborate to increase our wellbeing. Handful of organizations and researchers are already using surveys to quantify a range of concepts which had previously been extremely difficult to measure, like The Gallup Workplace Audit, The Leesman Index, Building Use Studies (BUS) Methodology and CBE Berkeley.

Company owners and directors think that sustainable buildings just save water and energy that contribute to 10% of the business operating costs. Although staff costs, including salaries and benefits typically account for about 80 or 90% of business operating costs. It is the value equation, not cost savings, that has driven the business case for energy improvements and green building certification in many markets and there is every reason to think that may begin to happen with health, wellbeing and productivity as well. Green buildings should focus on people and human beings, because human resources are the most important assets.

It is difficult to measure health and wellbeing because is subjective and personal. That is the reason this research focus on Brazilian culture and the way their offices function. The study evaluated real cases, close to Brazilian people and their satisfaction with the workplaces. (Preiser and Vischer, 2008) The survey included physical and perceptual metrics and not financial metrics.

2. METHODOLOGY

The research was conducted for occupants of seven LEED (Leadership in Energy and Environmental Design) certified offices under the CI category (Commercial Interiors), located in São Paulo city, in Brazil. An online questionnaire was applied via web, accessed by independents links by building. The link was sent by to each company's manager, HR or facilities representative, who was responsible for distributing to the office's occupants. It took approximately 15 minutes to them to complete the survey.

The development of the questionnaire was based on research literature and discussions with professionals who conducted similar studies, including the reputed IPT (Institute for Technological Research), Skanska England (one of the world's largest construction groups), Los Andes University and GBC Colombia. ISO and ASHRAE standards were used for the preparation of the questions and qualitative Likert's scale were rather used for the answers choices.

The goal of the questionnaire was to collect anonymously occupant's importance and satisfaction regarding the built factors of the building and workplace, such as: indoor air quality and ventilation, thermal comfort, natural daylight and lighting, acoustics quality, interior layout and ergonomics, green areas and views, aspect and perception, location, transportation and access to amenities. Personal data such as gender, age, work regime, work shift, workstation location and time working for the company were also collected.

Regarding indoor air quality and ventilation, the following points were assessed: ventilation, humidity, individually controlled ventilation, air speed, discomfort due to localized air streams, stale air and unpleasant odours, as well as the occupant's satisfaction level.

The goal of assessing the thermal comfort was to verify: thermal sensation in summer and winter, which period of the day there is thermal discomfort, feeling cold or hot at any given time of day and level of satisfaction with the thermal conditions of the working environment.

As for natural daylight and lighting, the use of natural lighting, user's control of natural or artificial lighting, amount of lighting (little or excessive) and user's satisfaction were evaluated.
